was called in those papers to one of the difficult problems which Borough Engineers have to face in some large towns, that is, what is to be done with the large amount of liquid and semi-liquid manufacturing refuse which is delivered from works where such processes as bleaching and dyeing are carried on? The subject is one which is of considerable interest, and the problem has been recently occupying the attention of the author and that of the Town Council. The total sewage flow of the borough in dry weather is about 6,125,000 gallons in twenty-four hours; of this quantity about 2,125,000 gallons per day gravitate down to the farm, and the remaining 4,000,000 gallons per day have to be pumped; the larger portion of the low-level sewage is brought down the Leen Valley sewer, and it is in the valley of the Leen where the principal difficulty regarding the manufacturing refuse is encountered. The river Leen is a small tributary of the river Trent, is 13½ miles long, measured along its course, and the area of its watershed is about 403 square miles. The flow of this river, of course, fluctuates very much, according to the seasons; gaugings were taken in the early part of 1891, and the lowest was on January 15, which was 901,549 cubic feet, or 5,634,681 gallons per day, and the highest gauging, taken during a somewhat heavy rainfall, was on January 24, and showed a discharge of 6,182,976 cubic feet, or 38,293,600 gallons per day. The normal discharge of the river in ordinary weather would be from 15 to 16 million gallons per day. On the banks of this river Leen, or contiguous thereto, there are about twenty-four bleach and dye-works, of which number seventeen discharge their waste waters into the river Leen, or into the tributaries and brooks, or into special surface-water sewers in connection therewith, and the remaining seven have been permitted to discharge their waste waters into the Leen Valley sewer previously referred to. The water used by the bleachers, &c., is not taken from the river Leen, but is pumped from copious springs in the magnesian limestone, in which strata water particularly suitable for bleaching and dyeing processes abounds in large quantities. The works are not concentrated in one particular district, but are scattered about in the valley of the river, and the distance from the uppermost works to the lowermost works, measured along the course of the Leen, is not less than four miles. The waste waters turned into the river from these works is about 3,000,000 gallons per working day when the local trades of lace and hosiery are fairly good. The processes of bleaching differ in various districts according to the nature of the goods. The following, however, is the method adopted at one of the largest works in this district:—The goods to be bleached are first passed through cold water and then boiled in caustic soda (sodium hydrate NaHO) and crich lime; they are then run through a solution of bleaching powder (chloride of lime) and afterwards washed and run through a weak solution of sulphuric acid which is called "sours"; they are then boiled in carbonate of soda and soap, washed and run through chloride of lime, washed, and again run through "sours" (dilute sulphuric acid), and a final washing completes the operation. In some works strong liquor ammonia is used as an alkali instead of carbonate of soda, and in all cases, of course, very large quantities indeed of soap are used in the operations. The chloride of lime in the waste waters effects a precipitation of the soap and other solids when these waters reach the river Leen, and the result is the accumulation of the offensive and noxious slime and mud on the banks of the river. The filthiness of the water and banks of the river appears to be an invitation to the residents on the banks to still further pollute the river by throwing in all manner of rubbish, &c. The existence of the various mills on the river tends to aggravate the difficulty, and render the precipitation more effectual as the damming up of the water to provide head for the water-wheels forms a succession of settling ponds. To make matters still worse, the river Leen does not deliver direct into a fast-flowing river of large volume, like the Trent, but enters the Nottingham canal, which flows through a densely populated part of the town, and does not reach the river Trent for upwards of two miles. In this canal, which is practically stagnant water, the deposition of mud and slime is continually going on, and in warm weather the nuisance is considerable. The normal discharge of the river Leen is from 15

to 16 million gallons per day; the discharge between 6 a.m. and 6 p.m., which would include the bleach and dye water, would in round figures be about 9 million gallons; the waste water from the works is, therefore, about one-third of the total flow of the river between the hours named. The problem is to effect the purification of the river, and the solution of this problem is not a very easy one. However, in reporting on this question to the Town Council, there appeared to the author to be three methods of solving the difficulty. 1. To connect the bleach and dye works in the district with the system of sewers, and allow their waste waters to mix with the ordinary sewage and flow down the main intercepting sewer; eventually it would be pumped and delivered on to the sewage farm, and therefore purified by broad irrigation on land. 2. To connect the waste waters from the works referred to with an entirely new and independent sewer, and conduct these foul waters to some convenient site and purify the same by precipitation and filtration. 3. To compel owners of works to abstain from polluting the river, and put down on their own works a plant or apparatus for purifying their waste water, either by precipitation or filtration, or both. The first scheme would involve somewhat heavy engineering works, but nothing of any very particular difficulty; it would be necessary to increase the pumping plant at the pumping station, to provide an additional pumping main, and to buy about 225 acres of additional land at the sewage farm; this would make the total area of the sewage farm 1,134 acres for say nine million gallons of sewage per day. The author said he was perfectly well aware that there are several very grave objections to this scheme; in the first place the three million gallons of bleach and dye water has very little if any manurial value; this, however, may be as truly said of the greater part of the sink washings from more than half of the property in the town; further, it was a matter of doubt whether the bleach and dye waters when mixed with the ordinary sewage would have any harmful effects on the crops at the farm; having given analyses of waste waters from various bleach and dye works, and also of mud from the bed of the river Leen, made by Dr. E. B. Truman, the Borough Analyst, the author proceeded to discuss the alternative means of dealing with the problem to be solved, and concluded his paper by describing the new Epidemic Hospital, which appears to be one of the most complete buildings of its kind in the country.

[We will resume our account of the meeting in our next.]

THE ARCHITECTURAL ASSOCIATION SPRING VISITS:

THE NEW TRAVELLERS' CLUB.

THE sixth spring visit of the Association took place on the afternoon of Saturday, April 30, when a large number of members assembled to inspect the new Travellers' Club, Piccadilly, designed by Messrs. Thomas & Frank Verity. Mr. Frank Verity kindly met the party, and gave an interesting description of the aims and objects of this interesting addition to the architecture of Clubland, and the difficulties met with in its design. The site is at the corner of Piccadilly and White Horse-street, and as it overlooks the Green-park, the situation is an ideal one for a club. The entrance is from the new street, and leads into a spacious hall with grand staircase. The morning-room faces Piccadilly and the coffee-room is placed on the right of the entrance facing White Horse-street. The first floor is occupied by a reading-room in front, and a two-table billiard-room and card-rooms at the back and side. The upper floors are devoted to bedrooms. A basement and sub-basement floors accommodate lavatories, kitchen, and offices. The work is hardly sufficiently advanced for an opinion to be formed of its aspect at completion. There are, however, scagliola columns and pilasters on the staircases, and glass mosaic pavings and portions of marble bands to the stairs visible. The front and side elevations are treated in Palladian Renaissance style, and are executed in Ham Hill stone, the present colour of which is a pleasant variation in the grey tone of most stone buildings in London. There is quiet dignity about the elevations, which is very pleasing. The building appears to be well planned and well lighted on all the upper

floors, and this has been successfully contrived in spite of difficulties with adjoining owners as to light. The work has been executed by Messrs. A. Bush & Sons, and Mr. A. W. Earle has acted as the clerk of works.

ARCHITECTURAL SOCIETIES.

THE EDINBURGH ARCHITECTURAL ASSOCIATION AT LINLITHGOW PALACE.—On Saturday last a deputation from the Edinburgh Architectural Association visited Linlithgow in connection with the proposed repairing of the ancient Palace. The deputation was met in the Palace-grounds by the Provost and Magistrates, the Town Clerk, and several of the members of Town Council. The object of the visit (says the *Scottish Leader*) was to assist the Town Council in the preparation of a statement as to what is actually necessary for the repair and preservation of the old structure. Accompanied by the local officials, the visitors made a minute inspection of the various parts of the building, and Mr. Ross, one of the deputies, submitted a number of written suggestions as to how the proposed repairs might be effected, and as to what was necessary for the proper preservation of the historical fabric. It is expected that steps will now be taken to have these suggestions brought under the notice of Parliament, and an endeavour made to induce the Government to augment the grant of 5000l. voted recently for the repair of the Palace. In connection with the subject certain important letters have been received by Mr. Ferguson, Town Clerk. Lord Rosebery wrote:—"I am in receipt of your letter. I have urged Mr. Munro Ferguson to take the line that if the Duke of Cumberland sequestrated the property of the Earl of Livingston for taking part in the Rebellion of 1719 when the Duke of Cumberland's soldiers burnt down Linlithgow Palace, it would be fair to apply the proceeds of the one to the repair of the other. That seems to me simple fairness and common sense." In his communication Mr. Munro Ferguson, M.P., says—"This is but one of the many examples where Scotland suffers from London Departments, where official regard for our national buildings is not to be distinguished from that indifference which prevailed too generally amongst us for 200 or 300 years. A better spirit has arisen in our time, and it is good to see Linlithgow leading the way towards the restoration of the finest of the ancient palaces of Scotland. Your action is worthy of every support, and your example cannot be too widely followed." Letters had also been received from Mr. M'Lagan, M.P.; Mr. Sinclair, M.P.; Mr. Fraser-Macintosh, M.P.; and others, all promising to give the object their heartiest support.

LEEDS AND YORKSHIRE ARCHITECTURAL SOCIETY.—A general meeting of this Society was held on the 29th ult., at the Law Institute, Mr. W. H. Thorp, the retiring President, in the chair. The hon. secretary, Mr. W. Carby Hay, read the annual report and balance-sheet which were adopted. The report was of a favourable character, the Society having had a successful year. There had been a gratifying increase in the number of associates; 11 lectures were of great merit, and listened to by better audiences than usual; the library had been considerably increased, and now contained most of the standard works appertaining to the profession. The Society, anxious to further the education of its younger members, had made grant of 10l. 10s. to the Yorkshire College towards the payment of a lecturer on sanitary science. The financial condition of the Society is satisfactory, there being a considerable balance at the banker's. The Travellers' Studentship, with 5l. 5s. added by the President, was awarded to Mr. T. Denton Brooks, having submitted the best set of drawings. Before the meeting concluded, Mr. Hobson proposed a vote of thanks to the retiring President in the very able manner in which he had fulfilled his duties during the past two years. Mr. Beever seconded the proposition, which was supported by Mr. Hall. The President suitably replied.

SOCIETY OF ENGINEERS.—At a meeting of the Society of Engineers, held at the Town Hall, Westminster, on Monday evening last, Mr. Josiah William Wilson, jun., President, in the chair, a paper was read by Mr. Samuel Herbert Cox, "Dry Crushing Machinery."

THE LONDON COUNTY COUNCIL.

THE London County Council resumed its weekly meetings on Tuesday last, the Chairman, Lord Rosebery, presiding.

Tenders.—Tenders were received (a) for the erection of a fire-brigade station at East Dulwich, (b) for repairs and alterations to the gas-meter testing station at Spitalfields, (c) for the erection of a gymnasium at Battersea-park, and (d) for the erection of a gymnasium and three bathing shelters at Victoria-park. (The lists are given on another page, under the heading "Tenders.")

The Limit of Height of Buildings, whether in old or new Foundations.—The Public Health and Housing Committee's report on this subject (published in the *Builder* for April 16) was again on the agenda, but it was ruled out of order, as not being within the terms of reference of the Committee.

The Shaftesbury Memorial Fountain, Piccadilly-circus.—The report of the Improvements Committee contained the following paragraph in reference to the fountain which is to be erected on one of the "islands" at Piccadilly-circus.

"On January 14, 1890, the Council assented to the appropriation, for the purpose of the Shaftesbury Memorial Fountain, of the remaining vacant space at Piccadilly-circus. Since that date the sculptor, Mr. Alfred Gilbert, has been engaged upon the work, and we are now informed that the fountain is almost ready to be placed *in situ*. It therefore becomes necessary for the Council to consider the question of (1) connecting the water-pipes with the fountain, (2) forming the foundations for the memorial, and (3) building the enclosing wall or balustrade in compliance with the provisions of the Metropolitan Improvements Act, 1858. We have ascertained that the cost of connecting the pipes with the water main in the subway in Piccadilly-circus will be about 80*l.*, and of forming the foundations and building the balustrade about 930*l.* It is possible that this estimate will be considerably reduced. We reminded the Memorial Committee that it would be necessary for this work to be done; and that Committee has expressed its regret at its inability, owing to lack of funds, to undertake the work, and has asked the Council to do it. We freely admit that this is by no means an unreasonable request, having regard to the fact that if the site were not appropriated to the Shaftesbury Memorial Fountain, the obligation under the Act of laying out the piece of ground as an ornamental enclosure and of building the enclosing wall would rest entirely upon the Council. We are confident that the refusal of the Council to incur this expenditure would preclude the Memorial Committee from laying the fountain upon the site, and the double opportunity of providing for a much-needed ornamentation of Piccadilly-circus, and for a perpetuation of the memory of the public man after whom the Avenue was named, would be irretrievably lost. We may add that the Highways Committee has given its consent to the connexion of the pipes with the water main in the subway at Piccadilly-circus. We recommend:—

"That, subject to an estimate being submitted to the Council for the purpose of requiring the sanction of the Council to authorise us to provide for the connexion of the necessary water pipes with the fountain and the formation of the foundations upon which the memorial will be placed, and the building of the balustrade around it."

The recommendation was agreed to without discussion.

Rosebery-avenue.—The Improvements Committee also reported as follows as to a proposal for the extension of Rosebery-avenue to Essex-road, Islington:—

"We have had before us a letter from the Vestry of Islington, suggesting that the Council should undertake the continuation of Rosebery-avenue along Owen's-row and Colebrooke-row into Essex-road. The Vestry states that such a thoroughfare as that proposed would afford considerable relief to the congested traffic at the 'Angel,' and that the advantages to be derived from the formation of the new street would be very great. We have asked the Vestry whether, in the event of the Council agreeing to undertake the work, it would be prepared to contribute towards the cost, but the Vestry states that in its opinion the new street should be a County improvement, and that the cost should be defrayed by the Council. Having regard to the unwillingness of the Vestry to contribute towards the cost, we are not prepared to advise the Council to carry out the proposed improvement. We therefore recommend:—

"That the suggestion that Rosebery-avenue should be continued to Essex-road be not at present entertained by the Council."

The Council concurred in this recommendation.

The other reports were disposed of by five minutes past four,—that is to say, all the reports had been gone through in an hour and five minutes, an event unprecedented in the history of the Council, as the Chairman remarked. But the sitting was by no means over. The agenda paper was full of "notices of motion." Some of these were withdrawn, but the others were not all disposed of when the Council adjourned at seven o'clock. The only one we need notice is that concerning

The "Fair Wages and Hours" Clause.—as to which Mr. Leon moved:—

"(a) That in future the 'fair wages and hours' clause be inserted in the contracts made with contractors instead of as heretofore being only put into the tender form, and that a penalty be imposed on breach.

(b) That 'fair wages' shall mean such rates of wages, and 'fair hours' such hours as have been agreed upon in each occupation between employers and the London Trades Unions concerned."

Mr. John Burns moved, as an amendment:—

"That all the contractors be compelled to sign a declaration that they pay the trade union rate of wages, and observe the hours of labour and conditions recognised by the London trades unions, and that the hours and wages be inserted in and form part of the contract by way of schedule, and that penalties be enforced for any breach of agreement."

Mr. Goodman seconded the amendment, and after considerable discussion the debate was adjourned.

THE INSTITUTE OF BUILDERS:

ANNUAL DINNER.

The annual dinner of the Institute of Builders was held in the Egyptian Saloon of "The Monaco," Piccadilly-circus, W., on Tuesday evening last, the President, Mr. Herbert Henry Bartlett, in the chair.

The President proposed the toast of "The Queen," "The Prince and Princess of Wales and the other members of the Royal Family," and "The Navy, Army, and Auxiliary Forces." Colonel Trolope, in responding to the last toast, said he very much regretted the absence that evening of Colonel Stanley Bird, who had caught a chill and was unable to be present.

Mr. H. T. Ashby proposed the toast of "The Houses of Parliament," coupled with the name of Major L. H. Isaacs, M.P., who, in reply, said the next Parliament would have some very difficult subjects to deal with, which would concern the general community, and particularly contractors and builders. One of the most important questions which would have to be disposed of was that of the proper relations between capital and labour, and in regard to that question there was certain to be a big fight. Up to the present time capital had been able to assert its claims, and labour had been compelled to relinquish some of the absurd demands which it had made. A short time ago a strike of the carpenters had to be endured by the masters, and he now understood that at no very distant date they would have to face another strike on the part of the bricklayers. It was quite clear that strikes could not go on in that piecemeal fashion, and that there must be a genuine attempt on the part of all concerned to bring those strikes to something like an end.

The President, in proposing the toast of "The Institute of Builders," said although they were not all members of the trade, he thought they must all take an interest in the calling, as it was one which affected them all. The tastes and requirements of man had so developed, and his ideas of a perfect habitation had become so complex, that a large number of different branches of the trade had been called into existence. We could not do without our houses, and it was important to us that those houses should be properly constructed. And as it seemed to be a modern idea that everybody should belong to a society, not for the purpose of self-glorification, but for aid, and for the benefit of their class, it came to pass that the builders formed a society. That society had grown and had become an Institute, and had found it necessary to obtain a charter; and now it was in a position to meet on equal terms with other corporate bodies. The ramifications of the building trade were so extensive that a surprisingly large proportion of the legislation proposed, in one way or another affected their interests, and the self-sacrifice of those gentlemen who gave their time on behalf of the Institute was deserving of all honour. There were committees and sub-committees in connexion with the Institute, and the matters which were dealt with affecting

the trade were very many. The President next referred to the Parliamentary work of one session, and proceeded to say that it was necessary to thoroughly discuss any proposed legislation, for they did not know how a little word, insidiously slipped into an Act, might affect their interests. They had in connexion with the Institute a library, and although he did not like to appear to be begging, he was sure the Library Committee would be glad to receive any volumes which gentlemen could give. Under the able President who preceded him, they had had a series of winter lectures which had been given with a view to the discussion of important subjects in connexion with the trade, and he hoped that those lectures would be started again. The building trade gave employment to more men than any other trade in the country, and it had been found necessary to keep almost what was going on. When they were beset on all hands by labour agitators, by entanglements of law, by constantly-increasing Parliamentary requirements, and the continual encroachments that labour was making upon capital,—and to his mind, notwithstanding the way in which some of the labour leaders regarded it, capital was the very staff of labour,—they felt that a body ought to exist which should adequately represent the important interests of their trade, and which should be so much in the trust and confidence of its members that it should at all times speak with authority and power.

Mr. Thomas F. Rider, President of the Central Association of Master Builders of London, then proposed the toast of "The Architects and Surveyors," coupled with the names of Mr. Thomas Blashill and Mr. T. F. Franklin.

Mr. Blashill, in responding for the architects, said that some portion of his professional career had been devoted to matters of arbitration, and he had always thought that there were two ways of dealing with differences: either to make those differences worse, or to lessen them, so that the end might be agreement. He was sure that all those present that evening hoped and wished to agree. The building trade might always rely upon the sympathy of the architectural profession, and he was very confident that those present would do what was right and proper in reference to the questions which were agitating their minds.

Mr. T. F. Franklin having responded for the surveyors, Sir John Colomh, M.P., proposed the toast of "The President," who replied.

The last toast, that of "The Visitors," was then proposed by Mr. J. Mowlem Bart, coupled with the name of Mr. W. H. Strudwick, who briefly replied.

Amongst the gentlemen present (besides those already named) were Messrs. F. J. Dove, H. A. Hurr, J. Norton, Joseph Randall, W. E. Stouer, Thos. Gregory, Wm. Brass, H. Gough, E. S. Henshaw, H. I. Sanders, Woodman Hill, Richard S. Henshaw, J. Hill, Basil Peto, T. M. Rickman, L. J. M-ston, Frank May, J. Howard Colls, and R. Neill, jun.

COMPETITIONS.

THE GLASGOW FINE-ART GALLERIES DESIGNS.—The five designers whose plans were rejected in the final competition for the new art galleries, concert-hall, and museum at Kelvingrove, have lodged through Dr. David Murray, of Messrs. Maclay, Murray, & Spens, an objection to the design which was accepted by the Executive Committee of the Association for the Promotion of Art and Music in Glasgow. The ground of the objection is that Messrs. Simpson & Allen's design does not conform to the conditions which were laid down for competing architects by the Committee. In these conditions it was stated that the central hall was to contain a minimum of 10,000 square feet, and the objectors allege that, according to the figured dimensions on the accepted design, it only contains 7,312 ft. 6 in. The difference is made up by including in the central hall what, it is maintained, are vestibules or corridors. In the final instructions to competitors, one of the clauses stated—"The central hall is not intended so much for vocal concerts as for instrumental music, and the better music is heard in the courts of the museum and the picture-galleries, corridors, and staircases surrounding the hall, the more nearly will the building meet the object of the promoters." It was also laid down that the central hall and the corridors and approaches were to be dis-

tinguished in the plans by different colouring. On these conditions the objectors have their allegation that the successful designers have included in their measurements of the central hall floorage which is not a part of it. The committee have forwarded the objection to Mr. Alfred Waterhouse, R.A., who acted as their assessor. The Glasgow Institute of Architects have also the matter under consideration.—*Glasgow Herald.*

NEW FREE CHURCH, AYR.—St. Andrew's Free Church congregation, Ayr, recently invited a number of architects to furnish designs for a new church to be erected on a site on Bellevue estate, near to Park Circus East. Seven sets of designs were sent in, and were submitted to the adjudication of Mr. Hippolyte J. Blanc, A.R.S.A., Edinburgh, who recommended the adoption of design "B," and which recommendation the deacons' court endorsed. The author of that design is Mr. John B. Wilson, Glasgow. The style of the building is modern Gothic. The form of plan suggested is that of a nave with two wide side aisles, the accommodation in the area being for 492, and in the gallery over each aisle and at the end of the nave, further accommodation for 268 is found. There is to be a spire, which will rise to the height of 146 ft. The cost of the building, without reckoning the spire, will be about 4,000l.

SCHOOLS, WOOLFIT, NEAR STOWMARKET.—In a competition among four selected architects for new schools for the School Board of Woolfit, near Stowmarket, the design submitted by Mr. Frank Whitmore, architect, Chelmsford, has been accepted by the Board.

LAYING-OUT NEW PARK AT NEWPORT (MON.)—Twenty-five sets of plans for this work have been sent in. The first premium of 50l. has been awarded to Mr. Mawson, landscape gardener, Windermere, the cost of carrying out his scheme being estimated at 10,761l.

Illustrations.

LLANDAFF CATHEDRAL.*

IN the difference in the sites of English and Welsh cathedrals, Professor Freeman says:—"Founders of Welsh cathedrals, unlike their English contemporaries, seemed to seek their dwellings in remote places rather for retired contemplation than for any active government of the Church, in sites suited rather for Cistercian abbeys than for cathedral churches." The English sees in several instances were removed to cities of greater importance, whilst the Welsh remain where they were originally founded to this day. There is no reason to believe that the cities of St. David's and Llandaff were at any time of greater importance than at present in a military or commercial sense, though the ecclesiastical population both in proportion and in actual numbers has no doubt declined. Some remains of the original clergy houses can still be seen, either in foundations or in walls, or built into modern work.

The situation of the Cathedral is one of great beauty, and in a way unique. It is surrounded on the south and west sides by wooded hills, and elsewhere by pleasant fields and meadows, which give to the Cathedral a character more distinctly rural than any other in the country. In this respect it differs from most of its English fellows, for whilst they, as a rule, are the centre and nucleus around which a busy city has grown, here at Llandaff, the "City" is little more than a village, consisting mainly of the ruined Bishop's Palace, the Deanery, and the Clergy-houses, and a few untidy, deserted-looking streets, all of which are to the south and west of the Cathedral, and high on a hill above it. From this hill a steep and picturesque lane, shaded with trees, leads down to the west front, and past it to meadows bounded by the river Taf, from which the city takes its name.

Taking Llandaff as a whole, there is little in its external appearance, except its beautiful west front, that is suggestive of a cathedral. In the absence of any central feature, such as a tower or lantern, or of transepts, or of collegiate buildings (for the ruined Bishop's palace has no connexion with the Cathedral, and might, indeed, be the ruins of a castle, so little is there

* This series of illustrations of the Cathedrals of England and Wales was begun in our issue of January 3, 1891. A list of those already illustrated, with particulars of future arrangements, will be found on page 363.

to mark its original purpose), the whole fabric might well be taken at first sight, externally at least, for an enormous parish church. The feature which is immediately noticed by

a student of architecture, and which gives the Cathedral its unique character, is the long nave, except at one point, unbroken plan, comprising the nave, choir, and presbytery under one roof.

Royal Academy Exhibition, 1852

the Lady-chapel projects at the east end at a lower level. The aisles extend the whole length of the church, and include one bay of the Lady-chapel. The one break in this line is the Chapter-house, which projects on the south side on the second bay westward of the presbytery aisle; on the plan it is a little suggestive of a transept. Another most strongly-marked characteristic is the absence, before mentioned, of any transepts or central tower. "In this respect," Professor Freeman says, "it is unique amongst Cathedrals of South Britain, and has at few parallels amongst churches of equal size, even when not designed as episcopal sees, as the present Cathedral of Manchester, Rochester Abbey, and the churches of Boston, Lincolnshire, and of S. Michael's, at Coventry."

In Llandaff, again, there is not the difference in detail between the nave and choir, viz., in the plan of the piers, in the arch mouldings, and in the treatment of the shafts dividing the bays; and the only difference externally between the latter and the presbytery is in the arrangement of the clearstory. Hence the external appearance loses a great deal in effect, a long line of roof unbroken, except where the Chapter-house occurs, and the general plainness and flatness of the treatment is very unsatisfactory, and must have been still more so in its original state, for the addition of the buttresses in the recent restoration helps to a great extent to relieve what would otherwise be a general monotony.

The ecclesiastical foundation of the See is said to be the oldest now existing in Great Britain still remaining upon its original site; but, although there is plenty of evidence to show what the original building was like (for a minute description of it appears in "Liber Landavensis"), no stone of an earlier building than that founded by Bishop Urban in 1120 now remains. The original Saxon church was most likely entirely destroyed to make room for its Norman successor, the principal remains of which are the large Early Norman arch behind the high altar, and which is one of the most effective features of the interior, and a portion of a window and wall on the south side of the presbytery, part of which has been cut away in a very arbitrary manner by the Decorated chancel.

The large Norman arch was, doubtless, the lancet arch of Bishop Urban's church, and his nave stood where the presbytery now is, whilst the site of his choir is now occupied by the present Lady-chapel. Judging from this, the original Norman church must have been a very small one, although, as the remains indicate, of a somewhat elaborate character. There is a theory that these remains are but a portion of a much larger church extending as far as the present west end, but the later work in the porches at the eastern end is much too advanced in detail to limit of the idea that they formed any portion of Urban's work; the latter is more likely to have consisted of only nave and choir without central tower or transepts, as no signs of these having existed eastward of the present Presbytery remain. Some foundations have, indeed, been found on the north side near the presbytery aisle, but what they originally formed is only very conjectural. There are more definite indications, however, on the south wall of the present presbytery, which seem to point to the fact that a Norman tower of an irregular polygonal shape existed over the present Early English vaulted bay into the Chapter-house; the core of the walls of this bay is evidently Norman, although the facing is Transitional, the walls here are very thick, and seem by their strength to have been built for a tower. The extent of Urban's church may have been the bay westward of this part.

Bishop Urban died in 1133, and there seems to have been an interval of about fifty or sixty years before building operation were again commenced. The external walls of the nave and choir, including the two Norman doorways, are attributed to Bishop Henry, of Abergavenny, who held the See from 1193 to 1218, the nave and choir and the vaulted bay to the Chapter-house being built during the latter years of his life, and that of his successor William Prior, of Oudcliff, whose death is recorded in 1229. The work carried out by these prelates is by far the most beautiful and interesting in the whole building, and well repays careful study. The detail is especially good and pure of its date, and is marked everywhere with great individuality, notably in the arch-moulds and

the manner in which these die upon the piers at the springing. The accompanying sketch illustrates this, and also the difference in the detail between the nave and choir before mentioned. The sketch shows the first bay of the nave with the last choir pier and the first pier of the nave.

As already observed, the chief beauty and the most attractive portion of the Cathedral is to be found in the west front. It was built at a time when the Early English style was at its best, and is entirely free (with the exception, perhaps, of the porch) from the slight Romanesque feeling which still lingers in the details of the nave and choir.

It is interesting to compare this front with that of Saint Remi at Rheims; the similarity of the treatment is very evident, the proportion and grouping of the windows in the middle stage is almost identical, and appears to suggest that the architect at Llandaff and Saint Remi was one and the same man.

The interior design of this portion, both in detail, arrangement, and proportion, is admirable; it gains a great deal in dignity by the difference in height between the level of the nave floor and of the ground outside, there being a fall of several feet at this point. The additional height thus gained is given to the stage occupied by the three great central lights, whose internal sill reaches nearly to the tympanum of the semi-circular doorway outside, the loss of proportion to the lower internal stage being made up by the depth below the external ground line. The manner in which the different proportions of the exterior and interior, necessitated by the two levels, are managed so as to give effect of dignity and good proportion to each, is very ingenious, and deserves close attention.

From the fact that traces of the springing of arches exist in the eastern bay of the aisle on each side of the choir, Professor Freeman believes that they were originally the western arches of a pair of towers, the position of

which would have been similar to those at Exeter, except that at the latter they are separated by the aisles from the church itself, whilst here they would have been built over them. If these towers ever existed, the Early English church would have consisted of two steeples flanking the choir, with two larger ones at the west front. This would have contributed a great deal to break up the general monotony of the design. Soon after the nave and choir were completed the Chapter-house was added by Bishop William de Burgh, chaplain to Henry III. (consecrated 1214, and died 1253), and probably completed by William de Radnor, 1256-1265. It is transitional from Early English to Decorated in style, clearly later than the nave and choir, having deeply-recessed lancet windows, with foliated heads. The plan is very unusual,—if not unique,—amongst Chapter-houses, for where they are usually either rectangular or polygonal in plan, here it is square and vaulted, in four compartments, with a plain central pillar. It has an octagonal upper story, finished with a high pyramidal roof.

During this time Urban's nave and choir existed, but on the completion of the Chapter-house his choir was removed, to make room for the next and last addition,—the Lady-chapel,—which was built about the latter half of the thirteenth century, and consequently is Early Geometrical in date. It was founded by Bishop de Breos, who was Bishop of Llandaff from 1265 to 1287, and whose tomb is in the Lady-chapel on the north side of the altar. This part of the Cathedral is fortunate in being to-day in practically the same condition as that in which its founder left it. It is a very good example of the period to which it belongs; but, by reason of its tall and narrow proportions, is in strong contrast to the rest of the work, and somewhat out of harmony with it. It is vaulted in stone of five bays, with Purbeck marble vaulting shafts, and has some good carved bosses at the intersection

of the groins. The whole detail is of a very simple and refined character. The external treatment is somewhat plainer, with long and narrow two-light windows between the buttress, these latter have three stages; the lower one has a gable or pediment at the height of the window-sill, and the upper one carried up to and terminating in the deep stone parapet which finishes the sides. The whole is covered with a low-pitched modern roof, considerably spoiling the external appearance. But, taken generally, the effect of this delightful building is quiet and dignified.

On the completion of the Lady-chapel, a complete repair and remodelling of the aisles was undertaken. It was apparently from one uniform design throughout, and originated at the east end of the aisles, the work there being contemporary with that of the Lady-chapel. In some parts the original walls were left standing, in others completely reconstructed from the ground. This work was so slowly carried out that it extended through the remaining portion of the thirteenth century, and probably through the whole of the fourteenth, when the present aisle windows, with their ogee heads and reticulated tracery, were inserted. It was at this time that all indications were destroyed, so far as the aisles are concerned, of the bases of the supposed towers. The earliest portion of Decorated date is that comprising the two bays of the aisle on the north side of the presbytery, and the work commenced but never completed in the rebuilding of Bishop Urban's nave.

Two arches were finished on the north side, but on the south the eastern one only; the next arch on this side was just started, leaving the head of a Norman arch and the commencement of the next one above, the latter cutting into the head of a Norman window just above the springing, and leaving the western jamb and the greater portion of the architrave. This peculiar stopping of the Decorated work, and the mixture of the Norman with it, forms one of the most interesting points in the Cathedral.

The north-west or "Jasper Tudor" tower and some tracery in the eastern windows of the aisles were the only additions of the Perpendicular period. The former was erected by Jasper Tudor, Earl of Pembroke, afterwards Duke of Bedford, and uncle of Henry VII. The Early English tower, contemporary with the west front, was probably destroyed at this time, but much of the old work in the lower portion was used in the re-construction of the new Perpendicular tower, and the latter still rests upon the original walls on the east and south sides.

The building of this tower was the last event in the architectural history of the Cathedral, until the first of those changes occurred which ended in the shameful state of neglect and decay in which Deans Bruce Knight and Conybeare found it, and from which they were the means of bringing it to the present,—on the whole,—satisfactory condition.

Few cathedrals have suffered more since Reformation days than Llandaff, for its history from that time until about thirty years ago is one of gradual ruin, spoliation, and decay. It was in such a dilapidated and unsafe condition in the year 1718 that the removal of the see to Cardiff was for some time seriously entertained. Storms, literal and figurative, have waged around its walls, playing havoc with its beauty, terminating in that of November 27, 1793, which destroyed the upper part of the north-west tower and a large portion of the nave. It was then left practically to the mercy of the weather for years, and in a pitiable state of decay, the walls of the nave and aisles were ivy-grown, and grass grew on the nave floor, whilst the aisles themselves were roofless.

A worse misfortune, however, awaited the Cathedral when it fell into the hands of Wood, the well-known Bath architect, about the middle of last century. A sum of about £7,000 was spent in converting the presbytery and the four eastern bays of the nave into what has been aptly compared to a Bath pump-room, but what was said by the architect to be a reproduction of an Italian temple. This incongruity existed for nearly one hundred years, until the movement for the complete restoration of the Cathedral commenced, as just mentioned, under Dean Bruce Knight in 1843; this restoration included the rebuilding of the presbytery, choir, and nave, and the external completion of the Chapter-house.

One or two other points of interest remain to be noticed; of these, the principal is the ruined Bishop's palace, which stands on the top of the

hill on the south-east side of the Cathedral. It was, apparently, mainly of the Decorated style, and very strongly fortified, and, as the remains indicate, had more the character of a castle than a palace,—indeed, it is commonly mistaken for the former. The greater portion,—nearly the whole,—was destroyed by fire in his wars against Henry IV. by Owen Glendower, who is responsible for the loss of many of the architectural beauties of Llandaff and elsewhere in the county. The old gateway, which forms such a picturesque adjunct to the Cathedral, and some ruined walls, are all he left standing of this, at one time, stately palace.

At no period in the history of the Cathedral does there appear to have been any cloisters, and there are but few stones left of its collegiate buildings. The principal of the latter class was the Archidiaconal Castle, said to have been of great magnificence. This was also destroyed at the same time as the Bishop's Palace, and by Owen Glendower. This castle formerly stood on the north-west side of the church opposite Jasper Tudor's Tower. In Browne Willis's time (the first half of last century), there was also standing to the north-east of the castle a prebendary and a treasury house, but both in very bad repair, and soon to be pulled down; and exactly east of the Cathedral, outside the graveyard, there was formerly standing a small college for the Vicars choral.

Llandaff once possessed a famous campanile, which stood about 120 yards south-west of the west front. There were but few such towers in the country, others being at Evesham, Chichester, and Salisbury; the latter, however, was destroyed by Wyatt in the beginning of this century.

Judging from an old description of the tower at Llandaff, which appears in "Liber Landanvensis," it was evidently of considerable size and fine design. The ground plan measured 42 ft. square, and the doorway,—that is, the wooden door itself,—was 13 ft. high and 7 ft. broad. The famous "Great Peter" bell of Exeter formerly hung here, but was taken down in the fifteenth century by Jasper Tudor, and exchanged to Bishop Courtenay, of Exeter, for five smaller bells.

Another interesting relic of the Cathedral as it existed before the visitation of Wood is the painting on wood from the back of the Bishop's throne, which formed part of the Decorated choir-talls, these latter, according to Browne Willis, were very refined in detail, and of an elaborate character. The painting represents the assumption of the Virgin Mary with seven attendant angels.

At the top of the picture on either side is an angel playing on an instrument of music, probably intended to mark her welcome into heaven. At the foot, on the left side, is an angel holding an escutcheon, on which are painted the arms of the Bishop and See,

and on the right a full length portrait of the Bishop himself, having a scroll coming from his mouth, on which is written the hexameter line:—

O Virgo scandens sis
Marshall cœlica pandens.

The history of this painting is very curious; during the Rebellion it narrowly escaped destruction, and was partly defaced by being covered with lamp-black. It was taken from its position during the alterations of last century, and built in the wall over Wood's Classic portico, where it was discovered by some workmen during subsequent alterations. It was then carefully cleaned and repaired, and is now on the staircase of the palace of the present Bishop. The Decorated altar-screen, which was removed to make way for the present modern one, is an excellent example of the work of that date; it was erected by Bishop Marshall, and is contemporary with the choir-stalls just mentioned. It now stands in the east end of the north presbytery aisle.

Llandaff Cathedral does not possess many monuments or tombs, although there are some deserving notice. Of these one is Decorated in style, and is on the north side of the Lady-chapel, and in the second bay from the west-end. It is of alabaster, and has nine canopied niches on each side, each containing a small figure of a saint; the whole tomb is in an unusually complete state of preservation. The tomb of Saint Teilo (whose statue is in the vesica of the tympanum of the west doorway) is interesting locally as being the tomb before which it was formerly the custom for people making purchases of land, &c., to swear to their bargains. Two curious tombs are those of Lady Audley, who is in a long robe and close muffler, with two monks bearing escutcheons at her feet, and of an emaciated figure in a winding-sheet, who fell a victim to disappointed love in the fifteenth century. C. E. M.

CARTOONS FOR STAINED-GLASS WINDOWS, EUSTON CHURCH.

THESE lithographs are reproduced from cartoons made by Mr. H. Ellis Woodbridge for windows which are now being executed by Messrs. Powell, for Euston Church.

The design is entirely executed in brown and stain on white glass, leaded in squares of equal size. The subject, as will be seen, is the visit of the three Maries to the sepulchre of Christ, on the morning of the Resurrection.

MONUMENT TO THE LATE MRS. ROWLEY, ST. NEOTS.

THIS monument, in the form of a canopied altar tomb, is now being carried out from the

signs of Mr. Frederick A. Walters, F.S.A., by r. Thos. Harp, of Lambeth, and will, on completion, be erected on the south side of the exterior of the chancel of the Parish Church of St. Neots, Hunts, of which the deceased lady's living representative is the lay rector. The position chosen is west of the sedilia and outside the altar rails. The effigy in white alabaster is habited in a heraldic mantle over the other armaments worn, and rests on a moulded slab of ark Derbyshire fossil marble, of which material is also the step or plinth on which the monument stands. The whole of the rest of the work is executed in Beer stone. Above the large arch supporting the canopy are floating angels bearing the family shields of the lady and her husband, while at her head, in the recess, is her own lozenge-shaped shield as a widow. The five niches surrounding the canopy contain figures of Our Lord in Majesty attended by angels. The rose and lily are, by special desire, largely introduced in the carving, not for the same reason the heart, emblematic of charity, over the main arch of canopy.

Notes of the Architectural Association has been understood in a sense that I certainly never intended it to bear.

Nothing was farther from my thoughts than to suggest you should make a clean sweep of your whole scheme and draw up a new one from the very beginning. The greater part of your plan seems to me excellent, though no doubt in some details you yourselves might admit of possible improvement. For instance, I thought it attempted rather too much in including certain branches of study, of which only a smattering could have been obtained within the limits of your course, and which I thought might therefore be left out till more essential things had been mastered. These are mere matters of minor detail.

The only thing of which I should like to see you make a clean sweep is the pointed reference in your *Brown Book* and curriculum to the Examinations of the Institute.

Believing as I do, and as all those with whom I am in sympathy believe,—yourself I am happy to think among them,—that the Student who works to pass and not to know is working in the wrong way, and with the wrong motive, and will never in that way qualify himself for an architect, I cannot feel any sympathy with an educational plan which contemplates examination as its goal.

When we met at your rooms we drew up and agreed to certain points.* My letter was not intended to do more than reinforce what we then agreed to.

I wish I had heard of the need of an explanation in time for publication in your journal (*A. A. Notes*), but I shall be glad if you will make this letter public among the members of the A. A., or in any other quarter that you may think proper.

In conclusion, I must express my regret, not unmixed with surprise, that some of your members should imagine I had ventured in any way to attack the independence of the Architectural Association, or, as one writer in your *Notes* puts it, to "dictate your future course of procedure." I cannot see how such an interpretation can be put on anything I have said or done. I was asked by you and others whether I would help your educational scheme, and I naturally replied that I could not join in it so long as it pointed towards examination, which I consider a misfortune. Surely this is not dictation. The Association is at perfect liberty to go its own way without any regard to me or my opinions; but when I was invited,—it matters not whether formally or informally,—to say on what understanding I would join you, I could not do otherwise than state my own views for what they were worth, and explain the conditions on which I should be glad to co-operate with you. I fail to see why this should, in Mr. Adams's words, have caused the Association "surprise, astonishment, and indignation." I may surely claim for myself that independence which the Association very properly values in its own case.—Yours very truly,

T. G. JACKSON.

14, Duckingham-street, W.C., April 28, 1892.*

SIR GILBERT SCOTT'S RESTORATIONS.

SIR,—Mr. Loftie, in his letter published in your issue for April 23, says that Sir Gilbert Scott "put forward a scheme for the destruction of the noble carved stalls" at Canterbury Cathedral. The stalls at the west end of the choir are of the time of Charles II., the canopy being profusely ornamented with wreaths of palm branches, swags, and cherubs, with the Royal arms in full relief over the doorway. These canopies Sir Gilbert Scott proposed to remove and place in the nave, in order to expose the rich stone screen, the work of Prior Henry de Estria, which is now completely hidden by them. This screen, the existence of which is known to few, resembles the side screens of the choir in general design, but is more elaborate in detail, having the spandrels of arches filled with richly-carved diaper work, also painted panels between the arched openings. The space between the cills of the arcade and the elbows of the stalls is filled with oak boarding and decorated, and the stalls of the prior and sub-prior have had canopies of stone. The original colouring of the screen is mostly in a perfect state of preservation, and agrees with traces of colouring still to be seen on the south choir screen and the back of one of the canopied monuments,—showing that this colouring was continued all round the choir. See illustration, p. 362.

Mr. Loftie remarks that at Gloucester Cathedral "nothing ancient that could be 'restored' away was left,"—a sweeping statement, leaving the erroneous impression that there is very little of the ancient work untouched.

Sir Gilbert Scott's work was chiefly confined to the choir, where he put new seats in front of the stalls, bringing back to their original places the ancient arched fronts and "shades;" he also removed the galleries.

The uninteresting modern screen at east end was taken down, and replaced with a reredos and side screens. The only work done externally was to the

*The following is the principal point referred to above:—That the instruction given by the lecturers and instructors in the studio should be directed solely to a thorough architectural training, without special reference to preparation for any examinations.—L. S.

porch, which was in such a state of decay that repairs were absolutely necessary to prevent the features from utterly disappearing.

Mr. Loftie also says that Manchester Cathedral "escaped" from Sir Gilbert Scott, but he has overlooked the fact that the ancient choir-screen, which had been cast aside as a thing of no value, was rescued by Sir G. Scott in its original position, and had it not been for him this fine oak screen would probably have been destroyed before now.

JOHN MEDLAND.

SIR,—The two letters, one from Mr. Loftie and one from Mr. Arthur Baker, printed side by side in your columns of April 23, and which seem to have been called forth by my humble effort to defend Wren's Library at Lincoln, are amusing and instructive reading.

Mr. Loftie is such a champion on my side, that he has not even had time to be correct in his facts.

It is, however, but too true that most of the buildings to which he refers have, in one way or another, been murdered under the pretence of restoration. Galvanised are left.

But—poor Mr. Baker—what can we say for him! He entirely misses the point, and is evidently living in the uttermost regions of outer darkness. Curiously enough, the monstrosity erected under the choir of restoring the south aisle, at Chester Cathedral, which Mr. Baker so much admires, was one of the pieces of gratuitously destructive restoration I had in my mind when I was mentioning Sir Gilbert as a man whose name must inevitably be classed—in time—with that of Wyatt.

At the same time, I speak of my old master, Sir Gilbert, with the highest esteem. In working so much destruction, he believed he was doing right. He spared neither time nor trouble. His ardent love for, and delight in, the buildings he was wrecking under the name of restoration, could not be exceeded. Had he lived in these days, I feel convinced that "repair," and not "restoration," would have been his watchword. A watchword which, it seems, Mr. Baker is quite unable to understand.

SOMERS CLARKE.

SIR,—It is scarcely correct to say "Worcester was the joint work of Sir Gilbert Scott and Mr. Perkins." Sir Gilbert was only called in to finish the choir and pave the nave. Perkins did the work of restoration; he saved the tower from the fate that befel Chichester, taking out and rebuilding two large piers. Perkins secured the stone vaulting that had been condemned as hopeless years before, and that narrowly escaped being substituted for wood.

Some of the mistakes that were made were not the fault of the architect, but of the authorities of the cathedral,—e.g., the geometrical west window, which ought to have been curvilinear. I have seen Perkins's design for the window in that date of style, and a magnificent design it was; but he was overruled.

Perkins was a man of retiring disposition, and was consequently overlooked; yet clever he certainly was.

Blunders were made; but I think some of our important modern men would blunder more and worse, had they the work.

W. LUNN.

Mateen, April 27, 1892.

SIR,—I would not for a moment question Mr. Loftie's right to his own opinion, on matters of principle and taste, or of the artistic power of any artist whether he be dead or living; but I do feel at liberty to protest against an author who has gained a reputation as an historian, passing from history to romance without giving his readers fair notice, and especially so when the deviation is made at the expense of the memory of that good and great man under whose spell it was my privilege to remain for sixteen years.

During the sixteen years I not only had an opportunity of witnessing Mr. Loftie's animosity to Sir Gilbert Scott, but of judging of the inaccuracy of both his past and present accusations.

Their inaccuracy is of two degrees,—the mitigated and the unmitigated.

Of the latter class are the statements: First, as regards his sight, which, far from being imperfect, was particularly keen; his fondness for fine and delicate drawings, and his appreciation of the finest detail on buildings being proverbial.

Then, as to his work, Messrs. Slater & Carpenter's reredos, at Chichester, is put to his credit or rather discredit.

He is said to have "restored the wretched screen at Winchester," whereas, before so wretched as to be only fit for destruction, it was replaced by a screen designed by Sir Gilbert. The restoration of the west front of Lichfield Cathedral is entirely omitted, and Scott and Lord Grimthorpe at St. Albans, and Cottingham and Pearson at Rochester, are pitched in company into the anti-restorationists' Gehenna without one word of proof of the justice of their joint or separate committal. One comparison should be sufficient to show that the work of Scott and Lord Grimthorpe was of an utterly different nature. Scott brought up the western end of the south wall of the nave, which was so much out of the

Correspondence.

To the Editor of THE BUILDER.

THE STEEPLE OF ST. ANTHOLIN'S.

SIR,—Referring to your "Note" in last week's number as to the former Church of St. Antholin, Vattling-street, I may inform you that the spire was undoubtedly the work of Wren.

About sixty years ago the upper part was found to be dangerous, and it was rebuilt by John Griffith; but my father, who resided in the parish in 1823, informed me that it was reduced in height, I think, about 15 ft. The capital which formed the apex was, I believe, removed to a garden somewhere in the suburbs.

In the bas-relief on the Memorial in Sizeane, I have endeavoured as nearly as possible to produce the original proportions of the spire. It may be interesting to remark that, in consequence of an irregularity in a notice calling a Vestry meeting, my father and I were enabled to rescind a resolution to remove the tower as well as the church; and matters went so far as to excavate the inside of the tower, and reinter some of the human remains found in the church, which were placed in specially-made boxes. But a parishioner, feeling that the site of the church would realise a much larger sum if the tower was removed, obtained an order in Council, and great astonishment was expressed both in the parish and outside when such order was signed. A deputation waited on the Ecclesiastical Commissioners, I think I may say headed by the former respected Editor of the *Builder* (Mr. George Godwin), who took great interest in the matter, to endeavor to get the order rescinded, but we were told it was impossible. The remains were, therefore, removed from the tower to the City of London Cemetery at Ilford, and the tower demolished.

I may say authoritatively that no doubt was ever expressed as to the spire being Wren's work.

The church as well as the spire was very interesting, on account of the elliptical dome set on an irregular octagon occasioned by the angle of the street.

If any of your readers take any interest in the matter, I shall be pleased to show them the drawings taken before the church was removed.

J. DOUGLASS MATHEWS.

ARCHITECTURAL EDUCATION.

SIR,—Since writing the letter which you kindly printed in your last issue, I have received the accompanying communication from Mr. Jackson, which, as it clears up a confused point in the correspondence under the above heading, I venture to hope you will kindly publish. I also send you the conclusion the informal meeting, held in my rooms on March 15, arrived at on the principal point then under consideration, as this is referred to in Mr. Jackson's letter. I hope these documents may satisfy Mr. Adams and those of your readers who have been able to follow this correspondence.

LEONARD STOKES.

7, Storey's-gate, S. W., May 3, 1892.

*DEAR MR. STOKES,—I am sorry to hear from you that my letter which was published in the

A. Masonry painted to imitate carved compartments. B. Carved diaper, gilt, on pale blue ground.
The Ancient Choir Screen, Canterbury Cathedral; portion showing stall and Remains of Canopy.
(See Mr. Medland's letter, page 361).

perpendicular as to be in danger of falling, without the least interference with the old work, and thus preserved this magnificent specimen of Medieval architecture which would otherwise have been totally destroyed; whereas Lord Grimthorpe pulled down Norman work, which was so strong that it required blasting, in order to carry out his own designs, and yet in the eyes of Mr. Loftie these are both "Vandalic operations."

To the former class I have ascribed the term mitigated, as I take the inaccuracies to lie rather in the meaning he intends to be attached to some of his terms rather than to the terms themselves. For instance, the word re-building which he frequently uses might, in ordinary parlance, refer to a partial re-erection of a building, or to an operation necessary to preserve a building, the old design and materials being reused, whereas Mr. Loftie uses it always as implying destruction of what was to supply something new and different.

"Scott rebuilt Chester, wholly destroying the exquisite charm of antiquity."
In this case "the exquisite charm of antiquity" was, unfortunately, caused by a decay of the facing of the walls, which, in the case of St. John's Church, Chester, where no restoration was attempted, caused the fall of the tower. And the "rebuilding" consisted of the absolutely necessary work of renewing the faces of the walls with sound stone, every detail of the new work being made exactly after the pattern of the old. Mr. Loftie's statement infers that the removal of the old stones was unnecessary; but he says nothing either in support of this, or to show how he would have had

the charm of antiquity preserved, or whether he would have allowed it to extinguish itself in its antiquity.

Again, the work at St. Asaph is spoken of as re-building, whereas the actual rebuilding was confined to only a portion of the wall and roof of the choir, which was a necessary work, and resulted in some archeological discoveries of great interest; the rest of the work being mainly the repairing and beautifying of the interior, and I may safely challenge any one who knows the cathedral before and after it fell into Sir Gilbert's hands to compare its present unfavourably with its past condition.

Again, at St. David's an unscrupulous use is made of the word rebuild. The rebuilding of the tower being only partial and confined to the piers, which were so rotten that the tower must have collapsed if Sir Gilbert Scott, with wonderful engineering skill, had not shored up the upper part of the tower and removed and rebuilt the piers one by one, and thus preserved the tower. And yet Mr. Loftie, though a professed lover of antiquity, allows his animosity to Sir Gilbert to transform this into an evil deed.

I regret that I have not time to deal with all the examples quoted by Mr. Loftie, but I think I have given fair specimens of the inaccuracy of his statements.

ARTHUR BAKER, F.R.I.B.A.

SIR,—I have just been shown in the *Builder* of the 22nd a letter from Mr. A. Baker, a former clerk of the Scots. He says that in the early days of the restoration of this Cathedral I pre-

vented Sir G. Scott from examining the closed and brick rebuilt west fronts of the porches, to find remains of the original ones, with a view to restoring them. It is impossible that he can be ignorant that the Committee, and on my motion, expressly authorised him (or possibly by that time Mr. J. O. Scott) to spend 100l. in that very investigation. The result was that they pulled down the whole of the two closed-up fronts, up to the top of the vaulting, and left the walls above supported on timber, which it would have cost twice as much to build up again if I had not restored the whole properly; and that they found nothing of any value. They did find some pretty bits of carving, which we did our best to keep as relics, but they gradually perished into dust.

Before that I one day found Longmire, the contractor for the defined works under the Committee, pulling something else to pieces. I asked him what for. He answered that Scott wanted to investigate something or other. Well, I said, I have no objection; but remember it has nothing to do with the contract, and we shall not pay for anything done without our order, as the contract says. And we heard no more of that, or any other such thing, until we had the application I have mentioned.
St. Albans, May 2, 1892. GRIMTHORPE.

THE GRISSELL MEDAL COMPETITION.

SIR,—In the *Builder* of April 16, I see that you publish the drawings which have won the Grissell Gold Medal for 1892. Will you kindly allow me space to criticise these drawings, and also to make a remark or two as regards the general conditions of the competition?

First, then, as regards the structure. The geological features of the cutting, over which the bridge is to be built, seem to have been ignored, and huge, unbeautiful (except perhaps to the contractor), and, to my mind, criminally wasteful abutments have been designed, where there was not the slightest need for any at all, nature having herself supplied rock sides to the cutting from which the arch should spring direct. I have roughly estimated the cost of the abutments as per drawing, and consider that they would require at least 5,500l. to prepare for and build. A "flying arch,"—so often met with on Brunel's railway works,—would have been all that was required; footings, of course, would have been needed if the rock was soft, and, perhaps, a pad of concrete beneath them. A much flatter curve, on the equilibrated principle, would have looked better, been safer, and saved in the sprandrel walls, although this latter would probably have been counterbalanced by the increase of span. Another point where I think Mr. Harlock has been guilty of waste is in the depth of his arch stones. The keystone of Cabin John Bridge, in America, with a span of 220 ft., is 4 ft. 2 in.; that of the Grosvenor Bridge at Chester (200 ft. span) is 4 ft. I think that both Molesworth and Troutwine would have been satisfied with 3 ft. 6 in. in the present case. If "architectural features" were sought by this excessive depth, I think they might have been gained another way, viz., by making the outside arch quoins *only* of greater depth, and feather-headed, both for appearance sake and also for getting some head and level foundation for building the sprandrel walls from.

Now, secondly, as regards the general conditions of the competition. Would it not have been well to state that economy of design, within the limits of safety, would be a most essential feature, to be considered in making the award? If this is not done in future, of what use at all is a design for this class of work. I take it that the prize drawings should be such that they would be suitable for actual constructional purposes, and not merely made up of eyeable lines, pleasing colours, and "architectural effects" on paper. Railway work, as at present carried out, is done on the safest and cheapest possible lines. If ornamentation is needful, let it take a third place, safety and cheapness ranking before it. To ensure economy in the future, I think it would be well to make each competitor send in quantities, and not merely one for his design. If this is not done I feel sure that wasteful drawings will be the result.
H. H. HUMPHREYS,
Stud. Inst. C.E.E.

P.S.—I had better add, perhaps, that I was not a competitor, nor, as far as I know, were any of my friends or acquaintances.

SAFETY OF LADDERS.

SIR,—As a test question in regard to the safety of ladders, permit me through your columns to put the following:

A ladder 60 ft. long and weighing 3 cwt., whose centre of gravity is one-third of the way from the foot, stands on a rough pavement and leans against a rough wall, its foot being 12 ft. from the wall. Will some one show by a graphical method of solution how near the top of the ladder a man weighing 1½ cwt. can ascend, the coefficient of friction for the pavement and the wall being $\tan^{-1} \frac{1}{4}$.
W. J. W.

CHRIST'S HOSPITAL.

MR.—Fourteen years having elapsed (copying in a widely-circulated statement) since a Royal Commission reported that "for a thorough reform the management and discipline of Christ's Hospital we think that its removal from London is indispensable," and the Privy Council scheme which came operative on January 1, 1891, providing station 63) that the Hospital Schools for 1,170 scholars of both sexes "shall be maintained within convenient distance from the City of London." I presume the public may expect soon to hear of nothing being done. Can anyone give any information?
BRICKS AND MORTAR.

The Student's Column.

ARMING BUILDINGS BY HOT WATER.
XIX.

BRICK-SET BOILERS (continued).

THE most customary way to set a saddle-boiler, especially of medium and large size, is to provide flues up and down along its exterior as follows:—The boiler is placed upon a level with the furnace, the height of this point being fixed by the position of the door, &c., of the furnace fittings that are furnished for the job. The front of the boiler comes up tight against the brickwork front (against which the iron furnace front is fixed), and the joint between the boiler and brickwork must be a thoroughly sound and tight one to prevent the draught and flame taking a short cut this way into the upper flue; see fig. 75.* This brickwork should be 9 in. thick.

Fig. 75.

There is frequently a difficulty in fitting the iron front and fittings to set securely against the front brickwork, owing to several causes. Firstly, the expansion and contraction of the metal, and, secondly, the opening and shutting of doors, and the use of stoking tools, are the chief causes of the brick getting loose. This happens especially if the fittings are merely secured with holdfasts in the brickwork. The object in referring to this is to explain a method of securing the front which will not only keep the fittings in place under the roughest of usage, but which will tend to keep the front brickwork tight against the boiler also, as is so necessary, as just mentioned. This method is to have iron rods or stays leading from the iron furnace front right round along the sides of the boiler and spring round its furthest end. These can be easily tightened up by having the front ends fitting through holes, screwed, and with nuts and washers.

From the illustration it will be seen that previous to the boiler being placed in position, the brickwork extension of the fire-box at back (for the boiler does not extend the whole length of the furnace) is exactly level with the top surface of the fire-bars. The bars are also exactly level with the end of the dumb-plate in front, the front ends of the bars coming just level with the front of the boiler as shown. Sometimes, when it is desired to place the boiler lower than usual, or to do with a shallower boiler-pit, the bars and brickwork are kept level, as just explained, at some two to four inches below the lower

edge of the furnace door, instead of being level with it. This inequality is made up by having the dumb-plate sloping, as fig. 76.

Fig. 76.

The common use of the dumb-plate now is to complete the furnace bottom from the bars to the front; it is a solid and strong plain plate, as bars are not needed here, and brickwork would do, only that clear way must be left beneath, the space below being the ash-pit. The dumb-plate is sometimes used in the manner originally intended, *viz.*, to place a charge of coal upon, that it may dry and volatilise some of its lighter gases, which, passing over hot fuel, are consumed, the charge of fuel being afterwards pushed on, a considerable reduction in smoke and waste products being the result. It will be noticed in fig. 75 that, from extreme front to back, the furnace bottom is quite level. This is how it should be in the usual way, and simplifies the stoking and reduces the chances of rough usage.

The furnace-bars usually occupy about two-thirds the area of the fire-box with a plain saddle-boiler, but the area varies with the pattern of the boiler, as has been fully explained (Art. XV). The rear ends of the bars are sometimes made to rest on the brickwork with a light flat bar beneath, or they may be supported on a stronger bar, clear of the brickwork, as shown. In any case, their upper surfaces have to be quite level with the brickwork in question. The front extremities rest upon the rebated edge of the dumb-plate, or in some cases the dumb-plate has no rebated edge, and both this plate and the fire-bars rest upon a strong bar which extends from side to side. This latter method is not so good as the former, not so neat, and no stronger, for the dumb-plate being supported by the brickwork at each of its ends, will carry the fire-bars well. The fire-bars are kept forward, as shown, so that the inner and direct heating surface of the boiler may have the fullest benefit of the heat and heated gases, &c., before passing away at the back into the flues.

The rear end of the boiler does not reach to the back wall by some 5 in. to 8 in. (according to size of boiler); this space forms the passage-way for the heated products from the furnace to the flues of the boiler. There is, however, some brickwork built in this space with the object of guiding the heated gases in the direction they are intended to go. In this space between the boiler-end and the wall at the back is firstly built a fire-brick bridge, as shown in fig. 75, extending about halfway up the back of the boiler; and as marked in fig. 77, which

Fig. 77.

shows the fixing work in plan, say 6 in. above the level of the fire-bars. The object of this "bridge" is, firstly, to prevent the fuel working from the fire-box into the flues; and, secondly, to check the too free escape of the heated gases, &c. As mentioned, this

bridge extends as nearly as possible half-way up, as shown at fig. 75, and also in the sectional elevation to be shown directly. With small boilers, a thick fire-brick slab is used for this purpose, but the space at back should be tolerably roomy; no barn will result as would happen if we made the other flues too wide. The action or direction of the flame at this point is to bug the boiler, to cling to it, we may say. This last illustration shows the two hot soot-doors that have to be provided for cleaning the lower parts of the flues; another soot-door is provided over the top of the boiler in front.

At a point outside the boiler, a little above where it commences to describe a circle, two mid-feathers have to be provided, one on each side, as fig. 78; they are marked "brick." The

SECTION ON A.B.

Fig. 78.

object of these feathers is to divide the flue-way round the boiler into three; they extend from the extreme back to within about 5 in. to 7 in. of the front of the boiler, as shown in dotted lines in the first illustration. From the last drawing just shown, it will also be seen that their position is a few inches above the brick bridge, or, in other words, there is a clear way for flame and heat to pass over the brick bridge and into the flues each side of the boiler underneath the feathers. This is shown by arrows on both figs. 75 and 77. After the flames have traversed the length of these flues to the front, they enter the top flue together, there being provision made for this by terminating the feathers some inches short of the front of the boiler, as shown in dotted lines at fig. 75.

They then pass along the top of the boiler from front to back, and into the chimney at the rear. It is supposed that with a low chimney and low draught the heated products have lost most of their heat after having made this journey.

To make the explanation as clear as possible, we have spoken of the flame and gases finding their way through these flues; of course, it is understood they are impelled or carried by the draught induced in the chimney.

This last drawing is in section and elevation across the front ends of the furnace-bars, and it will be noticed that the brickwork forming the bottom of the flues is also exactly level with the fire-bars and the rest of what may be called the base. The side flues are, as a rule, say, 4 in. for boilers up to 3 ft. 6 in. in length, and 4 1/2 in. up to 5 ft., and 5 in. up to 7 ft. This is large enough, as we must always remember that flame and heated gases and products, heat by contact only; that is, they must actually impinge against or touch an object, to heat it effectually.

It may be as well to explain the customary way of making the arched flue-way over the boiler, this method requiring no woodwork supports and suiting all sizes alike. After building up the brickwork at the sides to the point where the boiler begins to arch over, dry ashes are obtained and laid over the top to a thickness that agrees with the size of the flue required. The brickwork is then carried over, resting upon this bed of ashes, and when it is set, the ashes are raked out.

The final point to be mentioned is the second bridge, which is carried over, extending from mid-feather to mid-feather each side, and above the other bridge at back. This bridge is seen in the first illustration. It is introduced to prevent the flame taking a short passage up at the back of the boiler into the chimney, which will probably exist just there. Some make this bridge by carrying an iron bar from side to side, about 5 in. or 6 in. above the lower

* This and figures 77, 78, 79, are from the catalogue of Atkins & Son, Rotherham.

bridge, and building brickwork on this to the required shape and extent. This is not a good plan, for, unless the bar be a piece of small stout girder iron, it will contort or sag down, and cause very bad results. It is best to arrange to throw an arch over from feather to feather.

Fig. 79 shows the boiler finished complete,

Fig. 79.

the boiler itself being out of sight, of course. Boilers can be had with watery mid-feathers if desired; also the lower bridge at the back can be formed in the boiler with a watery through it, and when the boiler is arranged to be fed through the top, by a proper feed-hole provided, it can also have a watery front. The fixing of the saddle boiler has been dwelt upon rather fully, but it is necessary information, and goes far towards making a man content to fix almost any other boiler.

OBITUARY.

MR. LUMB STOCKS, R.A.—We regret to hear that Mr. Lumb Stocks, R.A., died last week at his residence in Holloway, after a short but sharp attack of influenza. For many years he practised the art, now almost extinct, of fine engraving, and his copies of Macaire's cartoons were published by the Art Union of London.

MR. F. J. ROBINSON, F.R.I.B.A.—We regret to hear of the death of Mr. Frederick Josias Robinson, of Derby. He was articled to the late H. J. Stevens, Fellow, and after passing some time in the office of Sir Gilbert Scott he entered into partnership with Mr. Stevens. He was fifty-eight years of age, and died from pneumonia supervening on a bad attack of influenza.

MR. GEORGE BIDLAKE.—On the 18th ult., Mr. George Bidlake, of Leicester, and formerly of Wolverhampton, died suddenly at Broadstairs, at the age of sixty-two. Mr. Bidlake was born in London, and educated at Merchant Taylors' School. He was afterwards articled to Mr. Kendall, a city architect, and was a student of the Royal Academy, where he won silver medals for his measured drawings of the Banqueting House, Whitehall, and for a design for a stamped druggist. Subsequently, he commenced practice at Wolverhampton, in which neighbourhood most of his works have been carried out. These comprise, amongst many other buildings, the Town Halls of Pontypool, Oswestry, Sutton Coldfield, and Bilton; work-houses at Dudley and Forlief; Tettschall College, Hundsworth Grammar School, Lichfield Museum, Wellington Market, South Staffordshire Hospital Extension; Queen-street Chapel, Wolverhampton, and many other chapels and churches; additions to Albrighton Hall and numerous houses in the counties of Stafford, Worcester, and Salop. Mr. Bidlake retired from practice in 1872, removing at the same time to the neighbourhood of Leicester, where he resided until the time of his death.

GENERAL BUILDING NEWS.

VILLAGE-HALL AND CLUB, WARMHAM, SUSSEX.—A village-hall and club was presented to the village by Mr. H. Harben, of Warmham Lodge, on Monday, May 2. The land upon which the building is erected was given by Mr. C. T. Lucas, of Warmham Court. The building consists of a hall about 51 ft. long and 24 ft. wide, reading-room 25 ft. by 20 ft., smoking room 25 ft. by 17 ft. 6 in., artists' rooms and caretaker's apartments. The hall has a semi-circular iron roof, the walls being lined with glazed coloured bricks in patterns. For the exterior, a simple treatment of the half-timbered style common to many parts of Sussex has been adopted. The building has been erected from the designs of Messrs. Battersby & Huxley, architects, London, by Messrs. J. Factor & Son, builders, of Horsham, at a cost of about 3,500.

CHOIR STALLS, ELYMSTOCK CHURCH, NEAR ELYMOUTH.—Some new oak choir-stalls have been placed in this church, made by Messrs. Luscombe from the designs of Messrs. Tait & Harvey, architects, of Exeter.

NEW CHURCH, WYBURNBURY, CHESHIRE.—On the 25th ult., the Duchess of Westminster laid the foundation-stone of a new church at Wybournbury, Cheshire. From stones which have been from time to time unearthed in course of excavation, it has been ascertained that no less than four churches have been built on the same site, the first existing probably about 1130. The church now in course of progress is being built on a slab of Portland-cement concrete covering the entire area. The work is being done by Messrs. Treasore & Son, of Shrewsbury and London, from the designs of the architect, Mr. James Brooks, of London.

CHAPEL, ST. MARGARET'S HOUSE OF MERCY, ROATH, CARDIFF.—On Saturday last the Bishop of Llandaff opened the new chapel situate in the grounds of the St. Margaret's House of Mercy at Roath, Cardiff, which is worked by the St. Margaret's Sisterhood, East Grinstead. The chapel consists of a nave and sanctuary with a small vestry. Accommodation is provided for sixty adults. The building is Early English in style. The materials is native stone, with box ground, stone dressings and weatherings. Internally the walls are plastered. The tile floors are from Messrs. Smith & Co., Coalville. The windows are glazed with lead lights and cathedral glass by Mr. S. Evans, West Smethwick. The ironmongery and gas-fittings are by Messrs. Brown & Co., of Birmingham. The whole of the works have been carried out by Messrs. Shanton & Son, of Cardiff, from designs and under the superintendence of Messrs. Veall & Sant, architects, of the same town.

CONSERVATIVE CLUB, CHORLTON-CUM-HARBY, LANCASHIRE.—On the 23rd ult. the Chorlton-cum-Harby Conservative Club was opened by Lady Exerton of Tatton and Mr. J. W. Maclure, M.P. The new building has been erected at the corner of Manchester and Wilbraham-roads, on a site covering an area of 2,000 square yards, from the designs and under the superintendence of Messrs. Darbyshire & Smith, architects, of Manchester. The principal entrance occupies a central position facing Wilbraham-road, and the various club-rooms are situated on the right and left of the entrance. The billiard-room, which is 40 ft. long and 25 ft. wide, contains two billiard tables, and is supplied with lavatory accommodation. The card-room and bar adjoin the billiard-room. At the other end of the building are the secretary's room, lavatories, and committee and reading-rooms; the two latter rooms being divided by a movable partition. The public hall, which is capable of holding about 800 persons, occupies the whole of the first floor, and is provided with both ladies' and gentlemen's retiring-rooms. The public and platform entrances are separate from the club entrance and from each other. A connexion is made between the club and hall for the use of members. A cooking-kitchen is also provided in the basement, with a hoist connecting the kitchen with the club and rooms above. A caretaker's house has been erected at the rear of the club. The exterior of the building is faced with Accrington red pressed bricks, relieved with Edward's Raabon buff terracotta.

The roofs are covered with Buttermere green slates. The heating apparatus is on the low pressure hot water system, and supplied by Messrs. Leach Bros. Mr. Owen Williams is the general contractor for the works. The cost of the buildings and furniture will be over 4,000. The building is provided with a clock tower.

PAROCHIAL INSTITUTE, WOODHOUSE, LEEDS.—A working-men's institute, which has been erected by the Misses March, has just been opened at Woodhouse, near Leeds. The building is faced with pressed bricks, having Bradford stone dressings, the roofs being covered with Buttermere green slates. The two entrances from Cathcart-street give access on the ground floor to a reading-room and a recreation room, each about 28 ft. by 20 ft. There is also a small lecture-room behind these two rooms, 31 ft. by 23 ft., fitted up with a platform. A large tea-making-room adjoins. A committee room, lavatories, and caretaker's house complete the accommodation on this floor. Near the two entrances are two stone staircases leading to the large lecture-hall on the first floor. This room is 70 ft. by 40 ft., and will accommodate about 600 people. The platform is constructed in sections, the permanent portion being large enough for ordinary occasions, while the enlargement makes it suitable for dramatic and other performances. The roof timbers are moulded, and spring from moulded stone corbels. Air trunks are fixed in the ceiling to carry away the vitiated air, which is extracted by one of Boyle's air pumps placed in an octagonal turret. The ground falling rapidly from front to back, the opportunity has been taken to construct a covered playground in the basement, which is lined with white glazed bricks, and lighted through an arcade of semi-circular arches. Messrs. Smith & Treadwell, of Leeds, were the architects, and Councillor Hannam has erected the building from their designs.

NEW CATTLE MART, GATESHEAD.—On the 25th ult. the new cattle mart for auction purposes was

opened at Redhough, Gateshead, by Messrs. T. and J. Maughan & Co. The mart is situated about fifty yards from the Gateshead entrance to the Redhough Bridge, and is within a short distance of the Newcastle Cattle Docks. It covers an area of about 1,350 superficial yards, and it has been laid out and erected by Messrs. Geo. Scott & Son, contractors, of Newcastle, under the personal supervision of Mr. T. Nelson. The sale mart proper, which is covered in, and lighted from the roof, is about 36 ft. square, and the sale space is about 24 ft. square. The whole of the pens and stalls are cemented throughout, and the whole of the alleys and the sale space are paved with cement blocks.

CORPORATION PUBLIC BATHS, STAFFORD.—The formal opening of the new baths recently erected in the borough of Stafford took place on the 19th ult. The elevations of the bath to the river and to Green-gate-street are in the half-timbered style, the material generally used being red brick. A clock tower, at present without a clock, is used as a shelter for the fire-escape. Within, there is a main swimming-bath, 83 ft. by 33 ft., and a ladies' swimming-bath (which at some future time may be used as a brine plunge bath), 60 ft. by 18 ft. The greatest depth of the large bath is 6 ft., and of the small 5 ft. 6 in. Each bath has a roomy gallery, and a suite of private baths opens on to the ladies' gallery. A suite of private baths for gentlemen is also attached, and there is a set of rooms and baths for the Turkish bath. There is provision for a number of private brine baths, which can be put in use as soon as the brine at the north and of the town become available. The cost of the whole is about 6,000, and the designs were by the Borough Surveyor, Mr. W. Blackshaw.

WELSH CHAPEL, SHADWELL, LEEDS.—The foundation-stones of a new Wesleyan Chapel at Shadwell were laid on the 27th ult. The design of the new chapel is by Mr. Geo. F. Danby, architect, Leeds. The building is to be constructed of stone, with an interior lining of bricks, and the edifice will be in the Decorated Gothic style, with open timbered roof. A large class room and minister's vestry will be provided. The whole of the wood-work will be of varnished pitch-pine, and the roof will be covered with Welsh slates.

BOARD SCHOOLS, BRECON.—The corner-stone of the new Board schools in Mount-street, Brecon, was laid by the Mayor of the Borough, Colonel Morgan, on the 15th ult. The accommodation will be for 193 infants, in three rooms on the ground-floor, where are also the cloak-rooms and lavatories of the mixed schools, and two classes of boys of 110 boys and 119 girls being above. Mr. E. H. Lings Barker, of Hereford, is Architect to the Board, and the contractor of these schools is Mr. B. Jenkins, of Brecon, whose contract amounts to 2,580.

SANITARY AND ENGINEERING NEWS.

WATER SUPPLY, BISHOP'S CASTLE.—A Local Government Board inquiry was held at Bishop's Castle, Shropshire, on the 25th ult., by Col. Luard, R.E., on an application of the Corporation for sanction to borrow 4,000 for works of water supply. Miles west will be collected on the hills about six miles west of the town, and brought in by gravitation. The engineer for the works is Mr. W. Wyatt, of Shrewsbury.

SEWERAGE, ABERGWYNNYF, SOUTH WALES.—The Sanitary Authority of the Rural Sanitary District of the Neath Union in the counties of Glamorgan and Brecon, having applied to the Local Government Board for sanction to borrow 7,000 for works of sewerage and sewage purification, an inquiry was held on the 20th ult. at Abergwynnyf by Major General Henry Darter Crozier, R.E., when evidence was given in support and against the granting of the loan. The scheme was virtually approved of by the opposing side, the main contention being that the work should not be done by the Rural Sanitary Authority, but by the New (Local) Board when formed. The process recommended is the International Company's process by "Ferrozene" and "Polarite," and is the first instance of its being introduced into Wales. The sewage will be conveyed to the outfall works by gravitation. The precipitating tanks are constructed for either the "quiescent" or "continuous flow," and a patent arrangement is to be applied to the polarite filter for automatically cleaning the top layer of sludge without having to remove the same off the beds for washing. The engineer for the scheme is Mr. W. E. Clason Thomas, of Neath.

BUILDING TRADE WAGES IN GENEVA.—According to a recent report of the United States Consul at Geneva on labour and wages in French Switzerland, carpenters, joiners, masons, &c., generally work by the hour, ten forming a day, for which they receive 4s. 2d. to 5s. When paid by the piece the rates are fixed so that they earn from 4s. to 5s. 7½d. a day. In these trades there are many employed and workmen who fix prices and broken out occasionally. Locksmiths and plasterers earn about the same wages, but in some cases more, viz. 5s. 7½d. to 6s. 3d. a day.

FOREIGN AND COLONIAL.

FRANCE.—In a cellar in the Rue de la Reine (Quartier des Gobelins), a large stone tomb has been discovered, containing bones, pieces of money of the time of Dagobert, and arms. The Service of Historical Monuments is taking steps to find out if an ancient Merovingian cemetery did exist in this neighbourhood, where for twenty years important archaeological remains had been discovered.—The General Council of the Vosges has just voted the necessary funds for the erection of a museum in the house of Joan of Arc at Domrémy. The Council have charged their President to petition the sculptor Antonio Mercié to assist the completion of the statue of Joan of Arc at Domrémy.—A committee has been formed in the Department of Indre-and-Loire for the erection of a statue of Joan of Arc at Chinon. This Committee has just appealed to the sculptors or models one-fifth size, which will be the object of a competition open till July 15. The statue will be 2.40 m. high.—The town of Toulouse has just opened a Museum of Decorative Art in the beautiful edifice known as the Collège Saint Raymond. This museum contains a Greek, Gallo-Roman, and Renaissance treasures which were before crammed into the Museum of Painting. It is M. Roussin, Inspector Architect of Historical Monuments, who has turned the edifice into its present use.—M. Diehl, Professor of the Faculty of Letters at Nancy, is charged with a mission to Tunis to study the ancient Roman inscriptions and the principal monuments of the Byzantine period.—The jury on the open competition for the construction at Biarritz of an Establishment de Bains de Mer has just given its judgment for the first degree. Out of twenty-four designs sent in four have been selected; these are by MM. Felix Collinand, architect in Paris; Gallinier Curvale, architect at Toulouse; Métiévier, architect of the Department of Gers; and Nodet, architect in Paris.—The Academy of Beaux-Arts has just chosen the subject for the Bordina Prize, to be awarded in 1894.—Continue the history of engraving on medals in France from the end of the 16th century to 1890. For the Troyen Competition, the prizes of which will be awarded in 1893, the Academy has chosen as subject, "The border of a pond in a wooded valley, with animals; effect of sun and storm clouds."—The celebrated panorama of the battle of Champigny, by the artists De Neuville and Detaille, which attracted such crowds a few years ago, is going to be parcelled out, and the fragments sold separately.—The artist Weerts has just finished a great allegorical ceiling, ordered by the State for the decoration of the Hôtel de Monnaie in Paris, and which symbolises the triumph of the Universal Exhibition of 1889.

MISCELLANEOUS.

COMPLETION OF THE WIDENING OF LUDGATE-HILL.—According to Colonel Haywood's report for last year to the City Commissioners of Sewers, the widening of Ludgate-hill (southern side), which was begun twenty-seven years ago, will shortly be effected in its entirety. The claims, amounting to nearly 83,500*l.*, in respect of Nos. 5, 7, and 9, have been ultimately settled for 32,000*l.*, the Commissioners giving the surplus land of Nos. 1 and 3, Ludgate-hill, together with Nos. 1 and 2, St. Paul's churchyard. These premises will be taken down within a few weeks' time, and the frontage set back in alignment with the new houses recently built. A well-known firm of tea and coffee dealers have already removed to other premises in St. Paul's churchyard, and Dollond, the optician's,—a business established in 1750, at No. 1, Ludgate-hill,—is re-opened in a shop lower down. The average width of the street was 43 ft. In 1868 they arranged with the London, Chatham, and Dover Railway Company for a widening of the over part of the hill on the making of the bridge and viaduct. In course of the next five years the properties Nos. 51—71 (odd), as far eastwards as St. Martin's-court, had been taken down, the block Nos. 37 to 47, and 5, St. Martin's-court, between the court and Pilgrim's-treet, was demolished, the block Nos. 11 to 35, between Pilgrim-street and Creed-lane, having been taken (in two portions) in the meanwhile. A conspicuous feature of the new buildings, by St. Martin's-court, is the City Bank, of which we published an illustration on 22 August last. The bank was planned and designed by Mr. T. E. Colclitt. From reports of the meetings of the Commissioners we gather that the sums expended upon the purchase of interests in the various properties will have amounted to about 375,000*l.* for, we think, 39 houses; a total that is subject to abatement, if the capitalised value of the ground-rents, estimated at 4,000*l.* a year, with other recoupments, be reckoned. Messrs. Joseph & Co. have been the architects of the two blocks of houses and offices at the corner of Creed-lane and Pilgrim-street.

A NEW DREDGING PROCESS.—A further trial of the new dredger built by Messrs. Simons & Co., Renfrew, for the New South Wales Government, and which is to be used in Sydney Harbour, took place on April 12 in the presence of a number of

people interested in harbour construction. The two suction pipes through which the sand, &c., is lifted, measure 20*in.* in diameter, and when the centrifugal pumps were in full operation drew up and deposited in the hoppers dredgings from the end of the river at the rate of 1,000 tons an hour, or about double the quantity guaranteed in the contract.—*Iron and Coal Trades Review.*

DISSOLUTION OF PARTNERSHIP.—Mr. R. W. Hitchins asks us to say that he has dissolved partnership with the firm of Messrs. F. Jones & Co., Perren-street, Kentish Town.

SCAVENGING IN NEW YORK.—The *Engineering Record* (New York) for April 16 says:—"We are glad to note that the New York Street-cleaning Bill, which was prepared in accordance with the recommendations of the advisory committee of citizens, has become a law. Under its provisions, the streets will be cleaned by a permanent corps of trained labourers, applicants for appointment in which must pass an examination as to character and physical fitness."

ELECTRIC ORGANS.—The new Hope-Jones system of electric organ control is to be called into requisition at All Saints' Church, Bristol. Mr. W. G. Vowles is about to build an additional choir organ, and to entirely reconstruct the present instrument in accord with Mr. Hope-Jones's patents, in such a manner that the whole of the organ can be controlled from a movable key-desk which will be placed at the entrance to the chancel.—*Electricity.*

THE KENNEDY DRY PRESS BRICK MACHINE.—Some months ago (November 14, 1891, p. 372) we noticed what we believe was the first public exhibition in this country of an American invention known as the Kennedy Dry Press Brick Machine. The exhibition took place at Southall Brickworks, Middlesex, and a large variety of clays were tried, including the white clay of Cambridgeshire, and slate from North Wales, from all of which bricks of very good form were moulded and turned out at the rate of four per minute, computed to yield 26,000 per day. Since then, the prospectus of a Syndicate has been issued. Mr. Nichols, the proprietor of the Thames Pottery Brick and Tile Works, near Southend, at the mouth of the Thames, has erected a complete working plant in a permanent building some 60 ft. by 25 ft. on the ground plan, and two stories high. The steam is brought from a boiler previously in use at 100 yards distance away to a steam-engine of apparently about 12 horse-power, fixed within the new building. The crusher which pulverises the clay, the hopper-elevator which carries the powdered clay to the sieve on the upper story, and the brick-making machine, which is seated on the ground floor, are each driven direct by separate belting from the engine. On Tuesday last the directors assembled at the brickworks to receive a large party of practical brickmakers, and other visitors, who came to see the operations. Besides the local brick earth, other clays were tried, including clay from Bridgewater forwarded by Messrs. Major & Co., and a remarkably adverse kind of fuller's earth sent by Mr. Lloyd Price of Bala. The latter pulverised into dust so fine that it filled the hopper-room, and came out by the windows like a fog. By shaking the speed of the crusher and the addition of a small percentage of moisture, bricks were, however, moulded from it. The chief feature in the results of the Kennedy machine is that drying before burning is eliminated. The bricks are smooth-faced all over, but an indentation or frog could be put on one or on both sides, if desired.

SMALL-POX HOSPITAL, BRADFORD.—Messrs. Morley & Woodhouse, the architects for this building, ask us to state that the scheme for the building (in regard to heating and ventilation), illustrated in the *Builder* of April 16, is patented by them in conjunction with Mr. E. Oldroyd, the heating engineer, and they wish this to be known in order that no one may inadvertently make use of it. While we are happy to publish the statement, we feel, however, some doubt whether the patentees will find that they have power to protect the planning and arrangement of a building by patent. The law on the subject may still be doubtful, but precedents are against it.

A NEW STRAIGHTWAY VALVE.—Messrs. Beck & Co. send us an illustration and description of the Handy Straightway Valve, a double-disc valve operated by a detachable lever instead of the ordinary wheel: the position of the lever showing the degree of opening of the valve. It is designed for low pressures, as more compact than the ordinary globe valve, and for such a purpose seems likely to be useful and convenient.

WORKMEN'S DINNER.—On the 30th ult. Messrs. Marsh, Son, & Gibbs, of the Bath Stone Works, Box, entertained about 100 of the men and youths employed at their stone quarries at Rudloe and Croysham, at a repast at Rudloe. The dinner was presided over by Mr. R. J. Marsh, the senior partner in the business, the vice-chair being filled by Mr. F. H. Gibbs. After the dinner, various toasts were proposed and songs contributed.

THE ENGLISH IRON TRADE.—Little change has occurred in the English iron market during the past week; the demand generally is of a hand-to-mouth character, although there is an improvement in the demand for crude iron in Cleveland. The returns

for this district show a reduction of stocks amounting to 75,000 tons. The production exhibits a decrease of 101,951 tons on the month. There are only four furnaces in blast, all on hematite. Manufactured iron is in restricted inquiry, and the tinplate market remains very dull. In steel there is very little doing, and rails are easier. Both ship-builders and engineers continue slack. The coal trade generally is not over active.—*Iron.*

CAPITAL AND LABOUR.

BIRMINGHAM.—The dispute at Birmingham between the master-builders and the bricklayers and their labourers still continues. The bricklayers demand an increase of pay from 8*sd.* an hour to 9*sd.* and the labourers ask for 6*sd.* an hour instead of 5*sd.* The strike has now entered on its fifth week.

CARDIFF.—A serious dispute has arisen in Cardiff affecting about 3,000 carpenters, joiners, plasterers, bricklayers, masons, and plumbers. After protracted negotiations, a strike has been resolved on. The questions at issue are piece work, sub-contracting, and importation of prepared stone and joinery. The masters have signified their willingness to grant an advance of 3*d.* per hour. The men demand 1*d.*

HARROGATE.—The *Leeds Mercury* says that the building trade at Harrogate is now practically at a standstill, the stonemasons being out on strike for an advance of wages. The masons only gave a week's notice before going out, and the master builders maintain that such a short notice is unjust, as they are fairly entitled to a month's notice before any alteration should be made in the rate of payment.

STAFFORD.—The bricklayers of Stafford came out on strike on Monday morning for a rise of wages from 7*d.* to 7½*d.* per hour. The *Birmingham Gazette* says that the officials of the Union met the heads of the different firms during the day, with the result that the advance was conceded by all except one contractor.

WORCESTER.—The bricklayers of Worcester still remain out for an advance from 7½*d.* to 8*d.* per hour. The house decorators and painters have accepted the 3*d.* advance which the masters offered when 1*d.* was claimed. Over 200 bricklayers' labourers came out on Monday for an advance from 4½*d.* to 5*d.*, but they decided to accept the masters' offer of an immediate rise to 4¾*d.*, and an advance to 5*d.* in May of next year.

MEETINGS.

SATURDAY, MAY 7.

Sanitary Inspectors' Association (Carpenters' Hall).—Mr. Frederick T. Poulson on "The Circulation of Rain Water." 6 p.m.
St. Paul's Ecological Society.—Visit to St. Paul's Cathedral. 2.15 p.m.
Edinburgh Architectural Association.—Visit to Pittendie Castle and Sealhead Tower.

MONDAY, MAY 9.

Surveyors' Institution.—Professor G. E. S. Boulger on "The Scientific Study of Timber." 8 p.m.
Society of Arts (Cantor Lectures).—Dr. Percy F. Frankland on "Recent Bacteriological and Chemical Research in Connection with the Fermentation Industries." II. 8 p.m.
Clerks of Works Association (Carpenters' Hall).—Monthly meeting. 8 p.m.

TUESDAY, MAY 10.

Institution of Civil Engineers.—Mr. A. P. Trotter on "The Distribution and Measurement of Illumination." 8 p.m.
Royal Institution.—Mr. Frederick E. Ives on "Photography in the Colours of Nature." I. 3 p.m.

WEDNESDAY, MAY 11.

Society of Arts.—Mr. G. L. Addenbrooke on "Uses and Applications of Aluminium." 8 p.m.
Civil and Mechanical Engineers' Society.—Annual Dinner, Holborn Restaurant.

THURSDAY, MAY 12.

Institution of Civil Engineers.—Students' visit to the Beckton Gasworks, the Northern Outfall Sewer, the Victoria and Albert Docks, and the P. & O. s.s. *Oceana*. (Leave Fenchurch-street at 9.18 a.m.)
Institution of Electrical Engineers.—(1) Continuation of discussion on Mr. A. P. Trotter's paper on "The Light of the Electric Arc." (2) Dr. J. H. Gladstone and Mr. W. H. Hibbert on "The Cause of the Changes of Electro-motive Force in Secondary Batteries." 8 p.m.
Royal Institution.—Professor Dewar on "The Chemistry of Gases."—III. 3 p.m.
Society of Antiquaries.—3.30 p.m.
Edinburgh Architectural Association.—Annual Meeting. President's Valictory Address. 3 p.m.
Dundee Institute of Architecture.—Mr. James Thomson on "Modern Sanitary Plumbing and its Defects." 8 p.m.

FRIDAY, MAY 13.

Architectural Association.—Nomination of Officers. Paper by Mr. C. E. Ashbee on "The Relation of the Architect to the Workman." 7.30 p.m.
Institution of Civil Engineers.—Students' visit to Woolwich Arsenal, the Works of the London Electric Supply Corporation, Deptford, and the Tower Bridge. (Leave Charing-cross at 9.40 a.m.)—Students' annual dinner at the Holborn Restaurant 7.30 p.m.

NORTHAMPTON.—For additions to a school at West Haddon, for the Heygate Schools Trustees. Messrs. Ingram & Shaw, George Richman & Leatherland. £125 0 Seal & Palmer, West A. Mott. 118 0 Haddon (accepted) 4112 10

NOTTINGHAM.—For proposed additions to Ilkeston-road Board Schools, for the Nottingham Education Board. Mr. A. H. Goodall, architect, Market-street, Nottingham. T. Barlow 42,475 0 J. Oberoff 42,115 0 Gilbert & Gabbitts 2,250 0 J. Cooper 2,131 0 A. B. Clarke 2,250 0 F. Wastnaby 2,113 0 Emerson & Franks 2,245 0 J. Shaw 2,111 0 J. Hutchinson 2,250 0 G. A. Pillatt 2,109 0 G. Bell & Son 2,225 0 B. Kenning 2,090 0 J. Attenborough 2,198 0 Thos. Cuthbert, Not. J. F. Price 2,154 3 tingham* 2,039 0 F. Evans 2,149 0 * Accepted.

PLYMOUTH.—For the erection of five dwelling-houses at Crown-hill (Knackerknowle), for Mr. Sampson Revell, of Truro. Mr. J. H. Keats, architect, 34, Bedford-street, Plymouth. Quantities by the architect.—Lapthorne & Good 42,579 0 F. C. Ambrose 42,158 0 R. Stanlake 2,202 0 J. Finch 2,150 0 J. Taylor 2,259 0 J. Cooks 2,147 0 J. Jubb 2,300 0 G. S. Bellabar 2,085 0 A. R. Leighton & Son 2,280 0 Reed, Birkitt & Co. 2,025 0 Watkins, Bryant, & Co. 2,238 0 W. B. Blake 1,859 0 T. May 2,198 0 A. N. Cole, Plymouth* 1,733 0 Tozer & Son 2,194 0 R. S. Gould 1,644 7 * Accepted.

RICHMOND.—For proposed new shop at the corner of New and Church roads, Richmond. Mr. Frank E. Smees, architect, 12, West Epsilthield, E.C. 2.—W. Lamb. [No competition.] 4173 0 0

RICKMANSWORTH (Herts).—For alteration at Hightfield, for Mr. R. L. Warwick. Mr. C. J. Ayre, architect, Watford. 4150 0 Waterman 424 0 Brown & Sons 4294 2 Turner, Ltd. 311 Dore & Co., Watford* 283 * Accepted.

RICKMANSWORTH (Herts).—For various repairs to the brewery house, for Messrs. Satter & Co., Limited. Mr. C. P. Ayres, architect, Watford.—B. W. 4445 0 Dave & Co. 4475 0 Waterman 448 0 Turner, Limited, Watford* 389 * Accepted.

SOUTHAMPTON.—For the erection of office, &c., in the Octagon, for Mr. F. Page. Mr. A. W. Colbreath, architect, 12, Portland-street, Southampton. Quantities by the architect.—H. J. Sanders 42,368 0 Reed, Birkitt & Co. 23,473 0 H. Stevens & Co. 5,242 0 Morgan, Islet, & Morgan, 4,438 0 P. Crook & Sons 5,499 0 J. W. Roe & Co. 5,332 0 J. Byer & Son 4,482 * Accepted.

SUTTON-IN-ASHFIELD.—For the proposed erection of twelve cottages, George-road, Sutton-in-Ashfield, for Messrs. Heath & Johnson. Mr. A. H. Goodall, architect, Market-street, Nottingham. E. Keeling 42,250 0 J. Crisp 42,289 0 J. Cooper 2,410 17 0 Goodband & Franks, 2,244 17 0 G. Bell & Son 2,490 0 J. F. Price 2,250 0 0 G. A. Pillatt 2,490 0 W. Savage 2,100 0 0 J. Hutchinson 2,540 0 G. Culliton 2,085 0 0 Thos. Cuthbert 2,510 0 Chantlers & Pellett, Sutton-in-Ashfield* 2,075 0 0 H. Vickers 2,300 0 * Accepted.

TORQUAY.—For additions to vestry and transept, St. Mary Church, Torrey, Devon. Mr. Geo. H. Follows, Torrey, architect, 3, Queens Anne's-gate, Westminster, London, S.W. Quantities by Mr. R. H. Wray Hale, 5, Duke-street, Strand, W.C. Messrs. E. L. Lusscombe, 41, 298 1/2; Fred. Mathews, 6640 John Parker 770 Alfred Harris, St. Mary Church, Edward Boyer 770 near Torquay* 4207, 1/2, 6d. 1/2 * Accepted.

TUNBRIDGE WELLS.—Accepted for a residence at Glipsa Cross near Tunbridge Wells, Kent, for Mr. G. G. Powell. Mr. C. E. Lawell, architect, quantities by Mr. R. C. Glend. Wallis & Son, Maidstone 41,633 0 0

WANSTEAD (Essex).—For the erection and completion of new residence and stables at Wanstead, for Mr. J. Richardson. Mr. Geo. Blowers, architect and surveyor, 46, Queen Victoria-street, E.C. 1.—Holland 41,479 0 W. T. Nichols 41,017 0 Barker 1,445 0 Chas. L. Cook 1,909 0 Grimes 1,073 * Accepted.

WATFORD.—Accepted for temporary bridge, restoring walls, &c., in yard at Cannon Brewery, for Messrs. Deakin & Co. Mr. G. P. Ayres, architect, Watford.—Dove & Co., Watford 4291 0 0

WELLINGBOROUGH.—Accepted for a residence at Hatton Park, Wellingborough. Messrs. Talbot-Brown & Fisher, architects, Wellingborough.—George Heuson, Wellingborough 41,336 14 0

WELLINGBOROUGH.—For erecting public swimming-baths, Wellingborough (exclusive of engineering work). Messrs. Talbot-Brown & Fisher, architects, Wellingborough.—Green Bros., Palmerston-road, Northampton 41,453 0 0

WELLINGBOROUGH.—For erecting twelve cottages, Stanley Estate, Wellingborough, for the Wellingborough Co-operative Society. Messrs. Talbot-Brown & Fisher, architects, Wellingborough.—George Heuson, Wellingborough 42,332 0 0

WORKSOP.—For trying a sewer at Hartill, for the Union Rural Sanitary Authority. Mr. W. T. Brown, surveyor, Sherwood-road, Worksop.—E. Dearden 42,315 17 6 C. Buckle, Hartill* 42,325 0 0 C. Miskin 300 0 0 J. M. Herriog 194 10 0 Thos. Meakin 474 0 0 * Accepted.

Rebuilding 189, Upper-street.—Mr. R. Maskall, builder, &c., 189, New North-road, writes calling our attention to an error in last week's list of tenders for this job. The name of the lowest tenderer should have been "Maskall," not "Marshall." The mistake was not ours.

SUBSCRIBERS IN LONDON and the SUBURBS, by prepaying at the Publishing Office, 1/6s. per annum (or 4s. 6d. per quarter), can ensure receiving "The Builder," by Friday Morning's Post.

TO CORRESPONDENTS.

J. S. H. (letter forwarded as requested).—"Lover of Fair Play" (should have enclosed his name and address. We cannot print communications not so authenticated).—C. G.—J. B.—E. T. S. (it is a piece of articles' bad grammar of which unfortunately we get too much. What the writer meant to imply is obvious enough).—T. P.—R. & Co.—W. W. L.—P. G. S. (too small).—J. P. (we cannot insert tenders without amounts, unless they are at per schedule of prices).—W. T. (we do not insert such items).—E. H. & Son (too late).—O. A. J. (we cannot undertake your letter).

All statements of facts, lists of tenders, &c., must be accompanied by the name and address of the sender, not necessarily for publication. We are compelled to decline pointing out books and giving addresses.

Note.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.

We cannot undertake to return rejected communications. Letters or communications (beyond mere news items) which have been duplicated for other journals, are NOT DESIRED.

All communications regarding literary and artistic matter should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

TERMS OF SUBSCRIPTION.

"THE BUILDER" is supplied direct from the Office to resident in any part of the United Kingdom at the rate of 1/6s. per annum in advance. To all parts of Europe, America, Australia, and New Zealand, 2/6s. per annum. To India, China, Ceylon, &c., 3/6s. per annum. Remittances payable to DOUGLAS FOURDRINIER, Publisher, No. 48, Catherine-street, W.C.

W. H. Lascelles & Co.

121, BUNHILL ROW, LONDON, E.C.

Telephone No. 270.

HIGH-CLASS JOINERY.

Architecture at the Paris Salon.

THE extent of wall space covered by architectural drawings at the Salon is enough to make a conscientious critic somewhat anxious. Two large rooms are filled with strainers (the framed drawing is not *de rigueur* in the architectural department), the whole of one side of the gallery flanking the great central hall of the Palais de l'Industrie, and two-thirds of the opposite side. Nor is it possible to make a selection out of the numbers very easily, or to settle at a glance what to pass over. There is a defiant equality of excellence in the drawing, for the most part, which renders selection difficult at first sight. Indeed, while one complains that architecture is cut short of room at the Royal Academy, one may at the Salon rather be inclined to smile at the liberality of space which allows of the exhibition of a whole set of half-a-dozen or more large geometrical drawings to illustrate one of the commonest of red and yellow brick villas, "La Marouette," by M. Saintier. But if the space is abused in some such cases, for the most part the liberality in this respect is a clear gain, as it enables architects to send drawings in which all the detail can be well and clearly made out, and the final effect of the building far better estimated than it can be from the small drawings with which English architects are obliged to content themselves.

As usual, the proportion of restorations is very large—the kind of things that are at once turned out of our Royal Academy, as matters of no kind of value; and along with these are a number of studies for buildings,—"projets," the drawings of works executed or commissioned being by far the least numerous. At the Academy the preference seems to be for representations of executed works, as far as can judge by the logic of facts; at all events we see this year some very bad drawings hung of executed buildings, and we know of at least one very fine drawing

of a restoration which has been refused. Either tendency might be defended. It may be urged on the one hand that the architectural portion of an annual exhibition should represent the work that has been carried out in the year. It cannot be denied on the other hand that restorations and ideal designs represent the kind of work which can be shown in drawings and in no other way, and that architects are so commonly restricted in their artistic ambition in the conditions of actual building that they may very well be glad to have opportunities of showing what they could produce if fate were kinder to them. Whether there are a large number of drawings of executed work sent in and refused we have no means of knowing; but we surmise that the character of the Paris architectural exhibition results from the tastes of the exhibitors as much as from the inclinations of the jury.

The place of honour is supposed to be in the two enclosed rooms rather than along the gallery. There we may notice first M. C. N. Normand's large coloured geometrical drawing giving his idea of the restoration of the Parthenon before the invasion of the Persians; i.e. the supposed Parthenon on the site afterwards just crossed by an angle of the Erechtheion. M. Normand shows us the front of a hexastyle Doric temple with a strongly-marked necking to the columns and a large and clumsy echinus; the triglyphs painted blue and the metopes painted with a geometric arrangement of the "honeysuckle" ornament; the back of the pediment is painted dark red with only a sun in the centre. It is not easy to see why the metopes should be supposed to be treated with flat painting in this temple, when metope sculpture was already known to have been used in more ancient examples. The drawing shows the other supposed objects of the Acropolis at the period, so far as they come within the line of sight; among other things, small temples or shrines cut after the manner of the timber-like rock-cut tombs of Asia Minor; a very doubtful suggestion. We can hardly imagine such structures getting deliberately made at Athens contemporaneously with such far-advanced Doric as the main temple shown in the drawing. Other details shown, "après les

résultats des dernières fouilles," look also far too archaic in form and colouring for the assumed period, the drawing seems to include types of very different periods in fact. But it is a highly interesting study, accompanied by large detail drawings, a plan of the Acropolis, and a section of the restored Parthenon with a colossal Athene not too archaic for the situation. The section represents the Temple with an entirely closed roof and no lighting.

M. Espouy, whose name is well known now in connection with Classic restoration drawings, exhibits a pretty restored view of the Wingless Victory temple, looking from the platform down to the plain, and a fine set of drawings of a restoration of the Basilica of Constantine. He gets a rich effect with the colouring of the coffered vaults; he fills the large windows with lattices in two well-known Roman forms; he restores the façade towards the Via Sacra with red marble columns on the ground-floor and green marble pilasters in the upper stage, with red spandrilis to the arches; the large piers are crowned with equestrian groups. This is all possible and probable, but the painting of the surfaces of the pendentives with a kind of Pompeian scheme of ornament—thin columns and wreaths—looks improbable and certainly architecturally out of keeping with the rest.

The room contains a couple of Mediaeval restorations, that of the château of Josselin (Morbihan), by M. Lafargue; a long narrow strip of building of which it may be said that it is a "castle" on the outer side and a "château" on the inner side; the drawings are large and powerfully coloured; and M. Roussel's restoration of the Porte-Tournisienne at Valenciennes, a building the plan of which shows a long rectangle with flat walls and small angle turrets at one side, and the other side covered by two immense three-quarter circle turrets filling up nearly the whole flank of the building.

Besides restorations, we find in the two principal rooms various more or less important drawings of a purely illustrative order. The largest are M. H. Boussac's elevations of the remains of the vestibule and tomb of Anna, at Thebes, a careful drawing showing the wall paintings as existing. M. Georges Chédanne exhibits, under the title "Etudes d'Architect-

ture Italienne," two beautifully-executed water-colours of Renaissance detail, a marble tomb with a recumbent figure, and a portion of the carved decoration of the cloister of the Sistine chapel. Draughtsmen who are interested in the production of truthful effects of colour and texture in water-colour should look at these, which are executed to perfection. Among the illustrative drawings may be mentioned also M. Gaida's drawings of the paintings of the west cupola of the Cathedral of Cahors, the property of the "Ministère de Justice et des Cultes," we presume drawings officially commissioned. M. Gaida gives a drawing of the whole cupola in line, which is divided into eight compartments by bands of decoration, while in the spaces are painted shrines each containing a draped figure; the head of the shrine is formed of two trefoil arches, which clash awkwardly with the heads of the painted figures. There is a complete set of coloured drawings giving the effect of the paintings as existing.

Two designs for practical work in the principal rooms call for notice. One is M. Marcel's "Palais du Senat Roumain," shown in a number of very large drawings. It is a heavy Classic building with a certain power and individuality about it. The plan, on a site forming an irregular trapezium, largest in the rear, shows a central state block running from front to back, consisting of a grand vestibule, a great Salle des Pas Perdus with aisles, and finally the theatre-shaped Senate-house at the back. The corridor communication to the subsidiary departments is entirely unbroken all round, a cross corridor running between the Senate House and Salle des Pas Perdus. The front elevation, an immense tinted monochrome drawing, shows a pediment with a colossal Ionic order of very thick unfluted columns, and thin base mouldings which seem crushed under the weight of the columns. On the other hand, there is an immense plinth moulding in the wings which is utterly out of scale with the rest of the mouldings. The wings are treated with a solid rusticated basement and a Tuscan order of pilasters above. The Salle des Pas Perdus shows a second larger pediment in the rear of the front one. There is an unquestionable power and solidity in the design, but the details, as already implied, are coarse and wanting in scale.

The other design referred to is that of a "Hôtel at Maison à Loyer" at Paris, by M. Escalier. The plan shows clever treatment of an awkwardly shaped site; the exterior designs are of very refined Italian type, the maison à loyer exhibiting the best and most refined style of Paris street architecture of this class. The fronts are shown in perspective in the most beautifully delicate shaded line drawings. There is not a pen-drawing in the Academy architectural room which would not appear coarse beside these.

M. Cordonnier's "Palais de la Bourse pour Amsterdam" is also in one of the separate rooms; it is shown in an immense line and tinted elevation drawing of florid Renaissance type with very coarse detail, great bulbous rusticated vousoirs and plinth stones, &c., and gables with all kinds of scrolls and nine-pin pinnacles. The tower is badly designed, with a heavy corbelled out stage half-way up its height; and on the other hand the ground-floor arcade along the façade is too light in detail for the superstructure. Whether this is a building to be executed or only a competition design is not stated.

Launching out into the wide sea of drawings in the galleries of the great hall, and taking first some of the restoration drawings, we notice a large and fine geometrical drawing by M. Dubois of the restoration of the lanterns of the great staircase at the chateau of Chambord, carried out last year. From the subsidiary drawings we gather that the lantern was entirely rebuilt, there is nothing to show from what data; it is in keeping with the general style of the chateau, though the spotty effect of the circles and diamonds of black marble introduced is not agreeable. M.

Charles de Wulf has a good set of complete geometrical drawings of a restoration of Hadrian's Villa at Tivoli, accompanied of course, in the French manner of thorough illustration of these things, by complete measured drawings and a bird's-eye view of the existing remains. An interesting restoration is that by M. Boonen of the Arch of Hadrian at Athens; he restores the upper portion, as others have done, with a small colonnade of three columns and an entablature cross-wise across the ends of the main cornice, resting partially on the main order of flanking columns below. M. C. Wable exhibits an interesting restoration of the manoir of Courhoyer, showing its L-shaped plan with the little chapel fitted diagonally into the outer angle, and the round tower restored with its projecting gallery with little arrow slits all round, and the conical roof over, giving it somewhat the appearance of a humming-top. There is, one must confess, a good deal of family likeness about these early chateau restorations, which are always to be found among the Salon architectural exhibits, though they are not this year so numerous as usual.

Among the numerous "Projets," studies for buildings, we can only name a few of those which present some special feature of character or originality. One of these is M. Dennes' "Etude Théorique" for a Hôtel de Ville, a good Classic elevation in which the three circular-headed doorways in the ground story are alternated with similar blank arches filled in with elegantly-designed tablets for *affiches*. M. Trihe exhibits a design for a monument to commemorate the reconstitution of the "Service d'Architecture" of Paris under Haussmann, appropriate enough to its subject; a blank wall with an Ionic order and inscription spaces between, with square pavilions at intervals surmounted by trophies; there is (unusually enough here) no plan to show whether any and what use is to be made of the space behind the wall. M. Simon's design for an "Eglise de Village avec Presbytère" is a semi-Romanesque kind of building with a slated spire of somewhat Swiss character setting oddly upon it; the complete working drawings of the spire, &c., are given, the principal elevation is tinted with the landscape in the rear to produce the effect of a perspective,—a method of treatment which French draughtsmen are fond of, and which has its recommendations. This is a very complete set of drawings, but as an example of the picturesque in modern church architecture it almost sets an Englishman's teeth on edge. One must allow something for national habits of design, but generally it seems to us (and various examples in this year's Salon would illustrate this view) that the French architects, while they nearly always succeed in classic work, invariably fail when they attempt the picturesque. M. Tronchet's "Projet d'Eden" is an Eden with the serpent in it; a great glass-house with dancing figures in stained glass in the semi-circular end of the building, a kind of mixture of Crystal Palace and Casino; not without ability, but essentially vulgar. A very different thing is M. Belestia's design for a museum for Nantes (presumably a competition design). This is a charming set of sketch elevations, showing a rusticated basement with arched windows all round, and an order above on the front elevation; the side elevation is a blank wall with angle pavilions and broken by an intermediate pavilion (not central) which marks the end of a cross corridor. The building is graceful and suitable for its purpose, and the design in complete relation to the plan. M. Pachianu's "Projet" for a library for Lyons has considerable merit; the main façade has three large semi-circular arches over which are large shrines for sculpture, with a broken pediment and reclining sculptures on each side; a horizontal line of attic wall connects the whole of these details by a common background; the design is unusual, effective, and suitable for its purpose. Another very able "Projet" is that by M. Hannotin for a

"Rendezvous de Chasse," evidently in connexion with a great man's domain, for it is palatial in size for its object. There is a great centre pavilion with one large room and very lofty high-pitched hip-roof, the wall design is Classic but a suitable picturesque effect is given to it by strongly marked and broken up rusticated treatment; the centre pavilion is balanced or accompanied by small brick and stone pavilions of somewhat similar character but of quieter treatment, of course entirely symmetrical in arrangement (that goes without saying in French design of this kind), but the whole thing is a success, because it combines architectural dignity and a certain palatial air with a treatment which suitably expresses its object, as the hunting or shooting pavilion on a great scale, and there are few better studied designs in the collection. M. Bruneau's study for a Lyric Theatre is too much like a kind of glorified conservatory, clever, but not sufficiently monumental for a theatre. M. Rixson's "Projet de Maison Suburbaine" is a tremendously high elevation of a modern chateau; there are several designs of this kind for imaginary town or suburban houses, and for the most part we may say they are much more commonplace than the designs of a similar kind which find place in the Royal Academy Architectural Room. Among other enormous "projets," apparently competition designs, is M. Loyau's "Un Casino," without merit of any kind that we can see; M. Mougnot's "Concours du Collège d'Epinal," carefully planned but an enormous barrack architecturally,—indeed there seems to be a kind of understanding among French architects to make scholastic and collegiate buildings as repellent as possible in appearance, giving them the aspect of prisons and barracks, as if education could have no connexion with architectural beauty or attractiveness, which is surely as mistaken a view of the matter as could possibly be entertained. These great establishments in France are generally well planned and very complete in a sanitary sense, but they are most uninviting-looking buildings. M. Guyon's "Concours pour la Construction de l'Ecole Boule" is no better in this respect. M. Delmar's design for a Hôtel de Ville for Nice has merit, but the treatment of the ground-story arcade is not in keeping, in point of style and detail, with that of the upper portion of the design.

Among the drawings of buildings executed or to be executed is a fine and large set by M. Huot for the "Hôtel des Postes et Télégraphes" at Marseilles. This covers a large irregular site, and though plain is treated with some architectural dignity. The entrance is through a great arched vestibule and the principal façade has large circular staircase turrets at the angles with a balcony and small cupola over them, which are architecturally effective; a square tower at the extreme back angle of the site (probably facing the sea) is terminated by an iron gable erection apparently intended for an electric lighthouse, it is of purely utilitarian design and looks an odd adjunct to the architecture. There are a number of photographs of interiors added, besides the complete geometrical drawings.

M. Rives's new entry to the establishment of Veuve Crespin et Dufayel is shop architecture in *excellent*, showing a tremendous archway filled up with glazing and gimcrack ironwork, and a dome and details apparently inspired by the front of the central 1889 exhibition building at the lower end of the Champs de Mars. Of M. Wable's design for a Palais des Art Décoratifs for the site of the Cour des Comptes we know not whether it is a mere *projet* or has a chance of execution, but it is fine and pompous kind of design which looks well in the bird's-eye view perspective. M. Parent's "Hôtel Excusé Avenue de l'Alma" is a very meritorious example of the Paris residence, well and compactly planned, designed with a central open oval elliptical open-plan, and a boldly sweeping staircase cleverly worked into an angle of the plan. It is shown partly by a cleverly

ected section with the portion beyond the
ane of section drawn in perspective.
chitecturally a little more might have
on made of the elliptical courtyard, which
a little too much broken up into bits and not
eated with sufficient breadth; but the whole
worth the study of those engaged on town
ouses. The street façade is of a quiet type
Classic design. Another Paris hotel (really
is shown by M. Dézermant, of what
ight he called a coarse type of Elizabethan
esign; the wooden details of doors and
antel are separately shown in drawings
hich would certainly not be admitted into
e Royal Academy (bad as are some of the
ings admitted there), and which are abso-
utely without interest of any kind. In the
an of the house we notice that the prin-
pal w.c. is in the centre of the house, close
to the drawing-room wall. We thought
rench architects were unlearning these
sanitary devices of house-planning by this
ne. Another domestic design shows the
ngitudinal section of a house entrance-hall
hich is decorated (?) by great circular
agues of red marble at regular distances on
e upper portion of the wall, with wreaths
rially encircling them. We can fancy the
te of anyone who sent in such a "notion"
interior decoration to the Academy! M.
apaine's drawings for a "Refuge-Ouvroir
ur Femmes" show a well-arranged plan on
riangular site, with quiet characteristically-
eated elevations in coloured brick. M. Farge
ows a creditable treatment of a railway-
ation front at Almería.

Among decorative designs, which are not
numerous and not mostly good, M. Parent
nds a set of drawings of a "cheminée
onumentale" for a great house, a study
polychromatic decoration; the drawings
e splendidly executed, but the design would
not find much admiration on this side of the
annel, and the colouring is crude and
ow; blue and gold predominating. M.
tonois sends a design for a monument
mmemorative of the siege of St. Jean-de-
pense in 1636, consisting of a thick column
stele with the model of a conventional
stle on the top; this part is well treated,
at the stone carved canons worked into the
se of the design are clumsily introduced and
et decorative in effect. M. Dohin's monument
mmemorative of the piercing of the Isthmus
Suez, shown in a slight perspective view,
based on Egyptian details, but is suitable
e situation and object. Another com-
memorative design is that of M. Legrand for
ountain to the memory of Germain Pilon.
is is triangular on plan, with a three-niched
le crowned by a group of female figures,
ed the statue of Pilon in one niche; the
sin and stole are stone or marble and the
ures bronze; the enormous bronze consoles
hich seem to ramp on the edge of the basin
posite the three angles of the centre
angle are very coarse in effect, architectu-
ral details entirely misplaced. While
eaking of decorative design we may men-
ion one pleasing though very unassuming
oured drawing by M. Hista of the wall
coration executed in the library of the
culté de Médecine at Paris; it consists
rely of a wall decoration and ornamental
eze, but it is agreeable in colour and in-
oroughly good taste.

The collection contains numerous drawings
d sketches illustrative of existing ancient
ork, many of them of much excellence.
ong these is a drawing of monumental
e, finish, and solidity, by M. Honoré,
a tower elevation of one of the doorways
d bronze doors of the façade of the
thedral of Pisa; a superb piece of illustra-
tive work of its kind. M. Gayet's great
of drawings and restoration of the Coptic
vent of Assouan is one of the most
markable sets of illustrative drawings,
a great scale and got up with im-
ense care and labour. Another coloured
vation drawing gives with the most
ute care the remarkable façade of
ancient church at Gisors; this is by
Boutron. Among sketches and illustra-
tive drawings of a less conventional order

are M. Stoughton's charming tinted drawings
of the Loggia of the Hotel d'Écovieille at
Caen; M. Sirof's "Souvenirs des Fortifica-
tions de Valenciennes"; M. Conin's sketches
of Eastern and Spanish buildings in bright
and free-executed water-colours; and M.
Breffendille's excellent set of water-colour
sketches under the title "Souvenirs de
Voyage," giving views of portions of St.
Mark's, the Alhambra, a ceiling in the Pitti
Palace &c., the last a splendid sketch of a
very difficult subject to treat adequately in
water-colour.

NOTES.

BERLIN is apparently about to
follow the example set by Vienna,
and appear to the world as
"Gross-Berlin." There has of
late years often been some serious contem-
plation of the question of an extension of the
city limits, and the various architectural and
engineering societies have given the matter
their attention. A hulky literature already
exists on the subject, and the local press has
spasmodically devoted a good deal of space
to the subject for a few weeks every year.
The whole question has been until now con-
sidered as one of the far future. Now we
suddenly hear that the Government has been
quietly taking action in the matter, and that
the first decisive step has been taken by the
Governor of the Province of Brandenburg, in
which the "County" of Berlin lies. He has
asked the municipal authorities to consider
the advisability of an extension of the city
boundaries, and to send in their views as soon
as convenient. The Government is much in
favour of the extension, while the Municipality
rather shuns the outlay which the
improvements necessary in the newly-
acquired districts of "Gross-Berlin" would
at first require. The sanitary arrangements,
water and gas supply, the street paving, and
the fire protection service would swallow
enormous sums during the first decade.
Probably the extension of the boundaries
will take place sooner than is generally
expected, and we should not be surprised if
the matter were arranged prior to the open-
ing of the great international show that will
take place some four years hence. The step
taken by the Governor of Brandenburg is a
very important one, and practically means
that (1) rapid action is required on the
part of the Municipality, and that (2) the
Government expects an affirmative reply.
A so-called municipal loan of seventy millions
of marks (some 3,500,000*l.*) has to be arranged
for this year, so that the executive Council
may be able to carry out the various exten-
sions and improvements they propose to
make in the course of the next four years,
i.e., until the close of the financial year
1895-96. Estimates show that a sum some-
what over one hundred million marks is
in reality required, but owing to various cir-
cumstances the whole sum is not to be asked for
at once. Among the expenses to be incurred
we notice the following:—(1) Some thirty-three
million marks for the extension of the sewer-
age system; (2) twenty-three millions for
the extension of the municipal waterworks; (3)
six millions for the extension of the gas-
works; and (4) eight millions for new bridges
over public waterways. Some extension of
the public slaughter-houses will cost four
millions, the erection of some more covered
markets five millions, while of the single
buildings not belonging to an extensive
scheme, a new lunatic asylum is alone to cost
2,860,000 marks, and an epileptic hospital
3,400,000 marks. We hope that where so
much money is to be spent for building
purposes, some attention will be paid to
architectural features, so that it may not be
said that other eyesores have been erected in
the shape of municipal buildings.

THE second reading of a Bill of a notice-
able character was not carried last week
in the House of Commons. We refer to the
Local Authorities (Purchase of Land) Bill.

The astonishing thing is that sensible men
could be found to support a measure of so un-
reasonable a character. To empower County
Councils to purchase land whenever it should
appear to the public advantage was a
thoroughly unbusinesslike proposal, for there
is nothing more necessary than that the
objects for which land may be compulsorily
acquired should be absolutely definite and
clearly for the benefit of the public. But the
further provision that a County Council
might have land valued, but need not pur-
chase for twenty years, and even at the end
of that time not purchase, but have another
valuation, was a proposal which would put
an end to all security of property, and be a
block to improvement. The provision that
the unearned increment of the land between
the time of the valuation and of the pur-
chase should not belong to the owner for the
purpose of compensation would also have
made landed property near towns absolutely
worthless for the purposes of private prop-
erty, for men do not buy property any more
than other things without a hope, at least,
that it will increase in value, and thus enlarge
the capital invested in it. It is also obvious
that County Councils must have become land
speculators pure and simple, whilst the door
would have been opened to various forms of
fraud. A more mischievous measure than
this of Mr. Haldane has seldom been seen.

THE Committee of the House of Commons
has quite rightly sanctioned the Bill for
a tramway across Westminster Bridge to a
point on the Embankment to the west of
Charing Cross. This action has displeased,
among others, the *Times* newspaper, which
makes itself ridiculous by urging, as one
reason why the Bill should not have been
sanctioned, that the beauty of the Embank-
ment will be spoiled by tramcars. There
really is no more ugliness in a tramcar than
in one of the numerous contractors' wagons
which are continually rattling up and down
the Embankment, but, if beauty is to be con-
sidered before the convenience of the public,
there are plenty of eyesores in London which
the *Times* might well devote its attention to.
As a matter of fact, there cannot be a
doubt that this tramway will be a
convenience to large numbers of persons,
and must, sooner or later, be extended to
Blackfriars. Our objections are in no way
lessened to the County Council becoming
proprietors of this and other tramways,
for reasons which we have more than once
stated, but that is a matter between members
of the Council and their constituents: for the
moment we, like the Committee of the House
of Commons, have only to consider whether
this piece of tramway is required in the
public interest, and it certainly is. If the
County Council lose money over it by allow-
ing their employés to work shorter hours for
higher rates of pay than trading companies,
so much the worse for the County Council
and the ratepayers. The public as way-
farer is not concerned with the pecuniary
results.

A CASE of some importance under the
Metropolitan Local Management Act of
1862 was decided by the Court of Appeal last
week. In the case of the London County
Council v. Cross, the latter had been charged,
before Justices sitting at Hampstead, with
having unlawfully erected a building beyond
the general line of building in a particular
road. The matter was brought before the
magistrates on October 28, 1891. On April 27
of the same year the building had reached to
the joists of the first floor. The Justices also
found, as a fact, that Mr. Cross began to erect
the house before April 27. It was conceded
that, by law the complaint should be made
within six calendar months from the time
that such complaint arose. The question,
therefore, had to be decided, When did the
matter of complaint arise? In the Divisional
Court, Mr. Justice Smith held that the
offence did not begin till the architect had
given his certificate; while Mr. Justice Den

man thought that the matter of complaint did not arise until the completion of the building. The Court of Appeal, however, did not agree with the Divisional Court, and considered that the offence was committed when the builder began to build beyond the proper line without the consent of the local authority. It followed, therefore, that the County Council had not brought the proceedings before the Justices within the necessary six months, and, therefore, the Court of Appeal dismissed the proceedings against Mr. Cross. This is not the only case which throws some light upon this point, but it is the latest, and in it all the previous cases are carefully examined. It lays down a plain and sensible rule that anyone can understand, and therefore, in the future, no difficulties should arise on this point, if the local officials keep a watchful eye on new buildings.

A MEETING of the Horse Accident Prevention Society was held on Tuesday at Cannon-street Hotel, to protest against the decision of the Commissioners of Sewers to repave Wormwood-street, St. Mary-axe, Barbican, Bridewell-place, and St. Paul's-churchyard, with asphalt instead of wood. The meeting was a very representative one of the omnibus companies, carriers, and other owners of horses. Among the statistics given we note the following figures:—1. Of 1,180 coachmen asked as to which pavement they considered the most dangerous, 1,045 considered that asphalt took the lead. 2. That official research in the City had shown that twice as many horses fell on asphalt as on wood. 3. That in 1890 the engines of the Berlin Fire Brigade were delayed by the falling of their horses once in every 110 miles when running on asphalt, and only once in every 750 miles on wood, macadam, and granite. These figures seem conclusive in regard to the greater danger of asphalt. On the other hand, we must repeat what we have before said, that wood pavement is in a sanitary point of view the most undesirable pavement possible for a crowded city.

THE third exhibition of art brass and copper work and smiths' work, under the auspices of the Company of Armourers and Braziers' is being held this week in the hall of the Company at 81, Coleman-street. The object of the exhibition appears to be to encourage and to mark the advance of brass work from year to year, and for this purpose the Company purchases each year representative exhibits; with lapse of years these purchases will become very interesting and valuable, and the advance must appear more marked than it is at present. The Company deserves praise for its efforts to emphasise the name of the designer and the craftsman, and for giving preference to the work designed and made by one hand. A very liberal list of prizes, ranging from 10*l.* to 2*l.*, has attracted over 400 exhibitors, and many of these are women. The work of the following schools is well represented by numerous exhibits:—The Lyzwick School of Art, Keswick; Keswick School of Industrial Art; the Birmingham Guild of Handicraft; the Birmingham Municipal School of Art; the Birmingham Jewellers' Technical School; the Corstorphine Brass Class, Midlothian; the Guild and School of Handicraft, Millend. The merit of several of the exhibits is of a distinctly high character, though it is to be feared that the majority do not reach a very high standard. The different uses of brass and copper are most distinctly shown, and the results of the different methods of workmanship form a most useful study for the architect or any other craftsman. We have not space to refer in much detail to the exhibits, but the wide range of the work may be gathered from the fact that there are no fewer than eighteen classes, which include specimens of hammered hollow ware, repoussé work, hammered work as applied to ornament, brazing, engraving, etching, chasing, damascening, specimens of

hollow-spun ware, saw-piercing, cored and *cire perdue* casting.

IT is stated that William Pitt's verses printed (and now for the first time) in the current number of the *National Review* were inspired by the prospect and associations of Coombe Wood, Surrey. The wood lies between Richmond-park and Wimbledon Common, and at present belongs to, we believe, the Duke of Cambridge. The Domesday Survey cites two manors here, since united: the one, of about 210 acres, as held of the Queen's fess by Humfrey, the chamberlain and collector of Queen Maud's wool-cess; the other, 300 acres, and afterwards known as Comb-Nevil, held of the King by one Ansgot. King John granted the joint property to Hugh Nevil, his justice of the forests and treasurer; in Edward I.'s time it was held by William de Nevil. Having reverted to the Crown on the Duke of Somerset's attainder, it was granted by Queen Elizabeth to William Cecil, Lord Burghley, and then, at Cecil's request, to Thomas Vincent, of Stoke d'Abernon, who rebuilt the manor-house. In 1753 the trustees of John Spencer, created Lord Spencer of Althorp, in 1761, bought it of the Harveys. Here, after some years' residence, died Lord Liverpool in 1828. From some springs on this estate Wolsey laid a water-supply for his palaces at Hampton Court, by way of Surbiton and so beneath the Thames. The original pipes, being of lead, were moulded in lengths of 25 ft. apiece, with an overlay along the seam.*

THE colliers, or charcoal-burners, of Croydon formed a favourite object for the jests and gibes of our satirists.—Barkley in his "Eclogues," and Crowley, for instance, —and comic dramatists in the sixteenth and seventeenth centuries. Grimme, the Collier of Croydon, figures in Robert Edwards's "Damon and Pythias," first acted in 1566, and a later comedy is entitled "Grim, the Collier of Croydon; or, the Devil and his Dame, &c." (1662). In Queen Elizabeth's time, indeed, the inhabitants were for the most part smiths and charcoal-burners, who gathered their wood in the forests round about, remains of which at Norwood, Addington, Carshalton, and Beddington have survived to our own day. Their trade flourished until as late as *circa* 1780, London being their chief market. In Collier's Water-lane, leading from the London road to Thornton-heath station, stands an old-fashioned tenement, bearing, on the Parchmors' road front, the date "1590," latterly a farm-house which, together with its land, is about to be taken for building purposes. Known as Collier's Water-farm, it forms, we believe, the last memorial hers of the charcoal-burners. It is the traditional home of Francis Grimes, the collier, who is said to have come off victorious in a dispute with Archbishop Grindal, who had taken umbrage at the clouds of smokes which at times invaded the precincts of his palace, by the parish church. A wooden cross, now decayed, inscribed "In memoriam (sic) Francis Grimes, Collier," stands in an orchard behind the house. "Collier's Field" appears in the plan attached to Mr. J. C. Anderson's interesting book, published two years ago, upon the award of the Commissioners to enclose the Croydon commons, with the occupiers' names for the period 1793-1803.

THERE seems to be, comparatively speaking, a lull in building operations in Oxford just now. The only new building of importance at present in progress is Manchester College, situated at the back of Holywell-street, and not far from the recently-completed Mansfield College. The roof timbers are now being fixed, but it is early yet to judge of the design. When the new Municipal Offices are erected, a picturesque but now sadly dilapidated building will disappear,—Nixon's School at the

back of the Corn-market. There is a good deal of effective detail about the little building, which is entirely of wood and plaster, and those who designed it have evidently been at work in some of the villages round Oxford, where much good work in windows and doorways still remains in houses of an otherwise humble character. We shall hope to give a sketch of Nixon's School shortly, made within the past few days.

IN an interesting letter in the *Times* of Saturday last, under the title "From Tideway to Tideway," Mr. Rudyard Kipling comments in very plain language on the municipal management of New York, and, in fact, on American conditions of life generally. He catalogues "the three pillars of moderately decent government" as regard for human life, justice criminal and civil, and good roads. With his remarks on the first two heads, which are trenchant enough, we are not directly concerned; but those on the New York streets are satisfactory from the point of view of the patriotic "Britisher," and ought to make grumbling Londoners most contented with their lot. Kerbstones rising from 2 in. to 6 in. above the level of pavement tram lines from 2 in. to 3 in. above street levels, building materials scattered half across the street, &c., are among the evidences of "slovenliness, sordidness, and want of capacity, which have roused in Mr. Kipling a feeling of contempt which is healthy enough but will not make him popular in the country in which he is travelling. As set-off to this picture may be taken the description of the suburbs of St. Paul, Minnesota, in the same letter, which is charming, and quite bears out the testimony of a writer in one of the American magazines to which we referred a little while since. As Mr. Kipling's letters to the *Times* *en voyage* are marked "To be continued," we recommend our readers to look out for them. For Mr. Kipling is one of those writers (not too numerous) who combine power of literary style with a keen practical observation of those little things (so-called) which often go so far to determine both the picturesque and the sanitary character of a city or a district.

WE have received a copy of *The Architectural Record*, a quarterly periodical published in New York, and which appears to contain some good writing on architecture, and has also a considerable number of illustrations. Unfortunately, however, the publication seems to be characterised by the absence of common honesty in regard to the appropriation of other people's property, which we so often have to complain of in American publications. We find among the illustrations four drawings which have been published in the *Builder*, viz.: Messrs. Kemson & Fowler's "Church at Pentre, Glamorganshire," Mr. Aston Webb's "Protestant Church and Parsonage, London," Mr. Jas. Neale's "St. Peter's Bushey-heath," and Messrs. Truefitt & Truefitt's "Schweppe & Co.'s Factory, Malvern." No acknowledgment of the source whence these are taken is made, but we can have no reasonable doubt that they are plundered from our pages, without the ceremony of saying "with your leave" either to us or to the original owners of the drawings, who might be supposed to have some right to be consulted in the matter. We cannot observe, by the way, that any reference is made to the illustrations, or any special use made of them; they are just introduced, apparently for the pleasure of plundering when there is no legal power to prevent it.

THE attack which has been made on Mr. Madox Brown in the Manchester Town Council, arising out of dissatisfaction with his last fresco at the Town Hall, seems peculiarly ungracious. Mr. Madox Brown has now been engaged for many years on the painting of the only series of important de-

* See an illustration in Brayley's "Surrey": 1841.

diver mural paintings in an English public building which is in the way of completion, and it appears that these have been tried out at the very inadequate remuneration, for such work, of 320*l.* per square. His last work of the series is now been made the object of a vulgar and violent attack in the Council, by a member who admitted that he knew nothing about art. We have not seen the picture, and do not know its merits, but a painter who has done such work as Mr. Brown has done the Town Hall deserves at least to be criticised with the utmost respect. The decision of the Town Hall Committee, that Mr. Brown should be requested to exhibit sketches of his pictures before proceeding with them, is not in the least unreasonable or unusual in itself; at the Paris Hotel de Ville every artist has been required to submit preliminary sketches of his work for the decorations, and the Manchester Town Hall Committee would have been quite justified in making that a condition at the outset. But to spring it upon the veteran artist now, near the close of his series of works, and as the sequel to a coarse and vulgar attack upon him, is at the least, a peculiarly unfortunate and ungracious kind of proceeding.

NHE bright May days of the early part of the week, in Paris at least, showed the French capital at its best, and nothing could be more charming than the effect, last Sunday morning, of the foliage in the Tuileries gardens (in many shades of green, but all light and vivid), contrasted with the many statues glistening white in the sunshine—the brightest light of all showing, by a happy chance of "composition," against the darkest top of trees; the two fountains, one in the foreground and one in the middle distance as seen from the Tuileries end, *jaillissans* (no English word gives it so well) between the masses of trees. A damsel with a bright red shade goes down the walk, giving the artist the one spot of bright colour needed to give point to the picture. Beyond the gardens the obelisk of the Place de la Concorde makes a pillar of silver in the bright misty sunlight, and, far beyond, the great mass of the Arc de Triomphe just shows its outline in the extreme distance. What a vista! How full of the impression of a refined and artistic civilisation. But alas! one turns one's eyes a little upward to take in more of the garden scene, and there, rising above the bright trees, is the great spidery, lanky, unmeaning network of the Eiffel tower, spoiling the scene of everything, intruding the associations of vulgarity and commercial display—the of the Philistine planted in fair Paris. How long are the Parisians going to leave it there to discredit their aesthetic sense?

ARCHITECTURE AT THE ROYAL ACADEMY.—III.

1,643; "Barton Pines, Paignton, Devon;" Mr. F. M. Simpson. This has very much the look of an old house; we presume it is a new one, an example of that rather over-acted simplicity which seems to be a charm to many over-architects nowadays. It is a house with great deal of wall, small windows with very small panes opened in the wall here and there, and with stone ball finials. From the plan it seems to be an addition to an existing house, hence perhaps the manner of treatment, but the old portion is not seen in the view. There is a pleasant old-world feeling about it, but it is questioned how much this is owing to a manner of the drawing.
1,644; "The Queen's Tower, Imperial Institute," Mr. Thos. E. Colclutt. A fine coloured drawing of the tower with just the dormers and eaves of the roof at the foot of it. The main object is to show the crowning stage of the tower, which has an octagon stage cleverly connected with the angles of the square sub-structure by what may be called Classic buttresses and flying buttresses; the octagon stage is open the four cardinal sides; above is a circular drum with thin pilasters alternating with the lights all round, and defined horizontally

by hands of red and white masonry; a lead dome with a little circular lantern rises above. There is a little too much of the strip-pilaster work, all down the substructure of the tower, and on the octagon and dome of the cupola; *tantjours perdris*, an overdose of a form of detail which is not very recondit in its signification. At the distance when the eye loses these pilasters a little, the whole makes a fine group, effectively treated in water-colour drawing.

1,646; "Mosaic Pavement of Staircase and Hall, and Copper Balustrade, 9, Chesterfield-gardens," Mr. G. Aitchison. The drawing does not indicate the texture of mosaic, but looks like inlay; the principal design consists of a border of black conventional dolphins on a white ground (dolphins play a part in other painted decorations of the same house), and in the centre white scrollwork of Renaissance type on a black ground, with smaller panels at the end. These and other smaller panels are arranged in reference to the position of doors shown on the plan; the whole will have a satisfactory effect but presents nothing very special in detail. The stair baluster, executed in hammered copper, is shown with a large free Renaissance scroll design repeating its general motif in each compartment, but with difference of detail.

1,647; "Sketch for the Unfinished Side of the new Quadrangle, King's College, Cambridge;" Mr. G. F. Bodley. We cannot say that the architects who are Academicians are doing much for the architectural room this year. This is a part of an elevation of a quadrangle building of which it is really difficult to say anything except that it is in domestic or collegiate Gothic style, has bay windows at intervals with gables over them and a tier of small windows between them, and a gate-tower of the usual collegiate class, with an oriel over the arched gateway. The style of thing is in perfectly good taste, but it is difficult to find any interest in it.

1,648; "Glenlyon House, Perthshire;" Messrs. W. Dunn and R. Watson. An elevation, treated with the effect of a perspective in regard to the landscape, of an exceedingly simple country house with plain windows and a round cone-capped tower at one angle, in which is apparently the garden entrance. Before it apparently is a hedge cut as a paling, at least this is the impression conveyed. The level lines contrast well with the undulating country shown in the rear, and the whole has the charm of simplicity appropriate to a medium-sized country house.

1,651; "A Street Corner;" Mr. Clarence Coggin. A corner house with a treatment of the gable on each face with Dutch Renaissance details; it is a somewhat hard little drawing, but effective as an idea for a brick corner house.

1,652; "Design for Stained Glass;" Mr. W. Griffiths. A very pretty little coloured drawing with a figure representing "Industry," entirely free from conventional Medievalism; an indication of drapery and trees over it forms a background to the figure. The detail is very delicately drawn on the small scale adopted, and the colour effect harmonious and with a certain individuality about it.

1,654; "Two of a Series of Windows for the Imperial Institute, representing the Arms of the British Empire, with Figures of Aborigines;" Mr. Clement Heaton. Designs for Classic round-arched windows of considerable originality. The lower portion has a wide coloured border with arabesque ornament, interrupted at the angles in one case, and at the centre of the sides in the other, by winged heads or masks on dark grounds; the angle treatment is the best. In the centre of the white glass within the border is a large kind of trophy design, an architectural shrine with base mould, corbels, and cornice having a circle in the centre in which emus are introduced in one design and a kangaroo in the other, and below the circle are seated aboriginal African and Australian figures back to back. Thesemicircular heads of the windows are treated in much the same way. The general effect is truly decorative, and the attempt to give the designs a symbolical signification is of course a distinct merit. The only query is whether the centre portion of the design, being decidedly architectural in character and detail, does not look out of place and unsupported when hung in this way, as it appears to be, within an expanse of white glass and without any appearance of constructional connexion with the frame design.

1,656 and 1,661 may be taken together, as they are by the same author and are hung together, and both represent the same "House at Northwood." The former is a pleasant little bit of what may be called humorous treatment of a small country-house, with a hubbous finial, like a pumpkin on end, stuck on the roof of a projecting apse; and a round rusticated arch losing itself against the wall of the "apse" which contains, as the plan shows, the staircase. No. 1661 is a rather rough pencil-sketch of the back of the same house with a more sober treatment, and an indication of clipped and shaped hedges, and bushes standing up in the middle of a formal garden. Plans are appended. The house is picturesque, but we can hardly think the two drawings merited the very good place which has been given to them.

1,657; "Municipal Buildings, Bury;" Mr. F. H. Tulloch. This drawing is shown in one of our lithograph illustrations this week, but in a different tone from the prevalent one of the drawing, which is worked in Indian ink, a tone that is apt to get rather heavy in ink-photo. It represents part of a design submitted in competition for the Bury Municipal Buildings, and is one of the best pieces of design and drawing among this year's Academy architecture. The contrast between the rich frieze and the plain turrets which intercept it is very picturesque; not less so the open lanterns of the turrets with their short colonnettes. The employment of short colonnettes seems to have been made intentionally a feature in the design, and gives a unity of character to it. We regret that there is no plan to explain the intention of this portion of the design, but at any rate it is an admirable piece of architecture, and one cannot but regret that it is not to be carried out.

1,658; "A Renaissance Ceiling;" Mr. J. J. Shaw. This may be called a satisfactory ceiling of its type; it contains rather heavy but rich-looking Renaissance scroll-work and ornamental figures in what appears to be a large cove, with many-winged harpy-like figures filling up the angles; a strong moulding and circle of ornament on the gold ground of the large centre panel, with little circles at the side. This is very mechanical, and the design would have been more attractive with a plain gold centre panel and nothing else.

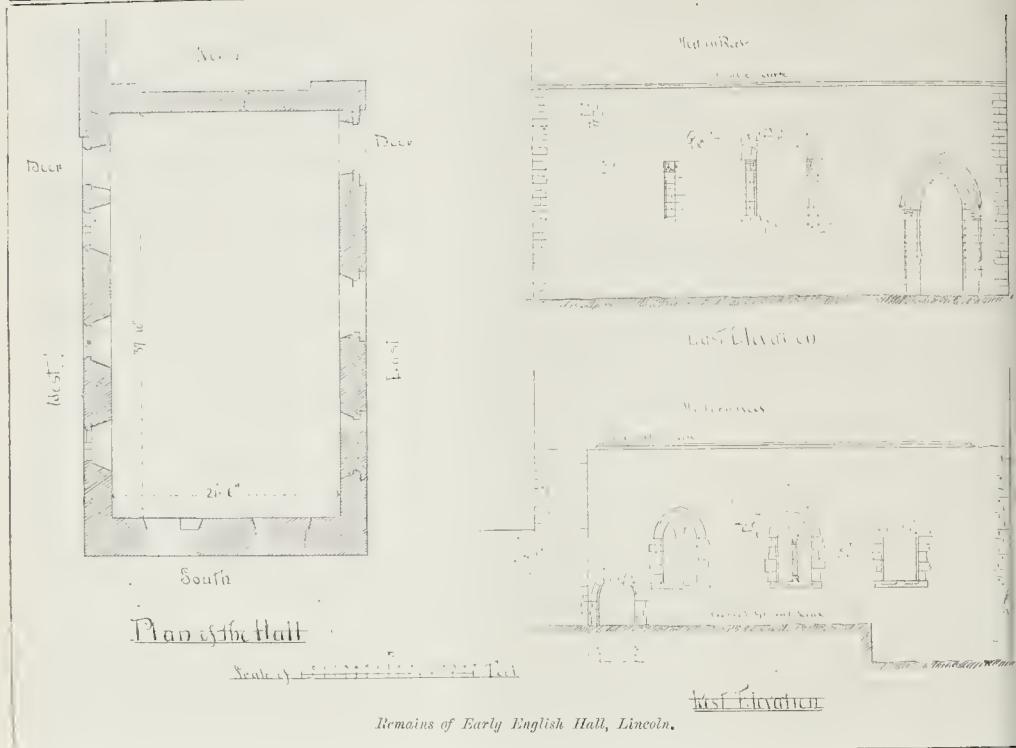

1,659; "Firsden, Lickey, Bromsgrove;" Messrs. Bateman & Bateman. This is a very nice watercolour, fine in tone and treatment, of a quiet stoue country house with red roofs and gables of varying sizes facing a lawn, at the side of which is a clipped hedge and terrace. The windows are simple unadorned ones introduced where they are wanted. There is a pleasing English feeling about the whole, and the drawing deserved far more to be hung on the line than some of those that have attained that capriciously-conferred honour.

1,662; "House and Studio, Holland Park;" Mr. G. D. Oliver. There is a certain sober whimsicality in the manner in which the modillioned cornice of the house part is stopped against Gothic-shaped buttresses flanking the bay window of the studio and billiard-room (one over the other); apparently the studio portion is an addition to a regulation street house, the two parts seem to have no relation to each other except in plan, and evidently "that's the humour of it."

1,664; "Sketch for a house;" Mr. Dudley Newman. A pleasant rapid sketch for a brick country house, with a feeling for colour in the drawing; unfortunately the lines are not all upright, a defect even in a rough sketch when we are dealing with architecture.

1,665; "Proposed Group of Almshouses, Linton, Wilts;" Mr. C. E. Ponting. Apparently on toned paper; very red houses with a gable at each end of the front with windows supporting its soffit, the wall (or partition) below the windows touched with white body colour for the plaster (that is what gives part of the character to the drawing); and these partitions again supported on window-panes, according to a prevalent fashion. There is no plan to show the meaning of the large arched doorway in the centre of wall, which suggests the idea that a carriage was to be provided as one of the appendages of the almshouses; and this is the coach-house. It is a pretty and picturesque little drawing, however.

1,666; "Design for New Municipal Buildings, Oxford;" Mr. Thos. Davison. This is a pleasantly composed design shown in a good pen drawing, though it consists really of little more than the putting together of features which have come

into common use in architecture lately, and suggests the idea of being like a great many other buildings, though it is an agreeable example of its type. There is no plan, consequently nothing to render the design intelligible.

1,667; "Design for Painted Glass." Mr. E. J. Chapman. Apparently a good bit of treatment of stained glass for a Renaissance building, in the Rococo Renaissance style, in light stain on white glass set in squares: too high for detail to be seen.

1,668; "St. Marylebone General Dispensary;" Mr. Beresford Pite. Evidently a bit of old building somewhere in the decayed portions of ancient Rome, patched up and furnished with doors and windows for modern use. In this sense the drawing is effective, but has an unhappy and desolate appearance, quite out of keeping with one's idea of a dispensary, as a place of relief to the bodily ailments of the afflicted.

EARLY ENGLISH HALL, THE CLOSE, LINCOLN.

OF the group of houses recently pulled down at Lincoln to afford a better view of the Minister from the north-east, only one had any claim to antiquity. The others were common-place tenements of the last or the present century, the loss of which there is no reason to deplore. The one exception was known as "The College House," being in fact the shell of a thirteenth century hall, in which the college of vicars and the other officers of the cathedral were entertained "feeding days," according to a fixed rotation, so many days being allotted to each dignitary. At first these "feedings" were given in the houses of the residentaries; but it was soon found more convenient to receive the guests in a common hall or refectory erected for the purpose. More than one such appears to have been built, as "halls" are spoken of in the plural, "aulae," in the directions for lighting the fires, which, as formerly at Westminster School, and other similar foundations, were kindled on the eve of All Saints' Day, October 31, and extinguished on Easter eve, without any reference to the time of year when it fell. That which has recently been discovered, and discovered only to be destroyed, is the only one of these halls, of which there is any trace. It belonged to the

early part of the thirteenth century and afforded a very good example of the domestic architecture of that period. When its original use had passed away, this hall, in common with many such structures,* was converted into a small dwelling-house by the introduction of floors and partitions. The windows were blocked up, modern sashes inserted, and little was left to indicate the architectural character of the building beyond the mutilated arched doorway of entrance (of which a sketch is given) and a single blocked lancet light in the southern gable. When these houses passed by purchase from the Dean and Chapter to Mr. Shuttleworth, and their demolition was begun, directions were given to the contractor to deal very carefully with this house, and to preserve every feature of antiquity. These instructions were complied with, and an opportunity was thus afforded to Mr. W. G. Watkins (son of Mr. W. Watkins, architect, of Lincoln) to measure and take careful drawings of every part. Some of these drawings are given as illustrations of this paper, and as a record of an interesting building now entirely destroyed.

The hall was 37 ft. 10 in. long by 21 ft. 6 in. broad, the walls being 20 ft. high to the table course. It ran from north to south, having its chief elevation, or "showside," to the east, and the plainer elevation, or "backside" to the west. On the east side, at the northern extremity, was the chief entrance: an arched doorway, 4 ft. wide in the clear by 11 ft. high,—a good example of a plainish Early English archway, with chamfered orders and nook shafts, of which only the foliated capitals remained. On this side there were distinct traces of two large windows, of which the jambs, the foliated capitals, bases of the shafts, and, in the northern window, the springing of the arch remained. The west side was plainer. There was a door of simpler design opposite to the chief door, and three windows, not opposite to the others, smaller and destitute of their ornamental features. Two of these, having been built up in the wall when the hall was turned into a house, were almost perfect. Of the third, only the jambs and sill remained.

* The Bishop's Palace at Hereford, and a portion of the Deanery at Winchester, are formed out of Medieval halls. The now unhappily demolished Gaisten Hall at Worcester was converted by floors and partitions into the modern Deanery.

They showed two lancet lights, with a shaft between, combined under one arch, the tympanum being unpierced. The central window of the three was the most perfect, and exhibited its old arrangements very clearly. They had never been glazed, the jambs not having been rebated for glass, but were closed with wooden shutters, of which the hooks remained, shutting to against the inner face of the window-shaft, left flat to receive them, the outer face being semi-octagonal. The holes in the jambs showed that the openings were protected by vertical and horizontal bars, of the latter of which one still remained in its place. In the south gable end were traces of two windows, and evidence of a door in the north wall communicating with what was probably the kitchen further north. This had been almost entirely destroyed, but on the west side part of the wall remained, containing one lancet window. The table-course on which the roof rested was formed of very large slabs, 18 in. broad.

It would have been very desirable if this interesting example of Early Domestic architecture could have been preserved. But after the removal of the floors and partitions it was in so ruinous a state that to have secured its preservation would have involved almost complete rebuilding, and have destroyed its value as an architectural document. All the moulded stonework and other architectural fragments have been carefully put by for re-erection.

EXHIBITION AT CARPENTERS' HALL.

THE Worshipful Company of Carpenters, exhibiting this week, at its hall in London, a collection of examples of woodwork, furniture, carving, and specimens of handicraft. This is a larger exhibition than the annual one and takes place every four years. This celebration is noted for endeavours to maintain its connexion with the trade whose name it bears, and its good work is done in a methodical manner. The British Institute of Woodcarvers at Chapel-street owes much to the company, which exercises some control in its management. Both Kings College and University College classes of construction have been largely endowed also by the company. The Institute at Stratford is now well known, with

swimming-bath and institute and hand-raft classes, and is a great boon to a densely-populated neighbourhood, and its success peaks volumes for it.

To encourage interest in this exhibition, prizes are offered for models in constructive carpentry, ornamental carpentry, specimens of joinery, carving, handwork, and the loan of objects illustrating the arts of joinery and carving has been invited. In the constructive carpentry division a first prize and silver medal has been awarded to Mr. E. Langdon, who contributes a model, carefully made, of a flying and raking shore. The flying shore would, in our opinion, have been better had the lowest struts been in the same plane with the other two. Mr. C. Rochester takes a second prize with a model of staging for carrying a steam crane. His is a framing in two stages with four corner posts. It is braced in a sound manner and would be probably strong enough for practical purposes; theoretically, however, the struts carried into the centre of the corner post, with no abutting timber behind it, is inadvisable. One of the struts are carried down to the level of the second staging in a better manner, but these require a stiffening piece from the outer post half way down.

There are more carefully and elaborately made models, about 9 in. long, of entrance gates, made by Mr. Benjamin Holmes. It seems a pity to encourage this style of work, as it is too small to be joinery, and hasn't the finish of cabinet work; it would merely produce finicking work. We note that prizes have been awarded to them. A model of shoring for capital and springing one of a church, carefully made in oak by Mr. F. E. Cutler, takes a second prize and bronze medal. An illustration of something very similar appears in *Violet le Duc's Dictionary*. The best of these exhibits are interesting models of scaffolds and scaffolding, centreing, &c. Mention could be made of Mr. Daniel Bryant's model of self-supporting queen-post partition, which takes a second prize and bronze medal.

In the joinery division there are five models of staircases amongst others. The first prize and medal falls to Mr. Geo. Welch, who exhibits circular stair with circular well. The lines of these stairs are very true and the workmanship good.

Mr. Alfred Wort secures the second prize with a model of geometrical staircase with spiral well. Mr. C. W. D. Boxall gains the first prize and medal for handrailing. Mr. Johnson and Mr. S. G. Lidstone take prizes for casements and sashes, and Messrs. T. Aston and Elias Evans prizes for lanterns.

Mr. E. Young also receives a second prize and medal for some good models of casements of sills to sashes, with a view to the solution of the weather and the removal of condensation.

The exhibits of carving are numerous and interesting. Mr. A. Halliday takes a first prize and silver medal for a carved oak chair-back, properly in low relief. The carving and work are vigorous. A second prize has been awarded to Mr. Charles Stephens' somewhat meagre carved oak frieze for chimney-piece. Mr. A. Vogt takes a first prize and silver medal for a vigorous carved capital of a column in soft wood; and a similar distinction is awarded to Mr. Anthony Smith for a carved bracket.

One of the most interesting exhibits is the case of Mr. James Osmond, which receives a first prize and silver medal. The contents are of artistic merit of no mean order, and comprise gorgeous models in clay, carved wood panels, and fan sticks, all in hard wood, the designs being Renaissance in character. We do not care for the subject of the centre object, labelled "The Cronies;" but, at the same time, the expression on the old lady's face is wonderfully rendered. A second prize goes to Mr. James Osmond for a study of a negro's head. The face has been sand-papered, and, though this in the ordinary way would be appreciated, it renders the shiny appearance of a negro face very effectually. Honourable mention and an award has been given to Mr. B. Harrison for a carved satinwood clock-case; the workmanship of this is excellent and the carving of some merit, but the attempt to cast a clock-case design architecturally is more than not unsuccessful, and this design is no exception; the faults of proportion being apparent in several cases.

A small table in this room shows a few specimens of the useful kind of instruction to be obtained at the Company's Institute at Stratford.

The smaller room adjoining contains the loan collection, and much interest is attached to this portion. Most noticeable is an English armoire, lent by Mr. Seymour Lucas, which is labelled "English Gothic Armoire, date about 1500," which may be safely considered of an earlier date. The tracery work is of great beauty. Mr. W. H. Spiller contributes a carved oak Italian chest, date about 1600, and an interesting case of inlaid guns and powder-flasks. Professor Banister Fletcher also contributes some objects of interest, among them a carved chair of the Carolan period.

A carved bracket in this room, by Mr. E. T. R. Boreman, takes a first prize and silver medal. The execution is excellent. There are some interesting specimens of work done by the Wood-carving Classes at Kings College. The reproductions of old furniture which are exhibited and executed by the Chiswick School of Arts and Crafts are interesting. The reproduction is exact and slavish; even the date, 1670, is carefully inserted. We hope traces of this sort will not mislead the careless observer. We understand that the judges were Mr. Seymour Lucas, A.R.A., Professor Roger Smith, and Banister Fletcher, and Messrs. Bartlett, Hill, Ryder, Howard, and Annonier. The exhibition is well worth a visit.

MAGAZINES AND REVIEWS.

The Gazette des Beaux-Arts opens with an article by M. Henri Bérardi on Raffet, of the recent exhibition of whose works something was said in our Paris Letter last week. M. Bérardi considers that Raffet will take a place in art history beside such masters as Delacroix and Meissonier. Some interesting sketches by Raffet accompany the article. M. Paul Lefort contributes an article on "Zurharan," with a number of illustrations from drawings in various museums; and M. A. Renan has an article which will be interesting to architects on the old city of Tlemcen, "the Pearl of Algeria," with illustrations of some of its Arabic architecture. "Le Musée des Artistes Contemporains," by M. Léonce Bénédite, deals with the present and possible future of the Luxembourg, which he considers by no means in a flourishing condition. The Museum is too small, and frequent promises that it should be enlarged have never been carried out. Foreign countries are badly represented; the country of "Leighton, Burne-Jones, Watts, Tadema," &c., is represented only by a work of a second-rate landscape-painter, Wyld (this was evidently written before the thrilling incident of the addition of Mr. Whistler's picture), and the museum is debared by its regulations from hanging more than three works by any one painter, so that a fourth work, however superior, is condemned to rejection in advance. The duty of such an institution as the Luxembourg, M. Bénédite urges, is to be absolutely eclectic, and to give full representation on equal terms to all schools and all countries. The number concludes with an article by M. A. Gayet on "La Sculpture Copte" with one or two curious illustrations.

The first article in the *Art Journal* is devoted to two notices of the late Mr. F. Leyland's collection of works of art, by Mr. Val Prinsep and Mr. Lionel Robinson, in which far too much importance is attached to the tastes and supposed influence of a self-made millionaire whose predilections in art were of a very one-sided nature, and who probably had not known nearly so much about art as he professed or was credited with by a clique of artists of a certain school to whom he played the part of patron. The article is very well illustrated by engravings of some of the well-known pictures of Rossetti and Mr. Burne-Jones which were in his collection, and of some of the rooms in the house decorated by Mr. Whistler. An article on Mr. David Murray by Miss Marion Hepworth Dixon is accompanied by reproductions from his leading pictures of the year. Mr. Charles Holme writes an article on old Japanese pottery containing a good deal of information, and illustrated by examples the majority of which are rather curious than beautiful.

In the *Magazine of Art* "The Royal Academy" is the subject of an article by the editor, in the course of which some strong but perfectly true remarks are made as to the narrowness of the Academy in refusing admittance within its ranks to artists in black and white—pen artists as they may be termed. Keene, it is observed, was admirably praised by the President in his speech at the annual banquet,

"and his praises have been sung by the whole artistic universe. Yet he was not thought fit to enter Burlington House." Messrs. John Tenniel, Linley Sambourne, and Edwin Abbey are equally unrecognized. But the fact is, as we have already observed in speaking of architecture, that the majority of the Academicians are people who think (or act as if they thought) that art means painting. The article is illustrated by some reproductions of pictures of the year, and (which is of more interest) by the studies made by Sir F. Leighton for the "Hesperides," "Bacchante," and "At the Fountain." An article on "Press-day and Critics," with portraits, is a new departure which will interest a good many readers, while others may be rather surprised to find among the "art-critics" some accomplished literary men whose knowledge of art is not generally supposed to be very deep. Mr. G. T. Robinson contributes an article to the "Artistic Homes" series on the decoration of ceilings, with illustrations on the decoration of charmingly ceiled rooms from old Renaissance houses. Other articles are a short one on Mr. Wedmore's book on Myron, and one on "The Dixon Request at Bethnal-green," by Mr. R. Jope-Shade.

The Antiquary contains, in its "Notes of the Month," a great many items of interest, and this department of the publication, which is being gradually expanded, is likely to become one of its most attractive features. Mr. J. Romilly Allen contributes a paper on "Archæology and Philosophy," in the course of which he urges, and rightly, that there should be a photographic department in connexion with all great archæological museums, "and every object should be permanently identified by means of photography." A strong article (unsigned) refers to "Doings at Lincoln Cathedral" in relation of course to the threatened demolition of Wren's cloister, in which the writer laments, and with reason, the extent to which Mr. Pearson has allowed himself to become identified with the removal and so-called "restoration" of ancient work. The writer avers that Wren's cloister is really the most valuable side of the four, inasmuch as the other three sides have been more or less modernised, whereas Wren's work is entirely original and remains just as it was built. It is probable, in our opinion, that the check given to the proposal by the discovery of serious dilapidations in one of the western towers will have the effect of preserving Wren's cloister by affording a decent pretext for backing out of a piece of work which has been so generally condemned. Other articles deal with "Bookbinding," "Ancient Leicester," "The Discovery of the coffin of Mrs. Margaret Godolphin in Breage Church, Cornwall," &c., &c.

The Edinburgh Review gives an article on "Dr. Schliemann's Last Excavations" sympathetic in tone, but admitting an element of good luck in his career, and a power of making the most of his successes. The *Review* admits that in his early days Schliemann was tempted into indulging in mere guesses which afterwards turned out to be untenable, but regards these as of no more importance in respect of the main quality of his work "than the first errors in an uncorrected proofsheet." The same number of the *Review* contains an article on "The Municipal Administration of London," not very favorable in its views of the London County Council. The attempt to govern London by a "committee of one hundred and thirty-seven people" the *Review* considers to be fraught with the gravest inconvenience, and speaks elsewhere of the necessary result of attempting to govern the affairs of London by "a number of small committees," in which there is no demand of personal responsibility. The fluctuating nature of the Council is regarded as another serious evil; "three years is but a short time" in which to make due acquaintance with the problems to be dealt with. The *Review* charges the "Progressists" with endeavouring to increase the popularity of London by increasing its attractiveness and lowering its rents, thereby increasing the already too great tendency to flock into London. "The keep the labourer on the land" is one of the great difficulties of the day, and the present policy of the County Council tends rather to increase than to diminish it. At all events the *Review* would not recommend the principle of building municipal dwellings and letting them at rents below the cost price. Rather it would recommend the Council to see

The Westminster Guildhall or Sessions-House, now in course of Demolition.

to it that no insanitary dwellings are allowed to be let at all; which latter is certainly a wholesome recommendation. The recent defeat of the moderate candidates the *Edinburgh Review* considers to have been due not so much to the influence of any definite principle in voting, as to the fact that the right sort of candidates were not forthcoming on the moderate side, and that there were few who appeared personally to be worth voting for. In conclusion, the *Edinburgh Review* urges that, in the conduct of the business of London, responsibility, economy and efficiency should be the three watchwords of the day.

The *Nineteenth Century* contains an article on "Stevens and the Wellington Memorial" by Mr. Walter Armstrong, which is appropriate just now, and is intended to show the public "how unique a thing deans and Parliament men have hidden away in a corner of St. Paul's." Mr. Armstrong possibly a little exaggerates Stevens. He admits, indeed, at the close, that Stevens invented no new method or detail, he worked with the materials left to him by the Renaissance, but claims for him, and we think rightly, a remarkable power of unity of conception, as illustrated especially in the Wellington Monument. It is a whole thing, one idea which is all in keeping; and a great idea. In stating that Stevens had a power of design only second to that of Michelangelo, it should be remembered however that Michelangelo came first, and that Stevens annexed his style and manner a good deal; some people think, too much. Nor is it quite true to say that Stevens was irreplaceable in his treatment of detail. Some of the smaller decorative detail of the Wellington monument is not good, as decoration, not truly architectural in character. But then painters know so little what decorative detail really means in this connexion.

The *English Illustrated Magazine* contains an article by the Dean of Gloucester, under the title "The Vanished Abbey," on the ancient Abbey of Evesham and what is known of it. The article is illustrated by sketches by Mr. Dittmar J. B'ow and Mr. E. H. New. The sketch given of Evesham Tower is hardly satisfactory, the other illustrations are good sketches and of some interest.

Scribner has a good article on "Rapid transit in cities," by Mr. T. C. Clarke, the first of a series. "The Problem" is the subject of this article, the solution is to be given in another number. One point of the paper is that the writer endeavours to show, and does show to some extent, that the means for giving more rapid transit by street railways are nearly always commenced by a ring round the city, and that in all cases this is found to have been a mistake, and to require correcting by cross lines, as Paris and London are now endeavouring or wishing to correct it the moral being that

rapid transit must take people where they want to go, and not where they do not want to go. In London the cross connexion is at present made by omnibuses. The writer thinks the travelling on the underground railway very small compared with the great population of London, which perhaps is true. "Unter den Linden" is a pleasantly-written article on the great Berlin promenade and its frequenters, Mr. Shaler's "Sea and Land" is a very interesting article, illustrated, on the action of the sea on coast formations, and the fourth number of Mr. Apthorp's "Paris Theatres and Concerts" is both entertaining and useful, giving an insight into the system of Paris theatre management in relation to the public.

The *Century* devotes an article to "Architecture at the World's Columbian Exposition," from which it appears that a great deal of thought has been bestowed on the consideration of the design of the principal buildings, of some of which we have given illustrations, though we may question whether they will excite quite the same admiration among European architects as Mr. Van Brunt, the author of the article, claims for them. Mr. Van Brunt is, we believe, one of the architects of the five principal structures, who, it is interesting to know, are all connected professionally with Mr. Hunt, the leading architect, as former pupils or assistants, a fact which will no doubt tend to promote a certain unity of architectural feeling in the structures to be erected. "Homesteads of the Blue Grass," in the same magazine, is a paper on old American houses of a certain district, with illustrations.

In the *Atlantic Monthly* the only article of special interest to our readers is one on "Private life in Ancient Rome," by Miss H. W. Preston and Miss Louise Dodge. It includes a description of the Roman house and its daily use.

The *Quarterly Statement* of the Palestine Exploration Fund is an interesting number, containing a report on "Excavations at Tell el Hes" by Mr. F. J. Bliss, with plans, and engravings of a good many objects discovered; a letter from Herr Schick on "Recent Discoveries at Nicophorieh," with drawings of some interesting sarcophagi and architectural details, and a "Narrative of a journey to Palmyra" by the Rev. G. B. Post.

The *Essex Review* for the April quarter contains the second of the articles on "Essex Churches," dealing with St. Michaels, Woodham Walter; the article is by Mr. F. Chaucellor, and is accompanied by a plan and a pretty sketch of the picturesque little church. The first of a set of articles on Parish Registers, by Mr. Robert H. Browne, is on the register of the same church, followed by one on that of Alphetstone, by Mr. C. Golding. Under the general heading of "Notes and Queries" a good deal of interesting information is collected.

THE GUILDHALL OR SESSIONS HOUSE, WESTMINSTER.

In the *Builder* for April 23 (p. 320) we referred to what we then spoke of as the "enlargement" of this well-known building. We now regret to learn that the building is being demolished, and that a totally new building of quite a different character is to be erected on its site, from a design by Mr. F. H. Pownall, the County Surveyor for Middlesex, for the use of the Middlesex County Council.

The Westminster Guildhall was erected, according to Elmes and Shepherd's "Metropolitan Improvements" (1828), by Samuel Pepys Cockerell, father of Professor C. R. Cockerell, R.A. The book does not mention the date of the erection of the building, but we believe it was about the year 1804. We have thought it would be of interest at the present time to reproduce Shepherd's engraving of it from the book mentioned.

THE ROYAL INSTITUTE OF BRITISH ARCHITECTS:

THE ANNUAL REPORT.

The annual general meeting of the Royal Institute of British Architects was held on the 2nd inst. We make the following extracts from the annual report, as adopted by the meeting:—

The Council have held twenty-one meetings since the announcement of their election at the first general meeting in June, 1891, previous to which two Council Meetings were held, making in all twenty-three meetings since the publication of the last Annual Report on May 7, 1891. Committees of the Council have also met for the consideration of matters connected with (1) Professional Practice, (2) Finance, (3) the Alliance of Non-Metropolitan Societies, (4) the grant of funds in furtherance of the Educational Scheme of the Architectural Association and (5) the award of the Royal Gold Medal.

During the official year (from the beginning of May, 1891, to the end of April, 1892) 64 Fellows have been elected, 29 of whom were previously members in the class of Associates; and 51 Associates have been elected. The number of Fellows is now 610, as against 560, and the number of Associates 794, as against 784 at the corresponding period last year. One Hon. Associate—Mr. Henry T. Boodle—has been elected, and the number is now 67. Five Hon. Corresponding Members—Dr. William Dörpfeld (Athens), Baron Max von Ferstel (Vienna), His Excellency Osmar Handy Bey (Constantinople), Professor Carl König (Vienna), and Herr Otto Wagner (Vienna)—have been elected, and the number is now 49. H.H. the Maharaja of Jeypore, G. C. S. I., has been elected an Hon. Fellow.

The losses by death, in the class of Fellows, since the issue of the last Annual Report, have been:— Isaac Barradale (Leicester), Edward H. Borneil, Thomas Henry Eagles, M.A., Philip C. Iardwick, F.S.A., Robert J. Johnson, F.S.A. (Newcastle), Harry Oliver, Alexander Peebles, Alfred Porter, Frederick J. Robinson (Darby), Edward J. Tarver, F.S.A., C. J. Toward (Wellington, N.Z.), Thomas Verity, and Vincent W. Woisey (Bristol). In the class of Associates: V. W. Kendall Clarke, Henry Carzon (Tenbury), Henri C. Elworthy (St. Leonards-on-Sea), and Russell Walker (Edinburgh). In the class of Hon. Associates: Sir John Coode, K.C.M.G.; and Rt. Hon. William Cavendish, Duke of Devonshire, K.G.; Sir John Hawkshaw, P.R.S.; the Prince Victor of Hohenlohe-Langenburg; and John Murray, F.S.A. In the class of Hon. Correspondents: Antoine Nicolas Bailly (Paris), Professor Giovan B. P. Basile (Palermo), and Cavaliere Pietro Rosa (Rome). In the class of Hon. Fellows: Professor E. A. Freeman, D.C.L. Literary notices of nearly all the above-mentioned members have appeared in the *Journal of Proceedings*.

At the general meeting, held on January 18 last, addresses of condolence with her Majesty the Queen and his Royal Highness the Prince of Wales, Patrons of the Institute, on the melancholy death of his Royal Highness the Duke of Clarence and Avondale, were voted; and the business of the Special General Meeting which was summoned for the same evening was postponed out of respect for the national loss.

The Preliminary Examination was held in November, 1891, and March, 1892, in London and Manchester. The Intermediate Examination of 16 Probationers last November, and 22 last month, was held in London. The number of Probationers is now 320, and the number of Students (all of whom were previously Probationers) is 41.

The Examination in Architecture, to qualify for candidature as Associate, was held last November in London, and this Spring in London and Liverpool, at which latter centre Mr. John Slater attended for the Oral Examination. The names and addresses of the 26 candidates (out of 40 admitted) who passed in November were reported to the General Meeting of December 14, 1891; those of the 49 candidates (out of 81 admitted) who have just passed were reported to the General Meeting of April 3, 1892.

Statistics of the Examinations of 1891-92 are here given in a tabular form:—

The Preliminary Examination.

Dates.	Admitted.	Not passed.	Relegated for periods.	Passed and Registered.
Nov. '91....	74 { 21 Exempted 48 Examined 5 did not attend.... }	3	6	60
March, '92..	80 { 29 Exempted 49 Examined 3 did not attend.... }	—	12	65
—	164 (8 did not attend)	3	18	125

The Intermediate Examination.

Dates.	Probationers admitted.	Relegated for periods.	Passed and Registered.
Nov. '91....	16	6	11
March, '92..	22	9	13
—	38	14	24

The Examination in Architecture.

Dates.	Applied.	Admitted.	Not passed.	Relegated.	Passed.
Dec. '91....	48	40	—	14	36
March, '92..	92	81	—	32	49
—	140	121	—	46	75

The Council think it worthy of attention that 140 applications were made in 1891-92 to be admitted to the Examination qualifying for candidature as Associate, the number of such applications during the preceding official year having been 106; while the number of passed candidates was 75, as against 49 in 1890-91, and 54 in 1889-90. During the calendar year 1891, the number of candidates who passed amounted to 50, amongst whom Mr. John Begg most highly distinguished himself, and was

awarded the Ashpatal Prize. At the same time the Board of Examiners highly commended Mr. Owen Fleming and Mr. Joseph William Twist (South Shields), also passed candidates in the Examinations of that year.

A Statutory Examination for the office of District Surveyor of London, and of Building Surveyor under local authorities, was held in November, at which two applicants presented themselves, neither of whom passed. The April Examination was held on the 28th and 29th ult., when six candidates presented themselves for examination under the Metropolitan Building Act, 1855, four of whom obtained certificates of competency to act as District Surveyors in London, viz:—John Albert Hill Knight (*Associate*), 40, St. Luke's-road, Clapham, S.W.; George Arthur Lansdown, 5 and 7, Warwick-street, Charing-cross; Frank John Waldemar Leverton, H.M. Office of Works, Whitehall; Robert Williams (*Associate*), 3, John-street, Adelphi, W.C. One candidate also presented himself for examination under other Acts, but the Council were not recommended to grant him a certificate of competency.

At the request of the Committee of the Architectural Association the Association scheme of education in course of establishment was discussed by the Institute, after a full explanation of it had been given by Mr. Frank Baggallay, President of the Association, at a General Meeting held last June; and at the adjourned Meeting in July a resolution was passed by the Institute authorising the Council to consider and decide in what manner and to what extent pecuniary assistance should be given towards the establishment and carrying out of the Association scheme. The matter having been previously discussed by a Special Committee and reported on by the Finance Committee of Council, final consideration was given to it by the Council at the end of last December, when they decided "That a sum of three hundred pounds (£300) be granted to the Architectural Association (London) in support of the A. A. Educational Scheme, such payment to be made in three equal annual instalments: on Jan. 30, 1892, Jan. 31, 1893, and Jan. 31, 1894, but that the grant of the instalments of 1893 and 1894 respectively be conditional on the A. A. Educational Scheme being then still in operation." This decision was reported to the Institute on January 25 last, and the first instalment of £100 was duly paid to the Architectural Association and acknowledged.

The Council having been asked by the Siamese Legation in London to consider and report on a draft curriculum of architectural study, which was submitted to them, for Siamese students resident in England, and desirous of becoming architects in their own country, sent, in reply, three papers of comments and suggestions prepared respectively by the Chairman of the Board of Examiners in Architecture, by the Professor of Architecture at the Royal Academy of Arts (London), and by the Master of the Architectural School of that Academy, which were offered for the consideration of the Siamese Legation, and duly acknowledged.

The Devon and Exeter Architectural Society and the Dundee Institute of Architecture, Science, and Art have been admitted to alliance with the Institute,—the number of such allied societies being now thirteen.

The Royal Gold Medal, 1891, for the promotion of architecture was presented to Sir Arthur W. Blomfield, A.R.A., for his works as an architect, on June 22, 1891. By a resolution of the Institute, passed on March 7, 1892, Monsieur César Daly, *Hon. Corr. Member* (Paris), was elected Royal Gold Medalist for the current year, for his literary works in connection with architecture; and General Sir H. F. Ponsonby, G.C.B., has written signifying the approval of the award by her Majesty the Queen. This having been communicated to Monsieur Daly, he has accepted an invitation to attend in London next June to receive the Medal from the hands of the President.

The annual Deed of Award of Prizes and Studentships was presented to the Institute on January 18 last, and published at length in the *Journal* of the 28th of the same month. At the presentation of prizes held on January 25 the President delivered an Address to Students on the Art of Planning; and the Hon. Secretary a Critical Notice on the designs and drawings submitted. The public exhibition of the drawings, which lasted from January 15 to 25, included the work as Pupil Student for 1891 of Mr. Sidney K. Greenslade. A selection of draw-

ings which had obtained prizes was forwarded to those of the Allied Societies who applied for them, and an exhibition of the same was held in Newcastle, Dundee, Glasgow, Liverpool, Sheffield, Leeds, Leicester, and Birmingham, under the respective charge of the Societies in those centres. The sum of money for foreign travel given under conditions with the Soane Medallion was increased last year to 100*l.*, and the minimum period of travel was also increased to six months. The successful competitor for the Tite Prize has now to travel in Italy for a period of not less than four weeks.

The pamphlet of subjects and conditions for the Prizes and Studentships of 1891-92 was published early in March. It will be seen therein that some notable modifications have been made in the programme and conditions of the Owen-Jones Studentship, which is now an annual Studentship, open to members of the profession under thirty-five years of age; and the Council have announced that in the examination of candidates' work preference will be given to that exhibiting acquaintance with the application of colour as a means of architectural expression, not alone by the use of pigments, but also in the juxtaposition and combination of different coloured materials.

Pursuant to Resolutions passed at the last Annual General Meeting, the Council appointed a Special Committee to "inquire whether it is not possible under By-law 9* for a small body of members to exclude from the Fellowship of the Institute qualified persons approved by the Council, although a large majority of the members of the Institute approve of the election; and if so, to suggest steps for the amendment of the anomaly." The Committee they appointed—consisting of Messrs. Arthur Cates, *Vice-President*, F. T. Baggallay, James Brooks, Thomas M. Rickman, Lacy W. Ridge, R. Phené Spiers, and Paul Waterhouse, members of their own body; with Messrs. H. C. Boyes, E. T. Hall, E. B. Panson, and J. G. Finch Noyes, *Fellows*, and Messrs. Charles Henman and Wm. Woodward, *Associates*—have sent up a unanimous Report, to which the Council have given their general approval, and which they propose to submit to the Institute at the General Meeting to be held on June 13, 1892.

The Institute Paper of "Suggestions for the Conduct of Architectural Competitions" has, for a considerable period, engaged the attention of the Competitions Committee, whose recommendations having been submitted to the Council were considered and approved by them. The amended Paper was brought before a General Meeting of the Institute on March 7 last, when a Resolution was passed that "The principle of the amended Paper of Suggestions for the Conduct of Architectural Competitions be adopted; and that it be left to the Council to issue the same as an Institute Paper, after due consideration of the suggestions made at that Meeting." The Council having since done so, the Paper will be shortly issued.

A Bill to provide for the Registration of Architects was read a first time in the House of Commons on March 2, 1892, and the second reading of it is announced for June 2. The Council have taken the necessary steps to oppose it.

The Art Standing Committee have held eleven meetings since their election in June, 1891, making, since the issue of the last report, twelve in all. Under the provisions of the By-law the Council appointed as additional Members of the Committee Mr. Alma Tadema, R.A., Mr. C. B. Birch, A.R.A., Mr. Ernest George, Mr. Leonard Stokes, and Mr. Alfred Waterhouse, R.A.; and in the course of the year they have filled up vacancies in the Committee by appointing Mr. W. Kidner, Mr. W. S. Weatherley, and Mr. T. J. Flockton (Sheffield). The Committee elected Mr. Waterhouse, R.A., Chairman, and Mr. R. Herbert Carpenter, F.S.A., Vice-Chairman; they also appointed Mr. W. D. Caröe, M.A., and Mr. Beresford Pite, Hon. Secretaries.

The subject of the disfigurement of Somerset House,—the possibility of taking action to deal with the building recently added to it by the authorities of King's College and to prevent the further addition of such works,—has largely occupied the attention of the Committee; and on their recommendation the Council, with the concurrence of the Institute at its meeting of November 2 last, entered into

* By By-law 9, Fellows are elected by ballot, one black ball to six white ones excluding from election.—Ed.

communication with the First Commissioner of H.M. Works and Public Buildings, forwarding at the same time the resolution passed at that meeting. By the reply of the First Commissioner, dated December 16, 1891, it appeared that the Office of Works had no power to prevent the addition which was then in course of erection at the eastern end of the river front of Somerset House. By a subsequent letter, dated March 22, 1892, the Council were informed by the First Commissioner that in the event of the authorities of King's College proposing to advance their buildings towards the Embankment, the Government had the power (1) to prevent any erection which would interfere with the light and air of Somerset House, (2) to require that any additional structures forming part of the river front of Somerset House should not be erected without their assent, and (3) to control any buildings proposed to be erected on the triangular piece of land at the south-east corner of King's College site. The correspondence on this subject has been published in the *Journal of Proceedings*.

The proposed demolition of Lauderdale House, Highgate, has been inquired into by the Committee, and some of their members were deputed to visit the old house and report thereon. It was decided that certain portions and fittings of interest might with advantage be retained, as examples of joinery of the period, in any building to be erected in the park; and the Council approved the Committee's recommendation. It is a matter of satisfaction to know that by the action of the London County Council the house will be preserved.

The threatened destruction of Bourne Old Hall, Lincolnshire, was considered by the Committee, and the Council addressed the Directors of the Great Northern Railway as to the architectural interest of the Hall and the advisability of preserving it if possible. The arrangements of the new line have now been made in a manner that will preserve the building.

The works of external repair to Gray's Inn Hall, in the removal of the stucco and the revealing of old brick and stone work underneath, have had careful consideration; and the Committee recommended the Council to take steps for the preservation of Emanuel Hospital, Westminster, by petitioning that the requisite assent of the authorities be withheld for its removal, and, failing success, to obtain the mention of this important matter in Parliament. St. Mary Woolnoth Church, and Grey Friars, Bedford, have also received the careful attention of the Committee with a view to their preservation. The Council, as far as possible, have adopted the Committee's recommendations in these matters.

The Committee have undertaken the arrangement of three Ordinary Meetings of the Institute during the Session. Those already held, dealing with the subjects of "Sculpture and Sculptors' Methods in relation to Architecture," and with "Stained Glass," have proved of considerable interest to the general body. The Committee hope that this series of meetings for the consideration of new and revised processes of decorative art may be continued and extended in Sessions to come; and the Council congratulate the Institute on the great success that has attended the efforts of the Committee in this direction.

The Literature Standing Committee have held ten meetings since their election in June, 1891, making since the issue of the last report eleven in all. The Council appointed as additional Members of the Committee, Mr. J. D. Crace, Mr. T. H. Eagles, M.A. (since deceased), Mr. R. F. Grantham, Mr. B. Ingelow, and Colonel Lenox Prendergast. The Committee elected Professor Aitchison, A.R.A., Chairman, and Mr. Alex. Graham, F.S.A., Vice-Chairman; they also appointed Mr. Paul Waterhouse, M.A., and Mr. R. Elsey Smith, Hon. Secretaries.

The Sessional Papers presented and read during the official year are:—

The *Journal of Proceedings* of 1890-91 (vol. vii.) contained 498 pages, with two double-page plates and a few illustrations in the text; and twelve numbers have already appeared of the volume for 1891-92. The Committee express themselves greatly indebted to a large number of gentlemen for leading articles and reviews of notable works, and especially to Messrs. Wyatt Papworth, A. E. Street, M.A., Paul Waterhouse, M.A., J. D. Crace, and R. F. Grantham, for valuable assistance repeatedly rendered.

The annual volume of *Transactions* [vii. New

Series] contained 416 printed pages with ten double-page plates, 195 illustrations in the text, and a frontispiece portrait of Mr. Alfred Waterhouse, R.A., the ex-President. With it was issued an Index to the volumes of the original series (1836-1884), printed at the sole cost of Mr. Arthur Cates. The Index was originally compiled by the Librarian, Mr. Alex. Beazley, and presented by him to the Council; and he also prepared the work,—some sixty pages quarto,—for press, in consultation with Mr. Cates.

By a resolution of the Council, confirmed at the last Annual General Meeting, the management of the Reference Library and Loan Collection of Books was entrusted to the Literature Standing Committee, and has been arranged for by the present Committee for the first time. They have had under their consideration the attendances of the Library officers, the recommendations for purchase of books and the examination of new purchases and presentations, the preparation of reviews of the most important works for the *Journal of Proceedings*, and the desirability of increasing the facilities possessed by country members for borrowing books from the Loan Collection. At the present time the Committee have under consideration the desirability of increasing the available accommodation in the Library.

The old Council-room having been partly fitted with bookcases is now used for the purposes of the Library.

The Library has been kept open on Saturday afternoons until 6 p.m. from October 1, 1891, to the end of March, 1892, but the Librarian reports only forty-two attendances during the twenty-five afternoons in that period. It has not been proposed to keep the Library open after 2 p.m. on Saturdays during the six months between April and September both inclusive.

The attendances of readers in the Library during the year numbered 3,482 (details whereof are given in a table in the report). From the report of the Librarian to the Literature Committee it appears that during the twelve months from April 1, 1891, to March 31 of the present year the additions to the Library amounted to 172 volumes and 104 pamphlets, and to the Loan Collection 29 volumes and 7 pamphlets, exclusive of parliamentary papers, reports, and transactions of societies, parts of works issued in a serial form not yet completed, and trade lists. The number of volumes presented to the Library was 98, and to the Loan Collection 7. Of pamphlets, 101 were presented to the Library and 7 to the Loan Collection. Of drawings, engravings, and photographs 172 sheets were presented. There were also presented 2 medals, one of the Paris Exhibition, 1889, and one of the Paris Société Centrale des Architectes. The number of tickets (exclusive of renewals) issued for admission to the use of the Library and Loan Collection was 107 (last year 91). The number of volumes issued on loan was 1,131 (last year 945). The attendances of members of the Architectural Association as readers in the Library were 280 (last year 304), and the number of issues on loan (both these items being included in the gross returns above given) was 86 (last year 117).

The Practice Standing Committee have held 11 meetings since their election in June, 1891, making since the issue of the last Report 12 in all. The Council appointed as additional members of the Committee Mr. Henry Curry, Mr. Arthur Cates, Mr. Gruning, Mr. Hansard, and Mr. Tabherer. The Committee re-elected Mr. Curry, Chairman, and Mr. Cates, Vice-Chairman; and Mr. T. M. Rickman and Mr. E. T. Hall, Hon. Secretaries. Besides incidental business of minor importance, the Committee have carefully reconsidered the Conditions of Contract in the amended form in which they were returned by the Institute of Builders, and have completed a further revised form of Contract and Conditions, which they are now sending back to the Institute of Builders for further consideration and conference.

They have given great attention to and have produced a draft Bill for the codification and amendment of the technical portions of the Metropolitan Building Act, which document has been forwarded by the Council to the Local Government Board, to the London County Council, and to the Commissioners of Sewers of the City of London. The Council trust that this work will receive at the hands of the public authorities that consideration and weight which is due to it as coming from a body of experts who have applied their special knowledge to the very technical subject of safe-

guarding the public in the important matter of building.

The Committee have also considered and reported upon the London Building Law Consolidation Bill put forward by the Local Government Board, and the amendments to that Bill put forward by the London County Council. The questions discussed in these Bills, suggestions, and amendments have been explained on behalf of the Committee by one of their Hon. Secretaries, Mr. Edwin T. Hall, at a General Meeting of the Institute on February 8, 1892.

In the matter of the Draft Bill prepared by the Local Government Board for the purpose of consolidating the enactments relating to the construction and use of buildings in London, the Council, through the President of the Institute, have submitted to the President of the Local Government Board some general observations on the Building Law now in force; and they have urged the necessity of amendment as well as of consolidation, which latter is all that is proposed by the Draft Bill in question. The Council are of opinion that, to make legislation on this important subject useful and effective, the introduction of an amendment Bill simultaneously with a consolidation Bill is imperative, at least, if the requirements of the present day are to be satisfactorily met. The Council have further urged the Local Government Board to make the use of fire-resisting materials compulsory in the construction of important and extensive buildings in the metropolis.

In connexion with these matters the Council have to report that at the beginning of last June, Mr. Cates was asked by them to attend before the Lords' Committee on the London Sky-signs Bill, but that their Lordships were content to accept the evidence he had given on behalf of the Institute, before the Commons' Committee on the Bill; and the Bill then passed.

The Science Standing Committee have held nine meetings. The Council appointed as additional Members of the Committee Mr. A. C. Blumer Booth, Mr. G. A. Pryce Curson, Mr. Frederic R. Farrow, Mr. Kidner, and Mr. P. Gordon Smith. The Committee re-elected Mr. Lewis Angell, Chairman, and Mr. Henry Dawson, Vice-Chairman; and Mr. Henry Lovegrove and Mr. William C. Street, Hon. Secretaries.

The Committee's Report on "Light and Air" was published in the *Journal of Proceedings*, and an invitation addressed to members of the Institute and other readers of the Journal to forward observations and suggestions in the matter of the several clauses of the Report. The Committee have expressed a hope that there may be an early reform of the present law of light and air, and that questions affecting the rights of owners of property in respect to adjacent buildings may be settled upon an intelligible and equitable basis.

The Committee have been principally engaged in making arrangements in connexion with the General Meeting of the Institute on May 16, when it is proposed that the important subject of the proper introduction and fitting of the electric light in domestic work is to be the subject of discussion. Mr. W. H. Preece, F.R.S., has kindly consented to open the proceedings with an address on the "Art of Interior Illumination," and a Sub-Committee have visited different places with a view to gather information, and to present a Report upon the various details connected with electrical installations.

The Committee have visited the recent Building Exhibition, and had under consideration some new building materials and mechanical appliances, and they propose to bring such of them as appear to merit special consideration before the Institute as soon as an opportunity can be afforded for the purpose.

The revenue account of ordinary funds for the year ended December 31, 1891, duly audited and signed by Mr. Joseph S. Hanson, *Ellom*, and Mr. Reginald A. Crowley, *Associate*, the auditors appointed at the last Annual General Meeting, is submitted with the report. It shows total receipts amounting (with a balance of £11, 13s. 3d. brought forward from last year) to £457, 7s. 1d. The total expenditure was £214, 0s. 5d., leaving a balance of £243, 6s. 8d., of which the sum of £157, 0s. 2d.,—made up of the balance brought from the Revenue Account of 1890, and a portion of the balance of the Revenue Account of 1891,—has been transferred to the Exceptional Account (for defraying expenses connected with the recent enlargement of premises.) The remainder, viz.,

St. OSWALD'S CHURCH, DURHAM.
Processional Cross

W. G. Estlin.
Aug. 1891.

ANCIENT PROCESSIONAL CROSS,
ST. OSWALD'S, DURHAM.

LITTLE is known of this cross, except that it was discovered in a package found in a mail-coach in an hotel yard in Durham, about thirty odd years ago. It was then sold to a Mr. Caldclough, whose widow subsequently presented it to St. Oswald's Church.

It is, probably, of late fifteenth-century workmanship. A similar one is now in the British Museum.

Figures and emblems are of "white" metal, the cross and arms being gilded. The silver knob and ebony shaft are modern.

THE ENGLISH IRON TRADE.—Quietness still prevails in the English iron market, although the probable early termination of the Durham coal miners' strike gives a healthier tone to business. Cleveland pig is 9d. lower, the decline being occasioned by the prospective settlement of the dispute. Manufactured iron is still in limited inquiry, and very little is doing in tinplates; but a better tone is apparent. There is but little change to chronicle in the steel trade; but in the north-west, ship-plates, angles, and tin-plate bars are all lower. Engineers and shipbuilders are only moderately employed. The coal trade generally is quiet. —Iron.

THE SCIENTIFIC STUDY OF TIMBER:
SURVEYORS' INSTITUTION.

At the ordinary general meeting of the Surveyors' Institution, held on Monday evening last, Mr. R. C. Driver, President, in the chair, Professor G. E. S. Boulger, F.L.S., F.G.S., read a paper on this subject. We extract some portions of it.—

It is, I think, a simple statement of fact to say that at present engineers, surveyors, and even timber-merchants recognise most kinds of converted timber (of which alone I am about to speak this evening), not only as to kind, but also even largely as to quality, by methods obviously and confessedly empirical.

In standing timber we often have foliage, flower, or fruit to guide us, in addition to that most important character, the ramification, or caulotaxis; and in unconverted timber we have the bark and often various superficial indications of internal disease or defect, or of probable inferiority. All these indications are absent in converted timber. Not only are we generally, at present, dependent upon "rule-of-thumb," but for many of the ordinary purposes of business we must, no doubt, necessarily, for the sake of rapidity of work, continue to be so. In the examination of wood, once for all, however, as in the testing of the comparative utility of various species or varieties in the inquiry as to the value of new foreign or colonial timbers, or in the selection by sample of large quantities of timber for important works of construction, a more thorough and more scientific estimate might well be applied, and it would be well if more uniform methods of testing were adopted. In any work of construction, for example, it is not only desirable, but practically essential, that the minimum strength of the materials employed, that strength which alone should be reckoned upon, should be known. The approximate durability of timber,—the only material with which I am concerned,—is also a matter of supreme practical importance; and, although, as the conditions under which it may be placed will vary, it is not possible to foretell this exactly, it may be very closely approximated,—more closely than has hitherto been usually done.

It might seem unnecessary to insist that, for any accurate knowledge of timber it is at least just as well to be acquainted with the latest results of scientific investigation into its minute structure, and even into its physiology and pathology. At the present day, moreover, when exact methods have, with the advance of science, found their way into so many branches of trade, one need not fear ridicule in advocating the use even of the microscope in such investigation. If, however, we turn to most of the recognised manuals for professional students, we find the information about the minute structure, growth, physiology and pathology of timber either altogether absent, extremely meagre, or hopelessly antiquated and inaccurate. In Tredgold's "Carpentry," as edited by Mr. E. W. Tarn in 1886, this part of the subject is professedly based upon Rhind's "History of the Vegetable Kingdom," a work published in 1840, and, even then, not very satisfactory. In Mr. Thomas Laslett's "Timber and Timber-trees" (Macmillan, 1875), a generally admirable work, the account of the general anatomy of timber, though having the advantage of a few illustrations, is but meagre, as it is also in the extremely accurate and valuable, though anonymous, "Notes on Building Construction," issued by Messrs. Rivingtons (Part III., chapter v.). In the late Dr. Franklin B. Hough's "Elements of Forestry" (Chicago, 1882), this part of the subject is treated in a very elementary manner though with fair accuracy of statement, but far too briefly.

It is not, I think, asking too much in the direction of scientific education to require that those practically concerned with timber should know as much about its microscopic structure as is contained in the admirably illustrated first chapter of Professor Marshall Ward's excellent little book, "Timber and Some of its Diseases" (Macmillan, 1889). Dr. Robert Hartig's little book, translated by Dr. Somerville as "Timbers and How to Know Them" (Nimmo, 1890), though containing rather minute descriptions of the microscopic appearance of 76 different woods, some of which, such as the rose, the vine, and the barberry, cannot be called timber, has in it no general exposition, beyond a glossary, as to the structure of wood. Such microscopic examination of woods will prove useful not only in the specific identification of timbers, but also

582. Gs. 6d., has been carried to the Revenue Account for 1892.

The revenue account of trust funds for the year ended December 31, 1891, duly audited and signed by the auditors before named, together with the balance-sheets of ordinary and trust funds, were also submitted with the report. . . .

The Council further submit an account of exceptional expenditure during the years 1890 and 1891, and during the three months of the year 1892. From this it appears that the sum of 1,146l. 18s. has been expended on the purchase of eighty-four shares in the Architectural Union Company, Limited, thus increasing the number of shares held by the Institute in that Company to 222, of which twenty pertain to the trust funds; while a sum of 2,180l. 18s. 6d. has been expended on the additions and alterations to the Institute premises, upon new fittings and furniture, and upon a new lease. . . .

HAMSTEAD HEATH STATION.—The directors of the London and North-Western Railway Company have selected Messrs. Kirk & Randall to carry out the work of enlarging and altering this station, the work of the late disaster, and the contractors have undertaken to complete the whole before the Whitsuntide holidays.

in the more difficult and often even more important discrimination between varieties of a single species. The same species from different districts, or grown under different conditions, may yield timber varying considerably in character, and, not improbably, in quality; and, though such differences will often be found, on the careful examination of the trees in bark, branching, leaf, flower, and fruit, to correspond to slight botanical distinctions, for practical purposes it is most important that such distinctions should be correlated with those of the timber. It is, therefore, useful to have a comprehensive classification of woods, based exclusively on characters presented by converted timber.

The difficulties in the way of such work are numerous. As regards not a few valuable exotic woods, some of which, such as the "Ballow" of North Borneo, or the "Pink Ivory" of Natal, may at no distant date come into use, either for constructive or ornamental purposes, we are as yet altogether ignorant of the botanical characters or position of the trees from which they are derived. As to others, even well-known native species, uncertainty is introduced by the ambiguity of the names used for them in commerce, and in some cases botanists have increased rather than diminished this ambiguity by minimising or altogether overlooking the facts of variation. The willow-wood, for instance, used in England, valuable from its non-resinous, and consequently non-flammable, character, its lightness, freedom from splinters, and durability whether in air or water, is mainly the product of *Salix alba*, though partly *S. Russeliana*, whilst, according to Mather, *S. fragilis*, the redwood willow, or stag's-head osier, produces the best timber, and is used in Scotland in ship-building, and in France the wood of *S. Caprea*, our goat-willow, is preferred. Poplar wood, again, is but little used in this country, though in France and Germany both *Populus canescens* and *P. fastigiata* are used for packing-cases, and *P. tremula* for flooring, as is *P. monilifera*, the most rapid-growing species, in Switzerland and North Italy. We, however, import from New York increasing quantities of a wood sometimes known in Liverpool as American, or yellow poplar, and at other times as American whitewood, or canary whitewood. This is no poplar, but the tulip-tree (*Liriodendron tulipifera*), a member of the magnolia family. Grown only for ornament in Europe, in America this tree is largely used for rafters, wainscots, roof-shingles, boxes, furniture, and turnery. The nature of the soil is said to have so marked an influence on the wood that in West Virginia three varieties are distinguished as "white," "blue," and "yellow poplar." The yellow alone is commonly shipped to this country, coming from moister, low-lying ground. It comes in waney logs or large planks, commanding a price equal to Quebec yellow pine (*Pinus Strobus*), and is now valued, for staining or polishing, by cabinet-makers, shop-fitters, and coach-builders. Its name, "white-wood" might cause confusion with the spruce (*Picea canadensis*), the "white-wood" or "white deal" of the Baltic trade; but the confusion among the coniferous woods themselves is quite sufficient without any new element of discord. Dr. F. B. Hough* and Mr. W. Stevenson† both speak of the varieties of *Liriodendron* as unrecognisable by outer characters and as purely due to soil, but F. A. Michaux‡ terms the more valuable "yellow wood" *L. tulipifera*, var. *obtusiloba*, indicating that there is a difference at least in the foliage as well as in the wood. The name "tulip-wood," used by Mr. Stevenson, is unfortunate, being commonly applied to the handsome Brazilian wood of the Lythraceous *Physocarpus floribunda*, though a Meliaceous wood of New South Wales, that of *Omentia renosa*, and *Uroplitis pendula*, in the same colony, have received the same name. Carpenters call all white deal "spruce," red and yellow deals from the Baltic "fir," and similar woods from America "pine," though both the last, at least, are products of species of Pinus. Take as a sample of confusion the trade name "yellow pine." In New Zealand, *Dacrydium Colensoi* yields a useful timber, so called. In British Columbia, *Pinus ponderosa* yields "yellow pine;" in Quebec, *P. mitis*; in Nova Scotia, *P. Strobus* or *P. rubra*; and in the

middle and southern United States, *P. australis*, to say nothing of "yellow deal" from *P. sylvestris* in Europe, and some half a dozen different "yellow woods." If we conversely take a single species, the wood of which comes to market under a variety of names, we find an equally confusing ambiguity. *Pinus sylvestris*, familiar to us as the Scots ("Anglice" Scotch) Fir, is proposed by Mr. Hurst, in his edition of Treggold, to call "Northern Pine" in consideration of its wide distribution in Northern Europe. Most writers on timber treat the varieties of this timber as if they were due solely to soil and climate. Thus, Mr. Stevenson says of it:—†

"On poor soil, at great elevations, it becomes a diminutive shrub; and in low situations, where it is a lofty timber tree, the wood on poor sandy soil is light, almost without resin, and of little duration; while on soils of a colder and more substantial nature it is red, heavy, and of great durability. It appears, also, that the same soil will produce both white-wood and red-wood trees; but, generally speaking, the former is found on the plains and the latter on the hills. . . . The quality of the timber . . . is dependent on the soil and climate. That grown in the south is thick-barked, carrying a great amount of sapwood, whilst that grown in the north is the reverse. Again, that grown in the south is hard and resinous, with live or red knots when converted, whilst that grown in the north is soft and non-resinous, with a large number of black or dead knots. . . . Such was the ignorance, in even high quarters, on this subject one hundred years ago, that the French Minister of Marine, in 1785, seeing the fine fir masts imported from Riga, sent out a M. Barbe, a masts-maker of Brest, to obtain seeds of the trees, which, upon being planted, produced, to the surprise of the French authorities, the common Scotch fir."

In addition to this geographical difference in the quality of the wood there is a local one, arising out of the nature of the soil. . . . Wood grown upon dry, elevated land, will be harder and more resinous than that grown on low, wet, or swampy soil. . . .

In trade it is recognised that red deal is superior to yellow, the best timber having its annual rings not more than $\frac{1}{16}$ in. across, and the autumn wood of a bright red, whilst inferior varieties are honey-yellow and over-resinous. Though only known in commerce by the names of their ports of shipment, there are undoubtedly distinct and important botanical varieties of this species. Without going as far as the Baron de Morogues of Orleans, who recognised no less than fourteen distinct varieties among the pines of Savoy alone,† and the long and careful study of thirty different forms by the late M. de Vilmorin, at Les Barres, between 1821 and 1882, we can hardly deny the importance of the five main types which he made out.‡ These are grouped in two divisions:—(1) with ascending branches, var. *rubra*; (2) with horizontal branches, var. *vulgaris*. Division 1 includes three sections:—(A) with close, pyramidal branching, as in some of the Riga pines; (B) with scattered branches and a symmetrical top, as in other Riga pines; and (C), with scattered branches, often very large and unsymmetrically developed, as in the Hagenau or German pine. Division 2 includes two sections: (D) with the branches in layers, tapering irregularly, as in the Geneva pine; and (E), thick and compact, as in the Briançon pine, that of the Higher Alps. Of those sections M. Vilmorin prefers the first (A), to which belong the pines of Smolensk, Vitelsk, Tchernigov, and Volhynia. Our Scots pine, which is inferior, is intermediate between sections B and C.

In English oak and elm, and in the false acacia or locust (*Robinia*), the question of slight botanical variation is also one of importance. It is commonly said that, of our two commoner varieties of oak, *Quercus pedunculata* yields the better timber. This opinion is probably based upon the fact that this variety generally presents a longer unbranched bole, thus yielding more straight timber of fair dimensions. Laslett, for example, whilst stating that the timber of *Q. sessiliflora*, sometimes called the Bay oak, is a little less dense and compact than that of *Q. pedunculata*, owns that, apart from dimensions, the two timbers so much resemble each other that "few surveyors are able to speak positively as to the identity of either."[§]

In concluding his paper, the lecturer said a few words as to the exhibition of timber, and illustrative specimens for educational purposes.

* Including the Conifera *Podocarpus latifolius* and *P. elongatus* of South Africa, besides several distinct donous angiosperms, some of which are used as yellow dyes.

¶ *Timber and Timber-trees*, p. 44.

Assuming that it is desirable that students, whether intending to be land agents or surveyors, should learn to recognise familiarly the woods commonly grown and employed, and to judge of their condition as to soundness and durability, he could only say that, at present, though we examined in that subject, there were but scanty facilities for the student to acquire such knowledge. The small timber museum at Kew was mainly of Colonial woods, and could hardly be called systematic; other specimens were lost sight of in the great general collection of economic products; nor did the collections of the Natural History Museum in Cromwell-road adequately fulfil this purpose. The requisite specimens need not occupy much space, as the number of species and varieties important to surveyors was not large.

Illustrations.

DESIGN FOR BURY MUNICIPAL BUILDINGS.

THIS fine drawing of part of a competition design submitted by Mr. F. H. Tulloch for the Bury Municipal Buildings hangs in the Architectural Room at the Royal Academy, and is referred to in our notes on "Architecture at the Royal Academy" on another page.

SCHOOL CHAPEL, TONBRIDGE.

The plan of this chapel is arranged on the same lines as our old Collegiate institution, viz., choir-wise, with a central passage about 13 ft. between the stalls. The dimensions of the building between the internal face of the walls are 155 ft. long by 36 ft. wide. Accommodation is provided for about 450 boys, twenty masters, and stalls at the west end for twelve other or head masters. On the south side of the nave a Founder's Chapel forms an important feature in the design; there are four openings, or arcades into the nave. This chapel is arranged for early services, and for the use of the families and servants of the masters, and for visitors the accommodation given is for about eighty-four. By this arrangement the boys and masters are completely separated from the other portion of the congregation; at the west end of this aisle is a large vestry for the choir and clergy. The main entrance is by a cloister of four bays running the entire length of the south side of the head master's house; the ceiling is groined by fan vaulting, and the walls are arcaded. At the west end is a staircase giving access to the organ-chamber, which occupies the upper part of the cloister, with three openings into the chapel. There is at the west end of the nave a large entrance for the boys connected with their playground.

The style of architecture adopted is that which prevailed in the latter part of the fifteenth century. The nave is vaulted in stone (and forms an important feature in the design), with a timber and lead roof over. The two turrets at the east end are staircases to give access to the roofs. These are to be covered with copper. The materials of the walls, both inside and outside, are to be the brown Ancaster stone ashlar. The estimated cost, with fittings, is about 17,000.

The architects are Messrs. James Brooks & Son, and the drawing is being in this year's Royal Academy Exhibition.

NEW REREDOS, ST. BOTOLPH'S CHURCH, BOSTON, LINCOLNSHIRE.

This reredos, or eastern screen, was unveiled, and dedicated by the Bishop of Lincoln in November, St. Andrew's day, last year. It bears the following inscription:—"In honour of Our Blessed Lord, and in memory of her brother, Walter Scrivener, this reredos was erected by Mand Scrivener, MDCCCXCI." The work is carried out as shown in our illustration, excepting that the upper niches are at present vacant.

The centre panel contains the scene of the "Last Supper"; those at the sides, "Moses Lifting up the Serpent," "Abraham Offering Isaac," "Jonah and the Fish," and "Elijah's Ascension." The seated figures are St. Gregory, Augustine, Jerome, and Ambrose. The single figures shown on the drawing are Our Lord, St. Peter, St. Paul, and the Evangelists; and in the wings, Joshua, Samuel, David, and Isaiah. St. Botolph, abbot and confessor, the patron

THE PHOTO ENGRAVING WAS MADE BY THE PHOTO ENGRAVING CO. LONDON.

DESIGN FOR CHIMNEY PIECE, ST. MARGARET'S, EAST GRINSTEAD—MR A. E. STREET, F.R.I.B.A., ARCHITECT.

THE BUILDER, MAY 14, 1892

NEW REREDOS: ST. BOTOLPH, BOSTON, LINCOLNSHIRE.—MR. W. SAMUEL WEATHERLEY, ARCHITECT

saint and founder of the church and monastery, is placed in the topmost niche. "His remains were buried here until translated to Ely and Westminster." This thirty-six small niches it has been proposed to fill with saints, either local or associated with Lincolnshire dedications.

The work has been executed by Mr. Elwell, of Beverley, from the design of Mr. W. Samuel Weatherley, architect, of London. This completes the oak-work east of the stalls, which has been in progress some time under the same architect's superintendence.

DESIGN FOR MEMORIAL TO MARY TUDOR.

The Society for the Protection of the Memorials of the Dead contemplate the erection of memorial tombs to Mary Tudor and Cardinal Beaufort in the Church of St. Mary, Bury St. Edmunds. The design for the first-named, here illustrated, is to be carried out in polished Hoptonwood stone with bronze cross and canopy.

The design is by Mr. Arthur E. Street, and this drawing from which the illustration is taken is in the Royal Academy Exhibition.

CHIMNEY-PIECE, EAST GRINSTEAD.

This chimney-piece, designed by Mr. Arthur E. Street, will stand in the Assembly-room which is shortly to be built in connexion with the new buildings of St. Agnes School, East Grinstead. The materials will be polished Hoptonwood for the lower and local sandstone for the upper part.

MUNICIPAL ENGINEERS AT NOTTINGHAM.

We now resume and conclude our report of this Midland Counties District meeting of the Incorporated Association of Municipal and County Engineers, held at Nottingham on April 29 and 30.*

After the reading of the paper by Mr. Arthur Brown (the greater part of which we gave in our last), the members adjourned to inspect the subways therein described, and were much impressed by the excellence of the work. One of the subways was converted for the nonce into an elongated haquetting chamber, and here the visitors were entertained at luncheon by Mr. Brown (the Borough Engineer) and Mr. John Parker (Surveyor to the Basford Rural Sanitary Authority). The guests included Aldermen Sir John Turley, Alderman Blackburn, Councillor G. Clarke, and Mr. F. Messon, the contractor. Illuminated by electric light, and decorated with flowers, this subterranean luncheon-chamber presented an appearance which was likened by some of the visitors to "a glimpse of fairydom." On ascending to the surface, the party witnessed a test by hydraulic power of a short length of stoneware drain-pipes fitted with Hassall's patent safety joint. The pressure was gradually applied by a pump until 100 lbs. to the square inch was registered. At this pressure the pipe cracked, but the joint remained intact. The result was regarded as exceedingly satisfactory, for of course no such external pressure in a drain-pipe would occur in practice. We gave a description of Hassall's patent joint, which appears to be an exceedingly efficient and reliable one, in the *Builder* for September 26, 1885, p. 417.

The members then returned to the Exchange Hall, where Mr. William Spinks, Assoc.-Mem. Inst. C.E., and Lecturer on Sanitary Engineering at the Yorkshire College, Leeds, read a paper on "Public Health Acts Amendment: some Suggestions in Relation to Private Improvements." He said that since the Association discussed the question of Private Improvements in 1886, he had had a great deal of correspondence, not only with Surveyors and Clerks to urban authorities, but also with property owners and agents, and many of the cases they had brought under his notice had occurred to him as being worth recording. During the past five years the Association had had a considerable influx of new members, and it would be well to ascertain the experiences and opinions of the new blood before any attempt was made to recast the sections of the Public Health Act

which dealt with Private Improvements. As the Council had invited the co-operation of members in the work they had in hand, the author had revised the remarks he made in 1886 upon "Suggested Remedies for the defects of the 150th Section, Public Health Act, 1875," and extended them in the directions dictated by the experience he had recently acquired. Most surveyors in their practice, in carrying out the section, had met with cases that were not apparently provided for, and which, being recurrent, it would seem to be desirable for legislation to be enacted, so as to embrace the most important points. Of course it would be impossible to frame an Act of Parliament to meet all exceptional and unusual cases, and one that would justly satisfy the various interests and parties involved. In the author's opinion reform was required in the direction hereafter pointed out. The interpretation of the term "street" should be made still more clear, and should include any road dedicated to the use of the public, whether built upon or not, even if it was not in the ordinary and popular sense a street. A road might be an important thoroughfare, largely used, and in a deplorable condition so far as the surface was concerned,—might be confined within walls or other fences, and fronted by agricultural land. There should be no doubt as to the powers for dealing with cases of this character. As to boundaries, in some instances roads had boundaries running down the centre, crossing them diagonally, or along the building line; possibly the adjoining authority might be a rural one. The present method of dealing with these cases was by mutual agreement. For the purposes of private improvements a street of this character should be placed under the exclusive management of one of the authorities, who should be able to deal with it precisely as if it was wholly within the district of that authority, and they should have the same rights against the frontagers for the recovery of expenses as if the whole street and premises fronting, adjoining, or abutting, were entirely within the district. These conditions obtained within the area governed by the Metropolitan Management Acts, and appeared to be a sensible provision, and the most satisfactory that could be made. As to notices, Mr. Spinks said he thought it would be generally admitted, and the cases that had been before the courts proved that the present method of service was altogether unsatisfactory and unreliable, however great pains might have been taken to be precise. The Manchester method of publication was by posting in the street and advertising in the newspapers, the posting being witnessed a given number of times, and a copy of the bill and advertisement being endorsed and filed for proof of publication if contested. This was considered sufficient notice to the owner, and the system might, with advantage, be made universal. There should be no option in the notice as to who should do the work. The system of allowing the owner to do it was bad, besides being impracticable. It was impossible to complete half a street. How could a man lay half a sewer, and what sort of a surface would there be if each half was laid at different times? The specification on the notice should be comprehensive and exact, and state the whole of the intended works required by the authority to be carried out, and they alone should carry out the work accordingly, and be responsible for its due and proper fulfilment. As to the character of the works required to be done, at this present time it was customary for an authority to adopt a hard and fast line throughout its district for the method of completing private streets, without any regard to the character of the property abutting on to different streets, or to the necessities of such streets. Such a system was manifestly unfair and absurd. Mr. Spinks cited an illustration of how this system worked in a suburb of Manchester, and exhibited a diagram showing (a) wide streets leading from one populous district to another: these were much traversed, and partially fronted by shops; (b) short cross streets, fronted by small houses, having no vehicular traffic but costermongers' carts, doctors' carriages, &c.; (c) *culs-de-sac*, fronted also by small houses; and (d) roads and avenues, fronted by detached and semi-detached villa residences. The whole of these roads were apparently, he said, completed exactly alike, the surfaces flagged and paved, whereas the surface of the main road was macadamised. The common-sense view to

take of cases like these, was, that each street should have been dealt with according to its necessities. The streets (a) being main arteries of traffic, and means of communication between one populous locality and another, and being fronted by important property, required strong foundations and durable surfaces, and the materials and workmanship should be of the best throughout. Streets (b) being streets which ran crosswise between main thoroughfares, and only having light traffic, or being fronted by cottage property, required lighter foundations and less excellent surfaces, but these, on sanitary grounds, should be impervious. Streets (c), courts, alleys, *culs-de-sac*, passages, &c., should be formed with impervious surfaces, such as flags or asphalts. Streets (d) were roads amongst better-class residential property, such as suburban roads and avenues in parks, &c. Having regard to the quality of the property, and the convenience and comfort of the inhabitants residing on this class of road, it might be desirable to complete these surfaces with macadam, asphalt, or gravel. Mr. Spinks said he was aware that the foregoing suggestions were surprisingly radical, and a complete reversal of present methods, and that some might see difficulties in administering such powers. His proposal was that each authority should declare that they would divide all incomplete or intended private streets into four such classes, and then to fix the standard of materials and finish required in each class. Of course there would be many objections to a body of citizens fixing for their fellow citizens such standards, inasmuch as committees were so subject to outside influences and pressure, as well as being guilty of sympathy with suffering property owners, and oftentimes the "outs" became the "ins," followed by a ruthless reversal of policy. To obviate all that, an impartial tribunal was suggested, such as an Inspector of the Local Government Board, who, after the declaration by the authority, should hold a public inquiry, and after viewing the character of the streets of the district, should take evidence as to the most suitable materials the locality afforded, and then fix the respective standard for each class of street, which should afterwards be adopted throughout the district. If after publication of notice to do the work the owner objected and considered the works excessive, an appeal to the magistrates, assisted by a professional assessor, would decide under which class the particular street in question would come. The great object should be for an authority to arrive at a satisfactory understanding with the owners before the works were commenced, and thus prevent disputes arising after completion which ought to have been cleared up at the outset. At the present time the owner was rather arbitrarily dealt with, having no remedy until Section 257 came into operation, and some such suggestions as the foregoing, if carried into effect, would afford him all the protection which was rightly his due, and by proceeding in the manner described there would be no difficulty in doing that equitably between the parties, as both the proposed courts would be open and impartial, and their decisions would only be arrived at after bearing and weighing the evidence of both parties. If it were left to the owner to have the right of appealing against the proposed works on the grounds of their being unreasonable, then appeals would be incessant, because there were so many owners who considered the interest of their own pockets as paramount, and not the comfort and health of the inhabitants occupying their houses; and to that class of men a cartload of gravel or ashes spread on a street made it a reasonable surface, and any expenditure beyond that he looked upon as downright extravagance. It should be remembered that, in large towns especially, the street was after all the playground of the children, amongst whom, unfortunately, in our manufacturing districts the death rate was so abnormally high. A child with its nostrils so close to the surface breathed and inhaled mephitic odours arising therefrom, which at the height of an adult person became dissipated in the air; so that on sanitary grounds it was imperative that the surfaces of this class of streets should not be precipitating tanks nor filter beds, but should be clean, dry, and impervious. It might be urged that to classify the quality of the surfaces of streets would inflict undue hardships on property, and would be inequitable in its

* See last week's *Builder*, pp. 355-356.

incidence; but on the other hand it should not be forgotten that when a man took land for building purposes on a main thoroughfare he generally did so with an eye on the "main chances," knowing very well that the traffic and the business it brought all tended to enhance the value of the property when erected; consequently it was better able to bear the increased burden of superior road-making. After dealing with the questions of estimate and preliminary apportionment, partial works, and the method of executing works, Mr. Spinks proceeded to speak of the sewers. He said it would be much simpler and more satisfactory if the cost of all sewers were charged direct to the district rates. The clean water that came into the town did so in pipes, the cost of which was charged to a common fund, but immediately the water was fouled and became sewage, the owner of the property had to provide means of carrying it away so far as was coextensive with his premises. The reasons for that anomaly had never been made clear. If the authority alone was responsible for the construction of sewers, surveyors would not feel hampered in designing them for private streets, nor would the question as to how far the sizes were reasonable ever be raised. If it should be found impossible to revise the existing system, powers should be given to an authority to contribute, if necessary, towards the cost of sewers in certain cases; for example, if for the purposes of a sewerage scheme it was desirable to construct an intercepting or trunk sewer in a private street, then the excess cost of such a sewer over one sufficient for the requirements of the street itself should be borne by the authority. The author had had a case of that sort in a road running along the boundary of one portion of his district, and that course was followed. It should also be made plain to the surveyor that he must only design sewers sufficient for the necessities of the street he was dealing with. The author knew several cases where sewers had been made as large as 3 ft. by 2 ft., when by no possibility could more sewage enter than would be discharged by a 9-in. pipe, and the defence for that had been that it was customary in the district to build sewers large enough for a man to traverse. Such reasoning was ridiculous, and the costs incurred through such ignorance should be thrown upon the right shoulders. The size of the sewer did not, so long as it was adequate for the duty it had to perform, in any way enhance the value of the property, and to expend money in sewers excessive in size and beyond actual requirements was wasteful, and an imposition upon property owners. After speaking of the method of dealing with old sewers, Mr. Spinks concluded by some remarks on levels, repairs, measurement of frontages, paving apportionments, and other subjects, for which we have not space.

In the afternoon the members visited the very successful sewage farm, 1,000 acres in extent, belonging to Nottingham, and situate at Stoke Bardolph. We are obliged to reserve a description of this farm for a future number.

In the evening the members dined together at the "George" Hotel, and some good speeches bearing on professional topics were made. Mr. Hodson in particular referring in terms of condemnation to the growing practice of public bodies declining to grant superannuation allowances to old officials even after many years of meritorious service at very inadequate salaries.

On the second day of the meeting (Saturday, April 30) the members assembled at nine o'clock in the Shire Hall (Mr. De Courcy Meade, President, in the chair) for the purpose of discussing the two papers read on the previous day. General approval was expressed at the character of the municipal engineering works at Nottingham, as described by Mr. Brown, and especially of the new subways, and it was agreed that the Corporation took a very enlightened and liberal view as to such matters. Mr. Spinks's paper was strongly criticised, and his proposals, both as to road formation and sewer construction, were condemned as impracticable. Admitting that there were difficulties to be encountered, it was the general opinion that things were much better as they are than they would be if Mr. Spinks's proposals became law.

Lord Belper, Chairman of the Nottingham County Council, having taken the chair, Mr. James Robinson, County Surveyor of Hampshire, read a paper on "County Manage-

ment of Main Roads." This chiefly dealt with matters of administration and finance. The writer was of opinion that inasmuch as the county authority had to provide the funds for the maintenance of the roads, they should have the first voice in the expenditure of those funds, and that could only be secured by the repeal of sub-section 2 of section 11. The roads could then be maintained either direct by the county authority (sub-section 1), or by agreement under sub-section 4. In the former event, power, if thought fit, could be given to the urban authority to appeal to the Local Government Board if they considered the roads were not being kept in a satisfactory condition.

In the course of a long and interesting discussion, in which Lord Belper, Mr. Hooley (County Surveyor of Nottingham), Mr. Davis (County Surveyor of Shropshire), and several other speakers took part, it seemed to be pretty generally agreed that many of the difficulties and disputes which now arise between county authorities and local authorities could be prevented by a friendly interchange of views between the respective surveyors, coupled with a desire on the part of the authorities to be reasonable in their requirements. Votes of thanks to the readers of the papers were heartily agreed to.

The proceedings of a very successful meeting were concluded in the afternoon by an excursion. Taking train to Mansfield, the visitors had a pleasant drive of ten or twelve miles to Welbeck Abbey, the seat of the Duke of Portland, by whose permission the conservatories and gardens, the picture gallery, the riding school, the stables, and certain of the subterranean passages and roadways for which the place is famous, were shown to the visitors. We may mention that a long description of these remarkable works was published in the *Builder* for September 22, 1888, under the title of "Welbeck Abbey and its Tunnels."

THE LONDON COUNTY COUNCIL.

The usual weekly meeting of this Council was held on Tuesday last, the Chairman, Lord Rosebery, presiding.

Tenders were opened for certain building works at the Cane Hill Asylum. We publish the particulars elsewhere. There were only three tenders sent in.

The Chairmanship.—Lord Rosebery reminded the Council that his occupancy of the chair was only of a temporary character, pending the framing of a scheme of organisation, and also with a view of enabling the Council to get into its work. Both of these objects had now been attained. As regarded the scheme of organisation, that had been agreed to by the Committee on the previous day, with a minority of only two against it. And, as regarded the Council getting into its work, it was clear from what occurred last week, when they got rid of all the reports in an hour and five minutes, that it did not need any further assistance in the conduct of its business. He hoped that now that things were so far settled the Council would consider as soon as possible the question of appointing his successor.

Electric and Cable Railway Schemes.—The Parliamentary Committee submitted a long report in reference to the electric and cable schemes which are now under the consideration of a Joint Committee of Lords and Commons. They recommended that certain propositions should be submitted to the Joint Committee indicating the attitude of the Council. These propositions were:—

1. That the size of the tunnels of the lines should be sufficient to allow in the future of an interchange of traffic with existing railway lines.

2. That underground lines should not follow the line of existing streets, but should go from point to point, the depth below the surface being such as to avoid injury or inconvenience to buildings in the line of the railways.

3. That the companies should only be allowed to acquire the right of forming the tunnels, without acquiring any absolute freehold in the soil, paying compensation for actual damage only.

The Committee held that the formation of more than one line between the north and south of London should not be encouraged, and they recommended the insertion of a clause giving the Council compulsory powers of purchase of the undertakings, sixty years,—in place of twenty-one years, as in the case of the tramways,—being allowed, to enable those who find the capital in the first instance time to obtain remuneration for their outlay.

Mr. Saunders moved as an amendment:—
"That the suggestion that only one such line should be constructed between north and south London be omitted, and that evidence be placed before the Joint Committee showing the importance of continuing into the country electric and cable lines which may pass under London, in order to relieve the congestion of population and encourage building in the suburbs, and that, subject to the above, the course recommended by the Committee be approved."

The amendment was seconded by Mr. Beachcroft, and after some discussion was agreed to, and the report of the Committee amended was adopted.

Brooke's Market, Holborn.—The Public Health and Housing Committee reported as follows as to this insanitary area:—

"The Council on October 13 last, in the resolution which committed it to the preparation of a scheme for the improvement of the area in Brooke's-market, expressed the opinion that the Holborn District Board should contribute at least one-half of the total cost of the improvement, and the District Board were duly informed thereof. A communication has now been received from the Board to the effect that they are willing to contribute one-half of the cost of the scheme provided such half does not exceed 3,000*l.*, and that the Council undertake to advance that amount to the Board on loan, the repayment being spread over a period of thirty years. The estimated net cost of the scheme is 5,950*l.* We are advised by the solicitor that the District Board cannot contribute towards the cost of the scheme without an order of the Home Secretary, and that it will be therefore necessary to apply to the Home Secretary for an order directing the amount to be contributed by the Board. We consider that the offer of the Board is a reasonable one, and, apart from the question of a loan to the Board of the amount contributed, which will doubtless come before the Finance Committee in the usual way, we recommend—

1. That the Council do, subject to an order from the Home Secretary, the offer of the Holborn District Board to contribute one-half of the net cost of the London (Brooke's-market, Holborn) Improvement Scheme, 1891, such half not to exceed 3,000*l.* in all.
2. That the solicitor be instructed to apply to the Home Secretary for an order directing the amount of the contribution by the District Board in accordance with section 46 (5) of the Housing of the Working Classes Act, 1890, having regard to the offer above mentioned.

The recommendations were agreed to.

Structural Alterations in Theatres and Music-halls.—The Theatres and Music-halls Committee reported as follows:—

"Under section 11 of the Metropolitan Management and Building Acts Amendment Act, 1878, the late Board was empowered in some cases to require proprietors of theatres and certain music-halls in regard to structural defects. Such power has since been transferred to the Council. When alteration was found necessary at any premises, it was the custom of the late Board, and the practice has been continued by the Council, before serving the sealed notice authorised by this section of the Act, to order a draft notice to be forwarded to the owner of the premises, containing a list of the alterations considered necessary, accompanied by a letter informing him that the Committee to whom the matter was referred would be willing to consider any objections to such notice, which he might transmit by a certain date, and that in the event of his forwarding such objections the Committee would be prepared to hear him thereon.

We have now to report that complaints have been made from time to time by persons connected with places of public entertainment coming within the scope of this section, that, in the event of alterations being considered necessary at their premises, the first intimation they usually receive required was through the medium of the press, which they considered extremely unsatisfactory. We have therefore taken the matter under consideration, and we recommend—

"That in future, in lieu of the service of a draft notice, the Clerk do forward a statement of the suggested alterations required at any premises to the owner of those premises, and do request him to send his observations thereon, and that the matter be reported to the Council until the service of the sealed notice is recommended by the Committee."

The recommendation was agreed to.

Quantity Surveyors and their Remuneration.—On the motion for the reception of the Asylums Committee's report, Mr. Robt. asked whether the quantities for the additional buildings at the Claybury Asylum had been taken out by one of the quantity surveyors appointed by the Council, and, if not, whether the quantity surveyor employed was to be paid at the rate which the Council's surveyors would.

Mr. M'Donagall, in the absence of the Chairman of the Committee, replied that the Claybury Asylum was commenced before the Cl

tion of the London County Council, and for the additional buildings it had been thought desirable to employ the same architect and the same quantity surveyor as were originally employed. He could not say what was the remuneration of the quantity surveyor.

The "Fair Wages and Hours" Clause in Contracts.—The notices of motion standing on the agenda in reference to this question were not reached until nearly seven o'clock, and their discussion was again adjourned until next week.

LIVERPOOL ENGINEERING SOCIETY.

The annual general meeting of this Society was held on the 4th inst., at the Royal Institution, Mr. John T. Wood, President, in the chair. The meeting was numerously attended.

The election of the Council and officers for the ensuing session, commencing in October next, was the first business. Mr. Robert E. Johnston, M.Inst.C.E., was elected President, and Messrs. H. P. Boulnois, M.Inst.C.E., and Prof. H. S. Hele Shaw, M.Inst.C.E., were elected Vice-Presidents.

The adjourned discussion upon the paper read at the last meeting by the City Engineer of Liverpool, Mr. H. P. Boulnois, M.Inst.C.E., entitled "Refuse Destructor," was then opened by Mr. John Price, who stated that he had seen most of the refuse destructors in the country at work, and was very much in favour of their use. He agreed with Mr. Boulnois in considering that refuse destructors were in almost all cases the best and only means of getting rid of house refuse successfully.

Mr. George Farren stated that he had examined the Liverpool Corporation's destructor, and was very much impressed with it.

Mr. McGinnis criticised very freely the present method of dealing with ashpit refuse, which he stated, is in most places very much behind the times.—Mr. E. R. Window dealt principally with an improved method for the collection of ashpit refuse.

Dr. Tatham, of Manchester, dealt with the subject as to how far destructors give rise to a nuisance to the surrounding district.

Various other speakers followed, and Mr. Boulnois replied to the various points raised in the discussion.

A vote of thanks was accorded by acclamation to Mr. Boulnois for his valuable paper.

ARCHITECTURAL SOCIETIES.

EDINBURGH ARCHITECTURAL ASSOCIATION.—On the 7th inst. the members of this Association, under the leadership of Mr. Thomas Ross, architect, visited the old castles of Pitteadie and Seafield, both situated in the parish of Kinghorn. Pitteadie, says the *Scotsman*, is a ruin in a state of tolerable preservation, although totally neglected. The castle is approached through a quaint round-arched gateway containing the carved arms and initials of William Calderwood, of Pitteadie, with the date 1686. The castle itself is considerably older than the gateway or than the name of William Calderwood, and existed in 1600. The castle appears to have been somewhat modernised about the time that Calderwood built the gateway. Previously the entrance-door appears to have been on the first or level, which was reached probably by a ladder from the outside, but this arrangement was changed, and a door was constructed on the ground floor and other improvements effected. The members walked from Pitteadie to Seafield Castle, a lofty ruined tower standing on the sea-shore between Kirkcaldy and Kinghorn, passing on the way through the farm-land of Grange, once the residence of Kirkcaldy of Grange. Of the house of Grange nothing appears to be left, and the only memorial remaining to show that the place was the residence of some one of at least the rank of a laird is the dovecot. Seafield stands on the bare sea-shore; the tower, exposed to the blasts which sweep the Forth, is not so well preserved as its neighbour at Pitteadie; it still remains in a sufficient state to give a good idea of the kind of accommodation to be had in such structures, where defence was of more consequence than comfort. Seafield was built by a family of the name of Moultray. The site of its building is not known, nor when they acquired the lands; but they were there in 1693, and must have been in possession before that time.

GLASGOW ARCHITECTURAL ASSOCIATION.—The weekly meeting of this Association was held in the rooms, 114, West Campbell-street, Glasgow, on the 3rd inst., the President, Mr. Alexander McGibbon, in the chair. A paper was read by Mr. Arthur J. Fryers on "Half-timber Work" illustrated by photographs and plates of old work. Mr. Fryers reviewed the subject briefly from an historical standpoint, and passed on to describe more fully the cottages of Surrey. He then went over the various points to be noticed in the detail of this class of work, such as the framing and filling-in, the roofs and harge-boards, the doors and windows, and the chimneys with their angle-nooks. He concluded by considering its adaptability to present-day requirements, and strongly advocated its use in Scotland, it being quite capable of standing the climate, and also as giving a very picturesque effect. Mr. Robert Hamilton opened the discussion which followed, after which a vote of thanks was awarded the essayist.

LIVERPOOL ARCHITECTURAL SOCIETY.—At the closing meeting of the session of the Liverpool Architectural Society, Mr. T. H. Harrison, the President, delivered an address upon "The Sciences as related to Art."

THE SANITARY INSPECTORS' ASSOCIATION.

The paper read at the meeting of this Association held on the 7th inst. at Carpenters' Hall, London Wall, Mr. Hugh Alexander presiding, was "The Story of a Rain Drop," by Mr. Poulson, Sanitary Inspector, Chelmsa. Prefacing his story by quoting the dictum of the reader of a former paper to the effect that "If the knowledge now possessed by sanitary experts could be made to thoroughly permeate the masses of the people, and if the sanitary laws were enforced, the physical, moral, and spiritual condition of the people of this country might undergo a complete transformation," the lecturer, in metaphorical language, showed the important functions performed in Nature's economy by a drop of rain. Chemistry, and particularly the discovery, by synthesis, a century ago, of the composition of water, by Sir H. Cavendish, had taught us that water was not an element, as believed for thousands of years, but a combination of two gases, hydrogen and oxygen, coming together in the proportion of 16 parts of the latter to 2 of the former, in 18 parts. The formation of vapours, born of the sun and the sea, and their behaviour under the influence of currents of air from the Arctic or the Torrid regions; proximity or distance from mountains, trees, or grass; and the different forms of hail, ice, hoar-frost, fog (white in the country, but a rich yellow in the metropolis) were interestingly traced. The practical effect of the power possessed by water of absorbing oxygen and carbon, and of being absorbed in varying proportions by alluvial soil, chalk, and sandstone, produced very beautiful effects in stalactite caverns, but deleterious effects on human health. In Derbyshire, the enlargement of the thyroid gland of the throat (the disease known as "Derbyshire neck") was an outcome of these varying relations upon each other of the soil and the rain. By its cohesive predilections, its fluidity, and its weight, rain formed the rivers, lakes, streams, and springs which were the sources of our water-supply. Before it reached the consumer river-water required to be filtered, and carried by mains and service-pipes into our houses and our cisterns; and in every varying situation it had to be studied and analysed to find out how it had been affected by or had affected the channels through which it had passed. Dr. Moncon Copeman had discovered that pure Spanish lead, from which all the silver originally alloyed with it had been eliminated, when employed for pipes, readily combined with the chemical elements of the water, and greatly prejudiced health in certain districts by lead poisoning. The course of the rain-drop was traced until it reached the tanks and reservoirs of one of the London water companies at West Molesey. The various processes and the apparatus of filtration were described, beds of sand, shells, and gravel, in all 8 ft. thick, being insufficient, in many cases, to remove the lime taken up from the rocks, as proved by the furry incrustations we found in the interior of our cisterns. The enormous importance of the knowledge of such facts would be gathered by considering certain astounding totals with regard to our water-supply which had been given in a recent report by General Scott, one of the examiners. London took from the Thames daily, 89,272,000 gallons; from the Lea 55,796,185; from springs and wells, 26,068,624; and a small supply (752 gallons) from Hitchgate pond, making a daily total of 171,727,721 gallons for 5,692,879 persons, or 30.06 gallons per head. The length of main-pipes required for this colossal distribution is 4,678 miles, more than half through the world. The engines required for pumping this water numbered 184 with a total force of 21,659 horse-power. For drinking

purposes alone, 104 filtering-beds, with an area of 1,021 acres of storage, are required for 215,702,000 gallons of filtered water, the unfiltered stock in store amounting to 1,800 millions of gallons more. The sources of supply and the characteristic qualities of water in different districts were described, and a curious fact was noted, to which the observations of the official examiners, Drs. Crookes Oaking, and late C. Heymott Tidy testified that in December, 1890, Thames water was found to have a peculiar faint taste, due to fog.

A brief discussion arose on the proposal of a vote of thanks to Mr. Poulson, which was accorded by acclamation.

The meeting subsequently considered a circular which had been sent round to members, notifying the arrangements proposed for the visit to Paris by the Association at Whitstable. It is proposed to leave London at 9 a.m. on Thursday, June 2, by the Nowhaven and Dieppe route, but some of the members desired to spend the 2nd prox. in London, and to cross the Channel by the night service. An influential committee of the Society of Hygiène of France has been formed, which includes MM. Cacheux, Péret, and Jotrain, of the Paris Municipal Council, and Drs. E. Moin, J. de Dietra Sante, and other gentlemen; and the Committee of the Sanitary Inspectors Association co-operating will include Mr. H. Alexander (Chairman of Council), and Messrs. Raymond, Tidman, Edwards, and Watson. In addition to the conference, the programme includes a banquet given to the Englishmen by the French society, and visits to the sewers of Paris, the irrigation fields at Genevilliers, workmen's dwellings at Passy, night lodging-houses, the Aulre disinfesting station, Montcais reservoirs, crematorium of Père la Chaise, cellular prison of La Santé, the Catacombs, and the Biffel Tower.

THE ARCHITECTURAL ASSOCIATION SOIRÉE.

THAT always well-attended annual gathering, the Members' Soirée of the Architectural Association, was held in the Westminster Town-hall on Friday, the 6th inst., when, under the auspices of the A. A. Lyric Club, there was produced what was described on one page of the programme as a "burlesque," and, on the succeeding page, as "a very pleasant Tragedy," entitled "The Princess's Idea," written by Mr. Theo. Moore ("after Tennyson and Gilbert"). The *DRAMATIS PERSONE* were:—*Prince Hilarión*, Mr. A. Brunwell Thomas; *Florían*, Mr. Ernest Rintz; *Cyril*, Mr. T. Honoré; *Gama*, Mr. J. P. Sutton; *Hildebrand*, Mr. A. C. Balmer; *Booth*, Mr. J. Douglas Scott; *Foreman*, Mr. C. H. Brodie; *Princess Ida*, Mr. H. Seton Morris; *Lady Blanche*, Mr. Theo. Moore; and *Lady Psyche*, Mr. Percy D. Smith. Scene i. of Act I. was supposed to represent the Association's Studio in Great Marlborough-street. Cyril, Florían, and Hilarión (students or assistants) are discussing with some freedom the hardships inflicted upon them by "the principals," and express their determination to

"— strike for better times all round :
Mors cash and shorter hours,—more things found."

In the course of further discussion, however, Hilarión and Florían disagree, one taking his stand on "art" and the "art-cult," the other on "good old common-sense." They draw swords, and are engaged in mortal combat when the "principals" (Hildebrand, an architect, and Gama, a surveyor) enter. The fight with swords ceases, but a worthy conflict ensues between the assistants and their masters, and the vulgarity of Gama, the surveyor, leads Florían to refer to him contemptuously as

"A man who dabbles in the sordid mixtures
Of ancient lights and party-walls and fixtures."

The scene ends with the strike of the assistants, and the resolve of Hildebrand and Gama to engage lady assistants. Scene ii. opens before "Castle Adamant" (a Ladies' College of Architecture), presenting in its *façade* a grotesque specimen of "eclecticism" in design, combined with a *reductio ad absurdum* of "sanitary plumbing." Before this *façade*, two of the "sweet girl graduates," Melissa and Psyche, are in the act of losing-up as to which of the two shall "black-in" a lot of competition sections, when the Principal of the College, Lady Blanche, enters, and sentences them to write "a schedule of disappiations." After a dance by one of them, there enters the Princess Ida, described on the programme as "a latter-day Jenny Wren" who sings a song in which she expresses the hope in her own heart, and her fellow lady students of architecture to "have nothing to do with drains, nor anything practical." At this point Hildebrand and Gama arrive, seeking an interview with the Lady Blanche for the purpose of engaging lady assistants. They withdraw for private converse, and Hilarión, Florían, and Melissa enter, Hilarión singing a song to Ida, with whom he is in love, though she disdains his suit, preferring to devote her life to architecture. Florían speaks of himself as "a lover of art" with "a thousand a year," and is denounced by Melissa as one of those who, having "his own pocket lined, drivels in the *Times* about surveying work being *infra dig.*," and wants to stop everybody else from getting a

living." (This denunciation, it should be stated, was warmly applauded by the audience.) Scene ii. concludes soon after the announcement that "the ladies are called out and embodied into a great force of architects." Scene i. of Act II. represents "works" in progress under the superintendence of Ida, and in charge of a foreman (Mr. C. H. Brodie), who in the intervals between 12 and 3 on a Saturday afternoon has been drinking "not wisely but too well" pending the arrival of the members of the A.A. on a "Spring Visit." The experiment of lady assistants not proving satisfactory, the male assistants on strike, and their masters, talk matters over, with the result that the strike comes to an end, and Scene ii. opens with a combined attack of principals and assistants on Castle Adamant, resulting, as the "bill of the play" puts it, in the "defeat of the ladies by the men, and the capture of the men by the ladies," and all ends well, after a song in which each of the leading characters sings a verse, the lines falling to Florian proclaiming him to be

"—An Art-ycrafty man,
Break-up-the-A.A. young man,
A sign-a-memorial, high-dictatorial
Certain I'm-right young man."

Hildebrand, on the other hand, declares that he is

"An Iconoclastic, City-bombastic
Pull-down-Wren's-churches old man."

There were many other songs and a few dances, and some striking bits were made concerning some of the professional topics of the hour. All the actors acquitted themselves very well, and at the close, they and the author were called before the curtain. The incidental music was played by the A.A. String Band. Mr. F. T. W. Miller acted as stage manager, and the scenery was painted by Mr. Percy D. Smith.

Correspondence.

To the Editor of THE BUILDER.

ARCHITECTURAL ASSOCIATION.

SIR,—I must ask you to be good enough to let me trespass once more upon your valuable space, which, when I last wrote, I had no intention of doing; but the letters from Mr. Leonard Stokes, and the one from Mr. Jackson, addressed to the latter, in which he explains himself, demand some remarks from me.

Mr. Jackson says, "Nothing was further from my thoughts than to suggest you should make a clean sweep of your whole scheme, and draw up a new one from the very beginning." If in this or in any other respect I have misinterpreted Mr. Jackson's meaning, I offer my apologies. To anyone who cares to study the correspondence which has passed, the opportunity is open, but, in the light of what I have learnt since Mr. Jackson's letter first appeared in *A.A. Notes*, I see nothing (with the above exception) of importance that I care to revise or omit. What I wrote was written with careful consideration, and I contend it has been a fair commentary on the matter before us.

Mr. Jackson's letter was perfectly frank; he stated that he wrote it, and had attended two meetings at the request of some of our members, who took his view. When I asked in your columns who those members were, and on whose authority they acted, a letter appeared, signed by eight gentlemen, members of the A.A., and also of the Institute, stating that they met Mr. Jackson but *once*, and that the letter was not written at their request. As to their authority to enter into negotiations with the memorialists, they candidly admitted they had none, and that they only represented their own particular views. Puzzled at the discrepancy between Mr. Jackson's assertions and the answer of these gentlemen, I again pressed for particulars. Then Mr. Stokes replied, "The two meetings referred to by Mr. Jackson in his letter to *A.A. Notes* had nothing whatever to do with one another."

"The first was held at my office, as already stated. The second was held at Barnard's-inn, when about fifty architects, all members of the *Art Workers' Guild*, were present. It was this meeting that asked Mr. Jackson to inform the A.A. as to what was being done, and not the first." The italics are those of Mr. Stokes.

A natural inference from the foregoing surely is—then no members of the A.A. were present: the natural comment, "What business was it of the members of the Art Workers' Guild to interfere in our concerns?" So, to clear up the matter, I wrote and asked Mr. Stokes whether he and any other members of the A.A. were at this last meeting. He tells me that he, Mr.

Simpson, and, perhaps, one or more were there. This information should have been given at once; it would only have been fair to Mr. Jackson, and due to the Association to have done so.

That I was not alone in the view I took of Mr. Jackson's letter is apparent, *vide* statement by the Committee, letter from the President-elect, and a letter from one of the eight members who met Mr. Jackson and his friends, and letters of approval from many quarters. Then Professor Kerr, I believe the senior of all the Past Presidents living, who has always taken a keen interest in the A.A., said at the Institute last Monday; "Indeed, they (the memorialists) are now attacking the Architectural Association, and seem almost likely to split it up,—a result which I am sure everybody here would deprecate." And even Mr. Stokes, writing on behalf of himself and the others, says of Mr. Jackson, "he puts his views into words so very different to those he used to us that, without some satisfactory explanation,—which I hope will be forthcoming,—it would obviously be quite impossible for the Association to accept his offer as it may at first sight appear to be laid down in *A.A. Notes*."

That there could be any objection to any members of the A.A. meeting Mr. Jackson and his friends with a view to seeing how the A.A. might be strengthened and its scheme of studies improved, I, for one, should never have raised. But when we learnt from Mr. Jackson his account of what the outcome of these particular meetings was intended to be, I confess to very great surprise. That Mr. Stokes, who must have known equally with Mr. Jackson what took place, should, after perusing the letter, have suffered it to appear in *A.A. Notes*, without the slightest comment or contradiction whatever, is to me astonishing; thereby, I maintain, he implied an assent. It now becomes the duty of every loyal member of the A.A. to support the Committee, and to see that the candidates standing for election on the House list, receive an unmistakable mandate to maintain its independence, continue the old policy of the A.A., and not receive help from any quarter whatsoever, the conditions of which it would be a dishonour to accept. When it is remembered that the A.A. asked the Institute to help forward their scheme; accepted their aid, also the liberal contributions made by members of the Institute; how, with any consistency, can they at the hiding of the memorialists reverse their policy and at the same time maintain self-respect?

COLE A. ADAMS.

SIR GILBERT SCOTT'S RESTORATIONS.

SIR,—I have already occupied so much of your space that I must apologise for adding another word to the controversy "on Sir Gilbert Scott's Restorations."

Although Mr. Somers Clarke has exhibited the weakness of his cause in taking refuge in epithets and personal opinions, he has done a service in giving the watchword of his party in the word "repair." A most excellent word, and if every one understood it in the same sense, and applied it in the same manner, there would be no further need of controversy.

The question still remains, What does Mr. Clarke mean by the term "repair"?

I send a drawing of the tower of Chester Cathedral before it was restored, and I should like Mr. Clarke to send you another for publication, showing how he would have repaired it, bearing in mind that the outside casing was rotten, and the inside of the wall liable to fall to pieces without proper support from the outside facing, as in the case of St. John's Church, and also that the whole of the original design and detail of the tower, up to the top of the cornice, could be ascertained from the remaining perfect stones.

With regard to the restoration of the apse of the south aisle, I hope an opportunity may soon arise of your readers seeing Sir Gilbert Scott's report. I quite admit that this is a work upon which differences of opinion may well exist, but I should prefer to hear opposing opinions expressed in argument founded on a knowledge of facts rather than in epithets.

Lord Grimthorpe's letter is very satisfactory, as he owns to having prevented Sir Gilbert Scott getting information which he required; this is a second case, as the one to which I referred he appears to have forgotten. I spoke only of what occurred before Sir Gilbert's death, as after he died I fell ill, and knew little of what happened. If Lord Grimthorpe had allowed Sir Gilbert Scott to spend 100l. in investigating, I should have been aware of it, as the investigations would have been made by myself.

ARTHUR BAKER, F.R.I.B.A.

MR. BAKER ON ST. ALBANS.

SIR,—Mr. Baker's last letter, saying that I "pulled down Norman work at St. Albans which was so strong that it required blasting, in order to carry out my own designs," is as false in every possible way as his previous one which I exposed last week; and as another, nearly two years ago, in another architectural paper, intimating that I somehow made away with the small relics which I had got the Committee to allow 100l. to search for, and which fell into dust soon after they were exposed to view, as Chapple told me.

After these specimens of his veracity, any one must have a singular taste and judgment who believes a word he writes. And any one who wants to know what was really done in pulling down ruinous and unsafe Norman work, of which a great deal came down as more dust, in baskets, and rebuilding it in the same style* may read it in my Guide-book of "The Cathedral and its Restoration," which has been current here ever since, and a very curious specimen of uncharitableness and self-justification it is, to be sold as a guide-book to a church dedicated to a faith of which clarity and humility are supposed to be cardinal virtues. Of its "veracity," we will give one typical example. It contains the statement, which Lord Grimthorpe had previously made in the *Times*, that this journal had characterised his west front at St. Albans as "not fit for a Methodist chapel," the words being in both cases put in quotation commas as our *typissima verba*, and he repeated the "quotation" again in an article in *Murray's Magazine*. The real words printed in the *Builder* were as follow:—

"The general look of the whole front may perhaps be best indicated by saying that it is very much the sort of Gothic which one sometimes meets with in competition designs for the larger class of Dissenting chapels,—effective in a showy way, but totally devoid of refinement."

This, it will be admitted, was a reasonable and moderate way of putting it; and in order to misrepresent the journal which criticised his architecture, Lord Grimthorpe put in print an absolute falsehood, which he has twice repeated in print since. After this we may say, in his own words (*supra*), that "any one must have a singular taste and judgment who believes a word he writes," or credits him with any claim to pose as the apostle of "veracity."—ED.

BOSTON CHURCH.

SIR,—A paragraph in a local newspaper stated that the west door of Boston Church is being restored. A few days ago I paid a short visit to this fine old building, which, to my dismay I discovered to be rebuilding, instead of a restoration. In vain I looked for some few fragments of the original work of which there were plenty in existence only six months ago, but not one was to be found, base shafts, cap, jamb, arch, and crockets ruthlessly swept away, not a particle left behind of the original work. Such is the so-called restoration of a most magnificent doorway.

AN OCCASIONAL VISITOR.

GRISSELL MEDAL COMPETITION.

SIR,—Your correspondent, Mr. Humphreys, has not fully considered the conditions of the competition, or my design for the same.

The conditions stated that the banks were to be "of sandstone rock." To quote an authority on the subject, "Rock is the best foundation, if homogeneous, but if cracks are found it cannot be relied upon, and is inferior to other materials." In the absence of reliable information, the experienced engineer adopts the least advantageous view.

The "criminally wasteful and unnecessary" abatements were spread out at the base, by means of battering walls, in order to lessen the pressure of foot super, on the foundations, and at the same time add a minimum of weight. This seems to have been overlooked by your correspondent. He finds to their being "unbeautiful," Mr. Humphreys find it a profitable task to put them into perspective and then reconsider his opinion.

With regard to the other criticisms, the rear for dimensions of keystones, voussours, abutment, &c., are clearly shown on my third sheet of stru-

*—L. Ed.
† *Builder*, August 11, 1883; page 172.

and details, which was not published by you," and I fancy not seen by Mr. Humphreys.

With reference to the conditions, my only complaint is that the time allowed was too short. This has been remedied this year, and I trust will be in the future, as I am sure better designs will be the result; after having worked out my strains, &c., I found far too little time remained for the designing of "eyeable lines and architectural effects."

HAROLD HARLOCK.

The Student's Column.

WARMING BUILDINGS BY HOT WATER. XX.

BRICK-SET BOILERS (continued).

THE description (and fixing) of the plain saddle-boiler was completed in the last paper, and the next, and nearest design is as fig. 80. This is practically a saddle-boiler

FIG. 80.

with flue-way carried through the top of it from front to back, as shown. The particular advantage of this top flue is that the flame and heat are thus brought beneath a heating-surface,—a horizontal surface that comes over the source of heat being of so much greater value than one that bounds it on the side, or one that comes beneath. To illustrate the method of fixing this boiler, some makers' lists show it in section, with the flame first passing through this flue from back to front and then passing over the top of the boiler to the chimney. So far as conducting the flames into this top flue at the back immediately they leave the fire, no objection can be raised, it being the best plan; but when the same issues from this flue in front, it would be much better to carry it down and along each end, so as to benefit by the vertical surfaces. Some of the more powerful boilers have iron midfeathers provided expressly to do this, and it is undoubtedly the best way. In any case, the flame should go through the top flue first. This style of boiler is made with two top flues, though it, one above the other, but it is not, in the best of the writer's belief, in great demand.

It should be explained that the few representative boilers now being referred to, are not the only patterns worth recommending by any means. They are merely a representative few that have seen good service, and therefore can be safely referred to.

The next and nearest approach to the last boiler is Fig. 81, a very powerful and efficient

FIG. 81.

boiler. It is practically a saddle, with water-way ends front and rear, and a flue-way through the top. In fixing this it is arranged for the flame to first enter the top flue at the back, and it leaves the front to be conducted down and along the sides under the midfeathers provided, and as the arrows indicate. This, as already explained, has to have a top feeder, as the waterway front does not admit of feeding from its point. A boiler of this shape will, in the larger sizes, heat up to 4,000 ft. of 4 in. pipe, and it can be well adapted for shallow drainage, where the boiler pit cannot well be made deep owing to water being found in the earth.

The figuring and other details would not have been possible when the drawing was reduced to the size of our page.—Ed.

too near the surface). The top surface of this boiler is not usually made use of; the brickwork rests upon it and the feeder nozzle projects through above. A soot-door would have to be provided opposite the top flue, for the easy removal of the dust or soot which will readily accumulate in it.

A good boiler, somewhat like the last in general character, is as fig. 82. This, like the

FIG. 82.

last, is not confined to one maker. It is so all intents a saddle-boiler with water-way ends, but the flue-way through the top is made in two distinct passages, as will be seen at fig. 83,

FIG. 83.

which is the elevation, in section, just through the feeding-nozzle. It will be noticed in this boiler that the top flues do not extend quite to the front, but have their sides cut away back some inches. This permits of the boiler front being huddled tight up against the front brickwork, and no intervening brickwork to give direction to the flame is needed. In this boiler, as with the last, the flame, as it leaves the top flues in front, is taken down beneath the midfeathers shown, so that it may operate on the vertical sides. The top is not used except to support brickwork; this being all that it is good for, as before-mentioned. Two top soot doors would be needed (in front) in this case.

FIG. 84.

Fig. 84 represents a still more powerful boiler, owing to its having an additional pair of flues through it, but this, let it be noted, necessitates a tolerably efficient chimney, which can only be gained by having it a sufficient height. (Chimneys will be treated separately.) With this boiler, the flames, as they leave the boiler, enter the two lower side-flues by an entrance provided in the fire-box. From these, as they make their exit in front, they are conducted into the top flues. After passing along these and out at the back, they are brought along and beneath the feathers, and pass from there to the chimney. It is a shallow boiler suited for shallow drainage, but having a high power, if the chimney is suited. This must enter our list of horizontal boilers, although there are very many more almost, if not quite, equally deserving of mention. It is strange how certain pattern boilers will be in favour in certain districts, but not elsewhere; and again a certain pattern may have a great demand for a certain period, then cease almost entirely; it may revive again or it may not. Every boiler-

maker can give peculiar experiences in this way.

The next form of boiler to be noticed is of an upright character, quite different to those already mentioned, as fig. 85. This is a very efficient form of boiler, and is particularly well adapted for those building works that extend up several floors, and which have an enormous pressure exerted in the boiler, that is, of course, at the lowest point. A cylindrical shape is best adapted to withstand a pressure. This pattern well fulfils what is so desirable in a boiler, viz., a shape that will envelope the fire, and it nearly approaches the inverted basin-shape that Hood spoke so highly of years ago. This has a top feeder, and is adapted for taking a charge of fuel. The hole shown in the front of the drawing is the flue-way from the interior of the boiler, and the brickwork is arranged so that the flame is caused to take the direction indicated by the arrows. The grating over the hole is merely to keep the fuel from falling through into the flues.

The lower front edge may be level with the rest of the boiler bottom, or it may have a little arched opening as fig. 85; this arched aperture

FIG. 85.

being just behind the stoking-door, and for the passage of the stoking tools into the fire-box. If this arched way is not provided, the boiler is propped up on fire-bricks and a stoking aperture thus provided for. Sometimes the feeding door, which is shown on top, projects from the top edge towards the front. This latter arrangement is for such times when the fuel cannot be shovelled in at the top. This boiler is practically fixed in a circular brickwork chamber, of such a width that the feathers reach each side tightly. Water-way midfeathers can be had if desired. They add considerably to results.

Wagstaff's segmental boiler is well worthy of notice. This is made in two shapes, the shape most known being of the ordinary saddle outline, as fig. 86. It is a cast boiler and the

FIG. 86.

sections are bolted together as shown. The form of the sections makes the interior deeply convoluted, which adds materially to the heating surface. Between each section will be noticed a vertical slot-like opening, the object of this is as follows. The boiler is not intended for flues in the ordinary way, but is placed on the customary level base with fire-bars suitably provided; the brickwork is then carried over it corresponding to the shape of the boiler, but leaving from 3 in. to 4 in. between. The front and back ends come tight against the brickwork.

When this boiler is in use, the heated products escape through the slots or fissures at the sides between the sections, and then, in their passage to the chimney, envelope or embrace the outer surface.

The reader is recommended to obtain lists of Weeks & Co.'s tubular boilers and Deard's coil boilers; both have novel features, and are in general use. For large purposes where a simple old pattern boiler may be preferred, the "Trentnam" or Cornish boiler can be inspected with advantage.

OBITUARY.

DR. JAMES THOMSON.—We regret to hear of the death of Dr. James Thomson, Emeritus Professor of Civil Engineering in Glasgow University, which occurred on the 6th inst. According to the *Times*, he was born in Belfast in 1822. His father was Professor of Mathematics in the Royal Belfast Academical Institution, and subsequently became Professor of Mathematics in Glasgow University. Many still alive remember the college career of his two sons, James Thomson and William Thomson (now Lord Kelvin). James Thomson chose the profession of a civil engineer, serving his apprenticeship in the works of the late Sir William Fairbairn. He began practice in Belfast, and held the office of engineer to the Belfast Water Commissioners. In 1857 he became Professor of Civil Engineering in Queen's College, Belfast. In 1872 he was elected to fill the Glasgow chair.

GENERAL BUILDING NEWS.

SCIENCE AND ART SCHOOLS, WESTON-SUPER-MARE.—On the 9th inst. the foundation stone of the new building in Church-road, Weston-super-Mare, to be used as a school for science and art teaching, was laid by Lord Dunsany. The building is Renaissance in style. The lower story is being built in local blue limestone, but the upper portion will be in Bath stone with faience panels. On the ground floor will be a science lecture-room, 36 ft. by 20 ft., with chemical laboratory and apparatus-room attached; three workshops, 20 ft. by 16 ft., for plumbing, wood and stone carving, and modelling respectively, also a master's room and lavatories, &c. These rooms are all 16 ft. in height. On the upper floor, which will be approached by a temporary wood staircase until the front portion of the building is carried out, will be two art rooms, each 60 ft. by 20 ft., one for elementary and the other for advanced work; also a small conservatory in which to keep plants in use for flower painting, &c. The building will be fireproof, having a concrete and iron floor. The contract has been let to Messrs. Thee, Palmer & Son, who are carrying it out under the immediate superintendence of the architects, Messrs. Price & Wooler, of Weston-super-Mare. The *Daily Graphic* of the 11th inst. gives a small review of the building, and two other illustrations connected with the ceremony of laying the foundation-stone, but omits to mention the name of the architect. We are surprised that a paper avowedly devoted to art should thus follow the bad example of most other daily journals, which seem rarely to think the architect's name worth mention.

PAROCHIAL BUILDINGS, NEWCASTLE.—On the 3rd inst., the new parochial buildings which have been erected in connexion with Jesmond Parish Church, Newcastle, were opened by Mr. N. G. Clayton. The style of the building is a free treatment of Tudor. The external walling is composed of secked rubble, with stone dressings. A ventilation turret is placed over the main bail roof. The architects for the work are Messrs. Plummer & Burrell, and the contractor Mr. S. B. Borton. The slating has been executed by Messrs. Kirk & Dickinson, the painting and glazing by Messrs. Robertson & Son, the plumbing by Mr. McPherson, and the heating by Messrs. Dinning & Cooke, all of Newcastle.

SHERWOOD FREE CHURCH, PAISLEY.—On the 21st ult., the new Free Church erected at Greenlaw, on the Glasgow-road, Paisley, was formally opened. The building is of red sandstone. The extreme length within walls is 74 ft. by 52 ft., having a recess in front over the vestibule, with one at the north end, immediately behind the pulpit. Entrance is obtained through a doorway in the centre of the south front, which leads into a vestibule, 30 ft. by 9 ft., subdivided by two ornamental screens, glazed with lattice glass. A gallery extends round three sides of the church, with a recess behind the south gable; and the roof, which has timbered arched ribs, rises to a height of 55 ft. above the level of the floor. A square tower, with pinnacles and octagonal spire, is situated at the south-east corner. The tower is 120 ft. high. At the corresponding corner an octagonal turret, 43 ft. in height, is erected. In the centre of the south gable is a traceried and cusped window, having eight vertical lights, divided by moulded mullions and transoms with arched heads. The side fronts have gables, forming eastern and western transepts, with two lancet and rose windows in each. The area of the church has two light and the gallery three-light side-windows with cusped heads, whilst the chancel, or organ recess, is lighted by single windows in side and a three-light window in back with arched heads. To the back of the church the hall, the vestry, and the mission-house have been placed. Mr. James Donald, of Paisley, is the architect. The total cost of the buildings will amount to over 4,000.

CO-OPERATIVE SLAUGHTER-HOUSES AT BRADFORD.—The Bradford Provident Industrial Society, Limited, has recently erected new slaughter-houses, cattle-sheds, stables, &c., at Dudley-hill. They are built on a plot of ground, 3,700 square yards in extent, and have frontages into Bolton-lane, Cutler Heights-lane, a new street which is to be called

Industry-street, and another thoroughfare, to be known in future as Bank-road. All the buildings are faced with stone, and special attention, it is said, has been given to drainage and ventilation. The yards and sheds are paved with setts. The total amount of the contracts is 4,175*l.* The following contractors have executed the works, from plans and specifications prepared by Messrs. Lycroft & Firth, architects:—Masonry, Messrs. John Moulson & Son; joinery, Messrs. K. Wilkinson & Sons; plumbing, Mr. Charles Nelson; concrete work, Messrs. T. Cordingley & Son; slating, Mr. Thomas Nelson; painting, Mr. Wm. Townson; ironfounders' work, Messrs. Taylor & Parsons. Mr. F. Moulson was clerk of the works.

RAILWAY STATION, BINGLEY, YORKSHIRE.—A new station on the Midland Railway at Bingley has for some time been in course of construction, and it will be opened about the beginning of July. The new station buildings have a frontage of over 100 ft. to Wellington-street, which will be considerably widened to form an entrance. The plans have been designed by Mr. C. Trubshaw, the Company's architect, and the works are being carried out by the superintendence of Mr. Austin, clerk of works to the Company. The site is a short distance from the present station, which, when no longer required, will be removed, and a large goods warehouse, 174 ft. by 40 ft., erected in its place. Mr. Trubshaw has designed a stone building for the offices and public rooms. An awning of glass and iron projects 18 ft. from the frontage, and, passing under it, the passenger passage is 12 ft. in width, lined with enamelled brick, the dado of chocolate-brown, and the upper portion of a light buff. On the Wellington-street level there is a booking-hall, 30 ft. by 20 ft.; a booking-office with two windows, 30 ft. by 12 ft.; a telegraph-office; and a parcel-office, 38 ft. by 25 ft. In continuation of the porch, an iron-girder footbridge, 14 ft. in width, is being erected over the lines. It will be lighted by side-lights, and roofed with zinc. The descent to the platforms is by stairs on either side of the bridge. For the easy transfer of luggage from the parcel office down to the platform, a sloping passage has been designed. Below the level of Wellington-street, on the down-line, there is a range of rooms, including the sanitary accommodation; a general waiting room, 28 ft. by 12 ft.; a porters' and lamp room; and other rooms and offices; and first-class and third-class ladies' waiting-rooms, each 19 ft. by 12 ft., with entrance-lobbies of enamelled brick. The buildings on the opposite, or the up, platform comprise a general waiting-room, 28 ft. by 12 ft., and two classes of ladies' waiting-rooms, first and third, each being 19 ft. by 12 ft. The platforms are 3 ft. above the level of the rails, and are each some 100 yards in length. On each side is an awning, glazed with glass and supported by iron pillars.

ST. PATRICK'S NEW SCHOOLS, WIDNES.—These schools in connexion with St. Patrick's R.C. Church were formally opened on the 2nd inst. The material used is St. Helen's pressed brick, with Rainhill stone dressings. All landings, steps, &c., are of Yorkshire stone. The schools, with the playgrounds, stand on 875 square yards of land. The architects are Messrs. Sinnott, Sinnott, & Powell, Liverpool, and the contractor was Mr. E. Mulholland, of Liverpool, and Great Crosby. The total cost of the buildings has been about 4,500*l.* The schools are built to accommodate 750 scholars.

CONSERVATIVE CLUB, ROATH, CARDIFF.—On the 4th inst., Mr. J. M. Maclean, M.P., re-opened the premises of this club, which have been rebuilt and enlarged, from the designs of Messrs. Veale & Sant, architects, Cardiff. The chief architectural feature is the principal entrance, which is in the Italian Renaissance style, executed in Forest of Dean and Corsham Down stone, richly moulded, and with massive corbels carrying a balcony over the entrance, in the pediment of which the arms of the club have been carved by Mr. Wormleighton, of Cardiff. The club consists of a large assembly-room, kitchen, private room, and committee-room on the first floor; billiard-room, smoking-room, reading-room, and bar on the ground floor, with a good entrance-hall and staircase. In the basement is extensive cellarage and a skittle-alley. The whole of the works have been carried out by Mr. R. Dinham, contractor, Cardiff, under the personal superintendence of the architects. The specialists employed have been Messrs. Brawn & Co., for the ironmongery and gas-fittings; Mr. S. Evans, for the lead lights; Messrs. T. Thomas & Sons, Cardiff, for the lift; whilst Messrs. Jones & Willis supplied the memorial brass which has been erected on the staircase.

NEW CHURCH, NEW KILPATRICK.—On the 5th inst. the Temple Church, New Kilpatrick, erected on a site on the farm of Temple of Garscube, granted by Lady Campbell, was opened. The new church is cruciform in plan, having two aisles, and transepts, with a deep chancel behind. The internal length is about 80 ft., and the breadth between the transepts 64 ft. The style of the architecture is Gothic, and the stone is rock-faced red freestone. The approach is from the Crow-porch, and the main entrance is through an open porch, thence into an inner vestibule, from which access is had to the area of the church. The inner

vestibule, which is the lower portion of the tower, contains a staircase leading to the back gallery. The area, including the transepts, is seated for 460 worshippers, and the back gallery for sixty. The church is principally lighted from windows in the clerestory, which is supported on stone arches carried on stone pillars, having ornamented moulded capitals and bases. The chancel is raised a few steps above the level of the floor of area of church, and partly screened off by a parapet stone wall with ornamental wrought-iron railing on top. The pulpit is of oak. The chancel is fitted up with oak stalls for the choir. The tower, rising to a height of 80 ft., is provided with a bell-chamber designed for a chime of bells. There is also vestry and session-house accommodation. The total cost is 3,500*l.* The church was designed by Mr. Henry Higgins, jun., architect, Glasgow, under whose superintendence the work has been carried out. The following were the tradesmen who executed the work:—Mason, Mr. W. McGaw, Mary-bill; joiner, Mr. W. Anderson, Glasgow; slater, Messrs. A. & D. MacKay, Glasgow; plumber, Messrs. Stalker & Daye, Glasgow; plasterer, Messrs. J. & A. Wilkison, Kirkintilloch; glazier, Messrs. McCulloch & Gow, Glasgow; painter, Messrs. John Orr & Sons, Glasgow; heating, Messrs. Mc Cormick & Sons, Glasgow; gas fittings, &c., Messrs. Buchans & McIntyre, Glasgow.

PROPOSED NEW BANK FOR ROTHERHAM.—The Sheffield Banking Company, Limited, have decided to increase their accommodation at Rotherham, and a new bank is about to be erected. The new building is to be erected on the site of the existing bank, including the vacant land on the south side fronting the Market Hall. The building will be a stone structure with a granite base, and will have a frontage of about 72 ft. on the east side, and about 42 ft. on the south side, with main entrance on the east. The ashlar in the outer walls will be obtained from the new red sandstone quarries at Canklow, near Rotherham. Messrs. Chas. Green, the contractor for the whole of the works. The foundation will be composed of a thick bed of Portland cement concrete, and the basement walls will be lined with either white-glazed or salt-glazed bricks in cement, backed with concrete walling. The main banking-room will be about 36 ft. by 27 ft. Adjoining this will be ante-rooms and manager's room. The manager's house will occupy the site of the present building. The plans have been prepared and the work will be carried out by Messrs. Hatfield, Son, & Garland, architects, Sheffield. The clerk of the works is Mr. W. Kaye, of Doncaster.

SANITARY AND ENGINEERING NEWS.

SEWERAGE, POCKLINGTON (YORKSHIRE).—The Vestry of the Township of Pocklington, near Hull, has consulted Mr. D. Balfour, M.Inst.C.E., Newcastle-on-Tyne, as to a scheme of main sewerage, and he has accordingly submitted plans and report.

WATER SUPPLY, HENLEY-IN-ARDEN.—The question of a water supply for Henley-in-Arden is now in a fair way of being settled. At the last meeting of the Stratford-on-Avon Rural Sanitary Authority, it was announced that a local company had been formed, and that Mr. J. E. Wilton, C.E., Birmingham, had been called in, to advise and to submit a scheme for the provision of a supply of pure and wholesome water for the town.—*Leamington Spa Courier.*

SEWERAGE WORKS, HORNSEY.—Colonel Charles Henry Luard, R.E., one of the Inspectors of the Local Government Board, held an inquiry at Hornsey on Tuesday, with respect to sanction to borrow 5,100*l.* for works of sewerage. Mr. T. D. Courcy Meade, M.Inst.C.E., who had prepared the scheme, explained the plans, and afterwards conducted the inspector over the line of proposed works. Colonel Luard expressed his approval of the scheme, and promised to report to the Local Government Board in due course.

WATER SUPPLY, CHESHUNT.—A Local Government inquiry was held at Cheshunt, Herts, on the 5th ult., by Major-General Carey, R.E., on the application of the Cheshunt Local Board, for sanction to borrow 3,100*l.* to complete the scheme of water-supply now being carried out. After the inquiry General Carey visited the works, and will report in favour of the application. The total cost of the works will be 32,000*l.* The engineer is Mr. T. Bennett, Assoc. Mem. Inst. C.E., Engineer and Surveyor to the Local Board.

ALTAR AND REREDOS, BELCHAMP ST. PAUL'S.—On the 2nd inst. the Bishop of St. Alban's dedicated a reredos and altar which have been erected in the Church at Belchamp St. Paul's, Suffolk. The reredos and altar are of oak, and have been executed by Mr. Harcourt Runnalls, and have been designed in plan, having two aisles, and transepts, with a deep chancel behind. The internal length is about 80 ft., and the breadth between the transepts 64 ft. The style of the architecture is Gothic, and the stone is rock-faced red freestone. The approach is from the Crow-porch, and the main entrance is through an open porch, thence into an inner vestibule, from which access is had to the area of the church. The inner

CHICAGO EXHIBITION, 1893.—The Royal Commission announce that applications for space in the British Section can only be received up to Saturday, May 21. Any applications received after that date will be filed in, case of any space becoming hereafter available, but will not be included in the final allotment.

William Siemens, F.R.S., and by portraits (not subsequently good-faithnesses) of Mr. Carl Siemens and Dr. Werner von Siemens. The establishment at Woolwich, which covers an area of 7 1/2 acres, is described and very fully illustrated by some thirty photo-engravings specially made for the purpose, showing the interiors of the many busy machine-shops and of other departments. The manufacture and laying of submarine cables are described, and the account concludes with an illustrated description of many of the instruments and appliances made at Woolwich.

FEDERAL REFORM ASSOCIATION.—The fifth monthly meeting of the Federal Reform Association was held last week in the Church House, Westminster. Among those present were the Archdeacon of London, in the chair, the Hon. D. Fortescue, Gen. Lowry, Rev. T. B. Johnston, Rev. R. B. Bamford, Dr. W. T. Greeno, Dr. Septimus Gibson, Dr. W. Squire, Mr. Vigers, Mrs. Leigh Hunt Wallace, and Miss Bayley. The Archdeacon said that London and other great towns needed more cemeteries within convenient reach, and each cemetery should be conducted as a natural underground purifier, where the dead are dissolved by the action of the earth and air, instead of being preserved in durable coffins. The extra cost of more numerous spaces required by such sanitary burial could be met by the abandonment of the prevalent extravagances of funerals.

DESIGNS FOR FLOORCLOTH AND LINOLEUM.—Messrs. M. Nairn & Co., floorcloth and linoleum manufacturers, of Kirkealdy, announce that in response to their invitation of January last, 470 competitors, residing throughout the United Kingdom, the Continent, and America, have sent in 1,089 designs for competition. With the assistance of Mr. A. F. Brophy, of London, they have decided that the prizes should be awarded as follows:—Class A: 1st prize, "Antrim," Mr. R. A. Boyd, London; 2nd prize, "Aristophanes," Mr. Andrew Forrester, Edinburgh; 3rd prize, "Only a Faery Blossom," Mr. John Cons, Hipperholme, near Halifax. Class B: 1st prize, "Meadowsweet," Mr. W. H. Edmead, London; 2nd prize, "Esperance," Miss E. C. Brothers, Canterbury; 3rd prize, "Aristophanes," Mr. Andrew Forrester, Edinburgh. Class C: 1st prize, "Help One Another," Mr. J. H. Park, Kidderminster; 2nd prize, "L. N. Z.," Mr. Isaac Jones, London; 3rd prize, "Meadowsweet," Mr. W. H. Edmead, London. Class D: 1st prize, "Carton," Mr. T. B. Widdowson, Leicester; 2nd prize, "Tattingstone," Mr. P. Claude Hooper, Ipswich; 3rd prize, "Aristophanes," Mr. Andrew Forrester, Edinburgh. Class E: 1st prize, "Meadowsweet," Mr. W. H. Edmead, London; 2nd prize, "Antrim," Mr. R. A. Boyd, London; 3rd prize, "Figure with Fleur-de-lis," Monsieur D. Van Walle, Paris. Messrs. Nairn add that several unsuccessful drawings of merit have been purchased by them, and the remainder have been returned to the senders.

SCAVENGING AND REFUSE DISPOSAL.—Under the auspices of the Sanitary Institute and the Norfolk

County Council, a lecture was delivered on Saturday last on "Scavenging and the Disposal of Refuse and Sewage" at Blackfriars Hall, Norwich, by Mr. P. de Courcy Meade, F.R.S. The lecture was well attended, principally by intending candidates for positions as Inspectors of Nuisances. The lecturer went very fully into the question of the collection and disposal of refuse. He described the "Street Orderly" system which has been in use in the City of London many years, and then gave some interesting figures as to various methods and the cost of removal of street refuse, watering the streets, and the use of the rotary brushes and other machines for the cleansing of streets and the removal of snow. He described at length the various systems now in use for the collection and disposal of house refuse, dealing very fully with the subject of refuse cremation and other systems in use throughout the country. Commencing with "Eyer's" Destructor," Mr. Meade described the various systems which have been tried with more or less success in the principal towns in England and Scotland, and he also described the Fume Cremator which is used in connexion with the destructor, and the various improvements which have taken place in furnaces for destroying refuse. The furnaces known as the "Perfectus" Destructor, the Horsfall Destructor, the system devised by Mr. Young, of Glasgow, that of Mr. Healey, the new furnace invented by Mr. Whitley, of Manchester, and others, were fully dealt with. The milder system was also described, and the lecturer concluded with a short description of the various systems now adopted for the purification of sewage. A few questions which had been given by the lecturer were printed and distributed amongst the students by Mr. Widdows, the Principal of the Technical School at Norwich. At the conclusion of the lecture, a vote of thanks was given to the lecturer, and a request was made that he would have the principal portions of his lecture transcribed and printed for the use of those interested.

MEETINGS.

- MONDAY, MAY 16. Royal Institute of British Architects.—Mr. W. H. Proce, F.R.S., on "The Art of Internal Illumination of Buildings by Electricity." 8 p.m. Society of Arts (Cantor Lectures).—Dr. Percy F. Frankland on "Recent Bacteriological and Chemical Research in Connection with the Fermentation Industries." III. 8 p.m. TUESDAY, MAY 17. Institution of Civil Engineers.—(1) Further discussion on Mr. A. T. Peters' paper on "The Distribution and Measurement of Illumination." (2) Five remaining papers.—Prof. W. C. Roberts-Austen on "The Measurement of High Temperatures." 8 p.m. Society of Arts (Applied Art Section).—Mr. William Simpson on "Mud, A Material for Architecture in Persia and the East." 8 p.m. Statistical Society.—Mr. J. S. Jeans on "The Recent Movement of Labour in Different Countries in Reference to Wages, Hours of Work, and Efficiency." 7.45 p.m. Royal Institution.—Mr. Frederick E. Ives on "Photography in the Colours of Nature." II. 8 p.m.

- WEDNESDAY, MAY 18. British Archaeological Association.—Mr. Cecil T. Davies on "Merchants' Marks of the Fifteenth and Sixteenth Centuries." 8 p.m. Society of Arts.—Captain W. De Abney on "Colour Blindness." 8 p.m. Royal Meteorological Society.—Three papers to be read. 7 p.m. Builders' Foremen and Clerks of Works' Institution.—Ordinary meeting. 8.30 p.m. THURSDAY, MAY 19. Society of Arts (Indian Section).—Mr. J. A. Baines on "The Administration of the Imperial Census of 1891 in India." 4.30 p.m. Society of Antiquaries.—8.30 p.m. Royal Institution.—Professor Dewar on "The Chemistry of Gases."—IV. 3 p.m. FRIDAY, MAY 20. Royal Institution.—Mr. J. Wilson Swan on "Electro-Metallurgy." 9 p.m.

RECENT PATENTS:

ABSTRACTS OF SPECIFICATIONS. 5,383.—DRAIN VENTILATION: I. Shows.—This invention relates to improvements in the ventilation of drains and sewers. According to the specification, sewer and drain gases are diluted with fresh atmospheric air, and are discharged into the atmosphere so diluted. The fresh air is effected from air taken from the atmosphere, or from a windmill, or from a fan, or from a pump, or from a trap, or other device by which the foul gases are given off from the sewer in a drain or sewer are discharged into the air. The gases so diluted will, it is urged, be far less noxious in all respects than sewer gases as ordinarily discharged from a drain. Stand-pipes are used for introducing the fresh air, and the inventor proposes that gas lamp pipes should be utilised, where possible, for such stand-pipes. 7,680.—GLAZING ROOFS: G. Emerson.—This invention is described as a simple and cheap means for securing glass in roofs, skylights, and the like, without the aid of putty. A longitudinal groove is ploughed out of each side of the bars of the roof, the groove extending the whole length of the bar. A sheet of metal or other suitable material is then taken, and with it the open or outer surface of the bar is covered, being forced into the grooves on both sides. Below the grooves are spread the lateral edges of this sheet, at right angles or thereabouts of the bar, projecting as far as may be desired. The pieces of glass are slid one by one into the completed roof, the glass acting as a cam. In the upper, or intermediate cans, a projection is made by which the lower edge of this piece of glass is held and retained. The next piece of glass is then slid along the grooves until its upper edge passes under the projecting part of the lower edge of the upper piece, when, in its turn, it is secured in position by one or more similar cams, and so on with the remainder of the glass. To remove the glass the process is reversed. 8,815.—DOOR LATCHES: W. M. Trousdale.—This specification refers to what is described as an improvement in latches, applicable to door locks or doors without locks, and consists in making a rectangular or triangular shaped latch, having the face and nose rounded and vertically pivoted to swivel parallel with the door, the latch being so weighted or acted on by a spring, and resting on a staple, that the projection of the latch, or latch point, just projects sufficiently far beyond the face of the door as to form a secure hold of the box staple fixed on the inside of the

door jam, when the door is shut. In withdrawing the latch the inventor applies a tang, curved and going through the door and working on a pivot, arranged so that the latch so that when the tang is raised it swivels the latch, and the door stops. This tang has handles at each end hanging downwards on each side of the door, or so arranged that on opening the door on entering, the hanging handle is pressed forward, and the latch is raised, and by the same pressure opens the door; in the reverse action occurring on withdrawing the hanging handle, the hanging handle being pulled, which swivels, and with the pull of the door, the same pulling action confined to the open door. Various forms of this latch are given in the diagrams attached to the specification.

9,419.—DAMP IN WALLS: W. P. Thompson.—This invention relates to a process for the manufacture of chemical preparations with which walls of houses are coated for the purpose of preventing the damp from penetrating. The process consists in first coating the wall with a thick solution, and then with a thin one, so that the damp cannot get through. The first solution is composed of stearine, saponified with caustic potash, acetic acid, and salicylic acid. These substances are heated in water to boiling point. A little phenic acid is added to destroy the unpleasant odor of the soap. The thin solution is composed of alum, chloride of calcium, and salicylic acid diluted with water, and a little phenic acid is also added. Any surplus water is evaporated off. The wall is added to these solutions. It is claimed that water runs off walls so coated, as it does off sheets of glass, without leaving them damp, and that the appearance of the coated surface is bright, and that, at all, and they are thus prevented from becoming dirty.

New Chapters in Greek History.

WE have been asked more than once, "Is there any readable hook that gives the outcome of all these recent excavations?" and up to the present time we have had always to reply the negative and dismiss the dejected querier with references to Jahrluchs and bulletins which we know perfectly well he is neither time nor inclination to consult. Professor Gardner has, we are sure, supplied very real need in the work now issued. "My endeavour," he says in the preface, has been to set forth briefly and, if possible, in a way tending to interest all phil-Hellenes, the gains which the excavations of the last twenty years have brought us in regard to our knowledge of Greek history, using the word history in the widest sense, as covering not only historical events but all sides of the activity of the nation. I have written," he goes on to say, "not for archaeologists, but for the ordinary educated reader, for those who are acquainted with the literature, or the history, or the art of Greece, and who wish to fill up the lacunae, or to learn in what directions the spade is increasing our acquaintance with ancient Hellas."

The book is in part a reprint. A considerable portion of chapter iv., the Palace at Mycenae; vi., Ancient Cyprus; vii., Naucratis and the Greeks in Egypt; viii., the excavations in the Athenian Acropolis; ix., Olympia and its Festival; xv., the successors of Alexander, have already appeared in the *Quarterly Review*; chapter ix., on reliefs and inscriptions of Athenian Tombs, in the *Contemporary*; xi., on Spartan Tombs and the Cult of the Dead, in the *Fortnightly*; parts i., on the Verification of Ancient History and on Recent Discoveries and the Homeric

poem, in *Macmillan's*. On the other hand, the chapters on Phrygia and Troas, Mycenae and the islands, Epidaurus and Ancient Medicine, Eleusis and the Mysteries, and Dodona and the Oracles, are mainly new. With the exception of the last chapter on the Successes of Alexander all the published articles are carefully revised up to date.

No one but a thoroughly furnished archaeologist could travel with comfort over a field so wide as the mere enumeration of the titles of the chapters indicates; no mind but one exceedingly wary and well-balanced could keep a safe foothold among pitfalls so precarious. Professor Gardner is all these things, and, most of all, he is a man of peace, contending steadfastly enough for the truth, but with little instinctive love of conflict. Naukratis, Mycenae, Troy,—their very names are as the trumpet to the archaeological war-horse; in Professor Gardner they stir the steady glow of a scholar's enthusiasm, but no heat and fury of the battle. How rigidly, too, he can resist what must have been temptation is shown by the significant fact that there is no chapter on that red rag, the Greek theatre.

We naturally turn first to see what Professor Gardner has to say on the question of supreme interest for the moment,—the relation of the Schliemann discoveries to the Homeric poems. The chapters that precede we need not dwell on in detail; they present admirable summaries of the explorations of Professor Ramsay in Asia Minor, and of the details of the Schliemann excavations. The account of these last was, in the main, written before the appearance of the English edition of Dr. Schuchardt's book. It is interesting to compare Professor Gardner's view with that presented by Dr. Leaf in his admirable preface to the English version. The issue,—for issue there is,—stands thus:—"Mr. Monro and Mr. Leaf are both disposed to think that most of the Homeric poems were composed by Achaeans before the Dorian conquest, and taken to Asia by the colonists." "This," writes Professor Gardner, "I cannot concede; for it seems to me certain that the poets who wrote them were speaking of a past which lay some distance behind them." To put it a little more fully, Dr. Leaf holds that there is, at all events, a possibility that

the oldest parts of the "Iliad" at least may be actual survivals in their present form from Achaean and pre-Dorian days. "This view, setting aside philological arguments as a working hypothesis, certainly relieves the archaeologist of grave difficulties; the poems are then allowed to depict actually and as contemporaries what they pretend to depict,—i.e., the Achaean age. We understand at once how they can present with such vivid life a state of manners and customs which must have been utterly unknown to the Ionians of the coast of Asia Minor." These Ionians were eager traders, democratic, full of enterprise, ever intent on widening their horizon, the very antipodes of the Homeric Achaeans, ancient families, aristocratic, patriarchal, conservative, stay-at-home. That an Ionian could depict such an age in life-like fashion is an assumption, Dr. Leaf holds, that strains all probability; for it not only assumes a trained historic imagination, but involves actual archaeological study such as is absolutely foreign to the genius of a young and rising nation. We confess we are with Dr. Leaf. The whole of Professor Gardner's argument for the wide chronological gap that separates the writer of the Homeric poem from the age he depicts is vitiated by this assumption of a certain archaeological consciousness in that writer or writer's mind. Anachronisms, Professor Gardner writes, "were kept out of their epic poems on the same principle on which a writer of pastoral idyls in our day would avoid the mention of the telegraph or telephone." We must register our distinct conviction on the opposite side, as we believe, with Dr. Leaf, that the writers describe in reality the age they profess to describe,—an age as regards the earliest parts of the poem contemporary with themselves, depicted by no effort of historic imagination; and, further, that this age is the age of the builders of the heathen tombs. On this supposition the Homeric poems are brought into close and actual contact with the Mycenae excavations,—a contact far closer than Professor Gardner will allow. So temperate, however, is his tone here, as always, that a misconception we believe to be somewhat fundamental scarcely vitiates at all his interesting account of the facts.

¹ New Chapters in Greek History. Historical results of recent excavations in Greece and Asia Minor." By Percy Gardner, M.A., Litt.D., Lincoln and Merton Professor of Classical Archaeology and Art, Oxford; and also Professor of Archaeology, Cambridge, with illustrations. London: John Murray, Albemarle street, 32.

The chapter on ancient Cyprus is a record of shame for England. We need not tell again the melancholy tale of the Cesnola excavations; perhaps the only civilised Government which would have tolerated such proceedings is the English: we wilfully tore up a chapter in ancient history committed to our charge, and civilised Europe is not likely to let us forget it. The Cyprus Exploration Fund is doing what it can with meagre resources to wipe out by private effort the public blot, but large sums are needed, and scarcely likely to be forthcoming before the excavations can be in an adequate way completed. Something, however, has been done. Three classes of tombs—Primitive, Phœnician, and Græco-Roman have been cleared out; the plan of the Temple of Aphrodite at Paphos has shown us how widely different was an Oriental sanctuary from a Greek temple; and a number of richly-painted terra-cotta statues have taught us something of the art of a people who thought more of dress than its wearer,—an art so lauguid that it imitated the style of any one of the more living arts of the nations round.

The story of Naukratis is told with special fullness and vivacity. The excavations there owed much to the zeal and scholarship of Mr. Ernest Gardner, and Professor Gardner's interest is rightly and naturally personal as well as professional. At Naukratis, we English have redeemed something of the prestige that we lost at Cyprus, and we have discovered most where we looked for least. Time, which has destroyed all that was splendid in the temples of Naukratis,—the marble pillars, the cultus statues, the dedicated vessels of gold and silver,—has made some amends by preserving to us their rubbish-heaps. As the temples became too full of votive offerings, dedicated and usually inscribed by the Greek traveller who had reached Egypt in safety, the temple officers would dig a trench, break up the anathemata for economy of space, and bury those they judged superfluous. From these trenches thousands of fragments of vases (many now in the British Museum), painted and inscribed, have been rescued. Before visiting these treasures, or referring to the official report and its plates, every reader will do well to run through Professor Gardner's interesting historical and topographical sketch, he will save himself much wandering in the by-paths of ancient history, and he could not take a safer guide.

The chapter on the excavations of the Acropolis is largely in substance a review of that very Dörpfeldian book, "Mythology and Monuments of Ancient Athens." To this book the most generous justice is done, though Professor Gardner himself refuses to give anything like exclusive attention to the voice of the charmer. He is not the least convinced by Dr. Dörpfeld's arguments as to the preservation down to the times of Pausanias of the "old Athene Temple." Still less does he hold with Miss Harrison that when Pausanias speaks of the Temple of Athene Polias, and the treasures it contained, he intends not, as all writers have hitherto supposed, a part of the complex building called the Erechtheion, but this most ancient Temple of Athens. He goes on to say, "at the same time she is obliged to allow that the very archaic wooden figure of Athene, which the people of Athens guarded as their most important and venerable treasure, was preserved under the roof of the Erechtheion thus acknowledging in her theory a weakness which if not fatal is at least serious." The fact is, we believe, that Miss Harrison considers the supposed Athene was originally no Athene at all, but an old stock image belonging to a cult that existed long before Athene came to the Acropolis, an image, namely, of *Gain-Pandrosos*, the early form of the goddess known as Demeter, and worshipped at Athens as at Thebes in primitive Pelægian days, just such an image as that of which Tertullian pertinently remarks "the Iliarian Ceres which is a formless effigy, and consists of an unhewn and shapeless stock." Such an image would rightly be housed in the old museum of cults, the Erechtheion.

The remaining chapters may be dealt with more briefly. In the account of Olympia so much space is given to the Athletic contests that its careful reading by large numbers of educated Englishmen to whom the bulk of archeology is unsympathetic may be taken as assured. Professor Gardner is an acknowledged authority on the subject. The two next chapters are to be taken in conjunction, and had we had the ordering of the book we should certainly have reversed their sequence. "Spartan Tombs and the Culture of the Dead,"—a most valuable and well-nigh complete study,—should have preceded "Reliefs and Inscriptions on Athenian Tombs." Beautiful—universally admired as they are—Athenian grave-reliefs have, as the author fully recognises, a coldness and emptiness of faith that is disappointing. "One closes the Corpus of Sepulchral Inscriptions with a feeling of surprise—surprise that a people so gifted as the Athenians should be so helpless and tongue-tied in the presence of death." We have written so lately on the subject of Athenian beliefs, as reflected in tombs and burial customs, that we cannot do more than say that the account of the Cultus of the Dead is admirable,—only noting that we do not think Professor Gardner allows sufficient weight to the influence of the art type of the Spartan on the Athenian reliefs. The chapter in Epidaurus is to us the least satisfactory of all, the account of the monuments, ground plan, and chiefly of the inscriptions is good and full, but Professor Gardner ignores wholly a book which he can scarcely have left unread; the "Isyllus" of Dr. Wilamowitz Moellendorf, a hook of which it is not too much to say that it revolutionises wholly our views of the cult of Esculapius. Professor Gardner seems still to hold (and we feel sure he must have his ground for so doing, only he nowhere states it) the old view we thought exploded of the late rise of the cult of the god—whereas Wilamowitz traces him back to the earliest days of primitive Thessalian worship. The chapters on Eleusis and Dodona, which might well have opened the book, are delightful reading. On the delicate ground of the mysteries the writer holds an even path between the absurd credulities of Warburton and the brilliant but too destructive rationalism of the great Lobeck. He points out in interesting fashion that in the Sekos of Eleusis we have the only one and ancient parallel to a Christian church or a place for the assembling of the worshippers. He also shows that the excavations have made clear that no elaborate scenic effects, such as the ascent and descent from and into subterranean chambers, could have been attempted. Into the complex question of the stratification of the various temples, wisely, in a book for popular use, he does not enter. In taking leave of a delightful book, we can only emphatically record that what the author has attempted he has attained. To use his own apt phraseology, he has fulfilled the mission of the archeologist—he has furthered not only the verification but the vivification of ancient history.

THE COMPETITION FOR THE CHRISTCHURCH NEW CATHEDRAL, VICTORIA, B.C.

THE drawings submitted in this competition have recently been exhibited at the Church House. The fourteen sets of drawings received, six being by Colonial and eight by English architects, have been judged by the assessor, Sir Arthur Blomfield, but the purport of his award has up to the present been purposely concealed.*

Briefly summarised, the conditions ask for a stone church in the Gothic style, to seat 1,200. The cost is to be limited to 30,000*l.*, and

* Sir A. Blomfield considers that it would be hardly right to make the award public in this country before the Committee at Victoria, by whom he was commissioned as assessor, can have received it and sanctioned its publication; and in this of course we entirely concur with him.

the design is to be capable of being carried out in three sections. Three premiums were offered, of 150*l.*, 100*l.*, and 50*l.* The assessor has selected the three best designs, we are told, and the final selection will be made by the Committee on the spot.

The three selected competitors will be required to prepare further plans and specifications, and the cost will be made a condition of payment of premium. No premium is to be awarded if the cost is 10 per cent. beyond the stated sum.

The site is on the top of a hill, which can be seen from the bay in approaching the town.

In the absence of the award of the assessor, we have made our own selection, and this has been the easier, owing to the low standard of design which marks the majority.

There is one design, that of "Old and New," which stands far beyond all others in artistic treatment, and there are two others which are good in a less degree, under the mottoes "Ars" and "Duomo."

The arrangement of the plan of "Old and New" comprises a nave of three bays with north and south aisles, which are to be retained for monuments unless extra seats are required, and for this purpose the windows are kept high. The nave is entered from a porch with west and north doors. There are also north and south transepts of small projection, and these are respectively flanked by the morning chapel and the vestries. The choir is surrounded by choir aisles, and the ambulatory at the back of the altar is prolonged into one walk of the cloisters, which surround a courtyard with a fountain in the centre. This is placed immediately behind the morning chapel, and on the opposite side of the cloisters to the west a rectangular chapter-house is placed. The variety of the plan is likely to lead to good elevations, and there is no disappointment in that respect. The west elevation is flanked by two towers which are kept plain in character. They are relieved by two rich staircase turrets placed against them, and finished with timber fleche roofs. The whole of the west end between these two turrets is occupied by a two-light, tracery window of much beauty of design. A flat arch below, spanning the whole width over the west doorway, is also a noticeable feature. Above the window a gable encloses a figure-subject of the Crucifixion. The gable is surmounted by an open stonework tower, standing on the piers of the porch, through which is apparent a slender spire. The treatment of the west end is original, and the lines of the steps that approach the entrance enhance the beauty that the design undoubtedly possesses. The angles of the transepts and the east end are each marked by a turret. The architectural quality of this design is much in advance of the remainder, and, in our opinion, to this must be assigned the first place.

The second place we should assign to the design by "Ars," which is treated in a plain Early Gothic style of a severe type, but the proportions are, in most cases, good. The plan shows a nave of six bays, north and south aisles. The entrances are from the west front and a south porch. A north entrance porch also leads into the transept. A central tower and spire mark the intersection of nave and transepts. The chancel is in three bays, and is furnished with return-stalls for the clergy. There are also choir aisles, and a passage at the back of the altar. It is proposed to build a octagonal chapter-house at the south-east corner, with entrance from the choir-passage.

The third place we should assign to "Duomo," though it cannot be called a very good design. The fault of the design is the massive, ill-proportioned exterior appearance of the domical covering, which has not been at all happily treated. The plan shows a narthex at the west end, with entrance from north and south, and a small circular baptistry in the west wall. The nave is in six bays, with north and south aisles, and a dome in wood marks the intersection. The south transept has an entrance porch and a gallery,

and a morning chapel and the Bishop's vestry on this side of the chancel. The chapter-house is at the east end. The choir appears to be too small. "Old and New" is really the only design of first-class merit; and those beyond the three we have mentioned do not present any qualities to call for serious consideration or description. The exhibition is robbed of much interest by the inevitable absence of the assessor's award and the names of the architects who have sent in designs. We shall await the issue of the award with some interest.

NOTES.

SIGNIFICANT feature of the recent discussion between Lord Salisbury and the labour delegates on the eight hours question was the unanimity with which all the speakers deprecated strikes. The unfortunate people involved in the Durham miners' dispute have certainly good reason to enounce in unmeasured terms this barbarous and, as it has proved, wholly abortive method of endeavouring to settle wages questions. The strikers themselves,—that is to say, the majority of them,—only very reluctantly recognised the futility of their demand for the old rate of wages, and it was not until last Saturday week that they empowered the Federation Board to try and arrange matters on the best obtainable terms. The Board offered, on behalf of the men, to resume work at a reduction of $7\frac{1}{2}$ per cent.,—precisely the terms submitted to them by the owners at the commencement of the dispute; but it was shown that it was now too late in the day to take that figure as a basis for settlement. Weeks and months of dead loss, owing greatly to the unreasonable hostility of the strikers, has placed the coal-owners in a far worse position than when they declared a $10\frac{1}{2}$ per cent. reduction imperative; while the men have sacrificed an immense sum in wages unavailingly and unnecessarily. That they are beginning to recognise that their policy has been a mistaken one is evidenced by an expression on the part of the Federation Board of their willingness, at the earliest possible moment after re-starting work, to recommend the formation of a Wages Board for the settlement of all wages questions in the future. Such boards have proved successful in various industries throughout the country,—and, we believe, in other districts, in the coal trade itself,—and the sooner the Durham colliers protect themselves in this way from the possibility of the recurrence of such a disastrous conflict as this, the better it will be for them and the country at large. There can be no doubt, however, that the mischief already done is to a great extent irreparable. For one thing, so much outside coal is getting a footing in places heretofore drawing their supplies wholly from the Durham pits, that some of the latter will never again, probably, have an output equal to that of the past, while the actual damage sustained at other pits through the compulsory stoppage of various necessary operations will also have the effect of preventing many of the men from resuming their work when settlement is arrived at. The miners' latest suggestion is the withdrawal of all previous offers, and the submission of the matter to open arbitration.

THE concession obtained by Mr. Blundell Maple in regard to cheap trains on the Metropolitan Railway, and, in consequence, of the Manchester, Sheffield, and Lincolnshire Railway at the London end, when completed, is of importance. The maximum fare for five miles and under, including return, is 1d., and for longer distances in proportion. This concession rendered any further discussion of a new clause in the Manchester, Sheffield, and Lincolnshire Railway Companies' Bill on its third reading last week unnecessary. This increase of facilities for workmen's locomotion will certainly make

this railway extension popular among large numbers of artisans, though it will in no way lessen the dislike with which the residents in the neighbourhood of St. John's-wood regard, and must continue to regard, the placing of a new terminus in this locality. Advantages of this kind procured for the artisan classes by Members of Parliament on the Conservative side, and such legislation as the recent Factory Act, are noteworthy, because they show that the interests of the working man are not neglected, even if he is not represented by members of his own class.

MR. LAWSON TAIT, the well-known Birmingham surgeon, last week unveiled a fountain and clock tower at Willenhall, which has been erected by the inhabitants to the memory of Dr. Joseph Tonks, who died at the early age of thirty-five. Among many suitable remarks, Mr. Tait, in his speech at the dinner given in the evening, threw out the useful and somewhat original suggestion that, instead of the senseless practice of erecting monuments to the dead in cemeteries, it would be a more useful tribute to their memory to erect drinking fountains and clock towers in the streets, place pictures in public buildings, and make improvements in schools. This is a suggestion which is worth taking to heart, and, though it might lead to the production of objects of indifferent taste at first, it must lead to useful results from a sanitary, if not always from an æsthetic, point of view. In the long run it would certainly lead to a more varied, and probably a higher, form of art than we find among the tombstones in the majority of churchyards and cemeteries. The rapidity of the growth of opinion in favour of cremation must help to the formation of new views of the construction of memorial to the dead; and, seeing that cremation is advocated solely on sanitary grounds, it must eventually become associated with other public sanitary measures like fountains, public buildings, playing-fields, public gardens, and the like. At present the memorials which are not raised in the churchyards and cemeteries go to the decoration of the church itself, but, while these need not be neglected, the town-hall, public library, market-place, and the streets, should not be forgotten. Even in the matter of restoration and preservation, there are many public objects such as market crosses, tollbooths, sundials, and bridges, which are falling to decay more from lack of thought of their guardians than wilful negligence, and the preservation of which would be more interesting and useful memorials of fellow-townsmen than the monotonous structures raised to them in the cemeteries.

THE first important step taken by the "Architekten Verein" of Berlin as regards the alteration of the general building regulations of 1887 was taken last week. The nature of the alterations thought necessary, from the architects' and land-proprietors' points of view, was described by Herr Heim. The main points for alteration, according to his report, refer to (1) the proportion of ground that may be covered by buildings on small sites, (2) the planning of basement floors, (3) the maximum height of the top floor of a house above the street level (at present only 17·5 metres), and (4) the more lucid wording of the disputed paragraphs of the present code. The proposals of the Architekten Verein (as well as those of the Vereinigung Berliner Architekten) will probably receive due consideration by the Government Board of Works when the alteration of the code is under their consideration, but we scarcely believe that concessions will be made where the owners of land and their professional advisers would most wish it, even at the cost of lesser light and air and a worse hygiene for the city. The authorities will probably grant facilities where they are least expected,—i.e., in those paragraphs which were framed to ensure the "fire protection" of the city. Some of these

paragraphs are practically of little use, as, for example, that which requires each house to have a passage through which a fire-engine, fully horsed and manned, can be run into a courtyard, a facility which no firemen have ever made use of. This regulation, which has caused endless trouble to architects, will probably be expunged, while, on the other hand, a provision for two staircases to all tenement mansions may be substituted.

THE case of The Churchwardens and Overseers of Norwood v. Salter, which was decided by Mr. Justice Hawkins and Mr. Justice Collins a few days ago, settles an important practical point of rating law. Without going into technical details, and into the construction of some Acts of Parliament, which, like a good many statutes, are obscure, it is sufficient to say that by the Poor Rate Assessment Act, 1869, the owner of houses under the annual value of *£*1. can contract with the parish to pay the rates instead of the occupiers, receiving in return a certain sum in the nature of discount. The object of this arrangement is twofold: the parish gets its rates with certainty and without difficulty, and the ratepayer in return for his responsibility gets a small pecuniary advantage. The question which the Court had to decide was whether, when the annual value of the house rose above *£*1. (in the present instance it reached *£*11.) during the period of the agreement, the occupier, and not the owner, could be charged with the rates. The Court decided in effect that the increase in the annual value nullified the agreement, and that the occupier, on whom the primary liability for the payment of rates falls by the general law, became *ipso facto* as responsible as if no arrangement had been made. If this decision proves, as we think it may, inconvenient in practice, some member of Parliament will have to remedy it by a statute.

FROM May 5 to 8, 1842, the great fire of Hamburg raged, and left a large part of the city proper in ruins. Last week the fiftieth anniversary of the rebuilding of the city was celebrated, and due regard was taken of all those who had so earnestly laboured at the time to overcome the difficulties of rapid reconstruction, and at the same time to improve the portions of the town which were destroyed. Amongst the hardest workers were the members of the "Special Building Commission," which included the civil engineer, W. Lindley, and the architect, G. Semper. This Commission, which was but three and a half years in existence, did wonders. Under its direction a very valuable survey of the site was made, the streets were newly laid out, new building regulations framed, public and private buildings rebuilt, and various improvements, including the first laying of a good sewerage system, the construction of gas and water works, and the reconstruction of harbour and canal embankments, carried out. Mr. Lindley was the member of the Commission to whom Hamburg owes the original plan of the reconstruction of the streets destroyed. Unfortunately, the great extension of road traffic was not foreseen, and hence the city at present has to complain of having too narrow thoroughfares. The development of Hamburg since 1842 is something remarkable, especially in the last decade. What with its new free harbour, which is continually being extended, and its excellent Board of Works, which pays attention to the artistic as well as the practical side of every improvement taken in hand, Hamburg may be said to hold its own as the finest of the Continental commercial ports.

WE regret to hear that there has been a serious proposal entertained to alter and add to the east end of the fine parish church at Wrexham. Of course we should maintain, as we have always maintained, that

if there is a real necessity to enlarge an ancient church to accommodate an increased congregation, practical requirements must take the lead. But, if we are to take the very full report of a recent vestry meeting given in a copy of the *Wrexham Advertiser* which has been forwarded to us, as a guide, it seems very doubtful whether the circumstances can be said to constitute a practical necessity. The main point in favour of the alterations seems to be that the Vicar wishes to get the organ removed to the east end, and there is not space for it there at present. In the present day, when an organ can be arranged to be played from any part of the church by electric connexion, there is not nearly so much reason for the eastern position as there used to be; the organist can sit with the choir, though the organ remain at the other end, and can thus hear them and regulate his accompaniment accordingly, and there is no doubt that the effect of the organ itself is far better at the west end of the church than in an organ-chamber or aisle near the chancel. The present position of matters is that a resolution was carried to the effect "that the further consideration of the plans and report be postponed for two months [one of which has now nearly run out], and that the Wardens obtain in the meantime an elevation and plan of the proposed alterations at the east end, and also consult a leading organ-builder as to the advisability of removing the organ from the west to the east end of the church." The architects who have been consulted are Messrs. Middleton, Protheroe, & Phillet; the head of the firm is the well-known Slade Professor of Fine Art, and we should hope that under such advice all possible respect would be paid to the claims of the ancient structure, and that nothing would be done in any case which would architecturally disfigure the church; but we very much doubt whether there are sufficient grounds for meddling with it at all. A correspondent at Wrexham assures us that the congregation is not increasing in numbers, owing to the fact that many who lived in the town are drifting out to the suburbs.

CORONERS' juries are not always the best guides in technical and professional matters, but a recommendation attached to a verdict recently given by a jury in America is hardly to be wondered at. During a high wind last April a building in course of erection in Chicago was blown down, six persons being killed and several more injured. At first the disaster was looked on as a natural result of the exceptional force of the wind, it apparently not occurring to anyone that, even for the short time that buildings are in course of construction in Chicago, they might be at the mercy of a gale springing up. The coroner's inquest, however, has brought to light some unpleasant facts, and the jury has had the courage to return a verdict in accordance with the evidence. The "architect" is said to have been simply a contractor, and therefore, presumably, with no professional training. The work was found to have been improperly carried out, and the inspection, which should have been made by the public authority appointed for the purpose, is described as having been a "mere pretence." The jury have, accordingly, found the accident to be due to criminal carelessness on the part of the Commissioner of Buildings, two of the inspectors of the Building Department, and the owner and architect of the building, and the case will be presented to the grand jury. The recommendation of the coroner's jury is that architects should be required to take out licences after proving their competency, but as no architect appears to have been employed in the case under notice, the recommendation has somewhat the appearance of a *non sequitur*.

ON June 21 will be offered for sale, at the Mart, the Lavington and Beechwood House Estates, of about 3,100 acres, in West Sussex, lying within Rotherbridge Hundred and the Rape of Arundel. Lavington (or

more correctly Woolavington) and West Lavington parishes consist of certain scattered portions. In the Conqueror's day the manor, being nine hides, was held of Earl Roger de Montgomery by Ivo, and of Earl Godwin by a Godwin. It subsequently passed to the D'Alhins and Fitzalans, and has become part of the honour of Petworth. The large house built here by a Garton in 31st Elizabeth was replaced with a smaller one, after J. Lewis's designs, in 1794, by John Sergeant, who had succeeded to the property on marriage with Charlotte Bettesworth. In the churchyard at West Lavington Richard Cobden was buried. This property, standing above the valley of the Rother, and comprising portion of the timber-covered Downs, commands a fine view over the Weald.

In a "Note" on November 16, 1889, we printed a brief description of Her Majesty's Theatre, which, together with the "United Hotel," is about to be demolished to make way for, it is said, a new hotel. The site has been that of an opera-house for nearly two hundred years, one having been opened by Betterton on April 19, 1705. The former house on this site is worthy of remembrance as that wherein some of Handel's works, including several of his operas, "Israel in Egypt" and "Belshazzar," and, we believe, "Acis and Galatea," were first performed in London.

At the Vienna Exhibition a gold medal for painting has been awarded to Mr. John R. Reid for his painting "The Shipwrecked," the same very powerful work, we presume, which was exhibited at the Royal Academy three or four years ago. This is the fourth gold medal which Mr. Reid has received during the past five years, the others being, Berlin 1887; Paris, 1889; Munich, 1890.

THE *Manchester Guardian* published on Tuesday a map of the drainage basin of the river Irwell, showing by varied shading which districts have undertaken sewage schemes, which have completed them, and which are still persisting in polluting the river. The districts have been thus classified in a Report recently presented to the Mersey and Irwell Joint Committee by their chief inspector. The local boards which pollute the Irwell are, according to the map, Whitworth, Ramsbottom, Bury, Radcliffe, Little Lever, Kersley, Failsworth, Droylsden, and Gorton.

ARCHITECTS in Wales (or some of them) seem to have an eye to business in a sense which is not to be approved, if we may judge from the prospectus of the "Wales and West of England Girder Company" which has been sent to us. Five of the directors are architects, and the circular states that the company "will be in a great measure co-operative in its transactions, embracing as it does architects, engineers, contractors, builders, iron merchants, &c., and therefore the Directors have every confidence in its success." Further on it is stated that "the Directors will give the preference in allowing shares to Consumers or Professional men who can introduce business to the Company." As far as the "professional men" are concerned that means, of course, that they are to specify the Company's iron work for use in their clients' buildings, in order to swell the profits of the Company of which they are shareholders. None of the "Director" architects, we are glad to find, are members of the Institute.

BARRETT BROWNING MEMORIAL, LEDBURY. The competition for the Barrett Browning memorial at Ledbury has resulted in the selection of the design by Mr. Brightwen Binyon, of Ipswich; that by Mr. Lunn, of Malvern, being placed second. The designs will be exhibited for a few days at the Town-hall at Ledbury.

ARCHITECTURE AT THE ROYAL ACADEMY.—IV.

1,669; "Reredos for Grayingham Church, Lincolnshire;" Mr. A. H. Skipworth. A very delicate little water-colour drawing; over the centre portion, in which is a sculpture of the Crucifixion, is a projecting semi-octagonal canopy of Late Gothic form and general detail; the side panels are filled with pierced ornament with a line ground behind, which is only partially orthodox, and partially a free floral detail. Two narrow niches divide the centre from the side panels. This is a delicate and original hit of work.

1,671; "Mosaic Pavement at Torcello;" Mr. A. C. Blomfield. Not exactly what is generally understood by mosaic, it is rather a marble inlay, of unusual colouring, the effect of which is well conveyed in the water-colour drawing.

1,672; "An Artist's House at Croydon;" Mr. C. Henman. It has three plans showing how the studio is connected with the house off a landing of the staircase, in a convenient fashion yet so as to keep it a little apart: the small house is compactly planned, but there is not anything in the design which especially marks it out as an artist's house, the architectural treatment being a common enough type of country-house picturesque. The studio window rightly makes a point in the exterior design.

1,674; "Cloisters, Xanten, Germany;" Mr. H. W. Brewer. This and 1,694 ("Choir, Xanten") are drawings which have appeared in our pages, or rather they are the pencil forms of drawings executed in ink for this journal. The subjects will be found in the *Builder* for April 5 and May 3, 1890. The pencil drawings are admirable specimens of effect produced without labour, being in fact very slight and free in execution, but quite complete in effect.

1,675 we have already noticed; 1,676 "Porch, Madena Cathedral," and 1,677, "Doorway, Genoa Cathedral," both by Mr. F. W. Bedford, are among the drawings, we presume, which were skied by the painter R.A. who wished to "cover the walls" in a symmetrical manner; they are probably good sketches, but cannot be seen. 1,678, the large frieze by Mr. Babb, we have already referred to; 1,679, the staircase of the Sheffield Municipal Buildings, to which we have also referred, is published in the present number.

1,680; "Staircase, Buller's Wood, Chislehurst;" Mr. Ernest Newton. A pleasantly-treated simple staircase interior, with an arcade of two arches over the first landing, carried on a column seated on the newel, and which is made to show up effectively, white against the shadowed portion of the upper staircase. The drawing is a slight but very artistically-executed one by Mr. Raffie Davison.

1,681; "Design for Memorial to Mary Tador, St. Mary's Church, Bury St. Edmund's;" Mr. A. E. Street. We published a lithograph from this drawing on May 14, to which we can refer the reader for the design, though it does not give the colour and marble texture, which are very well rendered in the drawing. This is a very interesting variation on the sarcophagus type of tomb, with what we take to be a bronze cross and canopy affixed to the top of it, in relief from the carved surface of the marble. The three small plaques in the side of the monument are filled up with yellowish veined marble, which we suppose has some purpose of taking inscriptions or engraved symbols, not indicated on the drawing; as mere plaques they cannot be said to have any decorative value, in regard to form at least, though the colour harmonises well with that of the darker marble. But in the main this is a very interesting and well considered piece of work. Perhaps the bracketed at the end have a little too much the suggestion of being clamps to hold the whole together.

1,682; "Corner of a Drawing-room;" Mr. J. Armstrong Stenhouse. The title is we believe a blunder of the Academy catalogue, and in that of another drawing which was not hung, the real title of this being "Interior of Hall and Ball-room." It is a pretty little water-colour drawing of part of a long room with an open hammer-beam roof, ornamented with pierced panel work. The millions shown in the largest window at the end cut very awkwardly into the circular arch of the window, but the general style and tone of the little drawing are admirable.

1,684; "Competitive Design for Municipal Buildings, Oxford;" Mr. Halsey Ricardo. A sketch competition design for Oxford Municipal

Buildings, a funny little elevation executed on grey paper, and the walls and mullions tinted white. Perhaps it owes some of its effect to this peculiar method of execution, but the treatment is certainly original; the lower portion is plain wall pierced by small mullioned windows and a low-proportioned round-arched door (modern American fashion) in the centre, the upper portion of the wall is almost entirely pierced by the range of large mullioned windows of the Assembly-rooms, with a cornice immediately on the top of the mullions; the large windows have piers between them with niches and statues, and a row of shields under the sills. The main feeling is Gothic, but the library on the right seems tacked on in a Classic style, possibly to harmonise with something round the corner in High-street; the site for the building is a very straggling one. A small plan is added. This little drawing shows a great deal of architectural originality, and we may surmise that the finally-selected design will not be anything as picturesque as this façade would have been.

1,686; "Studio House;" Mr. Maxwell M. Smith. This is noticeable as one of the few drawings showing a house entirely in geometrical drawings and plans. The house is planned chiefly for the studio, the other rooms merely collecting around that. There is however nothing out of the common in the design, except the little joke of breaking the long sloping line of coping of the lean-to roof of part of the offices by cutting a semi-circular coop out of it half way down, and placing a tone hall on each side, which is piquant.

1,691; "S. Miguel, Jerez, Spain;" Mr. F. W. Bedford. A good interior view, hung not so high as the other two by the same hand, though still too high to see the detail; but this is evidently a well-executed drawing of its class.

Two other drawings by Mr. Bedford, 1,699 and 1,700, "West Doorway, S. Miguel, Jerez" and "Interior, Cathedral, Genoa," are again skied on the other side of Mr. Babb's large drawing, balancing Nos. 1,676 and 1,677. These five drawings by one architect are thus all thrust up together on to a part of the wall where they cannot be seen, another instance of the unfairness and sturdiness with which the hanging of the architectural drawings has been conducted this year. It might at least have occurred to the "hanger" that if a man had sent in five drawings which were worth a place, it would have been fair to divide the honours of "the key," and to have put say two out of the five where they could have been seen.

1,692; "A Portion of a Proposed Memorial Church;" Mr. H. D. Wilkinson. This is rather a tame pen drawing, but it is an original design. The nave windows are large ones of Late Gothic type, but the buttresses between them are treated in a semi-Classic manner, the upper part above the string-course slightly hatched and cut off square below the roof-line, finishing on pedestals with figures on them. The lower part of the buttresses is connected by a wall nearly flush with them, with long low windows in it; it is not easy to see the meaning of this without a plan, there does not seem space for an aisle of passage, which the windows look like. However, this is at least a church with a little originality of treatment about it.

1,693; "Hunting Lodge near Malmesbury, Wilts;" Mr. H. Wilson. A light sketchy well-executed water-colour of a stone house of quiet domestic architecture, mullioned windows with Classic bits of cornice over them; there is character in the management of the octagon bay with the door in one oblique side of it, and the chimneys have a quaintness of their own.

1,695; "A Country Vicarage;" Mr. T. MacLaren. A capital little pen drawing, but the extreme and delicate plainness of the house will assert itself, perhaps, more than is expected, when it has only the light of common day to eat it off, instead of the glancing effects of the light in a cleverly-managed pen drawing. After all, we want a little architecture in a house, even of the simpler kind. Let the author ask himself the question candidly—Would this house have had a chance of being hung if sent in in the form of a couple of elevations, plan, and section? We doubt if in that form it could have any claim to be hung in the architectural room of an Academy of Arts. It is hung for the drawing, in which there is art, no doubt. But then, is that architecture?

1,697; "Entrance Front, New House, Milverton;" Mr. H. Field. There seems every effort to make it look like an old house, perhaps that

is the reason we are specially informed that is a "new" one.—It is shown in a pleasant sun-looking pencil sketch, rather spoiled by the rough and ready manner of indicating the trees.

1,698; "Altar Cross for Private Chapel, Welbeck Abbey;" Mr. H. Wilson. This is a fine piece of work and a grand drawing; Mr. Wilson's power of indicating texture and surface with the brush is remarkable, witness the drawing of the brass work here. The upper portion of the cross is treated in light enamel decoration, with circles of darker colour in the centre of the arms; at the crossing of the arms is a larger circle within a square, with the angles filled up with beaten ornament. The massive brass stem is also relieved by a circular enamel plaque affixed to it half way up, shewing the expulsion from Eden, and in the base the serpent and the tree are introduced in a richly coloured enamel following the lines of the brass work and contrasting finely with it. This is the finest drawing of decorative work in the room.

1,704; "Dining-room, house at St. Sebastian, Spain;" Mr. R. S. Wornum. A capital little water-colour drawing of a quiet but original little interior treatment of the wall of a room. The mantel is oak, and the room panelled with oak to a height half-way between floor and frieze; the mantel is carried up with ornamental paneling to the frieze; beneath it is a richly-carved sub-mantel end pilasters, enclosing a plain white marble chimney-piece contrasting well with the wood. The plaster frieze is pleasantly treated in delicate mouldings in relief, forming variously shaped panels.

1,707; "Aisle Window, Backburn Church; sketch design;" Mr. Ion Pace. A pretty three-light window with Old Testament subjects in panels under architectural canopies of the accepted type; the scheme and contrast of colour is effective.

1,703; "Interior of a Library in London;" Mr. G. Atchison, A.R.A. A little coloured elevation of a library with bookcases of an Elizabethan pattern ending in an entablature two-thirds of the height of the room, over which an effective wall-paper is delicately indicated. The chimney-piece is in a light grey marble with panels of darker and richly-coloured marble. The effect of the whole is very tasteful and harmonious, though showing nothing new or original.

1,701; "Interior of Nave, Gloucester Cathedral;" Mr. C. E. Mallows. This is the drawing published as part of our illustrations of Gloucester Cathedral in the *Builder* for Dec. 5, 1891. It comes out very well on the walls; being a pen drawing somewhat boldly and strongly executed it is none the worse for being hung a little high.

1,710; "Stained-glass Window, with Early Renaissance detail;" Mr. Clement Heaton. This is an unusual window design; a kind of conventional Renaissance tabernacle is erected on the window, leaving some space at each side; in the lower compartment of the architectural frame (which looks a little too like a fireplace) is a representation of the Nativity, in the upper more lofty arched compartment the worship of the Magi; over the cornice is a small shrine by way of "attic," in which an angel is seated. The space between the architectural frame and the edge of the window is filled with a string of knots of foliage on white glass ground, somewhat of the type of the modelled foliage in the jamb of the Baptistery of Florence doors; realistic sprigs connected on a sort of string. This is not good decorative design, though it is in keeping historically. The general effect of colour is good.

1,709; "One of a Series of Windows, South Side, British Church, Moscow;" Messrs. Ward & Hughes. A lofty two-light window treated in two stories, the upper showing the marriage at Cana, the lower the raising of Lazarus, each subject going through the two lights and divided by the centre mullion. It is notable for the good drawing and design of the figures and draperies, especially in the Lazarus subject, in which there is more of movement and expression in the figures than is commonly found in stained-glass design. The subjects are crowned with conventional representations of Gothic vaulting as frequently introduced as a canopy to niches.

FRENCH ART OF THE YEAR.

A CERTAIN special interest attaches to the Salon of this year, from an architect's point of view, owing to the presence of a larger proportion than usual of pictures avowedly studied and painted as ceiling or mural decorations, for the Paris Hôtel de Ville and other buildings. The French seem now to have fully adopted the system of executing such paintings on canvas and fixing them in their place afterwards, so that the large compositions executed for this purpose can be hung in a miscellaneous picture exhibition and judged along with the rest as framed pictures, before being finally placed *in situ*. This is convenient for those who wish to study such decorative paintings collectively, though it is hardly fair to the pictures themselves that they should be seen apart from the architectural framework for which they are intended; at least, it would not be fair if the paintings had the true character of mural decorative art. Unfortunately most of them have not, they have the character of easel pictures much more than of mural pictures, and really look more in place in an exhibition than they will on the walls they are intended for, except in the case of ceiling paintings which, painted to be seen horizontally, have to be hung vertically at the Salon, with rather curious results. This system of painting on canvas and then fixing up the pictures has the advantage of avoiding the chances of injury to the paintings from damp in the walls or efflorescence on the plaster, but on the other hand it removes the paintings from that intimate and monumental relation with the construction which seems the very essence of mural painting; and we cannot help thinking that the system has a bad effect upon the artists, and leads them to forget the true conditions of mural painting, and to indulge in vagaries on which they would hardly have ventured under the sobering limitations of fresco painting on the actual wall surface.

M. Benjamin Constant's "Paris Convient le Monde à Ses Fêtes," the painting for the central ceiling compartment of the Salle des Fêtes of the Paris Hôtel de Ville, though odd enough in idea, is perhaps the most successful work of its class in the exhibition. It has the merit of being painted as a picture on a limited plane, and not a perspective *di sotto in su*, as are many of the other decorative designs. "Paris" is represented as a lady in a hall dress seated in the clouds, and partially relieved against a break of blue sky, but the figure is kept so faint as to lose all realism and appear rather a suggestion than a figure. Below, geniuses in masses of drapery with a yellow glare, blow trumpets. The effect is somewhat violent in colour, but it is brilliant and decorative. The mistake is the introduction of a bit of the façade of the official buildings at the top of the Place de la Concorde, in the lower corner of the picture, the building being quite out of place in such a composition and appearing crushed beneath an allegorical figure leaning over it. It would have been much better if this realistic architecture had been omitted; it is out of the scheme. But otherwise, this is a brilliant and effective piece of work, though there will always be the difficulty of knowing which way up to look at it when it is in its place on the ceiling.

That is the mischief of ceiling painting, and the only defence for the system of painting in upward perspective from the eye (*di sotto in su*), which is a rampant sham, but at least one knows which way to look at it.

M. Ferrier exhibits a compartment for the ceiling of the same rooms, "Les Fleurs," also bright in colour, two women below out off by the frame, and a girl flying in mid-air with a basket of roses; not had as decoration, but fancy it on the same ceiling with Benjamin Constant's painting! The collection will be absurd; they belong to two different worlds of painting. Then we have M. François Flameng's immense, brilliant, and very cleverly-drawn ceiling for a private mansion, "Dans l'Olympe," the gods and goddesses drawn with their feet towards the spectator, and a circular temple in the angle appearing to stick out into space; a conventional representation of the Signs of the Zodiac forms a circle concentric with this across the middle of the picture. Some of the figures are admirable, that of Mars especially, seated on steps, and when the composition gets into its proper place on the ceiling it will be a fine thing of its kind, though the wrong kind. On like principle doea M. Moreau-Néret design "for a terminia hôtel" a ceiling surrounded by

APPOINTMENT.—Mr. Reginald G. Pinder, of Bourne-mouth, has been appointed Architect to the School Extension Committee of that town.

a trellis fence in upright perspective, and "Abundance," "La Chasse," "La Pêche," and other such personages playing in the blue sky. Then we have another Hôtel de Ville ceiling, M. Morot's "Les Danses Françaises à Travers les Ages," representing the dance of different centuries and costumes up to the modern waltz, carried out on clouds by figures in the costumes of the various periods; cleverly painted, but we fear amusing in a sense not intended by the painter.

A curious and clever experiment in decorative painting is that by M. Ruel, "L'Art Présentant à la Ville de Moscon la Peinture et la Sculpture Française," in which the figures of Painting and Sculpture are treated as if they were modelled figures executed in silver (life-size), and two little boys with symbolical shields occupy the centre of the composition in front of the principal seated figure. This is absolutely decorative, that and nothing more, and as a new experiment in decorative painting is worth attention. Among other decorative paintings are M. Aubert's "Patriarchs, Prophets," a processional decorative composition of the pure school, in one plane and on a gold ground (rather dull though); M. Bertain's clever design for a stained-glass ceiling,—but here again we have this system of vertical perspective, a row of foreshortened columns in the side panels of the glazing,—the centre panel showing flying figures which are spirited and effective; M. Debon's "Famille, Travail, Exercice, et Repos," a wall-painting for the Mairie of Saint-Maurice, in which modern figures are treated in a sufficiently conventional manner, and which tells its story well; and M. Ehrmann's lunette figures for spandrel spaces in the Salle des Fêtes of the Hôtel de Ville, representing Bretagne and Auvergne. These are very successful, well contrasted, combining decorative effect with spirit and meaning. But a vertical spandrel like this is no doubt a much easier problem than a ceiling. Finally, M. Tony Robert-Fleury has painted for the Hôtel de Ville a figure representing "Architecture," a richly-draped finely-modelled woman who holds a pair of compasses and leans on a carved Renaissance pedestal; this is a fine work both in design and colour, but impresses one as not powerful and monumental enough for a figure symbolical of architecture, and the head is small for the body, which adds to this impression. Change the "attributes," and the figure would better represent "Painting."

At the Salon one looks for M. Tattetgrain's picture as at the Academy one looks for Mr. Orchardson's. His work this year is a remarkable revival of a historical scene, "The Entry of Louis XI. into Paris, August 30, 1461." The picture is explained by a quotation from the chronicles of Jehan de Troyes. It is a street scene in Old Paris, showing the ancient houses, the crowd of sightseers, and the humours of the show; the three girls dressed as mermaids, standing in a tank of water; in the background on the other side of the street is a representation of the crucifixion by three men tied on crosses, which formed part of the show; in the centre of the street Louis XI. on horseback, and the knights in armour who formed part of the procession. Every detail in the picture is carefully studied, every figure in the crowd; perhaps the whole looks a little too clean and respectable for a Medieval crowd in a Medieval city. The other important historical picture is M. Detaille's representation of the marching out of the small garrison which defended Huningue against the Austrians in 1815, and were received with honours by their conquerors on evacuating the town. The scene is finely rendered, the brilliant uniforms of the Austrians contrast effectively with the poor array of the small band of defenders. Another fine picture of the historical class is M. Chicoto's "Mort de Pierre Cornille," the old dying man seated in a chair and his daughter kneeling by him: a picture perfectly simple in its composition and truly pathetic in expression. M. Kratki has added one to the numerous pictures of the retreat from Moscow, under the title "Novembre 1812," a snow landscape in the fall of the day, with the long columns of men straggling in parallel lines over the snow; a painting in which there is a tragic realism. M. Motte sends a painfully real picture of the destruction of the Swiss Guard at the Tuileries on August 10, 1792. A finer and more impressive war picture, because one with a poetic idea in it, is M. Rouffier's "Le Chemin de la Gloire," a bare landscape out-

across by an equally bare high road, at one side of which lie a dead cavalry soldier and, a little apart from him, his dead horse, while in the distance a troop of cavalry disappear over the hill. This is one of a class of pictures in which the French excel, and of which we have unfortunately so few to show among us; pictures which are interesting not only for their execution but for the thought which underlies them. M. Roussel's large painting, "Le Corps de Marceau Rendu à l'Armée Française," is a fine and impressive one of its kind; it is divided into two main groups, that of the officers awaiting the return of the body of their brilliant comrade, and that of the group who approach in the middle distance with his bier borne upon their shoulders; the spectator involuntarily identifies himself with the group in the foreground; the composition is natural and unforced, and tells its tale completely.

Among the figure pictures of the more imaginative class are some which detach themselves from the mass of paintings as of special interest. M. Gerome's "Is Conspréit" is a curious and original treatment of the subject; a long bare room nearly in darkness, at the further corner of which are three men seated at a table lighted by a single candle, two of them with their backs to the spectator; of the third only the profile is partially seen, but the expression of something sinister going on is completely conveyed. Nude studies are not quite as numerous or as unmeaning and devoid of point as we often find them. Among the more poetic works of this class the finest perhaps is M. Lewe-Marchand's picture from Dante of "Myrrha" (*Inferno*, canto xxx.), a naked figure crouched in the foreground of a rocky gorge; in the background Dante and Virgil turn back to look at her; the figure is finely painted and the face darkly expressive of evil passion; this is a poetic conception and not a mere figure study. Benner's "Printemps," a figure reclined on the grass partly in shade but with the head in full sunlight, is one of this painter's usual pretty idyllic conceptions. "Phœbe's Eveille," by M. L. Barthault, is a fine composition of ideal figures; M. Bouguereau's "Le Guépier," a half-nude nymph persecuted by a crowd of little Cupids, is as pretty and scholar-like as usual with him. M. Cabane's "Nymphé" (325) is a fine example of nude painting with no particular meaning or sentiment, but striking from the richness and freedom of its execution. M. Raphael Collin's "An Bord de la Mer," a party of girls dancing in a ring on the seashore, is one of a class of works in which idealism is sought for not in the conception of the subject but in the mode of execution; the figures are faint and dream-like in execution, and thereby removed from real life; but the painter has spoiled all by giving to these nude figures the pinched waists which come of the artificial conditions of tight dresses, a curious and unhappy intrusion of realism into what should be an ideal scene. M. Henri Martin, too, in his allegorical paintings, adopts a method of execution peculiarly suited to such subjects; we have not real bodies so much as suggestions, and this gets over a great intellectual difficulty of allegorical painting, in which frank realistic execution of figures is wont to contrast, sometimes almost absurdly, with the poetic character of the thought intended to be conveyed. Moreover, M. Martin's method of execution leads him into very fine prismatic though subdued effects of colour. He has not equalled this year his remarkable "Chacou sa Chimère" of last year, but "L'Homme entre le Vice et la Vertu" is a fine example of a painting with a moral, in which the moral has not been allowed to kill the painting, as too often happens.

The taste for medical and hospital pictures seems to have subsided again, at least we only noticed one this year; large pictures of scenes in primary and middle-class schools (educational art, one may call it) seem to be taking their turn in fashion. We do not find this type interesting. Among the immensely large pictures which are found only at the Salon may be noted M. Luminais's "Passage de la Mense par les Francs au IV^e Siècle," one of the "Gaulois" pictures, a raft propelled across a river with a crowd of men, a warrior with sword drawn and leather shield standing in front—a spirited picture, but spoiled by the bad painting of the water. M. Deully's "Orphée" is theatrical, but a new treatment of the subject, and M. Salgado's large painting, "Jésus," a

single white-robed figure in a dim twilight landscape, has a certain power and pathos. Among paintings of subjects of real life a very charming one is M. Debat-Ponsau's "A La Saint Roch; Vieille Coutume du Midi," apparently the priest coming out to bless the cattle, remarkable for admirable painting of peasantry and cattle, with the cathedral standing up as a background. M. Léonhard paints with pathos a group of Huguot prisoners (women) on a tower at Aigues-mortes, who were separated from their husbands and kept in semi-starvation; a powerful picture of the historical class. M. Jichir's "Misère," a poor painter in an obscure corner of a brilliant ballroom; M. Richemont's "Sacrifice," an interior with two ladies burning old letters, a painting of the modern flat and thin school of execution, very well drawn and lighted; Mr. Walter Gay's "Messe en Bretagne," are pictures with a distinctive character in idea or treatment. M. E. Michon paints a ghastly picture of the realities of a hull-fight; Mr. Bridgman contributes the unusual subject (for him) of a very beautifully-painted nude figure, "Le Songe;" and M. Lavery's "Une Equestrienne," a life-size painting of a lady on horseback, which has been seen in London, holds its place splendidly here, and looks all the better for being exhibited in a larger room, and with more space to see it than when it was in Bond-street.

The average of portraits for the year is good, and there are some remarkable ones. Among these may be mentioned M. Bonnat's uninviting but very powerful portrait of M. Renan, and the same artist's "Mme. L. N.," apparently in rivalry of Carolus Duran, a lady in a sumptuous dress of purple velvet with a yellow-lined cloak; M. Brouillon's portrait of "Mme. A. B.," in a white dress with the head thrown out brilliantly against a red background; M. Chartran's portrait of the reigning Pope, a very spirited and expressive performance; M. Choppart-Mazeau's portrait of his mother, an old lady in a fur cloak, painted in full daylight in the open air; M. Paul Dubois' half length of a young lady, noteworthy for its dignified composure of attitude and expression; M. Ferrier's characteristic portrait of a little girl in a green dress standing before a half-opened door; Mlle. Fornier's fine though slightly theatrical portrait of a noble-looking young lady in a primrose-coloured dress holding a greyhound; Mlle. Houssay's "Mme. la Comtesse A.," remarkable for the intellectual expression imparted to a plain but interesting face; M. Renouf's "Mme. X.," noticeable for the same kind of excellence; M. Salgado's frankly realistic portrait of a man lounging with his hands in his pockets,—one of the *déjà vu* order of portraits, and last but certainly not least, M. Benjamin Constant's portrait of "M. Anguste L.," a man in shooting dress seated on or leaning against the end of a table with a gun, a dog beside him. Few would put down to the account of M. Benjamin-Constant this sober-looking portrait, so quiet and subdued in colour, but it is one of the most lifelike and real things in the exhibition, and another proof of the versatility of this remarkable artist.

Where, O where, is the great school of French landscapists gone? The great men are departed, and seem to have left no successors. What strikes one especially is the dull and deadly colour of nature, the lack of air and sunlight in the majority of the landscapes. I am among some of the cattle painters in the Salon that we find the most vivid and real open-air effects, as in M. Merlot's "Troupeau dans les Marais de la Somme," which may be contrasted in this way with M. Marais' "A Retour" which hangs as a pendant to it, where the cattle are forcible and solid enough, but that is all. Again and again we find the same dull sky and livid colours in what is supposed to be the verdure. Those in which architecture or buildings are combined with landscape are the best, for buildings the French painters of the day generally treat well. M. Liepvre essays a large decorative landscape for a staircase; we do not like the notion of decorative landscapes, but this one is something of a success, being bright in tone and not too realistic. M. Besnard the king of the Impressionists, at all events does not shirk light and colour; he is represented only by one landscape, "Etang de Sologne" which is vigorous enough. There is tenderness of colour and light in M. Dieterle's "Le Calvaire de Crèquheuil-en-Caux," a scene

high down with a crucifix and a kneeling figure in the foreground. M. Gaillard's "Un min de Pré en Fleurs" is as hard as if they were paper flowers, and again there is a contrast with its pendant, M. Grivolos' "Bonnissans des osses," which has the freshness of nature. M. Guillemet's "La Seine à Confans" is a good balustrade landscape, and M. Louchet's "La Seine la Frette" has higher qualities, and is noteworthy for the harmony of the whole lines laid by sky and land in the composition. F. Pointelin's "Jorn" is a landscape with some of the poetry of nature in it; and F. Quignon's "Avouines en Fleurs," a sketch of undulating meadow country, is a really fine work, which we are glad to see the State has had the discernment to purchase. M. Schutzberg's "Les Bords de la Seine en Hiver" is a good real scene in its effect and lighting. But among such a large collection of paintings there are really very few landscapes that would give cause to any one accustomed to our modern English landscape school, in which at least we are far ahead of the French though it is only of recent years that this could be said. We may as well make the most of it, for it is only in this department of painting that we can pretend to heat them, including sea-pieces under the general head of landscape. The Salon sea paintings are even more bewildering than the landscapes. M. Knawasseg's "Coup de Mer à Tréguier" is water more like ice; the sense of movement is lost. M. M. Angeste Flameng paints a ship in a gale, "Marine" which at once leads us to ask whether the painter ever saw the sea, much less sailed on it. Certainly he never saw sea like that, nor a ship seated on it in the extraordinary way in which his craft is represented. The whole thing reminds one of the model ships on inflated paper seas which are sometimes made as toys.

It is curious to note that on going over to the new Salon in the Champ de Mars one loses to great extent this impression of dull and airless landscape. The New Salon is to some extent unquestionably impressionist in its tendencies, and the impressionists delight in painting effects of light, and seek for them. As regards choice of subject there is a prevalence also of southern landscapes and of their strong effects of light and shade. Generally speaking, however, the Salon of the Champ de Mars hardly justifies its separate existence. It has had a great success of course in Meissonier, and now it may be said that the lion of its exhibitions is M. Carolus-Duran, who however is really in direct opposition to what are supposed to be its prevalent artistic methods, and would be more in place in the old Salon. He exhibits, as usual, a collection of his brilliant and powerful portraits of dignitaries in whom the interest of portraiture is divided with that of dress, or rather the portrait is a portrait of the dress as well as of the lady. The finest is the portrait of the Comtesse de C—, in lilac satin against a background of an "old gold" velvet screen. There are other portraits by this artist of the same degree and kind of excellence, and a study of a semi-nude figure which is as fine in its way as the painting of the silks and satins. The New Salon has also its large decorative painting, by M. Puvis de Chavannes, a great success entitled "L'Hiver," and intended for the Hôtel de Ville. It consists of usual groups of figures mostly of great grade admirably grouped, and a landscape, painted in flat tones and with as little as possible of realistic truth, in the rear. The middle distance is partially occupied by trees nearly equal distances and with bare straight critical stems, which may be supposed to be decorative or to give a decorative character to the landscape, but which are not beautiful nor suggestive of nature. We have also M. Arnal's large decorative picture for the faculté de Médecine of Lyons, which would not have been painted, or not painted if it, had not M. Puvis de Chavannes led the way. It is a scene en plein air in a garden by a river side, with a bridge on the right (probably local scenery) and groups of learned men in more or less academic garments scattered about it, balanced or contrasted by groups of women and children, leaving wherever plenty of open space between the figures. It is a picture in a flat fresco style, and in that sense decorative, it (like that of Puvis de Chavannes) is deficient in warmth of colour for a really decorative work. M. Béraud, who astonished us last year by a painting of Christ in a Parisian

club-room, has repeated the same kind of idea this year in a picture of the Descent from the Cross, the body being taken down reverently by French *ouvriers*, one of whom shakes his fist at the wicked city below him which evidently takes the place of Jerusalem in the tragic drama; a Parisian lady kneels and clasps her hands with an expression of agony and contrition at the sight of the dead body. To say the truth, though we thought last year's picture striking in spite of its extraordinary combination of real and ideal, we doubt the wisdom in any sense, artistic or otherwise, of repeating the idea, and it very narrowly escapes the borders of bad taste, some would say irreverence. "Les Nauties Parisiens à l'Époque Gallo-Romaine," by M. Delance, is another decorative painting intended for the Salle d'Audience of the Tribunal de Commerce, representing the ancient Paris quay and the unloading of a galley, but the painter does not succeed in giving reality to the scene or rendering it very interesting.

One of the most prominent and clever pictures in the New Salon is an interior with four life-size figures, by an American lady, Miss Lee-Rohbins, under the title "Five o'Clock;" probably it is really a set of portraits, under which category it is defensible; as a mere *genre* picture it is far too large for the subject. Mr. Sargent's "Carmencita" is here, looking even more brilliant and powerful than it did at the Academy, as it is in a better light. Mr. Whistler is prettily largely represented. Mr. Lhermitte has followed the lead of M. Béraud by introducing a figure of Christ seated at table in a workman's caharet, under the title "L'Ani des Humbles," a fine picture, but this use of a sacred figure to produce what may be called a cheap sensationalism is much to be deprecated, and it is to be hoped we shall see no more of it. Among other things to be specially noted are M. Dagnan-Bonveret's portrait of a lady in white; M. Damoye's large landscape, "Un Marais"; M. Edelfeld's portrait of Prince Charles of Sweden; Miss Foss's "Ouvrière Fleuriste," an interior with a life-size figure (the artist is an American); M. Gandara's "Entre la Coupe et les Lèvres"; M. Karbowski's "L'Anniversaire," a cemetery scene of decking a tomb, with many figures, intended as a decorative painting for the Mairie of Nogent-sur-Maine; M. Mathey's "Portrait de Mlle. M.—"; M. Parrot's "Baigneuse," a figure seated on the bank of a stream in full sunlight; and M. Rondel's "Portrait de Madame H. R.—"

The attempt to keep up two Salons is more and more obviously a mistake; there are sufficient important works in the two to make a splendid collection if they were kept together, and the average level of both exhibitions suffers by the division. On the other hand the New Salon contains many very charming small landscapes which would be crushed under the numbers and inferior lighting of the Champs Elysées exhibition; and the real part for the New Salon, with its admirably lighted rooms, to take, would be to restrict the wall space and make it an exhibition of cabinet pictures, such as would not be seen to advantage in the larger Salon. It would have a *raison d'être* then; it has none now, as it can hardly be said to represent any special tendencies.

Sculpture is but poorly represented at the Champ de Mars, and architecture practically not at all; the old Salon completely holds its place in these two departments. The two most noticeable facts about the sculpture exhibition at the old Salon are that M. Falguière does not exhibit, and that M. Gerôme appears as a sculptor, with two curious and very highly-finished works, neither of which however can be called satisfactory. One is "Billone" (Bellona), a figure with the flesh parts in ivory and the armour and draperies in bronze; the figure has her mouth wide open as if screaming, a cohra reared at her side repeats the action; the thing is sensational and un-sculpturesque. M. Gerôme's other work is Pygmalion and Galatea, at the moment when the statue comes to life; still standing on the block on which she has been modelled, she turns to kiss the sculptor, who died in working tunic, stretches up to her embrace; the marble of the female figure has been tinted slightly, and the hair nearly realistically tinted, but this is not overdone; the decorative effect is very good; the failure of the work is that, while splendidly modelled, it is utterly deficient in hearty and sentiment, Galatea being a very ordinary female model; the poetry of the legend

has been entirely lost, and we see only an atelier study. Of the sculpture generally it may be said that it is not up to the highest level for the Salon, though there are many works which would give the artist a first-rate place in the Royal Academy sculpture-room. The central work is the half-size model by M. Peynot for his great monument "À la Gloire de la République" for the town of Lyons; a fountain with a column in the centre, with groups of figures planted against it on three faces, a fountain basin below with figures of Neptune and Amphitrite, and the female figure representing the Republic seated on the prow of a ship above. The half-size model gives the figures life-size or rather more. This is a grand work and very finely composed in a decorative sense. The same sculptor exhibits marble groups of the "Four Quarters of the Globe" for the chateau of Vaux-le-Vicomte, also a very fine and serious work. M. Mercif has a beautiful figure of "Le Regret," a heavily-draped female figure leaning on a tomb and placing flowers on it; apparently a monument; the treatment of the drapery and the indication of the pose of the figure within it are in the highest style of sculpture. M. Marquette exhibits a spirited group of a centaur and a female figure under the title "Nessus," but the subject is rather grotesque from the point of view of the present day. M. Frémiet exhibits a fine alto-relief equestrian statue of the Constable Oliver of Clisson. An American sculptor, Mr. French, exhibits a fine bronze alto-relief, "L'Ange de la Mort et le Sculpteur," the figure of Death, heavily draped and with part of the drapery forming a kind of hood and throwing the head into shadow, arrests the sculptor in the midst of his work; it is intended as a monument for the tomb of a sculptor. M. Lombard has a finely-composed group of Samson and Delilah, and M. Hugues a powerful work entitled "Victoire," a warrior who has conquered but is fainting from his wounds, supported by a companion. This is an illustration of the quality of original thought and conception which gives so much interest to a collection of French sculpture. There are a good many works, no doubt, which are simply finely-modelled figures, but there is a considerable proportion of subjects which show original thought either in the idea or the treatment. M. Charrou's "Sommell de Penfance" is one of these, an infant sleeping with a finely-modelled and draped figure of an angel playing a violin beside him, in illustration of the lines:—

"Il dort paisiblement; sur le violon d'or
Son ange interprétant l'harmonie éternelle."
Echante son sommeil, l'arbre de son aile."

Here the sculpture is a poem in itself: so also is the late M. Christophe's figure of the man clutched in the embrace of the Sphinx,—

"Dans l'éclair d'un baiser qui vaut l'éternité."

This is a marble group of which we remember right, the plaster model was exhibited in a previous year. M. Rongele's "Hero and Leander," again, is no mere group of figures, it is remarkable for the intensity of expression in the faces, which yet does not transgress the conditions of sculptural art. M. Chevalliant's "Génie de la Liberté," a bronze male figure *adossé* on a pillar or stele, is a spirited work, intended for a commemorative monument of the "Federation Brétonne et Angevine de 1790"; the architectural portion is designed by MM. Deperthe, the architects. The French sculptors set ours a good example in this respect, in almost invariably going to an architect for the design of the subsidiary details; nor is the architect's name and his share in the work ever overlooked.

DISCOVERY OF AN AZTEC CITY.—A party of Mexican labourers, while digging in the extension of the Santa Cruz Canal, Arizona, came upon what is believed to be an old Aztec city. They struck the first ruin in cutting through the desert about 20 ft. below the surface, where it had doubtless been covered up by sandstorms. Everything about the old building had been wonderfully preserved, owing to the alkali in the sand. The first building disclosed consisted of a triangular structure about 300 ft. in length and 200 ft. in width. The roof had caved in, but the wooden pieces by which it was held together were sound. They were pulled out of the old wall, and are on exhibition at Tucson. In the building was a stone trough in sections, held together with cement. There were eighteen bodies in the building, all of them of medium size, and their flesh was mummified. — *Anglo-American Times.*

THE ROYAL INSTITUTE OF BRITISH ARCHITECTS:
THE ART OF INTERNAL ILLUMINATION OF BUILDINGS BY ELECTRICITY.

At the ordinary general meeting of this Institute on Monday evening last, the minutes of the previous meeting having been read and confirmed.

The President (Mr. J. Macvicar Anderson) said that happily there was no preliminary business to stand in the way of the subject which was to come before the meeting and occupy their attention that evening. That subject was one of great interest not only to the public but to the architectural profession. That meeting had been arranged for by the Science Standing Committee, and he would ask Mr. Lewis Angell, the Chairman of the Committee, to say a few words by way of introducing the lecturer.

Mr. Lewis Angell said that as Chairman of the Science Standing Committee he had very much pleasure in introducing Mr. Preece to the meeting,—not that Mr. Preece needed any introduction. Notwithstanding his many engagements, he had been good enough, at the request of the Committee, to prepare a paper for their instruction. Of course the reputation of Mr. Preece as a scientist and as a specialist in electricity was well-known to them all. Electric lighting was at present making such rapid strides, and there was so much demand for it, that the Science Committee felt that the Institute should, as far as possible, be kept abreast of the subject. It was not desired that the discussion should run very much into the scientific and mechanical details connected with the generation and distribution of electricity, but rather that it should be directed to the artistic aspect of the question, so that the members might learn what was the most elegant and useful way of using the electric light in order to get good effects without painting the eye or offending the taste by violent contrasts, garish blazes, and deep shadows,—defects which had been only too apparent in many installations. It was desirable that architects should get out of the hands of the mere workman and gas-fitter, who had, as a rule, very little appreciation of the delicacies of light and shade and of the decorative harmonies. There was one practical point, however, to which architects must give their serious attention, and that was the steps to be taken to avoid danger in the use of the electric light. As an aid to their study of the question, Mr. Preece had been kind enough to provide the Science Committee with a working specification, which would, no doubt, be printed as an appendix to his paper.

Mr. W. H. Preece, F.R.S., Electrician to the Post Office, who was very heartily received by the meeting, then read his paper "On the Art of Internal Illumination of Buildings by Electricity." The following is an abstract of the paper:—

The art of internal illumination of buildings, the author considers, is just born, and will be an art in the future. Electricity is rendering theatres, hearable and houses healthier, while the architect is brought face to face with a new art, in which the aid of the electrician is required to solve some of the difficulties. History is silent as to the origin of tallow, pitch, wax, and oil, but gas as an illuminant came in with the present century. From the earliest days history, whether culled from paintings or writings, teaches that lights have been dim and crude until the middle of the present century. Light, by whatever means generated, follows the same laws, and is due to the rapid rhythmic undulations of the medium called ether that fills all space. Wherever there is light there is heat, and the hope of the philosopher to supply light without any heat at all is at present but a dream. Light cannot be produced without heat, and the higher the temperature the brighter the light. Colour varies with the rate of vibration of the ether, while changes of colour are due to the changes of wave-motion of the ether. Light may become so intense that all sense of colour is lost, and very bright illumination causes all colours to appear whitish. If light emanates from a point, its intensity diminishes with the square of the distance. The candle is the British standard by it at a distance of 1 ft. the standard illumination by which to measure the amount of light distributed by any other means. This standard Mr. Preece calls a "lux." The great problem is to diffuse light throughout a room so that it

be distributed uniformly over the working surfaces with an intensity of a lux. Sixteen-candle glow lamps suspended 8 ft. above the floor and fixed in 3 ft. squares, effect this very well; and groups of four such lamps fixed 16 ft. high produce a similar result. The light a lamp gives is owing to the expenditure of energy in its carbon filament; an electric current is driven through this filament by electric pressure, its resistance is overcome, it is intensely heated by the proceeding, and the result is pure unadulterated light. The energy expended per second by an ampere (the standard current), driven by a volt (the standard pressure), is called a watt. A sixteen-candle glow lamp takes sixty-four watts, which, assuming the lamps to be fixed 8 ft. high, means that one watt per square foot of surface is required to secure ample illumination from lamps so fixed. Therefore, in designing the normal illumination of rooms, Mr. Preece takes the floor area in square feet and divides it by sixty-four, which gives the number of sixteen-candle power lamps required, fixed 8 ft. high,—these being increased or diminished according to the purposes of the room, its form and height, &c. The adaptability of the eye to nearly every degree of light is very great, and it is almost impossible for it to judge accurately of the amount of light present; but it is not as a mere source of light that the glow lamp is superior to the gas-burner. The former can be put anywhere, and used without the adventitious aid of match or fire. It does not vitiate nor unnecessarily warm the air, and it simplifies the problem of ventilation, while it lends itself above all to the aesthetic harmony of furniture and decorations. Electric light is not always absolutely safe; security is to be obtained only by good design, perfect materials, first-class workmanship, and rigid inspection. Imperfect materials erected by cheap contractors lead to many disasters, on the other hand, it is stated no fire has occurred in buildings fitted up under the rules and regulations, and inspected by the officers, of the insurance companies in this country. Mr. Preece advocates keeping everything as much as possible in view, and not hiding the conductors under wainscots or floors or above ceilings. The glow lamp excited by three watts per candle is at present the most perfect source of domestic light, and when the patent expires,—in a year or two,—will be obtainable at one-third the present price. It is scarcely fair, Mr. Preece thinks, to say all light should come from the side of a room, as Lord Beaconsfield stated in "Lothair" when describing the lighting of Belmont. The House of Commons is one of the best-lighted chambers in London, and is lighted from the roof, a false glass ceiling excluding the heat and glare, and admitting only the light. What is wanted is to avoid the glare of the incandescent filament in the eyes, and to prevent the lamp from being too obtrusive; it can be shaded from the eye without its effectiveness being destroyed, and without the flow of light being obstructed or its quality being deteriorated. Judging from the Crystal Palace Exhibition, at which several leading firms have not exhibited, the electric light fitter has not seized upon the spirit of the age,—which is the rule of science over mere conventional aestheticism. Two exhibits at the Crystal Palace, however, especially deserve the author's consideration. The one is a Tudor ribbed ceiling erected by Messrs. Allen & Mannooh, who have applied glow lamps to the moulded intersecting pendants in such a way that the feeling of the artist is maintained by day, and is rather intensified, and not marred, by the artificial illuminant at night. The other is a bold attempt of Messrs. Rashleigh, Phipps, & Dawson to design in ironwork the whole of the fittings of a dining-room, so that they shall, in combination, convey an idea. The artist (Mr. Reynolds) has attempted to symbolise the solar system, the centre light over the table representing the sun, and the brackets on the walls the planets. A survey of the Royal Academy pictures, the author thinks, affords instructive study. There are many interiors, but few into which artificial light has been introduced. Having described several pictures in which artificial light has been introduced with more or less successful results, Mr. Preece, in conclusion, said he considers that Science is advancing with giant strides. Science has subdued nature so as to bring it within the compass of the human intellect, and Art must follow the knowledge thus acquired. These two being the

chief instruments of modern civilisation, the architect and engineer must work hand in hand.

Mr. John Slater, in proposing a vote of thanks to Mr. Preece for his paper, said it was exactly ten years ago since the Institute meeting-room was first lighted by electricity, but not without many difficulties in the regulation of the intensity of the current,—difficulties which had been overcome by the invention of the Sellen-Volkmar storage cells or batteries. Science, as Mr. Preece had said, had made great strides during the past ten years, but he (the speaker) was inclined to agree with him in thinking that no very great advance had been made in the way of artistic illumination by electricity. It was true that the theatres had had an entirely new world of possibilities opened to them, and that by the use of electric lamps in all sorts of positions they were able to get effects which would never have been dreamt of twenty years ago. Referring to the present Crystal Palace Exhibition, he thought there were some things there which were absolutely wrong. For example, there were candelabra with imitation candles, having incandescent lamps at the tops; this was a striking exemplification of the length of absurdity to which some people would go in their adhesion to old and past customs and ways. No doubt everyone who had seen the interior of the House of Commons at night would agree that it was a most admirably lighted interior; but then the lights which actually lighted that chamber were all hidden behind the ground-glass ceiling, so that none of the glare from the lights reached the eye, and the light was perfectly diffused. That seemed to him to be the sort of thing in the way of artificial illumination that should be generally aimed at, whether in public or private rooms. But he could not understand why Mr. Preece should praise the lighting of the House of Commons, and at the same time condemn as he had done, the use of ground-glass incandescent lamps. He (Mr. Slater) thought that unless we used low-power lamps, which were not economical, we were bound, in some way or other, to screen off the direct glare of the filament of heated carbon. If Mr. Preece could tell them how the glare could be avoided without any diminution of the effectiveness of the light they would all be very much obliged to him. Mr. Preece had alluded to the attempts which had been made, at the Crystal Palace and elsewhere, to accentuate the architectural forms of a ceiling by having incandescent lamps placed at the junction of the mouldings, or in little hollows. That undoubtedly was an exceedingly effective means of illumination, but it could not be denied that it was also, to a certain extent, a very extravagant method of lighting, because the reflectiveness of the ceiling was altogether lost. In conclusion, Mr. Slater said that he thought the Science Committee, in conjunction with Mr. Preece, were deserving of the hearty thanks of the meeting for having given them such an extremely artistic evening.

Mr. Henry Dawson seconded the vote of thanks, said that Mr. Preece was eminently deserving of their thanks for the very valuable and practical paper which he had given to them. He was glad to hear him emphasise the necessity of having good work, properly supervised, if danger from fire were to be avoided, and he thought it was a matter for congratulation that electricity could not be adulterated, and that the use of electric lighting would promote health and cleanliness by saving it air of our rooms from becoming over-heated and vitiated.

Mr. Sidney Vacher said that the discussion seemed to have a tendency to become limited to such details as the relative advantages of ground and underground glass. He should like to see the question discussed on a broader basis. How, for instance, would they light the Church of Sta. Sophia at Constantinople?

Mr. T. Taylor Smith said he thought the subject had been introduced at a very fitting time, because he were now acquainted with the technical necessities which were the foundation upon which we might work to produce pure art, truthfulness of design, or consistency of purpose. He thought it was fortunate that they now had in the electric lighting industries a very different set of people to those who were lunched out on the introduction of the gas industry. It was lamentable to see hanging over the fontwork lamps 3 ft., 4 ft., or 5 ft. in diameter shielded three or four fish-tail burners.

Mr. W. Bainbridge Reynolds said that in designing electric-light fittings, the quality of movement or unrigidity which differentiated the electric light from all other methods of lighting was one which should, he thought, be expressed in the design of the fittings, and consequently he thought that the best position for a glow-lamp was vertical and pendant.

Mr. E. Manville, Mr. R. C. Crompton, Mr. Aston Webb and Mr. Joseph Goddard, having spoken, the President put the motion for a vote of thanks, which was carried by acclamation. Mr. Prece, in reply, said he was much obliged to the meeting for thanking him, but he, in his turn, had to thank the audience for listening to him so attentively. He was rather sorry that his paper had not been more fully criticised, for there had been very little criticism indeed of any consequence, if he excepted that of the gentleman who complained that the subject had not been dealt with on a sufficiently broad basis, and who wanted to know how they would light the Mosque of St. Sophia at Constantinople? He was reminded, by that remark, of Mr. Dick, in "David Copperfield." Mr. Dick lived in a small room near Charing-cross, with which he was very well satisfied.

Somebody, alluding to the smallness of the apartment, told him that "there wasn't room to swing a cat there," to which Mr. Dick replied, "I don't want to swing a cat." Neither did English architects want to consider, at present, how to light up St. Sophia; they had to consider how best to light their own English interiors. Mr. Slater had twitted him with the fact that while he had objected so strongly to ground glass as an obstruction to light, he spoke approvingly of the lighting of the House of Commons, which was entirely through ground glass. It was quite true that the House of Commons was admirably lighted, the light being well diffused and distributed. But then Mr. Slater had probably never seen the gas-bill: he (Mr. Prece) had, and he knew how large it was and what a serious waste it represented. There was quite six times as much energy wasted in lighting the House of Commons than was really necessary. But people did not want to have the light directly in their eyes, and the problem to be solved was, how to avoid that in an interior which was to be lighted effectively and without glare, and, at the same time, with some regard to cost. He was not an advocate for ceiling lighting, except when the lights could not be put anywhere else. What was wanted was that the lights should be so disposed or arranged that they should fairly distribute the light in every direction. In conclusion, Mr. Prece referred to a number of the things exhibited in illustration of his paper, and said a few words as to the electric lighting of the Institute meeting-room, which, he said, was not as efficiently lighted as it might be.

On the motion of the President, a vote of thanks was accorded to the several firms who sent exhibits to the meeting, viz., Messrs. Benjamin & Froud; Messrs. Faraday & Son; Messrs. Walter Glover & Co.; Messrs. Laing, Wharton, and Down; Messrs. Strodé & Co.; The Planet Electrical Engineering Co.; and the Tayler-Smith Electric Co.

The meeting terminated with the announcement that the next meeting of the Institute for the present session will be held on Monday, May 30, when papers will be read on "Castings in Metal," &c. This meeting has been arranged for by the Art Standing Committee.

THE NOTTINGHAM SEWAGE FARM.

DURING the recent Midland Counties District Meeting at Nottingham of the Incorporated Association of Municipal and County Engineers, a visit was paid to the Borough Sewage Farm at Stoke Bardolph, as mentioned. The following description of the farm has been kindly furnished to us by Mr. Arthur Brown, M.Inst.C.E., the Borough Engineer:—

The question of utilising the sewage of the Borough, and thus preventing the pollution of the river Trent, was forced upon the Corporation as early as the year 1870. The riparian owners naturally objected to the sewage of the town of Nottingham being passed direct into the river, and threatened the Corporation with an injunction to restrain them from further polluting the river Trent. The Corporation, recognising the absolute necessity for an improvement being made in the condition of the river, immediately set to work to obtain the

necessary powers to enable them to commence operations. At this time, which was previous to the extension of the borough in 1877, the town of Nottingham was encircled by other outlying parishes, the sewage from which either delivered into the river Trent or into the river Leen, a tributary of the Trent. Parliamentary powers were obtained, and a joint Sewerage Board was formed, which consisted of members from the Town Council of Nottingham and from the various Local Boards of the parishes referred to.

The first step was to construct an intercepting sewer to pick up the sewage from the various districts; this was done about the year 1878.

The joint Sewerage Board had in the meantime thoroughly discussed the question of methods of purification, and, after visiting the principal towns in England, decided to adopt that of broad irrigation and downward filtration on land. For this purpose land to the extent of about 640 acres was leased at what was known as Stoke farms, about five miles from Nottingham. The rent asked for the land was at the rate of 57. per acre for a sixty years' lease, and it was found impossible to obtain the land for less than this rent, although a large portion of it was then only let at from 30s. to 35s. per acre. The rent is certainly very heavy, but the Corporation have the small consolation of knowing that they are not treated any worse than other towns when they have to buy or lease land for a similar purpose.

The dry weather flow of sewage is about 6,125,000 gallons per day of twenty-four hours. Of this quantity, 2,125,000 gallons flow down by gravitation; the remainder, however, has to be pumped. The length of the outfall sewer (from the point where the gravitation and pumping mains meet) down to the farm is about four miles, and the sewer is constructed of various shapes to suit the exigencies of the case; where it is in tunnel the sewer is a 3 ft. barrel sewer; where it passes through low-lying meadowlands it is 7 ft. wide by about 4 ft. high, with a flat top of York flags. For a length of 1,000 ft. through meadow lands the sewage is carried through iron syphons in duplicate, each 42 in. in diameter, and 1,000 ft. long. The ruling gradient of this outfall sewer is about 2 ft. per mile, and the discharging capacity is about 25 million gallons per day, so that ample provision has been made for the growth of the town.

The farm, as at present laid out,* has an area of 640 acres. An additional area of 269 acres has just been purchased from Earl Manvers, in order to provide additional land for farming purposes; this land is now being under-drained and laid out by the Borough Engineer, and will shortly be ready to receive sewage. The land is eminently suitable for irrigation, and is a natural filter which cannot be surpassed. There are on the top from 9 in. to 12 in. of light arenaceous soil; then about 1 ft. 6 in. to 2 ft. of fine sand, with very fine gravel; then 1 ft. 6 in. of fine gravel; then 12 in. of fine sand and lastly comes a bed of river gravel, varying from fine to coarse. The land being meadow land, near the river Trent, was fairly level, but still a considerable sum of money had to be spent on levelling the surface, propping hedges, and generally preparing the ground to receive the sewage.

Of the total acreage of 640 acres, about 150 acres were laid out as a filtration area, which was divided into plots, and upon which the sewage is delivered in turn in winter time, at night, and at other times and seasons when there is an overplus of sewage to be dealt with. This area is deep-drained, and has main drains of from 9 in. to 12 in. diameter, laid about 6 ft. deep, and being about two chains apart; the "feeders," laid "herring-bone" fashion, are of 4-in. agricultural pipes, and on this area are 10 ft. apart. The main drains on the remainder of the farm are laid four chains apart, and the "feeders" 20 ft. apart. For the drainage of the 640 acres of land, about 400 miles of pipes of various sizes were laid.

The carriers for delivering the sewage on to the land are laid at such a level as to command all the land on the farm, and at numerous points in the side of these carriers are wooden sliozes, which, when opened, allow the sewage to be delivered on to the land. The carriers are formed of earthwork lined with Portland cement concrete about 6 in. thick; they have

* Under the direction of the then Borough Engineer, the late Mr. M. O. Tarbotton.

stood remarkably well, and are in as good a condition now as they were when first constructed twelve years ago. The concrete was composed of cement and gravel, the latter being found on the ground. The distributing channels, which are opened by the plough, are formed on the crown of a very slight ridge, and these convey the sewage from the carriers over the land.

About 840 acres of the farm consist of ordinary arable land, 140 acres are permanent pasture, and 30 acres are occupied by the homestead, &c. Italian rye-grass occupies about 70 acres, and, in suitable weather, is cut about every six or seven weeks. Some of the rye-grass is made into silage, and is much relished by the cattle.

It was very soon realised by the Corporation that it was exceedingly difficult, and practically impossible, to sell the produce grown upon the farm, and acting upon the advice of their excellent farm bailiff, Mr. James Avis, they decided to keep and rear a large stock of cattle, so that the bulk of the produce should be eaten on the farm. Experience has shown that this is the only way to make sewage farming a success. Profitable it can never be, but this method reduces the loss to a minimum.

The stock of cattle on the farm at the present time is:—Beasts, 340; sheep, 300; pigs, 80; farm horses, 35; and young horses, 20. Of the beasts, about 90 or 100 are milch cows, nearly the whole of the milk from which is sent to London.

The land takes the sewage well, and the effluent could not be better. No difficulty has been experienced in dealing with the sewage during the severe winters of the past three years, and there is not the slightest sign of the land becoming clogged.

Although the sewage farm has been in operation for twelve years, not a single complaint has ever been made of any nuisance arising from the operations of utilising the sewage on the land. The neighbouring village of Burton Joyce closely adjoins the farm, and owners of property there have evidently confidence in the farm being carried on without any nuisance, as they are building villa residences within a stone's-throw of the farm.

THE ARCHITECTURAL ASSOCIATION'S SPRING VISITS:

THE NEW NATIONAL PORTRAIT GALLERY.

THE seventh visit of this season was made on Saturday afternoon last to the New National Portrait Gallery, now being erected from the designs of Mr. Ewan Christian. Owing to ill-health and consequent absence at Eastbourne, Mr. Ewan Christian was unable to be present, but Mr. Henry Christian kindly met the members of the Association, and explained the design of the Gallery very fully to them, and afterwards conducted the party over the building.

The design of the National Gallery has been preserved with great care in the new east front, but, owing to the great difference in levels, it was found impossible to continue that design further than the staircase block of the New Portrait Gallery, which is from that portion entirely different in style and treatment from the other part. This variation was also found desirable, inasmuch as the windows of the National Gallery would be far too small for the purpose for which the Portrait Gallery has been designed, and the arrangement in floors necessitated larger windows for giving the only light available. The basement is devoted to lavatories, stores, engine-rooms, and engineer's apartments, and large galleries, which, even in this position, are well lighted. The long narrow gallery to the left of the main staircase is to be devoted to sculpture. This staircase gives access to all the galleries in the main block intended for the exhibition of portraits, which are arranged on both sides of a wide corridor, lighted at each end.

The entire building is as nearly fireproof as a building can be made, even to the roofs of the large galleries on the top floor, which are of iron and concrete. The building is heated by hot air conducted by very large flues over the entire building, so designed as to be under the complete control of the engineer and attendants. After the members had carefully inspected the works under Mr. Henry Christian's guidance, a cordial vote of thanks was accorded to him for his kindness in attending.

Illustrations.

SHEFFIELD MUNICIPAL BUILDINGS:
GRAND STAIRCASE AND TWO EXTERIOR
VIEWS.

THESE three drawings in illustration of the Sheffield Municipal Buildings, showing the grand staircase and the two long sides of the building, are all hung in the architectural room of the Royal Academy, and were mentioned in our notes on architecture at the Royal Academy. As to the building generally sufficient information has from time to time been given in our columns, which it would be superfluous to repeat here.

The view of the staircase represents only the general scheme, the details have hardly been matured as yet (so Mr. Mountford informs us) and may be considerably modified. The walls are intended to be lined with polished Hopton Wood stone below, the arches being of Mansfield stone; the steps of Sicilian marble, the balusters of alabaster, their bases and capping of red marble. Everything in the building is to be English, except this said Sicilian marble. The columns will mostly be of red Devonshire marble.

It may be noted that the statue of Vulcan for the summit of the tower, and that of the Queen for the principal entrance, are now nearly completed by Signor Raggi.

MUSIC ROOM, "HIGHLANDS."

THIS room has been designed as an addition to "Highlands." Putney-heath, for Dr. Longstaff.

Its size is 48 ft. by 22 ft., with an angle nook at one end, and recessed alcove with second fireplace at the other, and a recessed bay with a music-gallery over. The mantelpiece is of Weldon stone and polyphant, by Mr. Hitch, of Kennington.

The floor has been specially constructed for dancing purposes. Evans & Swain's patent fireproof construction has been adopted throughout.

Over the room are billiard-room and smoking-room.

The work was executed by Messrs. Turtle & Appleton, of Wandsworth, from the designs of Mr. W. D. Caroe.

THE ARCHITECTURAL ASSOCIATION:

NOMINATION OF COMMITTEEMEN.

THE ordinary fortnightly meeting of this Association was held on the 13th inst., in the meeting-room of the Royal Institute of British Architects, Mr. F. T. Baggallay, President, in the chair.

The minutes of the previous meeting having been read and confirmed, Mr. E. S. Gale, honorary secretary, read a list of members nominated for election, and he also announced a list of donations to the general fund, amounting in all to 100l. 15s., including 20l. from G. T. Hine. He moved a vote of thanks to the donors, which was carried by acclamation, after a few words by the Chairman.

The Chairman said he had a great deal of pleasure in moving a hearty vote of thanks to the members of the A. A. Lyric Club and to the other gentlemen who contributed to the success of the entertainment at the recent *Soirée* of the Association. This was also agreed to by acclamation.

On the motion of Mr. F. T. W. Goldsmith, honorary secretary, votes of thanks were accorded to (1) Mr. Blashill, Architect to the London County Council, for kindly allowing the members to visit the Newington Weights and Measures Offices; (2) to Mr. Keith D. Young, for permitting them to visit the new Royal South London Ophthalmic Hospital; and (3) to Mr. Frank Verity, for giving them permission to visit the New Travellers' Club.

The President said he had, with very much regret, to announce, in accordance with By-law 55, that three casual vacancies had occurred on the Committee. They were most of them aware, to a certain extent, through was the resignation of Mr. Owen Fleming, Mr. T. E. Pryce, and Mr. Leonard Stokes. The Committee regretted those resignations very much; but without entering any further

into the matter at that stage, he would call upon Mr. Pryce to make a personal explanation.

Mr. T. E. Pryce, who was received with loud applause, said he wished to ask the President a series of questions, of which he had given him notice, and he wished to ask those questions before he made his statement.

The President said he thought it would be better if Mr. Pryce made his statement first and asked his questions afterwards.

Mr. Pryce said he should prefer to have the answers to his questions first.

The President: Very well then: ask your questions.

Mr. Pryce said the first question he had to ask was, whether it was not a fact that one of the chief charges made against the staff of *A. A. Notes* was the publication of a letter from Mr. T. G. Jackson, expressing views which were not those of the Committee, and which the Committee could not endorse?

The President: Not altogether.

Mr. Collard rose to order. He said that the meeting had assembled to hear Mr. Ashbee's paper. Was that to be deferred to the end of a long list of questions such as the one which had been asked?

The President said that in accordance with the By-laws they were bound to announce that the vacancies on the Committee had occurred, and it would not be in accordance with custom if they did not let the gentlemen concerned to make any personal explanations which they wished to make.

Mr. Pryce said his second question was whether it was not alleged as one of the reasons for altering the staff of *A. A. Notes* that it was desirable to bring that publication more under official control than it had hitherto been?

The President: Yes.

Mr. Pryce next asked whether the Committee, having received the resignation of the staff, was responsible for the publication of Mr. Earle's letter in the last number of *A. A. Notes*?

The President said that the acting Editor (Mr. F. R. Farrow) was alone responsible: the Committee and Manager had no knowledge of it. The Committee did not endorse the letter.

Mr. Pryce further asked whether the Committee knew of the prominent position which that letter occupied, and whether the Committee would have approved of the insertion of the letter if they had known of it?

The President, in reply, said that the present Manager had always declined to take a position of censorship over the *Notes*, and he simply occupied the position of Manager *pro tem.*, in the same sense as there was a publisher to a journal. The intention was to afford some control over the *Notes* by the future President, who had not yet come into office. The acting Editor, in fact, took the sole responsibility for the insertion of Mr. Earle's letter.

Mr. Pryce said he regretted that he had to make a somewhat disagreeable statement. The members were aware, from certain statements which had appeared in *A. A. Notes* and other journals, that a certain meeting took place some time ago at Mr. Stokes's rooms. With the calling of that meeting he had nothing whatever to do. The meeting was called for the express purpose of doing good to the Association, and the members who attended that meeting included, besides himself, Mr. Cresswell, Mr. Gale, Mr. Brodie, Mr. Millard, Mr. Fleming, Mr. Stokes, and Mr. F. M. Simpson. There were other gentlemen present, some of whom had been heard in that room. There were Mr. Jackson, Mr. Blomfield, Mr. Macartney, Mr. Prior, and Mr. Warren. Now he (Mr. Pryce) thought those who knew him well would not say that he was a "Memorialist" in the slightest sense, for he disapproved "Memorialists" had taken in connexion with the other body. But those gentlemen were men of very high attainments, and included the late John Sedding, who, he believed, would have been at the meeting in question had he been alive, for his help was always most willingly given when the Association was in need of it. The members of the Association who attended the meeting were all extremely anxious to enlist the services of some of the gentlemen he had named for the benefit of the Association. Would they not all like to have men like Mr. Blomfield, Mr. Jackson, and Mr. Norman Shaw in their Studio, criticising their drawings, and

helping them with their great and varied experience? For his own part he thought that any steps that they might have taken to get the assistance of those gentlemen in the work of the Association were deserving of approval and thanks, and that the willingness of the gentlemen in question to help them should not be perverted and misrepresented as an effort on their part to forward their views with regard to another body. He had fully and truly stated the motives by which those who called and attended the meeting were actuated. They met and discussed certain matters, one of which was the question of the alteration of the wording of the preface to the A. A. curriculum. Very little alteration was necessary, but it was a same time proposed to lighten the ship by omitting one or two subjects. The proposer of that meeting were brought before the Committee of the Association, perhaps not in the best possible way. The Committee rejected the main proposition, but with regard to the others, he did not think they had any strong feeling. In the meantime, certain letters appeared in *A. A. Notes* and in the *Builder*. Mr. Cole Adams in particular wrote to the *Builder*. He (Mr. Pryce) thought it was rather foolish to discuss such questions in the public prints, and for his own part he had refrained from joining in the correspondence. Those letters had undoubtedly exercised a certain amount of influence. Then followed the action of the Committee directed against *A. A. Notes* for the publication of Mr. Jackson's letter. A resolution was passed calling for the resignation of one of the Editors of that publication, and was plainly hinted which of the Editors was required to resign. Another resolution was passed nominating Mr. Farrow to act in his place. Now there was no doubt that the Committee had acted distinctly within its rights, but the question was how far the exercise of those rights was for the good of the Association. He believed that the Committee had adopted a line of policy which would be detrimental to the Association's interests. The Committee were, of course, for the time being, absolute masters of the Association; but he thought it behoved them to take carefully into consideration any such violent course as that had recently pursued. He thought it was prettily explained to the Committee that the staff of *A. A. Notes* would be likely to stand together; but that did not have any effect on the judgment of the Committee, whose action had the appearance of a desire to absolutely bind them to any policy which might be promulgated by the Institute. ("No, no!") Well, that was a matter of opinion. No one would say that he was an anti-Institute man, but he did not want to see the Association made simply a feeding ground for the Institute or any other society. He extremely regretted the action of the Committee, because he felt that it would keep the distinguished gentlemen whom he had named out of touch with the Association, and prevent them from helping them in any way. These were the chief reasons which caused him to send in his resignation as a member of the Committee, and he earnestly begged the members to consider the matter carefully before they endorsed the action which had been taken by the majority of the Committee.

Mr. Woodthorpe: But the proposal was sent out the word "Institute" from the "Brook Book" altogether.

Mr. Pryce, continuing, said he need not enter more into detail, but would only say that the action of the majority of the Committee, if endorsed, would keep away from the service of the Association eminent men like Mr. Jackson, Mr. Blomfield, Mr. Macartney, and others. The question was whether they might not be able to see their way to comprehend everybody,—to be catholic in the true sense of the word, and to continue their work for the profession at large and not in the interests of the policy of any one society. Those who convened the meeting wanted the Association to represent all shades of opinion in the profession and for that reason they had gone out of the way to attempt to get the active co-operation of the eminent men whose names had been mentioned. The majority of the Committee had not hacked them up in that landable effort and he regretted it very much.

Mr. Farrow said that Mr. Pryce had raised two points, the first by his questions, and the second by his explanation of the reason of his resignation. His questions had been directed practically against the last number of *A*

Royal Academy Exhibition, 1892.

PHOTO LITHO. SPRACUE & CO. 4 & 5 EAST WARDING STREET, FETTER LANE, E.C.

tes, for which, as the President had said, he (Farrow) was wholly responsible. He would like to ask Mr. Pryce, as a past Editor of *A. Notes*, whether it was not a fact that during his editorship of that publication he had never refused to insert any letter sent to him by a member of the Association, except on an occasion when he requested the writer to refer the matter before the Committee?

Mr. Pryce said he was not finding fault with the insertion of Mr. Earle's letter so much as with the way in which it was inserted. One of the great grievances of the Committee against the late Editors of *A. Notes* was that they inserted a letter from a prominent man whose views were not in accordance with their own, and that was the reason why a change in the editorial staff was insisted upon. Now, the Committee having changed the staff because Mr. Jackson's letter was inserted, the result of the insertion of a letter fifty times more proper, and in a much more prominent position. He alluded to Mr. Earle's letter, which is inserted in the form of a leaflet.

Mr. Farrow said he would ask whether, if an Editor of *A. Notes* received a letter from a member of the Association, he was not bound to publish it if he could possibly do so?

Mr. Pryce said he would not go out of his way to publish it as a leaflet.

Mr. Slater rose to order. He wished to know whether the question before the meeting was at all the rival views of Mr. Farrow and Mr. Pryce as to the management of *A. Notes*?

The President said he thought that they must allow the explanations to proceed.

Mr. Farrow said that Mr. Earle's letter was an engineering letter. Mr. Earle was on the "House List" for election as a member of the Committee, and he (Mr. Farrow) would have considered it a gross breach of duty on his part, as acting Editor of *A. Notes*, if he had inserted a letter from a member on the eve of an election. The letter was sent as an engineering letter with a view of influencing the election, and therefore he felt that he must insert it. He was quite willing to justify his action in that respect before any meeting of the Association. The other point which Mr. Pryce had raised was in his explanation why he had resigned his seat on the Committee. He had told them that he resigned because the action of the Committee had lost them the services of Mr. Jackson and other eminent men who might have been willing to assist the Association in its educational work.

Mr. Pryce: That is one of the details of it; is not everything.

Mr. Farrow, continuing, said Mr. Pryce had told the meeting upon what terms the assistance of Mr. Jackson and his friends was to be obtained. It was all very well for Mr. Pryce to say that they should have the assistance of Mr. Jackson and his friends; every one as agreed upon the desirability of securing the help of Mr. Jackson, Mr. Norman Shaw, and other gentlemen, but they were not all agreed upon the price which they were asked to pay for that assistance. What that price was, was clearly indicated in Mr. Jackson's letter inserted in *A. Notes*. His terms were, "Cut away from the Institute, and we will help you." It was true that in a subsequent letter, addressed to Mr. Stokes and printed in the *Builder*, Mr. Jackson had tried to explain away the offensive terms of his first letter. The Committee's view of the situation was very clearly indicated in their statement which appeared in the current number of *A. Notes*. The Association refused to bind itself either to the Institute, to the Academy, or to any other body, but sought to maintain a position of independence. The position which Mr. Jackson would have them take up was not an independent one. Mr. Jackson wished them to adhere to his views, one of which was that the members of the Association must not go in for the Institute Examination.

Mr. Pryce: Distinctly not.

Mr. Farrow: Well, the members had all had *A. Notes*, and they could read Mr. Jackson's letter for themselves. As to the request made to the Committee that one of the Editors should sign, Mr. Pryce had not told the meeting that at was not the first occasion on which objection had been taken on the Committee to the way in which *A. Notes* had been conducted. It was true that the Committee had previously passed no resolution upon the subject, the resolutions proposed by members of the Committee having been withdrawn out of courtesy to the Editors, but on the understanding that some

head would be paid to the expressed desire that *A. Notes* should be conducted in the interests of the Association at large. When the Committee recently suggested that one of the Editors should resign, they did not wish to make any invidious distinction, but they thought it desirable that at least one of them should represent a set of opinions not then represented on the editorial staff. He was quite aware that there was a section of members of the Association who were prepared to pay the price which Mr. Jackson asked for the help of himself and his friends, but he ventured to think that the members of the Association, as a whole, were not prepared to pay that price; and therefore the Committee did not think that *A. Notes* should be carried on merely as an exponent of one side of the question. Mr. Pryce had remarked that he did not wish the Association to be the feeding-ground for any one society. Nor did the Committee; they wanted the Association to be a feeding-ground for all societies, including the Academy, if the Academy would only help them, and would give them some little credit for the work which they did in the Association. Some of them might be aware that there was a petition now in course of signature asking the Academy to reform its Schools, so that they might be made more useful to the architectural student. The present members of the Committee of the Association, if they were re-elected, desired to maintain the Association as an independent body; they did not think that the Association, which had its own proper work to do, should bow down to the Academy or any other society, to Mr. Jackson, or to anybody else. They desired that a free representation of the diverse opinions which existed in the Association should be found in *A. Notes*, the journal of the Association, and they desired that the educational work of the Association should be fitted to prepare a man for the Institute Examination if he wished to go in for it, for entering the Academy schools, or for enabling him to pass any other test of his knowledge.

Mr. Leonard Stokes, who was received with loud applause, said it was his desire, if possible, to leave on one side all personal matters. He only wished to say that in retiring from the Committee he was acting up to the best of his lights. He should regret it if he were mistaken, but he had felt it an imperative duty to make some protest against the course which the Committee had taken in these matters. He and some of his friends met Mr. Jackson, as they knew. There were other men behind Mr. Jackson. He (Mr. Stokes) and those members of the Association who met at his rooms were anxious, if possible, to get Mr. Jackson and other gentlemen of eminence to help them in their work at the Association. There had been a great outcry raised to the effect that the independence of the Association would be sacrificed; but, of course, they were not going to take Mr. Jackson's terms if they did not like them. It was the unfortunate discussion of these matters in the newspapers which had raised all that storm about their ears. Now, it was one thing to secure Mr. Jackson's assistance, and it was another thing to hny off his active opposition. He (Mr. Stokes) had authority to tell the meeting that Mr. Jackson and Mr. Norman Shaw had under consideration a scheme of their own which they intended to start, though, as he happened to have heard indirectly, they would much prefer to help the Association, because it would be less trouble to them. The terms which some members had been so frightened about were very simple, and the idea that the Association was to lose all its independence was a mere bogey. All that Mr. Jackson and his friends said was that it was desirable that no reference should be made in the "Brown Book" to the Institute Examination, and they also suggested the omission of certain words in the "Brown Book." They desired to help in the work of giving a thorough training to young architects. But it was stated in the "Brown-book" that it was the object of the Association to obtain a good training for young architects. There was no desire to alter the Curriculum. He did not think that anyone had had much more to do with the Curriculum than he had; but he, and he believed the Committee itself would acknowledge the fact,—thought the amount of work which had been set for young men to do must be lightened. Mr. Jackson suggested that they should lighten it by omitting such subjects as Chemistry and Geology. Now, if they could see their way to fall in with Mr. Jackson's

views, they would secure his help; but, if not, they would lose it and that of Mr. Norman Shaw, who had both said that they would help provided they would simply omit the reference to the Examination. The gentlemen he had named held that the right thing for a young architect to get was a thorough training. Surely the Institute and everybody else would endorse that! The question whether a young man afterwards passed the Examination or not was not very important, provided that he had a good training. Mr. Jackson had said that if the Association provided the training, it was nothing to him if young men did go in for the Examination; let them do what they liked. He (Mr. Stokes) laid it down as a fact that they to the Association established the Curriculum with the only object of providing a sound training for young architects. In that Curriculum, asterisks were put against certain subjects which were necessary to be taken up by those who wished to pass the Institute Examination. But was it necessary that those asterisks should continue to be inserted? The Committee said that it did not want to lean either on the Institute or on the Academy. Mr. Farrow had said that they ought to help young men to get into the Academy, but yet the Committee would not allow a petition to lie in the rooms of the Association asking the Academy to reform its Schools! Surely there could have been no objection to the Academy improving its schools. The Committee were asked to sign in their corporate capacity, but they declined to do so. He demurred to Mr. Farrow's statement that the views of only one party in the Association had been represented in *A. Notes*; at any rate, if any members felt that their views had not been put forward therein, it was their own fault, for, as a rule, whatever was sent to the Editors for insertion was inserted. During his term as Editor, he could say that only one article that had been sent for insertion was suppressed, and that was a raly and Institute article. As to the Committee's statement in *A. Notes* that Mr. Jackson demanded that the Association should alter its scheme to suit his (Mr. Jackson's) anti-Examination theories, there was no adequate foundation for it; nor was there any justification whatever for saying that Mr. Jackson desired to convert the Association into the mere tool of the "Memorialists." He thought it was very unfair that the Committee should have made such a statement in the pages of *A. Notes*.

Mr. Owen Fleming said that as one who had been on the editorial staff of *A. Notes* from the first, he strongly protested against the statement that that publication had been conducted in a one-sided manner.

Mr. F. T. W. Goldsmith said that while he thought it was to be regretted that the incidents which they had been discussing had occurred, he thought it was satisfactory that the meeting should have heard the broad and comprehensive statement which Mr. Stokes had made; and he was sure that they were beginning to see that these differences, which had excited so much ill-feeling on both sides, were, apparently, diminishing in intensity, and things were acquiring a more normal condition than at first seemed likely.

The discussion was continued by Messrs. Brodie, Earle, Beale, A. H. Clark, Dicksee, and others, and eventually the meeting was brought to a close by the re-nomination as members of the Committee of those gentlemen who had been already nominated, but who had, in consequence of the differences discussed, declined to accept the Committee's nomination, viz., Messrs. G. H. Brodie, T. E. Pryce, F. M. Simpson, and L. Stokes. Messrs. Owen Fleming, Gerald Horsley, W. J. N. Millard, E. J. May, and A. W. Cooksey were also nominated as Committeemen, in addition to those nominated in the "house-list."

The discussion of these matters having occupied nearly two hours, the reading of Mr. C. R. Ashbee's paper on "The Relation of the Architect to the Workman" had to be postponed, the President expressing the regrets of the meeting to Mr. Ashbee, who kindly promised to attend and read the paper on a future occasion.

Messrs. Lansdown, Bartlett, Beale, and Rickards having been appointed scrutineers of the voting-papers, the meeting terminated.*

* Two letters bearing upon the subject of this meeting will be found in another column.—Ed.

ARCHITECTURAL SOCIETIES.

NORTHERN ARCHITECTURAL ASSOCIATION STUDENTS' SKETCHING CLUB.—The annual meeting of this Club was held on the 12th inst., at Newcastle. The annual report showed that meetings were held during last summer at Durham Cathedral and Castle, Morpeth Church, Tynemouth Priory, Ovingham Church and Prudhoe Castle, and Chester-le-Street Church and Finchale Abbey. A new series of meetings were arranged, and will start at Seaton Delaval Hall this Saturday, the 21st inst. The Committee were appointed as follows:—Messrs. R. B. Dick, J. W. Twist, J. W. Boyd, and Edmond Rich, Mr. C. G. Errington being re-elected secretary.

SHEFFIELD SOCIETY OF ARCHITECTS AND SURVEYORS.—The annual meeting of this Society took place on Tuesday evening, the 10th inst., at the School of Art, Mr. C. J. Innocent, President, in the chair, and there were also present Messrs. T. J. Flockton, F. Fowler, E. M. Gibbs (Vice-President), W. F. Hensoll, J. B. Mitchell-Withers, C. Hadfield (Hon. Sec.), and a large number of members. The Secretary's and Treasurer's reports were read and adopted. A ballot took place for the election of President, Officers, and Council for the coming year, Messrs. E. Winder and J. B. Mitchell-Withers, jun., acting as scrutineers. Mr. C. J. Innocent was re-elected President, and Mr. E. M. Gibbs, Vice-President, Mr. C. Hadfield Hon. Sec., and Mr. J. B. Mitchell-Withers Treasurer; and the old Council,—Messrs. E. M. Gibbs, T. J. Flockton, W. H. Lancashire, W. F. Hensoll, and W. C. Fenton,—were re-elected for the coming session. The Secretary announced, in terms of regret, the recent decease of Messrs. J. McInery and J. F. Wightman, Fellows of the Society. A very interesting and scientific paper on "Timber, its Growth and Characteristics," was read by Mr. W. H. Bidlake, M.A., of Birmingham. The paper was well illustrated by diagrams and specimens of various kinds of wood. The lecturer gave a graphic illustration of the structure and growth of the various kinds of timber. He also alluded to the various kinds of damage to which timber was liable when used in building construction from dry and wet rot, and other causes. At the close of the paper an interesting discussion took place, and a hearty vote of thanks was awarded to Mr. Bidlake on the motion of Mr. J. B. Mitchell-Withers, and supported by Messrs. Hadfield, Winder, and H. W. Lockwood.

GLASGOW INSTITUTE OF ARCHITECTS.—On the 13th inst. in the Bath Hotel, Glasgow, Mr. William Maclean, who acted from 1868 till 1889 as Secretary of the Glasgow Institute of Architects, was presented with a testimonial. Mr. William Leiper, A.R.S.A., President, presided. The testimonial took the form of a bust in bronze of Mr. Maclean, executed by Mr. Pittendreich Macgillivray, A.R.S.A.

THE LONDON COUNTY COUNCIL.

The usual weekly meeting of this Council was held on Tuesday afternoon last, the Chairman, Lord Rosebery, presiding.

Tenders.—Tenders for iron fencing at Battersea Park were opened by the Chairman. We print the list elsewhere.

Loans to Local Bodies.—On the recommendation of the Finance Committee, sanction was given to the following loans:—To Camberwell Vestry, 20,000*l.*, for contribution towards the purchase of land for the extension of Peckham Rye, term 48 years; to the Hackney District Board of Works, 1,500*l.*, for the purchase of land, erection of mortuary, &c., 30 years; to Rotherhithe Vestry, 3,800*l.*, for granite paving, 20 years; to the Wandsworth District Board of Works, 3,500*l.*, for purchase of site for store depot, 35 years; to the Islington Baths Commissioners, 5,000*l.*, for the erection of baths in Hornsey-road, 30 years; to the Stratford-by-Bow Baths Commissioners, 3,550*l.* and 7,550*l.*, for completion of baths, 30 and 10 years; and to the Managers of the Central London District School, 2,200*l.*, for the erection of buildings at Hanwell, 30 years.

Sewage Sludge and Sludge Ships.—The Main Drainage Committee reported that during the week ending May 7, 23,000 tons of sludge were taken to sea from the Northern Outfall at Barking, the estimated amount then remaining in stock being about 6,000 tons. On the sub-

ject of the general superintendence of the Council's fleet of sludge-vessels, the Committee reported as follows:—

"We are considering the arrangements to be made for the working of the whole fleet of sludge vessels belonging to the Council, when they are all completed and delivered. As the Council is aware, three are now in use, and the other two will be delivered very shortly. We are of opinion that one of the first things necessary for the proper and efficient working of the ships is the employment of a thoroughly experienced nautical man, holding a master's certificate, as general superintendent of the whole fleet. The person appointed would be required to communicate and advise, when requisite, with the Committee, and to relieve the other masters respectively when off duty. He should, moreover, be a person who has had charge of large bodies of men, and should possess good administrative as well as executive abilities. We think that the services of a suitable person could be obtained for a salary of 4*l.* a week, which is the same as that paid to the masters of the vessels, with an additional allowance of 2*l.* a month. We recommend:—

"That the Council do sanction the appointment of a general superintendent of the vessels as above described, and that an advertisement be at once issued inviting applications for the office."

This recommendation was agreed to.

Brockwell Park.—The Parks and Open Spaces Committee reported that

"In the plan for the purchase of Brockwell Park, the line of boundary cut off a corner of the walled-in garden, and as we are laying this out as an old-fashioned English garden, we think it desirable that the garden should be preserved intact. There is also a very narrow entrance to the park from Hernehill, which is the principal approach, and we think that a corner plot of land adjoining should be secured so as to form a better entrance. We propose that offers of 25*l.* a week, respectively should be made for these two plots, and we recommend:—

"That, subject to an estimate being submitted to it by the Finance Committee, as required by the statute, the Council do authorise the Committee to incur an expenditure of 420*l.* on capital account for the purchase of two additional plots of land to be added to Brockwell Park."

The recommendation was agreed to.

Alexandra Palace and Grounds.—The same Committee also reported that they were in communication with the Middlesex County Council and other bodies, and were considering the terms upon which the Alexandra Palace estate could be obtained as a public park. In the meantime, as the Council had decided to oppose the Bill now being promoted by the owners of the Alexandra Palace estate, because it proposed to repeal a clause in one of their Acts which prohibited them from building on 127 acres of the land, the Committee now reported that the repealing clause had been withdrawn, and they therefore recommended:—

"That, subject to the omission of the clause for repealing the prohibition to build on the 127 acres of Alexandra Palace grounds, the Council do withdraw its opposition to the Bill promoted by the owners of the Palace."

This was agreed to, after some discussion.

North Park, Eltham.—The same Committee further reported:—

"We have given consideration to the question of purchasing as a public park the remaining portion, 118 acres in extent, of North Park, Eltham. The Valuer estimates the cost of this property at 35,400*l.*, and, having regard to its distance from the populous parts of the county, we are not prepared, as no contributions have been offered by the local authorities or other bodies, to advise the expenditure. We recommend:—

"That no further steps be taken with reference to acquiring the remaining 118 acres of North Park, Eltham."

Mr. Evan Spicer moved that the matter be referred back for reconsideration; but, after some discussion, in the course of which it was stated that the land is Crown property, and has recently been leased by the Office of Woods and Forests for a short term of years to a golf club, the amendment was withdrawn, and the recommendation agreed to with the addition of the following words:—"until the local authorities or other bodies are prepared to offer some adequate contribution."

Alterations at the Cane Hill Asylum.—The Asylums Committee reported as follows:—

"We have to report that we have considered the three following tenders received for the further additions, alterations, and other works at the Cane Hill Asylum, viz.:

Reed, Blight, & Co., Plymouth	£15,416
Kirk & Randall, Woolwich	16,562
Rudd & Son, Grantham	16,666

It will be observed that the lowest of these tenders is 2,056*l.* in excess of the expenditure of 13,360*l.* authorised by the Council for the works under this contract. This additional amount, we are informed, will not cause any excess in the total estimates for the enlargement of this Asylum already submitted and approved. We recommend:—

"That the Committee be authorised, pursuant to the provisions of section 254 of the Lunacy Act, 1890, to accept, subject to the Secretary of State's approval, the tender of Messrs. Reed, Blight, & Co., at the sum of 15,416*l.*, provided that they agree to the insertion in the contract of the condition that they will pay the London rates of wages and observe such hours of labour as are generally accepted in London as fair in the trades they employ."

This was agreed to, after some discussion.

Appointment of Resident Engineer, Blackwall Tunnel.—The Report of the Bridges Committee contained the following paragraph:—

"The Engineer has informed us that the time has now arrived when a second resident engineer should be appointed to assist in the supervision of the Blackwall Tunnel works. The Council, in December last, decided to appoint two engineers, and one has been already appointed. At the time of selecting candidates, we saw Mr. Hay and Mr. Fitzmaurice, both of whom had had experience in work carried out under pneumatic pressure. The gentleman selected for the first appointment was Mr. Hay, and it was understood at the time that the second appointment should be reserved for Mr. Fitzmaurice, who is highly recommended by Sir Benjamin Baker. He was resident engineer on the foundation work of the Fourth bridge, which was put in under air pressure of 30 lbs. to 35 lbs. on the square inch, and he has a thorough knowledge of hydraulics, knowledge which will be largely required in manipulating the shield during the construction of the tunnel. We therefore recommend:—

"That, subject to an estimate being submitted to the Council by the Finance Committee as required by the statute, Mr. Maurice Fitzmaurice be appointed to fill the vacant post of resident engineer, at a salary of 600*l.* per annum, to supervise the works in connexion with the construction of the Blackwall Tunnel."

This was agreed to without discussion.

The "Rate of Wages and Hours" Clause in Contracts.—The remainder of the sitting was taken up with the resumed debate on this question, which has been before the Council for two or three weeks. Mr. John Burns, as we have already reported (see *Builder*, May 7, p. 357), has the following motion before the Council:—

"That all contractors be compelled to sign a declaration that they pay the trades union rates of wages and observe the hours of labour and conditions recognised by the London trades unions, and that the hours and wages be inserted in and form part of the contract by way of schedule, and that penalties be enforced for any breach of agreement."

To this a large number of amendments were put on the agenda, including that of Mr. Roberts, which was taken first by the ruling of the Chairman.

Mr. Roberts moved, as an amendment to Mr. Burns's motion,

"That a Special Committee be appointed to consider in what manner the Council can require its contractors to pay all employed on work for the Council the standard rate of wages."

Mr. Yates seconded the amendment, which, after a long debate, was voted upon, the result of the division being that the amendment was lost by 3 votes,—52 members voting for it and 55 against it.

Mr. Costelloe then moved a further amendment, which was still under discussion when the clock struck seven and the Council adjourned.

ROYAL METEOROLOGICAL SOCIETY.

The usual monthly meeting of this Society was held on Wednesday evening, the 18th inst., at the Institution of Civil Engineers, 25, Great George-street, S.W.; Dr. C. Theodore Williams, M.A., President, in the chair. Mr. B. E. C. Chambers, Mr. R. Law, F.C.S., Dr. W. A. Sturge, and Dr. P. Symes Thompson were elected Fellows of the Society. Five honorary members were also elected, viz.—M. A. D'Abadie, Dr. W. H. von Beudant, Dr. R. Billwiller, M. N. Ekholm, and Professor P. Tacchini. The following papers were read: (1) "Raindrops," by Mr. E. J. Lowe, F.R.S., F.R.Met.Soc. The author has made over 300 sketches of raindrops, and has gathered some interesting facts respecting their variation in size, form, and distribution. Sheets of slate in a book form, which could be instantly closed, were employed; these were ruled in inch squares, and, after exposure, the drops were copied on sheets of paper ruled like the slates. Some drops produce a wet circular spot, whilst others, falling with

reater force, have eplashes around the drops, he same sized drop varies considerably in the mount of water it contains. The size of the rop ranges from an almost invisible point to at of at least 2 in. in diameter. Occasionally large drops fall, that must be more or ss hollow, as they fail to wet the whole surce enclosed within the drop. Besides the rdinary rain drops, the author exhibited diarms, showing the drops produced by a mist oating along the ground, and also the manner a which snow flakes, on melting, wet the ates. (2) "Results of a comparison of Richard's némograph with the Standard Beckley némograph at the Kew Observatory," by Mr. M. Whipple, B.Sc., F.R.Met.Soc. This nstrument is a windmill vane anemometer, nd is formed by six small wings or vanes of luminium, 4 in. in diameter, inclined at 45 deg., etted on very light steel arms, the diameter of hich is so calculated that the vane should ake exactly one turn for a metre of wind. Its unning is always verified by means of a whirlng frame fitted up in an experimental room, here the air is absolutely calm, and, if necessary, a table of corrections is supplied. The eording part of the apparatus differs entirely rom any other anemometer, and is called the némocinémographe, and in principle is as ollows:—The pen, recording on a movable aper, is wound up at a constant rate by means f a conical pendulum acting as a train of heel-links, whilst a second train, driven by the an, is always tending to force it down to the over edge of the paper; its position, therefore, s governed by the relative difference in the velocity of the two trains of wheel-work, being at zero when the air is calm, but at other times t records the rate of the faa in mètres per econd. The author has made a comparison of is instrument with the Standard Anemometer t the Kew Observatory, and finds that it gives eceedingly good results. (3) A paper was also ead on the "Levels of the River Vaal, at Kimerley, South Africa; with remarks on the ainfall of the Watershed," by Mr. W. B.ripp.

Books.

A Guide to Electric Lighting. By S. BOTTONE London: Whittaker & Co. 1892.

MR. BOTTONE addresses himself, as we find from the title-page, to "householders and amateurs," and, as appears elsewhere, "to all who lay any claim to an intelligent knowledge of their surroundings"; that is, his aim is partly practical and partly educational. From neither point of view can he be said to have succeeded. The householder who should try to install the electric light in his own house, relying on the meagre and not over-trustworthy information to be found in this hook, would find his experiment an expensive one; nor, after he had called in an electrical engineer to set things right, would he find the "Guide to Electric Lighting" of much use in meeting the occasional difficulties that generally arise in private installations.

The amateur fares rather better; he is supplied with some useful tables, and with details respecting primary batteries which, however out of place in a treatise on electric lighting, may well be of service to him.

It is the gentleman in search of "intelligent knowledge" who is most to be pitied if he falls into Mr. Bottone's hands. Mr. Bottone is very fond of the word "intelligent." A reader of his class wants a clear exposition of the principles and elements of electrical science as applied to electric lighting; he does not want minute details (such as the specific gravity of the sulphuric acid in a cell) and trade illustrations of various machines, obsolete and otherwise; he is probably a man of some education, and when he reads "the resistance becomes additive; in other words, we must add the resistances of each of the cells together;" will be disposed to ask how many resistances each of the cells may possess; he may even have some acquaintance with applied mathematics, and form a low estimate of an instructor who (p. 45) measures "angular velocity" in feet per minute; or he may be so constituted that the accuracy of the information conveyed in the sentences—"If lighting lamps known as arc lamps (to be described farther on) by his intention, the preference will lie with machines which are series wound. If, on the contrary, incandescent lamps are in view, the shunt wound

or compound wound dynamo will be indicated,"—will insufficiently compensate him for the irritation produced by the sentences themselves.

Passing from the consideration of style to that of matter, it is as well to say plainly that when Mr. Bottone writes on dynamos, he is writing on a subject that he does not understand. If this appears to anyone a hard saying, let him read the calculations given on p. 46, and try to imagine the mental picture of a dynamo in the mind of a man to whom it seems sense.

There is a plentiful crop in this book of the errors usually found in writers whose physical ideas are in a fluid condition. Thus we have "electric energy in the form of current," "transformed into mechanical energy in the form of motion," and, again, "the conversion of mechanical energy into electricity." We are told that a "conductor becomes heated in proportion to the amount of current it has to carry, and to the resistance which it presents to the passage of that current." "Electricity itself is another form of motion," and that "the term watt has been introduced to indicate the amount of electrical energy contained in one volt by one ampere."

Even in describing the practical details of dynamo construction the author contrives to make mistakes; for example, he calls the collector rings of an alternator "commutators" (apparently because they do not commute the currents), and speaks of them as "insulated from one another, but each (sic) connected to the opposite ends of the armature wires."

There is one class of readers, however, to whom we can heartily recommend this book—Mr. Bottone refers to them as frequently raising the question: "Can a dynamo be driven by an electric motor which is itself actuated by the current from a battery?" To this species of "intelligent reader" the errors of which we have given examples will be of no importance; and they will, in accepting the author as their instructor, be under the guidance of an intelligence superior to, but not far removed from, their own.

A History of Water-Colour Painting in England. By GILBERT R. REDGRAVE. London: Sampson Low, Marston, & Co. 1892.

THIS is one of the South Kensington series of "Art Text-books," and gives a succinct account of the leading English water-colour painters, prefaced by a short chapter giving a very brief and concise history of the early art of water-colour painting. After that the book proceeds a good deal in the way of a dictionary of water-colour painters, the names succeeding each other in capitals as headings of paragraphs in which a short account of the artist and his method is given. Girtin and his methods are treated of at rather more length than most of the names, and the author gives evidence that Girtin's available palette was more varied than is usually supposed, and that no less than fifteen pigments can be enumerated among those he used, "a number," observes the author, "which would probably satisfy most of the water-colour painters of the present day, and far in excess of those in common use by the earlier masters of the art." It is interesting to know this, but we must say that Girtin's drawings do not in general produce the impression of the use of any such variety of colour. Some account is also given of the rise of the two leading Water-colour societies, which breaks in on the regularity of the biographical dictionary treatment. The main value of the book, however, is as a conveniently-sized reference-book for information about the date and artistic leanings and position of any water-colour artist about whom the reader may require information: it is more for that purpose than to read through. Some critical estimate of each painter, however, is given; these critical notes are written with sound judgment and perception, and the book fulfils very well its object of furnishing a "text-book" in regard to English water-colour painting.

The Architect and his Artists: an Essay to Assist the Public in Considering the Question, —Is Architecture a Profession or an Art? By William H. White, F.R.I.B.A. London: Spottiswoode & Co. 1892.

THIS is an amplification of a paper read by Mr. White at a provincial architectural society, some

part of which in its original form was printed in our column. There is a great deal of good sense in the paper, which those who are tempted to be exclusively "aesthetic" in architecture would do well to read; but we fail to see the point of the title, which is not such as to predispose the reader in favour of the hook. Mr. White combats, with much spirit and sense, the modern idea of some gentlemen that an architect should be solely a designer of artistic buildings, and that the engineer can look after construction and drains and the conveyer after surveying; but his title phrase "the architect and his artists," seems rather to imply that the converse arrangement may be upheld, and that the architect who is a practical man may be assisted by subordinate artists. That is what it practically comes to in many cases, but surely the situation is not an ideal one.

Royal Academy and New Gallery Pictures; 1892. London: Published at the Office of Black and White.

THIS is the best illustrated memorial of the principal pictures of the year that we remember to have seen. The selection has been well made, and the reproductions are exceedingly good, many of them really being charming little engravings, and much more than mere memorials. The illustrations are prefaced by a brief history of the Royal Academy, with portraits of and biographical notes on the work of the leading painters. Any one who wants an interesting and valuable memorial of the contents of the two leading exhibitions of the year cannot do better than purchase the Black and White book.

New Holidays in Essex. By PERCY LINDLEY. London: 30, Fleet-street.

THIS sixpenny guide-book, which can be carried in the pocket, gives a map of Essex, with some routes of interest marked on it, and some information, accompanied by illustrations of places to be looked at. It will be very useful to those who wish to take walking or cycling excursions in the county.

Correspondence.

To the Editor of THE BUILDER.

THE ARCHITECTURAL ASSOCIATION.

SIR,—As Mr. Pryce and Mr. Stokes referred, at the meeting last Friday night, to some resolutions passed at the informal meeting held at Mr. Stokes's rooms, and as they omitted to explain the main point in the resolutions which the Committee objected to, and as on Friday last individual members of the Committee were debarred, by the rules of procedure, from replying or further elucidating the resolutions referred to, we think it right that the Association should know the main point that the Committee objected to, and its reasons. The Committee were asked to pass a resolution to eliminate altogether from the Brown Book and Curriculum all reference whatever to the Institute Examinations, and Mr. Stokes informed them, unless this was done, Mr. Jackson and his friends would have nothing whatever to do with the Association, though they had previously promised to assist. This reference in the Brown Book is made only to give to those students who desire to enter for the Institute Examinations information as to subjects necessary for them to take up, but it is clearly stated "that the aim of the Association courses is to help members to fit themselves for their work as architects." We failed to see why Mr. Jackson and his friends should take exception to this, and we thought that if we gave way we should only be taking a side in the controversy between the Memorialists and the Institute. In his subsequent letter to A.A. Notes, Mr. Jackson explained more clearly what his views and intentions were in this respect, and to these the Committee could not assent. It is worthy of mention that the Royal Institute have just voted to the A.A. scheme 300*l.* without any reservations or conditions whatever. Mr. Stokes was hardly fair in charging the Committee with narrow-mindedness and bias in refusing to sign the petition to the Royal Academy with reference to the proposed reform of the Academy Schools, because he omitted

to explain the terms of that petition, and, as he had already resigned before it was considered, he could not know what occurred. The Committee did give the matter the fullest consideration, but they came to the conclusion that as it contained many statements with which they did not agree, and about which there would probably be much difference of opinion in the Association, it would be wrong for them to sign it in their corporate capacity, and so pledge the name of the Association without first giving the members an opportunity of expressing an opinion upon it. This they were willing to do, and offered to publish it in *A. A. Notes*, so that the members might have an opportunity of discussing it, but the promoters objected to this course on the ground that it was a private document and could not be published in the manner proposed. Under these circumstances, the Committee felt that they ought not to sign it as a body, or to allow it to be placed in the Studio for signature by individual members, as by doing so it would create the impression that they approved of it.

With regard to *A. A. Notes*: as it had for some time past given too great and exclusive prominence to a particular set of opinions, we asked for the resignation of one of the Editors, and, in order that there may be some official control over the journal, we passed a resolution making any future President manager—as he would be, for his term of office at any rate, the elected representative of the Association. This view formerly received Mr. Stokes's active support. We believe that the Association can only continue to be useful by maintaining the independent position which it has always held and defended, and which no one who knows its temper can suppose for a moment that it will sacrifice. It must not lean either upon the Institute or upon the Academy alone, or upon any support less broad than that of the whole body of architects and students of architecture in the country. It must recognise in its curriculum all tests, whether by examination or otherwise, of progress and efficiency, established by the Institute or by the Academy or by any other recognised authority.

This is the position we thought, and still think, the Association should maintain.

(Signed)

HAMPDEN W. PRATT.
WILLIAM BURRELL.
E. N. GALE.
F. T. W. GOLDSMITH.

SIR.—The whole of the difficulty of the A.A. arises from one cause, and the only question the members of the A.A. are called upon to decide by their votes is the following:—

Is the assistance of the Memorialists worth the price demanded by them for such assistance?

The price demanded is, that the A.A. shall purge itself from all connexion with the Examination scheme, and refuse to assist its members in preparing for same, thereby outting itself off from the large body of members of the profession which considers an Examination desirable.

Mr. Stokes and those who think with him say this price is not too great; but in my opinion the aim of the Association should be to enable its members to learn every branch of study necessary for an architect, and to hold an independent position free from dictation by any one.

I should much appreciate the assistance of the Memorialists, and regret that they should deem it necessary to demand such payment for it, but as they do so, in such unqualified terms, I must decline to accept it, and the members of the A.A. must decide for themselves.

WILLIAM BURRELL.
9, Adam-street, Adelphi, May 19, 1892.

BOSTON CHURCH.

SIR.—It is hardly worth while replying to the anonymous correspondent in your last issue except to state that the restoration now being carried out is not to the west door, but to the wall, arcade, and fifth courses of tower.

The work to the west door was completed in 1890 and, therefore, it is impossible to understand what original work existing "only six months ago" he looked for in rain.

If your correspondent had applied to me I should have been pleased to give every information in my power; I mention this because it must be known

to him that the late vicar, Canon Blenkins, who would readily have explained what had been done, died last February. W. SAMUEL WEATHERLEY.
29, Cockspur-street, London.

ST. PETER'S CHURCH, BUSHEY HEATH.

SIR.—In your issue of the 14th inst. (page 372) you complain with reference to the above and other drawings which were published in the *Builder*, and now appear in the New York quarterly, the *Architectural Record*. You write:—"We can have no reasonable doubt that they are plundered from our pages, without the ceremony of saying 'with your leave' either to us or to the original owners of the drawings, who might be supposed to have some right to be consulted in the matter." I agree with you. My drawings were not sent to the *Architectural Record* or to any other journal excepting your own, and no permission was asked or given by me that they should appear in the *Architectural Record*.

JAMES NEALE, F.S.A.

WARMING BUILDINGS BY HOT WATER.

XXI.

BUILDING WORKS—GENERAL INFORMATION—QUANTITIES.

IN treating of the heating of buildings the various phenomena relating to circulation, radiation, &c., are governed by precisely the same natural laws as in glass-house works. The circumstances and general conditions and the general points to be considered are, however, so different, that it becomes almost a distinct calling from horticultural works, and in many cases a man who can execute one may be almost at a loss with the other. The difference is as great as with those works for the supply of hot water for baths and domestic purposes, this being a quite distinct branch of practice.

One peculiarity of buildings works is the pressure that manifests itself when the pipes extend up two or more floors of a building; a pressure that needs consideration in many ways, particularly as to the joints of pipes, &c., which must be capable of withstanding it.

The pressure comes about in this way. When pipes extend any distance above a boiler, and they are charged with water, the weight of this water must be pressing downwards towards the boiler, and we learn from any work upon hydrostatics that the pressure so exerted is 1 lb. per square inch for every 2 ft. 4 in. height. In other words, if a pipe of 1 square inch area and 2 ft. 4 in. high, be filled with water, its contents will weigh 1 lb. If the pipe was set up on its end the weight of its contents, 1 lb., would be pressing upon what it was supported by. It is very necessary to avoid the notion that the pressure is in any way associated with the heat; it is merely weight of water. An apparatus extending, say, 32 ft. in height, would cause a pressure of 18 lbs. to be exerted upon every square inch surface in the boiler, or in the pipes near the boiler. As we rise above the boiler the pressure decreases in like ratio, that is, every 2 ft. 4 in. above the boiler the pressure become 1 lb. less, until we arrive at the top, where the pressure is nil. It is only vertical height that counts; it matters not how the pipes may be carried, the distance from the supply cistern at top to the boiler at bottom, in a vertical line, is the sum of the pressure exerted. It may be noted, that the pressure is identically the same whatever the size of pipe, whether they be, say, 1 in. or 4 in.; but the reader is referred to my elementary work on Hydrostatics for these details.

It should be mentioned, as there is an idea rather prevalent that the size or area of the feed-cistern in some way governs the pressure, that this impression is wrong. The contents of this reservoir make no difference in pressure except as to its height. If in one case a very shallow cistern was used, and in another instance a very high cistern, and this latter filled quite full, then the higher cistern would bring a greater pressure to bear, but only 1 lb. for every 2 ft. 4 in. of its height, the same as in a pipe. If we wanted to get the exact pressure we should measure from the level of the water in the cistern to the centre of the boiler, the shape or extent of the cistern need not be considered. It may be well at the same time to explode the idea that pressure assists the circulation. It does not do so, yet at the same time

as a high pressure means a high apparatus, a good circulation is always (or nearly so) obtained when a good pressure exists. It is, however, the height of the apparatus that increases the motive power, the pressure is merely a consequence, and has no active part in aiding circulation. If the pressure was down one pipe and up the other it would be a different thing, but the pressure is equal down all pipes, irrespective of whether the water has to travel up or down them.

The strain upon the boiler and pipes need not have any injurious effect. It makes care necessary in joining the pipes as just mentioned, and when the apparatus extends a good height, the shape of the boiler has to be considered. Many a saddle boiler has been braced inside by this cause, as it must be remembered that, say, 10 lb. pressure per square inch amounts to between two and three tons per square foot. Of course the larger the boiler the greater likelihood of its becoming misshapen by the strain. If the vertical height of the apparatus is mentioned to the boiler-maker he will say if the boiler selected is suitable.

If an apparatus burst through this great strain or pressure of water, no harm would ensue unless anyone be near enough to be scalded by the outrush of hot water (supposing it to be hot). The fracture would be merely a fissure and no expansive or rending force would be felt. If the apparatus had its expansion pipe and other outlets closed, an explosion would occur, which would have very different results.

In works of this kind there is, we may say, never any lack of motive-power or strength of circulation. The extent to which the pipes always run vertically gives us this. It is so different to horticultural work in which vertical pipe is absent. When the mains are quite vertical, which is often the case, the circulation is so rapid sometimes as to carry the water right past the branches, ignore them, so to speak, and provision has frequently to be made to obviate this. Sometimes the provision is in the form of stop-valves; but a natural and simple arrangement, if found necessary, is to joint the pipe at every branch, as Fig. 87.

The size of the mains differs more in these works than with horticultural apparatus. They vary from 1½ in. to 3 in. or even 4 in. The former size is only suited for moderate-sized works, but with vertical pipes it is quite astonishing what a quantity of hot water small pipes can deal with. When these mains are not used for radiating purposes, they should be covered carefully, as already described. There should be no loss of heat. Where cost will admit, it is best to enter towards having mains of sufficiently full size; it is a real gain, provided they are covered and cause no loss of heat. It will have been gathered that the higher the apparatus extends, the smaller the mains may be, to give certain results; but never run the risk of their being too small.

The water supply to these works is provided for by a cistern of the necessary capacity, as per the rule already given. Sometimes the water is added by hand, but in these works it is usually a ball valve that automatically makes good the loss. The particular objection to these articles is, that at the best, they are not very reliable, and in fulfilling this duty, the demand for water being so small, they get stuck and out of order for want of regular use. They should be looked to regularly. It is a not uncommon practice to terminate the upper extremities of the main flow and return in a small tank; it is a very good plan, and in several little ways is found a convenience. If the apparatus is hand-filled, the water is put into this tank, which will answer as a filling cistern. In many cases the highest part of the circulating pipes may be a coil, and no tank is

ermissible. The tank is only suggested when conditions are quite favourable.

The discharge of air from the apparatus is quite different to anything we have yet spoken of. It is practically impossible to use air-pipes; they would sometimes have to be 60 ft. long, & it would be imperative that they reach up to a point above the level of the supply-cistern, and as we should require one from every branch of pipes and every coil or radiator, the expense would be great, and they would be visible in all directions. The customary arrangement is to use air-cocks, one at each highest point; if pipes, one at each furthest extremity; if coils or radiators, then one upon the extreme top of each of these. The ordinary form of air-cock is as fig. 88, but a new one

having several good features has been introduced, as fig. 89 (section). Air-cocks need regular attention about once a fortnight, as air is continually finding its way into the apparatus, and collects at the highest points. When opening air-cocks to discharge air, it is necessary to hold a cloth over, as we cannot tell whether the air is all out until water issues, and the issue of water under pressure, however little, may do damage to wall-papers or decorations, &c.

When an apparatus is wholly devoid of air-pipes, it is very desirable to have an expansion pipe at some point. It is not absolutely necessary, as the cold supply-pipe and cistern allow or the actual increase in bulk of water, but if by apparatus overheats, and other such possible happenings, the expansion-pipe becomes useful. It is never a great expense.

QUANTITIES.

A cubical contents table is about the only practical means of arriving at the quantity of pipe needed in works of this character. There is a rule which is based upon the area of glass windows, the depreciation or loss of heat by walls (certain thicknesses, materials, and position), and the degree of ventilation, &c. This rule, however, is rarely, if ever, resorted to. If it were discussed here, it would involve many points, particularly as to aspects and ventilation, as to complete the rest of these papers by itself.

Good, when he gave his excellent though complex rule to the world, applied it almost solely to glass-house work which it is well adapted for, but he also, unfortunately, endeavored to make it apply to building works allowing so many cubic feet of air per person occupying the room or place. It will be seen what a weakness this introduces in the fact that, firstly and chiefly, the number of people has no relation to the size of the apartment. A small lecture-room may be calculated to have an average of 200 people in it, yet some private reception-rooms would be nearly as large and yet not exceed an average of 20 occupants. A rule founded this way will not work at all satisfactorily unless a variety of allowances be made, with doubtful results. It would be better to calculate the wall and window surface, but this is not so good as basing calculations on cubic contents.

In arriving at quantities in these works there are always some guesswork introduced and allowances needed,—in fact, the tables given by all writers are subject to this. In the use of the following table it must be seen that, firstly, as glass or windows are of ordinary area or amber; secondly, that the ventilation is normal (except in drying-rooms, &c., where unusual ventilation is allowed for). The place to be heated must not be naturally damp or exposed by being an addition to a main building, or standing out so that it is liable to rather cooling influences than ordinary. Again, consideration must be given as to whether the boiler fire has skilled or indifferent attention. In buildings, particularly residences, the attendant is very commonly a page-boy or man-

servant, who only knows that the fire must not be allowed to go out. All these things occur readily to the mind after a little experience. It is hard to say what allowance is necessary in these different cases, but supposing all of them to exist at once, it would necessitate doubling the quantity of pipe given in the following table.

This table is based upon the water in the pipes being at a temperature of 180 deg. F., and the lowest external temperature 20 deg. F. Ordinary conditions: A foot length of 4-in. pipe is as nearly as possible a superficial foot of surface; for 3-in. pipe add one-third: for 2-in. pipe the quantity must be doubled:—

Temperature required.	Quantity of 4-in. pipe required for every 100 cubic feet capacity in a brick-built room. Windows as usual.	Some of the uses for which the heat may be required.
50	6	Coach-houses, &c. Work-rooms, &c. Churches, bedrooms. Living-rooms. Drying-rooms, herbs, paper, &c. Free ventilation. This heat when empty and dry. Drying-rooms for coats, articles, laundry-work, &c. Full ventilation. This heat when empty and dry.
55	7	
60	8 to 9	
65	10	
70	35	
75	45	
80	60	
100	110	
110	140	
120	180	

For the higher temperatures given good attention at the boiler is necessary, and the water kept at or as near boiling-point as possible. The allowance necessary if pipes are in channels with gratings over (or coils beneath floors) is the same as with glass-house work,—viz., one-third more pipe needed. This commonly occurs in church work which has either lines of pipes in channels, or stacks of pipe here and there beneath the floor, with gratings over. The latter causes a very disagreeable amount of heat to be felt by those whose seats are near these openings.

SURVEYORSHIPS.

NELSON (LANCASHIRE).—Mr. J. W. Bradley, of the Borough Engineer's office, Leicester, has received this appointment, the salary of which is 250*l.* per annum. There were ninety-three applicants for the appointment. The office became vacant by the appointment of the present Surveyor (Mr. J. A. Crowther, formerly of Leeds), as Borough Surveyor of Boodle.

OBITUARY.

DEATH OF AN OLD DISTRICT SURVEYOR.—The death of Mr. H. J. Hammon took place recently. He was appointed in 1853 District Surveyor of St. Luke's, Old-street with the Liberty of Glass-house-yard, when there was a fierce contest with Mr. F. W. Roper, afterwards elected to the Holborn District. Mr. Hammon was in his eighty-second year, and for some years resided near Battle, Sussex. It is expected that the District will be added to one of the adjoining ones.

MR. GEORGE FREETB ROPER.—At the moment of going to press we hear with regret of the death of Mr. George Freetb Roper, whose name will be familiar to many of our readers. He died on the 14th inst., aged forty-nine.

GENERAL BUILDING NEWS.

REBUILDING OF ST. WENBURGH'S CHURCH, DERBY.—On the 26th ult., the Duke of Devonshire laid the foundation-stone of the new Church of St. Werburgh, Derby. Sir Arthur Blomfield is the architect, and in his plans for the new structure the present tower, chancel, and organ chamber, which are of comparatively modern date, are preserved intact. The new nave is to consist of five bays, and the total length will be 88 ft. 8 in., the width being 62 ft. 2 in. The body of the church will be 60 ft. high, with an open hammer-beam roof. The chancel will be 40 ft. 6 in. by 27 ft. At the end of the chancel there will be a seven-light window, with a carved reredos below. The walling will be of Coxheath stone, which from the exterior will be rock-faced, and in the inside hammer-dressed. The dressings will also be of Coxheath stone, except in the case of the finer parts of tracery, which will be worked in Hopton stone. The roof will consist of green slates with lead gutters, and stone-embattled parapets. The entire area of the nave will be paved with wood blocks, whilst the chancel, which will be divided from the nave by a dwarf screen, will have a tiled floor with steps of Portland stone. The seating accommodation will be for 878 persons. The con-

tract for the building was let to Messrs. Shillitoe & Sons, of Bury St. Edmunds, and the total cost has been estimated at between 11,000*l.* and 12,000*l.*

POLICE STATION, CATHCART.—Plans by Mr. Davidson, of Paisley, for a new police station at Cathcart, near Glasgow, have been approved by the County Committee. The style adopted is Scottish, and, as part of the building is three stories in height, it will be quite a prominent building in the district, where (as yet) the houses are principally of one and two stories.

HALIFAX MARKETS AND ARCADE.—These works have now let, and the contract for covering the roofs has been secured by Messrs. Helliwell & Co., of Brighouse and London, for their well-known patent system of glazing without putty. The architects are Messrs. Leeming & Leeming, of London.

RESTORATION OF PARISH CHURCH, GIGGLESWICK, YORKSHIRE.—The ancient Parish Church of Giggleswick, near Settle, has just been re-opened by the Bishop of Richmond, after extensive restoration. The work, which has cost some 2,500*l.*, has been carried out from the designs of Messrs. Paley, Austin, & Paly, architects, of Lancaster, the contractor being Mr. H. Brassington, of Settle. The work done includes the construction of an organ chamber and vestry, the erection of a heating apparatus chamber, the re-roofing of the entire fabric with oak and lead, the pointing of the stonework, the re-seating of the interior, and the erection of several stained-glass windows in the body of the church and the choir.

NEW LIBRARY FOR SOLICITORS, EDINBURGH.—The new library for the Society of Solicitors in the Supreme Courts of Scotland, was opened on the 12th inst. by the Lord Justice-General of Scotland, the Right Hon. J. P. B. Robertson. The site of the library is in the Cowgate, to which it shows a frontage of 150 ft., and as the Cowgate is at a much lower level than Parliament-square, the Society's premises, says the *Scotsman*, have been put in the topmost stories of the building, so that the top or main story is on the same level as the floor of Parliament House, with which it is connected by a bridge, which is a continuation of the corridor between the Inner and the Outer Houses. The four lower stories have been turned into artisan dwelling-houses, with shops on the basement. On the main or top floor, beginning at the west end, is an entrance-hall, lighted by four stained-glass windows. A staircase, executed in teak, leads from the hall to the flat below, and facing the entrance is the reading-room, 30 ft. by 22 ft. East of the entrance hall is the main library, measuring 74 ft. by 42 ft., with arched ceiling. Each side is divided into five alcoves, and the bookcases have been made part of the architectural features of the room. Each block is terminated by pilasters facing the interior of the room, and from the tops of these spring a series of elliptical arches supported on moulded and carved trusses. The windows are to be of stained glass. A gallery with ornamental iron railing runs round the sides of the room. Beyond the library, entering off it to the eastward, is the Society's hall, 40 ft. by 26 ft.; librarian's room and other accessories. The second story, entered from the staircase in the vestibule, is taken up with book stores, repairing and sorting rooms, consulting rooms for members of the Society, and heating apparatus. There is accommodation in the library and stores for about 70,000 volumes. The architect has been Mr. James B. Dunn, of Edinburgh, whose design was selected in competition. The cost of the site and building has been close on 30,000*l.*

ST. BARNABAS'S CHURCH, BELFAST.—On the 7th inst., the memorial-stone of St. Barnabas's Church, Donecain-gardens, Belfast, was laid by the Mayor of Belfast. The church is being carried out in the Early English style. The materials used are red perforated brick, with white Scotch stone dressings. The church when completed will consist of a nave 70 ft. long by 27 ft. wide, with north and south aisles, divided from the same by a series of moulded arches carried on cut-stone piers. The chancel, which is approached by an arch springing the full width of the nave, provides accommodation for organ and choir. The church at present being built will seat 550 persons, but when the north aisle is added accommodation will be provided for 770. The contract is being carried out by Mr. Thomas McMillan, of Belfast, from the plans and under the superintendence of the architect, Mr. Henry Seaver, also of Belfast.

RESTORATION OF WOODHAM MOETIMER CHURCH, ESSEX.—The re-opening, after restoration, of St. Andrew's Church, Woodham Mortimer, by the Bishop of St. Albans, took place on the 27th ult. With the exception of the south wall and the east end, the whole of the church, says the *Essex County Chronicle*, has been rebuilt. A new arcade takes the place of the north wall, and the old north transept has been replaced by an aisle. In the roof of the aisle are two dormer windows. The church has now also the addition of a new vestry; the old gallery and organ-loft, which stood at the west end of the church, have been pulled down, and the organ has been enlarged and repaired by Fincham & Co., of London, and placed in the transept. Previously there was no west window, but in the course of the alterations an old one was found beneath the plaster, and it has

been opened up and restered. Two windows,—one a Norman and the other Decorated,—were also discovered in the south wall after the plaster was stripped off, and they have been opened up. The old-fashioned high-backed pews have been replaced by modern benches of oak; the floors and aisles are laid with blocks of wood, and a new heating apparatus has been put in. The church furniture is of oak, the altar-table and rails and the pulpit and lecterns being made of old carved oak. The roof is of yellow deal, panelled and ribbed, with a plain cross on the chancel beam. In the east end is a three-light window with stained glass, the subject being the Nativity. The tracery is filled in with angels bearing instruments of music. At the side of the altar is another painted glass single-light window. At the south side of the chancel is a two-light window (replacing a single light) with two figures, St. Peter and St. John. The west window has two painted-glass lights representing the figures of Charity and Purity. The painted glass windows are the work of Messrs. Heaton, Butler, & Bayne, of London. The restoration has been carried out by Mr. H. Gozzett, son, at a cost of about 1,750l. The architect was Mr. Sidney Gambier Parry, of Westminster.

PROPOSED RECONSTRUCTION OF THE COUNTY BUILDINGS, EDINBURGH.—It is proposed to reconstruct the Edinburgh County Buildings, and, according to the *Edinburgh Evening News*, several members of the Justices of the Peace of Edinburgh, being dissatisfied with the plans prepared for the County Council, had new designs prepared for them by Mr. M. Farlane Cameron, architect, of Edinburgh. It is proposed to bring the frontage forward to the present line of pavement, leaving a small area light only at the north-west corner. A large entrance from George IV. Bridge is provided. The front is treated in Palladian Classic, and the lines of the present building have been retained. It is proposed to ask support from the Town Council in the matter.

CATHEDRAL OF ST. MACARTAN, MONAGHAN.—According to the *Freeman's Journal*, the Cathedral of St. Macartan, Monaghan, is fast approaching completion. It is a Gothic structure, and the foundation-stone was laid more than twenty years ago by the late Bishop M. Nally. The building was designed by the late Mr. M. Carthy, but since 1835 it has been in the hands of Mr. Hague, who has been responsible for the spire and the larger portion of the interior fittings and embellishments. The spire springs from a tower built against the southern transept of the church to the height of 245 ft., and is furnished with cathedral bells. Internally, there are five altars,—the high altar, surmounted by a baldachino, and the four side altars, each with a recess of interlaced marbles. The flooring and balustrades of the sanctuary, the choir, the side-chapels, and the baptistry are in mosaic of fourteen varieties of Italian marble. The statuary is from Carrara. On the western façade of the Cathedral is the statue of St. Macartan. The western door is flanked by two statues of St. Peter and Paul, and its tympanum is filled by a bas-relief in marble, representing Our Lord committing the keys of Heaven to St. Peter. In the colonnade of the northern transept are statues of seven saints. On the corresponding colonnade of the southern transept stand seven figures of personages interesting to the people of Clougher. On the southern front of the tower is a figure of Our Lord. There are seven stained-glass windows in the apse around the high altar, and in the four side chapels the altars are surmounted by stained-glass windows. The oak furniture of the Cathedral has been supplied by Messrs. Brien & Keating, of Wexford. The Cathedral organ is the work of the Messrs. Telford, of Dublin. The stained-glass windows were executed by Messrs. Cox, Buckley, & Co., London, and Youghal; Messrs. Early & Powells, Dublin; and Messrs. Mayer & Co., of London and Munich. The decoration of the Cathedral walls is the work of Mr. Mannix, of Dublin.

CHANCEL, PARISH CHURCH, UPHILL.—The parish church of Uphill, Somerset, was re-opened on the 10th inst., after the building of a new chancel, in addition to which new choir and clergy vestries, organ chamber, north and south porches, have been erected, and the nave reseated with oak seats. The architect for the work is Mr. G. F. Burr, of Hastings; and the contractor Mr. Charles Addicott, of Weston-super-Mare. The cost has been about 1,650l. The wrought-iron gates to the chancel-screen, which is of oak and carved chestnut, were executed by Mr. George Wilson, of Birmingham, from the designs of the architect.

PUBLIC BATHS AND PUBLIC HALL, CHEETHAM HILL, NEAR MANCHESTER.—Land has just been purchased and plans approved for the erection of public baths and a public hall in the Bury Old-road, Cheetham, Manchester. Messrs. Booth & Chadwick, of Manchester, are the architects. The public hall will be built on the higher and the baths on the lower land, but all the principal entrances will be from Cheetham Hill-road. The first-class swimming-bath will have a water area of 54 ft. by 27 ft., and the second-class bath one of 75 ft. by 24 ft. The latter will be surrounded by a balcony. The pavilion in which it is situated is so arranged as to be capable of being used as a gymnasium in the

winter months. There are twenty slipper-baths and three waiting-rooms. A residence for the superintendent will be situated over the ticket office and entrances to the baths, and in connexion with this department there is to be a tower for a public clock. The laundry and boiler-rooms are centrally situated between the two large swimming-baths, and the fall of the land will enable the boiler-house to be approached on the street level from Back Halliwell-lane. The public hall will be on the ground-floor level, and will be practically a separate building. The principal room will have a clear floor area of 64 ft. by 42 ft., and there will be a balcony gallery in addition. There will also be five reading and cloak rooms, with lavatories, &c., attached, a refreshment-room, serving-room, and a cellar kitchen. There will be an entrance-hall leading to the public-rooms; and the retiring-rooms for ladies and gentlemen will be placed to the right and left of it. Additional doors for occasional exit are provided from the public hall and from the large second-class bath pavilion. The design of the buildings is based on the Italian style, with some of the earlier features of the Elizabethan introduced in the windows, &c. The main fronts will be faced with Ruabon stock bricks and terra-cotta. The public hall will have a panelled ceiling, and be lighted by a series of mullioned windows.

RAGGED SCHOOLS, MANCHESTER.—The new buildings for Charter-street Ragged School and Girls' Home, Manchester, were opened on the 28th ult. by the Baroness Hylton-Clout. The new buildings are situated on a plot of land lying between Ashley-street and Charter-street. On the ground floor at the corner of Ashley-lane and Little Nelson-street is a mission-hall capable of accommodating 500 persons, with two public entrances in Ashley-lane and a platform entrance in Little Nelson-street. On the first floor, above the mission-hall, is a school-room to accommodate 700 children, with two class-rooms in addition to accommodate 40 each. The infants' school is placed on the ground floor, with an entrance through a yard from Charter-street, and an entrance for the teachers and visitors from Little Nelson-street. The room is 63 ft. long, and will accommodate 500 infants. The whole of the roof is of glass. There is a gallery for infants at one end of the room, which is to be divided off from the rest of the room by a movable partition, and there is a platform at the other end. The Girls' Home provides accommodation for about forty young women. The girls' sitting-room is 32 ft. by 20 ft., lit with three bay windows facing the south and east. This room is heated with one of Shorland's ventilating stoves. On the first floor of the home is provided a wash-house. The girls' kitchen is provided with a cooking range. The hot water for the kitchens and bath is generated in a boiler in the basement, and the water is circulated in copper pipes to the wash-houses, lavatories, kitchens, and baths. The materials used for the exterior are second brick with red dressings, and the walls inside have been pointed and colour-washed. The general contract for the work has been carried out by Messrs. Peters, of Rochdale, from the plans and under the supervision of Messrs. Maxwell & Tuke, architects, of Manchester.

CHURCH OF ST. GILES, LUSLEY, WORCESTER.—On the 25th ult. the foundation-stone was laid of the Church of St. Giles, Lusley, Worcester, which is being built near the site of the old church. The church is to be built of a red sandstone from a local quarry at Blackswell. The architects are Messrs. H. Rowe & Sons, of Worcester, and the builder is Mr. T. Collins, of Tewkesbury.

SANITARY AND ENGINEERING NEWS.

LEOMINSTER WATER EXTENSION SCHEME.—On the 10th inst., the Corporation of Leominster received the Local Government Board's sanction to the water extension scheme which was laid before Mr. T. Codrington, C.E., last June. The engineer for the scheme is Mr. John W. B. Rooke, the Borough Surveyor.

DRAINAGE, WHITECHURCH, CARDIFF.—At a meeting of the Cardiff Rural Sanitary Authority, held at their offices, Queen's-chambers, Cardiff, on the 11th inst., a scheme of drainage for the Parish of Whitechurch, prepared by their surveyor, Mr. William Fraser, was considered and referred to a sub-committee. The scheme is estimated to cost 6,500l., and includes over six and a half miles of stoneware pipes ranging in size from 9 in. to 18 in. in diameter, with all necessary manholes, ventilators, and automatic flushing tanks, &c., having an outfall by eight connexions into the Ystradyfodwg and Pontypridd main sewer, which passes through the district of the authority, emptying into the Bristol Channel near Rumney.

SEWAGE DISPOSAL, LUDLOW.—The Corporation of Ludlow is now considering the question of adopting a scheme of sewage disposal. In 1861 the town was sewered by the late Mr. T. Cunliffe, C.E., and a system of disposal, involving deodorisation and filtration, was then adopted. Since 1861, sewage, sanitary science has advanced, and the present Inspectors obsolete and out of date. The Corporation has lately made application to the Local Government Board for permission to extend

the boundaries of the Borough, and the Local Government Board have held a preliminary inquiry, the outcome of which is the Board has now sent the Corporation a map with a suggested boundary marked on it, with an intimation that it will be willing to entertain an application based on this, provided the Corporation can show that it has at the time of the application an efficient system of sewage disposal which can be made available not only for the present borough, but for the areas proposed to be added. The Corporation has passed a resolution that it will provide such a system, and has referred the question to a Committee to consider the details.

EXTENSION OF WATER SUPPLY, ROTHEWAY, BUTE.—On the 13th inst. the Rotheway Municipality opened the new extension and filter-works at Aseog Loch. The extension includes not only the erection of filters, but the raising of the loch by means of a puddled embankment, which raises the storage area 6 ft. above the former level. The engineers for the work were Messrs. Leslie & Reid, of Edinburgh, while the contractor was Mr. John Murray, Maryhill. The total cost of the work, including stripping the margins of the loch and beaching, is expected to be between 7,000l. and 8,000l.

SEWERAGE WORKS AT HENDON.—On the 14th inst. the Chairman of the Hendon Local Board, Mr. John Warburton, opened the new pumping station, which has been erected near Cool Oak-lane, to deal with the sewage from what is known as the Station district, forming part of the Low Level area. The latter comprises about 1,100 acres. It has become necessary to drain this district in consequence of the complaints made by the Regent's Canal Company, who own the Brent reservoir, at Hendon, and into which pollution from the houses in the Station district forced its way when the cesspools overflowed. The Thames Contractors also complained of the same state of things, the river Brent being a tributary of the Thames. The Board instructed their engineer, Mr. S. S. Grimley, A.M.I.C.E., to prepare the necessary drawings for the works, and in June, 1891, the tender of Mr. James Dickson, of St. Albans, was accepted for the sewer, which was constructed with Hassall's double-lined pipes, 18 in. diameter, surrounded with portland cement concrete. The tender of Mr. Joseph Weston, of Westminster, was accepted for sewerage and making up three roads leading to the outfall sewer, and the tender of Messrs. Crossley Brothers, of London and Manchester was accepted for the machinery. The total cost of the works has been 6,358l., being well within the engineer's estimate. Although the outfall sewer had to be laid about 8 ft. below the high-water mark in the Canal Company's reservoir, and closely adjacent thereto, and during the year of 1891, the leakage from all sources is not more than one-fourth of the capacity of the sewer. The machinery consists of two 7-h.p. (nom.) Crossley's "Otto" gas-engines, with tube ignition and all the latest improvements giving out about 11½-h.p. on brake. Each gas-engine drives a set of three-throw plunger-pumps, 18 in. by 10 in., by means of Victoria belt-throwing counter-shafts, 3½ in. in diameter, working in gun-metal bearings bolted to pump-frames. Each set of pumps will throw 350 gallons per minute, or over 500,000 gallons in twenty-four hours, into the high-level gravitating sewer through a 9-in. rising main about 800 ft. long, at a speed of thirty revolutions per minute. The sewage flows about a mile and a-half through the gravitating sewer to the outfall, where it is treated on the ferrocene and polaris process of the International Water and Sewage Purification Company.

STAINED GLASS AND DECORATION.

WINDOW, ST. JOHN'S CHURCH, LONGSIGHT, MANCHESTER.—A new three-light east window has been inserted in the chancel of St. John's Church, Longsight. The subject is the transfiguration of Our Lord. He being the central figure of the upper portion, with Moses and Elias on either side. Below are the figures of St. Peter, James, and John, one in each light. The whole of the masonry of the east wall is new. The works were designed by and have been carried out under the superintendence of Mr. Medland Taylor, Messrs. Heaton, Butler, & Bayne being the artists by whom the window was executed, and Messrs. Ekis & Hinchliffe the masons who did the stonework.

NEW WINDOWS, ST. ANDREW'S CHURCH, RADCLIFFE, LANCASHIRE.—On the 17th ult., the windows in the octagonal-shaped chancel of the Church of St. Andrew, Radcliffe, which had been filled with stained glass, were unveiled and dedicated. The twelve lights forming the seven windows have been filled with the following subjects from Our Lord's passion:—1. The supper in the house of Simon. 2. The entry into Jerusalem. 3. Christ purging the temple. 4. The institution of the Holy Eucharist. 5. Washing the disciples' feet. 6. The agony in the garden. 7. Christ before Caiaphas. 8. Behold the Man. 9. The way of the Cross. 10. The Betrayal. 11. The Crucifixion. 12. The Entombment. In each case the subject fills the whole light as far up as the spring of the arch, the rest being

led in with shields enclosed in foliated ornament... The tracery above each window contains an angel holding a shield upon which is shown...

MISCELLANEOUS.

THE CONVERSION OF GAUGE ON THE GREAT WESTERN RAILWAY.—The Engineer for May 13 contains an interesting article on this subject. At midnight this Saturday, May 21, the entire section of the line from Exeter to Falmouth, a distance of 113½ miles, will be closed to traffic, and handed over to an army of 3,600 platelayers, who will alter the permanent way to the narrow-gauge system.

THE CONCENTRATION OF POPULATION IN GREAT CITIES.—The Lancet of May 14, contains the first part of a lecture on this subject, recently delivered at University College, London, by Dr. G. V. Poore. It is full of suggestive points. Quoting from a paper read by Dr. Gould, of Washington, before the recent International Congress of Hygiene and Demography, he says that only half a century ago the urban population of the United States was 8½ per cent. of the whole, while to-day the urban population constitutes 29 per cent. of the whole.

INNOCUOUS WHITE-LEAD.—The Patent Innocuous White-lead Company (T. B. Freeman) send us a pamphlet of testimonials from chemists and others in regard to their "non-poisonous white-lead paint," which is stated by Professor Church to be "practically insoluble, so far as the lead is concerned in water or acids, and non-poisonous, and that it possesses the merits of ordinary white-lead as a pigment without its drawbacks."

THE TRADES' MAIDEN HOSPITAL, EDINBURGH.—The Trustees of the Trades' Maiden Hospital of Edinburgh have acquired Ashfield, a residence situated to the south of the city, which, with additions thereto, is to be adapted to the purposes of the Institution. Ashfield was designed by Mr. David Macgibbon as a residence for himself, and is an adaptation of the Scottish Baronial style.

THE LYRIC THEATRE.—Another of the London new theatres,—the Lyric, in Shaftesbury-avenue,—has just been placed in the market. This theatre, erected for Mr. H. J. Leelis, from the plans and designs of Mr. C. J. Phillips, architect, was opened on December 17, 1888. Its site covers 14,200 ft. superficial, of which 10,000 is held by an eighty years lease, running from 1886, at a ground-rent of 1,104l.; the remainder, with the buildings thereon, being freehold. The frontage to the Avenue is 148 ft. long. The upper floors are occupied as residential chambers. We gave a full description of the fabric in our issue of December 22, 1888.

THE DANGERS OF BARE COPPER UNDERGROUND ELECTRIC MAINS.—Our contemporary, L'Electricien, published, on April 16, an article with the above title, referring to the explosion which had recently taken place in a manhole belonging to the Edison Company, in the Rue Babouin (Paris). The statements contained in the article in question were such that, in view of the large use to which the bare copper system has been put in England, it would be imagined that English engineers would (unless in the case of the Edison Company there

had been culpable negligence) have experienced similar difficulties. We are informed, however, that this is not the case, and that, with the exception of explosions resulting from coal gas leaking into the conduits, no difficulties of the kind indicated have been encountered with the bare copper system in England. Such a thing as carbonising of, or deposition of, copper salts on the conductors is, in ordinary working, unknown. Where any section of the main has got to earth through breaking of the copper, the latter has, of course, generally been eaten through; but such an accident as this cannot fairly be attributed to the demerits of the system, and is, of course, entirely the fault of the workmanship. The growth of the bare copper system of underground mains has been so rapid (there being over 100 miles now laid in England) that, on reading our contemporary's article, we were inclined to conclude that the formations referred to were of so unusual a nature as to be unfairly described as a danger to which bare underground mains are frequently subject, and that they were rather the result of careless and inefficient engineering. We are glad to find that our opinion is confirmed by those who have had most experience with this class of work in England.—Electrical Plant.

CHICAGO EXHIBITION.—We are informed that the new building which is now in course of erection for the headquarters of the British Royal Commission will be generally characteristic of the best type of English half-timber houses of the sixteenth century. It is proposed to use terra-cotta somewhat largely in the lower story, with red brick facing and mullioned windows, so that the building need be a typical example of an old English house. The upper portion will be of half-timber construction, with overhanging and projecting gables. The plans and designs for the whole building have been prepared by Colonel Robert W. Edis, F.S.A., the honorary architect to the Royal Commission; and the whole of the internal fittings and furniture will be executed from his designs by Messrs. Johnstone, Norman, & Co.

THE PRODUCTION OF TIN PLATES IN THE UNITED STATES.—Owing to the strenuous efforts now being made in the United States to establish the manufacture of tin plates there, to the exclusion of the British product, the report on the subject just presented by Colonel Ira Ayer, agent of the American Treasury Department, is of special interest. The report of Colonel Ayer covers the period from July 1, 1891, to March 31, 1892, the former date being the day on which the McKinley tariff came into operation. The annexed statement shows the production of tin and terne plates by quarters:—

Table with 5 columns: Quarter ended, Works Established, Tin Plates (lbs.), Terne Plates (lbs.), Totals. Data for Sept 30, 1891; Dec 31, 1891; Mar 31, 1892; and Totals.

According to Colonel Ayer's report the average annual imports of British tin and terne plates for the three years ended June 30, 1890, amounted to 678,000,000 lbs. In the year ended June 30, 1891, the imports were 1,058,000,000 lbs. This large increase of 380,000,000 lbs. was due to larger importations in the first six months of 1891 to avoid the new duty of 2-2 cents per lb. imposed by the McKinley tariff. It is stated that, if the imports for the current year are made to meet only the actual wants of the United States, they will not exceed 300,000,000 lbs. For the eight months up to February 20, 1892, they amounted to only 177,000,000 lbs. The quantity of tin plates imported in the year ended June 30, 1891, which were used in the manufacture of exported articles, and upon which a drawback was paid, was 150,000,000 lbs. In 1890 it was 150,000,000 lbs., and in 1889 it amounted to 168,000,000 lbs. It is a stipulation of the McKinley tariff that, if after six years after the introduction of that tariff the quantity of tin plates made in the United States exceeds one-third of the quantity imported, the present duty of 2-2 cents is to be maintained. Taking the figures given above as a basis it is estimated by Colonel Ayer that the American manufacturers, in order to make the duty on tin plates perpetual after October 1, 1897, must produce in any one of the six years up to that date 50,000,000 lbs. of tin and terne plates.

ELECTRIC RAILWAY IN SIAM.—The contract for the electrical plant of the electric railway in Siam has gone to the United States, the Short Electric Railway Company of Cleveland, Ohio, being the successful competitors. The contract includes two 65-h.p. generators and six cars with a 20-h.p. motor to each car. It has been the custom lately for some of our authorities to congratulate this country on having allowed the Americans to go ahead of us in the application of electricity to industrial purposes. The line of argument taken is that the advances being made in this field are so enormous, that we shall do well to let the Americans go a bit ahead to show us the way, and so we shall

FOREIGN AND COLONIAL.

FRANCE.—A picture in the *Champs Elysees* has been cut with a pen-knife; the picture is 'Vibert's "Médéon Malade." It is not known who has committed this act of vandalism.—M. Amille Krantz, deputy of the Voges, member of the jury at the Universal Exhibition of 1889, has been nominated General Commissioner for the next Government at the International Exhibition of Chicago, in 1893.—The section for French works of art at the Chicago Exhibition will be opened on May 1, 1893, and closed on October 30.

—The fifty-ninth session of the Archaeological Congress of France will be held this year at Orleans. It will begin on June 22, and last till the end of the month.—An exhibition of paintings by J. Huet is to be held in the Galerie Georges Petit. M. J. Prevost has just offered to the Luxembourg Museum a picture by M. Weiss, called 'Femme du Masque.'—The picture by M. douard Detaille, "Sortie de la Garrison de Dinanville," has been presented to the nation by a person unknown, but who is supposed to be an American. The picture is to have a place in the Luxembourg.—At last the fees for the architects who have reconstructed the Hotel de Ville have been settled. This work has cost 23,545,836fr., of which the work of artistic decoration, they are shortly to proceed with the enlargement of the Musée du Louvre, by taking in the quarters occupied by the Prefecture of the Seine since 1879.

—The State has just bought for the Louvre a portrait of Eugene Delacroix, by Gericoult. A monumental door is to be placed on the Hotel de Clugny. This door is in a very fine style, and is the last vestige of the church of Saint Etienne des Grés.—Several French artists,—M. Hubert, Castellani, Duez, Ferrier, Flameng, Gervey, Allouart, J. P. Laurens, Rogebrasse, Merson, etc.,—are proposing to execute a panorama of France for the Chicago Exhibition. It will include the country, types, and manners and customs of a French province. A discovery has been made near Versailles of an amphora, containing a large quantity of Gallo-Roman money.—The general Council of Var has voted 400,000 francs for the enlargement of the Asylum of Pierrefeu, which was built in 1832, and which was the object of a very important commission, the first prize having been awarded to M. Violet and Geyler.—The railway to Ormieres from Aix-les-Bains is to be opened in September next.—The death is announced of the sculptor, Louis Vidal. He was born at Nîmes in 1831, and was a pupil of Barye, and received medals in 1861 and 1863. In latter years he had lost his sight.

BERLIN.—The question of a further alteration of the neighbourhood of the Imperial "Schloss" has been formally dropped, and the "Schlossplatz" is assumed the same aspect as was planned at the time of the first lottery which was opened for the purpose of raising money for the improvement of the site; and the memorial monument to Emperor William I. will have a place found for it on the east end of the railway to Ormieres from Aix-les-Bains. According to the *Colony Gazette*, this monument is now to be carried out by the sculptor Reinhold Begue and the architect Ihne.—There are a number of monuments in course of erection in the country. The one to be erected on the historical Kyffhauser had a foundation stone laid by the Duke of Schwarzburg-Rudolstadt on the 10th inst., this being the anniversary of the Peace at Schortensheim. Otto Schmitz is the architect.—The competition for the model of the sculptural parts on Bruno Hmitz' Soldiers and Sailors Monument at Indianapolis has apparently been decided in favour of the Berlin sculptor, Herr Nikolaus Geiger (*Nordd. Uig. Ztg.*). This is the second piece of monumental sculpture to be done in Berlin for America. The first piece was the Washington Monument for the city of Washington, which was in the hands of Professor Adolf Siemering. The bronze parts of this colossal monument are already for the most part in America.—The private view of the Berlin salon is on Friday. The local papers considered the show to be a fair one on the whole, although the old art of the Berlin art exhibitions, &c., the ranking quantity above quality, has been made by the judging committee with the purpose of filling their list. The sculpture hall excites most interest, rightly, perhaps, on account of the huge size of the exhibits.—The official "Architekten Verein" had a debate on the selection of a suitable site for the International Exhibition, and will give a prize of 250l. for the best proposition made, if accompanied by a rough plan of the grounds proposed. The three sites are deserving of attention at present, one in an outlying suburb, Wilmersdorf, (2), one in the Treptow Park, and (3), another on the edge of the grounds in the south-west of the city.

avoid those difficulties which they overcome by the light of experience. There would seem, however, to be one counterbalancing disadvantage at any rate, for whilst we are waiting, our more pushing cousins are establishing a very good connexion for the sale of electrical appliances abroad.

PUBLIC WORKS, NELSON, LANCASHIRE.—On the 17th inst. Mr. Rienzi Walton, Local Government Board inspector, opened an inquiry at Nelson in an application by the Corporation for sanction to borrow 10,000*l.* for electric lighting purposes, 10,000*l.* for purchasing a cemetery, 7,500*l.* for the erection of a public library and technical school, and for the appropriation of land now possessed by the Corporation as a site for the technical school.

PUBLIC WORKS, MANCHESTER.—On the 17th inst. Mr. S. J. Smith, one of the inspectors of the Local Government Board, held an inquiry in the Mayor's Parlour at the Town Hall, Manchester, respecting the application of the Town Council to borrow the sum of 150,000*l.* for purposes of electric lighting, and 12,000*l.* for providing a public library for the Openshaw district.—Mr. J. W. Southern, chairman of the Libraries Committee, said it was proposed to erect library buildings to cost 15,000*l.* It was estimated that the fittings would cost 1,750*l.*—Mr. James W. Beaumont, the architect, submitted plans of the proposed library. He stated that it was expected the building would be completed in twelve months.—Alderman Sir John Harwood then gave evidence relative to the application to borrow 150,000*l.* for electric lighting purposes. He stated that the Corporation had had the matter of supplying the electric light under consideration for the last ten years. In 1870 they got an order from the Board of Trade and confirmed by Parliament empowering them to supply electric lighting. They invited four eminent electrical engineers to prepare plans for the installation, each being paid 100 guineas, and their reports were submitted to experts. It was finally determined to adopt the scheme of Professor Dr. John Horkinson, who had been employed by the Corporation to carry out the work. The site on which they intended to erect the works was situated in Dickenson-street, off Portland-street.—Dr. Horkinson then explained the plans for the installation. The immediate outlay, he said, would be 78,715*l.* In addition there was the cost of the site and the cost of the additional machinery, which would absorb the whole of the 150,000*l.*—The inquiry having been completed, the Inspector visited the sites.

THE ENGLISH IRON TRADE.—Comparatively little change has taken place in the English iron market since last week, but in the Cleveland district there has been more inquiry for No. 1 pig-iron owing to a prospective early increase in the Swedish tariff. In all the pig-iron centres trade is very dull, and quotations remain practically unchanged. In the finished-iron trade business is confined to hand-to-mouth requirements, and there is little alteration of note in the steel trade. Ship-building material continues to prove the chief article inquired for. The triplate steel is slightly brisker, but values remain low. Engineers and shipbuilders show little fresh life. The coal trade generally is quiet.—Iron.

MEETINGS.

MONDAY, MAY 23. Society of Arts (Recent Lectures).—Dr. Percy F. Frankland on "Recent Bacteriological and Chemical Research in Connection with the Fermentation Industries." IV. 8 p.m.

TUESDAY, MAY 24. Institution of Civil Engineers.—Professor W. C. Roberts-Austen on "The Measurement of High Temperature." 8 p.m.

Guid and School of Handicrafts.—Mr. J. S. Thornton on "Sloyd." 8 p.m.

Society of Arts.—Mr. F. E. Ives on "Researches in Photochromy." 8 p.m.

FRIDAY, MAY 27. Architectural Association.—Mr. C. R. Ashbee on "The Relation of the Architect to the Workman." 7.30 p.m.

RECENT PATENTS:

ABSTRACTS OF SPECIFICATIONS.

5,875.—SASH-CORD FASTENERS: J. F. Munby.—This invention relates to what is described as an improved method for securing the sash-cords of windows to the sash-frames, and an improvement in the construction of a frame employed in the manufacture of appliances for the purpose. The appliance comprising the sash-cord consists of two lugs cast to, and formed in, a bracket mounted between the lugs, and carried eccentrically on a through pin is a swing catch, the outer edge being grooved and serrated for the purpose of holding the cord when threaded between the lugs and the serrated catch. The improved mould for the casting of the fastener is constructed so that several may be cast at the same time, the mould being formed in three parts, the two outer ones forming the box, and the inner one the core, having recesses on each side of it of the size and shape of the brackets, which are to be divided into the form of a pin is placed in the recess in the box, the latter being held by an eccentric handle. The mould for forming the serrated grooves, and to facilitate the stripping of the castings. The boxes have troughs formed in them into which the molten metal is run, and a series of holes in the troughs communicate with the interior of the boxes and the core.

9,162.—LOCKING WINDOW-SASHES: G. Chisholm, Junr.—This invention relates to an improved means for locking and unlocking, automatically, window-sashes, and providing means by which the sashes may be locked on the inside with the top sash partly open, and down, and at the same time prevent the sashes being opened from the outside. The inventor mounts in the central head of the window a frictional provision formed and lower sashes, a metal plate having a projection on it for carrying a small double-armed rocking lever, and also provided at its top and with a small bevelled guard plate, which projects beyond the upper sash. The rocking lever is caused to open by means of a shape with a pivoted double-armed bracket secured to metal plate of the lower sash, and in openings formed in this plate has two or more of said openings formed in it, one above the other, at any desired distance apart. The whole is such that the upper sash cannot be moved unless the locking lever is out of gear with it, which can only be effected by raising the lower sash, which,

prevent its being raised from the outside, is provided with a suitable anti-rattle device. 7,618.—WINDOW-SASHES: F. J. Gibbons.—This specification refers to an improvement in the locks of window-sashes. It consists more particularly in the combination with the lock proper of devices by which the key is locked in its location, the sashes themselves are locked in the desired position by the protrusion of the lock-bolt, and also of an indicator by which it is rendered impossible for the lock to be left unlocked, its thread being engaged by a socket rotatable in the lock-case by an external wheel key.

3,531.—METALLIC LATHING: G. Hayes.—This invention relates to lathing formed of sheet metal, and having at intervals throughout tongued apertures. It consists of a sheet metal lathing formed with corrugations throughout, and in the hollows of the corrugations (as they appear to its front or receiving face) are cut apertures in line lengthwise; the corrugations, with the tongues turned over backward from the openings in a direction lengthwise the hollow, and towards the next opening in line. It further consists of a corrugated sheet of metal lathing having tongued apertures at intervals in the hollows of the corrugations appearing to its receiving face, as shown in the drawings accompanying the specification.

NEW APPLICATIONS FOR LETTERS PATENT.

May 3.—8,292, G. Graham, Artificial Stone Blocks.—8,297, H. Hunt, Fire-grates.—8,296, W. Hewitt and A. S. Snelker, Steam-Boiler Machinery.—8,293, C. Sargent, Construction of Bricks.—8,381, C. Jehu, Ventilation of House-Drains.—8,394, H. Hunt, Mantelpieces for Fire-places. May 4.—8,403, S. Johnson, Attaching Door-knobs to Spindles.—8,450, W. Hewitt and A. S. Sauer, Composts for Paving or Covering Roads, Paths, or Floors, and for Manufacture of Paving-Blocks or Bricks.—8,472, C. Hawke, Covering for Walls, &c.—8,477, H. Berthold, Kiln or Drying Apparatus.—8,481, H. Berthold, Self-closing Door-hinge. May 6.—8,580, T. Carlaw, Window-Fittings.—8,583, T. Fawcett, Marking and Pressing Bricks, and in modification thereof, and in Clay-mixing or Grinding pans employed therein. May 7.—8,708, S. Moore, Electrical Fittings, such as ceiling roses and cut-outs.—8,714, A. Boulit, Pipe Connectors.

TERMS OF SUBSCRIPTION.
 "THE BUILDER" is supplied winter from the Office to resident in any part of the United Kingdom at the rate of 15s. per annum PREPAY. To all parts of Europe, America, Australia, and New Zealand, 20s. per annum. To India, China, Ceylon, &c., 30s. per annum. Remittances payable to DOUGLAS FOURDRINER, Publisher, No. 46, Catherine-street, W.C.

TO CORRESPONDENTS.
 W. M.—A. S. (We will endeavor to give you the information if it is not too far back).—H. H. (We have not space to notice the correspondence).—Amc wh. was there.—D. H. M. & Co. (too small).—B. M. B. (It is not necessary to go further into the matter; all our readers know the facts).—W. H. (We do not insert letters without names).
 All statements of facts, lists of tenders, &c., must be accompanied by the name and address of the sender, and articles matter should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHERS, and not to the Editor.
 Note.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.
 We are unable to undertake to return rejected communications. Letters or communications (beyond mere news-items) which have been duplicated for other journals, are NOT DESIRED.
 All communications regarding literary and artistic matter should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHERS, and not to the Editor.

PUBLISHER'S NOTICES.

Registered Telegraphic Address, 'THE BUILDER, LONDON.'

CHARGES FOR ADVERTISEMENTS.

SITUATIONS VACANT, PARTNERSHIPS, APPRENTICESHIPS, TRADE, AND GENERAL ADVERTISEMENTS.
 Six lines (about fifty words) or under 6s. 6d.
 Each additional line (about ten words) 0s. 6d.
 Terms for Series of Trade Advertisements, also for Special Advertisements on front page, Competitions, Contracts, Sales by Auction, &c., may be obtained on application to the Publisher.
 SITUATIONS WANTED.
 FOUR Lines (about thirty words) or under 2s. 6d.
 Each additional line (about ten words) 0s. 6d.
 PREPAYMENT IS ABSOLUTELY NECESSARY.
 *Stamps must not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable at the Post-office, Covent Garden, W.C. to
 DOUGLAS FOURDRINER, Publisher,
 Addressed to No. 46, Catherine-street, W.C.

Advertisements for the current week & issue must reach the Office before THREE O'CLOCK P.M. on THURSDAY, but those intended for the front page should be in by TWELVE O'CLOCK on WEDNESDAY.
 SPECIAL ALTERATIONS IN STANDING ADVERTISEMENTS OR ORDERS TO DISCONTINUE same must reach the office before TEN O'CLOCK on WEDNESDAY mornings.

The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c., left at the Office by reply to advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

PERSONS Advertising in "The Builder" may have Copies addressed to the Office, 46, Catherine-street, Covent Garden, W.C. free of charge. Letters will be forwarded if addressed in envelopes are sent, together with sufficient stamps to cover the postage.

AN EDITION Printed on THIN PAPER, for FOREIGN and COLONIAL CIRCULATION, is issued every week.

Now ready.

"The Dictionary of Architecture."

THE completion of the "Dictionary of Architecture" is an event which certainly calls for special notice in our columns. It has been in progress for forty years, during the

whole of which period the original plan and character of the work has been rigidly adhered to, and the last volume* issued is conducted on the same lines as the first. It is certainly rare to find a work of this kind, which has been spread over so many years, carried out so completely on a plan definitely framed from the date of its first publication.

To the concluding volume a preface is prefixed giving a short account of the manner in which the work was first started, and it may be of interest to some of the younger generation which has sprung up since the commencement of the work, to recapitulate briefly its history. The Dictionary, of late years especially, has been practically the work of Mr. Wyatt Papworth, and it was to his action that we are indebted for the first initiation of the idea. In 1848 he issued a circular letter setting forth the plan of the proposed "Society for the Promotion of Architectural Information, intended for the Revival and Restoration, Investigation, and Publication of Knowledge in Architecture, and the Arts connected therewith;" and a meeting was held at 10, Caroline-street, Bedford-square, on the 4th of May of the same year. A committee, comprising most of the leading architects of the day, was appointed, and the name of the "Architectural Publication Society" was adopted. The first publication of the Society consisted of detached "Essays and Illustrations," but the real plan of the Dictionary arose out of the preparation by Mr. Wyatt Papworth of a "List of Terms" proposed for an Encyclopedia of Architecture. This List of Terms afforded a practical suggestion

for the framework of such an encyclopedia, and the committee as existing in 1852 were of opinion that the carrying out of an encyclopedia on the lines thus suggested would be a work of so much usefulness that it ought to be commenced forthwith. The Committee in question numbered thirty people, of whom only six have survived to see the completion of the proposed labour. The names are given in the preface; the six survivors referred to are, we presume, Mr. Ewan Christian, Mr. H. B. Garling, Professor Kerr, Professor Hayter Lewis, Mr. Wyatt Papworth, and Mr. W. W. Pocock. Among the other names were those of Sir Charles Barry, Professor Cockerell, Professor Donaldson, Mr. George Godwin, Mr. Hanson, Mr. John Woody Papworth, and Mr. (afterwards Sir) William Tite. The opinion of this committee was that it would be impolitic to enter upon a publication of a large encyclopedia to be issued in successive parts, extending over a long series of years, "creating the apprehensions and exhausting the patience of subscribers," and that therefore the project should be carried out as a dictionary of explanation and references, with incidental woodcut illustrations, "so arranged as to be completed in about three years at the present terms of subscription." What actually happened was that the Dictionary was continued on the proposed basis as a work of reference and explanation only, but that its completion has occupied forty-four years instead of the three years calculated on, and certainly with that concomitant result of "creating the apprehensions and exhausting the patience of subscribers," which was supposed to constitute the special obstacle to the bringing out of an encyclopedia on a larger scale. In fact to many, especially of the younger generation, the "Dictionary of Architecture" became a kind of myth, heard of vaguely now and then, but the origin of which was lost in the mists of pre-historic times.

The cause of this extraordinary delay seem to have been, in the first place, the care taken in collecting correct information and in revision of the matter when in type; the system adopted of extreme condensation and repeated revision caused a disproportionate amount of labour over every page, and often

the sacrifices of a large amount of collected material. This was a delay of a creditable nature, consequent on the determination to have all the information as correct as possible. But the main cause of the interminable dragging out of the Dictionary has been want of funds, arising partly out of the fact that the architectural profession did not support and subscribe to the work to by any means the extent which had been expected. The list of subscribers is certainly not a long one for such a work. We presume that many architects considered the publication a dry one, that they did not care about accurate information so much as about artistic illustrations, and accordingly took no interest in the publication. In this they certainly made a mistake, which has delayed and crippled the production of a work for standard reference which in its own way is of the highest value. It is no doubt due to this deficiency of funds that the Dictionary has during many years, we believe, been left practically to the labours of Mr. Papworth, who in 1858 was relieved of the duties of hon. secretary which were undertaken by Mr. Cates, in order that he might devote his undivided attention to the actual work of the Dictionary. This we presume we may take as an admission that practically the work is the result of Mr. Papworth's study and researches, though we believe he has consulted and received assistance from others to a certain extent.

It is hardly possible that any one man should be able to treat all subjects for a work of this kind with the same degree of success, and if the work had been an encyclopedia of the extended type such a *tour de force* would be manifestly impossible. As the object of the Dictionary, however, is confined to the explanation of terms and the collection of information as to the further sources of study in regard to each subject, this is a matter of study and industry rather than universal genius, and the numerous papers by Mr. Papworth which have been published from time to time in our columns and in the *Transactions and Journal of Proceedings* of the Institute of Architects are sufficient to show that Mr. Papworth possesses in an unusual degree that kind of passion for research, and carefulness in the looking up and recording of facts, which form peculiar

* "The Dictionary of Architecture," issued by the Architectural Publication Society, with illustrations, Vol. viii. 1892.

qualifications for dictionary work. It might be expected that certain subjects which lie specially within Mr. Papworth's favourite line of studies would be better or more fully treated than others; but on the whole a very impartial attention seems to have been given to all classes of subjects. In the preceding volume of the Dictionary we noted some curious errors, partly of a literary kind, but these seem to have been rather accidental than essential characteristics. What they did show is that the practical extinction of the large committee of revision which formerly sat upon and sifted everything before finally passing it for press was a great loss to the Dictionary, and that in a multitude of counsellors there is safety, at any rate comparatively, from minor errors and inaccuracies.

Taking it all in all, however, the "Dictionary of Architecture" is a very remarkable monument of patience, care and industry, and when Mr. Cates says, in his leaflet accompanying the concluding volume, that "as a dictionary of explanation and reference the work stands alone," he is saying no more than may be legitimately claimed for it. We have remarkably illustrated dictionaries of architecture, in which the articles take the form of extended literary essays on each of the subjects handled; but the "Dictionary of Architecture" is really, so far as we know, the only work on an extended scale the object of which is simply to convey information as to facts, put in the most concise form, and accompanied by a reference to the titles of works from which detailed information can be obtained. This last is one of the most useful features in the Dictionary. Under each subject we find a list of books, periodicals (with dates), or other publications from which the subject can be studied. It must be admitted that these lists too often omit the more recent publications, partly because of the slow rate of progress of the Dictionary, partly we think from an element of the *laudator temporis acti* on the part of the author or editor, whichever we are to call him. We have noticed on another occasion Mr. Papworth's tendency to go a good many years back for his references and authorities, and ignore recent books and recent numbers of periodicals. Thus under the word "Theatre," we find reference to "Donaldson" on the form of the Greek theatre, but none to "Dürpfeld" or "Gardner." It may of course be replied that as "Theatre" comes in the earlier pages of the concluding volume of the Dictionary, the article must have been written some years ago, before the recent controversy had made itself felt. We fear that in a general way the Dictionary will be found in this respect always a few years out of date, and if ever a second edition of it should be issued, it will of course have to be brought up to date in this respect. However, all the numerous references to early and standard works and ancient publications retain their full value, and if the Dictionary had been produced as quickly as the original promoters intended it is obvious that it would now be much more out of date than it actually is.

The scope of the Dictionary includes every term that refers to anything connected with or relating to architecture, including of course eminent architects, and also eminent towns or places of architectural interest. Thus we find in two or three pages such a variety of subjects as "Tite," "Trieste," "Triforium," "Triglyph," "Trilithon," "Trimming joint," a set of words which includes a tolerably wide category of subjects. The Dictionary also serves as a repository and preservative of some ancient words which are nearly forgotten, and may in that way convey some unexpected information. How many of our readers ever heard of "Twichyngroes," or can tell of what place "Tysdrus" was the ancient name? As far as we have observed, no opinions peculiar to the Dictionary are advanced upon any of the subjects; it is confined to the statement of ascertained facts, or of opinions only as matters of history, as held at a certain time or place, or by this or that eminent writer. This is really a wholesome

reaction against the modern tendency to issue, as Dictionaries, what are really a string of independent essays embodying individual opinions.

In short the "Dictionary of Architecture" is a Dictionary pure and simple, a work to give information. It will be found deficient in regard to new facts or new opinions of the last few years, but it is a mine of information for all time preceding that, and information which we believe will be found to be exceptionally accurate and reliable. The work is beautifully printed on a large two-columned folio page, and is in every sense a monumental production, and one on the completion of which we may sincerely congratulate Mr. Papworth and his supporters. The cost of such a work of course puts it entirely out of reach of popular circulation; there are now in fact, we are informed, only twenty copies purchasable beyond those which are due in advance to subscribers,* and the Committee are under a distinct pledge not at any time to allow the issue of copies at less than the original subscription price, so that the market value of the book will always be retained. We hope, however, that the available public sale will not always be restricted to the aforesaid twenty copies, and that there may be a prospect of a second edition on the present sumptuous scale, but with such revision as will bring it as closely up to date as possible.

THE RIGHT OF QUANTITY SURVEYORS TO RECEIVE FEES.

It may be doubted if any point of practical importance has given rise to more legal disputes than that in regard to the payment of quantity surveyors for work done to enable builders to tender for work which has to be performed. In the well-known case of *Evans v. Carte*, which occurred in 1882, Lord Coleridge remarked that "it is quite monstrous that the employer should pay for the quantities,—that is, that he should pay for what it is the duty of the architect to do." In other words, he considered that the employment of a quantity surveyor was altogether improper. We have, however, now for our guidance a case definitely and clearly decisive on this point, differing materially from the *obiter dictum* of Lord Coleridge. We refer to *North v. Bassett* (Law Reports, 1, Q.B., 1892, p. 333). In the course of his judgment, Mr. Justice Mathew observed, "What is the usage which, upon these facts, it is sought to set up? It is one which I should have thought to be notorious—a usage that the fees of the quantity surveyor are paid by the builder whose tender has been accepted by the building owner. This is a sensible and convenient usage; it brings all the people together,—the builder, the building-owner, and the quantity surveyor,—and they all assent to it." Mr. Justice Smith says more briefly, "This kind of tripartite agreement is a sensible and convenient one." Here are two of the ablest and most shrewd judges on the bench, each noted for his commercial knowledge and common-sense, who approve of this usage.

The action was brought by a quantity surveyor against a builder in respect of

* Mr. Cates gives a list of the principal Institutions and Libraries in which the Dictionary is to be found, which it may be convenient to reprint here for the benefit of those who may wish to consult it. Mr. Cates's list is as follows:—Among learned bodies and Public Institutions may be named,—the Athenæum Club, the London Institution, the Royal Academy, the Inner Temple, the Middle Temple, the Surveyors' Institution, the House of Commons, the Commissioners of H.M. Works, the Lords of the Admiralty, the Carpenters' Company, and the Institute of France, Paris. The work will be found also in the City of London Library, Guildhall; the National Art Library, South Kensington; the Patent Office Library; the Libraries of the University of Glasgow, the University of St. Andrew's, the Queen's Colleges at Belfast, Cork, and Galway; King's College and University College, London; the Thomason College, Roorkee, Bengal; the Massachusetts Institute of Technology, Boston, U.S.A.; in the Signet Library, Edinburgh; also in the Free Public Libraries of Birmingham, Glasgow, Leeds, Liverpool, Manchester, and Sheffield; of Boston, U.S.A.; and of Melbourne, Victoria.

fees. It was a case of the most ordinary character, but it is of first-rate professional importance, because the Divisional Court not only thus emphatically approved of this notorious custom, but also sustained it as being good law. Therefore, until a Court of Appeal upsets the case, it must be regarded as making the custom valid, and, in a sense, proving the existence of it. But, unfortunately, there exist some discordant elements. In 1888, the case of *Priestley v. Stone* came before the Court of Appeal. This was an action by builders against a quantity surveyor for damages caused by his negligence in preparing an inaccurate bill of quantities. The Court of Appeal held that such an action could not be brought, because there was no privity of contract between the two parties. Lord Justice Lindley said:—"There was no privity of contract between the builders and the quantity surveyor. The custom relied on as to privity between them was not proved, and, even if proved, the custom would probably be held to be unreasonable and bad. . . . The real truth was, that the defendant was employed by the architect, and not by the builders." But if there is no privity, either by contract or custom, as seems to be the opinion of the Court of Appeal, how can there be a right to recover for fees against the builder? No doubt, in *North v. Bassett*, Mr. Justice Mathew remarked that "I am convinced that the Court of Appeal in *Priestley v. Stone* never meant to say that this usage was a bad one," and Mr. Justice Smith made a remark to the same effect. But this is rather a cavalier way of treating the judgment of the higher Court, or rather the expression contained in it.

It is possible that the decision of the Court of Appeal might well be supported so far as the particular case before it was concerned, because there was no proof of negligence on the part of the quantity surveyor. But the observations in regard to the relationship of the quantity surveyor and the builder are of importance, and cannot be lost sight of, for these seem to go farther than the case before the Court of Appeal, and in a sense to indicate a principle. Therefore there is still a skeleton in the cupboard; behind the clear and definite case of *North v. Bassett* there is the ominous shadow of *Priestley v. Stone*. For the present the Courts must act upon the decision of Mr. Justice Mathew and Mr. Justice Smith, but we shall be surprised if, some day, when the amount in dispute is large, the question is not taken to the Court of Appeal. Until, however, this event occurs, the decision, *North v. Bassett*, which is in accord with a long-continued practice, must be regarded as a binding decision. But it should be borne in mind that *North v. Bassett* was a case in which the work was done by the builder. We have yet cases such as our old friend *Moon v. Guardians of the Witney Union*, decided so long ago as 1837, where the contract has gone off. In that case it is by no means so clear that the building owner can be made liable for the fees of the quantity surveyor, though, perhaps, the balance is in favour of the contention, because the practice of employing a quantity surveyor is becoming more and more known to the general public, and is not regarded by them as so unreasonable as by the Lord Chief Justice of England.

NOTES.

We have received the Chief Engineer's annual report of the National Boiler and General Insurance Co., Limited. It is a readable and instructive pamphlet. Of course, practically every boiler user has his boilers insured, for of all the assurances that can be effected by the payment of a small annual premium, this, to a manufacturer, is as satisfactory as any. If there are any power users whose boilers are uninsured, then let it be a first and instant duty to remedy this state of things. This is very safe advice to give, but if further impressing is needed, let this report be perused. The information it contains is applied chiefly

recommending the purposes of the company, of course, but in doing this the Engineer has gone out of his way to make his report comprehensive, and much interesting and valuable information of technical character is included. It is possible that many boiler users do not know that in addition to the expense of replacing a boiler and recompensing the injured, when an explosion occurs, there is a considerable likelihood of a Board of Trade inquiry under the "Boiler Explosions Act." The result of this may be a heavy penalty imposed, if ordinary care and thorough and regular inspections by qualified men have not been resorted to. The insurance of a boiler removes this risk, or the necessity of periodical inspection is remembered by someone else besides the owner, and an insurance inspector is certain to be a qualified man. The causes of explosions and fractures may be summed up as follows:—Defective conditions, external corrosion, internal corrosion, general deterioration (which must occur to every boiler), internal grooving, mistake, negligence, overpressure, deficiency of water, deposit, malconstruction, weakness of tubes, safety-valves imperfect or improperly used or fixed, with a variety of causes difficult to ascertain. This is a formidable list, but does not embrace all the "causes difficult to ascertain" represented by a fair total by themselves.

An extract from a report of the Highways, Sewers, and Public Works Committee of the St. Pancras district which we have received, contains some observations on materials for roads, a matter on which we are still to seek the most perfect method. The road paving of Euston-road (by the Henson Road Wood Paving Company) has been seen up after lasting eleven years, the best of any mode of paving with wood, and the chairman of the committee (Mr. Jos. Thornley) asks the Unsanitary Department "in consequence of the unsatisfactory experiences we have had with yellow pine," to reconsider the decision to pave Tottenham-court-road with that material, and use an Australian hard wood. As a middle course, pitch pine is to be used. A quotation in a report on wood pavements in Australia, however, shows that even with the Australian woods, it is strongly recommended that the pavement of streets in Sydney with wood blocks be entirely discontinued. The principal reason given is that "the analysis shows that the blocks in actual use here have absorbed an amount of organic filth which is as much in comparison with the short time during which they have been laid, and which is distributed throughout the blocks in such a manner as shows that their complete impregnation is only a matter of time." Again the report continues:—"So far as the careful researches of your Board go, the porous, absorbent, and destructible nature of wood must, in their opinion, be declared to be remediable by any process at present known; and were any such process discovered, would be effectual unless it were supplemented by other which should prevent fraying of the wood." This opinion from Sydney, where you can command a far superior style of road pavement to what we can economically use here, is certainly significant. The author's own opinion has been for some time that that wood pavement will have to be abandoned, before long, on sanitary grounds; and what is so satisfactorily taken its place do not yet see. Asphalt is sanitary and cheap, but the cruelty to horses which it involves is a consideration which we have not yet passed over.

It appears that the Improvement Sub-Committee of the Manchester City Council, whether by intent or only by a happy coincidence, struck an effective side blow at proposed architectural defacement of the Manchester Exchange building by walling up the portico. The Sub-Committee have recommended that a new building line should be adopted from the Conservative Club along the street to Market-street. The effect of

this, we understand, will be to constitute the Exchange portico, with the approaches thereto projecting beyond the present solid portion of the Exchange building, an intrusion on the street, and with that status it will be there on sufferance. This will put the Corporation in a position to veto any conversion of present air-space into solid building by the filling up of the spaces between the octastyle portico as proposed. The line of Cross-street can never be made quite direct,—a small mercy for which the number who are thankful will probably increase, as very straight streets are very dreary. The recommendation of the Sub-Committee has to be sanctioned by the General Committee and the Council, but it is expected that this will be done. It is certainly a new and ingenious strategical way of defeating a proposed architectural blunder.

It appears that there is to be some question as to repairs to Linlithgow Palace, under the department of Scottish Parks and Pleasure grounds. In view of this, as we learn from a recent number of the *Glasgow Herald*, the Edinburgh Architectural Association have circulated among Scottish Members of Parliament their own report of the condition of the palace and the repairs necessary to it. Their circular is to some extent an anti-restoration circular, as they take special care to point out all the parts of the building which are in good condition and have no need of repair, though we think it contemplates or suggests rather too much nevertheless. For the restoration of the fountain in the centre of the quadrangle, "the most unique thing of its kind in great Britain" (as a matter of grammar we may observe that a thing cannot be "the most unique"—it is "unique" or it is not) "there is ample material for guidance; and the names of the figures that filled the few vacant niches on the exterior of the building are known." We fear this points to a sham restoration of fountain and figures, which will have no interest, and only introduces a false element into the building. In their recommendations as to the necessary repairs the Association are on safer ground, and we entirely agree with them that the building should be roofed without delay.

THE case of *Pendarves v. Monro*, reported in the current number of the Law Reports, should be noted, though it does not lay down a new legal principle, but simply emphasises and exemplifies one which has been for some time in existence. Article 41 of Roscoe's "Digest of the Law of Light" states that "when a right is claimed in respect of windows in a new building coincident, wholly or in part, with windows in an old building, the owner thereof must show clearly that the new windows are coincident with and contain the area of those which have acquired the right to light." This principle was enunciated by, among other cases, that of *Fowler v. Walker*, and it is this principle which *Pendarves v. Monro* emphasises. The identity of the old and new windows was not proved. "By reason of the omission," said Mr. Justice North in his judgment, "to keep any plan, there is no evidence which satisfies me that any part of an old window can be identified with any part of an existing window." In the work from which an extract has been given, the author states, in the note to article 41, that when a building is to be pulled down, a plan showing the position of ancient lights should be made and kept with the title deeds. The place in regard to which the dispute in this last case arose was in Sardinia-place, Lincoln's-Inn-fields, and the old houses were pulled down in 1872; therefore, being buildings in the centre of London, it was eminently desirable that plans should have been kept. The occupier of the building from 1869 to 1872 made an affidavit giving particulars of the old windows, and stating that he believed that the new windows "cover in whole or part the ancient lights." But, as we have seen, this was not enough,—the evidence was too vague. The practical result, therefore, is that without a plan it is almost impossible

to establish a right to light in respect of windows in a new building which have not themselves acquired a right, but are alleged to have such a right in respect of old windows in a demolished building, with which they are alleged to be identical.

IT is generally conceded that the electric light is the best of all, at least for the theatre. But it is no use having a good thing without the intelligence to use it aright. Naked lights, whether electric or otherwise, are unpleasant unless very far removed from the eye, nor is it desirable that the auditorium should be more brilliantly lighted than the stage. The neglect of such obvious considerations at Covent Garden provoked some correspondence in the *Morning Post* last week, happily concluded on Saturday by a letter from Sir Augustus Hare promising to "encase the offending lamps in soft salmon sash silk"—what an ear Sir Augustus has for alliteration!—and that "on German opera nights the lights will be turned out." But why only on German opera nights? Is Italian opera unworthy to be seen as well as heard? or are we to understand that the "music of the future" is a matter chiefly of *chiaroscuro*?

OUR New York contemporary, *Engineering News*, illustrates a monolithic concrete floor recently introduced by Mr. C. F. Terney, of 59, East 106th-street, New York. Concrete floors have been used in some large buildings in Philadelphia, in which the spaces between the beams have been filled in solid; but in the newer arrangement tubular spaces of an oval section, the longer axis being horizontal, are run parallel with the beams. Working in this way, it has been found that great strength is obtained with a comparatively small amount of material. The method of construction is described as follows:—"A temporary floor is suspended from the beams to support the concrete while setting, and a very rich concrete is laid upon it to a depth of several inches. The tubes are made of rich concrete, and vary in size according to the span of the beams, and their spacing and the total depth of the floor. The tubes are made in short lengths and in halves, and when laying them the joints are well cemented, and the outside is flushed all over with grout. The upper and lower halves of the tubes break joint with each other. The space at the sides of and above the tubes is filled with concrete of a cheaper grade than that used for the lower layer and the tubes." The tubes are placed near the upper surface of the floor. This is done so that there may be larger transverse area in the extension than in the compression plane, the compressive strength of concrete being greater than its tensile strength; the ratio assumed by the designer of the floor being 8 to 1. The inside dimensions of the tubes vary from 12½ in. and 9 in. for floors of 20 ft. to 30 ft. span, with 8 in. beams, spaced 5 ft. 9 in. apart, down to 7 in. and 4½ in. for floors of 14 ft. to 18 ft. span, with 5 in. beams, spaced 3 ft. 6 in. apart. The safe loads per square foot of floor are said to vary through the wide range of from 130 lbs. to 570 lbs. in some sample floors tested. The inventor computes the strength of the construction to be as follows:—In a floor of 20 ft. span, with 7 in. I-beams of 15½ lbs. per foot, and spaced 4 ft. apart, a load of 200 lbs. per square foot can be sustained with a factor of safety of 4. The total depth of the concrete would be 9½ in., and four tubes would be used, with cross sections 5½ in. by 8½ in. The total cost of such a floor is about 56 cents (say 2s. 4d.) per square foot, which is said to afford a saving of 25 per cent. in price over ordinary construction.

THE *Times* correspondent, writing from Paris on the 19th instant, announces that in making a cutting at Andrey for a new railway line between Argenteuil and Mantes, an extensive Merovingian cemetery has been uncovered, dating from the sixth

century. Andrey (or, rather, Andresis), lying fourteen miles distant north-west from Paris, stands upon the right bank of the Seine, near to Conflans, and opposite to the forest of St. Germain (which the Seins surrounds upon three sides), and just below the confluence of the Oise with the Seine. The Frankish dominion established in Gaul by Clodion and his son-in-law Meroveus, in the former half of the fifth century, included Artois, and extended from the Rhine to the Somme. On the death, in 511, of Clovis, grandson to Meroveus, whose conquests advanced further to the west and south, and comprised Burgundy and Aquitaine, the kingdom was divided amongst his four sons. Of these, Childebert I. reigned at Paris, Clothaire I. at Soissons, and Clodomir in Orleans. From 558 to 561 Clothaire I. reigned, alone, at Paris; and so did Childebert II. during the interval 575-584. After his victory over the Alemanni at Tolbiac, Clovis, influenced by his wife, Clothilda, embraced the Christian faith, together with 3,000 of his warlike subjects. "The new Constantine"—in the words of Gibbon—was baptised by Bishop Remigius in the Cathedral of Rheims. The first interment of a king of the Merovingian dynasty in St. Denis was that of Dagobert the Great, in 638.

THE Langdon Abbey estate, in East Kent, extending over about 654 acres, is to be offered for sale. The manor formerly belonged to the ancient barony of Avereanches (Folkestone), of which it was held by service of one knight's fee and ward to Dover Castle, by the family of Auberville, of Westenhanger. William de Auberville so held it, *temp.* Richard I. He founded here, in 1192, an abbey—since a priory—for some white Premonstratensian canons whom he brought from Leiston, in Suffolk, and dedicated it to the Virgin and St. Thomas-the-Martyr. At the Suppression, having a yearly gross income of 56*l.* 6*s.* 9*d.*, it was surrendered voluntarily by Abbot William Sayer and his band of ten monks. A list of the abbots, with a print of their seal, will be found in Hasted's "Kent," 1799, folio. King Henry VIII. gave the manor of West Langdon, with the priory site, to Archbishop Cranmer; it was subsequently possessed by, in turn, the families of Thornhill, who re-instated the house, called "Abbey Farm," Master Furness, and Coke. St. Mary's Church, described by Hasted as being in ruins, was rebuilt in 1869. In the vicinity are Shebbertwell (Shepherd's-well), or Siberts-well, so named after a Saxon owner, Sibert, whose, according to vol. i. of C. Greenwood's "Eptome of County History," 1838, 4to, the manor-house was built by Inigo Jones; and Waldershare, its mansion attributed to Jones also. But if, as it is said, Waldershare was built, *circa* 1705, for Sir Henry Furness, it could not have been erected in Jones's lifetime, for that architect died in 1652.

ANOTHER selection of Mme. Ronner's paintings of cats is on view, at the Goupil Gallery. The painting of cats is not the highest mission of art; if it were, Mme. Ronner would be the greatest artist of the day, since her painting, as far as cats go, is simply perfection; the cats seem to be alive, and the various expressions of the kittens, so unconsciously humorous and so difficult to catch, are charming. A life's close study could alone have enabled the artist thus to understand and reproduce the very life and feeling, one may say, of the cat tribe. Though the cats are the essential portion of the pictures and the chief object of the artist's studies, it must be observed also that all the accessories to the larger pictures are painted with great force; in "Un Bout de Toilette," "Les Antiquaires," "Amateurs de Jewels," the old casket, the tapestry, the jewels, and lace are beautifully finished.

MANCHESTER SOCIETY OF ARCHITECTS.—The first of the summer series of sketching visits was paid on the 14th inst. to Astbury Church and Moreton Hall, Cheshire, under the leadership of Mr. A. H. Davies-Colley, A.R.I.B.A.

ARCHITECTURE AT THE ROYAL ACADEMY.—V.

1,712; "Sheffield Municipal Buildings: Council Chamber;" Mr. E. W. Mountford.—Hung rather high; it shows a room with a flat ceiling divided into compartments with pendants at the crossing lines of the leading mouldings, the compartments filled in with tracery. The room is wainscotted to the foot of the large traceried windows, which come down lower at the end than at the sides. As far as one can judge from the drawing, the proportions look rather low for the area of the room. A richly-decorated cove connects the ceiling with the wall.

1,714; "Interior, New Church, Miles Platting, Manchester;" Mr. Leonard Stokes. A very fine pen drawing of a very original design. The aisles are for passage only, the church being practically one-aisled, the lofty piers are apparently of hexagon plan with the point towards the nave; they support ponderous plain-soffit wall arches springing from a lintel between pier and outer wall; the piers have thin cap-mouldings on each side, between which the vaulting ribs spring from the surface of the pier; for base-mould there is only a set-off. The piers are connected with the wall half-way by cross lintels worked into a kind of coffer shape and with bas-reliefs in panels on the sides; if these are a bond to the construction, as may be supposed, their form looks rather out of place in that position, they have no constructive expression. The sculpture, we understand, represents the Stations of the Cross. The roof is a simple quadripartite vault. Statues decorate the piers on the side towards the nave, and the chancel arch has a broad splay decorated with sculpture in niches. The whole is a very remarkable and novel architectural conception.

1,715; "Somerville Memorial Free Church, Keppoch-hill, Glasgow;" Mr. W. G. Rowan. A slight but well-tinted sepia drawing of a picturesque group of buildings, the plain tower with angle buttresses and a lantern stage, with short slated spire over, forming the centre of the group. What we take to be schools or a meeting-hall at the side, a plain low building, groups well with the rest, and sets off by contrast the richer treatment of the church gable at the other side of the tower. A plan would have been an improvement; there is plenty of room on the paper for it.

1,716; Mr. Webb's South Kensington design, we have already referred to; 1,719, "Mausoleum Windows, Hertingfordbury Church" by Mr. Jas. Fisher, shows a two-light window of quiet and unobtrusive colour, with a figure of an angel in each compartment, one of them St. Michael weighing souls, an antique superstition which is surely out of place in a modern window; the saint has rather too much the appearance of being in "Court dress." The drawing of the brackets on which the principal figures stand, as if they projected in perspective, is a mistake in stained-glass design.

1,721; "Dining-room and Library;" Messrs. Ernest George & Peto. The dining-room merely shows a bit of the woodwork and cornice; the library is a very good hit of perspective sketch lightly tinted in brown with a panelled ceiling in straight-lined geometric pattern with pendants, the walls are mostly plain, and are cross-lined as if divided into large squares, but what this represents it is not easy to see. The white marble chimney-piece has a wooden overmantel with long upright panels partially carved, and an entablature above. Over the two doors the woodwork is carried up to the cornice and decorated with a moulded balustrade, which seems a very unmeaning ornament in such a position. By the same architects is

No. 1,722; "Country House, Dorset;" an imitation Old English house of plain character with mullioned windows and a doorway flanked with columns, and with little pyramids on the attic, which are also repeated at the feet of the principal gables. The garden front is diversified by two bay windows, and what we take to be the servants' quarters front (there is no plan) is treated picturesquely, with an arcade under the end gables, and a little open balcony and arch above the door. If people wish to make believe to have an old house of the seventeenth century nothing could be better for the purpose.

1,723; "Portal, Sta. Maria Maggiore, Bergamo;" Mr. T. MacLaren. A very clear snappy little water-colour drawing.

1,724; "New Wing to St. Agnes School, East Grinstead;" Mr. Arthur E. Street. A plain

stone Gothic building with a great deal of solid wall-surface and high-pitched red-tiled roofs; a point in the design is made by carrying a broad band of similar red tiling along the wall half way up the building, confined by string-courses. The building is solidly built, pleasing and unpretensions, and shown in a very good water-colour drawing, but absence of a plan makes it impossible to understand properly the meaning of its disposition.

1,725; "School Chapel, Tonbridge;" Messrs. James Brooks & Son. This was published in the *Builder* for May 14, to which we may refer the reader. The design shows the traditional idea of a school or college chapel, carried out with some touches of new and original treatment.

1,726; "St. Augustine's Church, Brinkaway;" Messrs. Preston & Vaughan. A pleasing design for a small country church, with a little bell turret with a timber upper stage, which is picturesque, but looks out of scale with the rest of the building, *i.e.*, too small in scale and parts, it looks as if it had been designed to half the scale of the rest of the drawing. The drawing is apparently a very good one, hung too high to be properly seen.

1,727; "New Parish-room and School, All Saints, Plymouth;" Mr. Edmund Sedding. The architect seems to have caught something of the feeling of his late talented brother in the treatment of the staircase which leads to the upper floor, with porch over the top landing, but the detail of the building is rather coarse.

1,728; "Institute of Chartered Accountants: Portion of Elevation;" Mr. John Belcher. A large elevation in pencil on grey paper touched with white. Heavily rusticated piers between the ground story windows, with winged terminal figures over them, crossing a kind of plain frieze space between two string-courses, on which are painted on the wall surface, the names of various towns; the second story is perfectly plain masonry with cornice windows inserted, the upper story a heavy Tuscan order supporting the under side of the large cornice, the orthodox architrave and frieze being omitted. The large and rich modillion cornice, however keeps its place pretty well. A frieze of figures is introduced under the windows of this story, interrupted by the lower part of the columns. The rusticated treatment of the upper story windows is rather wild, but the whole is an interesting treatment of old materials in a novel manner.

1,731; "Interior of Turkish Bath, Avery Hill;" Mr. Thomas W. Cutler. This is part of the *matériel* of "Cutler v. North," and shows what complete and elaborate work the defendant in that *cause célèbre* had done for him. It is a brilliantly executed little water-colour showing an octagon room with Arabic foliated arcade and a ceiling divided out in one of the well-known forms of Arabic geometrical pattern; through the archway opposite the spectator is seen a further apartment in the same style. The prevalent tone of the decoration seems rather too blue, if the drawing represents it rightly.

1,732; "Grandtully Castle, Perthshire, as added to;" Mr. Thomas Leadbetter. There seem to be "two Richmonds in the field;" we published recently (March 12) a drawing of Grandtully Castle as intended to be added to by another architect; we know not which is the right man. This is a very disagreeable rough scratchy pen drawing, and there is no indication, either by plan or otherwise, which is new and which is old, the whole looking equally time-worn and dilapidated in the drawing.

1,733; "Seisdon Park: garden front as altered;" Mr. W. F. Unsworth. It is the same here; there is no indication of what Mr. Unsworth has done to the house, what is his, and what is not. It is a neat but somewhat hard pen elevation of a long terrace front of a Late Gothic house, with a ground floor arcade in the centre portion, and a tower-like mass on the left, which groups effectively with the rest.

1,734; "Municipal Buildings, Bath;" Mr. J. M. Brydon. This is the perspective view of the new Municipal Buildings which we publish in the present number, and to which we refer the reader in place of any description here. Considered entirely apart from the circumstances in which the design was made, this might be considered, perhaps, somewhat tame and wanting in architectural invention for an important new building of the kind. But when we consider that this was a building intended to group with and keep up the traditions of Wood's

old buildings, we cannot but congratulate Bath on having obtained a new Municipal Building which so completely harmonises with the architectural associations of the modern city, and which is in itself dignified and stately in composition. The introduction of the quarter-circle on plan at the angles, with the order and the hand of sculpture on the walls, is an effective incident which, while it is a touch above the level of Wood, is quite in harmony with the general spirit of his work. The drawing, in pen line, is an admirable one.

1,735; "New Travellers' Clnh, Piccadilly;" Messrs. T. & F. T. Verity. This is orthodox club architecture, with a Corinthian order of pilasters running through the first and second floors, and a cornice and an attic over. We mention it as a design of a well-known new club, but we are at loss for anything to say about the architecture more than we have said.

1,736; "View of the End of the North Transept of Westminster Abbey as restored;" Mr. J. L. Pearson R.A. This is a view from nearly the same point as that by Mr. John Begg, which was published in our first number of this year, and to our mind not so good a drawing. It appears to be either a pencil or a crayon-shaded drawing helped out with slight washes of Indian ink, and has a very finished look, but the tone is dull and melancholy. The architectural features of the restoration, on which we have before commented, are carefully shown, but the character of the whole is not so well conveyed as in our published illustration just referred to, especially in regard to the effect of the heavy angle buttresses and their pinnacles.

1,738; "Proposed Roman Catholic Church;" Messrs. Goldie, Child, & Goldie. An exterior perspective of a satisfactory church of the orthodox Gothic type, of reddish stone with a very solid-looking low square tower at the crossing. The colour of the drawing is rather harsh and inharmonious.

1,739; "Proposed Houses at Ledbury;" Mr. George C. Crocock. A pen drawing of rather a pretty and picturesque group of semi-detached small houses; each with an octagonal projecting bay which has only a row of small windows at top and bottom, the remainder being solid wall; the introduction of a half-timbered gable on the centre line of the block, and therefore half belonging to one house and half to the other, is rather an illogical treatment.

1,740; "St. Michael's Roman Catholic Church, Newcastle-on-Tyne;" Messrs. Dunn, Hanson, & Dunn. An interior of a solid orthodox late Gothic church, satisfactory enough architecturally, but not made the best of by the drawing, a pen drawing which has been too heavily lined, and without apparently any eye for effect or any feeling for touch in this kind of drawing.

1,741; "Design for St. Bride's Foundation Institute;" Mr. Thomas Garratt. This is a well-executed and effective water-colour drawing, showing the proposed new building as seen from the corner of some neglected churchyard or some such enclosure overlooking the street, and which forms the foreground. The new buildings are apparently meant to be brick and terra-cotta, and are effectively shown in the drawing, but the handling of the drawing goes for more in the effect than does the architectural design.

1,742; "Design for Parish Church of St. Peter Drogheda;" Mr. T. L. Watson. This is published in the present number, and, as will be seen, represents a satisfactory and well-composed exterior of geometric Gothic type, and a good deal recalling the churches which Scott used to build in this style. The tower and spire are finely proportioned and group well with the church. As in the case of No. 1,740, the design owes very little to the ability of the draughtsman, the drawing being in a poor hard scratchy style, with no artistic feeling about it.

1,743; "Kaikoura, Calne;" Messrs. Russell & Gilson. This is hung too high to be well seen, but we have a lithograph of it before us, which will be published among our illustrations in due time, and which shows it to be a picturesque country house of Gothic type, with some characteristic bits of detail about it. Among other things, an open square wooden gallery or gazebo is ornious planted out over the angle of the house on a double arrangement of timber corbelling, one beam partly seated on the wall, the others crossing it from the other wall. The house has a very decided look of a dwelling suitable for a mountainous neighbourhood, in

which the drawing shows it. The authors are to be commended for adding plans.

1,744; "Flats at Earl's Court-square;" Mr. R. A. Briggs. This is a good example of the effect which may be produced in a very plain utilitarian building by massing and grouping the windows. Two bays run right up the end of the building, the strong projecting cornice going round them; they are connected by light balcony railings, the solid floors of the balconies making deep shadows between the bays. There is a mass of unbroken wall immediately round the corner, and then the main entrance with a series of windows over it up to the cornice, and a segmental pediment. There is character and architectural effect in this, and as the drawing is an admirable one, the building gets full justice.

1,745; "Exeter Cathedral;" Mr. H. Needham Wilson. This is the view of Exeter Cathedral which was made by Mr. Wilson for the *Builder* Series of Cathedrals, and was published by us in June, 1891; it is balanced by Mr. Horsley's drawing of Ely Cathedral (1756), executed for the same series, and published on April 2 of this year.

1,750; "Pedestal for the Ayr Burns' Statue;" Messrs. Morris & Hunter. The designing of pedestals for sculpture is so much neglected in this country that it is gratifying to find an example of a pedestal carefully studied by an architect, and recognised as a thing worth exhibition at the Academy. The treatment of the pedestal is simple, but the mouldings (the stumbling-block of sculptors) are very carefully designed, so as to give solidity to the base and refinement to the upper portion. Beneath the crowning moulding of the pedestal runs a little kind of frieze of carved ornament in low relief, formed of foliage intertwined with scrolls bearing the names of towns connected with Burns' life; below on each face is a decorative nail-head for hanging wreaths on at anniversaries, each of which has a monogram worked on it; on the lower part of the pedestal are bas-reliefs in bronze affixed to the stonework. Larger details are given of all the architectural portions, and a small sketch of the complete pedestal and statue (Mr. G. A. Lawson is the sculptor). The whole is a carefully-studied sheet of architectural detail very well applied for its purpose.

1,752; "Frieze of the Sciences;" Mr. F. Murray. This is a sumptuous coloured elevation representing the upper portion of a marble internal wall and cornice, above which rises the architrave of a door in darker marble, and above on either side of the door-head are symbolical figures, draped, one with a maxillary sphere and one with a shield and coat-of-arms. A child figure or genius stands over the door. The figures are relieved from a lunette with a blue ground. The effect of the whole is rich; the tawdry gilded ornament over the upper part of the door architrave is a defect.

1,753; "Design for a chapter-house;" Mr. Heber Rimmer. This is the perspective of the design for which its author received the Soane medalion of this year, and on which we have already commented.

THE BARRETT-BROWNING MEMORIAL COMPETITION, LEDBURY.

It is the intention of the inhabitants of Ledbury to erect a memorial to their illustrious townsman, Elizabeth Barrett-Browning, who was the daughter of Mr. Edward Moulton Barrett, of Hope End.

Having secured a corner site in the centre of the town, and opposite the old half-timber Market-hall, with frontages of 30 ft. 9 in. and 36 ft. to the Homend (the principal street) and Eye-street respectively, the Memorial Committee invited architects to submit designs in open competition for a Clock-tower and Institute. In response to the committee's advertisement, forty-five sets of drawings were sent in, and these have this week been publicly exhibited at the Market-hall.

Amongst the "Conditions" issued to architects, the following may be noted.—The clock-tower to stand at the angle of the two frontages, and the centre of the dials to be 45 ft. from the ground. A vestibule, reading-room (33 ft. by 19 ft. 6 in.) and library annex to be provided on the ground floor, two classrooms and lavatory on the first floor, and caretaker's rooms above. The entrance preferred near the angle of the streets. The cost not to

exceed 1,600*l*. The selection to rest with the Committee (as already stated in our columns). Mr. Brightwen Binyon has gained the first premium of 20*l*., and the second premium of 10*l*. has been awarded to Mr. Lunn, of Malvern.

The conditions virtually determine the plan, and nearly all the competitors show identically the same arrangement, with, perhaps, the exception of Messrs. Gny Dawber and Langton Dennis, who have rather gone out of their way to make a simple matter complicated. The design of the elevations, and the grouping of the tower and the rest of the building, thus becomes of decisive importance. In the grouping, however, there is again a general unanimity, the majority showing a large gable supporting the tower towards the Homend, balanced by two smaller gables facing Bye-street. The tower designs are very varied.

A visitor to Ledbury is at once impressed with the quiet, homely character of the town, with its many half-timber gables, its fine, though somewhat rambling, church, and its picturesque timber Market-hall supported on massive chestnut posts. It is an old-world place whose romance has not yet been stifled.

It is, therefore, disappointing, almost exasperating, to notice how many of the competitors have submitted designs of a pretentious and fussy character, altogether out of harmony with the quiet surroundings. Either, it must be supposed, these architects have not taken the trouble to inspect the site or acquaint themselves with the town, or else having eyes they yet see not.

This does not apply to Mr. J. E. Newberry's quiet design, which, although not being very original or striking, would yet at once incorporate itself into the town. A simple square stone tower stands at the angle, and large, half-timber gables, with brick lower stories, face the two streets. But the half-timber upper story of the tower looks heavy, and mars the general design, and its semi-tipped gables present a very ugly sky-line. Walking down the Homend one would see the Memorial Tower clear against the sky, and its outline is therefore an important matter. Messrs. Radclyffe & Watson, of Birmingham, send a quaint and clever design, which is one of the best here. The extended base of the lantern tower is pierced on two sides by ogee archways, over one of which is a niche for a memorial statue. In the middle stage, the square plan below grows into a half-timber octagon by hold curved spays at the angles, and this again becomes constricted by an inverted ogee curve to a smaller octagonal lantern, with ogee roof. The upper story of the main building is of half-timber, and the roof is hipped back from both façades.

Messrs. Gny Dawber & Langton Dennis are represented by the most artistic set of drawings of the exhibition. Their plan, however, is not happy except for the direct light it affords to the reading room. The staircase, which has to be reached by crossing the reading-room, is cramped, and, having no well-hole, would not obtain much light from the lantern placed at the top. The "tower" is tile-hung, and does not extend to the ground, being developed by corbels from the angle of the building. Its upper story is suggestive of an Italian campanile,—a pyramidal roof supported by a colonnade,—and is a pleasing and clever piece of design. The main roofs are hipped back as in the last design, and the awkward outline thus occasioned is not so well corrected by the projecting dormers. The result is that as the roof lines slope up towards the tower, the tendency of the tower to look top-heavy is enhanced.

Mr. Brightwen Binyon's design both in plan and grouping follows the general type before described. It is a little jerky in outline. Thus in the elevation facing the Homend the ground story projects, the first floor recedes, while the gable one projects again. So too in the tower, which after rising without interruption for nearly 40 ft. carries a corbelled out half-timber stage, covered with a truncated pyramidal roof, from which rises an oblong lantern, with louvres, and whose roof is adorned with wrought iron cresting. A little more quaintness would bring the design more into harmony with its surroundings. The plan is well proportioned and convenient; the entrance vestibule is spacious and well lighted. It is questionable if the caretaker can be trusted with a dust shoot from his house on the top floor to the basement, as he will probably use it as a shoot for vegetable and other refuse.

Mr. Binyon proposes to face the building with best red local bricks, with red sandstone dressings. A hand of terra cotta or carved brick round the tower about 6 ft. above the ground will illustrate some subject taken from Mrs. Browning's poems. On the side of the tower next Bye-street is a drinking fountain. The estimate of cost is 1,600*l*.

It is a little difficult to understand the committee's choice in their award of the second premium. The lower part of the tower and building generally is of brick with stone dressings, and of rather commonplace design. The gables are half timber. The upper part of the tower—or rather upper half, for it is divided exactly in the middle of its height by a broad weathering—is entirely of stone of a florid Gothic character, with traceried window and crocketed pinnacles grouped in pairs and engaged to the sides of the tower.

Space does not allow a detailed notice of the more important designs of the remainder. Mr. A. Ardron sends a boldly-drawn design, showing a brick tower surmounted by a timber lantern. A half-timbered gable faces the Hemond, and an ornamental plaster one overlooks Bye-street.

Mr. J. Johnstone has a well-proportioned tower, but of a too monumental character, and in the perspective drawing the sky apparently forms part of the design. The staircase oriel window is not satisfactory. A design of an ecclesiastical character is submitted by Mr. C. R. Ashbee. The angle buttresses of the tower look very wry.

Messrs. W. Cook and W. G. Lewton send good examples of tower design, though in the latter the lantern looks too heavy for its supports. The designs of Messrs. Cronch & Butler, Honston & Honston, and J. W. Boyd are too ambitious, and miss the sentiment of the place, and so too does the "Greek Design" of Mr. G. S. Hill.

ROYAL ACADEMY SCULPTURE.

The central work of the year is unquestionably Mr. Onslow Ford's "Shelley Memorial," a work at once poetic in feeling and decorative in effect. On a slab or sarcophagus of dark veined marble lies the naked body of the drowned poet, a laurel sprig in bronze encircling the head. The base of the composition, in the same marble, is brought out in front in a semi-circular pedestal on which sits a partially-draped female figure, the muse of lyric poetry, leaning with the right arm on a lyre, the left hand stretched out as if commanding attention. On the pedestal behind sit, back to back, two winged lions, whose wings support the slab on which the body of the poet rests; the modelling of the head and mane seems suggested by Stevens's celebrated little lion figures which decorate the railing of the British Museum. The only portion of the design which rather jars with the rest is a too realistic bronze tree, with bare branches and rounded bright fruit, which grows from the pedestal at the back, and rather clashes with the ideal and perfectly sculptural character of the rest of the work. The bright bronze plaques with the name of Shelley engraved on it, and some bronze festoons bearing small inscriptions, also standing out brightly from the dark marble, increase the decorative effect of this very original monumental conception.

Mr. Alfred Gilbert's chief work is a posthumous bust, or rather half-length, of the late Baron Hindlestone, in his judicial robes. It is in gilded bronze, and the head is very forcibly modelled. Mr. Gilbert also exhibits a striking half-length in the same manner of execution, of Sir George Birdwood, holding in his hand a small Indian idol, to which he seems to be calling attention. Here also the head is remarkably expressive. An odd little nude statuette called "Tragedy and Comedy," a man holding a comic mask and at the same time looking down in alarm at an insect on his leg, which appears (from the action of the limb) to have stung him. It is a little sculptor's joke, not quite in the happiest vein. A superb chain of office for the Corporation of Preston, completes Mr. Gilbert's contributions to the exhibition. It is modelled with that largeness of style and multiplicity of detail which characterises Mr. Gilbert's work of this class, and in this respect is worthy of the best period of the Renaissance, but it looks rather an uncomfortable chain to wear.

Mr. Harry Bates's bas-relief of "The Story of Endymion and Selene—How she conveyed him in a sleep to old Mount Latmos" is one of

the most successful works this artist has produced. It is in low relief, and the car of Selene is drawn by two horses with wings on their feet, whose heads are modelled on the type of the Parthenon horse. The head and torso of Endymion are reclined in the arms of Selene, who sits on the right of the composition, her drapery making a moon-like outline round her head. The legs and feet of Endymion point forward towards the horses' heads, making a level line which is of great value in the composition as a contrast to the curved lines of the Selene figure, and as impressing on the whole group a sentiment of repose. The same sculptor's Memorial of the late James Tennant Caird, a bronze alto-relief figure of an angel in full flowing drapery writing on the top of a memorial slab, is fine in idea and in its spirited action, but the indication of the figure beneath the drapery is rather incomplete and the hips in fact seem lost, there is no place for them under the modelling of the drapery, which moreover is somewhat too disturbed in its folds and hollows. A beautifully-modelled little silver figure for a door-knocker is also defective in relation to its purpose, as there is no indication in it of anything to knock with, unless it be the heels of the little figure. A knocker should leave no doubt of its function; there should be something which is obviously meant to knock with, and there is no indication of that here.

Mr. Adrian Jones's great pyramidal group of "Duncan's horses," in the middle of the central hall, composed of three fighting horses, is spirited and energetic, but the subject is hardly worth the space it occupies and the talent rather to our thinking, thrown away upon it. Among the other works in the Central Hall, Mr. A. Drury's "Harmony," a nude female playing the violoncello and singing with open mouth at the same time, is rather odd in effect than beautiful, and some of the modelling of the figure seems more masculine than feminine in type; the bow-hand is fine and nervous, but the violoncello does not combine happily with a life-size ideal figure. Mr. Fehr's seated half-draped female under the title "Favourites" (the favourites being birds) looks as if the author had studied the feeling and spirit of Mr. Ford's work a good deal, especially in the head; it is a pleasing and graceful work, but hardly rises above that level. Miss Beatrice Browne's "Pearl" is one of those fancies about the pearl on which there has been rather a run of late years both in sculpture and painting; this is a nude figure of a young girl reclined in a rather uneasy attitude within a colossal oyster-shell; it is a carefully-executed piece of work, but fails in not being beautiful, and beauty is the one excuse for this kind of fancy; the face is plain and un-spirited, and the head uncomfortably posed. Mr. G. W. Wilson exhibits an effective and pleasing model for a wall fountain, an architectural alcove with Renaissance type of ornament, at the back of which stands a pretty female figure holding the conventional urn for the water to flow from.

To return to the Lecture-room, we find among the larger works in the middle of the room Mr. G. Frampton's "Children of the Wolf" we presume the infants Romulus and Remus carried home by the peasant who found them, a fine figure of a man; but there is a want of imagination in the work; it might be any stalwart man bringing home any two babies; there is not the slightest attempt to give special character to the children who certainly ought to show signs of their brutal bringing up, but they are two as innocent round-faced babes as one could wish to see. Power of modelling without power of imagination, which is at the root of so much of the shortcoming of English sculpture. Mr. Albert Toft's nude figure, "Fate-led," which was exhibited in plaster last year, is here in marble and seems considerably improved from the original model; the face conveys rather the idea of somnambulism, but it is a figure with an idea expressed in it. Mr. Fehr's little "Morning," a bronze statuette of a nude figure with her hair blown in the breeze, is a pretty conception.

Architects may look with interest on Mr. Peggam's two reliefs for the main entrance of the Imperial Institute, "Industry" and "Britannia," and feel glad that a sculptor of so much ability is employed on a class of work too often left to the race of "carvers." "Britannia" is the most original figure of the two, and the most powerful; "Industry," who winds a skein off a turning drum or reel, is awkwardly posed on the edge of a seat, with one leg stretched

right across the panel and the other doubled back, an indication of the sea forms a horizontal line of broken surface on the background of the panel. Still this is sculpture distinctly above the general level of decorative architectural sculpture in this country.

Mr. Onslow Ford's "Gordon Memorial Shield," presented to Miss Gordon by the Corps of Royal Engineers, is an interesting bit of decorative metal work; it takes the general shape of a form of shield familiar in Renaissance paintings, with an alto-relief of a naked St. Michael slaying the dragon, in an oval in the centre; around the margin are small figures of children intermixed with the usual chased ornament; the central group is the only portion which seems to have any symbolical reference to the subject of the shield.

Among the smaller works of the year Miss Ruth Canton's bronze head of "Azrael, the Angel of Death" has fine poetic character. Miss Esther Moore's "Head of a Boy" is a work with distinctive character, also Mr. Pomeroy's noble and dignified bust of "Miss A. Broke," a bust treated in a decorative manner, with a hand of conventional floral ornament surrounding the base. Miss Beatrice Angle's bust of "A Bacchante," and Mr. Partridge's "A Dream," a very low bronze relief of a head in profile, should not be passed over. Among animal subjects are several very clever little bas-relief studies of horses by Mr. Gilbert W. Bayes, especially "Carting Sand—France," in which there is a novelty of style and execution; and Mr. J. M. Swan exhibits two small bronzes of an "African Panther" and a "Lioness Drinking" which exhibit (the former especially) the same forcible realisation of animal character and action which we see in his paintings.

INCORPORATED ASSOCIATION OF MUNICIPAL AND COUNTY ENGINEERS.

The following gentlemen having satisfied the Examiners at the Examination held in London on the 1st and 2nd ultimo, certificates have been granted them by the Council:—

Anderson, J. R., London.	Hills, H. J., London.
Andrews, C. P., London.	Lloyd, C., Chatham.
Ball, J. B., London.	Shackleton, C. W.,
Bradshaw, J. B., Gates-	Cosley.
head.	Veit, L. J., Ipswich.
Cross, F. W., Walsall.	Yates, F. S., York.
Fitton, G., Reading.	

The next Examination will be held in Leeds, on Friday and Saturday, September 29 and October 1.

BATHS AND PUBLIC HALL, CHEETHAM, MANCHESTER.

THE design we publish for the New Bath and Public Hall, at Cheetham-hill, Manchester was selected by the Baths Committee of the Manchester Corporation, out of a number of designs submitted in open competition.

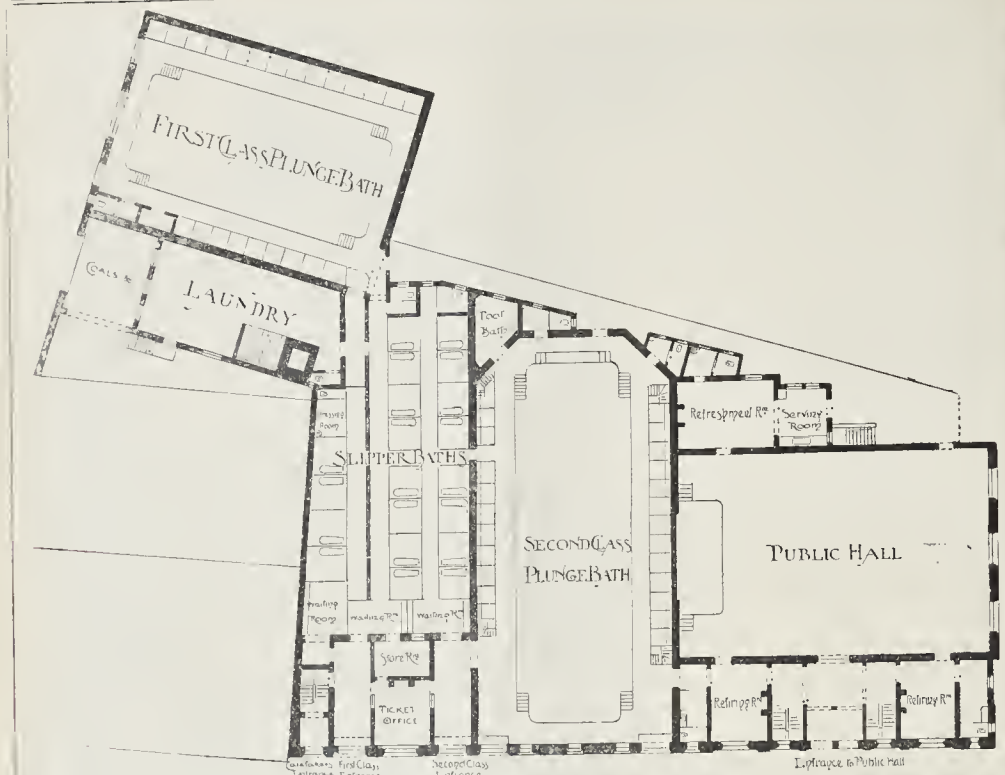

As will be seen from the ground plan, the site is very irregular in shape, with a good frontage to Cheetham Hill-road and another smaller frontage to Back Halliwell-lane. It has a fall of about 12 ft. from the highest to the lowest point. Advantage has been taken of this conformation of the site to place the Public Hall on the higher portion thereof, and the Baths on the lower, the Boiler House, Laundry, &c., being at the lowest point easily accessible for coals, &c., at the street level.

The first-class swimming-bath will have a water area of 54 ft. by 27 ft., and the second-class bath one of 75 ft. by 24 ft. The latter will be surrounded by a balcony for the accommodation of spectators on the occasion of swimming-fêtes. The pavilion in which it is situated is so arranged as to be capable of being used as a gymnasium in the winter months. The first-class swimming-bath is so planned that it can be used by ladies on such days as may be set apart for that purpose; and a special dressing-room has been provided for their accommodation. There are twenty slipper-baths and three waiting-rooms, and these will be classified as ladies' and men's first and second-class. A commodious residence for the superintendent will be situated over the ticket-office and entrances to the baths, and in connexion with this department there is a handsome tower for the reception of a public clock.

The public hall is to be on the ground-floor level, and be practically a separate building, designed to be capable of being used for

Premiated Design for Baths and Public Halls, Cheetham, Manchester: Perspective View.—Messrs. Douth & Chadwick, Architects.

Plan of Baths and Public Hall for Cheetham, Manchester.—Messrs. Booth & Chadwick, Architects.

lectures, public meetings, conversaciones, concerts, bazaars, dramatic performances, dances, and all other proper purposes. The principal room will have a clear floor area of 64 ft. by 42 ft., and there will be a balcony-gallery in addition. There will also be five retiring and cloak-rooms, with lavatories attached, a refreshment-room, serving-room, and cellar kitchen. There will be a fine entrance-hall, leading to the public-room; and the retiring-rooms for ladies and gentlemen will be placed to the right and left of it; and these will, by being placed close up to the main road, secure the large hall against the noise and disturbance arising from street traffic.

Additional doors for occasional exit are provided from the public hall and from the large second-class bath pavilion.

The architects are Messrs. Booth & Chadwick, of Manchester, who have received instructions to prepare the necessary working drawings, and to obtain tenders for the erection and equipment of the building.

THE ROYAL COMMISSION ON METROPOLITAN WATER SUPPLY.

The Royal Commission on Metropolitan Water Supply consists of Lord Balfour of Burleigh (Chairman), Sir G. B. Bruce, C.E., Sir A. Gaskin, D.Sc., LL.D., F.R.S., Professor J. Dewar, M.A., F.R.S., Mr. G. H. Hill, C.E., Mr. J. Mansergh, C.E., and Dr. W. Ogle, with Mr. Francis Gaskell as Secretary.

The Commission has held two sittings for the taking of evidence. It commenced its inquiries with the River Lea and the two companies that draw a great part of their supplies from that river,—the New River Company and the East London Company. When the sittings are resumed, the Lea Conservancy will be heard, and then the companies that draw their supplies mainly from the Thames. There are maps on the walls of the room to elucidate the evidence as to the local position of intakes and wells. The Commissioners have before them printed statements and tables which have been furnished by the companies; also communications from the Lea

Conservancy and from the local authorities in the districts referred to. The latter statements, from the questions that were founded upon them, appear to suggest that the water of the Lea is not always sufficient for the navigation and for the companies, that the water is polluted by the manure and other traffic carried on upon it, and that the wells in the Lea Valley, from which the companies obtain large supplementary supplies, have affected, or may affect, the wells of the local authorities. The main object of the companies was to show by expert evidence that their wells are practically inexhaustible, without affecting any other existing wells. The examination of the witnesses was mainly directed to the explanation of the companies' printed statements and figures, and in particular to the testing of the data for estimating the consumption of water per day per head of the population, the actual supplies from all sources, and specially the possible future supplies from the wells that have been sunk, and others that are projected.

The New River Company.

Mr. James Searle, for twelve years Clerk of the New River Water Company, was the first witness. He was told by the Chairman that he need not go through a history of the Company, because that was dealt with fully enough in the first eight paragraphs of the printed statement which had been handed in. Asked about the increase in the number of houses in the district supplied by the Company, he said that was also set out in the statement. From 1851 to 1871 the total increase was 31,000 houses; from 1871 to 1891, 35,000; making for forty years 66,568, or a yearly average of 1,664. The growth had been fairly steady, but in the last two years there had been a considerable falling-off, and the reason was that the Metropolitan district was to a great extent filled up, and the building was now chiefly in the Hornsey and Edmonton parishes. He afterwards explained that by "houses" he meant "supplies," and that in a block of buildings each separate tenement would be called a house; so that the yearly addition was 1,664 tenements. A private house let off in rooms would be called one house,

because there would be but one rated occupier; but each set of rooms separately rated was called a "supply" or a house, and therefore the Company's return of the number of houses would not coincide with that of the census. The average daily supply in 1891 was set down at 33,028,000 gallons, of which 22,500,000 were derived from the Lea, and the remaining 10,500,000 gallons from the Chadwell spring and from wells. The average increase in the period of forty years was taken as an index of the probable increase during the next forty years with the object of showing that the Company possessed the means to meet the demands arising from increase of population. The Chairman, however, asked, "Would not the true way of looking at it be to endeavour to find out what the average increase to the new ratio would be, rather than to deduce it from the average of the past?" The average daily consumption had been 24,440,000 gallons in 1872, and it was now 33,000,000; and said the Chairman, "If you apply that ratio of the 33 millions, which is the present consumption, would it not be fairer to say that in twenty years the increase would have been 44 millions, if the ratio is taken from the 33 millions now, rather than applying the same ratio of increase to the 33 millions as you do to the 24 millions?" The witness did not think the increase would be so fast. The present consumption per head, 28½ gallons, was taken as the basis of the estimate for the future. Not quite half the estimate was under constant supply. The consumption per head had increased with the growing desire for comfort and luxury; but the full effect of that had been already felt, as water-closets and baths were now fitted in all new houses, and had been freely used for 15 or 20 years. Dry weather in summer and continued frosts in winter were without equal in the strain they put upon the company. The largest supply in a single day had been 42 million gallons, and that occurred in January, 1891. The Company had sunk wells without Parliamentary powers because they were all put down on land that had been purchased.

Mr. Joseph Francis, Engineer to the New River Company, said that for twenty years he

had superintended the construction of the wells. Chadwell spring now yielded about 2,000,000 gallons a day, and the wells 5,500,000; but the daily available supply from these sources was estimated at 34,000,000 gallons of 23,500,000 more than was now taken. The 34,000,000 was arrived at by taking what each well could do, and had done for weeks together, pumping day and night, taking each well separately, and then adding the results together. The witness gave particulars of the wells, which we summarise in the following table: The first column gives the depth in feet, and the second the depth of the borehole from the surface for each well that has one, and the third the year of completion. In the case of Turnford Well, the well was first sunk into the chalk with borehole, and the deep boring was done from 1875 to 1880. The last column gives in millions of gallons the details of the estimate of 34,000,000 gallons as the available daily supply. Anwell Marsh was given as 2,800,000 gallons, and Hoddesdon as 2,180,000. The letter (h) indicates that the wells have headings:—

	Well. ft.	Boring. ft.	Year daily.	Million gals.
Broadmead	26	831	1879	14
Anwell End	72	419	1848	11
Anwell Hill (h)	90	160	1848	34
Anwell Marsh (h)	109	392	1885	23
Eye Common (h)	204	—	1886	34
Hoddesdon	54	408	1888	24
Broxbourne	197	—	1886	24
Turnford (h)	167	1,001	1867	33
Cheshunt (h)	130	157	1846	3
Hoe Lane, Enfield (h)	192	—	1886	34
Betshilo	142	300	1872	3
Highfield (h)	178	—	1887	3
Camphourne	213	—	1888	34

The general policy of the Company was to bring in the supply from the wells to supplement that from the Lea and the Chadwell spring. All the wells are in use except Cheshunt. Broad Mead well had yielded 1,500,000 gallons daily for seven weeks together. The figures by no means represented what could be got out of the wells by working the engines a little faster. There was connexion between the Turnford and the Cheshunt wells, which were a mile apart, and that was the reason why Cheshunt was put down at 750,000. Anwell Hill and Anwell Marsh to some extent affected each other; but the quantities named were given when both were at work, as they had been for a few weeks together. Only in the cases named did the pumping at one point affect the supply at another. He did not think there was any ground for complaint that their pumping operations had depleted other wells in the district, except so far as it affected any spring in the immediate neighbourhood of a well. The Chairman read a statement by the Cheshunt Local Board that the pumping operations of the New River and the East London Companies had drained two artesian wells sunk by the Board, and one artesian well of the Waltham Gas Company. These wells, 150 ft. deep and driven into the chalk, were three years ago overflooded, but now the water did not rise within 50 ft. from the surface, unless the pumping ceased for a long time. The witness did not understand that, because the level of the water in the Company's well had never sunk 50 ft. or anything like that, and the Board's Surveyor had reported the yield as satisfactory and the level as unaltered. He afterwards explained that they pumped down to the depth of 60 ft. or 70 ft., and when they stopped pumping the water rose, and the level was unaltered. The Comty Council of Hertford had informed the Commission that many of the rivers of the county now rose considerably below the point at which they had their source twenty years ago, and were much reduced in volume, that the volume of many natural springs was much diminished, and that the water-levels of the county were materially lower than in the past. Of these complaints the witness had not heard. Nor had he heard of a complaint by the Enfield Local Board, who were advised by their Surveyor that the lowering of the water-level in the chalk was due to the sinking of deep wells by the New River and the East London Companies. From Turnford Well northward, he said, there had been no lowering whatever of the level in the chalk during the fifteen or twenty years he had noticed or taken the levels. There had been no lowering of it since the new wells had been sunk. These replies suggested to Sir G. B. Bruce the question whether between Turnford and London there had been a falling of water; and the answer was that under London there had been a considerable falling

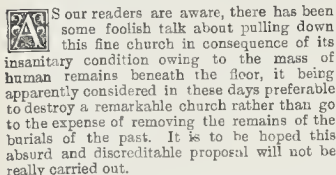

off, and that inflexion extended towards Enfield. Under London it was nearly 18 in. a year; and the standard water-level had been for some years falling. The Company had old wells they were not using now at Hampstead Heath and Hampstead-road, and at these wells they had the opportunity of measuring the water-line. It was sinking there although they were not pumping. The fall of water in the upper valley of the Lea no doubt arose from increased drainage. Fields were drained and the water that would otherwise water-log the upper part was drained off into the springs, and that accounted for rivers rising lower down. The water was taken off so much more rapidly than before that the upper ground did not get so well saturated. He had no doubt that the quantities of water named for each well could be depended upon, supposing all were pumped together continuously. There would not be a general depression, but a local one of depression at each well. There would not be danger of pollution from surface water, because the surface was covered with drift clay, sand, and soil, so that the water was filtered before it could get downward. He did not think that any wells the East London Company could sink in their district would affect the yield of the New River Company's wells; taking into account percolation and area, there seemed to be plenty of water for both for many years. "There must be a limit somewhere," said Mr. Hill; and the witness rejoined: "Yes, but we find that what we pump has practically no effect upon the surface level, and therefore it is evident that a very much larger quantity could be pumped without doing any appreciable harm." If the pumping were more than the supply, the level in the chalk might be lowered; but he had no fear that the demands of the companies would have that effect. Having investigated the matter carefully, they were quite satisfied that the water they were pumping would not go to feed springs or streams or rivers, except in local cases; the water was really passing down towards the south-east end of London, and it did not get into the rivers at all. The pumping would not affect the river Lea itself, but it would affect the Thames at Woolwich. There was no diminution in the discharge of the river Lea compared with a few years ago; and this was shown by a return put in giving the discharge at Fields Weir for each month of the year from 1880 to 1891. Mr. Mansergh pressed upon the witness the point that the wells were to be relied upon for four times the supply they yielded now. The witness said that was hardly it. They wanted an average of 47,250,000, and they had got 25,000,000. The 34,000,000 a day from the wells might be wanted only for a few days during the year. "But in a very dry season it would be longer than a very few days?" "Yes, but we never find that the maximum lasts very long." The 34,000,000 was not what it was proposed to draw every day; it was merely a store to meet any excessive claim that might come. The company had power to take 22,500,000 gallons from the Lea at a point a mile below Hertford, and he had never known a time when that quantity could not be got. The river Lea people had not complained that too little was left for navigation. Wet or dry seasons did not make an appreciable difference in the quantity obtainable from the river; the level of the water in the wells varied with the seasons to the extent of a few feet. The water from Belstilo was pumped into a reservoir; with that exception, all the water from the Lea, Chadwell Spring, and the wells was conveyed to London by the river, which was covered in for three miles, and partly so for a mile and a half. There was great expense in keeping it open in time of frost; but the full quantity could always be got through. The river was fenced almost throughout its course; surface streams did not run into it; and it was patrolled and watched and carefully guarded against pollution. The water given by the Chadwell Spring varied very much. The average was about 3,500,000 in the twenty-four hours; but 2,500,000 was the average for last year. For a short time it has been under 500,000 in dry seasons. The figures of 4,500,000 given to the Commission twenty-five years ago was rather too high. The river water may not always be so clear as the well water, but it is equally good for domestic consumption after it has been filtered. The lowering of the water level under London he attributed to the increased pumping that had taken place from under London itself, and the difficulty that the water had in getting down there, through the re-

strictions in the channels in the chalk. After wet seasons the level was higher in the chalk; after dry seasons it was somewhat lower; but changes did not follow immediately, and it was difficult to trace the connexion between rainfall and the level in the chalk, except in a general way. Asked what was the condition of the lower part of the Lea in summer time, he said there was always plenty of water in it. Reminded that Mr. Binnie had told a former Commission that the effect of the increased abstraction of water was "to reduce it in summer time to a stagnant pond," he replied that Mr. Binnie did not say there was a want of water, but that it was stagnant. The movement of the traffic would give plenty of circulation in the water if it was only kept free from sewage matter. "Of course, if you put sewage into it, it takes a very large flood to keep it always clear. There is no want of water at all." Pressed by the Chairman, the witness said the companies always left the navigation quantity, but sometimes took all that remained. There was always left as much as the traffic could need, and it was enough to keep the water from being stagnant, providing large quantities of sewage were not turned into it. The Chairman asked for the minimum discharge from the Lea at any period within the last five or ten years; but the witness had only the monthly averages, and one was as low as 44,000,000, although the daily average in that year (1887) was 104,000,000. At such a time the New River Company would still take its 22,500,000; but the East London Company, having storage reservoirs, would not take much from the river. Questioned as to the population and the nature of the country above the company's intake, Mr. Francis said that Linton was eleven miles above it, and the sewage of the town was kept away from the river by being taken to a sewage farm on high ground. The general character of the country through which the Lea ran was purely agricultural. The Lea Conservancy took great pains to prevent anything like pollution. There was a manure traffic in barges, and it went on to a small extent above the intake; but the navigation did not extend much above the intake, for it stopped at Hertford. It would be possible for each company to store about 10,000,000 gallons a day during the winter months of the surplus water of the Lea, but there was no scheme in hand; indeed, it would be possible for them to store 365 times 10,000,000 gallons, but, the Chairman pointed out, the storage would have to be at the rate of 20,000,000 gallons a day for half the year. Still, nothing had been done because well-sinking was a much simpler way of obtaining a supply. But, for all that, he wanted to test the storage plan. There was room at Walthamstow for reservoirs which would cost 300,000, or 400,000. The reservoirs would not be of great depth, and there would be no danger from a great head of water. The reservoirs would want pndding, because the London clay does not extend so far. "We know it is not as happy a site as we should like," but the Company had carefully considered the possibility of having to erect reservoirs. In the area from which the water-supply was derived, the increase of population was very slow, and it had been more than met by the increased precautions of the Conservancy in diminishing population. He did not agree with the statement that during flood time the water was exceedingly had. The worst time was just at the commencement of the flood, and means were taken to shut it off partially or wholly. As soon as the first flush was over, the water was not had. There was a good deal of sand and clay in it, but it was not polluted. It would not be true that the condition of the flood waters was "as bad as the main drainage outfalls at Crossness." The flood water at their intake was never had; it was turbid with sand, clay, and chalk; but it had not the offensive smell or the odour of sewage. The water from the wells was filtered with the water from the river, not because it needed it, but because it was cheaper to bring it along the river channel than to lay separate pipes. The New River water stood highest amongst the river-derived waters, and the river-borne pollution from navigation was gradually decreasing. The flood water, when stored, would be good water, provided you did not take just the top of the flood; and he did not think that the bulk of the water would have to be rejected on account of the pollution brought down by heavy rains. Tottenham, Enfield, Ware, Cheshunt, and Hoddesdon had independent supplies.

INTERIOR OF CHURCH OF ST. MARY
WOOLNOUTH.

Our readers are aware, there has been some foolish talk about pulling down this fine church in consequence of its insanitary condition owing to the mass of human remains beneath the floor, it being apparently considered in these days preferable to destroy a remarkable church rather than go to the expense of removing the remains of the burials of the past. It is to be hoped this absurd and discreditable proposal will not be really carried out.

The site has been occupied by a church for many centuries; the building preceding this one was injured in the fire of London, and repaired by Wren; why soon after this it was pulled down no one seems to know. The present church was designed by Wren's pupil Hawksmoor; the exterior, heavy and castellated as it is in appearance, has nevertheless a kind of defiant originality in the treatment of the principal façade. The interior, one of the most convenient (for congregational purposes) and one of the most architecturally effective church interiors in London, is a Greek cross in plan, with shallow arms, and three Corinthian columns at each angle (as shown in the drawing), with a segmental dome over the central area. The view shows part of the interior as it was remodelled by Mr. Butterfield in 1876, when the galleries were removed, but in order to preserve their fine carved fronts the architect brought him of the happy idea of fixing them as an architectural feature round the walls; their original use is sufficiently obvious to tell the history of the change.

The church was built in 1716. Among the persons connected with its history was the Rev. John Newton, the joint author with Cowper of the "Olney Hymns," who was rector of the church for twenty-eight years, and was buried there in 1807. The lithograph is from a monochrome watercolour drawing by Miss A. Fooks.

ILLUSTRATIONS OF OLD CHESTER.*

V.—THE LADY'S BOWER, WATERGATE-ROW
SOUTH.

This very interesting little court, with its covered gallery, measuring only about 16 ft. by 14 ft., is in this series illustrated for the first time, as it is very little known, and has fallen into a dilapidated state, much to be regretted. In the view no attempt has been made at restoration except the removal of a wall under the gallery and abutting against the column, to form a passage for the convenience of a house in the rear, and the introduction of mullions in the windows, which have been modernised. All the woodwork is oak, elaborately carved. In the adjoining mansion, now in the occupation of Mr. Maddon, cabinet maker, are some interesting remains, including a noble fireplace of great height, now almost hidden, and a pendant of great beauty, and at the back of this tenement is a house before alluded to, in which are remains, including fragments of stained glass, a fine old stone fireplace, and other carvings, which will form subjects for future illustrations, when the whole will be fully described, with some account of the distinguished Cheshire family who originally made it their town residence. THOMAS P. IVISON.

MUNICIPAL BUILDINGS, BATH.

This is the amended perspective view of Mr. J. M. Brydon's accepted design for the new Municipal Buildings at Bath, the elevations and plan of which we published on January 9 of this year. We did not then give the perspective in accordance with Mr. Brydon's express wish, as he was not satisfied with it in its original form.

We gave a very full description of the design and plan in our review of the competition designs on December 26 of last year, to which it is unnecessary to add anything here; we may mention again that the block on the right or south wing contains the municipal offices proper, and that on the left or north wing contains the technical schools. The plans for

* For preceding views of this series, see *Builder* for February 6, February 27, March 12, and April 9 last.

the whole are in hand, and will be carried out substantially as in the competition design.

The drawing from which the illustration is taken is exhibited at the Royal Academy.

DESIGN FOR PROPOSED R. C. CHURCH
OF ST. PETER, DROGHEDA.

The illustration shows a drawing submitted in competition for an Irish church several years ago.

The church was designed to take the place of an existing structure on the same site, and the Sacristy and other buildings shown on the right of the drawing had been built as an addition to this older church, and were to be preserved in connexion with the new church, and this to a small extent controlled the design.

The internal dimensions of the proposed church were as follows:—Total length, 138 ft.; width over aisles, 58 ft.; ditto over transepts, 88 ft.; and height, 52 ft. 6 in. The spire was 220 ft. high. Confessionals were provided in the nave between the buttresses of side walls.

Mr. T. L. Watson, of Glasgow, is the designer, and the drawing is at present in the Royal Academy Exhibition.

THE ROYAL COMMISSION ON METRO-
POLITAN WATER SUPPLY.

(Continued from p. 419.)

Mr. Ernest Collins said he was the engineer in charge of the distributing works of the New River Company, and was responsible for the tables laid before the Commission. The average supply per head per day for all purposes, trade and domestic, was 27.10 gallons in 1872, 28.77 in 1881, and 28.49 in 1891. Constant supply had been introduced, and extended to 17,557 houses in 1881, and in 1891 to 68,000, out of a total of 154,568. The increased consumption from 1871 to 1891 was partly due to the bad state of the fittings in Shoreditch. In 1883 the company made great efforts to suppress waste; and it now employed thirty-eight waste inspectors, while Deacon's meters were largely used to detect flow at night. An average of 28 gallons per head per day ought to be taken as the maximum consumption for trade and domestic purposes for the New River district. Fifteen years ago a directly-supplied closet was quite exceptional. Now every 20th house had a water-closet, and houses above 25th had often two, and a barb. Future increase would perhaps bring more efficient means of checking supply. London, he thought, could not be compared with any other town, because London had more baths and water-closets. The consumption had reached 32½ gallons per head per day in July, 1887, and 32 in July and August, 1881. The average was arrived at by dividing the total by the number of supplies and estimating seven and a-half persons to each. The figures had been tested by experience. It was reckoned that about a quarter of the supply went for trade purposes, including railways and breweries and street watering. He put 28 gallons per head as the maximum, because there was still great waste going on that could be prevented. The constant supply was the most economical with proper fittings, but the intermittent without them. People who had put on proper fittings on notice were impatient for constant supply, and the Company were obliged to give it,—when perhaps only ten houses out of fifty were ready for it. The consequent waste he estimated at 3,000,000 gallons a day.

Mr. Edmund L. Morris, engine-superintendent, gave evidence as to the capacity of the engines at the wells. At most there were two sets of machinery; but the stand-by power was in the number of wells, at which, in the aggregate, the quantity of water pumped was only one-third of what could be pumped. Mr. Morris has also charge of the filtering operations, which he described in detail. He said there was no test other than that of colour for the efficiency of a filter-bed. When the sand was scraped clear of foreign matter, and then it was quite again. Sir A. Geikie asked, "Can you be sure that you take away all the organic material?" and the answer was, "All the particles are separated and washed, and it is thoroughly cleaned."

The Chairman remarked that this concluded the evidence put forward as specially referring

to the New River Company; but at the next sitting Mr. Francis was requested to furnish a plan showing for each well the normal level of the saturation, the level to which the water rises after pumping has been stopped for some time, and then the level to which the water must be pulled down by pumping to give the quantities mentioned in the table.

The East London Company.

Mr. W. B. Bryan, Engineer to the East London Company, was asked to describe the company's intakes. He said that at Chingford Mill they had two intakes,—a high-level intake at the mill-head to supply their high-level reservoirs, and one at the tail of the mill to supply the low-level reservoirs. They took out of the stream flowing past their works on the average 32,000,000 or 33,000,000 gallons a day. In time of drought, the amount of water that passed below the intakes was not very great; but it was never reduced to nothing. The navigation having a prior right, was always full. The witness was reminded that the average quantity taken was 36,000,000 in 1891, and 37,000,000 in 1890, and he assented to the statement that the New River Company might, if they chose, take over and above their 22,500,000, one-half of what was taken by the East London Company; except so far as the latter took water when the river was in flood for storage in their large reservoirs. The Conservancy took a much water as they required for the navigation, and the East London Company never objected to the Conservancy taking its full amount. It might be that it had taken "only as much water as was necessary for the passage of the traffic," but he was not aware that any complaints had been made to his Company. He estimated that it would be safe for his company to take 30,000,000 gallons a day from the Lea. It had taken nearly its full amount from the Thames—9,750,000 for four weeks in 1885; and he believed it might safely have taken 10,000,000. The quality of the water at the point at which they got it was improving; and it was not taken when the river was in flood, when the Company relied upon its large storage reservoirs in the valley of the Lea. Field's Weir is at the junction of the Stort and the Lea, and the quantity of water passing over it after the New River Company had taken its allowance was stated before the River Lea Committee to be 15,300,000 gallons a day; but the witness said that was quite a mistake, due to the erroneous way in which the gaugings had been taken. This led the Chairman to remark: "What we want to know is the minimum quantity going over the weir for a certain number of days or weeks in the summer." The witness said he could give every day for twelve years; and he mentioned a day in August, 1887, when the quantity was 22,185,000, and another in October, 1888, when it was 30,000,000. But, in 1888, two wells were in process of construction and water was pumped into the river, but it would not exceed 1,000,000 gallons a day. The most adverse condition to be encountered was a prolonged frost, followed by a dry summer. Then the Company must draw upon its wells and its storage reservoirs. Still at the worst it might count on getting 20,000,000 a day out of the river. If 40,000,000 a day were required, 20,000,000 would be taken from the Lea, 10,000,000 from the Thames, and the remainder from the wells and the storage. The full storage capacity was 910,000,000 gallons. There was no means of telling why water was taken daily from the River Lea. When the Lea was in flood the intakes were absolutely closed, sometimes for a week together and sometimes longer. On the Lea works there were about twenty-five acres of filter-beds, and the maximum out of use at any time was about three acres. The pumping machinery was a high-class and doing splendid duty, and there was adequate stand-by power. The table furnished to the Commission showed that the average daily supply had increased 10,000,000 gallons a day in eleven years, but it was estimated that in the future the increase would be only 2,000,000 gallons a day in five years. The increase was now all in the Essex district. The average population per house in the London district was about 7.62; in the Essex district, it was only 6.1. The company took the population, and divided it by the number of supplies to get the average of each house or supply. The number of supplies in 1891 was 172,310. It was believed that 33 gallons per head per day was an excessive estimate for the next four

ears, because so much water was now wasted through the absolute carelessness of the poorer classes. Then immigrants washed their clothes by putting them under the tap, and letting the water run for two or three days. There were portions of the district in which the consumption was as high as 70 gallons per head per day. Thirty inspectors were employed in checking waste, and, while it was watched, the night line would be reduced, but it would rise again to the day line in the following week. The yearly increase in the number of supplies culminated in all London in 1882, and then it was checked with the decrease in jerry-building. It was most difficult to estimate what the population was at any particular time in such a district, because the population was so migratory, and one or two big strikes would reduce it very much. It was impossible to tell what the East-end of London would be like in a few years time, because a check must come to the increase of the population within the Metropolitan area. In West Ham the sites for new houses were limited, and if the population went further east, to Barking, it would be in the district of another water company. In wealthier districts the consumption per head was less than it was in poorer districts; and he had found it the same in Blackburn. In the Company's district there were 80,000 or 90,000 houses at a water rental of less than 15s., and that indicated that the rental was weekly. When a house got dirty the occupants would change into a clean one, and it was difficult to know how many were actually occupied at any given time. The witness was requested to furnish the Commission with a return of the number of gallons of water used per head per day, and to prepare it with a keen appreciation of the importance which was attached to it. "The pollution of the Lea from its traffic was infinitesimal, and the bulk of the traffic stopped below the Company's intakes. The two Companies pay an annual sum for securing the sanitary supervision of the river, and immediate attention to any reported pollution. The Conservancy have informed the Commission that there are thirteen sewage-treated towns above the East London intake, and sixteen towns—eight sewage and eight cesspool—above the intake of the New River. The witness said he knew only about Hertford and Chesham. In the latter case the effluent was now carried for several miles into the Company's intercepting drain, which discharges it some miles below the intakes. Hertford used a precipitation process, and the effluent flowed through a ditch to the Lea. No doubt, said the witness, the organic impurity in the East London water was greater than in the New River, for two reasons: first, their intake was in a better position; and, secondly, they had a greater admixture of well-water. The difference was about 50 per cent. on the average; and it was mainly due to the well-water. The present and the possible yield of the Company's wells and springs was the subject of many questions. In the Company's statement the daily average of water taken from wells and springs was set down at 3,681,000 gallons. Mr. Bryan now gave the quantities pumped from the wells as follows:—

	Gallons.
Waltham Abbey	800,000
Chingford	500,000
Walthamstow	400,000

The remainder, which would be nearly 2,000,000, he said, came from the springs at Hanworth. In the statement it was said that the existing wells would yield 11,000,000, and from other wells "some of which are being sunk," they could get 13,000,000. This statement elicited from the witness the story of the Hanworth springs, and led to important questions. At Hanworth, four miles past Hounslow, and two miles north of the Thames, there were gravel springs which yielded 2,000,000 gallons a day. It is lifted by centrifugal pumps, so it is difficult to say the exact amount. A trench around the filter beds was being puddled, on account of the pressure of land water. It was found to be a volume of good water. On Mr. Bryan's advice, tunnels were driven to collect it. It was a permanent supply. There was a bank of clay which held up an immense amount of water in a gravel bed of 70 or 80 square miles. The water was running on its way to the Thames. Pumping did not seem to have any effect upon it. The water flowed over the edge of the bank in four or five places. It was simply a small portion of the surplus that was taken. "Where does it come from?" was asked. From a large

area which is permeable, and is little built upon. "Then, practically, it is surface water?" said the Chairman. Yes, it is. The water has been analysed several times, and the Local Government Board gave permission to use it four years ago. The following conversation ensued:—

The New River Company tell us they are pumping, on the average, 8,500,000 gallons a day. So it comes to 10,000,000 or 11,000,000 a day from the chalk wells. In your statement you say that from the Company's existing wells in the Lea valley you can get 11,000,000. That is about 9,000,000 more than you are taking now?—Yes.

And from other wells, "some of which are now being sunk," you think you can get 13,000,000?—We do.

Thus you propose to take 20,000,000 more than you are taking now?—Yes.

And the New River Company propose to take 23,500,000 more?—Yes.

So that the two propose to draw daily 44,000,000 more from the chalk than now?—Yes. From our present wells we have taken continuously 7,000,000 daily.

For how long?—Until the pumps gave out, for three or four months at a time. Some of it we pumped to waste and some we ran into our filter beds. From the Lea Bridge well we have pumped continuously for six months, and we have had as much as 3,500,000 a day passing to the last day.

During the construction of the well at Waltham Abbey there were complaints of depression in four public wells at Waltham Abbey and Chesham, but Mr. Bryan found the explanation to be that their pumps were out of order. In reply to further questions he said:—

I think it is safe to assume that we and the New River can take 44,000,000 gallons more, because there is an immense volume of water running to waste in a south-easterly direction into the Thames, down towards Purfleet, Grays, and that neighbourhood. Our wells immediately fill up when we cease pumping. At Lea Bridge we have 6,000 ft. of tunnel, and as soon as we cease to pump the water fills the tunnels quickly, and, as soon as it reaches the shaft, it comes up the shaft at the rate of 40 ft. an hour. At Walthamstow the action is very rapid. At Waltham Abbey our pumps are drowned by about 140 ft. of water. We cannot reduce the level with our existing pumps to nearer than 128 ft. from the bottom of the well. It is difficult to make any estimate of what we are pumping when we have got workmen down below. On this the Chairman said, "And that makes it difficult for us to form an estimate of what you have really been doing." The following occurred in subsequent conversation:—

You have powers to sink wells beyond those you have exercised?—Yes.

What length of headings have you driven?—At Waltham Abbey about 600 ft.; at Walthamstow about 600 ft.; at Lea Bridge about 6,000 ft. At Lea Bridge we have driven headings at a very low level. The chalk was so hard it had to be blasted with dynamite. After driving 1,000 ft. and finding no water, we abandoned the lower heading, and came up 60 ft. higher. All complaints of our affecting previously existing wells have been groundless, and at present they are drawing all the water that is needed. Of the 910,000,000 gallons, 600,000,000 can be drawn off by gravitation.

Have you formed any idea what would be the effect of getting these 44,000,000 gallons extra from the chalk?—As far as my district is concerned, I do not see how it can affect the surrounding country. There is the London clay, which is a very compact mass, lying between the Thanet base and the surface, so that, whatever water comes from below, it cannot affect the surface close to our wells. I cannot see how the abstraction of any amount of water from the chalk underneath the London clay, so far as the London clay extends, can affect either the surface springs or the country generally.

I suppose there is a limit to the quantity to be got from the chalk?—I should think there is.

There must be a point at which you would begin to draw on the streams from the surface, must there not?—The streams have no connexion with the wells where the London clay is.

I am speaking of where you have the chalk?—We have not any chalk in our district; there

is no outcrop of it in my Company's district. All down the valley, if you dig 2 ft. you come to the water from 2 ft. to 3 ft. in the gravel.

How are the wells lined?—We support them with cylinders 15 ft. in diameter at the surface. We seal these into the London clay, so as to absolutely exclude any water from the gravel.

With respect to the depletion of the Lea, the Chairman quoted a letter from the Conservancy to the Company on March 17, stating that there was difficulty in keeping the navigation below Old Ford up to a proper head, and that at Limehouse Cut the navigation had been stopped at times for want of water. The witness said that up as far as Chingford the Lea was always full. The Thames tides went into the Limehouse Cut, and left a considerable deposit of mud. The Conservancy had filled up a compensation reservoir, which had been constructed by the Company. The tide used to flow in and out, and thus the reservoir acted as a flushing tank, but the Conservancy had filled up the reservoir with dredgings. An extra 5,000,000 a day would be nothing in six or seven miles of river. Neither would it place the Company in difficulty, because they had always sufficient water in their storage reservoirs, and they had never objected to the Conservancy taking their full amount.

The witness further stated that the East London Company has secured excellent sites for more storage reservoirs. Turbid water is not taken. In flood and rainfall the intakes are shut down until the water is in good condition; and they have never been unable to fill up their reservoirs a few days after a flood.

Sir F. Bramwell said he had been consulted on these matters by the East London Company. He handed in a table prepared from the publications of Mr. Lass, which showed that from 1881 to 1890 the houses or supplies of the East London Company's district had increased from 130,086 to 167,989. He also produced another table giving corresponding figures for all the eight companies. The estimate of 33 gallons was, he thought, largely in excess of what it ought to be; including the trade supply of 6,000,000 or 7,000,000, the estimate ought to be from 25,000,000 to 27,000,000 at the utmost. The East London would do with this supply without stinting anybody if it had the same assistance from the local authorities as other companies had. The average price or cost of the East London Company's whole supply was 4-18 7/8d. per 1,000 gallons; and for the eight companies, including the East London, the figure was 7-11 1/8d. Where the customers acted with reasonable fairness, the constant supply system took the least water; and waste arose mainly from carelessness and indifference. The East London Company was peculiarly situated in its power to pump from the chalk large quantities of water running to the river or the sea. He could not conceive that any amount of pumping would ever affect places in the district,—Luton for example.

Professor W. Boyd Dawkins said he had made it his business to master in detail the geology of the district, and in particular the area of the chalk and the area of the London clay. The water which the East London Company obtained from wells, sunk mostly through the London clay, was obtained from the rainfall which came upon the chalk; and the area of the chalk in the Lea valley was about 275 miles, including outliers. On this area 1 in. of rainfall a year would give 11 million gallons a day; and there was a percolation of not less than 10 in. a year. The chalk was an enormous porous sponge, the upper half being more porous than the lower half, and the whole something like 400 ft. in thickness. The streams were on the surface of this mass, which was more or less saturated. At Mimms, south of Hertford, all the surface-water went through three or four swallow-holes bodily into the chalk, proving in that case the capacity of the chalk to take 20 square miles of surface drainage. The chalk was full of swallow-holes in which that sort of thing went on, and, therefore, 10 in. was a very moderate amount of percolation. To the east, in the valley of the Roding, the Company could intercept water on its way down to the line of the Thames, and so largely increase their supply. He had seen water passing from the chalk into the Thames, and he was fully persuaded there were vast masses finding their way through it, to say nothing of certain large isolated springs which came bodily into the Thames. These masses did not come through the London clay; they came through the

chalk. The surface of the chalk was extremely irregular, especially under London. He showed by a section from Sevenoaks to the line of the Thames the gradual descent of water from an altitude of 172 ft., and said it was the same on the other side of the river. There was a general lowering of level due to increased drainage, which might also diminish percolation; but that did not apply to wells in London that had been sinking a long time, because water could not get to them to compensate for what was taken out. That would not happen to the Company's wells, because they were nearer to the area of the exposed chalk, and the yield of these wells showed that there was certainly very much more water in the district than there was under London in the chalk. The Company had wells with a capacity of 4,000,000 to 5,000,000 gallons a day, but no well under London had produced much more than a fourth of that. This underground water certainly came from the surface of this area, and possibly adjoining areas. "Then," said the Chairman, "rainfall and percolation cannot be the bases of estimates." Pumping on a large scale would have some effect on the surface drainage, and probably on the streams; but the area was so extensive that a large amount of water might be taken without much danger to the surface.

Mr. Wm. Topley, F.R.S., F.G.S., said the water at the Lea Bridge well was largely derived from the tertiary sands, and this source of supply could be more largely utilised. If this water were not pumped it would go to feed the general supply in the upper part of the chalk under London, which found its way down to the Thames and flowed out along the Thames. The gravels of the Lea were in direct communication with the sands of the tertiary beds. He saw no reason why a large amount of water should not be drawn from the gravels of the Lea. All along there was gravel underneath and along the sides of the river, and whenever it was tapped it was water-logged. If any harm was done by taking that water it would be to the river lower down. What was done at Lea Bridge was a capital example of what could be done by developing old wells and making new ones in the Roding and Stort valleys. It was impossible to say what would or would not happen, but none of the existing wells were sufficiently near the outcrop to be a source of danger to the neighbors of the East London Company. There seemed to be something exceptional in the Lea valley in the large amount of water that could be drawn, and in the wells not affecting each other. Two wells in the Stort valley might, perhaps, yield 3,000,000 gallons between them. Of course, there must be a limit beyond which it would be unsafe to go, but he did not think the proposals of the Company would reach that limit.

Mr. J. H. Barnes, C.E., handed in tables showing the monthly flow of the Lea from 1880 to 1891 at Field's Weir, and, asked for the lowest, said it was twenty-one millions in September, 1891.

Mr. W. C. Young, consulting chemist to the Lea Conservancy, handed in analyses of water from the intakes made in 1884, 1886, and 1891, and said they showed a considerable diminution in organic pollution; but the Chairman, remarking that analyses taken at such an interval did not convey any idea to the mind, preferred to examine Mr. Young as the witness of the Conservancy rather than as the witness of the Company, and, therefore, deferred further questions until the case of the Conservancy is taken.

The Commission will resume its sittings on the 30th inst.

THE LONDON COUNTY COUNCIL.

The usual weekly meeting of this Council was held on Tuesday afternoon at Spring-gardens, the Chairman, Lord Rosebery, presiding.

The Water Question.—Mr. Dickinson, the Deputy-Chairman, reported that the Committee of the House of Commons which was considering the question had expressed their willingness to pass the London Water Bill, provided it was limited to conferring powers to conduct inquiries and negotiations and to promote Bills in Parliament, and to pay all the necessary expenses thereof; but that they were not prepared to constitute as the Water authority either the Council or the Joint Committee of the Council and the City Corporation, as was proposed by the Bill. The effect of that decision was to give to the

Council all the powers originally asked for by them, but to deny to the Corporation for the present year the representation sought by them on a Joint Statutory Committee. Under the circumstances, therefore, the Corporation's representatives had asked to be permitted to consider what action should be taken, and the matter had consequently been adjourned, in order that they might decide whether or not they should insist upon the Bill being abandoned, or would proceed with its promotion in the altered form.*

Organisation of the Council's Work.—The Vice-Chairman (Mr. John Hutton) presented a long report by the Special Committee on Organisation and the methods of conducting the Council's business. The Committee made a number of detailed recommendations, the first of which was the creation of a new Committee, to be called the Establishment Committee. Other recommendations were as follows:—

"That, with respect to officers charged with technical or professional work under the control of a single Committee, and who are not heads of departments, all recommendations for their appointment shall be made direct to the Council by that Committee after consultation with the Deputy-Chairman."

"That, with respect to officers charged with technical or professional work under the control of particular Committees, more than one in number, and who are not heads of departments, all recommendations for their appointment shall be made to the Council by such Committees jointly after consultation with the Deputy-Chairman."

In cases where the work of the officials is not confined to particular Committees, the question of appointment shall be dealt with by the Establishment Committee as a matter falling under the reference to them."

The recommendations were agreed to after some discussion, in the course of which Mr. Hutton strongly urged the necessity, in the interests of economy and efficiency of administration, no less than in the interest of the health of the Council's employees, of obtaining a site and erecting new and adequate municipal buildings. The central building in Spring-gardens was totally inadequate to the needs of the staff and its work, and it now had to be awkwardly and expensively supplemented by a number of scattered houses. The inconvenience of this scattering of the staff was very great. Another thing was that many of their employees were now working in rooms which were positively unwholesome.

The "Rate of Wages and Hours" Clause in Contracts.—The discussion of this question was resumed. As we have already informed our readers, Mr. John Burns raised the question by the following motion:—

"That all contractors be compelled to sign a declaration that they pay the trade union rates of wages and observe the hours of labour and conditions recognised by the London trade unions, and that the hours and wages be inserted in, and form part of, the contract by way of schedule, and that penalties be enforced for any breach of agreement."

To this Mr. Costelloe moved last week the following amendment:—After the first word "That" to insert the words "except as regards work intended by the Council to be done outside London."

Mr. Sydney Webb seconded this amendment, and, after a long discussion, the amendment was negatived by 73 to 32.

The further discussion of the matter was adjourned to a special meeting fixed for Friday afternoon, the 27th, at 3 p.m.

The Council adjourned at 7 o'clock.

COMPETITIONS.

HIGHER GRADE SCHOOL, WINCHESTER.—In this competition, we understand that the successful competitors are Messrs. Pink, Farrow, & Nisbett.

WILLESDEN FREE LIBRARY.—We are informed that the designs of Messrs. Newman & Newman, of London Bridge, have been selected in competition for the new free library to be built at Willesden-green.

BURSLEM BOARD SCHOOLS.—We understand that in the recent competition for new schools at Hill Top and Longport, for the Burslem School Board, the plans of Mr. A. R. Wood, of Tunstall, were adopted, and that he has been appointed to carry them out. The Longport school is intended for 400 boys and girls, and the Hill Top school for 400 boys, with rearrangement of the Board-room and Offices.

* At the sitting of the Parliamentary Committee on Wednesday, Mr. Liddle, Q.C., on behalf of the London County Council, said that that body desired to proceed with the Bill in its altered form, which was subsequently ordered to be reported to the House for third reading.

BRITISH ARCHEOLOGICAL ASSOCIATION.

At the meeting of this Association on Wednesday, May 18, Mr. J. W. Grover, F.S.A., in the chair, the progress of the arrangements for holding the Congress at Cardiff were detailed. Mr. Loftus Brock, F.S.A., exhibited a series of articles which had been found in recent years in various parts of London, in proof of the existence of a settlement on the site of the City in prehistoric times. The articles consist of bones split for the extraction of the marrow, bone spear-heads hacked into shape by flint implements, and pottery not worked on a wheel. The chairman produced an old Bible covered with embroidery in silver and colours, most probably the work of the nuns of Little Gidding. Mr. Wells reported the discovery of prehistoric remains which have been made in cutting a watercourse on the Wray Park estate, Maidenhead, on land which had once been a bog. At a depth of 7 ft. or 8 ft. the antlers of red deer, used as a pick, have been met with, together with a portion of a human skull, flint implements, and a stone axe, which, after having been cut and polished, had been repolished at a later date. Many hazelnuts were also found, and cockle shells, the latter being refuse of food. The chairman spoke of a ford which appears to have existed at Maidenhead in Roman times, and probably for a period long anterior. Mr. Earle Way exhibited a small collection of Egyptian antiquities, the principal of which was a cone of a foundation deposit, with an inscription. A paper on "The Merchants' Marks of England" was then read by Mr. R. Davis. This was an exhaustive treatise, in which the rise of the use of merchants' marks was traced from early times to our own. Old Acts of Parliament were cited in which Merchants, 1420, were to make barrels with a sign; and others required Goldsmiths to have their marks while in action. Old documents were produced in which certain witnesses had affixed their marks, the latter being distinctive and not a common sign. Thumb marks from the actual thumb of the witness were also noticed. Arms and marks were sometimes used by the same individual when qualified to bear arms, and the instance of Wm. Canynge and some others were mentioned; while the shield of John Terry, 1524, in St. John's Church, Maddermarket, Norwich, bears his arms, those of the Mercers' Company, and his Merchants' mark. Many of these marks are based upon a cross, apparently in token of good faith. The paper was illustrated by drawings of over 500 examples from monumental crosses, documents, stained glass, and seals.

Correspondence.

To the Editor of THE BUILDER.

ANCIENT FONT AT ST. ANDREW'S HOSPITAL, NORTHAMPTON.

SIR,—This font is of admirable workmanship, though now much worn by its 300 years of desecration and exposure. It was found in a midden immediately outside what I believe to have been the southern doorway of the ancient priory church, or chapel of the Augustinian Canons of St. Andrew's, of which the present St. Andrew's Hospital grounds, extra parochial formed the country house. Their town house, famous as that in which Thomas A'Beckett, Archbishop of Canterbury, took refuge after the stormy scene with Henry II. in the castle, was situated near the river, upon the site of the London and North-Western railway-station, closely adjoining the castle hill.

The font is of late twelfth-century character, and of Barnack stone. These quarries,—still discernible as "hills and hollows,"—so the local term for such ground runs, became exhausted towards the end of the thirteenth century. This is sufficient, even without the clear architectural evidence, to prove the antiquity of the object in question. It has, I am told, though this cannot well now be seen, as it serves as a flower-basket or stand, no drain. This proves it never to have been accommodated to the Protestant form of baptism. According to the Catholic rite, the water of baptism is blessed but once a year (on Holy Saturday), and a drain would have been sure to "weep" in that time. It is thus only necessary in Catholic churches to bale out the fonts once a year. In the Protestant rite the priest blesses the water at each baptism, and if a drain were not pro-

ded, it would be necessary to bale out the water at every christening. The absence of a drain thus proves this font, thrown out of the church into the midden (in which, three hundred years after, it was found) upon the dissolution of the priory by Henry VIII., and the desecration and ruin of the church which it once adorned, never to have served for the Protestant rite. There further remain clear traces of the hinge and staple of a wooden cover for securely locking up the font, as is required by the Catholic rubrics to this day. Of the building

from which this font has been removed, i.e., the Priory church of St. Andrew, considerable remains, as I believe, exist in the farm buildings lately in the occupation of Mr. J. Perkins, and now the property of the Hospital of St. Andrew. These appear to me of very early character, probably like the neighbouring churches of Earl's Barton and Brisworth, of pre-Conquest date. The nave, aisle, and transept can be clearly traced, and only the choir or sanctuary, and part of the north-wall of the nave, have entirely disappeared. An hour's digging would recover at least the general plan of its eastern termination. GEO. GILBERT SCOTT, F.S.A.

The Student's Column.

WARMING BUILDINGS BY HOT WATER. XXII.

COILS AND RADIATORS.

THE distinction between a Coil and a Radiator is not at all clearly defined, unless we rely upon the fact that the former usually has its pipes fixed horizontally and the latter vertically. At the same time, if we fixed a coil on one of its ends, as is done sometimes, it would scarcely constitute it a radiator. For the information of those who have not used these latter articles, it may be explained that they are, to all intents and purposes, coils, but with pipes of an ornamental character, always having the pipes fixed vertically; and, by ordinary decoration, they can be made of sufficiently good appearance to need no casing. They are also cast of such a section as to hold but little water, so that results are more rapidly obtained, but, of course, they just as rapidly cool as the fire goes down.

Radiators are practically the outcome of experiences gained with the ordinary horizontal pipe-coils. In the first place, these latter appliances are at the best of times ugly; this necessitates their being surrounded by a case, solely with the idea of hiding them, unless in an unimportant position. The case, however inexpensive, generally costs more than the coil; sometimes, when well-finished, four or five times as much. Then the case goes a good way towards neutralising the effects of the coil, as it will be understood that more heat is obtained from exposed pipes than those encased in any way. The coil case also introduces another bad feature by usually making it an impossible matter to dust and keep the pipes clean, and the horizontal pipes lend themselves to the collecting of dust more readily than vertical ones. The difference in heat diffusion between a clean pipe and one coated with dust is sufficient to surprise some people, but if it be remembered that dust is wholly composed of poor heat-conducting materials, as fibre, wool, cotton, grit (silice), &c., no wonder need be felt. Dust is almost as effective as silicate cotton in preventing the dispersion of heat.

The fact that horizontal pipes collect dust and vertical ones do not, has led to the general adoption of the latter arrangement with the tubes of radiators. Horizontal coils, in cases as just mentioned, are great sufferers in this respect, and so are pipes in channels, &c., and even exposed coils and pipes are sometimes allowed to get covered with dust, and the results are lessened accordingly.

With nearly all the present radiators the necessity of a case is supposed to be obviated by their being cast of a design equal in appearance to a casing itself, and if additional

finish is needed, they can be fitted with marble tops. Nearly all the makers' lists show them also made in pedestal or columnar form as well as flat, and other shapes to meet different requirements. As regards appearance, they can always be picked out in two or more colours if desired, and it has been already explained that the ordinary decorative paints and colours have no prejudicial effect upon heat diffusion. Bronze powders and gold leaf are not however to be recommended, except to a very limited extent.

The last point in particular to be mentioned respecting radiators is that they hold but little water. By this is meant that a certain superficial area of radiating surface has less water in it than the same area of a round pipe. It can be seen that the less water an apparatus contains the quicker it will become heated up, and it is quite possible to get the same area of radiating or heat-giving surface (capable of furnishing the required temperature) by radiators with one-half or almost one-third the water that would be held if the radiating media

FIG. 90.

consisted of the ordinary 4-in. pipes. It is, however, necessary to again mention that, although the small amount of water is heated the quickest, it is also the quickest to become cool as the fire goes down. The small amount of water also shows any irregular stoking, as the degree of heat radiated is rendered irregular also; when the body of water is large, these effects are not noticeable, the water acts as a reservoir or medium for the storage of heat.

With glasshouse works the 4-in. pipe is decidedly the best; the results are rendered as equal as it is possible to get them. The same applies to any of those places where heat is required night and day regularly. When, however, quick results for just a matter of a few hours are needed, smaller pipes are used, as, for example, a 2-in. pipe, although so much less superficial surface of a 4-in. pipe, does not hold more than about a fourth of the water, and the results are quicker in proportion. Where quick results, and also good appearance, are needed, nothing can excel some of the forms of radiators.

The common form of coil is as fig. 90, being a pair of cast ends, with pipes inserted as

FIG. 91.

shown. The joints between the pipes and box ends are either made with yarn and lead, or more commonly, perhaps, with borings (the rust joint). A good coil can be made up by using one of the different forms of patented joints, in which an india-rubber collar is the jointing material. These joints are not expensive, and the saving of time is considerable. They also have a good appearance, and are expansive (this will be referred to again). Space will not permit of giving details of all the different forms of radiators introduced; reference to the advertisement columns of this and other papers will furnish all the details required in this respect; but to illustrate the difference between the ordinary box-end coil just shown and the more modern appliances referred to, fig. 91 will make it plain what an improvement has been made.

There are several radiators made and arranged so that fresh air can be introduced and caused to pass over the heated surfaces and so be warmed. These are generally termed venti-

lating radiators, but they have no particularly active effect in causing ventilation. If outlet or exhaust ventilation exists (either by ventilating flues or the ordinary fire-place opening), then the inflowing fresh air will enter by way of these openings, and it will be warmed by contact with the hot surfaces.

There is one point in connection with these ventilating radiators that needs discussion, which is their effect upon the moistness of the air. This subject was dealt with somewhat fully when speaking of the necessary saturation of the atmosphere in glass houses, but it may be mentioned here that, when provision is made to increase the temperature of inflowing air we

FIG. 92.

ought, at the same time, to provide for the increase of moisture that it needs and should have, in ratio with the heat it attains. This is provided for by some makers, who make the top castings of a trough-shape to hold water, with an ornamental cover over. The temperature air attains by contact with these pipes, however, is not so great as to demand this provision of moisture in every case; the engineer must use his judgment in this respect. In hot-air works, where air is heated by contact with stoves and flue-pipes, the moisture question is very important.

Amongst hot-water fitters there exists a considerable difference of opinion as to how coils,

FIG. 93.

&c., should be connected; that is, at what point in the coil the pipes should be inserted. Many seek to get one pipe at the top and one at the bottom, as fig. 92, but there is no occasion for this, if both pipes are connected at the bottom, the coil will heat just as effective. It must not be supposed that because both pipes are at a low point the hot water will pass in and then out without the top portion of the coil getting hot. The coil will heat just as well as one pipe at the top and one at the bottom, which is supposed to possess the advantage of causing the water to circulate right through, as it certainly does. There is one advantage this latter method has, in the fact that if the top

FIG. 94.

pipe is carried from the extreme top, probably no air-cock will be needed.

If a single coil or radiator is on a branch flow and return, the connexion may be made as fig. 93. If it should be one of a series on a branch service, then fig. 94 is a good method. This latter way gives all the radiators, from the first to the last, a chance of getting hot without much interval in their times of heating. If we had, say, four radiators, and caused the water to circulate through the first one before it had any opportunity of getting to the second, and through the second before affecting the third, we should cause very irregular results indeed. Seeing what advantage radiators have under

certain conditions, it is to be expected that a hot-water pipe with full area of surface, but holding less water, will be introduced for those works needing rapid results. It would be a very simple matter and certainly useful in many cases where pipes have necessarily to be used, yet where heat is required at the shortest notice. It could be made of a section that would the least readily collect dust.

GENERAL BUILDING NEWS.

DUNBLANE CATHEDRAL.—During the past three years this cathedral has been undergoing a complete restoration, and will be re-opened,—it is hoped by the Queen,—in September next. The nave, as our readers are aware, has been roofless for about 250 years past, and the choir, with the chancel arch built up as a gable, has been used as the parish church till the present restoration was commenced. The choir was considerably restored about twenty years ago, but not sufficiently to prevent continuous decay which threatened the structure. There are still many unfinished details which must remain until sufficient funds are subscribed to complete the work. A new organ, worthy of the proportions of the restored cathedral, and enclosed in a fine oak case, is being built by Mr. Eustace Ingram, of London, and will be erected in a chamber on the north wall of the choir, over one of the side chapels. The whole cost of the work, exclusive of the organ, will be about 20,000. The architect is Dr. Robertson, of Edinburgh.

VOLUNTEER DRILL HALLS, EXETER.—On the 23rd inst. the Duke of Cambridge opened the new drill halls which have been built for two of the branches of the Volunteer forces in Exeter. One of the buildings has been erected for the accommodation of the First Rifle Volunteers. It occupies the site of the old theatre in Bedford-circus and a portion of the city wall. The hall is 100 ft. long and 50 ft. wide, with a gallery at one end capable of accommodating 200 persons. In the basement under the hall there is a shooting-gallery 90 ft. long, a large armoury, and large store-room. On the west side of the building is an entrance hall and staircase, with an orderly-room on the ground floor 27 ft. by 18 ft., and over the orderly-room off the landing of the stairs an officers' room and a sergeants' room. A clerk's office and an adjutant's office adjoin the orderly-room. On the extreme west side is a dwelling-house. The roof of the hall is of slate, with a large central skylight. The other roofs are of red tile. The other building is situated in Friar's walk, Holloway-street. The architect was Mr. S. Wilkinson, and the builders were Messrs. Tree & Boley, of Exeter.

NEW WESLEYAN CHURCH, LICHFIELD.—On the 20th ult. the Rev. Dr. Stephenson (President of the Wesleyan Conference) opened a new church which has been erected in Tamworth-street, Lichfield. The building has been constructed by Mr. Williams, of Tamworth, from the designs of Mr. Thomas Guest, architect, Birmingham. The new building will accommodate upwards of 300 people, and is to cost about 2,000. It consists of nave, aisles, and chancel, two vestries, and an organ chamber. Stained glass has been introduced into the chancel windows.

EXTENSION OF PREMISES, BRISTOL.—Extensive additions are now in course of erection for Messrs. J. S. Fry & Sons, cocoa and chocolate makers. The new building has three frontages, that to Union-street being 55 ft.; Nelson-street, 125 ft.; and Little St. James' Back, 68 ft. A portion of the ground and first floors will be used as offices, the remainder of the building as a factory. In addition to a well-lit cellar, lined with white glazed brick, there are five floors, constructed with cast-iron girders and columns. The fronts up to the second floor are built with granite from the West of England Granite Quarries, Penryn; the remaining portion being built of Cattybrook buff bricks, with red Mansfield frieze, strings, &c. The whole is being carried out from the designs and under the superintendence of Mr. Richard Milverton Drake, architect, of Bristol.

BOARD SCHOOLS, KINGSWOOD, BRISTOL.—On the 20th inst. the new board schools at Kingwood were opened by Mr. Campbell-Bannerman, M.P. They are designed to accommodate 834 children, and have been erected at a cost of 8,000. The building is a semi-Gothic gabled structure, occupying a frontage at Warmley-hill of 150 ft., or a total frontage to the main road of 175 ft. The inner construction of the schools is on the class-room system, each standard having a separate class-room allotted to it. They are divided into three divisions, for boys, girls, and infants, and around the exterior of the building play-yards are provided. The work has been carried out by Mr. J. Perrott, of Bristol, from designs by Mr. W. T. Bernard, also of Bristol.

NEW CHURCH, EDINBURGH.—On the 18th inst. the foundation-stone was laid of St. Cuthbert's new Parish Church, Edinburgh. The site, at the west end of Princes-street-gardens, and near the junction of Glasgow Herald, with Lothian-road, has, says the *Glasgow Herald*, been occupied for centuries by a succession of church buildings. The fabric which has recently been dismantled was erected about the middle of last century, and was mainly a parallelo-

gram, measuring externally 98 ft. by 71 ft., while the new fabric has an internal length of 101 ft. and a width of 63 ft. Transverse projections are formed on the north and south sides, and choir accommodation is afforded in the apse, 38 ft. deep and 33 ft. wide, forming an extension of the nave. The only part of the former church allowed to remain is the tower, the lower part of which will form a porch entrance from the west end, and leading from it will be a vestibule of about 66 ft. long by about 17 ft. wide. From this vestibule egress doors are also provided, and two staircases lead to the gallery above. In addition, there are two staircases at the east end leading to the galleries in the transepts, and doors of egress are also provided there and on the ground floor of the transept. The eastern staircases are enclosed within tower projections, which are designed to be carried up above the roof to a height of 100 ft. in the form of campaniles. Externally the structure is designed in a phase of the Renaissance. The side facades are divided into a series of bays with square-headed and corniced windows on the ground-floor, the gallery level being defined by a cornice and string-course treatment, upon which rest the windows for the main lighting of the church. These windows are circular-headed, with archivolts moulding springing from pannelled pilaster impost. The transept projections are treated in a similar way, but with the windows grouped, and the upper part terminated in pediment form. The junction of the roof with the wall-head is treated with ornamental cornice and parapet. At the east end, the apsidal treatment of the end of the church forms a feature, the main horizontal lines being continued from the main building. Its upper stage is divided by pilastered treatment in low relief, marking it with a series of bays, in each of which a moulded and corniced window supplies the lighting of the interior. The upper part of the apse is treated with pannelled parapet-decorated cornice, and in semi-dome form the roof returns to the main gable line of the church, which is elevated in pediment form to receive it. The roof will be covered with lead, ribbed and pannelled. The accommodation in the new church will be nearly equal to that in the church demolished, namely, about 2,000. The cost is estimated at between 18,000 and 19,000. The mason work is at present being carried out by Mr. White, builder, and the carpenters are Messrs. Beattie & Sons, Mr. Hippolyte Blanc, of Edinburgh, is the architect.

CONGREGATIONAL CHURCH, LAUGHARNE, CARMARTHENSHIRE.—On the 17th inst. the new Congregational Church at Laugharne was opened. The building is erected in the main street. The architects were Messrs. George Morgan & Son, Carmarthen, and the builder was Mr. James Reese, of St. Clears.

PUBLIC OFFICES, SLAITHWAITE, YORKSHIRE.—On the 19th inst. Mr. W. Varley laid the cornerstone of new offices intended for the use of the Slaithwaite Local Board. The buildings will form a block at the corner of Lewisham-road and Station-road, and are being erected from plans prepared by Mr. J. B. Eagland, architect, Slaithwaite.

NEW CHURCH, SMETHWICK.—On the 24th inst. the Lord Bishop of Lichfield consecrated the new Church of St. Michael's Mission at Smethwick. The church is situated in Crockett's-lane, adjoining the Central Board Schools. It is in the Early English style. The interior is formed of nave and aisles, with baptistry and double porches at the west end, chancel raised some 4 ft., morning chapel, north transept, and organ chamber. Underneath the chancel is a parish-room, 47 ft. by 35 ft., and also a vestry on the same level. The church will accommodate 650, and the cost, including 500 for the site, has been 5,000. Mr. H. Wilcock was the builder, the architect being Mr. A. E. Street.

PARISH CHURCH, MORETON-IN-THE-MARSH.—The Bishop of Gloucester and Bristol has just re-opened this parish church after considerable improvement and enlargement, from the plans of Mr. E. H. Lingner Barker, of Hereford. Three galleries have been pulled down, the chancel has been extended 10 ft. eastwards, the south aisle 7 ft. southwards, and a chancel aisle added on the south side.

TECHNICAL AND FISHERY SCHOOL NEAR DUBLIN.—A technical and fishery school is about to be erected at Kingend, near Dublin. The Earl of Pembroke has generously placed a sum of 4,000. at the disposal of the Pembroke Township Commissioners to carry out the necessary works. The plans of Mr. W. Kaye-Parry, M.A., architect, of Dublin, have been selected in open competition for the proposed buildings, which will be commenced forthwith.

THE DECORATION OF THE LEEDS TOWN-HALL.—The Corporate Property Committee of the Leeds Corporation met yesterday, and considered a number of tenders sent in for the decoration of the Leeds Town-hall. A list of eight tenders was reduced to two,—namely, those of Messrs. Dobie & Sons, Edinburgh, and Mr. J. Beckhinder, London. These were with reference to the Victoria and Vestibule only. The Committee appointed a deputation to visit various buildings in other towns which had been decorated by these firms, and to report. —*Leeds Mercury* (May 25).

SANITARY AND ENGINEERING NEWS.

SEWERAGE WORKS, KING'S NORTON.—On Friday, May 20, Mr. Bienni Walton, M. Inst. C. E., one of the Engineering Inspectors of the Local Government Board, held an inquiry at King's Heath as to an application by the King's Norton Rural Sanitary Authority to borrow 10,500. for works of sewerage and sewage disposal for the village of King's Norton and the surrounding district. The scheme, which was prepared by Mr. Robert W. Coffey, A.M. Inst. C. E., the Engineer and Surveyor to the Authority, was fully set forth and explained by him to the Inspector, after which he was subjected to severe cross-examination by Mr. Hugo Young, barrister, on behalf of several landowners and by Mr. J. S. Pritchett, barrister, on behalf of Messrs. Baldwin, the owners of Sierborne Mills. The scheme, which provides for deposition, filtration, and irrigation, was supported very fully by the evidence of Mr. E. Pritchard, M. Inst. C. E., and much of the opposition to it was based on the fear that it was the intention of the Authority to establish a "destructor" on part of the site. After a protracted inquiry, the inspector was driven round the district to be dealt with, and to the land proposed to be utilised as a sewage farm. The Inspector will make his report to the Local Government Board in due course.

FOREIGN AND COLONIAL.

FRANCE.—On Sunday the "Bourse du Travail" was opened. It has been built by M. Bouvard, and is situated in the Place de la République, at the corner of the Rue du Château d'Eau and Rue de Bondy. The statue of Manuel Rey, which was erected on the very spot in the Avenue de l'Observatoire where the hero of Moskova was shot, is shortly to be taken down to make room for the extension of the line from Paris to Soeaux. The statue will be re-erected further on, in the Boulevard St. Michel. The prizes for the open competition for the statue of Claude Chappe, inventor of the aerial telegraph, have been awarded. The first prize has been awarded to M. L. B. (sculptor) and Farcy (architect), and they are to execute the work. The second prize has been given to M. Boisseau, and the third to M. Pezieux. This monument is to be erected on the Boulevard St. Germain, near the Ministère de la Guerre. The Archaeological Society of Auteuil and Paris are going to erect busts and commemorative bas-reliefs which are to be placed on houses which have been inhabited by celebrities, such as Franklin, Voltaire, Hugo, Boileau, Molière, Racine, &c. On the other hand, we hear that the house occupied by Lamartine, near the Trocadéro station, is likely to be demolished. The museum of Caracassone has just been enriched by a magnificent portrait of the poet Joseph Chénier, and also several relics belonging to André Chénier, who was executed in 1793.

Madame la Duchesse d'Uzes, who is known in the artistic world under the name of "Manuela," has just given one of her works, a marble statue of the Virgin Mary, to the church of Poissy. This statuette was inaugurated on May 19. It is announced that the beautiful Château de Montrabech, near Lezignan (Aude) has been destroyed by fire, a great number of precious documents have been lost; a few works of art and some Gobelin's tapestry was all that was rescued. The artistic exhibition of Tours, which opened on May 15, is to close on August 31. The art at Troyes, opened at the same time, is to close on June 30. A National School of Agriculture is to be opened at Rennes. The sculptor Rodin has been commissioned to erect the monument at Nancy to the memory of the painter Claude Gellée, called "Lorraine." It is to be unveiled on June 20.

The Municipal Council of Rouen are erecting a statue of Gambetta in the place which bears the name of the famous orator. A discovery has been lately made at Rouen in the courtyard of the famous Hôtel de Bourgtheroulde in demolishing a little construction which served as a porter's lodge, the sill of a window was brought to light, covered with sculptures, interesting both from an artistic and historical point of view. This decoration consists of an acutcheon, with banded and garlands of flowers supported by children, all in high relief. The demolition of the little hatterments has also revealed the existence of a gallery of half-timber work of the style of the sixteenth century, leaning on a low arcade, like those which are to be seen on the old houses in Rouen. At Châlons-sur-Marne, some rare medals have been discovered, one of which is the portrait of Posthumus, Emperor of the Gauls, who was assassinated in 267. The artist who worked at Havre has just lost one of its best painters, M. Lanfant, at the age of seventy-eight years.

BERLIN.—In a hall adjoining the premises occupied by the annual salon, there is an exhibition of the models sent in by sculptors for the competitions which has been opened for the purpose of obtaining a suitable design for the Frederick Memorial Monument on the battle field at Wörlitz. An enterprise has been started the object of which is to support in the nearest possible form, the majority of all designs sent in for the numerous architectural competitions held annually in Germany. Each number of the publication appears as soon as

ossible after a competition has been decided. Until now the only publications of competition drawings were the small woodcuts in our contemporaries or the very expensive lithographic folios of an architectural publisher.

HAMBURG.—In connexion with the fiftieth anniversary of the rebuilding of Hamburg after the great fire of 1842, a description of the conflagration and work of reconstruction has been written by Herr Faulwasser, an architect. The total loss occasioned by the fire was at the time estimated at 35,000,000 marks; the payment to firemen, and that for the overcrowding of the city and its waterways, about 600,000 marks. Although the fire retarded Hamburg's development for several years, it certainly was of a great benefit to the town, and caused it to have its present stately appearance and good hill of health.

MISCELLANEOUS.

SANITARY LEGISLATION A CAUSE OF OVERCROWDING IN CITIES.—Dr. G. V. Poore, in the concluding portion of his paper on "The Concentration of Population in Cities" (appearing in the *Lancet* of May 21) says: "It needs to be pointed out that the overcrowding of cities, which is admittedly the greatest of all sanitary evils, is the direct result of sanitary legislation. When, some forty years since, it was recognised that water-carried sewage inevitably poisoned the wells, no attempt was made to protect the wells from pollution; but the surface wells were compulsorily closed, the inhabitants were sold in bondage to the water supply companies, and the houses were compelled to pollute our rivers. These measures have given a fatal facility for overcrowding, and wherever a line of sewers is taken the speculative builder follows; or, not being hampered by questions of water-supply or filth disposal (the sanitary authorities relieving him of all responsibilities in this matter), he is able to erect buildings without any curtilage, and with any height, almost, that he chooses. He is assured that this state of things is not limited to London or the big towns. The notion that houses are as well without curtilage as with it has infected the country, as anybody may see for himself when travelling by railway. . . . We have engendered a stingy habit of mind towards the question of space round houses, which almost amounts to national insanity."

INFECTED BY TELEPHONE.—"The possibility of infection by the use of the telephone mouthpiece by successive speakers has been hypothetically discussed before now. A Dundee correspondent brings forward some facts in support of the possibility of such an occurrence. Dr. Anderson, the Medical Officer of Health for Dundee, who has had the matter submitted to him, has given a very sensible answer, which sums up the position in a practical manner: "If a person who is suffering from sore throat of an infectious nature brings his mouth into close, or even near, relation to the mouthpiece of a telephone instrument, I think, in the act of speaking and expiration of air from the lungs and throat, it is possible that infectious particles might adhere to the instrument. I think that an instrument which is so much exposed to the human breath should be frequently cleansed, whether the instrument be in a public or private room, and perhaps the simplest and most convenient cleanser is warm water and carbolic or antiseptic soap."—*British Medical Journal*.

PICTURES OF 1892.—The *Pall Mall Gazette* issues two books of reproductions from pictures of the year, one with prints in various tones of colour, the other in black. The latter, which seems to have been only a secondary issue when the first was out, print, is in some respects the best, as the tints used in the other edition are not all well chosen; some of the landscapes being printed in treated tints very much at variance with our associations with the tones of natural scenery.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.—It is announced that the next annual general meeting will be held at Edinburgh, commencing on Wednesday, August 3. The President-elect is Sir Archibald Geikie, LL.D., D.Sc., F.R.S., F.R.S.E., F.G.S., Director-General of the Geological Survey of the United Kingdom, corresponding Member of the Institute of France.

PATENT FOR LITHEONITE FLOORS.—The Burgess Ward of the London Temperance Hospital, Hampstead-road, which was opened by the Duchess of Westminister on the 11th inst., has been laid with Bassants' patent 3/4-in. parquet flooring 1,700 ft. of which were required. Mr. Bassant is likewise just received a contract for 7,000 ft. of a patent 3/4-in. teak parquet flooring for three wards and nurses' rooms at the East London Hospital.

RECONSTRUCTION OF BONAR BRIDGE VIADUCT, NETHERLANDS.—On the 20th inst. a special meeting to discuss the rebuilding of the fallen viaduct at Bonar Bridge was held at Arday, Ross-shire, by a joint committee of the Ross and Sutherland County Councils. Mr. Charles P. Hogg (of Messrs. Hogg & Hogg, civil engineers, Glasgow), submitted plans prepared by that firm, which were adopted. The new bridge will be composed of bearing steel girded for three spans of 140 ft., 105 ft., and 70 ft. respectively, resting on masonry work at

either end, and supported by stone piers in channel. There will thus be a clear waterway of 315 ft. instead of 260 ft., as formerly. The roadway will be 25 ft. wide, and will have a hardly perceptible gradient, but the approach from the Ross-shire side will have a gradient of 1 in 30.

THE CONVERSION OF GAUGE ON THE GREAT WESTERN RAILWAY.—In connexion with this notable operation, which was accomplished at the end of last week, the *Engineer* of the 20th inst. gives some interesting particulars of the first broad-gauge train used by the public, which ran on July 4, 1892. Our contemporary also gives illustrations and descriptions of two of the early broad-gauge engines.

THE SANITARY INSTITUTE.—We hear that Sir Charles A. Cameron, F.R.C.S.I., D.P.H., Medical Officer of Health, Dublin, has accepted the Presidency of the Congress of this Institute to be held at Portsmouth in September next.

DRAIN-PIPE TEST AT NOTTINGHAM.—In our report of the proceedings of the meeting of the Incorporated Association of Municipal and County Engineers at Nottingham, it should have been stated that the stoneware drain-pipes used in the new subways in that town (and of which we recorded a test on p. 381, ante) were manufactured by Messrs. John Knowles & Co. We were not informed of this at the time, or we should have mentioned it.

A NEW AUTOMATIC SELF-FLUSHING CLOSET.—Messrs. John Knowles & Co., of King's road, St. Pancras, are now showing what they claim to be "the first and only double-action self-flushing water-closet." It is named the "Presto," and is a closet of the "wash-out" type, although the automatic arrangement can be applied to hopper or any other flush-out closets. By a simple method of gearing, the seat is slightly depressed, and the water in the pan rises from the seat the closet is flushed. This is the first action. The second action is brought into play when the closet is used as a slop-sink or urinal. The seat is of course turned up for either of these purposes, inducing a preliminary flush, and the full flush is obtained by returning the seat to its normal position. The mechanism is exceedingly simple, and appears likely to get out of order, the flushing-cistern being discharged by means of a rod or chain connecting it with the seat-action.

CHISWICK LAND AND KENTISH TOWN FREEHOLDS.—Mr. Walter Hall, of Chancery-lane, offered to a crowded auction room on Wednesday last, at the Mart, City, about nine acres of freehold building land (together with a mansion thereon), having a long frontage to the "Duke's avenue." The bids started at 10,000, and, by degrees, reached the sum of 13,500, at which they stood for some time, when the auctioneer stated that he exercised his discretion of buying in the property, as he could do better by private negotiation. The shop property at Kentish Town, with frontages to the main Highgate and Forest roads, was eagerly competed for, and eight of the ten lots offered were sold, realising a total of 4,210.

MEMORIAL WINDOW, MANCHESTER CATHEDRAL.—A new stained-glass window, in memory of three members of an old Manchester family,—the Craigs, of Ancoats and Soedley,—has, says the *Manchester Courier*, just been erected in the library of Manchester Cathedral. The window is of four lights, and illustrates the text, "They found Him in the Temple, sitting in the midst of the doctors, both hearing and asking them questions." The work has been done by Messrs. Heaton, Butler, & Bayne, of London.

ARTISANS' DWELLINGS AT ESSEN.—In the course of some proceedings relating to the welfare of German artisans, some interesting information was given by Herr Krupp's representative. Herr Krupp had in 1891 rented dwellings situated in closest proximity to his works to no less than 3,659 of his workmen. The erection of these habitations cost him over 11,000,000 marks, and the ground about 1,200,000 marks. After deduction of all running expenses, such as repairs, &c., the money spent brought an income of about 2 1/2 per cent. Of some 600 dwellings erected in outlying districts the income was 2-5 per cent. Owing to the special facilities offered, some seventy of the men already owned their houses.

LEGAL.

ALLEGED BREACH OF CONTRACT:

RICHARDSON v. MATHEWS.

THIS was an action tried in the Lambeth County-court, and brought by Mr. J. O. Richardson, builder and contractor, Peckham, against Mr. Mathews (of the firm of Ashton, Green, Mathews, & Co.), slate merchant, St. Mary Axe, to recover the sum of £97, being the extra cost incurred by plaintiff in executing 145 squares of slating in consequence of an alleged breach of contract by the defendant. Mr. Robertson, barrister, appeared for the plaintiff, and Mr. T. Poulter, barrister (instructed by Messrs. Hunter & Downes), for the defendant.

Plaintiff's evidence was given at the sitting of the court on Tuesday, the 17th inst., when the case was adjourned until Tuesday last, when Mr. Mathews and other witnesses were heard for the defence.

The claim was for extra cost incurred by the plaintiff (beyond the price quoted by the defendant) in executing the slating in question, and for the hire of tarpaulins, &c., rendered necessary by the alleged breach of contract by the defendant.

For the defence, it was contended that there was no contract.

It appeared that the plaintiff wrote to the defendant asking for a quotation for 145 squares of Penrhyn slating, no time being named for the execution of the work. The defendant offered to do the work at 22s. 3d. per square. The plaintiff wrote to the defendant on a Friday accepting that price, and requiring the defendant to commence the work on the following Monday. The defendant was unable to comply with that request, and said that three days was not sufficient and reasonable notice for a work of such magnitude; that they had not a sufficiency of the particular-sized slates required for the work in stock; and that it would take ten days or a fortnight to get them from the quarries.

Evidence was called by the defendants to show that it was unreasonable and unusual to expect work of the magnitude in question to be done at such short notice. The witnesses examined were Mr. C. W. Jones (the defendant's manager), Mr. S. R. Parker (a member of the firm of Patman & Fotheringham, builders), Mr. Alexander (a builder carrying on business in Bow-road), Mr. C. J. Devereux (manager for Messrs. Jarvis, builders, Hackney-road), and a member of the firm of Roberts, Adlard, & Co., slate merchants. These witnesses all deposed that it was the custom for builders, when about to tender for a work, to ask for quotations for certain materials from the merchants who dealt in those materials. The builder who tendered was accepted usually wrote at once to the merchant whose quotation best suited him, saying that he had obtained the contract and would probably want the material in about three, four, or six months, as the case might be. Within a week or two of the time arriving for roofing-in, it was usual to give the merchant another reminder, so that he might be fully prepared. The two or three days elapsing between Friday and Monday was not adequate notice for a work of the extent in question. The mere giving of a quotation by a merchant did not constitute a contract. Quotations of that kind were given by merchants every day.

Counsel for the parties having addressed the Judge, he immediately found for the defendant, with costs. He held that the defendant had not, in giving his quotation to the plaintiff for the work, entered into any contract, and therefore he had not committed any breach of contract.

CAPITAL AND LABOUR.

BRICKMAKERS' STRIKE IN WEST LONDON.—The strike of brickmakers in the Shepherd's-bush and Acton districts, which has now been in progress, we understand, for about seven weeks, still continues. The men ask for an increase of 9d. per thousand in the price paid for moulding, which, if granted, would, the masters say, entail an increase in the price paid for other processes involved in manufacture. The London Conciliation Board have endeavoured to bring both parties to an agreement, but without success. Two meetings have taken place at the London Chamber of Commerce, Botolph House, Eastcheap, at which representatives of the masters and men have met. The number of stools idle is about sixty. Therefore there must be between five and six hundred men and boys concerned. The Kent and Essex and the Cowley Brick-masters' Association have expressed their sympathy with the masters, and have, we are informed, entered into an arrangement with the Shepherd's-bush and Acton masters to make for them all bricks they require, so that the probabilities are that unless the strike very soon collapses, no bricks will be made in the strike districts this season.

MEETINGS.

MONDAY, MAY 30.

Royal Institute of British Architects.—Four papers on "The Metal." (1) Mr. Alex. Graham, F.S.A. "On the Application of Metals to Architectural Design in all Countries." (2) Mr. C. Kral. "On the Precious Metals." (3) Mr. H. Loagden "On Castings in Iron and Brass." (4) Mr. Herbert Singer "On Castings in Bronze." 8 p.m.

Surveyors' Institution.—Annual General Meeting, to receive the Report of the Council, &c. 3 p.m.—Annual Dinner, Holborn Restaurant. 4.30 p.m.

TUESDAY, MAY 31.

Institution of Civil Engineers.—Annual General Meeting, to receive the Report of the Council and to elect the Council and Officers for the ensuing year. 8 p.m.

Society of Arts (Applied Art Section).—Mr. William De Morgan on "Lustre Ware." 8 p.m.

WEDNESDAY, JUNE 1.

Royal Archaeological Institute.—(1) Rev. Professor Venables to receive the Report of the Council and to elect the Council and Officers for the ensuing year. 8 p.m.

Society of Arts (Applied Art Section).—Mr. J. H. MacMichael on "The Grey-ware." 8 p.m.

LONDON (Continued).—For church fittings, &c., to Kirk Andrew's Church, Longdon, Cumberland. Mr. Temple L. Moore, architect. Quantities by Mr. John B. Lofting, 4, Great Queen-street, Westminster. £1,296 3 6 Elwell £1,163 7 6

BINGWOOD (Hants).—For residence at Bingwood, Hants, for Mr. J. Cogan Conway. Messrs. Lawson & Donkin, architects and surveyors, Bournemouth. £2,095 W. Hoare £1,650 Barrow & Entwisle 2,065 Hayward, Peaton, & Co., 1, 640

SHOTLEY BRIDGE.—For rebuilding a farmhouse at Medowley Grange Farm, for Mr. Jas. Hunter, Aston's Hill, N.R. Messrs. John Smith & Son, architects, Rose Cottage, Shotley Bridge. Wilbur & Gilson £275 16 0 Taylor & Robinson, J. F. Thompson & Co. 418 11 7 Melonies' £416 14 8

SOUTH FIELDS.—For alterations and additions to the business premises of Messrs J. & H. Carruthers, Ocean-road, South Shields. Mr. Henry Greaves, architect, Albany-chambers, South Shields.—Brown, Robt. £251 6 2 Goodwin & Son, South Robertson, W. J. £53 18 6 Shields' 413 16 0

SOEWERY BRIDGE.—Accepted for the erection of a floor cloth manufactory in two divisions, together with warehouse, engine and boiler-houses, and approach-roads, on the site of the Cuildr Cotton Mill Works. Mr. T. L. Pickett, architect, Halifax.—Messrs. and Builders.—Nathaniel Calpan & Son, King Cross, Halifax. £312 0 0 Carpenter and Joiner.—James Lister, Hebleton Bridge 680 0 0 Fletcher and Glaser.—James Madocks, Soewery Builders 120 0 0 Slaters 120 0 0 Slaters 120 0 0 £1,792 0 0 [Iron beams, trusses, &c., from Belgium.] [Foundation work already in, and stone, slates, and bricks provided by proprietor.]

TANFIELD (Durham).—Accepted for the erection of schools at Tanfield Lea, for the School Board. Messrs. Davidson & Beattie, architects, 31, Grouse-street, West, Newcastle-upon-Tyne.—A. E. Davis, Birmingham, Co. Durham £2,025 4 11

WALTHAMSTOWN.—For the erection and completion of additional classroom accommodation adjoining to the Protestant Avenue Schools, for the Walthamstow School Board. Mr. W. A. Longmore, architect, 7, Great Alie-street, Whitechapel.—Burrett & Power £281 18 6 E. Evans £430 Airey 434 Kelland, Stoke Newington' 428 Walling 429 [Architects' estimate, £140.] Accepted.

WOOLWICH.—For additions to the Woolwich Polytechnic. Mr. H. Church, architect, Woolwich.—Cheslin & Son £1,020 Young & Lonsdale £957 Mumby & Sons 1,015 Muir & Willis 949 H. Brown 688 Hildway 945 Chapman 995

The Builder Cathedral Series.

Table listing cathedral series with columns for name, date, and price. Includes entries for Canterbury, Lincoln, Exeter, Hereford, Worcester, and St. Paul's.

THE HEREDOS, ST. PAUL'S. Reprinted from "The Builder," January 28, 1888 (55in. by 11 1/2 in.) on stout paper, uncoloured, for binding, 6d.; by post, 8d.

PORTFOLIOS, for Preserving the Plates uncoloured, 2s. 6d.; by post, 3s. London: Office of "The Builder," 46, Catherine-street, W.C.

SUBSCRIBERS IN LONDON AND THE SUBURBS, by prepaying at the Publishing Office, 19s. per annum (or 4s. 9d. per quarter), can ensure receiving "The Builder," by Friday Morning's Post.

TERMS OF SUBSCRIPTION. "THE BUILDER" is supplied direct from the Office to resident in any part of the United Kingdom at the rate of 19s. per annum

PUBLISHER'S NOTICES.

Registered Telegraphic Address, "THE BUILDER," LONDON.

CHARGES FOR ADVERTISEMENTS.

SITUATIONS VACANT, PARTNERSHIPS, APPRENTICESHIPS TRADE, AND GENERAL ADVERTISEMENTS. Six lines (about fifty words) or under 4s. 6d.

SITUATIONS WANTED.

FOUR Lines (about thirty words) or under 2s. 6d.

Advertisements for the current week's issue must reach the Office by THREE o'clock p.m. on THURSDAY, but those intended for the front page should be in by TWELVE noon on WEDNESDAY.

SPECIAL.—ALTERATIONS IN STANDING ADVERTISEMENTS or ORDERS TO DISCONTINUE same must reach the Office before TEN o'clock on WEDNESDAY.

The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to Advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

Persons advertising in "The Builder" may have Replies addressed to the Office, 46, Catherine-street, Covent Garden, W.C. free of charge. Letters will be forwarded if addressed envelopes are sent, together with sufficient stamps to cover the postage.

AN RITON Printed on THIN PAPER, for FOREIGN and COLONIAL CIRCULATION, is issued every week.

READING CASES, NINEPENNE RACH. By Post (car-freight) postd. 1s.

HOWARD & SONS

25, 26, 27, BERNERS STREET, W., MANUFACTURERS AND CONTRACTORS

Deal Dadoes, from 1s. 3d. per ft. super. Oak Dadoes " 1s. 8d. Walnut Dadoes " 1s. 11d. Oak, 1 inch Parquet Floors, laid " and polished, from 27. 10s. a square.

Prices given for all Interior Work, Doors, Architraves, Over-doors, Chimney-pieces, Stoves, and Hearths.

BILLS OF QUANTITIES.

THE BATH STONE FIRMS, LTD.

FOR ALL THE PROVED KINDS OF BATH STONE. FLUATE, for Hardening and Preserving Calcareous Stones and Marbles.

DOULTING FREESTONE.

THE OHELNYOH STONE. The stone from these quarries is known as the "Washley Bed," and is of a very crystalline nature, and undoubtedly one of the most durable stones in England.

THE BRAMBLEDITCH STONE. Is of the same crystalline nature as the Oshelnyoh Stone, but finer in texture, and more suitable for fine architectural work.

Prices, and every information given, on application to CHARLES TRASK & SONS, Doulting, Shepton Mallet.

London Agent—Mr. E. A. WILLIAMS, 16, Craven-street, Strand, W.C. [Adv.]

HAM HILL STONE.

The attention of Architects is especially invited to the durability and beautiful colour of this material. Quarries well opened. Quick despatch guaranteed. Stonework delivered and fixed complete. Samples and estimates free. Address, The Ham Hill Stone Co., Norton, Stoke under-Ham, Somerset. London Agent: Mr. E. A. Williams, 16, Craven-st., Strand, W.C. [Adv.]

CRAIGLEITH STONE.

UNEQUALLED for Staircases, Steps, and Landings, especially for Public Buildings with great wear. VERY HARD, and NEVER WEARS SLIPPERY.

SOLE AGENTS for England, J. & A. CREW, Cumberland Market, London, N.W.

Asphalte.—The Sycocel and Metallic Lava Asphalte Company (Mr. H. Glenn), Office, 42, Poultry, E.C.—The best and cheapest materials for damp courses, railway arches, warehouse floors, flat roofs, stable, cow-sheds, and milk-rooms, granaries, tin-rooms, and terraces. Asphalte Contractors to the Forth Bridge Co. [Adv.]

SPRAGUE & CO., LITHOGRAPHERS AND PRINTERS.

Estate Plane and Particulars of Sale promptly executed.

4 & 5, East Harding St. Fetter-lane, E.C. [Adv.]

QUANTITIES, &c., LITHOGRAPHED accurately and with despatch.

METCHIM & SON, 20, Parliament-st., S.W. "QUANTITY SURVEYORS' TABLES AND DIARY." Revised and Enlarged for 1892 now ready, price 6d. post free 1d. [Adv.]

THE PORTLAND STONE QUARRYING AND WORKING COMPANY.

Stone of the Best Quality may be obtained in Blocks, — OR ESTIMATES FOR — EVERY DESCRIPTION of WORKED PORTLAND STONE DELIVERED or FIXED UPON APPLICATION AT THE COMPANY'S OFFICES, 54, OLD BROAD STREET, LONDON, E.C.

Inland Navigation in Russian Europe.

RUSSIA in Europe is happily provided by Nature with numerous broad, deep, and long rivers, navigable to a greater distance than is found practicable in any other European country, which, with their tributaries, have a collective length of 53,000 statute miles. These rivers act as the conduits of four great rain catchment basins flowing respectively into the Baltic Sea, the Arctic Ocean, the Caspian Sea, and the Black Sea. Art, with comparatively little effort, has contrived by the construction of a few short canals connecting the different navigable river systems here, and there, and at one point or another canalising for a short distance some of these natural avenues, to provide for placing in direct inter-communication the whole of the mileage of this magnificent system of inland waterways. This system of inland navigation is placed under the control of the Ministry of the Ways of Communication. Of the official computation of 53,000 miles, there is, however, so far,—up to the beginning of 1890,—only 42,935 miles of inland navigation actually included under the jurisdiction of this body. The active function of the Ministry of the Ways of Communication is discharged by a department known as the Superintendence Bureau of Navigation. Of the 42,935 miles of inland navigation administered by the Bureau, 9,758 miles are stated officially as being only capable of navigation by rafts, 20,268 miles as being navigable by boats, leaving 12,559 miles of waterways without any definite specification. The canalised portion of natural rivers is given as being 2,392 miles, the collective length of the purely artificial canals being 1,336 miles, this making the trifling proportion in relation to the whole mileage of 3,728 miles of artificial and semi-artificial waterways.

By far the most important of the Russian arterial waterways are certainly those which form links in the several through chains of navigation which connect the Baltic Sea at St. Petersburg with the Caspian Sea at

Astrakhan. Of these there are three, in each of which that majestic waterway, the Volga, or, as the Muscovites style that river, "The Ocean's Nurse," is the principal factor. Rising in the Valdai hills, some 200 miles east by south of St. Petersburg, at 550 ft. above the sea level, it traverses the provinces of Tver, Jaroslavl, Kostroma, Nijni-Novgorod, Kazan, Simbirsk, Samara, Saratoff, and Astrakhan, where it enters the Caspian Sea, which, being 113 ft. below the sea level, makes the total fall of the Volga, from its source to its *débochure*, 663 ft., which, distributed over a sinuous course of over 2,000 miles (of which 1,794 are navigable), averages the mild gradient of less than 4 in. per mile.

The Volga, with its tributaries, the chief of which are the Oka and the Kama, forms the main avenue for the chief industrial region of Russia, comprising twenty-one provinces, inhabited by 40,000,000 people, out of a total population of Russia in Europe of 90,000,000. The navigation of the Volga and its chief tributaries, according to the varying degree of latitude, is open for a period of from 199 to 220 days, the navigation usually being closed about the middle of Novsmer. During this period of open navigation some 55,000 voyages are made by barges, rafts, and steamers, the aggregate tonnage ascending and descending being 5,000,000. The upward freights consist mainly of grain, timber, mineral oils, and Eastern produce, the downward cargoes being chiefly metals, minerals, textiles, and other manufactured products. M. Nicolas de Sytenko, Engineer to the Russian Government, and a member of the Aulic Council, in a memorandum published in 1890, while admitting that there are no official statistics available, computes that, as an inside estimate, the volume of traffic on the Volga during the open season amounts to 2,900,000,000 ton-miles. Besides several thousands of craft of various dimensions plying on the Volga, there is a fleet approaching 900 steamers, partly engaged in the towing of barges and partly in the conveyance of cargoes. In connexion with the traffic of the Volga and its tributaries there are some 5,000 large barges built yearly, many ranging from 300 to 500 tons, and a considerable number with a

remarkable capacity, vising with ocean steamers,—5,000 to 6,000 tons. Very few of these survive more than one voyage, when they are broken up for firewood. Although, as the crow flies, the Baltic Sea and the Caspian Sea are only separated by an interval of 1,250 miles, the inland navigation from Astrakhan to St. Petersburg is twice that figure; the route by the Marie Canal system, the one most in vogue, being 2,507 miles in length. We in this country, who send 8,000,000 tons of coal yearly to London by rail from the Midlands at forty miles per hour, are apt to smile at the speed with which the phlegmatic Russ is content on the Volga navigation. This slow rate of progression largely explains the reason why most of the vessels are broken up after a single voyage. After making due allowance for passing through locks, rapids, and other hindrances, the average voyage for sixteen hours per diem is twenty-four miles,—say, including the stoppages, one mile and a half hourly. This slow speed along 2,507 miles of navigation,—say twenty-four miles during each twenty-four hours,—averaging 105 days, coupled with a doubtful chance of obtaining a return cargo, has led to the general destroyal of these craft after a single journey.

What is known as the Marie Canal system is in effect a continuation of the navigation of the Volga from Rybinsk, which place is an extensive emporium for the commerce of the western provinces of European Russia, and finds, during the open navigation season, employment for 100,000 men and 5,000 craft. From the Caspian, the line of navigation by the Volga to Rybinsk is 1,794 miles. The distance from Rybinsk to St. Petersburg by the Marie Canal system is 713 miles. The principal traffic on the Marie Canal system consists of grain for St. Petersburg, and, notwithstanding the construction of railways connecting the fertile basin of the Volga with the Baltic ports during the last thirty years, the volume of traffic conveyed upon this navigation system has been doubled during that period. Fully recognising the growing expansion of traffic between the Volga grain districts and the Baltic Sea, the Ministry of Ways of Communication have decided to improve the Marie Canal system. The present locks of the Marie

system for vessels 139 ft. 2 in. long, 28 ft. beam, with 4 ft. 8 in. draught are being superseded by locks of superior dimensions, namely, 227 ft. 6 in. in length, 34 ft. 2 in. beam, with 5 ft. 10 in. draught. The facilities thus being provided will enable vessels carrying 655 tons of grain to proceed right through to St. Petersburg without breaking bulk at Rybinsk, and thus save the cost of transhipment.

The second route, connecting Astrakhan with St. Petersburg, proceeds from the Volga a little above Rybinsk, whence it utilises its affluent, the River Mologa, thence by the River Tschagodolska, the Lake Volksjoe, the River and Lake Sominko, and the canalised River Voltzine—where the summit level is attained at an elevation of 570 above Lake Ladoga. Thence falling to the Ladoga Canal and proceeding by Lake Kronpino, it enters the Marie Canal system, after a course of 466 miles from the Volga. This route is far inferior to the Marie Canal system, which it falls into, though shorter, as it but affords passage for boats 63 ft. in length, 14 ft. beam, and the light draught of 2 ft. The last route to be mentioned as being a through chain of inland navigation between the Caspian and the Baltic Seas, though not the least in importance, and the first in a historic sense, was initiated through the enterprise of Peter the Great in 1698, after his famous tour of discovery throughout Europe in search of knowledge likely to be of advantage in the betterment of his own country. That monarch was induced by two considerations to connect by a series of short canals the navigable lakes and rivers intervening between Astrakhan and his newly-formed capital and Port of Petersburg, now denominated St. Petersburg. The principal object was the conveyance from the Caspian Sea to his new seat of Government of the rich products of Persia and the Orient generally. The other and equally important motive was that the provision of such facilities as would be thus afforded would also be of material advantage in a military sense, eventually as a valuable factor in defensive operations. This system commences from the Volga at Tver, a fortified city, the capital of the Government bearing that name, and an *entrepôt* for the commerce between Moscow and St. Petersburg. Proceeding from Tver by the river Twertza to the water-parting between the Baltic and Caspian catchment basins, which is traversed by the Twersk and Taninsk Canals, it follows the river Msta, upon which the town of Vjini-Volotchok is situated, from which the system is named, thence continuing by other rivers till it arrives at the Ladogskij Canals, which join the Neva at Schüsselberg. The length of this system is 539 miles, of which only 31 miles are artificial waterways. It is navigated by trains of barges and rafts, and accommodates vessels 119 ft. in length, 28 ft. beam, but with only 2 ft. 2 in. draught. This shallowness has led to this route being, to a large extent, superseded by the Marie system.

The St. Petersburg or Pontiloff Ship Canal, which was opened for traffic on May 27, 1885, affords direct access to St. Petersburg for large vessels which had previously to load from or discharge into lighters in the Cronstadt roadstead. It extends from the Fortress of Cronstadt, which is situated on an islet at the head of the Gulf of Finland, to the Port of Goutouyeff, on an island of that name at the mouth of the Neva, immediately in front of St. Petersburg. This maritime canal, including about one mile of the Neva, is 18½ miles in length, with a branch canal of 2½ miles connecting the main line with the Catherinkoff mouth of the Neva, thus making in all 20½ miles. The minimum bottom width of the Pontiloff Canal is 210 ft. and the depth 22 ft. This navigation saves at least ten days' delay in arriving at St. Petersburg, and saves expenses equal to more than the amount of freight between that city and the United Kingdom. The total cost, including wharves at Port Goutouyeff and Pontiloff, has been 1,325,000*l.* The works were commenced in 1878 and completed in

1884. A small charge is made for the use of the wharves at Goutouyeff and Pontiloff. Three basins, with a collective area of 430 acres, have been formed by widening the canal for the accommodation of the import and export trade.

The White Sea and the Baltic Sea are connected by inland navigation, but the route is very circuitous. Vessels can ascend the river Dwina from Archangel to its affluent the Suchona, thence the navigation is continued by canals which connect the Lakes Kuhinskoe, Bielozersk, Onega, and Ladoga, from which latter access is obtained to the Neva, and thence to the Gulf of Finland. A project has been under consideration since the time of Peter the Great for making a more direct avenue by way of Lake Onega which would save 1,000 miles, the present route being about 1,500 miles. The canal contemplated by the Russian Government is intended for the passage of barges of about 100 tons, and is computed to cost from 750,000*l.* to 1,000,000*l.*

Like the Baltic and Caspian Seas, the former sea and the Black Sea have been connected by several systems of inland navigation. The first of these was the enterprise of Stanislaus, the last King of Poland, about 1790, who made a canal which connects a tributary of the Western Bug with one of the Dnieper, this navigation being known as the King's Canal. Another inter-sea connecting canal is of Polish inception, connecting the river Stchava and the river Pripet, thus providing passage from the Niemen to the Dnieper, and consequently connecting the Baltic and Black Seas, the former at Memel and the latter at Kherson. This navigation is thirty-four miles in length, and affords an outlet for the agricultural produce of the intervening region principally to the Baltic Sea. This is known as the Oginsky Canal. A third route is formed by the Western Dwina or Düna, thence by its affluent the Ulla, which is connected by a canal about thirty miles in length with a tributary of the Beresina, which is an affluent of the Dnieper. This connecting link is known as Beresinski Canal, which thus performs the function of placing Riga, on the gulf of that name, in connexion with the Black Sea at Kherson.

At the beginning of the eighteenth century Peter the Great devised the Ivanhoff Canal, to provide a passage from the Black Sea to the Caspian Sea, by uniting the Don with the Volga *via* Lake Ivan. This was realised at the beginning of the present century, but the passage from the Gulf of Taganrog to the Volga Delta at Astrakhan is too devious to be of practical use. A much more practicable project has received the approval of the Russian Government for the connexion of the Black Sea with the Caspian Sea by means of a navigable canal, a little over thirty-five miles in length, traversing the water parting between the Don and the Volga, which is formed by the Surpa Hills. The deepest cutting will be across the Surpa ridge, averaging 140 ft., and can be effected without difficulty. The Volga-Don Canal is estimated to cost 2,800,000*l.* It involves the construction of thirteen locks, which are to be constructed so as to contain at one time a couple of vessels of 210 ft. in length, 42 ft. in breadth, with 7 ft. draught. The Caspian Sea trade has attained dimensions that Peter the Great never dreamt of. The execution of the Volga-Don Canal, on the lines contemplated, would create trade of much larger proportions, and would largely restore Astrakhan its former prestige as the chief *entrepôt* for the commerce between Russia and Persia and the East generally.

Among recently-completed Russian canals is that connecting the rivers Vytegra and Kovja, which forms an additional link in the chain of navigation between the Caspian Sea and the Baltic. It was completed in July, 1886, at a cost of 350,000*l.* The surface width is 70 ft., the depth 7 ft., and the line of navigation 15½ miles. In 1887 the Russian Government raised 2,500,000*l.* for the bissection of the Isthmus of Perekop, which connects the Crimea with the mainland of

South Russia. The line of navigation will be 73 miles, the surface width 12 ft., and the depth 12 ft. The works were commenced during 1888 under the direction of M. Louis Coiseau, one of the chief engineers of the Suez Canal. The total outlay is estimated at 8,000,000*l.* The voyage from Odessa to Maripol, round the Crimean Peninsula, is 434 nautical miles, while the Perekop Canal will lessen the distance to 295 nautical miles. The works were announced to be completed in 1893, but this is very doubtful, as the Russian Exchequer has more demands upon it than can be complied with. The *Gazette Russe* in the spring of 1891 commented severely on the neglect of the upper waters of the Volga navigation, which have become shallow through silt.

The primary reason for making the Perekop Canal has not been the exigency of commerce, but the necessity of quicker transit of the fuel required by the Black Sea Fleet from the Donetz collieries, and as affording greater security for coaling in emergency than by the open route around the Crimea. The capital outlay on the Perekop Canal would be much better applied and would be more in consonance with the wishes of the traders of Russia, if devoted to the efficient maintenance and improvements of the inland waterways. The roads of the Russian Empire, with the exception of that from St. Petersburg to Moscow, which is probably unrivalled in the world, are in a wretched condition. This, to a large extent, arises from their being covered with ice and snow for many months in the year, when sledge travelling is universal.

Space forbids a more detailed account of the extensive system of the inland waterways of Russia, but there is one, probably the longest inland navigation anywhere, situated within the limits of the Russian Empire which could not well be passed over without mention. There is a considerable volume of traffic between St. Petersburg and Pekin in the exchange of the several products of the two countries. In Traushaikalia, on the confines of the Mongolian frontier of China, there is a produce exchange of which the world in general hears but little.

The Russians and the Chinese, who are both zealous guardians of their respective frontiers, have effected a definite delimitation of the boundary-line by a long timber structure, which is the scene of the brokerage transactions concerned in the exchange of produce. One narrow exit on the north side of this international mart opens into the Russian dominions, another, on the south side, opening into the Chinese. That portion of the town on the north side contains the Russian community of Kiakhta, and that on the south the Chinese one of Mai-ma-tchin. At sunset a bell is rung, when transactions cease, and both parties retire within their respective boundaries. The Chinese chiefly transport their goods to Mai-ma-tchin on camels; it is five days' journey from Pekin to the Great Wall of China, and forty-five days more for the crossing of the Great Mongol Desert. From Kiakhta the goods are conveyed by water on the Salenga River, thence by the Lake Baikal, and *via* Irkutsk, by the Angara (or Upper Tunguska) to Yeniseisk, where that river enters the Yenisei. Here the break of sixty miles occurs, the goods having to be carried by land from Yeniseisk to Makoffskio-Ostwg, whence an avenue is formed by the Ket River to its confluence with the Obi River, which is traversed until that river is joined by the Irtysh. From this point the Irtysh is ascended as far as Tobolsk, which is a considerable centre for the inter-trade between Europe and China. A little above Tobolsk the route is continued from the Irtysh by the Iset River, connected with the Tchuovaya River, which falls into the Kama River some twenty miles above Perm, the principal emporium of the Russo-China trade. The Kama joins the Volga near Spask, at a point fifty miles below Kasan on that river, the chief *entrepôt* for the inter-commerce between European Russia, Siberia and Bokhara. The length of this navigation system cannot be

precisely stated, but, as the distance taken as the crow flies from St. Petersburg to Kiakhta is 2,500 miles, it cannot well be less than 4,000 miles. The caravan track from Mai-ma-tchin to Pekin is 1,050 miles. It might be said that a conveyance involving 4,000 miles of inland navigation and 1,000 miles of overland transit would be so costly as to be prohibitory. Taking the two extremes of St. Petersburg and Pekin, the sea route between the Peiho and the Neva, or the Yellow Sea and the Gulf of Finland, *via* the Behring Straits and the Arctic Ocean, is about 12,500 miles, and if by the Straits of Malacca and the Suez Canal, then the voyage would be about 9,500 miles. This circuitous navigation traverses the greatest land-locked area in the world, and collects and distributes traffic from regions remote from any sea-port.

NOTES.

ROBING Peter to pay Paul is not a sensible way of doing business, but it is the principle on which the London County Council appear to be about to act in the execution of work. The motion of Mr. Burns, amended by Sir T. Farrer, was carried on Friday last, and it pledges the Council to oblige all contractors to pay the rate of wages and observe the hours of labour recognised by the trade unions in the place where the contract is to be executed. Of course contractors will have no objection to this, since they will make the County Council, if necessary, pay a larger sum for the work to be done. The persons who will suffer are the ratepayers of London: in other words the general community of the Metropolis will be to some extent taxed for the benefit of a particular class who happen at the present moment to be the most energetic section of the electorate. This is simply another form of protection, and does not in the least differ in principle from the old protection abolished by Sir Robert Peel, which protected the agriculturalists of the country at the expense of the general community of Great Britain. In the days of agricultural protection the farmers and landowners were the strongest electoral force, now the management of the affairs of the metropolis the artisan is the most powerful force. The result of such a system of protection is not to produce either better work or greater comfort for the artisan. For the master must pay high wages simply because it is so laid down by the Council, not because he workman is better, and this same high rate of wages will attract more men to the metropolis, so that the competition among the workmen is increased. After a certain period of time the folly of this system will probably be perceived by the general community of London.

WHEN we last alluded to the Durham miners' strike, there seemed to be every probability of an early settlement of this disastrous dispute; but two weeks more have passed, and still no work is being done. When the men got so far as to offer to accept an immediate reduction of 10 per cent, it would have been a satisfactory termination if the masters could have seen their way to allow a resumption of work on this basis. It appears, however, that they were unable to do so, and it is not for any one unacquainted with the extent of their losses to impute blame to them for the firm attitude which they have taken up, though it was impossible to repress a feeling of disappointment at the failure of negotiations which approached so nearly to a settlement of the question at issue. The proportion in favour of continuance of the strike had gradually dwindled down till a large majority were in favour of a compromise; but the allot last Saturday on the question of submitting to the full 13½ per cent. reduction, resulted in a majority of no fewer than 1,026 for resuming an attitude of non-surrender. The distress in the district must by this time be very acute,—though the

statements with regard to its extent are rather confusing. The *Colliery Guardian*, for instance, remarks in a leader: "Possibly the case is overstated when, in the petition forwarded this week by the Cleveland Ironstone Miners' Association, it is said that 28,000 human beings are on the verge of starvation." While in an article on the subject in the very same issue (May 27) we read: "There cannot be less than 27,000 men idle through no fault of their own, and, with their families, some 140,000 persons must be on the verge of starvation." It must be regarded as fortunate that the mediation of the Bishop of Durham has been accepted, and we may now venture to predict an early settlement of the dispute with a much greater degree of certainty than before. Bishop Westcott,—who happens to have been presiding at a meeting of the Arbitration and Peace Association only this week,—is respected by both parties, and, in spite of being *ex officio* a royalty owner, can be trusted to approach the subject with impartiality, combined with a benevolent earnestness which will, we trust, result in healing the breach. [Since this was put into type, we are glad to learn that the mediation of the Bishop has been successful, and that the masters have agreed to reopen the pits at the 10 per cent. reduction originally proposed by them.]

THE Committee of the House of Commons which had under consideration the London Council's Bill in which this question of "betterment" was again raised, this time in reference to the proposed bridge at the west end of Cromwell-road, threw out this clause by the casting-vote of the chairman. The manner in which the principle of "betterment" was to be applied was by means of a rate on certain owners who might have been assumed to benefit by the bridge. It is just as well that the committee refused to sanction this principle, for the House of Commons itself had already done so, and there is no reason to suppose it would not have done so again. As we have more than once said, if the principle of "betterment" is to be allowed, it must be sanctioned by the Legislature and made applicable to the whole of England. But if this principle is adopted, it seems difficult logically to refuse to enlarge the principles of compensation. Thus, at present, persons get no compensation if the prospect or view of a house is spoiled by a work in respect of which property may be compulsorily taken. If, then, the vague "betterment" principle is to become law, it would be unfair not also to introduce an equally vague "worsenment" principle. The more the question is looked at in a practical light, the more difficult also does the just application of any such principle appear, and, therefore, however specious it may seem at first sight, we are convinced it will never commend itself to the general sense of the community.

ALTHOUGH the Earl of Wemyss's amendment on Monday last, to make the provisions of the Water Companies' (Regulation of Powers) Bill applicable also to corporations which supplied water, was withdrawn,—and with good reason, as it would have led to an indefinite postponement of the measure,—the tone of the debate on the amendment was such as to leave no doubt that the question of regulating the powers of water-supplying corporations will be raised again before long. As Lord Grimthorpe pointed out, in the case of companies supplying water the corporation was always on the spot to watch the action of the companies; but when the corporation held the water-supply in its hands, there was no controlling power whatever over them, and any resistance to their action could only be made by a small man fighting a battle against a great corporation; a most unfair position for the consumer who had any cause of complaint. Water is a necessary of life and health, and in regard to the latter point the health of separate members of the community, or at all events the sanitary condition of separate houses, is a matter in which the community

at large is practically interested. One house reduced to an insanitary condition for want of water may lead to disease which will affect or infect others in the neighbourhood; and as there is a growing tendency in the present day towards the theory that the water supply of a town should be undertaken by the municipal authorities, there is good reason for the demand that such authorities should be tied down from manipulating or cutting off the water supply in an injurious manner by any arbitrary and ill-judged exercise of official rights.

ON Friday, May 27, Dr. Oliver Lodge read before a full meeting of the Physical Society an interesting paper, reviewing the attempts that have been made to ascertain the relative motion of the ether and the earth. After pointing out the difficulties that arise in explaining astronomical aberration on the undulatory theory, and the consequent necessity of assuming that the ether is not stagnant, he proceeded to give an account of the various experiments that have been devised by Maxwell and others to prove that there must be at least a partial flux of ether with respect to the earth. The results were for the most part negative, though with great ingenuity it was shown that some that appeared negative were consistent with either hypothesis. The final conclusion was that the problem must still be considered unsolved. Without going into details, the question that naturally occurs to an outsider is: If the ether is not carried along with the earth, why should it move with the sun? and if it does not move with the sun, why take the earth's velocity in its orbit as the velocity of the earth relative to the ether?

THE Post Office service is gradually being released from many of the trammels which have so long hampered it, a large instalment of reforms being given to an appreciative public on June 1. Foremost among these is the abolition of the fee for re-directing letters,—no charge being now payable provided the letter is re-posted within twenty-four hours after delivery, and that it has not been opened. This regulation applies to letters only, and it will be advisable to procure a copy of the new rules for information as to exceptions and definitions. Under the latter heading mention may be made of the new classification of book-post matter, which is considerably extended, and now covers a much larger number of commercial, literary, and other documents than heretofore. The Post Office authorities are to be congratulated on their efforts to increase the efficiency and popularity of the service,—a policy contrasting very strongly with that which has been pursued in this Department in the not very remote past.

THE concessions referred to in the foregoing paragraph are rapidly reducing the number of counts in Mr. Henniker Heaton's formidable indictment of the Post-Office a year or two ago; but the "Member for Australia" is one of those indefatigable persons to whom such proverbs as "half a loaf is better than no bread" afford no excuse for slackening of exertion. The goal of "Imperial Penny Postage" is being more vigorously aimed at than ever, and in a pamphlet just circulated, Mr. Heaton gathers up and reiterates the forcible arguments which he has been persistently pressing upon the Government and the Postmaster-General for some years past. Although, of course, a strictly non-political question, our modern Postal reformer is evidently sorely disappointed at finding the Dissolution almost upon us without the change for which he has toiled so hard being accomplished by the Government of which he is a supporter. He has gone so far as to offer to furnish Bank guarantees against loss for a period of three years; but there seems to be some special obstacle which hinders the desired reform, the nature of which is not apparent.

The whole question, we should judge, turns upon the cost of transmission from shore to shore; for, as we are relieved of the distribution of outgoing letters in return for free delivery of those we receive, inland and foreign conditions are really equal in all respects, plus cost of conveyance abroad. Mr. Heaton argues that we are paying far more than we ought for this service; and that it should not cost the 150 per cent. above the inland rate which is now charged is evident from a comparison with the ridiculously low rates for the postage of newspapers, &c. If the loss on the postage of printed matter is so small that we can afford to carry 4 oz. of printed matter to any part of the world for a penny, the day cannot be far distant when a letter weighing half an ounce will cost no more. The point upon which we think Mr. Henniker Heaton is building too much is the great increase of correspondences he anticipates between emigrants and their friends. Probably commercial correspondence would increase considerably with a reduced postage; but we venture to suggest that it is frequently less a question of the few cents for the postage, than a disinclination for letter-writing, that affects the frequency with which the emigrant and "the old folks at home" correspond with each other.

THE daily papers state that the Terrace (which consists of sixteen houses) along the southern side of Kensington-road, and covering about four acres in all, was sold a few days ago for 170,000. We are authoritatively informed that the purchase, being for building purposes, includes only Nos. 1-7 (Shaftesbury House) and the two cottages numbered 8 and 9. These houses have large gardens extending to Chéniston-gardens in the rear; whilst that of Shaftesbury House, No. 7, reaches much farther southwards. They have had many celebrated inhabitants. At No. 1 lived Sir Henry Cole, K.C.B.,—died April, 1882,—who was educated in the Blue-coat School, and to whom was due most of the success of the Exhibition in 1851. No. 6 was the home,—and, we understand, the last home,—of John Leech, where they show the screened attic he had made to lessen the annoyance by street-music, from which he suffered. Into No. 7, a home of the third Earl of Shaftesbury, author of the "Characteristics"—but since rebuilt—Sir David Wilkie removed, in 1824, from No. 24, Lower Phillimore-place, on the opposite side of the main road. Coming up to London in 1805, Wilkie lodged in Chelsea: at No. 11, Norton—now Bolsover-street, Marylebone; and at No. 10, Sol's-row, by the southern end of Hampstead-road. In 1811, the year of his election as R.A., he went to a friend's house, No. 11, in Lower Phillimore-place, and shortly afterwards removed, with his mother and sister to No. 24, From Norton-street he sent, as Haydon tells us, his "Blind Fiddler" to the Academy Exhibition of 1806: and there he painted his "Chelsea Pensioners" (1822) for the Duke of Wellington, and now, we believe, at Apsley House; the "Reading of the Will"; "Duncan Gray"; "Blind Man's Buff"; the "Penny Wedding"; and the "Rahbit on the Wall." In 1825 he left the Terrace for a three years' stay on the continent,—a visit which wrought a change in both his style and class of subjects. For some while before he left England in 1840 for a tour in the East, Wilkie had occupied the present Maitland House, next to the harracke: in his day it stood in Vicarage-place, Church-street, Kensington.

ON Monday next Lord Rosebery will formally open Brockwell Hall Park. The park, about 78 acres in extent, lies on the rising ground between the road from Herne-hill to Lower Norwood,—to which it has a long frontage, lined with elm trees,—and Lower Tulse-hill. To the north lies that part of Water-lane which is now called Dulwich-road, and lies over the

course of the Effra river. Six years ago the park was to have been taken over for building purposes, but after protracted negotiations has been secured for the public enjoyment. At the final meeting of the Brockwell Park Committee, held on April 9 last, it was announced that the total purchase moneys, 119,500*l.*, are derived from the following contributions:—The Charity Commissioners, 25,000*l.* out of the surplus funds of the City Parochial charities; the vestry of Lambeth, just within which parish the estate lies, 20,000*l.*; the vestries of Camberwell and Newington, 6,000*l.* and 5,000*l.*; the Ecclesiastical Commissioners, 500*l.*; Mr. J. J. B. Blackburn, owner of the adjoining property, 2,000*l.*; and the London County Council, 61,000*l.* The last-named payment and that by the Charity Commission are made as including, in each case, a contribution of 12,500*l.*, which would otherwise have been payable in respect of Raleigh Park, Brixton, in the event of failure to secure this larger area: see our "Note" of September 3, 1887, and our report on August 3, 1889, of the Council's meeting of the previous Tuesday. Brockwell Hall was built, 1810, for John Blade, a glass dealer on Ludgate-hill, after the designs of D. Riddle Roper, architect. In 1829 the property, originally 60 acres, passed to Joshua Blackburn, his son-in-law.

THE groups of buildings at the head of the Mound immediately to the west of the Free Church College in Edinburgh, extending westward to and including Ramsay Lodge, have been acquired by a syndicate for the purpose of erecting on the site a set of chambers, to be used as students' quarters, studios, &c. The site is one of the finest in Edinburgh. From its high position overlooking Princes-street-gardens, the new buildings will form a conspicuous feature in the view looking southwards from that street. The existing buildings possess no architectural character, although an attempt was made by the proprietor, the late Lord Murray, to give some architectonic expression to the portion comprising Ramsay-gardens and Ramsay Lodge. The matter was placed in the hands of the late Mr. Billings, who attempted to improve Ramsay Lodge by the doubtful expedient of throwing out a heavy iron balcony. He also carried out a battlemented terrace in front of Ramsay-gardens, with a castellated lodge at its east end, but one morning, after heavy rain, the terrace and new lodge slipped into the valley below, and since then nothing further has been done to beautify the site. Ramsay Lodge was built by Allen Ramsay, the poet, as a residence for himself, and from the oddness of its form was known as "Allen's Luggy.*" In Ramsay-gardens resided the late well-known editor of the *Scotsman*, Alexander Russell. At one time, it is stated, the Government was desirous of obtaining Ramsay-gardens as a site for military quarters, for which purpose it is most suitable, owing to its proximity to the Castle, but the negotiations for a purchase fell through. The chief drawback to the situation is the steepness of the access, which during a severe frost is rendered impassable to vehicular traffic. The plans for the new buildings have been prepared by Messrs. Sydney Mitchell & Wilson, and show a picturesque group, a conspicuous feature of which is a tower surmounting an archway over Ramsay-lane, which intersects the line of frontage. We understand that it will be some time ere actual building operations are commenced.

THE accommodation placed at the disposal of the Royal Commission on Metropolitan Water Supply cannot be deemed creditable to the authorities,—at any rate, so far as the room in which the inquiry is being held is concerned. This room is an awkwardly-shaped apartment on the third floor of Trafalgar-buildings, Charing Cross,

* Luggy—a wooden basin used for porridge and soup.

at the Whitehall corner of Northumberland-avenue, in the building which was the temporary home of the National Liberal Club, and the room in question, if we mistake not, was the former grill-room of the Club. If the grill had been there this week the room could hardly have been warmer. The room is low in proportion to its size, and certainly inadequate to accommodate between fifty and sixty persons, the number present when we looked in on Monday afternoon. The sun was shining brightly and warmly on the windows, which had to be opened in order to avoid asphyxiation; and, to exclude the direct glare of the sun, the crimson blinds had to be drawn. The opening of the windows admitted not only air, but the noise of the street traffic, so that it was very difficult at times to hear the Commissioners' questions and the witnesses' answers; the drawing of the crimson blinds, which the sunbeam half penetrated, had the effect of imparting to the proceedings a hue strikingly in keeping with the *couleur de rose* view which some of the companies' witnesses seem inclined to take of the question, or of suggesting (most unwarrantably, no doubt) that the witness,—who sit facing the blinds, with the full red glare in their faces,—were blushing at the shortcomings of the companies, or were addicted to stronger libations than they themselves are concerned in supplying. Seriously, however, we think it is greatly to be regretted that no better accommodation could be provided for the holding of this important inquiry,—which affects the well-being of the whole of the inhabitants of London, and which is, indeed, of national importance,—than the room which we have described.

IT appears that there is some feeling in Berlin that German characters should be used in lieu of Latin ones on the new set of street-nomination plates which are about to be fixed at the corners of the thoroughfares in that city. This novelty would be a great nuisance to those non-Germans who visit the Prussian capital, and are not well acquainted with the German language. In a city which delights in the constant increase of non-German visitors and tourists, such so-called "patriotic" pettiness as is only shown in Russia need not make itself prominent. The German characters are even more unsuitable for street signs than the Russian or Polish ones, on account of their elaborate lines. A Russian character can, at all events, be deciphered at some distance, even if it is not understood.

ARCHITECTURE AT THE ROYAL ACADEMY.—VI.

1,755; "Nos. 190 and 191 Queen's Gate, South Kensington;" Mr. F. G. Knight. This is the drawing published in the *Builder* of February 13 of this year. The houses are good examples of the modern brick London architecture. The fronts are very simply treated, but the variations in the treatment of windows and other details give a certain interest to every part, and it is noticeable how the same features—the bay window, the porch, the gable, &c.—are varied so as to give each house a distinct character, yet keeping them sufficiently in harmony with each other as two contiguous architectural fronts.

1,757; "Design for Free Library, Stoke Newington;" Mr. Ernest Rintz. This is a very nice unpretending little coloured elevation in brick, to which interest is given by the treatment of the windows in accordance with necessities of the interior. A plan is added.

1,759; "Nymans, near Crawley;" Mr. Leonard Stokes. This is a sensible way of showing the additions to a house; a plan is given showing the added portions in black, and a sketch of the original house given in the corner. The old house was an oblong mass with an entrance door flat in the wall and a single bay window marking the dining-room, on one side of it. The architect has thrown out a square porch which rises above into a short tower breaking the line of the eaves; the bay is finished with gables, concave curves and a spare panel of carving on the front face; a similar gable is added to the

extension on the right; to right of this a large wing is thrown out, of which the ground floor is a billiard-room with an open verandah round it forming circular pavilions at the angles; these are only on the ground floor. Is there enough light for the billiard-room? is the only question. The plan shows various smaller internal alterations. The house has been given character and picturesqueness, in a reserved and quiet manner. The projections of the eaves appear to have been increased, giving a strong shadow. We recommend others who exhibit drawings of additions to old houses to follow Mr. Stokes's example, and send drawings which show intelligibly what the additions are.

1,758; "Drawing of the Crucifixion at St. Rémi, Rheims;" Mr. J. P. Seddon. A small but apparently careful copy in colour of this curious and interesting piece of ancient stained glass, in which the crucified figure occupies the centre long panel, the arms extending on two cross panels, over two saints in the side panels. Beneath the feet of the crucifix are the symbols of the cross and a face probably representing the sun, the symbol of Christ as the light of the world.

1,760; "The Tate Library, Brixton;" Mr. Sidney R. J. Smith. This is a pen perspective effectively executed, giving some additional interest thereby to a design which is suitable and solid-looking, but not of very much architectural interest.

1,761; "Coats Memorial Church, Paisley; Entrance Front;" Mr. Hippolyte J. Blanc. A pencil perspective sketch executed in a masterly manner, with firm yet free touch. It shows the west end of a Gothic church approached by a very lofty flight of steps, at the top of which is a triple porch of somewhat Continental character, a large west window above, and the whole flanked by octagonal turrets which spread out the composition and add much to the effect of the whole, but there is no plan to show their function. Presumably they are stair turrets. The lower portion of a tower is shown in the rear. The whole is a very powerful composition, though the west window strikes us as of rather coarse design.

1,762; "No. 191, Queen's Gate, South Kensington: Hall and Staircase;" Mr. F. G. Knight. This is the interior published in the *Builder* of March 17, to which we refer the reader. It is a pleasant bit of staircase architecture, but it seems a pity to repeat in these days the old illogical use of a square block of architecture mounted on the top of a column.

1,765; "Church of the Good Shepherd, Gospel Oak; South-east View;" Messrs. James Brooks & Sons. A beautifully-executed pen drawing, showing the exterior perspective of a church in true Gothic spirit, but without being a mere copy of old Gothic. As the girth of the building is peculiar, it is a great pity that a small plan was not added to explain it. It appears to present a nave with three aisles of nearly equal height, all terminating in gables, and low narrow side-aisles for passage. The buttresses are treated in an unusual and very massive manner, in lines sloping outwards between the set-offs. There is a double-gabled transept, against which the low lean-to aisles stop; the middle aisle of the nave is flanked by turrets partly attached into the walls. The windows are simply treated in Early Gothic style, with a little geometric tracery in the heads of some of them. The remarkable point about the church is the look of monumental massiveness and solidity which it presents.

1,766; "Part of Second Court, St. John's College, Cambridge;" Mr. W. H. Thorp. An artistic little sketch, with a good deal of character in it.

1,767; "Convent of Sta. Paula, Seville, Spain: Doorway;" Mr. A. N. Prentice. A coloured elevation, "measured and coloured on the spot" and as such of value and highly creditable to the artist. It shows a Gothic doorway in thin courses of darker and lighter bricks, with a broad band of elaborate tiled (?) ornament over it, with circular medallions painted with small figure subjects. This and the decoration in the spandrels of the arch are very carefully and minutely shown, and the drawing is a valuable record of design and colour.

1,768; "Battersea Polytechnic Institution;" Mr. E. W. Mountford. As a drawing this is not very effective in execution, and seems to have been hurriedly executed; it is drawn in pen and tinted in a rather showy style in Indian ink. The grouping, with the two narrower Elizabethan-like gables grouped in the centre, and the larger straight-lined gables at the end

wings, is effective, and the three stories are well contrasted in the intervening portions of the front, in regard to the treatment of the windows; the ground story has a large semi-circular headed window in each bay, above are two long windows coupled, and the upper story, just under the roof, has small circular windows between Elizabethan-like pilasters. For an institution of this kind it is a dignified and suitable front, but just falls short of being architecturally interesting, for which the style of the drawing may be partly to blame.

1,769; "Cottages, Eaton Hastings, Berks;" Messrs. Ernest George & Peto. Very charming cottages in a simple unpretending Old English style, with the form of low mullioned windows which is more conducive to domestic happiness in humble life than any other form; we cannot give a reason, but we are convinced that it is so. Whether the ornaments of halls and niches on the top or at the foot of the gables add to the effect may be questioned. They are simple enough ornaments, undoubtedly, but just a little worn-out.

1,770; "New Premises, Heath-street, Hampstead;" Mr. Keith D. Young. Not very attractive at first sight, but this is a capital little water-colour drawing, and shows a good solid treatment of shop-fronts with three-centred arches over the large windows; and the octagon turret over the angle gives a certain distinctive character to the block, which is carried out in brick with light-coloured stone dressings.

1,771; "Pastoral Staff for the Bishop of St. Asaph, designed by the late J. D. Sedding;" Mr. H. Wilson. The drawing is by Mr. Wilson, and is a water-colour drawing which is quite a study in colour and texture. The staff takes the orthodox form of a knob with a crook and a little sculpture subject (Christ's Charge to Peter) within the crook; but the details are treated with the freedom and originality usual in the late Mr. Sedding's work. Above the knob is a little shrine of two stories of niches with small figures in them, the spandrels over the niches being filled up with delicate foliage of a more unconventional type than in Medieval work. The side face of the crook is lined out by the centre by a small continuous ornament of repeated leaves on either side of a stem, interrupted at intervals by jewels. The whole is a very refined piece of work.

1,772; "Reredos in South Transept, St. Alban's, Teddington;" Mr. A. H. Skipworth. A pencil elevation showing a square panel above the altar, of the same width, with a late Gothic moulding and the usual "perpendicular" square flower enrichment, and an enriched cornice with angels and shields; above this are three niches with canopies, and figures on octagonal pedestals, which are designed in imitation of work in Henry VII.'s Chapel; this was done "by request," so the architect is not responsible for the choice. This part of the work, however, appears rather heavy in comparison with the cornice below, which does not seem to give it sufficient support. A panelled screen the height of the vaulting impost of the church forms a background to the whole.

1,775; "The Wave, Tremadoc, N. Wales: alterations and additions;" Messrs. Douglas & Fordham. This is one of Mr. Hodgkinson's fine sepia drawings; there is nothing to show what are the alterations and what is original; the greater part of the house is in a solid Gothic style with mullioned windows, the porch on the left and the portion to left of it, with lofty mullioned windows, appear like part of an old Jacobean house; but what is new and what is old we can only conjecture. It seems extraordinary to us that so many architects in these cases should be content (apparently) with merely getting a good draughtsman to make a drawing which "will get into the Academy," and leave the reason and method of their work entirely unintelligible.

1,776; "Mission Hospital, Jerusalem;" Mr. Beresford Pite. This is a frame of very prettily-executed coloured geometrical drawings, two sections, elevation and plan. The work is treated in an Oriental style, with wooden verandahs ornamented by pierced work in the upper part, and there is a low eastern-looking dome over the entrance-hall. The plan is that of a pavilion hospital with large wards for men and smaller ones for women on the opposite side of the corridors, an isolation ward and private ward divided up into small rooms or cubicles. Whether the arrangement of the administration portion in similar blocks on each side of the entrance, but not closely connected,

would be convenient, may be a question. There is a refreshing originality about the work and the manner of showing it in the drawings.

1,778; "Bury Municipal Buildings;" Mr. A. N. Bromley. This gives the perspective view of the building accompanied by a small plan. The site is triangular, and the reception rooms occupy the greater portion of the principal front. The Sessions-house is in the centre of the building parallel with the main front, and the principal committee-rooms in convenient proximity with it in an adjoining portion off one of the main corridors. The defect of the plan is that the all-round communication is not complete, being hooked at one angle. Architecturally the building is effectively grouped as a whole, but the details are rather commonplace.

1,780; "Design for Stained-glass Window: Tree of Jesse;" by Mr. G. W. Rhead. This is a pencil drawing showing only the linear design without the colour; it is to be commended both for the well-filled effect of the design, and for the conventional and decorative treatment of the "tree," which takes the form of branching scroll-work of Early Gothic character: Jesse "trees" are too often treated in a too realistic manner.

1,781; "Monument to the late Mrs. Rowley, St. Neots;" Mr. F. A. Walters. This is the design which was published in the *Builder* of May 7, and is a fine modern example of a monument in a Medieval form. The monumental figure lies under a richly-foiled canopy arch, with a lofty and richly-decorated ogee gable rising over it, terminating in a finial which forms part of the bracket for the central figure of the group in niches at the top of the composition. The space above and on either side of the ogee is divided by mullions which rise into pinnacles dividing the niches at the top. Angels are sculptured in bas relief here, holding shields, their figures and wings crossing and breaking up the vertical lines of the mullions. The effect of the whole ought to be very fine and decorative in execution. The figures are nearly life-size.

1,783; "Stables, Pewsham, Wilts.;" Mr. C. E. Ponting. Two drawings executed on brown-toned paper and whitened where the plaster covering occurs on the building, as in another drawing by the same architect, already referred to. The stables are quietly picturesque in appearance, but owe something of their effect to the manner of execution of the drawings, which gives a certain degree of exceptional character.

1,784; "Design for a Small Country House;" Mr. G. C. Horsley. Two small elevations, slightly tinted, and two plans, and (a detail often forgotten) the north and south point shown in connexion with the plans. The design is of a quiet cottage-like type with mullioned windows.

1,785; "Convent of St. Marcos, Leon, Spain: Façade;" Mr. A. N. Prentice. This is a delicate little coloured elevation of a façade of plateresque architecture, with a "fronton" looking something like a big timepiece breaking the line over the central arch, but a delightful and interesting specimen of Spanish Renaissance of this type. The drawing, stated in the margin to have been measured and coloured on the spot, is executed with remarkable delicacy, and is a high credit to the patience and taste of its author.

1,786; "Nos. 39 and 40, Margaret-street, Cavendish-square;" Mr. F. L. Pearson. Street fronts in red brick, with a variegated skyline formed by a large scroll at each side and two semicircular gables in the middle. On the ground floor a shallow segmental arch is carried right across each front, grouping the door and ground-floor windows under it, and offering an apparent support to the balconies. The windows are treated with brick mullions and brick mouldings over them, the whole being carried out conscientiously in a brick style which is suitable, but of which the details are not very interesting. One is always glad, however, to see a complete brick front for a street house, as a protest against the inferior and patchwork effect of "brick with stone dressings."

A NEW CLOCK (has just been fixed at the new training stable, Newmarket, to the order of Captain Heaton, of Steworth-park. This clock was made by Mr. J. W. Benson, of Ludgate-hill. It shows time upon a dial 3 ft. 3 in. diameter (illuminated by electric light), and strikes the hours upon a 2-owl bell.

LETTER FROM PARIS.

A FEW days since the posthumous exhibition of the works of Ribot was opened at the Ecole des Beaux-Arts. By general consent this exhibition, which is closed to-day, is one of the finest and most interesting exhibitions for some time past. The collected works were not numerous; the 150 pictures and 170 drawings had been carefully selected, and formed a compendium of the work of the old artist who was great and original, and showed a sincere love of Nature, even in his mistakes. We had his copies of Watteau, done in the period of his early struggles; then his studies from everyday life, humble interiors, peasant girls at work; small pictures valuable for the minute care expended on their execution. His portraits also must be mentioned, so powerful in their light and shade effects, and a few great pictures as vigorous as those of Ribeira. Then the drawings and studies showing the inner work of his artist life, his knowledge and his industry combined. This fine exhibition has added much to his posthumous renown.

Though the Salon of the Champs Elysées has still a month to remain open, the members of the Société des Artistes Français are already organising the jury for their next year's exhibition. The painters propose to appoint, for three years, sixty jurors chosen from among those who have received honours and those who have exhibited at least five times. Twenty members from among these would be chosen by lot each year. It remains to be seen whether this arrangement will give any more satisfaction to the easily dissatisfied tribe of artists.

In the section of engraving, the médaille d'honneur has been given, by thirty-one out of fifty-two votes, to M. Paul Mauron. This artist, a native of Avignon, has exhibited this year two fine lithographs, a "Tête de Mérovingien," after J. P. Laurens, and "La Tentation," after Bourguignon.

At the Hôtel Drouot there has been a sale recently of the works of the painter Audrien, not very much known except as a pupil of Delacroix who had acquired the art of copying in a curious fashion the style and colouring of his master. One result is that a good many drawings were sold on this occasion under the name of Delacroix, which were probably only clever repetitions of the work of that master. The regular picture dealers kept in the background and left to some amateurs the satisfaction of having, as they supposed, obtained original works by Delacroix at a very low price. Among the works sold were a very fine series of sketches of the decorations executed by him for the Salon de la Paix in the old Hôtel de Ville. These pictures, the authenticity of which is not disputed, have been purchased by the Municipality, which has rightly wished to obtain and preserve these unpublished documents of a fine work by the master, now destroyed.

It is announced that the house in the Rue de Furstenberg, where Delacroix long lived and worked, has been distinguished by a marble slab affixed to it, recording the date of his birth and death. His studio still exists and is now occupied by a talented painter, M. Maillard.

A Parisian journal has published recently a decorative composition commissioned by the Government from M. Joseph Blanc, and which is to be reproduced at the Gobelins manufactory. It appears to be intended that this tapestry should figure at diplomatic audiences, and should accompany M. le Président on his journeys, in order to decorate the places where official receptions are held in his honour. It is a curious idea, and it hardly seems that the head of the State ought to require, to keep up his personal prestige, a "toile du fond," as they say in the theatre, packed up amid the Presidential luggage and displayed wherever he stops on his journey; a kind of accessory which will be more likely to create a smile than to impress the imagination of the crowd. It is said, however, that the procedure is not without precedent, and that in former days the Kings of France, when they went about, were followed also by their State tapestries which successively adorned all the châteaux where they stayed. In the present day of plainer manners travelling decorations can hardly be considered a necessity, and M. Carnot, who in his tastes and character is simply itself, would be the last person to wish for such accompaniments. As for the composition of M. Blanc, it represents in the centre (always according to aforesaid journal)

the monogram of the Republic surrounded by the collar of the Order of the Legion of Honour. On each side of the central motif is seated an allegorical figure, the one representing Truth, the other Justice. Above, a child or genius with difficulty restrains the ardour of the emblematic bird of Gaul, represented in full crow. At the bottom reposes a lion, emblem of the popular power,* kept in restraint, by chains of flowers held by two Cupids. Plugs and attributes relating to Agriculture, Commerce, and the Arts, fill up the composition. Taking into consideration, however, the proverbial slowness of work at the Gobelins, it will probably be four or five years before this piece of official decoration is completed, and it is generally thought that it will prove to be an "immemorable" in the literal sense, and will never enter in its travels.

The Louvre has acquired for the department of modern sculpture two fine busts by Carpeaux, that of M. Delaborde of the Institut, and that of M. Fiore, who, under the second Empire, was a brilliant operatic star. The Cluny museum has obtained a curious miniature in oil representing Benvenuto Cellini, and some splendid Arab textiles of the Byzantine epoch, resembling those preserved in the treasury of St. Sernin at Toulouse.

The mortuary dépôt constructed at Père la Chaise has just been inaugurated. It is the first establishment of the kind in Paris, and is expected to be of great service to the poorer classes of the population. The general style is naturally very sober; the interior arrangements are most carefully carried out. The floor in the halls is in mosaic; the walls, painted in oils, are bordered with a wainscot of black marble. All the work has been directed by the architect, M. Formigé, who has for a long time been studying similar establishments in other countries. In the Church of Notre Dame des Champs a mural decoration has just been inaugurated. It has been executed by M. Joseph Aubert, and represents "The Glorification of Our Lady of the Fields," the patron of horticulturists and the cultivators of the environs of Paris. This important work has been under the direction of M. Ginals, architect. It is announced that the new Minister of Public Works, M. Viette, has the firm intention of carrying out the study of metropolitan railway working, already begun by his predecessor. Will some happy solution come to him soon? We can hardly think so, though the Minister has expressed his willingness to present it to Parliament by the end of June. We may notice in passing that the pictures, pastels, and sketches of Madame Berthe Morisot are now on view in the Bonssod-Valadon Gallery in Boulevard Montmartre. Madame Morisot was sister-in-law of the painter Manet, and one of his best pupils.

The recent death of the painter on enamel, Claudius Popelin, has been a serious artistic loss. Popelin was born at Paris in 1825, and studied first under Picot and Ary Scheffer, and made his début in the Salon in 1852 by a remarkable picture, "Dante reading his poems to Giotto." From 1860 he gave himself almost exclusively to enamel painting, and produced in this form his portraits of Julius Cesar, Pico della Mirandola, Napoléon III., &c., and a composition called the "Renaissance of Literature," which gained him a medal in the 1865 Salon. He had not exhibited since 1867, but continued to execute remarkable enamels. He published also various works, notably one entitled "Cinq Octaves de Sonnets," illustrated by engravings of his own. He leaves a son, M. Gustave Popelin, also a painter of great talent, who gained the Prix de Rome in 1882.

THE ENGLISH IRON TRADE.—The news of the termination of the Durham miners' strike will be welcomed on all sides, as there is now a probability of business returning to its normal level. By the intercession of the Bishop of Durham the masters have been induced to accept an immediate reduction of 10 per cent. With the near approach of the holidays there is little doing in the English iron market. In most of the crude-iron centres a quiet tone is observable; but rates, generally, are firm. Manufactured iron is in sluggish request. "T" plates are in fair demand; but the steel market shows little inquiry. Shipbuilders and engineers are only moderately employed. The coal trade generally exhibits fair movement.—Iron.

* Tennyson came near anticipating this emblem in the picture symbolising The People in the "Palace of Art."

"Here played, a tiger, rolling to and fro
The heads and crowns of kings."

The present emblematic animal seems to be, however, "a very gentle beast, with a good conscience."

THE ROYAL INSTITUTE OF BRITISH ARCHITECTS:
CASTINGS IN METAL.

THE fourteenth general meeting of this Institute for the present session was held at Conduit-street on Monday evening last, the President, Mr. J. Macvicar Anderson, in the chair.

The minutes having been confirmed, the Secretary read a long list of gentlemen nominated for election as Fellows, Associates, and Honorary Corresponding Members.

The President said that as they had a somewhat full programme to get through that evening, he should not venture to occupy their time with any remarks of his own. There were no fewer than four papers to be read, the first of which would be by Mr. Alexander Graham.

Before calling upon Mr. Graham he wished to intimate with regret that Mr. Alfred Gilbert was unable to be with them on that occasion; he much regretted his inability to attend. An interesting letter had also been received from Mr. Alma Tadema, regretting his inability to be present.

Mr. Alexander Graham, F.S.A., then read a paper giving an interesting historical outline of the application of metals to architectural design in all countries.

The Precious Metals.

Mr. C. Krall followed with a paper on working in the precious metals. The following is an abstract:—

The structural and main features of architecture being never, or very rarely, cast in precious metals, the author dealt with those of furniture, decoration, and articles of use, in which gold and silver had been employed in all ages down to the present. It was surprising, on investigating what parts of such work should be cast as against parts made of hammered plates, to find how limited the legitimate use of casting in precious metal was; while, apart from its intrinsic value, the quality of the heavier cast silver and gold work was very inferior to wrought. First among the legitimate uses of cast work was high relief sculptured work, that was, all such parts which would first be modelled in clay or wax, and which, to work by hand, meant a great deal of costly and tedious handwork, and necessitated a number of solder lines. Thus a figure or animal 1 in. high, with legs and arms or wings projecting, would be cast. Secondly, the decorated mouldings with patterns that repeat, and all such parts which offering resistance, required greater thickness of metal than could easily be worked out of sheet-metal. Thirdly, the number of repeating ornaments, perforated borders, and crests, of which a few copies only were required, and which would not justify the engraving of a steel die for stamping. A figure, 18 in. high, however, would rarely be cast, particularly when modelled in high relief. This would be embossed out of thin plate, as a whole or in sections, and soldered together or nailed down to the wooden or other foundation,—a process used by the ancients, and in Byzantine art as well in the present day. Precious metal was never cast in its pure and soft state, but was used in its harder alloys, the composition varying according to the colour and the amount of hardness desired. The process of casting flat work, mouldings, and ornament, was by the sand moulds; that of hollow work, with sand cores and by the wax process. The latter was the better for uniform thickness. By sand moulds the thickness varied greatly, which caused the thicker parts, in cooling, often to fall in, which was very detrimental to the work, and often impossible to correct. Knowing what parts should be cast, the designer would work with great advantage, and in many cases effect an easier and cheaper working. Silver and gold work was not now, he was glad to say, estimated chiefly by its weightiness; the lighter it was, the more carefully it must be made, so as to be strong in all its parts. In designing silver and gold work it must be borne in mind that even plain mouldings did not always turn out satisfactorily in cast work; and that for all better work they were made in flat or turned up in sections of wrought tough metal and joined together. Mouldings suitable for stone or wood should not be introduced. Old work should be examined, much of which was to be found in the museums, and in which it would be found that the mouldings affording the greatest charm were mostly very indistinct and often mere repeti-

ions of lines or combinations of squares and round wires, with now and then a hollow and twisted wire between. The old goldsmiths had no lathes and no machinery; they filed, engraved, watched, or rolled their mouldings; and for tracery work soldered one plate above another, with a round wire sometimes laid over it. Mr. Krall concluded by exhorting designers to study the old work and learn its mysteries, and to let designs be carried out under its influence; then, whether cast or wrought, or made by any other process, the work would give satisfaction, and give delight both in the present and in the future.

Castings in Iron.

Mr. H. Longden read the third paper, on castings in iron. He said that in the usual process of iron-founding, wooden models were made by skilled model-makers, whose training was quite apart from that of a carpenter or cabinet-maker. The sides of the model or any slivered parts must not be square, but slightly "stripped" or bevelled to ease the draught from the sand. The model was laid on a board on the floor of the foundry which was covered with sand, a cast-iron casting box, called the "bottom box," which was put on the board over the model, and the foundry end sifted over the model, first through fine riddles until the whole surface of the model was equally covered with it, and then through a coarser riddle. The sand was carefully and evenly rammed with iron rammers until the box was filled. The whole was then turned over, and the board which was cramped to the box taken off, and the "top box" was put on, and the filling with sand and ramming process was repeated until the model was completely enclosed in evenly, lightly, and yet firmly rammed sand. The making of the channels through which the molten iron was to run into the sand matrice was an important matter, and had to be carefully arranged. The "top box" was then removed and the model taken out, leaving a beautiful impress of the ornament, if any in the sand, which was carefully dusted over with fine-ground charcoal. Where the surface of a casting was to be full of ornament, the model was often put in again and evenly pressed upon the charcoal to give the fine surface seen on good castings; and this must be done with perfect accuracy of register, the slightest inaccuracy blurring the impress. The two boxes were then cramped together again with iron cramp and wedged with wooden edges. Casting with cores was another kind of moulding, and one requiring much skill and patience. If a great number of castings were required, instead of a wooden model cast-iron models were used. Wooden models were sometimes carved, and at others made the groundwork of modelling in wax or in gesso if the effect desired were specially soft. There was also a very pretty process called "reversing" by which a casting may be made from a solid block in plaster or wood. The choice of the iron for castings was an important matter, different mixtures being used for different castings. That of the iron now used was smelted from the ore by "hot-blast," but when great strength and tenacity were wanted the older fashioned "cold-blast" was still utilised. When the iron was melted in the cupola, or furnace, the casting began. The furnace was "tapped" near the bottom with an iron bar, the white hot molten iron ran down a spout prepared for it into ladles of iron protected from being burnt by sand. The ladles were carried by the moulders to the casting boxes and the molten metal poured through the gates or channels into the place prepared for it in the casting boxes. When the iron had been long enough in the ladle to set, the top box was taken off and the casting taken up with the tongs, the loose sand about it removed, the gates knocked off, and it was reared up to cool until the next morning. Cast-iron some time ago had fallen into a certain disrepute; but with the further study of materials it had been found that it had qualities of cheapness and usefulness as well as of reproducing a suitable model with perfect precision and delicacy. In designing for cast-iron, it was to be remembered that when the models were paid for, enrichments cost nothing suitably applied. This facility for ornament, though a temptation to the unwary, in the hands of a master produced fine results. The ornament, if applied, should rarely rise to much relief. A front for a fire must have a due proportion between its parts; the bars must be of the right plan and section; a grating must be evenly in the thickness of the parts; a

casting should not be enclosed with heavy mouldings like a frame; and many other rules, simple and reasonable, could be learnt from any competent founder. Mr. Longden concluded with the opinion that respect for the real conditions of the work to be done, as was always the case, would produce a finer effect than clever *tour-de-force*, such as imitating wrought-iron, stone, or wood in cast-iron.

Castings in Bronze.

This was the subject of the fourth and last paper, read by Mr. Herbert Singer, and of which the following is an abstract:—

The author considered the subject of bronze castings a very wide one; the most ancient metallic objects yet discovered having been made of it. Pure bronze was simply nine parts of copper and one of tin. A vast number of alloys, however, were produced for different purposes, and the Japanese were said to use 200 distinct alloys; delicate colours depending on the alloy used. The author, having referred to the ancient knowledge of the existence of tin in Great Britain, was of opinion that the proportion of five parts copper and one tin was the alloy of the bronze implements of the ancients. It gave a hard substance, but would not suit many of the bronze productions of the present day. The brothers Keller, who worked in France in 1699, used for their alloy 91½ parts of copper, 5½ parts of zinc, 1½ of tin, and 1½ of lead for statuary work; others used only about 82 parts of copper. The sculptors during the Renaissance were often their own founders, and generally used a metal of good quality, in order that their work might not be injured in the casting. Having referred to the alloys of brass and the contraction inevitable in the use of copper, Mr. Singer thought bronze statuary would be a more exact reproduction of the sculptor's model if an alloy similar to bismuth could be found that would give no contraction. If bismuth were not so expensive it could be used with great advantage in the composition of bronze. The subject of alloy led to that of soldering. The Romans had not used solder, but it evidently had been used by the Saxons. The alloy for gold solder was silver, for silver solder silver and brass, and for bronze a mixture with brass made a good solder. The two processes of casting bronze into any required form were known as the "sand" and the "*cire perdue*." The founders of early ages used the wax, or latter process; but it had not been and was not so much practised in France as in Italy, perhaps because a very fine sand could be found near Paris by which the best castings by the "sand" process could be produced. This sand was also much exported, both to England and America. Mr. Singer then proceeded to describe moulding by the sand process. For statues of more than life-size it was necessary to have a lofty foundry in order to raise the large flasks from the pit in which the large pieces of metal were cast. The pit should be at least 12 ft. square and 10 ft. to 12 ft. deep. The flask for a statue 10 ft. in height would weigh 5 tons or 6 tons and should be so constructed of plates that it could be increased or reduced in size to suit the dimensions of the model. The model to be cast being then placed in the flask partly filled with sand, the preparation of the mould was commenced. The making of the mould, which had been well described by Mr. George Simonds as the concave or negative imprint from which the positive or convex imprint was to be obtained, would sometimes take three months, according to the number of pieces. The core had then to be prepared, and was a rough copy in sand of the original model, slightly reduced in size over the whole surface; the difference between the size of the core and the model giving the thickness of the bronze casting. The core was held in place by iron bars so as to leave half an inch of space between the exterior face of the model and the interior face of the mould. The mould and core being thoroughly dried, the flask was then lowered into the pit, and the molten metal run in. The flask, if all had gone well, being unscrewed, and the runners, or channels, which conveyed the metal to different parts of the mould being cut off, there should be but little work to complete the bronze statue. For the "*cire perdue*" or "lost wax" process a very different method was followed. After describing the old process adopted by Cellini of building up the core first, Mr. Singer dealt with the present mode in which the plaster moulder and the bronze founder relieved the sculptor of the mechanical part of the work. The sculptor modelled the work in

clay or wax, the plaster moulder reproducing it in plaster, making probably several copies; one was handed to the bronze founder, whose first duty was to make an exact reproduction in moulder's wax, with a core inside it. He might effect this with a gelatine or a piece-mould,—according to the subject. If a piece-mould, the work was laid down and the lower part covered with clay; upon the upper part the liquid plaster, of the consistency of thick cream, was moulded into appropriate forms fitting together; the whole being protected and kept together by one large outside piece. The upper part being completed, the work was turned over, the clay from the lower part removed, and it was treated in the same way as the upper part. If using gelatine, the moulder covered the work with clay of the thickness the gelatine needed to be, and on the clay he formed two coats of plaster to keep the work steady. The clay was then removed, and the gelatine poured into the place it had occupied,—a mould of gelatine being the result. Having, whether by the piece-mould or gelatine method, obtained a complete mould the moulder formed a core inside it. The mould being taken apart, the core was pared down to allow as much space between it and the mould as the metal should occupy. The mould being put together again with the pared core inside, the wax was poured in, producing an exact reproduction of the original model. The wax was then handed to the sculptor, who removed all seams and generally "touched it up." Being returned to the moulder, he then made the mould to form the metal, which mould was composed of a substance, kept secret by most founders, applied in layers until there was a tolerably thick coating all over the work. A cage made of iron was then formed round the work, and sand rammed between the spaces. The whole being placed in a muffle, the wax was melted by means of gas, the mould thoroughly dried, and, while still hot, taken out of the cage, and, if necessary, placed in an iron flask and the metal poured in. It only remained to open the mould, remove the core, clean the casting, take off the runners, and apply the patina. An eminent sculptor had described the wax method of bronze-founding as an art, the sand as a trade. He (Mr. Singer) considered that an exaggeration. For some work, and where cost was an object, the sand process was the best. For others, especially where casting of the highest excellence was required, the wax process was the one to use.

A discussion followed, in which Messrs. J. M. Brydon, Onslow Ford, George Simonds, Starkie Gardner, G. Aitchison, H. H. Statham, W. White, Sidney Vacher, and H. R. Pinkham took part, and a vote of thanks to the readers of the papers having been carried by acclamation, Mr. Singer and Mr. Alexander Graham replied to some of the points raised in the course of the discussion, of which we will give a summarised report next week.

It was announced that the next meeting of the Institute (which will be a business meeting) will be held on Monday, June 13.

THE ROYAL COMMISSION ON METROPOLITAN WATER-SUPPLY.

THE Commissioners have held three sittings this week, and their inquiries have been mainly on the lines indicated in last week's *Builder*, with respect to the two companies first taken in hand. As the New River and the East London Companies* draw their primary supplies from the Lea, its conservators followed the companies with evidence as to the quantity and quality or purity of the water. The witnesses put forward by other companies were examined upon statements previously sent in by the companies at the request of the Commission. The examination in each case resolved itself into a rigid scrutiny of facts and figures as to present and future sources of supply, storage capacity, areas for filtration, machinery for pumping, actual and prospective supplies in proportion to population, the methods of ascertaining the population, and fixing the average of supply per head per day, and the data for determining the growth of population, the increase in the use of water for baths and closets, the waste by neglect and bad fittings, and the saving to be effected by vigilant inspection under present

* For report of evidence relating to these companies see last week's *Builder*, pp. 418 et seq.

or more stringent regulations. Many questions were put as to what constitutes a house or a supply, and the means of arriving at the average population for each. In some cases the facts which have been ascertained for small areas have been found to concur with the result arrived at by dividing the estimated population by the number of supplies. The estimates taken, it was said, were those of the Registrar-General; and Dr. Ogle thereupon remarked that for the whole of London the Registrar-General uses the figures of the water companies; that there are no census returns of tenements; that a house is not a tenement; and that in one of the Peabody buildings there are 716 tenants. The Chairman of the Commission, Lord Dalfour of Burleigh, appears to regard it as a matter of vital importance to ascertain with all the accuracy possible the actual population of a company's district and the actual supply, so as to test the stated averages of consumption, and in this way to obtain correct data for estimating the probable requirements of the future.

The Lea Conservancy.

The points to which the examination of witnesses was directed were two—the sufficiency of the water to meet the requirements of the navigation and the present demands and any future demand of the water companies; and the pollution or purity of the water. The witnesses were Mr. Geo. Corble, Clerk; Major Flower, Sanitary Engineer; Mr. Joh Child, Engineer; and Mr. Young, Consulting Chemist; who, however, was offered as the witness of the East London Water Company rather than of the Conservancy.

From the evidence of Mr. Corble, it appeared that last year there had been a correspondence between the Conservancy Board and the water companies about the supply of water, and the Board also received complaints from traders of the shortness of water in the lower reaches of the navigation. Only once during last summer was the full quantity of water reserved for the navigation passed down, and on that day the water in the lower reaches was exceptionally low. The Board had at all times to consider their obligations to the water companies, and they never took more water than was necessary for the navigation, nor allowed any to run away that the companies might want. The conservators and the companies accommodated each other on "give and take" principles, and did not enforce legal rights. The Conservancy for a long time was unable to obtain a substantial conviction for the pollution of the river with sewage, because the magistrates leaned to the side of the towmen; but now proceedings could be taken before a county court judge, and that had been done in one case with a good result. There was a diminution in the harge manure trade which was partially diverted to the railway. A good deal of gas lime was brought up the river; and from these there was a little pumping at night time; but the harge owners are prosecuted if they are caught at it. These things are above the East London intake, but below that of the New River.

Major Flower was examined in much detail as to the actual or possible sources of pollution, and he stated how the sewage of many towns and villages was disposed of. He said there was no pollution above Hertford, and at Hertford it was local and did not affect the water at the intakes. It was below the New River intake and fifteen miles above the East London. He had condemned it strongly as "black, filthy, and shining" before the Rivers Pollution Commission in 1886, and the treatment had not altered since. The Conservancy had not remonstrated against the discharge of maiting water. A map exhibited and professing to show "recognised pollutions" represented things unfairly. It was a "most unfair map." There were eighty-seven black dots above the intake of the East London; and he did not recognise them; they did not exist as pollutions, although they might exist as possible sources of pollution, if people neglected their duty. The water of the river was at one time deteriorating, but now it was improving. The valley, and he thought that was due, not to pumping from the chalk, but to the rainfall. He had seen the Lea above Luton so dry that you might put it into a 6-in. pipe. The East London's source of supply was perfectly sound and satisfactory; there was no pollution which affected the company's water. There was prac-

tically no sewage pollution above the New River intake.

Mr. Child was examined as to the records of the flow over Child's Weir, and was desired to give the lowest flows for certain definite limited periods, the chairman remarking that, whilst there was doubt about averages, there was none about a minimum. Excepting at Ware, below the junction of the Mainfold ditch, he had never observed any signs of sewage contamination. His analysis of various samples did not indicate any serious pollution of such a character. There was some evidence of slight contamination by organic matter of vegetable origin in some places from the Stort, the Ash, and the Lea, above Hertford, and this was accounted for by the fact that the rivers were there very full of vegetation. Immediately below the Ware Mill Lock, and for some distance further down, the Lea, especially in hot weather, presented every appearance of sewage pollution. The water was dark, and had an offensive odour, and there were many pieces of black, slimy substance seen floating on the surface. This was caused by the discharge of the effluent from the Hertford sewage works into the Mainfold ditch, which joined the river Lea just below the Ware Mill Lock. The effluent from these works was extremely weak in sewage matter, and the effect upon the appearance of the river was much worse than would be expected. He had no doubt that this was due to the development of sewage fungus in the cutting which conveyed the effluent from the works to the ditch. This growth appeared to possess the property of absorbing the albuminous matter, and also the chlorides and other inorganic matter from the effluent, and of giving them up to the water when decomposing or distilled. Its decomposition was also accompanied by the formation of sulphuretted hydrogen and sulphide of iron, which produced the unpleasant odour and dark colour of the water. The black, slimy mass found floating on the river below the Mainfold Ditch was this fungus in a decomposed state. Analysis of the water from above and below the ditch showed the effect of the sewage effluent, and this, although generally slight, was unmistakable. The point below the ditch at which the samples were taken was not in the main stream of the river, but in a practically stagnant pool. Lower down the river, below the junction with the main stream, nearly all trace of the pollution was lost. He was of opinion that although this pollution was objectionable locally, it did not affect the quality, as regarded the quantity of organic matter present, of the water of the river at the intake of the East London Company at Pondersend. In 1891 he made analyses of samples of water taken above and below each tributary or probable source of pollution to ascertain the condition of the water of the Lea as regarded the quantity of organic matter in solution. The results showed that the river was at the time in a remarkably pure condition, that the tributaries did not add to the amount of organic matter, that no appreciable pollution reached the river from the sewage farms, and that the water at the intakes contained less organic matter than the water at the sources of the Lea and the New River. He had no hesitation in saying that the water at the East London intake had improved of late years, and that throughout the year it was generally of excellent quality as regarded freedom from organic matter. In April of this year he had made a series of analyses which showed that there was a sudden increase of organic matter in the water below the junction of the river Stort, but it was of vegetable origin, and of no importance, and the amount gradually diminished until at the East London intake it was little more than one-third of a grain per gallon, which was appreciably less than in 1891. On both occasions the weather had been fine and dry for about three weeks before the samples were taken. The analyses, therefore, showed the normal condition of the water when unaffected by floods; and they conclusively proved, by the small quantity of organic matter present in solution, the excellence of the water as a source of public supply. He had also analysed samples of water after filtration and samples of that from the well, and submitted the detailed results.

The witness was examined, or rather cross-examined, at considerable length as to the time and manner of the selection of the samples, and also as to analytical tests. His theory as

to the action of the fungus was founded upon actual experiment; but for a long time it was a puzzle to him. He did not think there was a process known which would remove soluble organic matter; and it was this which promoted the growth of the sewage fungus. He had not heard of the sewage fungus anywhere else. It improved the water up to a certain point, and then polluted it. Asked to explain the statement that other analyses showed the East London water to contain on the average 50 per cent. more organic matter than the New River, he said he did not believe it was so.

The West Middlesex Company.

The statement submitted by this company gave a history of the undertaking from the incorporation of the company in 1806, and a description of the works. The twenty-first paragraph was as follows:—

"In 1886 an agreement was made with the Thames Conservancy by which, in consideration of a further payment of 1,000*l.* per annum, they granted the company permission to take from the river a daily quantity of 4½ million gallons in addition to the 20 millions now allowed to be taken under the original agreement with the City Corporation, whose duties in this respect were afterwards transferred to the Thames Conservators."

The intake of the Company is at Hampton, from the Thames, and the water gravitates from the river to the engine wells through two 48-in. cast-iron pipes. Here are three engines and eleven boilers; the engines are capable of pumping 59,750,000 gallons in twenty-four hours. The engines pump the water into the reservoirs at Barnes, a distance of eight miles and a half, through two 36-in. mains. At Barnes there are four reservoirs capable of storing 117,500,000 gallons. The water is admitted at one end of the reservoir, and drawn off at the other, so as to allow as long a time as possible for subsidence. There is a filtering area capable of dealing with 39,000,000 gallons in twenty-four hours, taking the rate of filtration at 2½ gallons per square foot per hour. The filtered water is conveyed to the engine wells at Hammersmith by gravitation through two 36-in. cast-iron pipes laid in the bed of the river. At Hammersmith there are ten engines, with thirty-two boilers, and 35,877,280 gallons can be supplied in twenty-four hours. All these engines pump against an average head of 175 ft. during the day and 195 ft. at night. There are four service reservoirs.—Campden-hill, Kensington; Barrow-hill, by Primrose-hill; Harlesden-lane, Willesden; and Platt's-lane, Kildespond, by Finchley-road,—with an aggregate capacity of 13,422,000 gallons. At Barrow-hill, three pumping engines, with eight boilers, raise the water to Kildespond reservoir, and can pump 5,175,000 gallons in twenty-four hours, pumping against a maximum head of 150 ft. The works occupy over 96 acres of land, and the Company has over 7 acres of spare land.

The number of "supplies" in 1891 was 74,482, being an increase of 49,284 since 1851. The additions in periods of five years, going backwards, had been 6,702, 10,191, 9,471, 5,992, 5,885, 5,135, 2,998, and 3,000. In periods of ten years, going backwards, the additions had been 16,893, 15,373, 11,020, and 5,998. The most important paragraphs in the statement are those which relate to the estimate of increased supply required in forty years' time. The directors say that, although they have always endeavoured, and with success, to anticipate and provide for the requirements of the future, they have not, until requested by the Commission, turned their attention to the question of what their policy would be at such a distant period as forty years hence. They claim indulgence "when attempting, in the short time allowed, to answer a question such as no municipal authority or board of directors would think of dealing with without much more consideration and assistance." They add that there are in the Company's district 5,820 acres outside the Metropolitan area, which may at some future time be built over; but it is considered that there is not any probability of more than half this space being covered within the next forty years. This 2,910 acres, with an average of twelve houses to an acre, would give 34,920 houses. Over the Company's district, including Marylebone and parts of St. Pancras and Paddington, the present average is 7½ persons per house. The following is a tabular synopsis of the figures and estimates given. The estimates (a) are based on the

assumption that half the area outside the Metropolis will be covered in forty years. The estimates (b) are based on the assumption that the same increase that has taken place since 1851 will continue for the next forty years:—

	1891.	40 years.	1931.
Houses	74,482 +	34,920 =	109,402 (a)
	74,482 +	49,284 =	123,766 (b)
Population...	577,235 +	270,630 =	847,865 (a)
	577,235 +	381,952 =	959,187 (b)

Supply per head per day last year... 29 gallons.
Average, last ten years..... 27 6/8 "

	Persons.	Gallons.
(a) 847,865 at 29 gallons =	24,588,000	
" " " 28 " =	23,740,000	
(b) 959,187 " 29 " =	27,816,433	
" " " 28 " =	26,857,236	

Daily quantity now authorised... 24,500,000

The directors think it not improbable that they may, by negotiation with another company, acquire a part of the unauthorised right as authorised by the Thames Conservancy Act of 1878; and, in addition, they are advised by expert engineers and other scientific authorities that a much greater quantity than that now authorised could be taken from the Thames, even at times of exceptional drought, without involving the necessity of any additional provision for storage by the companies, and without injury to any interest. The directors further think that by constructing reservoirs when required by the increased demand, double the quantity might be taken without reducing the flow of the river more than has already been done and without affecting any water level that may be thought desirable by the Thames Conservators or other authority, and the supply thus taken would be free from the objections which might be urged against water taken in times of flood. The directors are also advised that an enormous quantity can be derived from wells sunk in the chalk area, the water from which now finds its way direct to the sea, and that a large supply may also be obtained from the gravel beds.

The witnesses examined on behalf of the West Middlesex Company were Sir W. H. Wyatt, Chairman, Mr. Harvey, Mr. Wybroo, and Mr. Willis. Mr. Harvey estimated the storage capacity at 8 1/2 days' consumption; the Chairman called it 7 1/2 days, making certain allowances. As to organic impurity, the water was 30 per cent. better than it was in 1868. Mr. Wybroo said the number of supplies increased from 1880 to 1884, when building speculation was at its height; but since then the rate of increase had fallen, and last year it was lower than in any of ten years following 1876.

We will next week continue our report of the evidence.

Now that the question of London water supply is engaging so much attention, Mr. Edward Stanford, of Cockspur-street, Charing-Cross, has very opportunely issued a "Water Supply Map of the County of London," showing the boundary of the jurisdiction of the London County Council, and the areas supplied within the county by the various water companies, distinguishing the areas under constant supply. The map will be found very useful in following the proceedings of the Royal Commission.

THE RELATION OF THE ARCHITECT TO THE WORKMAN.

AS ILLUSTRATED BY THE WORK AND METHODS OF THE GUILD AND SCHOOL OF HANDICRAFT.*

You have asked me to speak to you on some subject bearing on the practical work which, as an architect, I am engaged in, and to illustrate it, if possible, by reference to the actual processes of production followed in the carrying out of this work.

So I have chosen as my title "The Relation of the Architect to the Workman," and shall try and give you a few ideas that I have sought to work upon now for some years, and such insight as I am able to upon this theme, illustrating it not so much by actual instances of work produced, as by description and explanation of the system of work that has made this production thus far possible, and would seem to tend to its further encouragement.

I shall arrange my subject broadly, therefore,

* A paper read on the 27th ult. before the Architectural Association by Mr. C. R. Ashbee, M.A., as elsewhere mentioned.

under two heads, the first more theoretical, the second, inasmuch as it is intended to illustrate the first, of a more practical character, and having definite application to such materials as it would seem convenient in the course of a brief hour to touch upon.

On the threshold of my subject, I would say that this relation of the architect to the workman, the right understanding of it and its application to one's work as an artist, seems to me to be the most important part of that larger subject often called "The Relation of Architecture to Life." I suppose to most of us here, the relation of architecture to life is a question fraught with meaning in more senses than the narrow one of our own bread-and-butter; but I would challenge each one of you to put his interpretation on the question, and to ask himself what it actually means to him in the everyday humdrum of things. How he feels it; whether in the multitude of great architectural work, whether in the poverty of good building, whether in the absence of style, whether in the eclecticism of choice, whether in his dealings with clients, with builders, with workmen, or how? How as an English architect, and as a private individual?

For my part, I think the relation of architecture to life in modern times cannot but be regarded but as of the slightest. To *our* life, as architects, it means much, and always will; to *our* life as a nation it means little,—unfortunately for us. As a nation, we have small sympathy for, and scarce any understanding of, architecture, and what sympathy and understanding there is, is limited to a few in the profession and their supporters. As a nation, we love *show* and *vulgarity*, with its concomitant, cheapness; we love poverty of construction and its symbol, the iron girder; we love *luxury* and its resultant, the ill-considered moulding. We have not the great sympathy which could build the cathedral and forget the name of the architect; or the great power of reserve that could leave, in the consciousness of their harmonious development, the hundred details of the building to the craftsman. Architecture is no longer democratic, no longer understood of the people: it has lost its corporate significance. As a nation, we do not love architecture; we are content to let our mouldings be struck with compasses, and our subtle details be evolved by the office-youth; and we firmly believe, that when the assessor of the Royal Institute of British Architects has told us, or our representatives, the local committee, that this set of plans is the best we can possibly expect for the money, that it is good architecture we have got, and we thereupon proceed to what is called "merge the premium in the percentage."

I was comparing lately the conditions of some recent modern competition clauses, and the ethical frame of the English mind which these portrayed, with the document issued by the Florentines for the rebuilding of their cathedral in the year 1294. The British parallel, as it is familiar to most of you, I shall not give; the Florentine being less so, I will give you a portion of it. Here is the key-note of it:—

"Since the highest mark of prudence in a people of noble origin is to proceed in the management of their affairs so that their magnanimity and wisdom may be evinced in their outward acts, we order Arnolfo, Head Master of our Commune, to make a design for the renovation of Santa Reparata in a style of magnificence which neither the industry nor the power of man can surpass, that it may harmonise with the opinion of many wise persons in this city and state, who think that this Commune should not engage in any enterprise unless its intention be to make the result correspond to that noblest sort of heart which is composed of the united will of many citizens."

It was this "united will," this "noblest sort of heart," which those old hughers felt could only be expressed by Architecture,—the mother art. It seems somewhat of a mockery to speak of Architecture as actually being the mother art nowadays. Look at the walls of the Royal Academy at this moment,—is it true? Look at Gower-street,—is it true? Look at Greater London, "the desert of London town, grey miles long," "the desert of London town, mirk miles broad,"—is it true? Look at the public-house, the restaurant, the Nonconformist chapel, the average shop, the sunbath villa, the Board school, the railway junction, the pit village, the factory town, and ask again,—is it true? When that phrase was invented, building and architecture were synonymous terms; we draw a subtle distinction, and say with truth, *Yes*, those he buildings: what we wish to deal with is architecture,—the art of the Chief Builder,—*αρχι τεχτων*,—the essence of building.

Possibly what we say is true in a double sense, but the truth is a bitter one.

Now, I do not say these things as a tirade at existing circumstances. Trades are futile and unnecessary to us as practical men, but I say them in order to point at ways that, by the energy mainly of the young architect, may be bettered, and at facts existing in modern life which, if rightly understood by him, will give him the opportunity of bettering them. Having spoken therefore of the national sympathy for architecture, I now regard the architect in his relation to existing things.

To me it seems that this divorce of architecture from the national life leaves its mark on him, and injuriously. He is not, if I may say so, and using the expression in the largest sense, sufficiently educated, not sufficiently,—if one may put it in the famous term of the Italian Renaissance,—humanist. His scope and sympathies in the first place are not wide enough, and then his technical training is not sufficiently all embracing. He finds that his "profession" or "art,"—I use either word,—is only becoming recognised as one of the polite arts or professions. It does not stand by the law, or the work of the doctor, or the schoolmaster, or the many services of the State, or the University in the public eye. Its position is doubtful, and it ministers in the main to the private comfort of wealthy men, not to the common heart of a great people.

As regards his method of work, he feels himself but a link in the productive chain. He sits in his office and makes designs, and he has a connexion through specifications with contractors who carry them out; and he frequently anathematises a man of straw, who is known to him under the name of "The British Working-man," when they are not carried out properly. My contention is, therefore, that the architect as yet is not sufficiently educated in his relation to the "body social." It is, perhaps, unfair to say that he is (in a non-political sense) too conservative, but he has not that wide training in life which should make him sympathise with the greater movements of his time. His training is a narrow one, in the four walls of an office. He does not touch life directly, as the doctor or the clergyman; he does not get glimpses into men and manners like the lawyer.

Here, then, we ask ourselves, if this be true, how can it be best remedied? And we are brought face to face with the question of the relation of the architect and the workman. The architect has to understand his position as a workman in relation to other workmen; more than this, he has to feel his responsibilities in organising and directing their work; and more than that still, he should feel some direct responsibilities likewise in training and educating them. Thus only will he deserve his title as architect or chief builder.

I will return to the consideration of this directly in detail, staying for a moment to consider the question in its bearing on a question very dear to all of us,—*style*, the language of architecture. The architects of the later nineteenth century have settled the question of style; they have almost ceased to dogmatise; the Battle of the Styles has been fought out, and a rough-and-ready compromise has been made between eclecticism and originality. That is style in its external sense; but I believe we have gone deeper: the inner question of the origin of style is what we have now to solve. The origin of style lies not in the theories, not in the forms of art, but in the social relations of men to men, in their state of society, in their habitude to one another, in the leisure they may have for the thinking out of problems and the creation of forms. In short, the origin of style is a social, not an artistic question. The question of style, therefore, is solving itself for the young architect, and will do so more and more as he grasps his relationship to the workman and the body social.

I repeat, then, that the young architect has to feel that he is a workman in a privileged position, in the position of giving other workmen their line of work. He is to be the "chief master of our Commune;" to fulfil this high function rightly he must come into close and direct relationship with his fellows in every possible way.

Barry, I believe, once suggested that it would be a good thing for an architect with capital to invest it in building operations, and such work as might be in connexion with architecture. That suggestion was a very wise and far-seeing one. Barry's age was, perhaps, not fully ready

for it, but it has been and is being at the present day acted upon by architects in various ways. Regarding capital as the force that binds workmen together, regarding also the other great cohesive forces which were undiscernible to Barry,—the workmen's movements, &c., which are tending to a reconstruction of industry at the present day; regarding also the advisability, nay, necessity, of commencing (especially for the young architect) in the *ministering arts, the crafts*, in other words, rather than in the mother art direct; and regarding in the last instance the necessity of the frank recognition of the architect's connexion with industry, Barry's suggestion, which implies the closer union of the architect to the body social, we might all set before us.

But I would give this suggestion more definiteness, and at the same time limit it. I would like to see applied to it the system of the old Craft Guild; or such conditions as were possible of a society that produced the greatest architecture of all time. In this society we find the right relation,—a more human relation between the architect and the workman.

Now, it seems to me that there are three ways in which we are approximating to what was good in the old system. Three phases of modern developments which it behoves especially younger men to study, and which all of them comprehend,—this better relation of architect and workman upon which I would seek to fix your attention to-night. These three things I might term "Craft-Guild, Potentialities," and they may be distinguished as follows: There is—

1. The existing connexion of architects with trade for artistic purposes.
2. The workmen's movements that are daily convulsing industry.
3. The educational movement that is making progress with rapid strides.

I will take them in order.

First of all, the existing connexion of architects with trade for artistic purposes,—the architect and the shop, let us call it. In the relation of the architect to tradesmen we see these guild potentialities. We see it among the men employed by some of the leading architects,—his builders, his furniture makers, his painters, and so forth. I will put it plainer. In some cases the architect is in a position in which he can place his building with a particular builder with whom he has worked for years; or, if the contract is to be competed for, he can limit it to some three or four of those who have worked for him and whom he can trust. In this the guild element enters. In some cases an architect, or group of architects, support a business in which stuffs, or furniture, or materials are produced specially from their designs, and to serve the purpose of their buildings. I use the word *support* advisedly, for, if their work is conscientiously done, more money of theirs goes into these businesses than ever comes out of them. Here, again, the guild element enters. In some cases, again, the leading architects attract round them various small workmen,—painters, carvers, sculptors, ironworkers,—men of some special ability, whom they have met with in the course of their professional experience, and to whom they continue to give small jobs in one or other of their works. Here, above all, the guild element enters because of the educational element, and because there is a constant and direct relationship between the employing architect and the producing craftsman.

Now, it seems to me that we younger men have to take up this side of the professional tradition, one might almost call it, and develop it. Here is a portion of our heritage that is worth having; in this there lies a future.

We should get into closer touch with our builders, our carvers, our decorators. We should welcome, instead of glancing at them with the eye of false shame, the efforts of artistic agencies of the shop; and, above all, we should unite to us a body of men,—young men, if possible,—who are capable of ministering to the various crafts dependent upon architecture.

The step from this to the completed Craft Guild is a social one, and one that time must bring. The atoms at present are distributed, but the personality of the architect should unite them. Their interests, at present, are discordant. A loses what B gains; the architect has it in his power to make them harmonious by uniting them with him. Their training at present is incomplete, and each, if left to himself,

would ruin the ensemble; the architect, as having the grasp of the whole, has it in his power to teach, and to so give each his place that left to himself he shall be trusted to understand his own limitation. I am a painter, and must feel the relation of these reds to the whole scheme of colour; I am a joiner, and must understand that this panelling must range with the architectural treatment of the frieze and cornice; and so forth.

I should be as opposed as any man to the idea that the architect should be connected in any way with trade or with dealing, or should receive any remuneration other than that professionally established for professional services, or for purely artistic work of his own hands in connexion with it; but inasmuch as the architect's work is productive, so he should be in immediate touch with production: but I hold that an architect should have a workshop at his back and come into constant relation with a body of men in various crafts educated with and by him.

2.—Then we come to the next point,—the workmen's movements,—the great underlying questions of the development of industry, its re-organisation, the evolution of co-operation and co-operative societies,—(a purely Medieval repetition in many respects). These things the young architect should study, and should learn to make use of and not to shun.

The real interests of the day are, and probably will be for the next decade or so, social: not political, not artistic, not directly educational. I hold it the duty of the young architect, if he wishes to get more into touch with life, to learn to take an intelligent interest in these workmen's movements. The knowledge or interest of the architect in them at present is often limited to the "strike clause" in the contract. I know it is the opinion of many artists, professional men of standing, that the art may take care of itself, that social questions and ethics have no place whatever in art; and they accept the teaching of what may be called the reaction,—an inevitable one,—to the doctrines of John Ruskin. They hold that all the architect should care about is the final work produced. Does it or does it not conform to his design,—no matter how it has been produced? This may be right enough for the landscape painter or the artistic antiquarian, but I hold it to be absolutely and fundamentally false for the architect. I insist that the architect is in the position of the highest producer, and so should he bear the responsibility of the highest production.

He should study it, get to see its bearing on his work and those that work under him; he should seek to unite them co-operatively as producers, and without middlemen between them and him. There is nothing so painfully instructive to one as reading the habitual tone of scornful unsympathy expressed by the leading building papers whenever a question relating to workmen's movements, strikes, and industrial struggles come forward. These papers, presumably, express professional opinion, but they are unreservedly biased in favour of the employer as against the employed. It is for the young architect to study better these relations of capital and labour. If he does, he will see that there is no real antagonism between capital and labour: that the apparent antagonism of the present day is in the first instance, one in the *degree of remuneration for services*; in the second instance, in the *degree of control* between master and men.

3. Now to my last factor in modern movements, to which also lie guild potentialities,—the educational developments. The old apprenticeship system is dying out. It still remains in a somewhat unsatisfactory condition in architecture; and in such crafts as book-binding, that have in them some of the old-world element undestroyed by the machine, where the hand still holds, and which have not yet quite sunk into the slough of industrial despond; but for the most part it is finished. Side by side with it we see a new growth,—the technical school, which is even offering to take its place.

But the technical school never has taken and never can take its place. The technical school must be either a combination of primary education, as in the case of the Welsh intermediate schools, and so aim at the more harmonious education of the child; or be a continuation of the work in life, as is the case with such classes at polytechnics and technical institutes which seek something other than merely to "gild the leisure of the clerk." It can

never, as far as we can at present see, teach the actual trade itself as an apprentice should learn it; and certainly, according to the Technical Education Act, it may not even profess to teach it.

Edward Bellamy, in his "Looking Backward," made the trenchant statement that, in the new state, a new force must take the place of the "master's eye" of the old trade system. This new force was "the perfectness of the organisation." I would accept this entirely, insisting only that perfectness of organisation comprises "humanism."

Now, with the apprenticeship system dying, with the technical schools admittedly not fulfilling requiring conditions, and with the organisation of industry imperfect, what is the educational outlook, as far as the architect is concerned? We have, it seems to me, to recognise that the apprenticeship system, regarded educationally, has been destroyed by subdivision of labour, and it is this subdivision of labour that we architects have to grapple with, and that we, by virtue of our position, can be of service in. We must help in the educational side of that re-organisation of industry that is taking its place, not only in our own immediate art, but in all the handicrafts subordinate.

I would urge you all to consider how far it is not within the scope of the profession, by entering more into the study of the crafts, by approaching more the men in their movements, by working more in workshops and less in offices, to supply somewhat that which is wanted educationally, to enter into this educational movement in its humanist and its technical side which we see going on in all hands. You yourselves are entering into it in a most excellent manner at the Architectural Association; it is being taken up by the County Councils in most parts of the kingdom; and it may be said to be living, from the Universities down to the Board Schools. We architects should take it up for the future of the profession and all that depends on it.

I have now indicated the three main lines in which it would seem to me that in dealing with the question of the relation of the architect to the workman we younger men, having in mind the greater and more comprehensive development of the profession, have to look,—its development, in fact, more in conformity with the ways and methods of the Medieval guild. Let me now sum up the position of the architect as I conceive it should be, in his relation to the workman,—an architect's ideal, if I may be allowed the term.

We should, in the first place, then, regard ourselves more as workmen on whom fall the duties of production and of organisation, and less as gentlemen of the office. As far as our own training goes, we should draw as little as possible, but with our hands work as much as possible; or, rather, I should say, we should seek to express our detail designs as much as possible in *actual material* and not on paper,—that is to say, in the workshop. Working thus in the workshop, we should grow into the sympathies of the workshop, and then seek to develop our position as organisers and employers of industry. We should train up a body of men with us; it is only by educating workmen in architectural principles, and ourselves in the relation of the handicrafts to our work, that style,—real living style,—not the shell of it in a modern Gothic church or Queen Anne mansion,—can come. At present we act as a disintegrating force, and tend to keep the craftsmen asunder. We have sense enough to see that we can get better work from them when they act as units than when they are under the control of a contractor or a big firm. It should be our effort to secure the advantages of freedom and spontaneity of work which a guild system would give without losing those advantages of business method and order which the present system ensures. We ought, in fact, not to use a good craftsman as an artistic convenience, as we are tempted to do at present; but we should hold him, hand him to us,—as it were, take him into partnership with us,—and so take more responsibility for the *man* and less responsibility for the *work*. By so doing we shall avoid that waste which at the present day always tends to convert the good craftsman into the had employer of labour. The architect, more than any other person, has the blame of this; the architect, more than any other, ought to strive to prevent it.

It is not for me to pretend to lay down any

system that shall even pretend to meet those difficulties, I merely say that some efforts at reorganising of industry, in so far as it affects architecture, on the principles of the Craft Guild, seem to me to be the right ones; and that the ideas which I have endeavoured to set before you contain the main principles that have guided my own creative work in the Guild and School of Handicraft since I took my degree and served my apprenticeship. I will now give you, in a few words, the method and system of the creative and educational work of the Guild and School, in which, if nothing else has been done, at least we have made an attempt to establish a more healthy relation between the workman and the architect.

That closes the more theoretical part of my subject, and I should now like to sketch out for you, in a few words, what the ways and methods of the Guild and School of Handicraft are. You must understand that this Guild and School is not a thing that has been suddenly created in a doctrinaire manner. It has grown up in a perfectly harmonious and gradual way in the course of a short period of time—five years, though. But its growth claims to be spontaneous. It was not pre-conceived as a system, and then established in the manner that Rousseau and reformers of his type would seek to establish a thing; but it has grown up by two or three men coming to work and read together, and then, feeling that they had to make their work a little more practical, taking up work with their hands. That has led to the establishment of the *School* on the one hand, and the *Guild* or workshop on the other. The Guild and School, therefore, has two distinct parts: first it is a productive workshop, conducted on the lines of an industrial partnership, in the same way as some of the northern co-operative societies are conducted,—such, for instance, as the Woodhouse Mills in Huddersfield; secondly, it is a school in which are trained workmen,—men and boys,—who are still at work at home. We also train elementary teachers in various forms of handicraft. We therefore consider that we have two lines of teaching going on in the school: one where the young artisan is taught, and the other where the elementary teacher is taught,—that is, the teacher who is going to teach the artisan of the future. Of course, the school is and always must remain a small concern, and we regard it as a hunting-ground for our future artisans. We entirely disapprove of the sale of anything in the nature of school-work. We consider that that is wrong. It is, I know, being done all over the country. But we hold that no school-work must be sold; that the school is educational, and must not be regarded as directly productive in any sense whatever. The result is, we give vigour to our workshop. It is in the workshop where the Guild is established, and it is in the workshop where we carry on the training of the apprentice when he passes out of the school. When he is bound apprentice he is bound to the society as a corporate body. He is taught his trade, or craft, in the production of work of which I have brought a few specimens for you this evening. I have not been able to bring any specimens of work which bear more particularly upon architecture, because one cannot bring in a chair, panelling of rooms, or other large and important pieces of work relating to building. I have brought some specimens of leather work; one little specimen of woodwork treated with *gesso*; some specimens of hammered copper, specimens of hammered gold and silver work, castings, metal turning, hammered hollow-ware, &c. There are also two printed volumes: one, the Transactions of the Guild and School, which contain addresses by many eminent artists, delivered at our workshop, and taken down by a reporter and thus preserved; the other is the Manual of the Guild and School of Handicraft, published three days ago, which contains the latest expression of our work. I have brought copies of each of these books, and I should like to be allowed to present them to the Association. As regards the way in which we work, however, the Guild has as yet no place where it exhibits or displays its things, and the reason is that the workmen of the Guild are anxious, in the way I have mentioned in the theoretical part of my paper, to work with architects. Therefore, the bulk of the work which is done there is done in connexion with architects, who come and visit the workshop and talk with the men. Of course, most of my own work goes there, and it is always a

delight for me to see the whole thing, from top to bottom, if I can possibly manage it, passing through the Guild workshop, because one feels that one has there men whom one has trained up into an understanding of their craft and of the right treatment of materials. Therefore, there is always going on a good deal of work which is either architectural work or work for architects. As regards the place itself, I can only say that I hope you will come and pay it a visit, and see it for yourselves. We have got an old eighteenth-century house, built by Gibbs, that we have had our eye upon for many years. It was formerly in a park by itself, but it is now built round, although it has a nice garden at the back. We have laid out a lawn and have built our workshops along the lawn; and there is thus always a pleasant outlook, and the work is, therefore, done under better conditions than usually prevail in a London workshop. I shall now be very happy to answer any questions which you may care to put to me about any of the processes in detail, but I refrain from going into a practical description of these processes for fear of wearying you with technicalities. In conclusion, I would only repeat my invitation to you to come and see the place for yourselves, and not only I, but all my colleagues, will be only too happy to welcome you.

[An interesting discussion ensued, the speakers being Messrs. H. O. Cresswell, Leonard Stokes, Sidney Vacher, E. W. Monntford, A. E. Bartlett, Sidney Tugwell, and the Chairman, and Mr. Ashbee replied to some of the points raised. We are obliged to defer our report of the discussion until next week.]

THE LONDON COUNTY COUNCIL.

The "Rate of Wages and Hours Clause" in Contracts.—A special meeting of this Council was held on Friday, the 27th ult., to consider this subject, which was adjourned from the previous meeting of the Council, as mentioned by us last week. The following motion, it will be remembered, had been moved by Mr. John Burns:—

"That all contractors be compelled to sign a declaration that they pay the trade union rates of wages, and observe the hours of labour and conditions recognised by the London trades unions, and that the hours and wages be inserted in and form part of the contract by way of schedule, and that penalties be enforced for any breach of agreement."

Mr. Beachcroft asked whether counsel's opinion had been taken as to the legality of the stipulations proposed, in the event of the motion, or its substance, being carried.

The Chairman (Lord Rosebery), in reply, said that the questions had been submitted to an eminent counsel, Mr. Meadows White, Q.C., who had given an opinion, in which he said:—

"I may say generally that I do not see anything in stipulations defining the *minimum* of wages or the *maximum* of hours which would be held contrary to law or so far opposed to public policy as to be illegal."

This case is, I think, without precedent. The subject is therefore not free from doubt, but I am of opinion, on the whole, that a clause could be framed so as to secure the right to liquidated damages for breach of such stipulations. . . . I should advise that liquidated damage should be specially stipulated for in each case, and that it would not be prudent to rely on a general stipulation applicable to all the stipulations in the contract. There would be nothing contrary to law in a stipulation entitling the Council in the event of breach to determine the contract, but, of course, such a stipulation would be subject to the usual incidents of forfeiture clause, and I think that a provision that the Council might themselves pay to workmen underpaid or not paid according to the terms of the stipulation and recover or deduct the amount would be valid. . . . It would avoid many difficulties if a schedule of wages could be agreed upon, framed on the proposed principle, or that reference could be made to some authority or existing scale of wages, rather than to leave the language indefinite."

Sir Thomas Farrer moved, as an amendment to the motion, to omit the word "London," and to insert after the words "trades unions," the words, "in the place or places where the contract is to be executed." He said as Mr. Burns's motion stood, and according to the construction put upon it, there could be no doubt that they would be compelled to apply London trade union rates and rules to the country contracts. That seemed to him to be a most objectionable thing to do. Mr. Burns proposed by his resolution to prevent Londoners getting the benefit of the cheaper labour in the country. Another important aspect of the question was that the adoption of the resolution would keep country contractors from tendering. That

meant they were going to exclude country contractors and country workmen from London work. (Mr. Burns: Why not?) Because it would be setting one class of workmen against another.

Lord Monkswell pointed out the impracticability of London rates and conditions of labour being imposed all over the country. The contractor would rather let his men work in the country, and they in London did not wish them to crowd up London. Many people would be put to great inconvenience for no reason. He also objected because the local workmen who might still be employed outside London would be made into a privileged class who would receive higher wages than their fellow workmen working for the local needs only.

After a long discussion, in the course of which Mr. Burns's motion was strongly supported by Mr. Martineau, Chairman of the Asylms Committee, and other speakers, on the ground that it would result in good work and so be productive of true economy, the amendment was carried by a majority of 10, sixty voting for it and fifty against.

Mr. Costelloe and Mr. H. P. Harris moved further amendments, which were negatived, and eventually Mr. Burns's motion as amended was agreed to, and it was resolved that it should be referred to a Special Committee to consider how best to give effect to the resolution. It was also agreed to refer the following proposed additions to the resolution standing in the name of Mr. Stockbridge on the agenda paper, viz.:—

(1.) Should any workman in the employment of the contractor be not paid the schedule wages then the Council shall be at liberty to deduct from the money payable to the contractor under the contract a sum equal to double the amount of such deficiency, and the Council shall be at liberty out of such sums so deducted, to pay the contractor's workman any deficiency in their proper wages, for the whole of the past term of the contract.

2. The contractor shall undertake to keep proper time books and wages books in connexion with the contract work, and such books shall at all times be open to the inspection of such person or persons as may be appointed by the Council for this purpose, and the contractor shall, under a penalty, be bound to make and deliver to the Council, whenever required, a declaration that the hours and wages set out in the time and wages books are correct, and that he has paid the several sums charged therein.

Mr. Leon had given notice to add to the resolution the words:—

"But London rate of wages shall be paid by every contractor to all workmen employed on any London County Council work within twenty miles of London."

He asked that these words should also be referred to the committee, and the suggestion was adopted.

The Council then adjourned.

At the ordinary weekly meeting of the Council on Tuesday last, Lord Rosebery presiding, there was little business of special interest to our readers, except the nomination of the Special Committee on Contracts to consider the foregoing matter. It was resolved that the following members should constitute the Committee, viz., Messrs. Hood Barrs, Branch, Burns, C. Harrison, Lyon, Roberts, and H. R. Taylor.

After transacting other business, the Council adjourned over the Whitsun recess.

BUILDERS' BENEVOLENT INSTITUTION: ELECTION OF PENSIONERS.

The seventy-sixth election of pensioners in connexion with this Institution took place on Thursday, the 26th ult., Mr. B. E. Nightingale, President, in the chair.

There were six candidates,—two men and four women,—and there were vacancies for one man and one woman.

The successful candidates were William Rowland, 579 votes, first application; and Margaret A. Richardson, 3,626 votes, being her seventh application.

Votes of thanks were given to the scrutineers (Messrs. T. Stilling and T. F. Rider), and to the President, and the meeting terminated.

DISSOLUTION OF PARTNERSHIP.—Messrs. Tolley & Son, architects and surveyors, 86, Cannon-street, inform us that they have dissolved partnership by mutual consent as from March 25 last. Mr. Tolley retires from practice, and Mr. James Tolley, jun., will carry on the business under the old style of "Tolley & Son." Mr. Tolley retains his appointment as District Surveyor for Sydenham.

OXFORD CATHEDRAL.*

SERVING both as the Cathedral of the diocese and as the Chapel of the College, Christchurch Cathedral holds a unique position amongst our episcopal buildings. The changes it has undergone since its foundation have each left their mark on the fabric, and lend a large amount of interest to its plan and detail, and give a fairly clear record of its gradual development from early times to the present.

In dimensions, it is the smallest of our cathedrals, its total internal length, with the modern bay added to the nave, being but 175 ft. Its position, too, well set back from all the principal approaches, and much hidden by the great buildings of Wolsley's College, deprive it of that importance and dignity which is generally associated with a cathedral church. But it possesses a picturesqueness quite its own, and the peculiar form which the plan takes east of the crossing is a point of great interest,—an interest which is increased in the light of recent discoveries. With the exception of the west walk of the cloister and three western bays of the nave, the church remains much as it was at the Dissolution. The monastic buildings have necessarily fared worse, as they were, with the exception of the refectory and the Chapter-house, destroyed to make room for Wolsley's new works.

Founded originally in the beginning of the eighth century by King Didan, and existing as a nunnery under his daughter, Frideswide, it was, three centuries after, converted into a monastery of Secular Canons, and later of Canons Regular of St. Augustine, and so remained until the sixteenth century, when Cardinal Wolsley obtained its suppression, for the purpose of founding the college which was to bear his name, and which is now represented chiefly by his alterations to the Cathedral, and the great "Tom" Quad, with its hall and unfinished cloisters, standing between

* This series of Illustrations of the Cathedrals of England and Wales was begun in our issue of January 3, 1891. A list of those already illustrated, with particulars of future arrangements, will be found on page 450.

the Cathedral and the present main street. The peculiarities of plan, and the curious mixture of detail, have afforded, and still afford, much matter for discussion and research, although of late something has been done which tends to clear up the mystery which enveloped the north-eastern portion of the church. The original church of Didan and his daughter, afterwards Saint, Frideswide, was doubtless a humble structure, and, if not of wood, was of small dimensions. At the commencement of the eleventh century the nuns of St. Frideswide were massacred and the church burnt; and afterwards additions were commenced by King Ethelred II. About 1120 further additions were made by Prior Guimond, and the consecration took place sixty years afterwards (1180). In these cases it was probably the endeavour, so far as was possible, to keep the original church, sanctified as it had become by the presence of St. Frideswide's burial, as an integral part of the structure, and it is this point which makes the ground plan at the present time one of so much peculiarity and interest.

The church now comprises a nave of four bays with aisles (and a modern bay or vestibule westward), a central tower, a north transept of three bays with a western aisle, a south transept of two bays, and an eastern chapel dedicated to St. Lucy, and a choir of four, the central alley of the presbytery being carried one bay beyond. On the north side of the north choir aisle are two aisles of later date, the first being the Lady Chapel, of thirteenth-century date, and the outer, or north, aisle, known as St. Katharine's, or the Latin Chapel. Both these aisles occupy in their western bays the site of the eastern aisle of the choir. It should be noted that, although the nave and south transept are at right angles, the eastern arm bends to the north, and the north transept, being at right angles with the choir, turns a little westward. The projecting portion of the presbytery is not in line with the rest, turning a little more to the north.

In 1887 Mr. J. Park Harrison, to whom we are indebted for much information with regard to the discoveries, had excavations made outside the east wall of the north choir aisle and Lady Chapel. The result was the finding of founda-

tions of three apses, in all probability forming the eastern termination of the Early church which Didan founded. It will be noticed on reference to the plan that these foundations coincide with two rough arches which still exist in the east wall of the aisles, and there are distinct traces of a central arch now nearly covered by the Norman buttress. How far this wall is ancient is difficult to say. At first sight it appears early, and the fact of the new Norman choir having been built south of what was the south aisle of the Saxon church, seems to point to the fact that it was intended to keep the original building temporarily at least. There is no reason, however, to suppose that the Norman design was not completed. The vaulting shafts of the north aisle still remain, and also the angle of this aisle with the east aisle of the north transept. In addition to this a chapel was thrown out eastward from the northernmost bay of the east transept aisle, and it is quite possible that the north aisle of the Saxon church might have been retained, occupying as it would the space immediately north of the north aisle of the choir. Whether or not this was the case, any of the original building which might have been standing was swept away in the thirteenth century.

And it is here that we find the first evidence of something unusual in the plan. The two eastern bays of the Lady Chapel are 2 ft. wider than the others. At first sight this is apparently Decorated work, but on closer examination it will be found that the vaulting shafts including the one at the north-east angle are Early English. Bearing in mind that this aisle stood on the site of the Saxon church in which St. Frideswide was buried, it is not impossible that this widening was necessary to increase the accommodation for worshippers at the shrine of St. Frideswide. It so happens that the foundation-wall of this addition would be clear of the older foundation of the Saxon building, the early foundations not being considered strong enough to bear the newer and heavier load. This addition was the Lady Chapel, and occupied a similar position to the "Elder Lady Chapel" at Bristol, which was also an Augustinian house.

The next alteration was in the fourteenth century, when the chapel at the north-east

angle of the transept was removed, the north wall of the Lady Chapel opened out, and a very beautiful chapel was erected of equal length with the Lady Chapel, and now known as St. Katharine's or the Latin Chapel. About this time also the eastern termination of the chapel on the east side of the south transept was removed and a large three-light window,—with tracery of somewhat similar design to those at Dorchester Abbey,—was added. This chapel is known as St. Lucy's Chapel, and is now the baptistery, with a modern font.

The south transept is of three bays, as the north; the southernmost bay, however, is of two stories, the lower being formed by the slype which leads from the cloister to the cemetery eastward, and the upper being a gallery approached by a stair from the inside of the transept which was formerly a communication between the church and the dormitory. The same arrangement, in a slightly modified form, exists at Bristol, but there the Chapter-house immediately adjoins the transept and there is no slype.

With the exception of the rich pendant roof of the choir and Presbytery, the additions made in Perpendicular times were chiefly confined to the insertion of windows and doors, and the rebuilding of the Cloister Court. The outer wall of the north nave aisle appears to have been rebuilt at this time, and the vaulting here is in cement, and a had imitation of earlier work.

The general character of the interior is one of simplicity. Only the aisles and the choir are vaulted. The nave, transepts, and tower have wood ceilings of late date. The peculiar arrangement of the arcades,—the caps being at two levels, carrying an upper and a lower series of arches,—will be best understood by reference to the view of the interior of the transept (see lithograph). The caps themselves vary much in character, the earlier ones being in the choir, with some curious carving, resembling Saxon ornament, while those in the nave are more fully developed, bordering on Early English foliage. It is thought that some of

weather, and afterwards incorporated in a larger scheme. The whole series of these caps, from east to west, form a very interesting study of the progress of carving. The view across the transept which we give shows some of these caps.

The most important of the monuments are all in the north-eastern portion of the church, standing in close proximity to the shrine of St. Frideswide. The most interesting objects here now are the remains of the shrine itself. Some fragments of what appears to be Forest marble, with delicate carving, were found, forming the sides of a well in the yard south-west of the Cathedral, and they have been set up under the easternmost arch between the Lady Chapel and the north choir aisle, stone having been used to fill in the missing parts. A portion of the plinth formed a step with the carved portion turned inwards, and another was found built in a chimney in "Tom" quad. This interesting piece of work is probably the shrine which was in course of construction in 1270, and to which St. Frideswide's relics were removed in 1289. It measures 7 ft. in length by 3 ft. 6 in. in breadth, and consists of an arcade of two arches at the sides, and one at each end. There was no vaulting inside, the arch moulds being repeated on the inner face, and mitring with a slightly projecting cornice moulding which served as a ledge in which the upper part of the structure, containing the shrine proper, was fixed. The spandrels throughout are filled with very beautifully carved foliage—the carving being very naturalistic, and suggesting a later date than is ascribed to it. The plants represented are: on the south side, the greater celandine, maple, and columbine; on the north side, ivy, oak, and sycamore; at the east end, vine and fig; and at the west end, white thorn and bryony.* It should be noticed that the foliage at the angles takes the form of pastoral staves, either by accident or design. The intermediate spandrels on the north and south sides are circular in form, with heads in the centre. A large portion of the plinth has been found, showing a series of quatrefoils with heads of queens on the south side, and at the west end, that of a bishop. Very delicate foliage is worked on a little roll moulding at the angle, and foliage instead of a head occupies the centre and end panels on the longer sides. Much of course is still missing, and considering that the fragments already found came from places some distance apart, it is difficult to organise a search in any one particular part of

the fabric with any hope of finding more. After the shrine the most interesting monuments are those arranged under the arcade between the Lady Chapel and St. Katharine's Chapel. Under the east arch is a large stone tomb richly panelled, with a staircase at its western end leading to an upper chapel or loft, constructed of wood, and of later date than the tomb. It is supposed by some to have been a watching-chamber to guard the shrine of the saint, as at St. Albans, but at present there is no satisfactory evidence as to where the shrine itself stood, and it seems more likely that the loft was used as a chantry chapel in connexion with the tomb below. In the next bay westward, is the beautiful tomb of Elizabeth, Lady Montacute, who died in 1359, and who gave Christchurch Meadow to the Priory for the founding of a chantry. The effigy itself is a very fine piece of workmanship, the ornament on the dress being rendered in *gesso* and coloured. On each side of the tomb are six standing figures, which are excellent examples of the costume of the period, and which will be found, as well as the principal effigies, finely engraved in Hollis's "Monumental Effigies."

The next tomb westward is that of Prior Alexander de Sutton, 1294-1316. The effigy of Purbeck lies under a canopy composed of three gables supported on shafts of Purbeck. There were formerly figures at the angles, but only one,—at the north-west angle,—remains at all complete, and still has a little of its original colour. A tomb, with the recumbent effigy of a knight,—said to be Sir George Nowers, a companion of the Black Prince, occupies the next bay, which is actually the old eastern aisle of the transept. These two last-mentioned monuments were shown in a sketch given in *Builder*, August 9, 1890, in our account of Oxford, and also some of the caps from Prior Sutton's tomb. In the floor of the Lady Chapel are several stones of interest. Two contain brasses,—one to John Fitzalan, 1452, and another to Edward, son of Hugh Courtenay. Immediately south of Lady Montacute's monument is a stone with a large cross in the centre, and the following remains of a marginal inscription in Lombardic characters:—

JOHAN : DE : COL . . V . LE : GIST : TOT :
DIEV : (illegible) MCCO (or MERCI) . POVR :
LAME PRIER : DIS : JOURS : DE : PARDON :
AVER : AMEN.

In the adjoining north aisle of the choir is a stone commemorating, "Andreas de Soltre Quondam rector Ecclesie de Kalley."

In this aisle is also a fine brass to James Coorhoppe, Canon of Christchurch 1546, and Dean of Peterborough, who died in 1557.

Under the north window of the transept is a

small altar tomb to James Zouch, who died in 1503, and near St. Lucy's Chapel, a monument to Bishop King, the first Bishop of Oxford, who died in 1557. It is not, however, in its original position, having been removed from the choir.

In the Latin Chapel are some stalls, *temple*, Wolsey, and probably forming part of his choir fittings. The poppy-heads are very elaborate. We give two, showing the way the Cardinal's hat and tassels were worked into the design. The windows of the Latin Chapel are shown in the view of the exterior, with their flowing tracery. Some of the glass is of the same date, and includes figures of SS. Frideswide, Margaret, and Catherine, Etheldreda (?) and the Virgin and Child. In the borders are various animals, monkeys being introduced both here and in the glass now in St. Lucy's Chapel. This latter is a fine example of reticulated tracery with elaborate cusping. The glass, too, is interesting, of early fourteenth-century date, and including representations of St. Cuthbert (with St. Oswald's head), St. Blaise, St. Martin (giving his cloak to a poor man at the gate of Amiens), the murder of Beckett, and St. Augustine preaching to his clerics.

The upper floor over the slype, which forms a portion of the south transept, as before mentioned, is now used as a small museum, and contains several specimens of early stonework and carving, found from time to time. Amongst these is the base of a cross with sockets, central shaft, and two side brackets for figures. (See illustration on page 441.)

In the Chapter-house, which is a fine specimen of Early English work, is some interesting old glass, of Wolsey's time and later. The entrance to the Chapter-house is Norman, and just within, lying on a stone bench, is the slab which covered the remains of Ela, wife of Thomas de Newburgh, Earl of Warwick, and daughter of William Longspée. It was brought here from Rewley Abbey, and is an interesting specimen of its date (thirteenth century). The cloisters have been extensively restored. All the vaulting is modern except that in the south walk and the two southern bays of the east walk. There are some foundations, evidently of some important building, still visible in the garth. They would seem, however, to have no connexion with any of the portions now in existence. The interior of the Cathedral has been restored, and new choir fittings and a *redos* put up. The pulpit is a fine specimen of Jacobean work. Some good modern stained glass, from designs by Mr. Burne-Jones, should not be overlooked. It is placed in the eastern windows of the aisles and in that at the west end of the south aisle.

THE ARCHITECTURAL ASSOCIATION:

ELECTION OF OFFICERS FOR 1892-93.

THE last meeting of this Association for Session 1891-92 was held on Friday, the 27th ult., Mr. F. T. Baggally, President, in the chair.

On the motion for the confirmation of the minutes of the previous meeting, one or two members took exception to one or two passages in the minutes as read, and on the suggestion of Mr. Leonard Stokes it was decided to postpone the confirmation of the minutes until after Mr. Ashbee had read his paper.

Mr. C. R. Ashbee then read a paper on "The Relation of the Architect to the Workman," which we print on another page, deferring the discussion until next week. A hearty vote of thanks was given to Mr. Ashbee for his paper, and for kindly coming a second time with it, under the circumstances mentioned in the *Builder* for May 21, p. 401.

The Travelling Student's Notes.

Owing to want of time, Mr. Kotaro Sakurai, the A. A. Travelling Student of last year, did not read the "Notes" of his tour, but they appear *in extenso* in the new number of *A. A. Notes*. We can only find space for a brief summary of Mr. Sakurai's paper. The author commenced by expressing his thanks to the members for having awarded the Studentship to him last year. He travelled in Somersetshire, commencing his tour on July 7. The first two weeks were spent at Wells, in studying the cathedral and its precincts. The chief glory of the cathedral, he said, lies in its interior. The staircase to the Chapter-house he characterised as "one of the most unique" pieces of work that he had ever seen; while for ingenuity of design, attained with graceful effect, few if any, can equal the Lady Chapel. The parish church of St. Cuthbert possessed a magnificent western tower of remarkably bold design for the period in which it was erected. Besides the ecclesiastical buildings, there are many examples of domestic work, both in the cathedral precincts and town. While at Wells, the author took trips to Glastonbury and Croscombe; the latter place is well worth a visit, for, besides the beautiful church, rich in Jacobean woodwork, there are many old houses, among which is a bay window of a quaint type. He also visited the village of Cheddar, alliteratively two more "C's" of equal interest might be added,—the Church, and the Cross: the former contains a good deal of woodwork and a rich simple design. The hexagonal market cross, of simple design, has been restored recently. The author's next halt was at Langport, which (although not containing much of interest, to be above the average) is a good centre for touring the numerous churches in the neighbourhood. Those at Curry Rivel, Long Sutton, and High Ham are specially noteworthy for richness of oak-work. At Mincely there are considerable remains of the Benedictine Abbey of SS. Peter and Paul, founded by Athelstan in 939. Most of the existing parts date from not long before the Dissolution of the monasteries,—*i.e.*, a portion of the richly-pannelled cloisters, the kitchen, the ante-room, and a large chamber over, with a fine mantel-piece and linen pattern panelling round part of the wall. Close by is a fifteenth-century thatched cottage, long used as

the vicarage house. Hish Episcopi is the nearest church to Langport, and perhaps the most important one in the neighbourhood, as it has one of the best towers of the "Tannton type." The charm of the structure consists chiefly in its elegant details, admirable execution, and the delightful colour of the Ham Hill stone employed. The church at Martock, a typical old country town, is a large structure of the usual local type. The nave of six bays, covered with an elaborate tie-beam roof, is a good specimen of late fifteenth-century work, but perhaps not quite equal in merit to the enthusiastic description of Mr. Freeman, who says:—"The nave is a notable instance of the idea of a great parish church, thoroughly worked out,—a nave as perfect in its own style as the nave of a cathedral." The chancel is undoubtedly that of the older church, and contains five lancet windows at the east end and a curved brace roof. On the south side of the church there is a fourteenth-century manor-house, retaining the original arrangement of the hall (with a good roof), kitchen, and offices, in a perfect state. While staying at Martock the author visited the churches at Kingsbury Episcopi and Stoke-sub-Hamden. The former has a tower almost identical, though somewhat inferior in detail, to that of Hish Episcopi, but the church, itself with its fine rood-loft and screen, is much better in every respect to the last-named. Stoke-sub-Hamden Church, cruciform without aisles, was originally Norman, but now combines work of every period, from Early Norman to Late Perpendicular. The author next went to South Petherton, and saw the house known as "King Inn's Palace," the hall of which has been much restored. He next visited Barrington Court, Montacute House, Odcombe, Preston, and Yeovil. In conclusion, Mr. Sakurai sums up the characteristic features of Somersetshire architecture, speaking highly of its domestic work, but criticising highly he calls the "confectionery-like" treatment of many of the church towers, and also expressing the opinion that the position of the towers,—almost invariably at the west end of the nave,—was a most difficult one for the production of an agreeable composition. He had rarely met with any truly successful *façade* thus designed (he did not say this of Somersetshire only); the ends of the aisles, as a rule, formed very awkward terminations, and the arrangement necessitated the use of a large west window in the lower stage of the tower, where the appearance of solidity was much needed.

On the motion of the President, a hearty vote of thanks was given to Mr. Sakurai for permitting his paper to be merely "taken a read," instead of reading it, as usual.

Minutes, &c.

The meeting then reverted to the question of the minutes, which were ultimately confirmed, after one or two emendations suggested in the course of a rather heated discussion, which principally turned on the question of the validity or invalidity of the nomination, made and received at the previous meeting (see *Builder* for May 21, p. 401), of Mr. Gerald C. Horsley as a member of the Committee. It appeared that in the view of the Committee, Mr. Horsley is not a member of the Association, and therefore his nomination to serve on the Committee was invalid. It seems that some months ago Mr. Horsley (for some reason which was not stated) wrote to the secretaries resigning his membership. The receipt of that letter, it appears, was duly entered on the minutes at the time. But it was stated by Mr. Stokes that, at the request of the Committee, he had an interview with Mr. Horsley, in order to induce him to withdraw his resignation. The result of that interview was that Mr. Horsley verbally withdrew his resignation of membership, and Mr. Stokes said he distinctly recollect reporting Mr. Horsley's withdrawal of resignation to the Committee. The majority of the Committee appeared to have no recollection of this, although Mr. Pryce and Mr. Brodie said they distinctly remembered Mr. Stokes reporting the result of his interview with Mr. Horsley. At any rate, there was no entry on the minutes mentioning Mr. Horsley's withdrawal of resignation, and the majority of the Committee, or the officers (the matter was not made quite clear), had, since the meeting at which Mr. Horsley was nominated to serve on the Committee, decided that his nomination was not valid, and that any votes given to him would be lost, whatever might be his position on the poll. It was

pointed out by Mr. Stokes and other speakers that this was a very unfortunate circumstance; that it was a pity that some member of the Committee had not taken objection to Mr. Horsley's nomination when it was made at the previous meeting; and that Mr. Horsley himself was present at the meeting when he was nominated, and, in answer to a question from the President, said he would be willing to serve,—which (said Mr. Stokes) showed that Mr. Horsley himself was quite under the impression that he was still a member of the Association.

Three new members were nominated for election, and the following gentlemen, nominated at a previous meeting, were duly elected, viz., Messrs. W. G. Horseman, J. W. Honit, E. O. Sachs, G. W. Stone, P. J. Groom, A. M. Sinclair, A. W. Moore, A. Hannaford, R. T. Grove, A. R. Dannatt, H. W. Anderson, and G. F. Grover.

Among the donations to the library was Part XXIII. of "The Dictionary of Architecture," presented by the Architectural Publication Society. A vote of thanks was accorded to the donors.

On the motion of Mr. F. T. W. Goldsmith, a hearty vote of thanks was given to Mr. Ewan Christian for permitting the members to visit the new National Portrait Gallery, as reported in the *Builder* for May 21, p. 399.

Travelling Student for 1892.

The President announced that two sets of drawings had been sent in for the A.A. Travelling Studentship, and the Committee was of opinion that the Studentship should be awarded to Mr. Thomas Arthur Sladdin, and that a second prize of 5*l.* should be awarded to Mr. E. A. Richards. Whilst regretting that there was not a larger number of competitors, the Committee wished to express their high appreciation of the excellence of the drawings sent in.

Election of Officers and Committee.

The President having called for the report of the scrutineers of the balloting papers,

Mr. Beale, one of the scrutineers, said he wished to be allowed to make a personal explanation. He said he happened to be the proposer of Mr. Horsley as a member of the Committee, and he felt that some discredit would attach to him (Mr. Beale) unless he said that he had no reason to suppose that Mr. Horsley was not a member of the Association at the time; furthermore, he was quite sure that Mr. Horsley believed himself to be a member of the Association. Under the Committee's ruling, he (Mr. Beale) and his fellow-scrutineers were of opinion that the balloting papers were all invalid and that the election was void, and therefore they did not think that there was sufficient ground for presenting their report.

The President said that the voting papers were not invalid and the election was not void. The only thing would be that any votes given to Mr. Horsley would be lost.

Mr. Beale said he was sorry that he could not present the report.

The President: You must present the scrutineers' report, if you please, or one of the other scrutineers must do so.

Mr. Beale: I am sorry I cannot.

The President: I call upon the meeting to support the chair (loud and long-continued applause).

Mr. Beale: Sir, as it is the evident wish of the meeting, I comply with your request, but it is entirely under protest. I feel that I am presenting a report on invalid voting papers.

The President then read the report of the scrutineers on the result of the voting, which was as follows:—

President: Mr. H. O. Cresswell.

Vice-Presidents:—Mr. Paul Waterhouse, 414 votes, and Mr. E. Woodthorpe, 391 votes.

Committee: F. T. Baggally, 421; E. W. Montford, 421; F. R. Farrow, 375; W. Burrell, 301; J. Stokes, 301; W. J. N. Millard, 272;

* Mr. Spynne Beale has sent us a long letter, detailing the reasons of this action taken by the scrutineers, to which we cannot give space; we may merely mention that there appears to have been a difference of opinion as to whether Mr. G. C. Horsley, who had early in the year resigned membership, had or had not formally withdrawn his resignation, as he had been invited to do. The scrutineers counted the votes under the impression that those for Mr. Horsley were valid, while it was stated afterwards at the meeting that Mr. Horsley was not a member. The scrutineers therefore considered the lists were informal or invalid.—Ed.

E. J. May, 265; A. W. Earle, 246; A. C. Bulmer Booth, 232; and W. D. Caröe, M.A., 228.*

Hon. Treasurer: Mr. Hampden W. Pratt.

Hon. Librarian: Mr. J. W. Stonhold.

Hon. Secretaries: Messrs. Ernest S. Gale and Mr. F. T. W. Goldsmith.

On the motion of Mr. Cresswell, President-elect, a vote of thanks was accorded to the scrutineers; and on the motion of Mr. Leonard Stokes, a hearty vote of thanks was given to the retiring President, and to the retiring Vice-Presidents (Messrs. F. R. Farrow and E. W. Montford) for their services during the past year. Mr. Baggally was highly eulogised by Mr. Stokes for the indefatigable manner in which he had discharged the exceptionally onerous duties of the year, especially in connexion with the first year's working of the new curriculum.

Mr. Baggally having briefly replied, the meeting terminated.

The Annual Dinner.

The work of the session was brought to a close very amicably and pleasantly by the annual dinner, which was held at the "Criterion" on Tuesday evening last, Mr. Baggally in the chair. The toast of "The Queen and Royal Family" having been duly honoured,

The Chairman proposed "The Royal Academy," which he spoke of as the only body, besides the Association, which had ever done anything for the training of architects. Although there was no doubt that the Academy might do more, admission to its Architectural School was rightly looked upon as of the greatest educational advantage to a young architect. He regretted that there was no Academician or Associate present to respond for the toast, which he coupled with the name of Mr. H. L. Florence, a former gold medalist and travelling student of the Academy.

Mr. H. L. Florence, in responding, said he regretted that they had not the advantage of the presence of some member of the Academy, who might have been asked to respond to the toast. He noticed that the toast appeared on the list as "The Royal Academy." He should have preferred to reply for "The Royal Academy of Arts." He could conceive such an academy, in which Architecture would take her rightful place as an elder sister of the Arts, and not be a mere Cinderella.

The next toast was "The Royal Institute of British Architects," proposed by the Chairman, and coupled with the name of Mr. J. M. Brydon, who replied.

The toast of the evening, "The Architectural Association," was proposed by Mr. W. Hale, President of the Birmingham Architectural Association, who said he was a member of the London Association forty years ago, in the days when it used to hold its meetings in Lyon's Inn Hall. With the toast was coupled the name of Professor Kerr, the first President of the Association, who, in reply, made an interesting speech contrasting the Association as it was forty-five years ago and as it is now.

The other toasts were "The Visitors," proposed by F. T. W. Goldsmith and coupled with the name of Mr. Knowles, President of the Northern Architectural Association; "The Instructors and Studio Visitors," proposed by Mr. Leonard Stokes, and responded to by Mr. E. W. Montford and Mr. Holmes; "The President-Elect" (Mr. H. O. Cresswell), proposed by the Chairman; and "The Retiring President and Officers," proposed by Mr. Cresswell and coupled with the names of Mr. F. T. Baggally and Mr. E. S. Gale. During the evening some excellent singing was given by members of the A.A. Lyric Club.

* NEW SURVEYS OF LONDON PARISHES.—The Vestry of St. Mary, Newington, have commenced a re-survey of the parish for drainage purposes, and we understand that Mr. Alfred Mark, who has recently been engaged upon similar work, under Mr. Charles Mason, Surveyor to St. Martin's Vestry, Charing-cross, has been entrusted with the work, which will bring the whole of the plans of the district (632 acres in extent) up to the present date. Mr. Mark previously prepared a new map of the Parish of Islington, under Mr. J. Patten Barber, Chief Surveyor to the Vestry.

* The number of votes recorded for the unsuccessful candidates was not announced, but, in answer to a question by Mr. Dicksee, the President stated that Mr. Horsley had not received a sufficient number of votes to place him amongst the first ten candidates.

Books.

Laxton's Builders' Price-Book for 1892. Seventy-fifth edition. London: Kelly & Co. *Lockwood's Builders', Architects', Contractors', and Engineer's Price-Book for 1892.* Edited by FRANCIS T. W. MILLER, A.R.I.B.A. London: Crosby Lockwood & Son. *Sporn's Architects' and Builders' Price-Book.* By W. YOUNG, Architect. London: E. & F. N. Sporn.

THE demand for these books finds sufficient proof in their regular re-appearance year by year, as also in their steady increase in bulk. The veteran "Laxton," now in its seventy-fifth edition, numbers about 760 pages, of which nearly 200 are devoted to trade advertisements. We have already stated our opinion that a table of prices might and should be drawn up in a more scientific manner than is attempted in any book we know, and we are therefore unable to express unqualified approbation of the works before us. At the same time, we are glad to notice that within these limits a real effort is made to write the books up to date, and to keep the prices tolerably coherent. Specially noticeable is this in respect of the new kinds of wood now used in joinery, and in the matter of new sanitary appliances. The demand for the latter has greatly increased of late, from the awakening of the public intelligence to the vital importance of sanitation, and the large space given to them in these pages is well employed. It would be convenient to be told whether the prices set out for the various patent fittings include in all cases the same percentage of profit, or whether they are merely list prices subject to varying discounts.

One of the uses of a price-book should be to assist builders in calculating prices for themselves, to meet the multitude of cases which arise wherein the stereotyped items do not apply. This function cannot be adequately discharged without a carefully-prepared analysis of a large number of prices, showing the elements of which they are made up. In "Laxton" last year a chapter appeared entitled, "On the Adaptation of a Price-book to Meet Varying Rates of Wages," which was certainly a step in the direction we have indicated. The approximate proportions of labour and materials were there given in the cases of several trades, each trade being treated as a unit. Thus the cost of labour in bricklayers' work was put at one-third of the whole, in carpenters' and joiners' work at two-thirds, and so on. This is obviously very rough, and we are not concerned at the moment to say how near to accuracy these ratios may come. But it was a welcome effort, and we regret to see that this year, so far from being carried further, it is abandoned,—although the compiler of the carpenters' prices seems to be unaware of the fact (p. 99). We may be asked, why, when the books are to all appearance satisfactory to the trade, depart from the present system? We reply that the trade does not rely on them for serious pricing. It is, indeed, something of a misnomer to call them price-books. They are a compendium of handy information on matters connected with building, and would command a sale if there were not a single price in them. To say nothing of tables of weights of materials, tables for calculating weekly wages, tables for ascertaining the value of leases, annuities, &c., model conditions of contract, the Metropolitan Buildings Acts, with cases and decisions thereon, the By-laws of the London County Council and the List of District Surveyors, we may obtain from these volumes instruction in mensuration, in the art of measuring a holder's work of all kinds, in perspective drawing, and in classical design. Nay more, we may here learn that "few men realise the importance of trifles; stored, they make one man's fortune; neglected, they cause another's ruin." There are few trades in which this occurs more frequently than in the builder's! ("Laxton," p. 399). Notwithstanding the apparent plethora of price-books, there still remains room for one which shall not only give tables of prices, but shall examine and explain the principles on which they are based, and the methods by which they are arrived at.

The First Principles of Mechanical Engineering. By JOHN LEMAY and C. H. W. BIGGS. London: Biggs & Co., 1892. To write a book on Mechanical Engineering without using any but simple mathematics is

a much more difficult task than most people would imagine, since laborious and tedious description is the penalty to be paid for despising algebraical formulae, and the result, instead of being a scientific treatise, is but a popular hand book on the subject. Valuable information may, however, be given even in this way, and the authors have left but few subjects untouched between such limits as the mechanics of antiquity and modern screw-cutting gear. A good deal is said about mechanical drawing, materials and stresses, sources of mechanical power, and such subjects, and although the book contains but little that is original, yet the explanations and descriptions, besides being well illustrated, are always written in a clear and simple manner, suitable for the class of readers for which the work has been prepared.

The Beam, or Technical Elements of Girder Construction. By WILLIAM LEWIS BAKER, A.M.C.E. London: Chapman & Hall, Limited, 1892.

ONE of the first things that should be mastered by the student commencing to study engineering is the strength of girders and beams under the various conditions of loading to which they may be exposed, and in the above little book this subject is treated in a very clear manner, and without employing complicated algebraic formulae. Commencing with an explanation of the elementary principles, the author shows how to ascertain the stresses in cantilevers and beams, and also how the different parts of cast-iron and plate girders should be proportioned to resist these stresses. The methods of computing the stresses in simple lattice girders are also dealt with, and by a series of well-chosen examples the author illustrates what calculations are most frequently required in the ordinary practice of the architect and engineer, and students wishing to become acquainted with the elements of the subject could not do better than to study carefully this little book.

Palliser's Specification Blanks. New York: Palliser, Palliser, & Co.

THIS is a specimen of one of the skeleton forms of printed specification published by Messrs. Palliser & Co., of New York, the object of which is of course to shorten specification writing (which is a gain) and to take a good deal of the thinking out of the architect's hands, which is not a gain. The skeleton in this case is rather too much filled up, and moreover is not suited for English practice, which would require a form for itself differing from that of the States. We do not much approve however of skeleton specifications, except those which an architect draws up and lithographs or prints for his own use. If that is carefully done it saves the trouble of writing over again permanent requirements and forms a memorandum also, and it then represents the architect's own practice derived from his own thought and experience, and he is likely to leave it so far open as to leave room for the specification of the special requirements of each separate building. But a published form of specification only tends to do away with individuality of work and to save an architect the trouble of thinking out fully the carrying out of his work; and we do not think any architect of original power and ability will ever care for published specification forms. They may be useful to those gentlemen who at present (we believe there are not a few) leave the quantity surveyor to write the specification: but even they will want an English and not a New York edition.

Brick for Street Pavements: an Account of Tests made of Bricks and Paving-Blocks, with a Brief Discussion of Street Pavements and the Method of Constructing them. By M. D. BURKE, C.E. Cincinnati: Robert Clarke & Co., 1892.

A LARGE part of the contents of this pamphlet was included in a report made to the village authorities of tests of material to be used in paving streets at Avondale, of which the author was "village engineer" (we presume "village" has not precisely the same meaning in the States as here). The tests were made upon specimens of granite and of various bricks, and the results of chemical analysis, absorption tests, and of crushing, transverse strength, and abrasion tests are given. The specimens are numbered in the tables, and a description of the quality

of each specimen given in the text, referring to the tabular number. The object of the pamphlet is, as a sequel to these tests, to recommend the use of granite as a pavement, as the best substitute for granite in an economical sense. With a hard brick this may be worth trying, but in regard to towns it is not of course a noiseless pavement, and that (in a comparative sense) is almost a *sine qua non* nowadays. Engineers and road-surveyors will, however, in any case find the statistics of interest.

Popular Map of England and Wales: in cloth case. Edinburgh: W. & A. K. Johnston.

THIS is one of the best cheap and portable maps of England that has been issued. It is a very full one, admirably engraved, and on a scale about double that of the usual larger type of atlas map. A detailed map of the environs of London is added in the margin. The map folds into a sufficiently small case to carry in the pocket. It is sold either mounted or unmounted, at the price of 1s. and 2s. respectively, but we should recommend the mounted map as the better economy. These folding maps, on mere paper, always tear after a short usage, even of the most careful kind.

House Drainage Hydro-noms. By G. M. LAWFORD. London: Geo. Gill & Sons.

THIS very small publication consists simply of a card printed on both sides and made to double up so as to go easily into the pocket. It contains tables of velocity, inclination and discharge of house drains, weight of lead pipes, water pressure, and cisterns' capacities and usual stock sizes, with a few general memoranda. It is very useful as a reference card for data which are often wanted and not easily carried in the memory.

Some Notes on the Public Health Act, with an Appendix on London Fog and Smoke. By HARRY G. ASSITER. London: Crosby Lockwood & Son.

THIS is one of the numerous commentaries on the spirit and hearings of the Public Health Act, which have appeared since that Act was passed, and gives a useful *résumé* of its provisions and of their practical results when put into action. The author adds a short essay on the smoke question, which he has taken up a good deal, in which he urges the application of legal restriction against creating smoke to domestic fireplaces as well as to factories. Mr. Assiter can see (what some people cannot) that the public will not accept stoves or anthracite coal as a substitute for the open fire, and falls back upon the recommendation of a modification of the present system of combustion, which he observes "is not a difficult matter," but he does not say what modification he proposes, which rather takes away the point from the whole essay.

Camping Out. By ARTHUR A. MACDONELL, M.A. London: G. Bell & Sons, 1892.

WE do not know why this book has been sent to us, as it has no sort of relation to our special subjects of interest; but for any of our readers who want to make a hoating and camping-out holiday we can recommend it as a readable book, with a great many useful suggestions for novices in open-air living.

Correspondence.

To the Editor of THE BUILDER.

VICTORIA CATHEDRAL COMPETITION.

SIR,—My attention has been called to the fact that my designs for the new cathedral at Victoria, British Columbia, were published in the *Building News* last week.

May I ask room to state that this has been done entirely without my knowledge and consent, and much against my wishes.

THE AUTHOR OF THE DESIGN MARKED
"NEW AND OLD."

June 1, 1892.

A QUESTION OF BUILDING PENALTY.

SIR,—In June, 1891, a builder entered into a contract for the erection of a building which was to be completed by October of the same year under a heavy penalty. This building was not completed for the following reasons:—

1. There was an extra depth of excavation, and

consequently an extra quantity of foundation, owing to bad and insecure ground.

2. The architect gave orders for commencing the building before the land was properly conveyed, thereby preventing the builder from proceeding with the works.

3. Various alterations were ordered to the interior walls.

4. Iron built girders were ordered in lieu of wood framing, causing many weeks delay.

5. A very glaring mistake in the quantities, whereby a quantity of extra work was caused.

6. Numerous alterations at completion, caused by the local authorities objecting to pass the building till alterations had been done to the satisfaction of the surveyor.

7. Delay in getting details from the architect, some of which were not delivered, but had to be prepared by the builder long after the works were specified to be completed.

The architect has given the proprietors a final account and also a certificate, less the error in quantities. The proprietors now object to pay the builder unless he will allow the amount stipulated to be paid if the building was not completed within the specified period.

Are the proprietors entitled to deduct this sum where it is not the fault of the builder, but owing to the numerous alterations?

Who should the builder apply to for the amount of the error in quantities?

If any of your readers would kindly give their views, it would oblige,

A CONTRACTOR.

FIRE-BRICK.

SIR,—Will you be good enough to allow me the assistance of your pages to inquire what make of fire-brick is considered to be the best in the market, and the means of ascertaining and procuring a report of the refractory qualities of any make of fire-brick?
J. C. KENWOOD.

The Student's Column.

WARMING BUILDINGS BY HOT WATER.

XXIII.

EXAMPLE BUILDING WORKS.

IN the following few examples it has to be mentioned, as was done when giving examples of horticultural works, that it may never fall to the reader's lot to erect an apparatus like any one of them; but by describing, and also illustrating, one or two methods of carrying out the works, great assistance can be rendered to the unskilled. The principles are thus made more clear, and once the principles are grasped, nothing else can be gained except by actual experience. The examples are merely enquired requirements, and the possibly best way of meeting them. It is impossible to do more than this, as there are but very rarely two works anyway resembling one another.

Fig. 95 shows a convenient little arrangement (it can hardly be called an apparatus) to give

warmth into a room adjoining or near the place where the fire is. The coil is supposed to be at the back of an ordinary open-grate fire, and furnishes heat to a few feet of pipe or a small radiator, which, however, should not be far away. This drawing shows a coil of three 3-in. pipes, the top pipe being continued upwards as the flow, and the lower one forming the return. Two unions are shown just above the fire-box to facilitate the removal of the coil if eventually it becomes fractured. There is no doubt it will fall one day if it has much usage, as dirt will find its way into the pipes, and eventually fill up the lower one, and cause it to split. If steam quality tube is used, it will last very well for several years, only having use in the winter. A piece of copper tube for the coil would do well.

It is hard to suggest what actual work this little appliance is capable of doing, it depends upon several things. Firstly, the size of the fire; if it is a fire-box holding a good thickness of fuel, that is a mass of fuel deep from front to back, very effective results are obtained. If the fire-box has wholly fire-brick at back and sides (as with all good modern grates), it helps matters, and the attention to the fire will affect the heating of the pipes. In putting pipes, containing water, in the fire of an open grate, we introduce a cooling influence that may completely spoil the utility of the grate, for it must be particularly noted that the combustion effected in an open fire is very different to that in a close stove or boiler, with the important assistance it has by the draught that is induced. With a close stove the draught passing through the fuel (and not over it as it does with a grate fire) causes combustion to proceed briskly irrespective of cooling influences, and this speed of combustion can be regulated, just as may be required, by the damper.

If the grate fire-box is not a large one, three pipes will have a deadening effect upon the fire, and two or one pipes only must be used for small requirements. The uses of this arrangement are that a radiator can be put into a neighbouring room, which is perhaps of such a size as not to be heated by its own fireplace; or it may be used to introduce a little warmth into a room that is not used regularly. If the coil was in a large fire it might be made to heat efficient radiating pipe for the warmth a billiard-room should always have when out of use.

The water-supply may be provided for by a little cistern in any convenient place where it is not seen, or, the radiator may be fitted with a little vase filling cup at top as shown. The latter article then acts as an air vent. In any case an air-cock will be needed at the highest point in the radiator to allow for the escape of air as it is being filled. No stop-cock would be required with this apparatus; but a draw-off service (for emptying purposes only) might be found useful if it can be conveniently placed.

The next example, fig. 96, illustrates two radiators in connexion with a small independent

boiler, for heating an entrance hall or other similar purpose. Of course, coils or hot-water pipes could be used in place of the radiators, if so desired. There is scarcely a better purpose to which heating works can be put than this. The great gain that is effected by providing warmth in an entrance hall cannot be over-estimated. This part of the house, with the staircases leading from it, has been likened to an artery, as it furnishes a constant current of air to the rooms and places that lead off from it. It must be known by everyone that in nearly all cases the greater part of the air entering a house (and the volume is great) enters by the doors and openings it can find on the ground floor. This inflow is necessary, as the chimneys in a house require air, also the occupants of course, and the house itself can well be likened to a great chimney, for an upward current of air, as a rule, always manifests itself inside. These conditions, perhaps, do not exist, or at any rate to such an extent when a good system of ventilation is provided; but this, unfortunately, is absent in too many cases.

Assuming that a considerable volume of air finds its way into the house by the best route it can, the larger proportion will pass through the entrance hall, and, as a rule, this part of the house is very cold; all doors in the vicinity have disagreeable draughts to them; and the staircases are in quite a bad a state. By intro-

ducing heat in the entrance hall, a really important benefit is obtained. The heating medium should be placed as near the outer doors as possible, so as to contribute its warmth to the incoming air. By this means the hall is made agreeable if not quite warm; the air entering the rooms is tempered, and that which passes up the staircases goes to make the upper parts of the house less cold. By keeping the boiler fire alight through the night, the very disagreeable degree of cold experienced in the halls and staircases at early morning is prevented. Engineers are particularly cautioned against using the same quantity of radiating surface in an entrance hall as they would in a room, if they want to make a success of the job. These places are not usually expected to be of as high a temperature as a room; but, notwithstanding this they require 50 per cent. more pipe. The necessity for this is due to the air of the hall being in tolerably rapid motion always; being taken by the rooms, and particularly the staircases, leading from it. If the gain effected was generally known, no residence of any pretension would be without heat in the entrance-hall.

In this example a small, independent boiler is shown, which would be situated in a cellar or basement room below. From the boiler is carried an inch flow and return service, by the best route (observing the principles already dwelt upon), and the pipes can be carried first to one radiator and then on to the other, or can be taken to a central point and branched each way as shown. If the pipes be carried first to one radiator, and then on to the other, the connexion to the first would have to be as fig. 94 (Art. XXII.), or the second coil would be much longer than the first in heating.

In branching the services as illustrated, a little better rise should be given to the pipes which extend furthest, so as to equalise results each way. There would be no need for stop-cocks in a little apparatus like this. The cold supply would be provided by a small cistern as shown, either filled by hand, or with a ball valve. If the latter, the cistern should only fill just an inch or two, so as to allow for the expansion of water when heating. An air-cock would have to be fitted in each radiator, and cleaning plugs, and an emptying cock should be provided to the boiler.

The pipes from the boiler should be 1 in., as just mentioned, but there would hardly be need for the branch to each radiator to be more than $\frac{3}{4}$ in. It will be seen that the cold supply-pipe has the customary dip in it to prevent the heated water circulating into the cold-water tank. The way in which this acts has been fully explained, and does not need repeating here.

SURVEYORSHIPS.

SALFORD.—A meeting of the General Purposes Committee of the Salford Town Council was held on the 27th ult., at the Salford Town-hall, presided over by the Mayor, Mr. Alderman Keeney, for the purpose of appointing a Borough Engineer and Surveyor, in the place of Mr. A. Jacob, who has retired. Out of the large number of applicants for the position, the following five candidates were selected to appear before the committee:—Mr. Geo. J. C. Broom, Borough Engineer of St. Helens; Mr. J. Corbett, engineer, Manchester, who lately resigned his office as a Salford councillor; Mr. H. C. Marks, Borough Engineer of Dewsbury; Mr. H. T. Marten, deputy Borough Surveyor of Bradford; and Mr. John Price, Engineer and Surveyor to the Toxteth Park Local Board, Liverpool. The voting resulted as follows:—Price, 22; Corbett, 21; Marks, 18; Broom, 13; and Marten 12. The selection of Mr. Price will come before the next meeting of the Council for confirmation.

GENERAL BUILDING NEWS.

THE PROPOSED EXCHANGE ALTERATIONS, MANCHESTER.—The Improvement Committee of the Manchester City Council met on the 25th ult., and had under consideration the plans submitted by the Directors of the Manchester Royal Exchange for the extension of the building in Cross-street. In view of the proposed alterations, the Sub-Committee had recommended the adoption of a new building line in Cross-street, the practical effect of which would be to put an end to the present scheme of the Directors. The Committee gave their full and unanimous approval to the proposal of the Sub-Committee. The new building line for Corporation-street, from Market-street to Hanging-ditch, was also approved.—*Manchester Guardian*.

PROPOSED PARISH BUILDINGS AND CLUB, BURTON-ON-TRENT.—Lord Burton, having presented the town of Burton-on-Trent with the present St.

Paul's Institute and the adjoining club premises for municipal buildings, has consented to erect a new church institute. The site selected for the building is at the corner of the Grange field. The building will be practically divided into two portions, viz., the club and the Sunday-school. The chief entrance for Sunday-school and parish purposes will be from St. Paul's-square, while the club premises will have a separate entrance, also from the square. The main entrance will lead direct to the lecture-hall, 66 ft. by 40 ft., which is to have walls of coloured brickwork and a panelled plaster ceiling. There will be a raised platform at the end, and retiring-rooms will be provided, these being approached by a separate staircase and entrance. On the same floor will be the parish-room, 35 ft. by 22 ft., and a large kitchen. A side entrance will be provided to the lecture-hall, and access will be given therefrom to the boys' and girls' yards, which will be fitted up with the necessary offices. At the south end of the building will be the caretaker's residence. Cellars will be built under the parish kitchen and class-room. A staircase near the side entrance will give access to the upper floor of the Sunday-school and parish-rooms, and over the lecture-hall three class-rooms, each 17 ft. by 16 ft., and a teacher's reading-room in connexion with the general library of the club, will be provided. On the same floor will be a class-room, 40 ft. by 33 ft., and a smaller one leading from it. The club premises will be over the parish-room. The club-room will consist of a reading-room, 27 ft. by 22 ft.; a billiard-room, 44 ft. by 22 ft.; club-room, 25 ft. by 22 ft.; and library, 30 ft. by 12 ft. There will also be the Secretary's room and lavatory. The staircases in the public parts of the building are to be of stone, and all the floors will be fireproof. The height of the rooms will vary from 15 ft. to 20 ft. The main corridors will be 7 ft. wide, and screens with folding swing doors will be fixed inside all outer entrance doors. Siemens' patent regenerative lamps are to be used for lighting purposes, and there will be open fireplaces in the class-rooms and club-rooms, and hot water pipes for heating will be laid over the whole building. Block floors will be laid throughout. Messrs. Thomas Lowe & Sons, of Burton-on-Trent, whose tender for 9,925*l.* has been accepted, will be the builders. The work will be carried out from the plans prepared by Mr. Reginald Churchill, architect, Burton-on-Trent.

ADDITION TO SCHOOLS, MIDDLETON, LANCASHIRE.—Extensive additions are being made to the Parish Church Schools, Middleton, consisting of two large class-rooms, new entrances, cloak-rooms, staircases, and offices. The external walls will be faced with South Oursam parpoints, relieved at all openings with dressed Huddersfield stone. The floors to be woodwork, pitch-pine. The works will be carried out by Messrs. Grundy & Sons of Middleton, under the supervision of Mr. T. A. Fitton, architect, of Middleton.

RESTORATION OF ST. LAWRENCE CHURCH, JERSEY.—On the 18th ult. the old parish Church of St. Lawrence, Jersey, was re-opened after restoration. The work, which was begun in 1889, has been completed under the direction of Mr. John E. Trollope, of Messrs. Giles, Gough, & Trollope, of London. The old church, said the *Jersey Express*, dating from 1199, had been allowed for centuries to fall into decay. Both the exterior and interior of the edifice have undergone renovation. The contractors were Messrs. Woodsford & Harris, and Mr. Cuzner has done the flooring and paving. The passages are all floored with oak blocks, the remaining part of the floor being in deal blocks. The pulpit and font are the gift of Mr. Elias Collas, of La Folie. Two stained-glass windows have been placed in the chancel, both representing scenes in the life of St. Lawrence. There has been acquired a new oak lectern and two oak sanctuary chairs, designed by Mr. John E. Trollope, and executed by Mr. Harry Hems, of Exeter.

MINERS' HALL, SILKSWORTH, DURHAM.—On the 21st ult. the corner-stones of the new Miners' Hall at Silksworth were laid by Mr. Samuel Storey, M.P., and other gentlemen. The new building will occupy a central position in the village, and will cost about 4,000*l.* The building will be of red brick, with stone dressings, having a length of 80 ft., by 45 ft. wide, and height inside 30 ft., the height from the floor to the vane on the turret which will surmount the roof being 66 ft. 6 in. There will be an entrance hall with a check office on the right-hand side, and a committee-room on the left. At the far end of the hall there will be a platform, with a lobby on each side, in addition to two retiring-rooms on the right of the platform. There will be a gallery above the check office and committee-room. On the right-hand side of the building, on the ground level, will be a reading-room, with a billiard-room above. There will also be a heating chamber, and offices and conveniences. The window of the gallery will be filled with lead lights. Mr. Henry Gieves, of South Shields, is the architect, and the contract is being carried out by Mr. T. P. Shatto, builder, of Sunderland.

RESTORATION OF BURNAL CHURCH, YORKSHIRE.—On the 12th ult., the Church of St. Mary, Brig-nall, was opened, after restoration, by the Bishop of Ripon. Funds did not admit of the renovation of the exterior, and where such actual repair has been done was necessary to preserve the structure from

FIG. 96.

decay. The three lancet lights of the east window have been filled with stained glass from the studio of Mr. C. E. Kempe, of London, representing the Crucifixion and St. Mary and St. John, which, together with the pulpit and retables, is the gift of Miss Easton, of West Layton Manor. The architects for the restoration were Messrs. Johnson and Crawford-Hick, of Newcastle-upon-Tyne, and the contractors were:—For mason and general repair, Mr. J. Kyle, Barnard Castle; woodwork, Mr. R. Snaith, Darlington; plumbing and glazing, Mr. C. Hedley, Barnard Castle; carving, Mr. R. Hedley, Newcastle-upon-Tyne; gliding, Mr. R. Halfnight, Sunderland.

ENLARGEMENT OF SCHOOLS, IDLE.—A memorial-stone of a new wing to the Church schools at Idle, Yorkshire, was laid on the 14th ult. by Mr. C. J. Vint, of Bradford. An assembly hall is being erected, and a re-arrangement of the old schools is being made. The cost of the additions and alterations will be about £1,600. Messrs. Kendall & Bakes, of Leeds and Idle, are the architects.

CONGREGATIONAL CHAPEL, BEDWAS, MONMOUTHSHIRE.—A new Congregational Chapel has just been erected at Bedwas. The building is 39 ft. long by 34 ft. wide, and it has accommodation to seat 320 people. The plans of the new chapel were prepared by Mr. Edmund Jones, Caerphilly, and the contractor was Mr. Thomas Rossiter, also of Caerphilly.

NEW CHURCH, APPERLEY BRIDGE, YORKSHIRE.—The foundation-stone of a new church for Apperley Bridge and Greengates was laid on the 7th ult. by Mr. John W. Garnett, of Greengates House. The new edifice is situated at the top of Apperley-road, in the parish of Eccleshill. Besides chancel, organ chamber, and choir vestry, there will be sitting accommodation provided for about 300 persons. The building is from the designs of Messrs. Kendall & Bakes, architects, Leeds. The estimated cost, including furnishing, is about £3,000.

BANK PREMISES, ST. HELENS.—The enlarged premises of the Manchester and Salford Bank in St. Helens have just been completed. The old premises have been enlarged by the addition of the adjoining shop and a public-room. The dados and counters and desks are of polished walnut. A consulting-room for the manager is enclosed with glazed panel screens, and lighted by a dome. The heavy columns and girders necessary to carry the first and second floors of the building have been relieved by fibrous plaster, and cornices of the same material form a panelled ceiling. A strong-room has been formed of concrete walls 18 in. thick. Outside, the front of the building has been faced with Aspatia (Cumberland) stone. The total cost has been 2,200*l.* Messrs. J. & W. Gandy, St. Helens, were the architects, and the builder was Mr. R. H. Davies; Messrs. Critchley Bros. & Co. have executed the decorations in the bank and the lighting of the building.

PRIMITIVE METHODIST CHAPEL, RIPLEY, YORKSHIRE.—On the 27th ult. the memorial-stones were laid of a new Primitive Methodist Chapel on the Nottingham-road, Ripley. The architect is Mr. H. Gill, of Nottingham; and the contractor Mr. H. Gill, also of Nottingham. The estimated cost of the chapel is 2,000*l.*, including Sunday-school premises for 300 children. The chapel accommodation is for 450 persons.

EPISCOPAL CHURCH, STRANRAER, WIGTOWN.—On the 25th ult. the new Episcopal Church of St. John, Stranraer, was opened. The church is erected at the corner of London- and Bellevilla-roads. It is seated for 180 worshippers. The building is in the Gothic style, built of whinstone, with red freestone facings. The entrance is at the south-west corner facing London-road. The interior consists of a nave, with chancel at the east end. Within the altar-rails there are seven Scriptural panels in oak. Mr. J. C. Macfarlane, Stranraer, was the architect, and the work was executed by local contractors.

SCHOOL BUILDINGS, &c., LEEDS.—On the 27th ult. the Right Hon. W. L. Jackson, M.P., laid the foundation-stone of a new Sunday-school and the Parochial Institute for All Hallows', Burley, Leeds. The Sunday-school will accommodate 1,100. There will be separate departments for boys, girls, and infants, and also a number of class-rooms. The boys' schoolroom will measure 50 ft. by 39 ft., and 14 ft. high. It will be lighted by windows on three sides. The girls' schoolroom will be 60 ft. by 30 ft. That portion of the building to be used as a parochial institute will be entered from Hartwell-road. On the second floor there will be a large assembly-room. The architects are Messrs. Kally & Birchall, of Leeds, and the contractors are Messrs. Wood & Airey. The total cost of the undertaking is estimated at about 3,000*l.*

REBUILDING OF FALSTONE CHURCH, NORTHUMBERLAND.—The small church of Falstone, on the Scottish border, was almost entirely destroyed by fire in December, 1890, only the walls of the tower and a height of 3 ft. or 4 ft. from the ground of the main walls of the church escaping destruction. It has just been rebuilt from plans prepared by Messrs. Plummer & Burrell, architects, of Newcastle, together with the addition of a small chancel. Messrs. Martinson & Walton were the builders. The stained-glass three-light traceroad east window, by Messrs. James Powell & Sons, of London, was the gift of Mr. Thomas Spencer, and

the memorial font, by Messrs. Jones & Willis, was the gift of Miss Pictou. The plumbing and joiner-founder's work has been executed by Mr. Scott, of Byker; the tinted glazing by Mr. Bagley, of New-castle; the painting by Mr. Forbes, of Birtley, North Tyne; the green Westmoreland slating is by Mr. C. Nicholson, and the oak parkolee screens, the pulpit, and the retables dado were the work of Mr. Ralph Hedley, of Newcastle, from designs by the architects. The bell was founded by John Taylor & Co., of Loughborough, Leicestershire. The church is heated with a Musgrave stove with a descending flue. The aisles and chancel are laid with mosaic work by Mr. J. F. Ehner, of London, borders, monogrammes, and symbols being inlaid in the chancel flooring, this work being executed by Italian and Venetian workmen. The lamp pendants and brackets, communion rails, and pulpit reading-desk are supplied by Messrs. Hart, Son, & Peard, of London. The choir-seats and reading-desk and the external doors are all of oak. The church is internally cooled with a wagon-vaulted hoarded roof, divided into panels by longitudinal and transverse mouldings, having bosses at their intersection, and with a moulded and quatre-foiled pierced cornice course. Buttresses have been introduced to the exterior of the church and to the old tower. The door hinges, vestry and other fittings, are made from the architects' designs.

RESTORATION OF PARISH CHURCH, HERRINGWORTH, LINCOLNSHIRE.—The Bishop of Peterborough re-opened on the 10th ult., the parish church of Herringworth, which has undergone restoration, under the superintendence of Mr. H. M. Townshead, architect, of Peterborough. The fabric has been under repair during the last nine months, and the work has been executed by Mr. S. Halliday, builder, of Stamford. The chancel has been restored at the cost of Mrs. Tryon, of Bulwick Hall, as a memorial of her late husband. There is a new pitch-pine roof in the chancel. In the roof the greater part of the roof is new, and is mainly of oak. The roof has been reroled. The seats are of pitch-pine. The old Jacobean pulpit has been restored. The nave has been refloored with wooden blocks. The screen has been restored, and the galleries in the church removed. The upper part of the steeple has been rebuilt. During the progress of the work part of an old Norman font was found in the wall of the chancel, and the relic is to be inserted in some conspicuous place in the building.

STAINED GLASS AND DECORATION.

MEMORIAL WINDOW, THORPE SATCHEVILLE CHURCH, LEICESTERSHIRE.—A stained-glass window, consisting of three lights and tracery, the subject of which is "The Crucifixion," has been placed in the east window of Thorpe Satcenville Church, near Melton Mowbray, to the memory of Martha Madeline, the late wife of Mr. Edmund Arthur Paget. The work has been carried out by Messrs. Winfields, Limited, of London.

MEMORIAL WINDOW, PARISH CHURCH, YARDLEY, WORCESTERSHIRE.—A stained-glass west window, placed in Yardley Parish Church in memory of the late Mr. Joseph Barrows, was unveiled on the 1st ult. The window is by Messrs. John Hardman & Co., and has been erected under the superintendence of Mr. J. A. Chatwin. The subject illustrated is that of our Lord coming in glory with His saints and angels to judge the world.

MEMORIAL WINDOW, JEDBURGH PARISH CHURCH.—A stained-glass window has just been put into the east end of the north aisle of Jedburgh Parish Church in memory of the late Mr. and Mrs. Charles Anderson, of Glenburn Hall. The window is composed of two pointed lights, with cusped circle above, and is by Messrs. Clayton & Bell, London.

STAINED-GLASS WINDOW, PARISH CHURCH, BODMIN, CORNWALL.—A stained-glass window has recently been erected in the south aisle of Bodmin parish church by Mr. George Henderson, J.P. of Bodmin, in memory of his wife. The window has been made to correspond in form as nearly as possible with two others recently unveiled as military memorials. In the upper lights of the old tracery figures of angels have been inserted bearing scrolls. The four long lights are occupied by the aged prophetess; 2, St. Mary, the Blessed Virgin; 3, St. Elizabeth, her cousin, mother of St. John the Baptist; 4, St. Mary of Bethany. Above them are canopies, surmounting groups illustrative of the parable of the good Samaritan. The window has been supplied by Messrs. Clayton & Bell, London.

THE TURNERS' COMPANY.—The Worshipful Company of Turners announce that they will offer this year, according to custom, their silver medal, the best specimen of Turning in Wood or Pottery. Objects for competition are to be delivered at the Mansion House during the week ending Friday, October 21. Further information as to the competition may be obtained from Mr. Edgar Sydney, 53, Gresham House, the Hon. Secretary to the Competition Committee.

FOREIGN AND COLONIAL.

FRANCE.—The National Gobelin Manufacture has just executed a tapestry for the National Library, the designs for which have been painted by the artist, J. B. Lavastre. This tapestry symbolises "Mechanism."—The Académie des Beaux-Arts has awarded the "Jean Raynaud" prize to the painter Joseph Blanc for his work "The Battle of Tolhuac," which is in the Pantheon.—A Roman mosaic formed of black and white cubes has been found at Lyons on the rope railway to Furville. A fine mosaic has recently been found at Saint-Colombe-la-Vieille (Rhône). This mosaic represents "the works of the field," and the allegories of the Seasons framed in a rich border.—In destroying the foundations of a house at Cahors (Lot) the workmen have brought to light the ruins of a Roman habitation, the walls of which bear traces of fresco painting, and the halls are paved with mosaic. They have also found some potteries, money, and many interesting things in bronze and marble.—The wooden suspension bridge of St. Pierre at Toulouse has been entirely destroyed by an incendiary.—The work of arranging the historical museum in the house of Joan of Arc at Domremy (Vosges) is shortly to be commenced. The sketches of the paintings of Leneveu at the Pantheon are to be placed there, also the original casts for the statues of Joan of Arc, by Chappé, Frédéric, Paul Dubois, Chattroussé, and Persier. There are also to be some tapestries made especially for this object at Gobelin from the designs of M. Puvion de Chavannes, and the collection will contain the principal portraits of Joan of Arc, from the equestrian statue which is in the museum at Cluny to the picture of Ingres, with the pictures which represent her in all the most stirring events of her life. The line from Argenteuil to Nantes has just been opened. It passes through a very rich and picturesque part of the country, crossing the Oise by a very strong metal viaduct and going over the Seine on a stone bridge.—The Society of "Souvenirs Français" has commissioned M. Ridet, architect, of the town of Laval, to design a monument, which is to be erected in the town, in memory of the last battle fought by the army of the Loire, January 18, 1871. The monument is composed of a tumulus ornamented with a figure of "Le Patrie" veiled and surrounded with palms. The execution of the sculpture is confided to M. Eugène Legueult, sculptor. The inauguration is fixed for the month of September.

—An inhabitant of Toulouse, who has recently died, M. Maury, has left his fortune to his native town. Amongst many other charitable works, he has created two annual prizes for painting and sculpture and a prize for architecture, which are to be distributed equally every year.—The new line from Grasse to Nice has just been opened.—There is a project to build a large military hospital at St. Cloud, to replace the one now in Paris; the scheme is being violently opposed by the inhabitants of this pretty town, which is such a favourite resort with tourists.—A statue of Lazare Carnot, grandfather of the President, has just been inaugurated at Carnot (Algeria).—The Prince of Monaco has just bought the magnificent domain of Bonrepas, one of the most beautiful of Tarn and Garonne.—We regret to learn the death of M. Eugène Chenantais, architect, at Nantes. He was late president of the Society of Architects of the Loire Inférieure, and member of the Central Society, the congresses of which he followed with great interest.

NORWAY.—The death is announced of Herr Norden, a prominent Christiania architect. The coffin was born to the grave by eight leading architects.—An electrical exhibition has just been held in Christiania, and it is contemplated to hold an industrial exhibition there next year.—Work has now been commenced on the new Customs House in Christiania. The cost of the building itself is estimated at 25,000*l.*, and the total cost of the entire establishment complete at about 36,000*l.* The work will occupy about three years.—The Storting has decided upon the erection in Christiania of an historical museum. The frontage will have a length of 83 metres, and there are to be three storeys with basement. The entire cost of the structure is estimated at about 39,000*l.*—The ancient timber church at Husted, in Throndhjem's Amt, purchased by the Society for the Preservation of the Ancient Norwegian Monuments, is to be thoroughly repaired by Herr Hofund, architect.

SWEDEN.—The catholic community in Stockholm has acquired a site for its projected cathedral at a cost of 16,000*l.* It is said that the funds required for the edifice are also secured. It is estimated that the building of it will occupy five years.—A monumental chapel is to be raised over the remains of the late Capt. John Ericsson, the famous inventor, in the cemetery at Filipstad, and two monuments of 400 ks. and 200 ks. are offered for the best designs.—New barracks are to be erected in Stockholm for the Horse Life Guards at a cost of 120,000*l.*—The Society of Artists in Stockholm has arranged a grand lottery of pictures, in order to raise funds for a new exhibition building, to which all leading Swedish artists have contributed, including Prince Eugen.—The Swedish Crown Office has decided to purchase the site of the former Swedish Theatre or Opera House, Stockholm, for a sum of 25,000*l.*

—A company has been formed for the purchase of the Circus in Stockholm, in order to rebuild it so as to form an industrial and art exhibition building with winter gardens. Plans, &c., for the new buildings have been prepared by Herr G. Lindgren, a well-known Stockholm architect. —A new so-called "villa suuhur" is in course of being built three and a-half kilometres from Stockholm on the sea shore.

DENMARK.—The death is announced of Professor De Peteresen, a prominent Danish architect and a member of the Copenhagen Academy of Arts. He was the son of a porter in the Ministry of Finance, and rose step by step to his high position by his natural genius.—Prof. Meldahl, the present architect to the so-called Marble Church or Cathedral in Copenhagen, upon which work has been in progress at intervals for over a century, has discovered twenty-two drawings in the archives of the ministry of the interior, showing that the French architect, Jardin, was not the original designer of this great edifice, but that this honour belongs to the Danish Col. Eigtved, the builder of Amalienborg Palace. He made his design to the church in 1754, or two years before Jardin, but the leading architect of the same is the same as that underlying the design for the projected Berlin Cathedral.—It appears from a communication to the Rigsdag that the Danish Government has under consideration some very large building schemes in the ensuing years, considering its limited resources. They include a new National Library, to cost 122,000*l.*, exclusive of site; a new Metron, a public school; enlargement of the Theatre Royal; a new technical college for teachers; a new observatory; removal of the arsenal to a more convenient site (at a cost of 120,000*l.*); new barracks for the Life Guards (to cost 45,000*l.*); and finally there are the old plans for the re-building of Christiansborg Palace, a new House of Parliament, and new central railway station.

BERLIN.—The result of the competition for a suitable model of the memorial monument to the Emperor Frederick III, which is to be placed on the battlefield of Woerth, shows three sculptors, classed first and equal. They are Herr Baumhach, Herr H. Hidding, and Professor R. Maison. The architect, Herr Pfann, one of the winners of the Great Memorial Competition, assisted Professor Maison in the conception of his design, whilst the architectural draughtsman, Herr Riehl, helped Herr Hidding. Both architects are members of the atelier of the new Houses of Parliament in course of erection.—The foundation-stone of the new central railway station at Cologne has been laid, with some ceremony.—An "artists' home" is to be erected in Rome, at the expense of the Prussian Government, for the benefit of artists and art students. The cost of Herr Genick's design, which is a timber building, and has approval, is estimated at about 400,000 francs. Besides ample accommodation for artists, who will only make a short sojourn in the "Holy City," there will be twenty-four large ateliers for resident painters and sculptors, and a mutual reception and exhibition hall.—The fashionable summer resort, Wiesbaden, is to have a new theatre. Designs were invited from Messrs. Fellner and Helmer (Vienna), Messrs. Seppner and Kratich (Hamburg), and Professor Freuden (Aix-la-Chapelle). Their work has been criticised by the Prussian Royal Academy of Works. Although isolated, the proposed building will be difficult to plan on account of the position of the site selected.—Another huge terminus station is to be erected in Germany. This time it is Dresden that wishes to compete with places like Frankfurt. A competition for the design has been opened. From the "programmes" we see that the building will cost 275,000*l.*, the prizes offered have a total value of 1,000*l.*, the sending-in day is September 1, and the assessing jury will comprise of nine very prominent architects and engineers.—The Frankfurt Baron Rothschild has offered the town of Osnabrueck some 6,000*l.* for its historical Imperial goblet. The Prussian Government will, however, try to prevent the sale.

ST. PETERSBURG.—An international competition for the design of a new bridge over the River Neva has been opened. There will be three prizes,—(1) 6,000, (2) 3,000, and (3) 1,500 rubels, and some extra prizes if the assessors think fit. The River Neva is 650 metres broad at the point where the bridge is to cross it. Six million rubels are at the disposal of the authorities for building purposes. The sending-in day is in the middle of October. The French language can be used (Centralblatt der Bauverwaltung). The bridge will be a most important feature in the city; it will commence just opposite the Marble Palace and replace the old wooden one now in use.

DOVER HARBOUR.—The Admiralty Pier having been transferred to the Dover Harbour Board, Mr. Edward Druce, who formerly held the position of Resident Engineer in charge of the pier under the Board of Trade, has retired upon a pension, and the maintenance of the pier has been placed under the management of Mr. A. T. Walsley, of Westminster, the Engineer to the Dover Harbour Board.

MISCELLANEOUS.

EDINBURGH ARCHITECTURAL ASSOCIATION.—The annual general meeting of this Association was held on the 26th ult. in the Architectural Hall, George-street. Mr. W. W. Halsey, President, Vice-President, in the chair. In his report, the Treasurer stated that the membership was now 278, and the balance in hand 176*l.* The reports of the other office-bearers were submitted and approved. Mr. Robertson intimated a new departure of the Association in the fact that the institution would be housed next year in the Royal Institution, where a new field of usefulness would be entered upon in connexion with the School of Applied Art, in which the members of the Society were so much interested, and which the Association had undertaken to support in every possible way. The increased advantages of the Association would be only equalled by the increased opportunities of usefulness which the new scheme opened up to them. The following office-bearers were elected:—Past President, Mr. J. Kinross; President, Mr. W. W. Robertson; Vice-Presidents, Dr. R. Anderson, LL.D., and Mr. T. Ross.

OCKWELLS MANOR HOUSE.—In a "Note" on April 6, 1889, we adverted to the then contemplated sale by auction of the Okholt, latterly Ockwells, Manor-house and grounds, about 2½ acres, in Bray parish, Berkshire. The sale was effected on June 4 of that year, at a bid of 2,500*l.* That same property, together with a farmhouse and 360 acres of land, will again be put up at auction, at the Mart, in July next. To what we said before as to the antiquity of the house, we may now add that it was built by John Norrey, Master of the Wardrobe to King Henry VI, and Esquire of the body to Edward IV, but not quite completed by him in 1465. Before his will that year—he died in 1487,—he bequeaths "to the full building and making up of the chapel, with the chamber adjoining, within my manor of Okholt, in the parish of Bray, not yet finished,—x. l. s." A correspondent, writing to the *Gentleman's Magazine* of December, 1795, says that a considerable portion of the house, damaged by fire, was in ruins, to his own knowledge, thirty years previously. But the entrance hall, the paved cloisters beyond, the great hall with minstrel's gallery, and some other interesting portions of the building, have been preserved.

THE NICARAGUA CANAL.—From a report just issued, it appears that last year a sum of 875,000*l.* was expended on the Nicaragua Canal works. The canal itself has now been completed for one mile to a depth of 17 ft., and a breadth of 270 ft. Of the ship railway, twelve miles have been completed.

HORSEY MAIN ROADS ARBITRATION.—The Order of the Local Government Board on the reference from the Horsey Local Board and the Middlesex County Council for the determination of the amount to be paid to the Board by the Council in respect of the cost of maintenance and repair during the year ending March 31, 1891, of the main roads within the Horsey district (mileage about 2½ miles) has only just been received, although the inquiry by Mr. Thomas Codrington, M.Inst.C.E., F.G.S., one of the Government Inspectors, was held so long ago as in the month of December last, occupying two whole days. The counsel engaged were Mr. Alexander Masonman for the Board, and Mr. Alexander Glen for the Council. Mr. T. De Courcy Meade, M.Inst.C.E., Engineer and Surveyor to the Local Board, Professor Henry Robinson, M.Inst.C.E., Mr. E. Purnell Hoyle, Nottingham County Surveyor, and Mr. F. Smythe, Surveyor to the Finchley Local Board, gave evidence on behalf of the Board, and Mr. F. H. Pownall, Middlesex County Surveyor, on behalf of the Council. The Council had offered to pay towards the cost of maintenance nineteen-twentieths of the amount, including establishment charges, but not exceeding the County Surveyor's estimate,—viz., 2,730*l.*,—of the net cost reasonably and properly expended, and offered their cheque accordingly, which was returned by the Board. The Board claimed to be repaid the total amount expended, including establishment charges. The amount awarded is 3,221*l.* 5*s.*, being 491*l.* 5*s.* in excess of the amount offered. The costs incurred by the Local Government Board,—27*l.* 14*s.* 4*d.*,—are to be paid one half by each party, who bear their own costs of the reference. No reasons for the terms of the award are given. The accounts presented include a sum for footways according to the well-known Warminster canal. The Horsey Local Board, at their meeting held on Monday last, unanimously passed the following resolution:—"That the Streets Committee be and are hereby empowered to give instructions and make all necessary arrangements in regard to the amount to be paid to the Board by the Middlesex County Council in respect of the maintenance and repair and improvement of the main roads in the Board's district during the year ending March 31, 1892, and in regard to the negotiations and communications with the Council thereon, and, in case arbitration of the Local Government Board has to be resorted to, the instructing of counsel and engaging of skilled witnesses and otherwise."

SOUTHPORT TOWN COUNCIL, so far as relates to the scheme for the construction of a marine park and lake, and the effecting of other improvements on the north foreshore, may be said to be practically accomplished, and the formal opening of the park and lake by the Mayor, Aldermen Dr. Pilkington, will take place on the 20th inst. The improvement scheme included, in addition to the construction of a marine park and lake, the widening of Nevill-street bridge, and the removal from it of the old lattice girders, as well as the widening of the promenade from the bridge to Seaham-road, and the continuation of the lower promenade from the pier to a point opposite Seaham-road. The width of the bridge has been increased to 86 ft., and has been cleared of all obstructions; the promenade itself has been widened to 40 ft., the carriage-way to 36 ft., and the footpath on the opposite side to 10 ft. This extends for over a quarter of a mile on the north side of the pier. The work of laying out the marine park into ornamental gardens and lawns is being executed by the Corporation's head gardener, Mr. Halsewood. At the foot of the park, and separating it from the lake, is the lower promenade, 50 ft. wide, approached by five sloping pathways. It is laid with concrete, and paved over. The lake is 27½ acres in area. It is 920 yards long and over 200 yards across at the widest part, and there will be a uniform depth of 3 ft. of water. The lake can be emptied by means of two rows of outlet pipes 24 in. in diameter, and water can also be admitted by this means. The slopes are formed of concrete, and there is a footpath round three sides of it laid with the same material. The lower promenade is protected from the lake by iron railings. The harbour is 60 yards long by 60 yards wide, and the main landing-stage is 250 ft. in length by 50 ft. wide; whilst the small landing-stage, fronting the boat-house is 150 ft. long and 24 ft. wide. At the entrance to the landing-stage is a ticket-office. The boat-house is a red brick building, the outside walls of which are relieved by rows of white enamelled bricks. The roof is railed round, and will be used as a promenade. The first boat-shed is 50 ft. square. The next boat-shed is 96 ft. long and 50 ft. deep, and beyond this is a cushion-room and a lumner-room. The promenade over the building is planned and caulked all the way along, except the portion over the cushion-room and lumner-room, which is laid with corrugated tiles. The boat-house is surmounted at one end by a large iron tank of 25,000 gallons capacity, standing on pillars. This will contain a supply of water for street-watering purposes. Another feature of the scheme has been the erection of a pavilion in the Marine Park. The roof of this building forms part of the promenade, and is supported by iron pillars. The inside walls are lined with white enamelled bricks, with rows of grey bricks at intervals. It is 220 ft. long and 48 ft. wide in the centre; it will hold about 1,500 persons, and will contain ample lavatory accommodation. The whole of the work has been executed under the direction of the Borough Surveyor, Mr. William Crahtree. The setting-out of the ground has been done by his son, Mr. Walter Crahtree, and since June last the Assistant Borough Surveyor, Mr. R. P. Hirst, has had the general supervision of the carrying out of the work.

CAPITAL AND LABOUR.

STRIKE OF BRICKLAYERS, REDDITCH.—According to the *Birmingham Gazette*, three months since the bricklayers of Redditch and district gave their employers notice that they should on June 1 require an additional 1*d.* an hour, their present rate of wages being 7*d.* per hour. It seems, however, that the masters declined to accede to the demand, and the result is that the whole of the men came out on the 31st ult. The number is about 70, and this throws out of employment a corresponding number of labourers. At the present time the building trade is extremely brisk in Redditch, and it is regrettable that the men and the employers have not been able to arrive at an amicable arrangement.

MASONS' STRIKE AT NELSON, LANCASHIRE.—On the 23rd ult., in consequence of the strike of masons and wallers in Nelson and district, about 200 labourers were prevented from resuming employment. At the request of the workmen, a conference took place between representatives of the masters and the men, but with no result, the masters adhering to their resolution not to concede the advance in wages from 8*d.* to 8½*d.* an hour until after the expiration of three months' notice, whilst the men were equally determined to adhere to the seven days' notice, which expired on the 21st ult.

MEETINGS.

SATURDAY, JUNE 4.

Edinburgh Architectural Association.—Annual Excursion, Drumlinrig Castle.

WEDNESDAY, JUNE 8.

FORSBROOK IMPROVEMENTS, SOUTHPORT.—According to the *Southport Visitor*, the object of the Foreshore and Improvement Committee of the

COMPETITION, CONTRACTS, AND PUBLIC APPOINTMENTS.

COMPETITION.

Table with 4 columns: Nature of Work, By whom Advertised, Premium, Designs to be delivered. Includes 'New Masonic Hall'.

CONTRACTS.

Table with 4 columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, Tenders to be delivered. Lists various construction projects.

CONTRACTS.—Continued.

Table with 4 columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, Tenders to be delivered. Continuation of construction contracts.

PUBLIC APPOINTMENTS.

Table with 4 columns: Nature of Appointment, By whom Advertised, Salary, Applications to be in. Lists various engineering and surveying roles.

Those marked with an asterisk (*) are advertised in this number. Competitions, p. iv. Contracts, pp. iv, vi, & viii. Public Appointments, p. xviii.

SATURDAY, JUNE 11.

Architectural Association.—Visit to new Music School, Harrow, Mr. E. S. Prior, architect; and to other school buildings and houses at Harrow. Meet at Harrow Church at 3 p.m.

Junior Engineering Society.—Visit to the Works of the Patent Victoria Stone Co., Stratford. 3 p.m.

RECENT PATENTS:

ABSTRACTS OF SPECIFICATIONS.

10,045.—WINDOWS: S. J. Wilde.—This invention relates to an appliance to prevent windows rattling. It is a clip formed in two separate parts, of brass or other metal, one part being fixed to the meeting-rail of the lower window sash by means of screws, and the other to the meeting-rail of the upper sash in like manner.

10,106.—VENTILATORS: H. Hutton.—This refers to an invention for attaching an apparatus to hopper-shaped wall or window ventilators, or to any ordinary ashles and sliding frames for the interruption of smuts and dirt, the avoidance of draught, and for automatically cleaning the gauze forming a part of the apparatus.

11,013.—SASH-FASTENERS: C. E. Levin.—This invention claims to be a strong, simple, and self-gripping burglar-proof appliance for window-sashes, sliding panels, ventilators, and other fittings where it is desired that such fittings should be rendered secure from one side or from rattling. The invention consists in the use of curved or cam-like pieces of material suspended or supported upon a point placed at such a position in relation to its outline that its own weight, or a spring, or electro-motive force, or other suitable available force, causes the cam to press with an initial force against the frame of the window or other like part, not being the same part as that to which the cam itself is suspended or supported.

521.—COILS: W. T. & R. Smith.—This patent refers to what is described as an improved chimney top, cowl, or ventilator, the essential features of which are the employment of two vertical tubes or channels placed more or less parallel with each other, but not absolutely side by side, and not necessarily both of the same dimensions or contour externally or in cross-section. The top end of the one of the tubes or passages, intended to be the lower tube when finished, is bent or curved, or diverges from the vertical in any desired manner, and joins the upper tube at or about its centre. At this point suitable horizontal plates are provided in such a manner, relative to each other that a down-draught entering the top of the upper tube is prevented from passing down the lower tube, as both ends of the upper tube being open, the down-draught passes harmlessly through it. At the same time the horizontal plates do not obstruct the passage of the smoke or vitiated air, but provides a curved passage therefore from the lower to the upper tube, and this will there be met by the down-draught in the upper tube, in which case it would ha

carried thereby through and out at the lower end of the upper tube, consequently the down-draught in the upper tube, however severe, would tend to improve rather than deteriorate the up-draught in the lower tube.

NEW APPLICATIONS FOR PATENT.

May 16.—9,217, J. Ezod, Ornamentation in Clay, for architectural and other purposes.—9,235, J. Kymr-Jones, Refractory and Non-conducting Bricks, Blocks, Tiles, Slabs, and Pipes.—9,251, J. McGlashan, Ornamentation and Decoration of Walls, Ceilings, etc.—9,258, J. J. Leitch, Hardening of Plaster, and the development of colours mixed therewith.—9,268, E. New, Device for Loading Brick from Machines.—9,279, F. Miller, Laying Wood Pavements.

May 17.—9,293, J. Brown, Chimney-pots.—9,322, A. Bonik, Pavements.

May 18.—9,408, C. Taylor, Heating or Warming Dwelling-houses, Warehouses, Buildings, etc.—9,421, J. Jones, Construction of Casement Window-Frames and Sliding-sashes.—9,427, J. Jeffreys, Joining Cast-Iron Pipes.—9,449, W. Williams, Hot-water Apparatus for Heating Greenhouses, Baths, and Buildings, etc.—9,462, H. Donlton and C. Morris, Joints for Earthenware Pipes.

May 18.—9,543, J. Castie, Mills for Grinding Cement, &c.

May 20.—9,583, R. Bocoek, Siphon Clusters for Flushing Water-closets.

May 21.—9,669, W. Jones, Water or other Closed Seats and Frames.—9,698, J. Grubb, Sliding Gas Pendants.

PROVISIONAL SPECIFICATIONS ACCEPTED.

6,147, W. Davies, Coin Freed Apparatus for use in connexion with coin-closets.—7,440, J. Hunt, Roof Outlets.—7,008, E. Heyes, Electrical Fittings.—7,071, W. Beaumont, Pneumatic Apparatus for Wood-working Machinery.—7,031, E. Waller and S. Smith, White Lead.—7,744, J. Bloomfield, Plaster.—8,381, H. Hunt, Mantelpieces for Fireplaces.—8,473, C. Hawkes, Covering for Walls, &c.—8,477, X. Charles, Kilm or Drying Apparatus.—8,583, F. Fawcett, Machinery for Making and Pressing Bricks and in Moulds therefore, and in Clay Mixing or Grinding Pans employed therein.—8,706, S. Moore, Electrical Fittings, such as Ceiling Roses and Cut Outs.

COMPLETE SPECIFICATIONS ACCEPTED.

(Open to Opposition for Two Months.) 9,519, W. Pain, Carpenters' and Joiners' Hammers, 10,270, R. Hodges and E. Lilley, Door Indicators.—12,049, W. Deeming, Pipes for Sanitary and other purposes.—8,928, J. Henderson, Joiners' Jobbing Bench.—1,502, W. Thompson, Plaster for Building Purposes.

Jno. Mowlem & Co.	97 0 0
W. Griffiths, Kilpis	738 5 2
Jas. Dickson	832 11 0
land-road, N.E.	738 5 2

(Surveyor's estimate, £743.)

SUBSCRIBERS IN LONDON AND THE SUBURBS, by prepaying at the Publishing Office, 13s. per annum (or 4s. 9d. per quarter), can ensure receiving "The Builder," by Friday Morning's Post.

TERMS OF SUBSCRIPTION.
"THE BUILDER" is supplied sixpence from the Office to residents in any part of the United Kingdom at the rate of 19s. per annum in advance. To all parts of Europe, America, Australia, and New Zealand, 26s. per annum. To India, China, Japan, &c., 30s. per annum. Remittances payable to DOUGLAS FOUNDRIER, Publisher, No. 46, Catherine-street, W.C.

TO CORRESPONDENTS.
E. W. T. (the preservation of the general design is not affected by such a detail as that a little variety in detail is even preferable.)—J. B. (the proposal is absurd, as wheeled traffic in crowded streets cannot keep to a straight line.)
All statements of facts, lists of tenders, &c. must be accompanied by the name and address of the sender, not necessarily for publication. We are compelled to decline pointing out books and giving addresses.
Nors.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.
We cannot undertake to return rejected communications.
Letters or communications (beyond mere news-items) which have been duplicated for other journals are NOT DESIRED.
All communications regarding literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

PUBLISHER'S NOTICES.
Registered Telegraphic Address, "THE BUILDER," LONDON.

The Restoration of the Choir of Peterborough Cathedral.

On Thursday last week, June 2, a special service of much stateliness was held in Peterborough Cathedral, in the presence of a very large congregation, for the dedication, by the

Archbishop of Canterbury, of the costly furniture and adornments which have been added to the choir since its formal re-opening in October, 1890.

The character of these additions, from their costliness and elaborate workmanship, demands a special notice. The whole of them have been designed by Mr. Pearson, R.A., who has thus set the stamp of his architectural ability on the decoration of one of our noblest cathedrals, which his engineering skill had already saved from a threatened ruin. Much as has been already done for the substantial repair of the fabric in the taking down and rebuilding the central tower with its sustaining piers and arches, and in the under-pinning of the north aisle and transepts, at the cost of more than 31,000*l.*, the struts which still extend their unseemly bulk at various points of the fabric, especially at the north-east corner of the Eastern Chapel, indicate that this most essential work is by no means complete, and that a large expenditure will be still needed before the Cathedral can be said to be in a state of complete security. The west front especially, the chief glory of the edifice, causes much anxiety. The façade is leaning outward bodily, and the whole calls for speedy attention to forestall possible disaster of no ordinary seriousness. This careful survey, we understand, Mr. Pearson will commence as soon as he can be provided with the necessary scaffolding, which, as our readers do not require to be informed, "means money," and a good deal of it. May it be forthcoming. The eastern angle of the chapel beyond the apse or "new building," as it has been commonly called since it was first erected more than four centuries ago, the ceiling of which is one

of the most admirably-designed examples of fan-tracery in the kingdom, evidently from the same hand as King's Chapel, Cambridge, has also given way, through the failure of the foundations, and requires underpinning and repair. When we add that the masonry of the gables of the transepts is in many places insecure and requires extensive repairs, and that the corner turrets of the central tower, which has now a painfully equat appearance reminding one of Winchester, still have to be built, it will be seen that the Dean and Chapter have much on their hands before the external works are finished. We have said nothing of the building of the south-western tower, which is so urgently needed to balance its sister to the north, and complete the harmony of the western prospect. For this long-desired work no very large sum would be required, and we have often hoped, and hope still, that one of our northern millionaires, when he catches sight of the unfinished design as he passes by on the railway, may be fired with the desire of immortalising himself by undertaking it.

But it is time that we pass from what remains to be done, to that which is the proper subject of this article, viz., what has been done by way of internal decoration.

Under this head we have to speak of the Bishop's throne, the choir pulpit, both presented by the present Dean, Dr. Argles, the choir pavement,—also the gift of the same munificent benefactor, who had previously given large amounts to the works of material restoration, and the cleaning of the stonework of the nave,—the choir stalls, presented by various donors, together with the litany desk and other minor matters.

The throne and pulpit are both placed, somewhat unusually, outside the ritual choir,—which has been brought back from the eastern limb to its ancient place in the first two bays of the nave,—against the south-east and north-east piers, respectively, of the great eastern lantern arch. This position was rendered almost necessary by the throwing open of the transepts,—as at Westminster Abbey and Norwich,—for congregational purposes. However advantageous this arrangement may be for the accommodation of hearers and worshippers, to throw the transepts into the choir without any intervening

creens, is as injurious to the general effect of the building as it is contrary to the intentions of the original builders. Light iron grilles, similar to those which occupy a like position across the lesser transepts at Lincoln, would have satisfied the eye without materially interfering with sight or hearing. When so much still remains to be done, and the inflow of funds is naturally not so plentiful as in the first enthusiasm of the movement, we hardly like to suggest fresh expenditure; but there is hardly any work which would be more rewarding in general effect. Screens are even more urgently required for the arches on either side of the constructional choir, which, now that it is denuded of all furniture and fittings, looks painfully naked and open. Grooves in some of the huge Norman columns show where such screens once stood, and where it is to be hoped they will ere long stand again. Though we cannot profess to be admirers of Blore's woodwork which, however admirable in material and workmanship, shows a fatal want of recognition of the difference between wood and stone to work in, we should have been glad if, when Dean Monk's choir, dating from 1830 (the year, one may say, from which dates the first commencement of the movement for cathedral restoration), was dismantled, the fronts of his strangely-designed stalls had been used to screen off the aisles. They have been so employed on the north side of the nave to form choir and clergy vestries in the aisle, and that with an effectiveness which makes us the more regret their removal from the choir.

To turn from noting deficiencies to the description of the costly works dedicated last week. The first to challenge attention is the new throne, which, from its position, is conspicuous in the eastward view almost as soon as the cathedral is entered. This has been executed in oak by Mr. Thompson's workman at the cost of 1,250*l.*, and, as we have said, has been the gift of the dean. "It was not every dean," the bishop remarked at the luncheon, "who wanted to build a throne for his bishop." Though the conventional type of an episcopal throne, as a choir stall of greater loftiness and richness, has been maintained, Mr. Pearson has given a

degree of originality to his design, by omitting the front legs of the canopy, which rests on curved supports coming forward from the back. The canopy is very lofty, ending in a tall, crocketed spirelet reaching halfway up the triforium, and comprises three tiers of rich tabernacle work, connected by delicate pierced fenestrations. The angles of the principal canopy are accentuated by square turrets of pierced work,—lanterns we may almost call them,—also ending in spirelets. The niches of the canopy contain statuettes of abbots and bishops of Peterborough. In the lower tier are Saxulf, the first abbot, Cuthbald his successor, De Seez the builder of the choir, Benedict the builder of the nave, St. Hugh of Lincoln (of which diocese Peterborough formed part till the Reformation changes), and lastly, John Chambers, the last abbot and first bishop. In the upper canopy are figures of Bishop Dove,—a favourite preacher with Queen Elizabeth, who called him "the Dove with silver wings,"—and of Bishop White Kennett, the eminent antiquary and historian.

Against the corresponding pier on the north is the pulpit. The body is of circular outline, ornamented with panelling and tabernacle work of somewhat excessive richness, and broken by projecting niches containing figures of the Apostles St. Paul, St. Peter, St. John, and St. James. Between these are wide panels, with carvings in high relief of Our Lord's parting Commission to His Apostles, the Day of Pentecost, and Saxulf Preaching to the Gyrvians. The pulpit rests on an elaborately-carved polygonal base, with niches containing statuettes of four of the Abbots connected with the building of the Cathedral. The figure-carving of the pulpit is by Mr. Hitch, who is responsible for the greater part of the carving at Truro Cathedral; that of the throne, we believe, was executed at Peterborough, under Mr. Thompson's superintendence, by his own workmen.

Passing westward, and entering the ritual choir, the whole range of stalls, nineteen in number, has been completed on the south side, filling the two bays of the arcade comprised within the limits of the choir. On the north side only seven stalls have as yet been erected, leaving twelve to be made up. There are also six return stalls at the west end, three on either side of the entrance. Eighteen of these stalls having been given since 1890, were included in the service of dedication. They exhibit semi-hexagonal canopies, with ogee, crocketed, and traceried gables, flying buttresses and pinnacles rising into elaborately carved niches with ogee pediments containing statuettes, the design finishing in a lofty crocketed spirelet. The ornamentation of the lower canopies is rather crowded, and suffers from excess of richness. In common with the throne and the pulpit, the carved work is somewhat too profuse and "busy," and a quieter and bolder design would have been more effective. The wearied eye craves for repose. The two terminal stalls at the west end for the dean and vice-dean are loftier and more elaborate in treatment. They are three stages in height, with two tiers of statuettes, and have taller spires. The sides of the terminal stalls flanking the entrance bear panels carved with legends from the history of the abbey,—the wonder-working arm of St. Oswald, the apparition of the angel to Ethelwold, &c. The canopies of all the stalls are groined within, with bosses at the intersection of the ribs. The statues in the niches present a sculptural record of the history of the fabric in its successive representative personages, from Peada, the founder of the monastery, to Archbishop Magee and Deans Saunders and Perowne. Other statues illustrate the history of the Church of the O. T. and N. T., as represented by the Patriarchs and Prophets, the Apostles and Evangelists. The selection and arrangement is the result of careful study, and will repay examination. The fronts to the central range of stalls on each side are relics of the old Benedictine choir, now once more

restored to their original place and use. The ogee panelling and traceried work, divided by small buttresses and crocketed pinnacles of remarkable beauty, has been made good from the traces left after the Puritans had brutally torn off the carved work, leaving the plain wood behind. The new stall-fronts have followed the same model; we wish their hue could have been adopted. The whole of the new woodwork looks painfully raw. But this is an evil that time will mend. We must not forget to mention a handsomely-carved Litany desk executed in oak, the gift of Mrs. Rigg, the daughter of the late Archdeacon Davys, which stands in the centre of the choir.

The most distinctive feature in the refitting of the choir is the sumptuous pavement of tessellated work and inlaid marbles, which as long as the Cathedral stands will perpetuate the name and record the munificence of Dean Argles and his daughter. This pavement has been designed by Mr. Pearson, and carved out by Italian workmen under the superintendence of Mr. Robert Davison, of London. The whole of the marbles employed are from Italian quarries, of rich and varied hues, contrasting and yet harmonising. The cost has been little, if at all, short of £2,000, the original estimate, we need hardly say, having been largely exceeded. The pavement is divided into sections, increasing in richness of material and complexity of design as it advances eastward. The ritual choir and the lantern space are paved with tessere of a subdued red, green, and white, arranged in a geometrical pattern, the low tone satisfying the eye without distracting it. The floor of the eastern limb is divided into three chief sections corresponding to three bays of the arcade, the sanctuary and altar-space forming a fourth section in which the decoration culminates. The bays are separated by steps of polished marble of various kinds, the first step being of the black Frosterly marble flecked with white madreporas, familiar to us in the Chapel of the Nine Altars at Durham; the two next are of Levanto marble of a reddish-brown with white veinings. The remaining steps, as well as those of the footpace of the altar, are of pure Pavonazzo with exquisite veinings. The design of the pavement of the first two bays is the same. Four large parallelograms of Pavonazzo are set in a framework of deep red porphyry, the intervening cruciform space being occupied by interlacing bands of cream-coloured tessere forming circles and lozenges on a tessellated ground of red and black. The third bay, though of much more elaborate design, is hardly so effective. The design comprises three square compartments laid transversely from north to south, each containing four panels of Cipollino, framed in hands of "opus Alexandrinum," made up of squares, triangles, and diamonds, of brilliantly-coloured marbles, which are again set in a broad border of mosaic of white squares on a light green ground. The design of this bay strikes us as too much scattered and somewhat deficient in decision of outline. Bolder lines would have been more effective. The fourth bay shows a system of interlacing bands, enclosing alternately large and small octagonal spaces, the small octagons being filled with rich plaques of marble, the larger being divided into eight triangular panels of marble mosaic of varied patterns. At either extremity of this bay is a long panel of intersecting circles, filled with rich mosaic. The altar footpace, and the three steps, are as yet unfinished. They are to be inlaid with rich mosaic enclosed in marble bands. The pavement north and south of the altar is of "opus sectile," exhibiting hexagons of Pavonazzo, between lozenges of a rich marble resembling our English serpentine. The entire design is finished on the outside with a long band of red marble extending the whole length of the Presbytery. Though, as we have said, the pavement might have proved more effective if greater simplicity and boldness of outline had been adopted in some parts, it must be acknowledged to be a magnificent work,

which calls forth admiration both for the elaborateness of the design and the richness and beauty of the materials employed.

The reredos, side screens, altar rails, and credence-table are still deficient, and wait the liberality of future donors. The place of the two first-named is temporarily supplied by rich hangings. Behind and over the altar is a tester of crimson and orange velvet, plain but effective. On either side are curtains of a dull green, entirely excluding the view of the apse and of the chapel beyond, which is to be regretted.

Among the desiderata enumerated is the reconstruction of the organ. We observe that it is proposed to place it in the triforium, as at Canterbury. This may be necessary, but it is much to be regretted. An organ enclosed in a case, such as men were once able to design and might design again, is a grand and beautiful object, and when placed, as we hold it ought always to be placed, on architectural as well as musical grounds, on the centre of the choir screen, it is of inestimable value as breaking the protracted vista, suggesting something beyond, and creating "that mystery of things half seen," which, as the late Mr. Street has truly said, "is the secret of many of the greatest successes of mediæval architecture." When the funds allow the Chapter to undertake the choir screen, which is one of the first wants of the Cathedral, to hide the plain and ugly hocking of the screen stalls, we hope that no foolish outcry for an unbroken view from end to end, which our Cathedrals never had nor were intended to have, will prevent their putting the organ in its proper place, over the entrance to the choir, provided it is in any way practically possible from the organ-builder's point of view. The difficulty of course arises from the increased size of modern organs, especially in the department of the pedal, which includes the largest pipes in the instrument. But we think it may be possible, if the difficulty is fairly faced; and it would be better to reduce the contemplated size of the organ to some extent in order to get it into this position, as it is unquestionable that a rather smaller organ in the central position is more effective than a larger one placed in the triforium, while the architectural effect of the organ in the triforium position is of course entirely non-existent.

NOTES.

Two very important resolutions are to be brought forward at the meeting of the Institute on Monday night, by Mr. Charles Barry and Mr. Searles-Wood, both having for their object to provide that within a limited period it shall be declared that every candidate for Fellowship of the Institute shall be an Associate, or shall have passed an examination qualifying him for Associateship, "except in such special cases of age, merit, or distinction as shall justify the Council in dispensing with such examination under Section 3 of the Charter." The reason for the movement is that at present men just past the prescribed age of thirty may be qualified to be elected as Fellows, and that it is an anomaly that a man who before that age would have had to enter the Institute through the medium of the examination for Associateship should, by merely waiting till he is thirty, be able to evade that test and enter as a Fellow. The Council have received various memorials in recommendation of this policy. That the present condition of things is an anomaly there can be no doubt; but the proposal is practically very much the same as a proposal for the examination of candidates for Fellowship, though it is perhaps a better way to put it. The proposal has a great deal of support, we believe, from provincial members especially.

MISS OCTAVIA HILL, in a letter to the *Times* of Tuesday, makes an eloquent but we fear fruitless appeal against the passing of the Manchester and Sheffield

Railway Bill by the House of Lords. After noticing that Parliament is asked to sanction the sudden and irrevocable destruction of a residential district of comparative quiet, against the strong representations of the London County Council, "the only body which can judge of London as a whole," Miss Hill continues:—

"This railway proposes to destroy two squares; to invade acres of space covered with cheap, pleasant houses with gardens; if constructed it would in a great measure cut off the whole poor district of Lisson-grove from its natural playground, —Regent's Park,—which at present is approached by pleasant wide streets with little traffic, safe for small groups of children to traverse alone, wide breathing spaces, now bright with labour and lilac hanging over the low garden walls.

I believe the line to have been thus planned with the sole view of its being cheap to the promoters.

It has been said that these leases will fall in in about fifteen years, and that the public has no security that when they fall in the ground may not be more thickly covered. That is no doubt true, but that is no reason why fifteen years of healthy life with gardens and good air should be snatched away by Parliament,—years which will distinctly influence the life of many a child now three or five years old."

There could hardly be a more forcible and touching plea put in against this last attempt to destroy the comparative quiet and repose of a whole district of London. As we have said, we fear the appeal is hopeless now. Years hence, when London has all been turned into one racketing-ground of noise and traffic and piled-up buildings, people may begin to find out, when it is too late, that there are more vital interests to the comfort of life than rapid locomotion, and that in search of that convenience London has been made all but unbearable as a place of residence either for poor or rich.

THE inquest on the death of the two men who were killed in the extraordinary railway collision at Birmingham has resulted in a verdict of manslaughter against the driver of the Midland train, and no other verdict seems possible on the evidence. The length of time (nearly an hour) which the jury occupied in arriving at this verdict was probably owing to a natural reluctance to bear hardly on a driver who appears to have a good record of long service with his Company; but as the evidence leaves no doubt that the signals were open for the London and North-Western train, and as it was proved that they were (of course) so constructed that they could not be open for both lines, there is no room for doubt that the Midland driver was going against his signals. According to the evidence of Mr. Loveday, the chief inspector of traffic for the Midland Railway, there are "confusing elements" in respect to the signals near the junction, which appear to alter their position owing to the curve and the interposition of a chimney. In that case some responsibility, not very easily to be defined, would seem to be placed on the company. The more serious matter is that, as far as the signalman at Duddesdon Mill-road box could judge, the Midland driver paid no attention to his "caution" signal; and that he did not act as if he had seen it is obvious from the remainder of the evidence. It remains to be seen whether this was actually a case of culpable carelessness, or whether it is one of those instances which will occur at times, in railway traffic as in other matters, when the human machine unaccountably fails for a moment; when the eye sees what it expects to see, or does not see what it does not expect. Such momentary fallacies do happen from time to time, even to very careful and methodical men; whether this was one of them it is difficult to say; the trial may throw more light on it.

IT is clear that Mr. Goschen's change in the incidence of the patent duties has not in the least satisfied those persons who are interested in this subject. We have recently received a circular from a Patent Law Reform Association, which appears to be composed chiefly of Lancashire men. The

subject cannot adequately be dealt with in a very short space, but the fact is clear that the question has now reached the point whether any but nominal patent duties are to be any longer in existence. The duty of about 7% in the United States must be regarded as merely nominal. It may be that the increase of patents under a nominal duty would compensate the Exchequer for the loss in actual amount on each patent. It is questionable whether a patentee, more than an author, should be taxed for the purposes of revenue; but, be that as it may, it is well that we should not hide from ourselves that the time has now come when the point above stated has been arrived at. The issue between moderate and nominal duties will obviously have to be decided early in the life of the next Parliament.

IT is noticeable that in the recent Report of the Select Committee on Theatres there is no suggestion of the advisability of any general regulative to promote the safety of theatres, applicable to the whole kingdom, which would surely be desirable, instead of leaving each municipality to formulate its own regulations according to its own perceptions. It may be added that in addition to fire-resisting construction and good planning for exits, it would very much increase the confidence of audiences if the rule were followed which has been established in Berlin and some other continental cities, of compelling the management to keep on the premises a "fire-watch" composed of men who are retired firemen, familiar with the best methods of guarding against fire or combating it if it arises. The few recently-built theatres in London are as safe in regard to structure and planning as such buildings can be made, but the existing majority are only as safe as they can be made without entire rebuilding; and the knowledge that there was always, by legal regulation, a sufficient number of competent and experienced firemen on the premises would tend to give audiences that feeling of security that the building would be properly looked after, in the event of any accident, which does more than anything else to check panic.

BROCKWELL-PARK, Herne-hill, was formally opened on Monday morning last, amidst the rejoicings of the neighbourhood, by Lord Rosebery, Chairman of the London County Council, who commended the action taken by that and other bodies in saving this important "luug" to the neighbourhood, which is fast being covered with bricks and mortar. In addition to the new colony of houses which has sprung up at the top of Milkwood-road, opposite Herne-hill station, we notice that on Herne-hill itself, between the church and Poplar-walk, four new roads have already been marked out, so that this hitherto semi-rural neighbourhood will soon be materially changed, and there is likely to be ample need for the park as a breathing-space in the near future. Hardly had Lord Rosebery left the park when an event occurred which cast a gloom over the remainder of the day. Mr. T. L. Bristowe, M.P. for the Norwood Division of the Borough of Lambeth, in the midst of whose constituency the park is situated, and who had taken a prominent and active part in its acquisition, was suddenly taken ill, and died in the park after the lapse of a few moments. Mr. Bristowe's death at the very moment of the full fruition of his efforts in an important work has elicited widespread feelings of regret amongst men of all parties in his constituency.

THE threatened demolition of Emanuel Hospital, Westminster, is much to be regretted on more grounds than one. Not only is it a very interesting and picturesque old building, a peculiarly favourable specimen of its date, but the ground in connexion with it keeps an open space where open space is much wanted. The region neighbouring on

Victoria-street is rapidly becoming a collection of enormous heaps of building, the height of which is quite out of proportion to the ground they cover; and it is on that account all the more desirable that any unbuilt space in the vicinity should be preserved intact. We are glad to see, therefore, from a letter in the *Times* of Thursday, from Messrs. Horne & Birkett, the solicitors representing some of those who are opposed to the removal of the building, that an application has been made to Mr. Justice Chitty on behalf of the Dean of Westminster and others for leave to appear and submit arguments why the building should not be demolished, and that this application has been assented to. It is to be hoped that the result will be the preservation of the hospital and its grounds as now existing.

THE great controversy between the Prussian Royal Academy and the "Verein Berliner Künstler" as to the management of the Berlin Art Exhibitions has been settled by compromise, neither body receiving the Government permission necessary for independent action. The "Verein Berliner Künstler" and the Prussian Academy will henceforward mutually arrange all the official art exhibitions which are held, each body being equally represented in the management. The Government reserves the right of revising the "programme" of the exhibitions, and also of deputing a representative to watch the proceedings of the joint committees. The "Verein" will, to a certain extent, incur the pecuniary risk of future exhibitions; they are to be managed with the capital of this society, which will have the benefit of any profits, but also the responsibility for deficits. The Government support consists of a loan of the halls of the Landes-Ausstellungen-Palast free of charge, and the vote of a substantial sum for purchases. A committee of connoisseurs (selected by the Minister of Education, &c.) will act as advisor to the Government as regards the purchase of exhibits, and the Emperor is to be requested to act as patron. The art exhibitions are henceforward to be of more national interest than the usually purely local ones held under auspices of the Academy. At certain intervals large international exhibitions, similar to last year's, will be arranged. It is to be hoped that under the new rule more attention will be paid to architecture, which has hitherto been very badly provided for in German art exhibitions.

WE note with pleasure that the German Emperor has selected Sir John Everett Millais to be a holder of the Order "Pour le Mérite" (Arts and Science Division, Foreign Section). It is the highest Prussian distinction, and is only given with the consent of the Knights of the most honourable order.

A DISCOVERY of very great interest has been made at Silchester, Hants, during the excavations that have been going on, on the site of the Roman city. This is the complete ground-plan of an Early Christian basilica of small dimensions, situated near the south-east corner of the Forum. As the earliest example of a Christian place of worship in the British Isles its value is great, and lends additional interest to the discoveries that are being made at Silchester. We hope to give a ground-plan and some more particulars next week.

THE new market for fruit, vegetables, and flowers, which is to be opened on the 13th inst., in West Smithfield, completes the tale of central markets erected by the Corporation, under statute. It will supplant Farringdon Market, and takes the place of one that was built, for the same goods, in Farringdon-road, opposite, but which, before its completion, the Corporation decided to open for the sale of fish, and which was so opened in May, 1883, having cost altogether 450,000. As the fish traffic resulted in a heavy loss,

the building was converted, by Mr. A. Peebles, the then City architect, and at a further cost of 12,000*l.*, for the sale of poultry and provisions. Of the works for a new fruit market, as planned and designed by Mr. Peebles, we gave descriptions in our columns on September 13 and November 1, 1890. Messrs. Rudd & Son, of Grantham, took the contract, at 41,973*l.* for the basement and sub-structure. The super-structure was estimated to cost 15,500*l.* On February 28, 1885, we adverted to the establishment by the London Riverside Fishmarket Company of a fish market at Shadwell.

IT is stated that St. Mary's Hospital, Paddington, is to be added to, at an estimated cost of 100,000*l.*, as a memorial to the late Duke of Clarence. The present hospital, enlarged a few years ago, was built in 1845-9, of red brick with stone dressings, after the designs of Mr. J. H. Wyatt and Mr. Thomas Hopper; according to Cassell's "Old and New London;" in William Robins's "Paddington, Past and Present" (its preface dated in 1853), we read that Mr. Hopper was the architect, and made no charges for his professional labour. The entire plans were for five separate divisions, or blocks, with a total capacity of 350 beds.

A NEW form of cowl for chimneys and other minor ventilation, has been patented by Messrs. Wheeler & Sons, for which considerable merits are claimed, and which may fairly be classed as a good specimen of revolving cowls on the archimedean screw principle. The chief features of the cowl are the use of twin blades to the screw, the introduction of coned louvres within the wind-blades to prevent the admission of rain and snow, and careful provision for decreasing the friction of working parts, which is always the weak point of revolving cowls. The use of phosphor bronze for bearing surfaces, and the reduction of bearing points to one by careful balance of the cowl, tend to the reduction of friction.

THE vitality of some of the popular errors about the history and development of architecture is extraordinary. The notion that Gothic vaulting arose from an imitation of trees has been exposed and laughed at by every competent architectural critic for years back, and it is needless to say here that it is an idea which no one could entertain who had given the slightest intelligent study to the history of the development of Gothic vaulting. Yet in a critical article in the *Times* of the 6th inst. on the life and works of Gustave Doré—an article, moreover, which as far as its notice of Doré's work goes is marked by a very sound spirit of criticism,—we are told, in reference to Doré's appreciation of Gothic architecture, "that he loved to go wandering in the forest solitudes of the Vosges, under those colonnades of stately stems with their arching foliage which had furnished the Gothic architects with their designs" (!) When are we to be rid of this nonsense? The writer of the article in question is evidently a man of education and thought in regard to some forms of art; let him, before he next refers to architecture in print, read any illustrated sketch of the development of Mediæval vaulting, by a competent exponent of architectural history, and he will then perhaps realise that architecture is not a subject to be dragged in for literary illustration without some knowledge of the scientific facts of its history and development.

THE development of new proposals for plundering the architectural profession under the name of "competition," has been going on fast of late years. It is always of interest to note a new feature. The last we hear of has been furnished to us in the form of the conditions for a limited competition to which some eminent Dublin architects have been invited. We suppress all names, as it

has not been publicly advertised; but after giving the particulars for the building the instructions proceed;—

"It is to be understood that no fees or commissions are to be payable to any architect who may send in plans as above, and that the building committee do not bind themselves to adopt any of the plans that may be submitted."

This really deserves the distinction of being the best joke of the kind that has yet been made; it is difficult to decide whether it is the offspring of pure audacity or pure innocence; or is it a characteristic development of Irish humour?

ARCHITECTURE AT THE ROYAL ACADEMY.—VII.

1,788; "New Tower, St. Mary's Church, Lynton;" Mr. H. Wilson. A water-colour drawing of a very original church tower, showing how its author has been trained in the school of the late J. D. Sedding, whose work he seems to be carrying on in the same artistic spirit. The tower is nearly plain up to the belfry stage, where conical traceried windows are inserted, with a stupa over the dividing mullion; a low-pitched leaded roof of concave outline projects its eaves boldly, and the buttresses stop flat under them; the wrought-iron gargoyles at the angles look a little thin and out of keeping with the solidity of the rest. The angle staircase turret appears to penetrate the roof and finishes in a small lantern a little too suggestive of a pigeon-house; but the whole is picturesque and original.

1,789; "East Window, Skelton-in-Cleveland Church, Yorkshire;" Messrs. Shrigley & Hunt. A five-light window with a figure of Christ in the centre light on a rather larger scale than the figures of saints in the other lights, which we think a mistake; the general colour-effect of the window is very good, and the architectural canopies are treated with due subordination and mass well with the whole; but here again we have canopies which project in perspective and leave platforms in perspective for the figures to stand on, which is contrary to the true principle of stained glass; and having this appearance of bulk, there seems nothing adequate to support them.

1,791; "Figures from the Workmen's Window, Law Courts, Birmingham;" Mr. P. H. Newman. We published these figures in the *Builder* for July 25, 1891, with the decorative adjuncts to one figure only. The effect of the whole is very rich, and interesting as an unusual introduction of Renaissance architectural detail in stained glass; but the effect of the heavily-colored perspective niches is here again very solid for a surface intended to transmit light, and the boots, aprons, braces, and other details of working-men's costume have an odd effect in stained glass. If it were determined to treat the figures as realistic types of working-men this could not be avoided, and the conundrum has been solved perhaps as well as it could be under these circumstances; but we should have preferred emblematic to realistic figures for a window. These would have been quite suitable for wall painting; a window is another affair entirely.

1,793; "In Heaven their Angels Always Behold the Face of My Father": Design for a Stained-glass Window for Rydal Church;" Mr. Henry Holiday. This is a true example of decorative stained-glass, entirely clear of realism or perspective; the design is made up of winged children's figures (the purple wings furnishing a valuable element in the colour design), bearing scrolls with texts, the figures and scrolls intertwined with foliage, with a sky background. This is an unusual and very fine and successful piece of stained-glass design.

1,794; "Portion of the East Window of Bath Abbey;" Miss Emma Knight. A very fine and powerful illustration of old stained glass, giving almost the rich effect of the glass itself, at least to an extent seldom produced by pigments.

1,797; "Design for a Window at All Souls' College, Oxford;" Messrs. James Powell & Sons. A Renaissance window in small square leadings, of which the border is an admirable piece of ornamental design; in the centre is an architectural niche with a figure of Wren in his habit as he lived, with a panel with arms and supporters below the niche. The mistake of this is that this architectural erection seems to be hung in air in the middle of a white space,

and has nothing to support it, nor is the figure in blue coat and hockled shoes happy in effect. A medallion portrait with a less architectural framing would have been better for a window.

1,798; "The Baptistery, Florence; Zodiac Panel in Pavement;" Mr. R. W. Schultz. A very careful pencil-drawing, slightly tinted in places, showing the pavement on plan, with the joints of the main slabs carefully marked. This affords an admirable study for real decorative work in pavement inlay; the artist has attempted no more in his representation of the signs of the Zodiac than is quite within the powers of inlaid work; and though the design is generally symmetrical, there is an entire absence of that minute care for asymmetry which would tend to give the design a mechanical hardness.

1,800; "Design for a large Town House;" Mr. Arthur Bartlett. A very pretty and original design, shown in a tinted pencil-drawing; it is not easy to see, however, what can be the function of the little windows between niches and colonettes which form the only openings in the mass of wall on the ground floor. Architecturally the effect is charming, but how does it fall into the plan, and what becomes of any entertaining room on the ground floor? A plan might have solved the riddle, but none is given. The upper portion shows a recessed centre with mullioned bay windows running through two stories and stopped by the soffit of a balcony connecting the end wings. The lanterns over the wings are the least happy features, and seem out of place and nameless.

1,802; "Glasgow Art Gallery, Competitive Design;" Mr. A. N. Prentice. A curious but very picturesque design of somewhat Spanish character. The centre feature is a circular tower with a conical roof and lantern, rising from a square central block, and flanked by circular turrets which sit on the angles of the square. The rest of the building is a long nave extending both ways, with a transept terminating in an apse abutting against it. The ground story is kept quite plain, only broken by entrance-doors, the upper story richly treated with rows of small circular-headed windows very deeply recessed, and the eaves projecting in an immense cove over. The transept is kept quite plain, affording a base for the ornate treatment right and left of it. The author seems to have been strongly influenced by his sketching tour in Spain, and the whole look of the building is as if designed for a hot country (the presumable roof-lighting is kept out of sight behind a balustrade on the roof); one certainly could not fancy it in Glasgow; but it is a brilliant architectural conception nevertheless.

1,803; "River Nook, Wrayshury;" Mr. T. E. Colcutt. This is published among the plates in our present number, to which we refer the reader. By Mr. Colcutt's courtesy we are enabled also to give the plan of the house, which is not shown on the drawing at the Academy.

1,804; "Drawing-room Ceiling, Ashridge;" Mr. T. Strehthill Smith. It is impossible to deny boldness and vigour to this ceiling design, but that is all it can claim. It has all the worst and most rampant vulgarities of Louis Quinze taste; immense cartouches with the usual gilt shoulder-knot kind of feature dear to the period; bundles of instruments and other things sticking out from the margin, heavy garlands festooned horizontally, &c. The centre portion is occupied by a copy of Guido Reni's "Aurora," a composition quite out of place on a ceiling, and the ragged outline of the frame which surrounds it has a very bad effect. The author has reproduced faithfully and with spirit the characteristics of one of the worst periods of decorative taste.

1,805; "Convalescent Home, Chatham," and 1,806, "Housa at Royston, Herts;" in one frame, by Mr. John Belcher, may be taken along with 1,813, "Studio, Melbury-road;" and 1,814; "Mark Ash, Ahinger," also in one frame, and by the same architect: four small water-colours of characteristic and pretty little buildings. In 1,813 and 1,814 the figures are evidently wrongly placed or wrong in the catalogue; 1,814 is the studio; it is to the architect's credit that it is quite obviously so, even without any plan. "Mark Ash" is an exceedingly pretty specimen of a small country house treated in "picturesque cottage" style.

1,808; "Flixton Hall, Suffolk;" Mr. F. B. Wade. This is apparently an addition to the old Elizabethan house: a plan is given showing the extent of new and old work. The additions

consist of a large conservatory forming the main garden entrance, new garden fronts to the drawing-room and morning-room, and a very extensive return wing of lower buildings in the same ornate style, containing kitchen and other offices, and another conservatory towards the garden court. The house is in the richest Elizabethan style, of brick with stone dressings, paneled balustrades, and brick chimneys and pinnacles, but as all the work shown in the perspective view is new, we cannot tell how far this is a carrying on of the design of the original, or how far it is a creation of a modern Elizabethan house. If the latter, it is very completely done and in a very rich and pleasing style, though it cannot be said to present any originality of idea or detail. The octagon turret above the garden entrance is a very pleasing and picturesque feature. The drawing, a large water-colour in the true "architectural draughtsman" style, is weakly executed and not good enough to do full justice to the building.

1,811; Caer-hnn, North Wales; Mr. T. M. Lockwood. A good sepia drawing of an exceedingly solid stone house with mullioned windows, this portion contrasted with the half-timber work of the secondary portions of the house, which seem to shelter behind the solid mass of the other portion. If, however, this is a new house all built at the same time, it has too much the appearance of two different buildings of different dates. There is no plan to give any explanation on this head.

1,812; "St. Bartholomew the Great, E.C., the New Transepts," Mr. Aston Webb. Three fine solidly-executed line drawings in one frame, showing the interiors of the two transepts and an exterior view of the north transept and porch. In the north transept the triforium arcade is carried round, with three lancet windows over, which show cusped heads externally, but internally are masked by arches with traceried heads divided into two lights by (apparently) Purbeck or other marble shafts, which are shaded darker in the drawing. In the south transept the triforium arcade is stopped, and the end wall above the main arcade occupied by three large two-light windows with geometrical tracery in the heads. The drawings are by Mr. C. E. Mallows.

1,815; "Gloucester Cathedral, Interior of Choir," Mr. C. E. Mallows. This is the drawing published in the *Builder* of Dec. 5, 1891, as one of the illustrations of Gloucester Cathedral.

1,816; "Design for a Window, Trinity College, Oxford," Messrs. Jas. Powell & Sons. This is another example of a Renaissance architectural shrine with a figure hung in the middle of white squared glazing; but it is less open to objection than No. 1,797, because the architectural framing of the figure is treated in a more light and decorative manner and with less of architectural formality and squareness. Still, even here, the niche is too much as if hung in air. Apart from this objection, the design is graceful and effective in its dealing with decorative details which have the sanction of precedent, though they are anything but pure in taste.

THE APPLICATION OF METALS TO ARCHITECTURAL DESIGN:

ROYAL INSTITUTE OF BRITISH ARCHITECTS. The following is an abstract of Mr. Alexander Graham's "Historical Sketch of the Application of Metals to Architectural Design," read at the meeting of the Institute on the 30th ult., as an introduction to the three papers* read by Messrs. C. Krall, H. Longden, and H. W. Singer on "Castings in Metal":—

The application of metals to the adornment of buildings might be traced to a very remote period of the world's history. The exact period when the work of the hammer and the chisel was supplemented by acquaintance with the earthen mould was not recorded, but tradition attributed this distinction to Phrygia. The art was, however, probably known to the Israelites in the time of Moses. The beating of copper must have been familiar to the earliest races, and the leathers shield with its studs of glittering copper was probably the earliest piece of decoration applied to buildings. The earlier founders made their castings as thin as possible, and attached them to a wood foundation with pins of metal; and this

would account for the scarcity of ancient examples, whether in copper or in bronze. It was doubtful whether the Phrygians made any progress with their invention, but it spread with rapidity in other countries. The walls of Babylon were defended by a hundred gates of bronze, and metal was extensively used both for the construction and adornment of buildings in Chaldea and Assyria. The gates of Balaawat, composed of plates of beaten bronze, made for Sardanapal II., about 650 B.C., were now to be seen in the British Museum. Philostratus said that the palaces of the kings of Babylon were "covered with bronze which caused them to glitter in the sunshine." The use of metals applied to buildings in Persia appeared to have been restricted to covering their brick and timber construction with thin plates, sometimes adorned with work in *reponssé* and inlays of gold. At the present day the gates of the Mosque at Isfahan were covered with laminae of silver, adorned with inscriptions and arabesques in gold. The forging of metals for decorative purposes preceded the casting in moulds. We had to turn to the Egyptians for the earliest artistic representations of the human form. They first used pure copper, being ignorant of the fact that by the admixture of a little tin its hardness could be increased. Among the metals in common use among the Egyptians was *astimu*, or electrum. There was a dearth of skilled workers in Judaea, and we learn from the book of Samuel that "there was no smith found throughout the land of Israel"; and this was probably the cause of their defeat by the better armed Philistines. The Phoenicians, who had at their command the commerce of the then known world, were able to place at the disposal of Solomon those who were the most skilled in metal-work, and amongst them Hiram of Tyre. The resources of the men who cast and chased and worked those masses of brass and silver, and even of gold, for Solomon, must have been equal to our own, though the methods might have been different. The date of this manufacture was a century before the birth of Homer, and a century and a half before the building of Carthage by Dido. Among the Greeks the application of the metals to decorative purposes was restricted. Copper and bronze and the precious metals were mere playthings in the hands of the Roman, and the traditions as to metal-work that had been maintained in Assyria and Egypt had been strengthened in his hands by an increased love of art and by the natural aspirations of a wealthy community. During the long period of the so-called Byzantine and Romanesque styles the same methods prevailed; there was an extension of art knowledge, but an absence of invention or originality. The most beautiful works at this period had their origin in strong religious sentiment, but they belonged rather to the arts of the jeweller and the goldsmith than to those pertaining to structural adornment. In France the bronze gates of the Church of Saint-Denis showed that the art of casting was familiar in that country as early as the twelfth century. The names of the artists in metal formed the history of metal-work during the most stirring centuries of the Christian era; and most of these masters in art were architects at that happy period of the world's history in which architecture was regarded as the art *par excellence*, to which all others were kept subordinate. At the Reformation the dry bones of art refused to be reanimated into life; the English Revolution effected nothing worth recording for the goldsmith or metal-worker; and the Restoration brought with it but few works of art, except perhaps the statue of James II. in Whitehall-gardens. The Gothic revival gave little more than a few improved patterns of gas-standards and altar-rails, but it enriched our literature with many valuable works on every known branch of metal-work. To architects the interest of metal castings was in their use in the adornment of buildings; and lessons from past history were of little practical value unless turned to account for the benefit and delight of mankind.

In the discussion which followed the reading of this and the three other papers mentioned, Mr. J. M. Brydon, in moving a vote of thanks to the readers of the four papers, said that Mr. Graham's interesting introductory historical sketch had invested the subject with a sort of literary halo. Mr. Krall, with his intimate knowledge of the precious metals, had told them of many processes, but the substance of his remarks seemed to be that there was very little casting resorted to in the treatment of the precious metals, although there were occasions when cast-work was employed; but even when cast-work was employed, the artists very skillfully adapted the means to the end, so that when the work was produced it was very difficult to distinguish the wrought-work from the cast. Mr. Longden, as a practical ironfounder, had very ably and very lucidly described to them the *technique* of casting in iron. There were several gentlemen in that room who were not so very old as not to be able to remember that in the years following the Gothic revival it was considered to be quite the correct thing to scoff at anything cast, and to shrug one's shoulders at everything except wrought-iron; but we heard of the greatest artists in the world working in cast metal-work. Mr. Longden had, however, omitted to mention Alfred Stevens's magnificent castings. Mr. Singer had discoursed of practical bronze casting, and had explained the difference between sand castings and the wax process. It seemed to him (the speaker) that the great difference between the one and the other was that the wax process gave much more intimately the touch of the sculptor himself than the sand process did.

Mr. Onslow Ford, A.R.A., said the real difference between sand casting and the wax process, from the sculptor's point of view, was that the bronze produced by the sand process was five times removed from the original model, whereas the wax casting was only twice removed from it; and those two removes were so slight that a casting, when perfect, had the appearance, even to the artist who made the model, of being an exact reproduction of his design in bronze. Mr. Singer, in his paper, had said he hoped that we should be able in time to produce castings as good as those which were produced in the fifteenth century; but he (the speaker) should like to say that Mr. Singer had produced castings as fine as any that had ever been done in any period of the world's history.

Mr. George Simonds said that Mr. Singer had spoken of the sculptors of the Renaissance, Cellini and others, adopting the extremely laborious and risky process of first modelling the core and then making their wax over that, afterwards covering it with a mould, and firing and casting it, so that if anything went wrong the work would be lost, and the whole thing would have to be recommenced. But although they worked thus on many occasions, they were perfectly well acquainted with the process of making the piece-mould, and they had the replica of the original work to fall back upon in case anything should go wrong. Cellini himself gave a long description of both processes. Mr. Singer had referred to casting work by the two processes combined. That was a very important thing, and, as far as he (the speaker) knew, Mr. Singer was the first who had done it. It seemed an obvious thing to do when making a large statue for outdoor purposes,—or, indeed, for indoor purposes,—because in such cases it was obviously a fearful waste of time and expense to use the *cire perdue* process throughout. In the statues that were put up all over England it was not worth while to cast a man's coat by the *cire perdue* process, but it was worth while to cast his head and hands by that process. He fully endorsed what Mr. Onslow Ford had said as to the excellence of the castings produced by Mr. Singer.

Mr. J. Starke Gardner said the four papers had been so excellent that there was really nothing to say about them in the way of criticism. With regard to one point raised in Mr. Graham's paper, he thought they must take it that metal was originally cast, and not beaten. They could not go beyond the prehistoric bronze period, and all the metal that they found of prehistoric date was cast metal, and, as far as they knew, it was all cast by something approaching to the sand process,—*i.e.*, it seemed to have been cast in a mould of rather porous stone, which, of course, in the case of simple castings was equivalent to the loamy sand now used. Mr. Krall had said that the value of the precious metals was formerly much greater than it was now, but he did not know what authority there was for that statement. So far as his (the speaker's) reading went, the precious metals of antiquity were of rather less value relatively than they were at the present time. Cast-iron was very much appreciated during the Renaissance, and he (the speaker) questioned whether Inigo Jones ever used anything but cast-iron, for he could not find examples of wrought-iron

* Abstracts of these papers were printed in last week's *Builder*, pp. 454, 455.

in any of his buildings; and Wren, as they all knew, used cast-iron for his railing round St. Paul's Cathedral, not because it was cheaper, for it cost 12,000*l.*, but because it was the very finest thing that he could do there. He thought no wrought-iron railing that could be put round the Cathedral could possibly look so noble and dignified as the present cast-iron railing. When properly used, cast-iron was not a brittle substance; it was only when we tried to do too much with it that it failed. There were many specimens of modern cast-iron work that were good and appropriate. As instances, Mr. Starkie Gardner mentioned the railing outside the New Travellers' Club and the park gates at Hyde Park Corner.

Professor Aitchison, A.R.A., said he had great pleasure in seconding the vote of thanks to the readers of the papers. Their friend Mr. Gilbert, the great sculptor, once told them that they made a great mistake in using bronze so little in their architectural work, and that where ornament was to be frequently repeated it could be modelled by our best sculptors and produced in bronze at a very small cost,—at a less cost, in fact, than it could be carved in stone. He (the speaker) happened at the time to have some internal work to do, and the owner wished all the capitals of a certain part to be alike. About a dozen of them had been ordered, but there were more to do, and it struck him that bronze could be successfully used for the purpose. Mr. Gilbert was kind enough to model one of those capitals for him, and they were cast in bronze and put up at a lower price than those which had been carved in mahogany. Bronze stood well in any climate, even in our own. It was true that it became ink-black in London, but still, it preserved its form, and was not made sufficient use of, considering that architects could now avail themselves of the skill of some of our best sculptors for modelling it. The objection to its use for the highest work of fine art,—the undraped human figure,—was that although it was almost imperishable if left alone, it was melted down in times of trouble. Thus several of Michelangelo's celebrated statues had been turned into halberce or into cannon. So far as cast-iron went, they knew a good deal about it, but he was afraid that although they knew a good deal about it they did not make nearly the use of it that they might; and though he believed he was opposed to the views of most of the members of his profession, he still looked forward to a time when it would be used to a very much greater extent than it had been. He looked forward to the style of architecture of the world,—the civilised world, at any rate,—being entirely modified by its use. When brick, stone, and rubble were almost the only materials to be had, it was necessary that arched and domed forms should prevail; but now that we had a material that was enormously stronger in cross-strain than stone or marble, it seemed to him that our architecture should naturally take the form of the old post and lintel of the Greeks. Although he believed cast-iron could not be cast with the perfection of bronze, and could not be chased,—so that ornament on it might not be perfect,—still, when it was used on a large scale, it was obvious that in a thing that was removed many feet or many yards from the eye, elaborate fineness would be absolutely thrown away. Where columns 50 ft. or 60 ft. high were used, it certainly seemed unnecessary that they should have the same perfection in the finish of the ornament that would be required were they close to the eye. In concluding his remarks, Professor Aitchison recalled some interesting historical points connected with metal-working and metal-casting.

Mr. H. H. Statham asked Professor Aitchison how many centuries he would give for the duration of a monumental work of architecture in cast-iron? He once asked Sir Benjamin Baker how long the Forth Bridge would last, and the answer was that with proper care it ought to last five centuries. Now, mild steel, the material used for the Forth Bridge, would probably last a good deal longer than cast-iron, but even five centuries was a comparatively short period in the life of a monumental work of architecture in brick or stone.

Mr. William White, F.S.A., said he thought that if ever architecture should become iron, it would cease to be architecture.

Mr. Sydney Vacher said he had understood, from a gentleman who contemplated adorning a public work of his with bronze statuary, in place of either stone or terra-cotta, that, taking

into consideration the fees which the sculptor would charge, his fonder's bill would be so large as to prevent him from employing bronze statuary instead of statuary in other materials. It would be interesting if the meeting could be afforded some idea as to the percentage of difference of cost between executing statues from the clay in marble and executing them in bronze.

Mr. Pinker, in reply to the question raised by Mr. Vacher, said that bronze was certainly much cheaper than marble.

Mr. Singer said as to the relative cost of bronze castings compared with other materials, it compared most favourably with, and was far cheaper than, marble, and he only wondered that that metal was not more used for architectural enrichment, as, when a repeat of the same ornament occurred, the cost would be but little.

Mr. Onslow Ford, A.R.A., said it might interest the meeting to know that, if the same bust were carved in marble, and also cast in bronze, it would cost in marble, including the marble and the labour of producing it, from 35*l.* to 50*l.*; whereas in bronze it would cost from 20*l.* to 25*l.* He thought that was about the proportion.

The President having put the vote of thanks to the meeting, it was carried by acclamation, and.

Mr. Alexander Graham acknowledged the compliment on behalf of the readers of the papers. He said that the only point raised which he had to answer was that mentioned by Mr. Starkie Gardner with reference to early castings. He (Mr. Graham) had never for a moment doubted that the primitive races were acquainted in some way or other with the fusion of ore, but he had always doubted whether they were acquainted with the art of finishing the metal, whatever it was, into form, otherwise than beating it with a hammer.

The meeting then terminated.

THE ROYAL COMMISSION ON METROPOLITAN WATER SUPPLY.

WE resume our report of the evidence tendered before this Commission,* giving first analyses of the statements submitted to the Commission on behalf of the London Water Companies, in compliance with the request which the Commission had addressed to them, and then explanations offered by the witnesses called in support of the statements. In a conversation which took place at the last sitting, the Chairman said the Commission did not expect that any conclusions they might come to would be absolutely free from discussion, but they felt strongly they ought to narrow the field of inevitable discussion as much as possible, especially on such points as population, number of gallons per head, and area to be built over,—points on which all who had watched the inquiry would see that there was an "unusually wide scope for conjecture and for estimate." In order to secure the strict relevance and utility of the evidence, the Commission must receive in advance the fullest information, in writing or in print, of the points that witnesses were going to deal with; and, subject to that condition, the Commission would err on the side of letting in evidence rather than excluding it, especially on the larger branch of the inquiry, the geology of the Thames and Lea basins, and the available supplies of water. Mr. Hollams, on the part of the Water Companies, rather complained of the Commission being put upon their defence, and said it was for the County Council to support its vague accusations. The Chairman repudiated the idea of there being any accusation, but Mr. Hollams maintained it was for the County Council to justify the necessity for the Commission, and suggested that the County Council's witnesses ought to be cross-examined by counsel. But the Chairman would not hear of that. Mr. H. L. Cripps, on behalf of the County Council, said the justification for the Commission was the growing feeling in London that inquiry was really called for; and he suggested that the county of Hertford, represented by Sir Richard Nicholson, should

* See *Builder*, pp. 418, 425, ante. It should be stated that in last week's *Builder*, page 436, second column, the scientific evidence as to the condition of the water in the Lea was (as mentioned in an introductory paragraph) given by Mr. W. C. Young, Consulting Chemist to the Conservancy Board, whose name was accidentally omitted at the commencement of his evidence, after that of Mr. Child.

precede the London County Council by tendering evidence on the conflicting claims of the London Water Companies and the county of Hertford to the water supplies of that county. The Chairman, however, desired first to hear the London County Council on the points involved in the first part of the enquiry,—population, requirements, present supply,—and then to take the larger question. Mr. Hollams complained that the Companies did not know what the London County Council's "case" was; and the Chairman said, "We want to know, in the first instance, what everybody's case is, before everybody knows what everybody else's case is; and I am going to stick to that." Then Mr. Hollams claimed, and the Chairman conceded, the right of reply and refutation.

The Grand Junction Company.

This Company's statement named the successive sources of its supply,—Paddington, Chelsea, Kew Bridge, and Hampton, on the border of Sunbury in Middlesex. There are two intakes,—one at Hampton, and the other a mile higher up on an island opposite Kenton Court, Sunbury. Filters, reservoirs, and machinery are all adequate to any possible increase of demand in the near future. Besides the intakes, the Company has works, used for ten years, for the natural filtration of Thames water, which is passed through extensive beds of gravel and sand and then pumped into the reservoir. The number of "supplies" of all kinds at the end of 1891 was 57,535; and the quantity of water pumped in the year (deducting for slip in the pumps) 6,203,000,000 gallons, or 17,000,000 a day. This is 7,500,000 short of what the Company may take. Constant supply prevails over four-fifths of the service, and will soon embrace the whole. With good fittings, constant supply does not materially increase demand. Of the 57,535 supplies, 34,626 are within and 22,909 outside the county of London. These figures include 5,000 nonoccupied houses. "The Census returns show 77 inhabitants for each town supply, and 54 for each suburban supply." (We quote these words because of a statement, mentioned last week, by Dr. Ogle, who is at the head of the Statistical Department of the Registrar-General's office, that the Registrar-General takes his figures from the Companies.) There are, therefore, continues the statement, 266,620 persons within and 123,708 outside the county of London; total, 390,328; or, deducting for nonoccupied houses, 350,000. If the rate of building for the last ten years is continued for forty years (which is considered impossible), the population would reach 584,969, for whom 24,500,000 gallons would give 42 gallons per head. Tables support the conclusion that the population in both districts will not increase in the future as it has done in the past. The average number of persons per house within the Metropolis has fallen from 8.2 to 7.7, and the numbers of houses and of people have diminished in some parishes. In the suburbs the average per house has fallen from 5.6 to 5.2 in the past ten years. Within the Metropolis the number of supplies has actually decreased. The prevention of waste would make the present supply go further, but only a moderate supervision is exercised, because the supply is in excess of the demand. The storage is sufficient for seven days' consumption. Although five Companies take daily 100,000,000 gallons from the Thames, the lowest summer level remains unchanged. The Company are satisfied that they could, like others, augment their present resources by large supplies from the gravel beds and the underlying chalk. They have promoted a Bill to do this, but it was rejected by the Commons on the second reading. Official reports prove the good quality of the water now supplied, and the death-rate in the Company's districts is low. Taking the census returns of inhabited houses and population in six parishes,—St. James, St. George, St. Marylebone, Paddington, Kensington, and Hammersmith,—for 1881 and 1891, an appended table shows the average per house reduced from 8.2 to 7.7. The local averages are 9.4, 6.9, 9.2, 8.1, 7.5, and 7.0. The figures are also given for nine extra metropolitan places, and show a reduction from 5.6 to 5.4.

Mr. Fraser, the Company's engineer, was called, and explained that the natural filtration process was a totally different thing from the gravel bed supply of the East London Company. The filtration process was simply passing the river water through gravel beds.

The process was used only when the river water was bad. The witness held that the maintenance of the level of the river was a proof that it was not depleted by the Companies, although the Chairman held that the level was rather governed by the lock below. The present supply for all purposes, according to the figures, was 48 gallons per head per day. It was a high figure, no doubt,—11 higher than any other Company, and 17 higher than the New River. The quantities were right, the numbers of supplies were right, but the Company had no means of checking the population returns. The district included clubs and railway stations, which were large consumers. The Carlton Club was supplied by meter.

The Chelsea Company.

The Chelsea Company mentioned in their statement that they first took water from the Thames at Ranelagh. They were compelled by the general Act of 1852 to remove their intake above the influence of the tide; and they then got powers to take the water from the Thames at Seething Wells, Kingston. Next, to avoid discoloration from sudden floods in the Mole, in 1875 they removed the intake to West Molesey, four miles higher up the Thames. There are now four subsidence reservoirs, holding 140,000,000 gallons, sufficient for a supply of two weeks. The water is invariably bright and clear; few complaints are received from customers; and when had colour is complained of it is found to be due to dirty cisterns or local canals. The reports of Messrs. Crookes, Odling, & Tidy, and of Dr. Frankland show the Company's water to be good throughout the year, and this is largely due to the capacity of the storage reservoirs, and the extensive filtration area. The average daily supply during the last twenty years is shown by a table to have varied from about 8,500,000 gallons to over 10,000,000 in 1885 and 1887, and 9,250,000, 9,500,000, and 9,750,000 in the last three years; and the number of supplies has risen from 27,949 to 35,630. Last year the maximum daily average for the month was 10,838,290 gallons in July, and the minimum, 9,351,607 in March. The daily average per head of the population was 34.6 gallons. The population of the district on December 31 was set down at 287,362 persons, and the number of houses supplied was 36,250. Shut in by the river and other Companies, the district contains only 523 unoccupied acres, chiefly in Fulham, and on these 10,500 houses may be built. Forty or fifty years hence there may be a total of 46,770 houses, which, at eight persons per house, will give a population of 375,000, and, at 35 gallons per head, will give a daily requirement of 13,125,000 gallons, or, say, a maximum of 15,000,000 gallons. The high average of eight persons per house is taken purposely. According to the Census returns for 1881, the average number of persons per house was 7.3, and in 1891 it had fallen to 7.1. Eight persons per house is a very full number to allow over the whole district. An average of 35 gallons per head is a very liberal estimate, because in the class of property likely to be built in the new district it is estimated that the outside quantity used will be 25 gallons per head, inclusive of trade supplies, road watering, &c. The eventual maximum of 15,000,000 is, therefore, a very full figure. The Company have power to take 24,000,000 gallons from the Thames during the twenty-four hours, and under an agreement with the Thames Conservancy they may take 2,000,000 more, making 26,000,000. This is more than double what is now taken, and 7,000,000 more than the estimated possible future maximum. The Company have machinery, capital, and spare land to meet increasing requirements.

Mr. Richard Hack, engineer, stated that the Company had abstained for as long as ten days together from taking water from the Thames. Three years ago all the four reservoirs were cleaned out, and, as a rule, one a year was done. The depth of the deposit was 4 in. or 5 in. The rate of filtration was $\frac{1}{2}$ gallons per square foot of filtering area, the recognised rate being 2 $\frac{1}{2}$ gallons. The area of filtration was the reason of the specially good quality of the Chelsea water. The filtering beds were cleaned out every eight or ten weeks. The Company had experimentally taken water from the gravel 100 ft. from the margin of the river, and from a sample, Dr. Tidy had pronounced it to be spring water. There were no buildings near to pollute this water. The object in taking

it would be to prolong the time the intakes from the river might be closed. The limitation on the river supply applied to each twenty-four hours; and one day's deficiency could not be made up by excess on another day; but if 3,000,000 gallons were taken from the gravel it would not be part of the river supply. The gravel area averaged 8 ft. or 10 ft. in depth, overlying the clay down the valley from Windsor.

Mr. A. C. Gill, a district engineer, said that in the returns empty houses were balanced by a delay of six months in reckoning new houses. He thought the census taken at Easter was misleading, because many persons would be out of town; but he was reminded that many of the residents of St. George's, Hanover-square, were out of town eight months in the year, so that the Easter census would fairly approximate to the average. He admitted the importance of discrimination in speaking of houses, tenements, and supplies, and on this point had a long conversation with Dr. Ogle, who referred to model dwellings as a disturbing element in estimates and approximate returns. With rigid inspection, there was no reason why constant supply should lead to greater consumption, but with the Company's surplus of water, waste was not of great consequence.

Mr. G. H. Gill, the Secretary, said the Companies' Act gave them the power to take water from any springs on their own land.

The Southwark and Vauxhall Company.

In the statement submitted by this Company, the following figures are given: 24,500,000 gallons may be taken daily from the Thames; 3,000,000 can be obtained from "collecting works" at Hampton—"natural filtration works," which cover an area of 39 $\frac{1}{2}$ acres; 3,000,000 may be obtained from the well at Streatham. 30,500,000 is thus the total quantity available. 10,500,000 may be obtained from seven wells yet to be sunk. 43,000,000 gallons is, therefore, the prospective supply. 25,000,000 gallons is the estimated requirement in 1892 for a possible population of 1,215,457, at 25 gallons per head, 18, or 19 for domestic supply, and 6 for trade supply. The Thames, it is said, could afford a much larger quantity than is at present abstracted from it, not only from the daily flow, but by storage in reservoirs, which would be constructed as required. "All the sources and statistics point to the fact that the Company has sources of supply within itself, or at its doors, which will meet all requirements for a period far beyond that for which any reliable estimate can be formed. Neither would the Company be at any difficulty in raising the capital for the extra works as they become necessary, the experience of the past proving that the increased revenue is more than sufficient to meet the increased interest on dividends which will become payable on the increased capital." The object of the works in progress at Streatham is to obtain an auxiliary supply from the chalk. A boring has been sunk through the chalk to a depth of 1,142 ft. With the temporary machinery 1 $\frac{1}{2}$ gallons were pumped daily for weeks. The maximum depression it has been possible to effect in the level of the water has been from a depth of 48 ft. to a depth of 97 ft. from the surface. It is, therefore, inferred that a supply of from 3 to 4 millions can safely be estimated as available from this source after the completion of the works in the course of next year.

The present total supply is 23,653,412 gallons daily, which, with an average population of 841,989, equals 28'09 gallons per head, of which 5'89 is for trade purposes, leaving 22'20 for the actual domestic supply. In the districts constantly supplied (now 87,310 "supplies" out of 113,781), the waste-water-meters show the progressive reduction of the supply per head for domestic purposes only to 21'71 for 1887, 20'72 for 1888, 19'57 for 1889, 18'53 for 1890, and 19'70 for 1891. It is in this experience that the future estimate for domestic supply is reduced to 18 $\frac{1}{2}$ gallons.

Full details are given as to storage, pumping, and filtering. At Hampton are three storage reservoirs that hold 20,000,000 gallons; a new one is proposed, to hold from 50,000,000 to 60,000,000 gallons. The filtration works cover 33 $\frac{1}{2}$ acres; three filters 3 $\frac{1}{2}$ acres; an extension will make this filtering area 7 $\frac{1}{2}$ acres. At Battersea are reservoirs for 46,000,000 gallons, and 1 $\frac{1}{2}$ acres of filters; at Nunhead, reservoirs for 18,000,000; at Forest Hill, reservoirs for 1,000,000 gallons.

Mr. J. W. Restler, engineer, in his evidence mentioned that one of the reservoirs at Hampton was being converted into filters, and thus the storage was reduced to 60,000,000 gallons, equivalent (as the Chairman said) to less than three days' supply; but (said the witness) there were in addition 21,000,000 gallons of filtered water stored. That would add a day's supply, although the storage of filtration water could not be "depleted to nothing at all;" but the company did not lay any stress on storage. The intakes from the Thames were never closed completely. "You take flood water at all times?" "Yes, we have to take it." But this involved no disadvantage as regarded quality. Of course, the filters were clogged more rapidly, and they had to be cleaned more frequently. The early flood water was the worst that had to be dealt with, but the draught of it was minimised, because at times of flood the "natural collecting works" gave one-half the supply. These works were used in two ways. Water was taken from the ballast beds first, without any water from the river. The ballast beds were also charged by means of pipes directly from the river. The Thames water was often let into the gravel bed; but in times of flood this was quite unnecessary, because there was so much water in the ballast itself that 10,000,000 or 12,000,000 gallons a day could be pumped without difficulty. This water did not come from the river, because the level in the ballast was higher than the level in the river. At that point the river was coated over with a very thin suspended clay,—a sort of puddled surface. The sides of the river seemed to be practically tight. Sometimes this water was pumped into subsiding reservoirs, but as a rule let to filters. Dr. Tidy had described it as magnificently pure water; and, seen through a 2-ft. tube, it was clearer than the ordinary artificially-filtered water. He did not regard this as Thames water, although ultimately it might find its way into the river much lower down. He thought the Thames itself flowed through the centre of a ballast bed, which extended from about Staines right down almost to the metropolis. The whole bed was charged with water, and it must at some time have got charged from the Thames, but he did not think there was any direct connexion, certainly in that neighbourhood, between the Thames and this ballast water. When building operations threatened the purity of this source of supply, this company and the Grand Junction constructed a puddle wall between the Thames and the outcrop of the ballast, at the northern end of the works. That reduced the quantity to be obtained from them; and so it was put down at 3,000,000 gallons instead of 5,000,000 gallons; but the lower side remained unaffected by the wall; and on that side any sources of pollution were too remote to affect the water. Describing the works at Streatham, the witness said the level of the ground was 110 ft. above ordnance datum; the well itself was 10 ft. in diameter down to 148 ft. from the surface; it was 9 ft. in diameter down to 191 ft. from the surface; it was 7 ft. 6 in. down to 244 ft. from the surface. When the sinking was being made, the water broke in at a depth of 212 ft. from the surface. It was really in the Thanet sand formation the water was found; the cylinders were carried down to, but were never actually sealed into, the chalk. The cylinders are in a bed of flints, practically on the chalk; but, of course, overlying the chalk. From that point a 30-in. boring was taken through the chalk to a depth of 813 ft. Then there was some 24-in. pipe, which went through the sandy chalk and marl. Below that, a length of 20-in. pipes got through the upper green sand and the gault to 937 ft. Below that, again, there is a line of 18-in. pipes, which are all in the gault. They go right through the gault; and at 1,073 ft. is reached a sort of red sandstone. There the boring was reduced to 15 in., and it went down to 1,094 ft. 6 in. After leaving the chalk, the whole boring was lined down to the bottom of the gault. There was a 4 in. boring,—a trial boring, really,—and that was taken down to 1,271 ft. That was also in the sandstone. There were no faults met with till quite the last few feet, and it was just a point whether it was the old or the new red sandstone. It was not green sand; the lower green sand was never found at all. There were just traces of what was supposed to be the lower green sand after the gault, but only traces. The machinery was put down primarily with the object of draining the well, so as to get cylin-

ders into the chalk and drive headings. The capacity of the pumps was under two millions a day, and, running them hard, the water could never be got lower than 95 ft. from the surface, so that the water was depressed by pumping 49 ft. Water was not being pumped from the Streattham well. The official sanction had just been received to use it as a source of supply. When the machinery was up, he had no doubt they would get 3,000,000 gallons a day. The seven wells that were to give 1,500,000 gallons daily were not sunk yet. Some fourteen years ago the advice of a number of eminent geologists was taken as regarded the best positions and the quantity of water that might be derived, and this estimate was based upon the reports they sent it. The Company had power to sink wells anywhere, and to take water therefrom. The Company's storage would be small for the large quantity of water used if it were not for the 10,000,000 or 12,000,000 gallons of naturally filtered water obtained when it was most needed.

Asked by Professor Dewar to explain why in December, 1891, the company's water was the only water that was turbid on six occasions, he said it was a difficult matter to trace, because they did not know of the analysis until a month after it was made. The same as to February, 1891. It was not that there was any lack of filtering area. If it was coincident with the taking in of flood water, it would look as if that was the explanation. On days when he had expected a chance of turbidity, because the filtration was working at its maximum, there had not been complaints, and for days when he thought they were all right complaints had come a month afterwards. The extension of the filters would reduce the chance of this trouble, although he would not say it was due to bad filtration. Sometimes he had thought it was due to samples being taken from points at which the water had been lying stagnant in the main. The points and the dates could be traced, and Professor Dewar remarked that it was certainly strange that the complaints should occur only in the case of this company. The average rate at which the filters worked was two and a half gallons per square foot, but at Hampton it sometimes reached three gallons. There did not appear to be any relation between the turbidity and the rapid working of the filters.

Dr. Ogle asked the witness to explain the curious fact that the amount per head given by this company was only about half that given by the Grand Junction. He said the Grand Junction gave constant supply, in reliance upon the house-to-house inspection of fittings. If this company did the same, its supply would be from 58 to 60 gallons per head. But the company checked its whole supply by waste-detection meters,—automatic registers,—which detected an enormous amount of waste that would never be seen otherwise,—waste from underground pipes and broken services, and numberless other causes. In addition, the company kept a check on the fittings by regular inspection. There would be less consumption on the intermittent system if the fittings were as good as for constant supply; but with better fittings the consumption was lessened by constant supply. It would be infinitely less if there were the same control over fittings that there was in the Midlands and the North. In some fairly respectable, small houses of £27 or £28 a year, where proper care was taken of the fittings, the supply was only 6.73 gallons per head per day. These houses had closets, but not many had baths. Baths and hot-water supplies did not much affect the consumption, and there would be an ample margin for them if waste could be checked. If the waste-meter system were adopted universally throughout London, the average consumption could be reduced to 2½ gallons. It was specially difficult to give constant supply economically in this company's poorer localities. If the water were shut off, the people would steal the fittings and sell them.

Mr. Joseph Lucas, called as a geologist, said in the course of his evidence that there were no scientific means whatever for forming an opinion that would be worth the paper it was written upon as to the quantity of water that could be obtained from the Streattham well. Still, he believed it was probable the 3,000,000 gallons expected would be raised when the machinery was completed, in eight months' or a year's time. The Streattham well water, he believed, came from the Wandle, which had a volume of

17,000,000 to 20,000,000 gallons a day. The pumping dried artesian wells at Tooting, but that only prevented the water running to waste in the Wandle.

Mr. Wm. Topley supported the opinion that it was probable the well would yield 3,000,000 gallons daily. The pumping affected a well at Teddington and one at Anerley.

The Lambeth Company.

This Company's statement is a descriptive and historical review copying twelve closely-printed foolscap pages, and divided into sixty-seven paragraphs, which include several statistical tables. The principal source of supply is the Thames, from which 24,500,000 gallons may be drawn daily, and this may be augmented by from 6,000,000 to 8,000,000 gallons from the gravel beds, which were discovered and utilised in a manner analogous to that described in the case of the East London Company. From 7,000,000 to 8,000,000 gallons are taken when the Thames is in flood and the river intake closed. Borings have been sunk to the chalk, and reported on as favourable sites for wells, but none have been sunk, as there is a large margin in the present supply, and larger quantities can be taken from the Thames and impounded in storage reservoirs to meet future needs and to tide over periods of flood on drought. At West Molesey, where the 24,500,000 gallons may be taken, the capacity of the pumping power is 42,500,000 gallons, and of the subsidence storage 125,000,000 gallons. The filtering area at Ditton is 9½ acres; and the capacity of the covered reservoirs for filtered water is 28,750,000 gallons. There are large margins of pumping power at Ditton and at Brixton Hill. As far as this company is concerned, there is no need for a supply from Wales or any distant source. The company can meet any demand likely to arise in its district for the next forty years. A great saving can be effected in the present consumption by the prevention of waste. It is believed that by the use of waste meters and by inspection, the consumption is now 7,000,000 gallons less daily than it would have been with the same population in 1871. The following are daily averages in gallons for the last three years:—

	Pumped.	Per Supply.	Per Head.
1889	18,235,739	204	29.17
1890	18,776,432	205	29.35
1891	19,736,466	213	30.36

The following figures exhibit the decrease in the average daily consumption:—

	No. of Supplies.	Population.	Gallons per Head.
1871	45,000	295,000	44.04
1881	69,123	483,861	39.76
1891	93,703	655,921	30.36

Mr. S. H. Louttit, Secretary and General Manager of the Company, said that the gravel-beds extended from the river for some miles inland. The Company were entitled to take the 8,000,000 gallons from the gravel in addition to the 24,500,000 gallons from the river. The water was not practically abstracted from the Thames. At a long inquiry by the late Mr. J. T. Harrison, in 1880, the question of this underground water was gone into very fully, and Mr. Harrison and Col. Hildyard, his assessor, concluded that the water came from the direction of the Bagshot sands, and came under these gravel beds in very large quantities. During the severe frost of 1890-91, in eight days 64,750,000 gallons of this water were pumped, and there was no trace of exhaustion or diminution at the end of that period. The chance of pollution was very remote, the nearest building to this source of supply being a cottage three-quarters of a mile away. Chertsey was six miles from the intake, and the pollution from that district would flow into the Wey. The largest average daily quantity of water ever pumped was 22,561,743 gallons, in the week ending January 23, 1891. The calculation of the future available supply depended partly upon the estimate of what could be saved, which was pretty well known. The constant supply question had been gone into scientifically, and every diastich with constant supply was under one of Deacon's waste meters. These gave daily records of the water passed, and their use, coupled with inspection, showed what could be saved. It was from the experience thus gained he concluded that, taking the whole district, 22 gallons per head per day was an ample supply. Some divisions

recently inspected gave 19.53 per head, and, as compared with the half year ending March, 1891, the half year of the greatest frost, it was a reduction of a gallon per head. In four new districts in Streattham, the average was 21.16. The saving by constant supply for the past twenty years amounted to 75.91 gallons per supply. At the rate of supply of 1871, the present total would have to be increased by 7,112,843 gallons, to 40 gallons per head; and yet the supply was better now than it was then. When great waste was discovered in a meter division it was inspected, and defects remedied, and that generally brought the average down to 12 or 14. After a short time it went up to 18 or 20, and then another inspection brought it down again. The meter supply, and that for road water and sewer flushing was about 23 per cent of the whole supply, or 6.36 gallons per head per day, and this made the total 26.87. In the past, when consumption was largest, there were great complaints about pressure, because water would not reach the upper services; but there were no such complaints now. Supplying statistics that had been asked for, the witness said that 22,561,743 gallons was the highest daily average for a week,—that ending January 23, 1891; 20,557,884 gallons was the daily average for December, 1890, and January and February, 1891; 20,268,231 gallons was the daily average for July, August, and September, 1887; 20,439,600 gallons for July, August, and September, 1889; 20,420,820 gallons, for January, February, and March, 1891; 28,411,025 gallons might be required in 1931 to give 25 gallons per head per day; 30,500,000 gallons were now obtained from the Thames and the gravel beds, and this is "irrespective of the water that can be obtained from the chalk. The directors are advised that they can obtain 3,000,000 gallons per day from a well at Selhurst, where they have just sunk a boring." In a final explanation on the statistical question Mr. Louttit said he had taken a population of eight persons per supply in constant supply divisions, and that was a reasonable figure, considering that the supplies were in the most thickly-populated parts of the district. The census returns of inhabited houses confirmed the correctness of the returns submitted by the companies in a remarkable manner. The population worked out at exactly seven per house in the Lambeth Company's district.

Mr. T. F. Parkes, the Company's Engineer, said he desired to emphasize what had been said as to Companies having more control over fittings. If they had as much as provincial Corporations and Companies, the reduction of waste would be facilitated. The Company ought to prescribe the fittings to be used, and not the holder. He would have the fittings brought to be stamped by the Company as approving of them. He would not limit the supply to the fittings of any selected tradesman, but would have free trade in fittings provided they were efficient according to a recognised standard.

In answer to Mr. Mansergh, he said that of the 19,000,000 or 20,000,000 gallons supplied from Brixton, about 9,000,000 gallons were supplied by gravitation, and the balance was pumped to Streattham, Selhurst, Norwood, or Rockhill, which was a maximum lift of 357 ft., to which must be added 25 ft. more over a standpipe.

Questioned by Professor Dewar as to the water being turbid on nine occasions in February, he said the filters were acting perfectly, and something must be due to the place where the samples were taken. This was the cab-rank in St. George's-road, and it was not near a dead end, but it was in the centre of the main.

Evidence concerning the Kent Company was then taken. We have a report of this in type, but must defer it until next week for want of space.

After the Whitsuntide holidays, the Commission will hear the cases of the Hertford County Council and the London County Council, which are expected to traverse that of the companies as to the sufficiency and fitness of their resources.

ASSISTANT-SURVEYORSHIP, NEATH. — At a meeting of the Neath Rural Sanitary Authority on June 8, the salary of the Assistant-Surveyor was increased from 104½ to 120½ per annum.

Thompson and Lea's Safety Arrangement for Jib-Cranes.

A SAFETY PROVISION FOR CRANES.

THE erection of modern edifices, particularly those of great height,—which so many now-a-days are,—has involved the increased use of "Scotch" derrick cranes for the hoisting of materials. The accidents which happen with these cranes are quite different from those which occurred in the days of the hod. But it is only when the nature of the accidents with the derrick is considered over any extensive series that one sees that it is not so much from the load being dropped, or by any failure of the heaving-chain or gear, that accidents occur, as it is from what at first sight seems a minor source altogether. It is the jib-chain of the derrick which is most frequently in trouble. The danger from the jib is twofold. If it comes down by the run, it smashes interior staging or external scaffolding and walls, and everything in its way. If it be suddenly brought up by a check-chain, the whole derrick may be cantled, and there is worse wreckage still. It is granted that these accidents are infrequent; they are nevertheless very ugly matters when they do occur. The chief source of evil in the "jib-chain," or the chain which passes from the head of the jib to the top of the derrick-mast, is not so often from breakage as from the chain being unavoidably short, and therefore apt to run off from the drum. No effective remedy for this has hitherto been provided.

The most that has been attempted has been to put a second loose chain lower down between the jib and the mast. This is no real security, but a delusion. What has now been done by Messrs. Thompson and Lea is a very simple and efficacious arrangement introduced into the ordinary metal head of the jib, whereby the instant that the jib-chain breaks or ceases to hold, the heaving-chain takes up the jib and maintains it as well as the load at the end of it. What is done is this:—The pulley over which the heaving-chain runs has ratchet teeth attached to each side, and in the stirrup to which the jib-chain is usually fastened there is a hooking-on rod provided with a spring at one end and a lever at the other attached to the two pawls which work into the ratchet teeth. When the jib-chain is holding on, the spring is drawn home and the pawls are kept out of contact with the ratchet teeth. But if the jib-chain breaks or becomes loose, the spring, being released from compression, pushes forward the lever, and the pawls engage with the ratchet. Thus the pulley is immediately gripped and the links of the heaving-chain are imprisoned in the pockets of the pulley, the jib being thereby as firmly grasped in its angle of position as it was by the jib-chain itself. The merit of this invention is that the remedy for the accident is so close at hand, and that of two chains running side by side, the one takes

up the work of rescue the instant the other gives way. The spring is not a cumbrous affair, the side ratchets add very little to the dimensions of the pulley, the stirrup is no longer than the one in ordinary use, as the rod and the spring work within it, and the lever and pawls within the head in the space behind the pulley. (See illustration.)

In some tests of the appliance which were made on Wednesday on the Albert Hall Estate by the contractor for the new buildings of the Royal College of Music, a three-ton derrick crane, fitted with the safety appliance here described, was employed. The jib was 45 ft. long, of 10½ in. timber, and weighed 15 cwt. A large hock of stone was slung on the end of the heaving-rope, and the jib-chain, hauled taut, was secured at the drum end by a hemp rope. The chain on the drum was then unwound, so that the rope held the jib. This rope was then cut with a hatchet, and the metal head of the jib did not fall 6 in. before the spring lever and pawls had acted, and the jib was firmly held by the heaving-chain on the pulley. This experiment was repeated many times with the like results. A model derrick, showing a modification of the invention to cranes in which wire ropes are employed was also experimented with, and gave equally successful results.

MAGAZINES AND REVIEWS.

The *Gazette de Beaux Arts* contains an article by M. Edmond Pottier on "The Salons of 1892," a well-studied and thoughtful piece of criticism. The writer maintains, at the outset, that two conclusions are to be drawn from the present condition of French art as shown in this year's exhibitions; first, that the study of the art of the past has not shut the eyes of artists to modern subjects; secondly, that the restlessness of modern art does not represent "une marche aveugle vers les abimes," but that there is a vital principle to be discerned in it. The various nude studies of the present period, M. Pottier regards as the direct legacy from Greek art; the very names of classical legends or personages appended to them indicate this; the varieties of treatment are great, but the true source of inspiration is the same in all. In connexion with this portion of the subject M. Pottier urges that a closer study of the silhouette figures in Greek vase-painting is worth the modern painter's attention. The taste for allegory shown at present in French art is a kind of reaction against the influence of realism; M. Benjamin Constant's decorative picture shows a desire to escape from the commonplace and prosaic treatment of allegory: "The ideal is eternal." In summing up, M. Pottier concludes that modern French art is under the domain

of two distinct influences; the great style of Italian Renaissance, coupled with a research after special effects of colour and lighting derived from the great Dutch painters. M. Salomon Reinach contributes an article on the "museum of antiquities at Vienna, with some fine illustrations of early Medieval sculpture. M. Germain Papat has an interesting article on "La Décoration Théâtrale à la cour de Louis XIV.," giving curious illustrations of the rich but preposterous costumes designed for ideal characters on the French stage of the period; "Diana" in a gorgeous flounced dress, with feathers on her head, and a bow and arrow in her hand; and other extravagances of similar type.

The *Revue des Deux Mondes* has its article on the Salon, starting with a view the very reverse of that of M. Pottier in the *Gazette*, and regarding contemporary art as of an anarchist or nihilist character. There is too manifest a struggle to astonish, to gain notice from the press, and the *Revue* recommends the artists to live more to themselves and to the thoughtful study of their art, and think less of the public and the journalists; advice certainly not uncalled for in France at present. The old Salon it notes as "less unquiet" in its aims than the new. The *Revue* makes the same comment which we made in regard to the paintings for ceiling decorations at the old Salon,—that it is impossible to judge rightly of them when hung on a wall, in a perfectly different position from that in which they are intended to be seen.

In the *Art Journal* an article on "Some English Shrines," by Mr. Vernon Blackburn, gives descriptions of shrines in various English Cathedrals,—that of the Black Prince at Canterbury; Bishop Hatfield's, at Durham; Wykeham's, at Winchester; Edward the Confessor's at Westminster; with illustrations by Mr. Symington, which give the chief value to the article. "The Private Art Collections of London" this month deals with Sir John Pender's collection at Arlington-place, with illustrations of some of the rooms and pictures, the latter including Sir F. Leighton's popular and pretty "Phoebe." Mr. R. J. Slade contributes an article on "Mr. Thorne Waite," and Mr. Claude Phillips commences some articles on the summer exhibitions at home and abroad which are well illustrated, and as thoughtful criticisms are welcome reading in comparison with the foolish and malevolent literary onslaughts on painters which seem the fashion of the day.

In the *Magazine of Art* the Editor gives a review of the Royal Academy—somewhat *couleur de rose*. The first page is occupied with an endeavour to justify Mr. Watts's "She Shall be Called Woman," but we fear it is unconvincing. That Mr. Watts has formed a very lofty intellectual and moral ideal of the art of painting we all know—honour to him for it; but it is no less evident that his ideal has occasionally led him to forget the realities of pictorial representation. An article on "Scenic Art," by Professor Herkomer, is of rather special interest. He attacks the conventional arrangement and lighting of the stage, and gives two pictures of the actor as seen from the gallery and the actor as seen from the stalls, to show the absurdity of anyone posing for an audience distributed over so large a vertical angle. Quite true, but the question is, how is a horse to pay without galleries except at a higher average of prices? Professor Herkomer also gives sketches of the face as lighted from the footlights and the face in diffused light; and explains that his own abandonment of footlights at his Bashey Theatre was originally only a happy accident. We rather doubt, however, if footlights will be disestablished. They have the advantage at all events of separating very completely the players from the audience, leaving the players more isolated from the spectators and consequently with a feeling of greater freedom. To remove the footlights would be like taking down a wall of partition. "The Pupil of the Eye as a Factor of Expression," by Dr. Wilks, is a short practical paper from the physiological point of view, which may be suggestive to painters. In another article Mr. W. F. Dickes replies to his critics in regard to his theorise on Holbein's "Ambassadors" picture.

In the *Antiquary* Mr. Ward continues his "Notes on Archaeology in Provincial Museums," dealing in this number with Shrewsbury. A short article called "The Antiquary among the Pictures" suggests a review of archeological lore as exhibited in Royal Academy pictures

but in fact it does not draw any attention to questions of archeological correctness in painting, which might very well and usefully occupy such a journal as the *Antiquary*, but is mere chit-chat without even an attempt at criticism; a kind of writing that is of little value. Mr. Henry Barber contributes an article on the Cistercian Abbey of Maulbronn, with birds-eye views (from old representations) and a plan.

The *Fortnightly* contains an interesting and learned astronomical article by Mr. W. Huggins on "The New Star in Auriga," and a remarkably insolent and violent article on "The Royal Academy Exhibition" by Mr. G. Moore, whose qualifications for the assumption of the status of an *ex cathedra* critic may be sufficiently estimated by the fact that he proclaims Mr. A. Moore and Mr. Whistler the two greatest artists of the day, whose non-acceptance by the Royal Academy into its ranks is the *terribilis causa* of Mr. Moore's wrath against that body. The grouping together of two painters of such opposite aims as representing the highest achievements of art is amusing; one might almost be inclined to say that if Mr. A. Moore is right Mr. Whistler must be wrong, and *vice versa*. Some of the writer's criticisms on individual artists and individual pictures are just enough; but the whole tone of the article is offensively typical of the spirit in which literary men seem nowadays to think they have the right to dictate about art. The same number contains an equally one-sided and conceited article on "The Two Salons," signed Elizabeth Robins Pennell. In the eyes of these two modest critics, it should seem, nearly all painters are fools, and all exhibitions contemptible. The tendency of reviews to the publication of this kind of literary abuse of contemporary art is a very disagreeable sign of the times.

The *Nineteenth Century* contains an article by the gifted lady who writes under the name of "Vernon Lee," on "The Tuscan Sculpture of the Renaissance," an article which however is rather ingenious than convincing. It is a comparison between Greek and Renaissance sculpture, with the object of proving that the latter is more truly decorative sculpture; that the Greeks only sought to give the human form correctly in a manner based on clay modelling, while the Tuscan sought for the decorative effect of the figure. It is noticeable that the writer only refers to Greek sculpture as work in the round, and appears to have entirely forgotten the Parthenon frieze, to which not the slightest reference is made. Such an omission is in itself sufficient to very much weaken the argument; and we may add that if Vernon Lee really believes that the Greek Doric style of architecture consisted of "little more than the imitation of the original carpentering," she has a good deal to learn on that subject.

The *National Review* publishes an article by Mr. E. J. Gibbs on "London and Rome," a comparison of the two cities in regard to wealth, influence, and agreeableness. Mr. Gibbs brings forward reasons for thinking (as we have always thought) that the immense wealth of Rome under the Empire has been little realised, and that it was positively and not only comparatively as great as that of London, while its standard of luxurious living was incomparably higher (or lower); and that in population Rome was more on a par with London than it first appears, the suburban districts not counting as part of Rome, as in these days they count as part of London. In comparing the advantages of life in the two cities Mr. Gibbs emphasises the fact that in ancient Rome every citizen could have the run of bathing establishments on such a scale of luxury as the world has never seen equalled, for the payment of an entrance fee equal to about half a farthing.

In the *English Illustrated* we find another of those articles on great railway workshops which are now becoming rather a fashion, each railway taking its turn apparently; now it is "The Midland Railway Locomotive Works at Derby," by Mr. C. H. Jones, an assistant locomotive superintendent of the Midland, with illustrations from photographs taken by Mr. Scotton, the company's official photographer. Though there has been a good deal of this lately, we like to see such articles, which may give the readers of popular magazines a little better idea than they have at present of the colossal and varied labour which underlies the daily work of a great railway establishment.

In the same number is an article on "Dunster and its Castle," by Mr. Graham Wallas, with illustrations by Mr. E. W. Charlton.

In the *Revue Géographique* the greater part of M. Trogan's "Lettre de Paris" is occupied with the leading pictures in the two Salons, and though this is a mere magazine article written in a bantering way much good sense and sound criticism, as well as some happy hits, and is quite worth reading in both senses. Over the tendencies of some of the leading works of sculpture M. Trogan is melancholy; M. Gerôme's "Bellona," suggests to him a sign for a dentist, a patient opening the mouth wide; and the colour staines represent "L'art du hondoir. Qu'on nous redonne les Dîanes de Falguière"; and one cannot but echo the wish.

In *Scribner's Magazine* Mr. Shaler gives his second article on "rapid transit in cities," giving "the solution" of the problem. His solution is apparently electric railways in the streets. This, however, pre-supposes (after the horses have ceased to be frightened by them) streets of sufficient width to allow for this alongside of the ordinary traffic. In many cities the streets where rapid transit is most demanded will not admit of this; and it is too late to rebuild them. The American's objection to underground railways is neatly put—"Americans do not like to go underground until they are dead."

The *Century* has an article on Budapest, under the title "The Rise of a New Metropolis." It is illustrated by sketches by Mr. Joseph Pennell, which convey some idea of the remarkable manner in which this city has attained, in so short a life, to the appearance of a first-class modern city. An article on "Early Political Caricature in America" contains many reproductions of old caricatures, remarkable for vigour and malice, though a good deal of their point is necessarily lost now.

To *Harper's Magazine* Professor Waldstein contributes an article on "Funeral orations in stone and wood," relating especially to the bas-relief of "The Mourning Athene from the Acropolis," which forms the frontispiece to the number, and which is a curious mixture of archaic style and comparatively late or "modern" sentiment. The knowledge we now have of the existence of an archaic or "pre-Raphaelite" school in later Greek art might have been supposed to furnish the explanation of this; but Professor Waldstein is disposed rather to regard the bas-relief as the work of a sculptor trained originally in the earlier and stiffer technique, but who had entered into the more poetic sentiment of the later day. He would suggest about 470 B.C. as the probable date of the work.

In the *Atlantic Monthly* is a continuation of the interesting article on "Private Life in Ancient Rome" by two ladies, to the first part of which (in the preceding number of the same magazine) we have already referred. In the same number is a pretty little poem in praise of "Nuremberg," by Julia R. C. Dorr.

The *Cornhill Magazine* includes a short article on "Curiosities in our Cathedrals," a readable summary of some out-of-the-way peculiarities in the design or the contents of various cathedrals which are not popularly known, though familiar to archaeologists.

All the *Year Bound* includes a fairly good article on "The Loan Collection of Pictures at the Guildhall," followed by a pleasantly-written chapter on "Florence in Spring."

THE ENGLISH IRON TRADE.—With the intervention of the Whitsun holidays the English market remains very quiet. In Cleveland, many of the works will be started as soon as a sufficient supply of coke can be obtained; but work will not be in full swing for some weeks. No. 3 G.M.B. is firm at 11s. 9d. There is practically no change to record with regard to any of the other pig-iron centres. In tinplate the volume of business passing is fair; but the manufactured-iron trade continues dull. Steel works are also inactive. Shipbuilders are less brisk, and engineers remain dull. The coal trade is rather quiet.—Iron.

THE NEW CROSS-COUNTRY RAILWAY.—At Chesterfield, on the 7th inst., Mrs. William Arkwright performed the ceremony of cutting the first sod of the projected trunk railway line, which is to cross England from sea to sea. The new railway, which is 175 miles in length, will form a connecting link between the eastern and western coasts.

Illustrations.

THE THREE TEMPLES AT SBEITLA, NORTH AFRICA.

AS we have commented strongly on the procedure of the Hanging Committee of the Academy this year in regard to architecture, especially with reference to some of their rejections, we may give point to our criticism by mentioning that this interesting restoration of three Roman temples from an existing remains, by an architect who has given special attention to the illustration of ancient Roman work, is one of the drawings which the person who looked after the hanging of the architectural drawings (whoever he was) considered not worth a place. The rejection of a drawing such as this, by an architect who can not only bring archeological learning to the subject but can make his own drawings, while space is found for commonplace horses bearing the names of men who have to pay a draughtsman to make a drawing for them, is discreditably only to the Academy, not to Mr. Graham, whose work would no doubt have found a good place among the architectural exhibits of the Salon, though it did not recommend itself to the eye of the carpenter in the Royal Academy architectural room.

Mr. Graham sends us the following article in respect to the site and restoration of the temples:—

"A glance at a map of North Africa is necessary to give the reader an idea of the geographical position of Sbeitla. Three days' journey from Tunis, either along the coast by way of Soussa or across country by Zanfour, brings the traveller to Kairouan, and a ride of about seventy miles from that holy city in a south-westerly direction enables him to reach the banks of the pretty stream that once skirted the walls of the ancient city of Sufetula. The modern name of Sbeitla is an Arab corruption, as that of Sbiha, some thirty miles further north, represents the original name of Sufes. Whether this word Sufes was associated in old times with *Suffetes*,—the two supreme magistrates who ruled over Carthage, and whose title bears a resemblance to the Hebrew *Shafetin*, mistranslated in the Bible, Judges,—is open to doubt. The history, however, of Sufetula is so intimately interwoven with the progress of Christianity in North Africa, and with the first disastrous encounter of a Christian population with the followers of Mahomet, that European as well as Arab historians have given it a special place in their records. Ehdriis, the Arab geographer of the twelfth century, tells us that "Soheitla was, before the Arab invasion, the town of Gerges (Gregory, King (prefect) of the Romans of Africa; it was remarkable for its extent as well as for the beauty of its situation, for its abundant water, for the mildness of its climate, and for its wealth; it was surrounded by orchards and gardens. The Musselmans conquered it during the first year of the Hegira, and put the great King Gerges to death." Other writers tell us that this Gerges, sometimes written Gregorius, had revolted from the Byzantine Empire, and had made himself ruler of the whole country from Tripoli to Tangiers, making Sufetula his capital. With the appearance of the Arabs in this remote corner of North Africa commenced the struggle for supremacy between the representatives of Christianity and the followers of Mahomet. The city, having no walls of defence, soon succumbed to the invader. Gregorius was slain, and the treasure of a numerous and wealthy population passed into the hands of the victorious army. With this calamity the records of Sufetula cease, and Christianity in Africa received a blow from which it never recovered.

The monumental remains are extensive, though it would be difficult to define the exact boundaries, owing to the absence of external walls. The lines of streets and the foundations of numerous buildings, both public and private, can be traced for nearly a mile in one direction, and somewhat less than half a mile in another. Its ruined edifices, many of them of noble proportions, bear ample testimony to the wealth and importance of Sufetula prior to the Arab invasion. The principal monument that has withstood the ravages of time and the neglect of more than twelve centuries, consists of a range of three temples, placed side by side and partly attached. They may be assigned to the

reign of Antoninus Pius, A.D. 138-161. The porticoes formed nearly the whole of one side of a large walled enclosure, measuring about 240 ft. square, to which access was obtained through a monumental gateway facing the temples. This gateway, in very fair preservation, is still standing. The back walls of the three temples formed the back of the enclosure, and behind them ran one of the main streets of the city. The central edifice is of larger proportions than the two that flanked it, and is of a more ornate character. Its order is Composite, the others being Corinthian. They are all tetrastyle and pseudo-peripteral. The cells of the middle temple has engaged columns at the sides and back, but the others have pilasters only. The back walls of the three temples, the entire cells of the central one and a greater part of the flank walls of the side ones are still standing. The porticoes are overthrown, but the bases of many of the columns are in position as well as the lines of steps. The broken monolith shafts, which were more than 30 ft. high, with their enriched capitals and huge fragments of sculptured ornament, lie piled up one on another in a majestic and imposing mass. The enclosure appears to have been paved with immense slabs of stone, which are still visible some 4 ft. below the present surface. Around it was a colonnade and, from the general appearance of the remains and the number of *frusta* of shafts of varying dimensions, it is reasonable to suppose that there were other shrines or votive monuments within the enclosure. The entrance, as already stated, was through a gateway of three arches, and within the gateway was a portico connecting the colonnades on either side. It was evidently intended that the entrance should face the central temple; but, for some unaccountable reason, it is fully 20 ft. to the west of the central line or axis of the enclosure. The custom of enclosing sacred edifices with walls of defence originated at some remote period when temples were used as depositories for the treasure of a city, as well as for affording shelter to women and children in times of invasion. At Carthage, for instance, the chief temple in the city, dedicated to Æsculapius, stood within the citadel. The Parthenon at Athens was within the walls of the Acropolis, and the temple of Jupiter in Rome was in the Capitol. At Balbec also there is an enclosure commonly called the *Hieron*, bearing some resemblance, though on a larger scale, to this one at Sufetula.

The illustration is a restoration of the three temples and of a portion of the enclosure, being

the result of actual measurement on the spot and of sketches of the details of the architecture. It is satisfactory to know that the Société des Monuments Historiques is keeping a watchful eye over these interesting remains as well as over the other ruined edifices and inscribed stones, and that in course of time our knowledge of this ancient city and of the important part it played in the spread of Christianity during the rule of the Byzantine Emperors may be largely extended.

The appearance of Sufetula, as it was in the fourth and fifth centuries, is easy to imagine. Situated on rising ground, at a point where the great highway from Carthage to the interior intersected the main road from Theveste seawards, its position was a commanding one. A fertile soil, forests of pine-trees, and a never-failing river of pure water that ran by the city walls, contributed to make Sufetula a place of delight for the wealthy colonists of North Africa. To-day it is a dreary, unpeopled spot, lying "remote, unfriended," in the midst of a trackless country. The waters are still there,—a perennial stream, pure as crystal, but the trees are gone, the plains are arid or clothed with rough herbage, and all signs of habitation have long since passed away. Yet, in spite of prevailing desolation, this spot, so far removed from human dwellings,—its ruined fanes outlined sharp against the sky, its weird stones standing ghost-like on the outstretched plain, the stillness of the air broken only by the babbling of the waters,—has much to charm the eye and quicken the imagination.

ALEX. GRAHAM, F.S.A."

HOUSE AT WRAYSBURY.

This house is being built near Egham Lock, from the designs of Mr. T. E. Colcutt, the materials employed being red brick, stone, and oak; the bricks are of special make, from the Cranleigh brick works, and work six courses to the foot in height. Mr. Messum, of Twickenham, is the builder.

The drawing is exhibited at the Royal Academy.

RETABLE FOR ST. ALBAN'S CHURCH, TEDDINGTON.

This retable, designed by Mr. A. H. Skipworth, will be executed in either Clunch or Ancaster stone, and will be partially coloured and gilded. Mr. L. A. Turner will carry out the work, the modelling of the angels being most probably entrusted to Mr. Dressler.

The drawing is exhibited at the Royal Academy.

REREDOS FOR GRAYINGHAM CHURCH, LINCOLNSHIRE.

This reredos is of oak, slightly stained and partially coloured, gilded, and silvered. The centre panel, in copper gilt, is the work of Mr. Conrad Dressler. The woodwork was executed by Mr. L. A. Turner, of Orde Hall-street, from the designs of the architect, Mr. A. H. Skipworth.

The drawing is exhibited at the Royal Academy.

WORKING MEN'S UNIONIST CLUB, AYR.

This club, which has been opened this week, is built from the designs of Messrs. Morris & Hunter. The large bay window in the end on the ground-floor forms part of the club reading-room; the three windows above light the ante-rooms attached to the hall, and the centre one opens on to the balcony as a convenience for open-air speeches when required. The half-timber gable above forms part of the club-master's residence.

There are three distinct exits with separate staircases from the hall. The club contains, besides the hall, a billiard-room, recreation-room, and reading-room. The hall will seat 600 people. The cost of the whole was limited to 2,500*l.*, hence the building has necessarily been kept plain and simple in its architecture.

ST. JUDE'S CHURCH, PRESTON.

This church is now approaching completion for the new parish of St. Jude's, Preston. The general character of the design is that of late Decorated Gothic. The walls are carried out with smooth-faced Yorkshire parpoints and Rainhill stone dressings, the interior dressings also being in Rainhill stone. The total accommodation is for 645 persons, and, in addition, there are chapels on the north and south sides of the chancel, which may be used for seating. The organ is placed in the gallery over the south chapel. The chancel floor is well raised, and choir vestries, &c., provided underneath. The clergy vestry is at the east end of the south chapel, and connected with the choir vestry by a passage and steps. The baptistery is at the west end, and the main porch and entrance at the north-west corner, with smaller entrances at the south-west corner and north-east end of north aisle. The design is by Mr. R. Knill Freeman, of Bolton and Manchester. The contractor for the whole of the work is Mr. Thomas Croft, of Preston; the sub-contractors being Messrs. Tullis (mason); Mr. W. White-

side (joiner); Messrs. Walmsley (plumbers and glaziers); Mr. Cook (plasterer and painter); and Messrs. Bradshaw & Son (slaters). The heating by hot water has been carried out by Mr. Seward; and the choir-stalls, &c., of oak, by Messrs. Bell & Copeland; all of Preston.

THE ARCHITECTURAL ASSOCIATION: THE RELATION OF THE ARCHITECT TO THE WORKMAN.

In the discussion which followed the reading of Mr. Ashbee's paper* on this subject,

Mr. H. O. Gresswell said he had great pleasure in proposing a vote of thanks to Mr. Ashbee for his paper, especially as he had attended twice there to read it. Considering that they in the Association had been discussing educational methods a good deal of late, it was very interesting to them to have a paper from what he might call an entirely fresh mind,—in other words, from a gentleman who had not been following the ways and work of the Association, but who looked upon the education of the architect from a somewhat different standpoint. Mr. Ashbee had introduced them to the workman's side of the question, and perhaps with advantage, for they were possibly a little too much inclined to look at it from the employer's or contractor's point of view alone. He did not know how they would get on with the communal system, and in general he was hardly prepared to follow some of the theories enunciated by Mr. Ashbee without having had the opportunity of reading the paper. He thought there was a great deal in it, but that it wanted more consideration before he felt able to discuss it with very much profit. He thought their sympathies were very much with Mr. Ashbee on the question of the desirability of young architects mixing with workmen, and seeing work in the workshops, and he hoped that the Association would be able to do something to bring its members more in contact with workmen. Probably the Guild and School of Handicraft might be able to give them some assistance in that direction. Mr. Ashbee had spoken against architects working too much upon paper. They had, he (the speaker) was afraid, been accustomed to think too much upon paper, and no doubt, if they could think with materials rather than on paper, they would be able to take a wider grasp of their work; but in dealing with buildings pure and simple, it was difficult to see how they could be dealt with on any other material than paper. If one was considering the planning and arrangement of a building, or if one had to make details of the masonry work of that building, he failed to see a better method of working them out than on paper, unless they adopted the mason's method of setting out the work on boards, which, after all, came to pretty much the same thing. He trusted that the members of the Association would have an opportunity of visiting the workshops of the Guild and School of Handicraft, where they might learn much that was useful.

Mr. Leonard Stokes said he should like to be allowed to second the vote of thanks, especially as it was partly his (the speaker's) own fault that Mr. Ashbee had to come there a second time. He thought they could not be too grateful to Mr. Ashbee for the lucid and somewhat new light in which he had put the whole question before them. As he had said, our modern life must of necessity have a great influence on modern architecture. A great deal of the work produced now was merely in supply of a demand for cheap grandeur, which became cheap vulgarity. The great idea of the present day was to make a show. Possibly that might be a fault of our social system, and it was for architects to endeavour to persuade their clients to be a little more reserved,—to accept designs for buildings which showed far greater reserve than much of the stuff which was now built. It was very difficult to persuade a client that a simple design was better than an elaborate one. The uneducated client thought that an elaborate thing was the best. Of course, the question of style came in. "Style" was an odious word, but if they went to work conscientiously he thought they could let style alone. So long as a building was a good one, it did not matter what the style was. As to what Mr.

Ashbee said about young architects mixing with workmen, he (the speaker) thought that was a matter of great importance. It was very desirable that workmen should become more in touch with the architect and the designer. As matters were ordered at the present time, the workmen never, or hardly ever, got sight of the architect's drawings. The bricklayer was set to work in one place, the mason in another, and the carpenter in another, but they were all working in ignorance of each other's work, and had no idea of what the building would be like as a whole when finished. How could they, under such circumstances, be expected to take any very lively interest in their work? He thought it would be a very desirable, although a very simple, step in the right direction to allow the workmen to look at the drawings occasionally. Let them put it in the contract, if they liked, that the workmen should be allowed to look at the drawings once a week. Many of Mr. Ashbee's remarks, on such questions, for instance, as apprenticeship, and the possibility of architects being able to get at the labour market directly, without the intervention of the middleman, were of great interest. He thought it would be a great good if the architect could more often come into contact directly with the individual workman who was to carry out work from his designs. In conclusion, he desired to express the thanks of the meeting to Mr. Ashbee for having brought down so many interesting specimens of the Guild and School of Handicraft.

Mr. Sydney Vacher said he should like to say something on the opposite side of the question. If an architect could go direct to the trained workman, why could not the public? Why have an architect at all? As to the architect consulting the workman, he failed to see the advantage of it. Would they have the British sailor consulted about the handling of a man-of-war? Must not the architect, like the commander of a vessel, be the responsible head, and must not each of them be able to rely on implicit obedience to orders? Was it not the first duty of the architect to supply the best building he could for his client? While he could not assent to all the propositions laid down in Mr. Ashbee's paper, he (the speaker) was delighted to see the work of the Guild and School of Handicraft, because it was educating the workman; and if they could find a workman who had originality, they should give him a suggestion, and leave him to work it out. Of course, that method of procedure was not possible with regard to the whole work of everyday building. While it helped to educate the workman, it also helped to educate the architect, who naturally felt bound to keep in touch with what was going on. Above all, it helped to educate the public, and that was what was wanted more than anything else. It had been said that the present was an age of show, but every age had been an age of show. No doubt one evil of the present day was that we lived too fast; we were too fond of living beyond our means. Everyone was trying to obtain gorgeous show or smartness for a minimum of expenditure, and but few would pay for the real thing. That was the complaint everywhere. There was another thing which struck him, and that was whether, if these schools and guilds became very powerful, would not they be attacked by the modern unionism? Mr. Ashbee had said that apprenticeship was being killed by the modern subdivision of labour, but in his (the speaker's) opinion apprenticeship was being killed by modern unionism,—it was being killed by the enormous number of unskilled workmen who were driving down the standard of work to a dead level. One was constantly hearing of the difficulty of taking boys as apprentices by the builders; the men struck against it. It seemed to him that the technical schools were now attempting to supply a real substitute for the workshop training of apprentices; and he thought that sooner or later the Government might have to take steps for the compulsory education of the craftsman. One suggestion he might make, arising out of the work of the Association, was this: that, if any members found themselves, as the result of their work in the classes, unlikely to succeed as architects, owing to inability to grasp theoretically, that was to say, on paper, either the artistic or the constructional part of the work,—perhaps both,—why should they not turn their attention to craftsmanship? Many men who now spend their lives as clerks or assistants would have

a much finer position if they became craftsmen. By the Committee of such a school as Mr. Ashbee's, such men should be welcomed, and when successful, as they became known, many architects would be only too glad to employ them, giving to a craftsman in each trade, a share of a building, just in the same manner as in Scotland the architect, instead of giving out his work to one contractor, gave it to many.

Mr. E. W. Mountford said he fully agreed with Mr. Ashbee that the interests of the workman and the interests of the architect were identical. He agreed, too, with the previous speaker that modern trades unionism had many faults, and that it did a great deal of harm in some respects; but in other respects it did a great deal of good. He believed that every step towards improving the wages of workmen (and up to a certain point) shortening their hours of labour was a step in the right direction. Those who had had the misfortune to work with builders, generally in a small way of business, who employed non-union men, to whom they paid less than the union rate of wages, knew, to their cost, that such men were, as a rule, utterly incapable of producing really good work. In his experience, men who got higher wages undoubtedly did a higher class of work than the men who got low wages, and it was always best to entrust building work to good firms of contractors who were known in the trade as paying the highest wages. Such firms retained a large staff of men who were capable of doing the best work. There was one point on which he could hardly agree with Mr. Ashbee, and that was when he said that an architect should do as little as possible on paper. It was no doubt desirable that the architect should be able to model a little, but he thought it was quite out of the question for an architect to become sufficiently conversant with the whole of the many trades concerned in building to be able to explain to the workman, in the material itself, how every detail of the work should be executed. To properly learn any one of the trades concerned in building was the work of almost a lifetime. Although an architect might, perhaps, learn to be a decent bricklayer in the course of a few years, he could not possibly expect to become a good mason unless he gave up many years to the work. But, of course, without being able to do the work himself, he ought to know how it should be done, and in order to give his instructions to the workmen, he was bound to have recourse to drawing-paper or tracing-paper. He cordially supported the vote of thanks to Mr. Ashbee for his paper.

The discussion was continued by Messrs. A. E. Bartlett and Sidney Tagwell; and the Chairman (Mr. F. T. Baggallay) having put the motion for a vote of thanks to Mr. Ashbee, which was carried very heartily, Mr. Ashbee replied to some points raised in the course of the discussion, and the meeting proceeded to consider the affairs of the Association, as reported in our last.

ARCHITECTURAL SOCIETIES.

EDINBURGH ARCHITECTURAL ASSOCIATION.—By permission of Messrs. R. Irvine and D. Harris, the Sketching Class of this Association will meet at Royston House, Carolina Park, Granton, at three o'clock on the afternoons of Saturdays June 11, June 25, July 2, and July 16, to make measured drawings and sketches of the south front of the mansion. The Class will be conducted by Mr. J. Watson and Mr. J. N. Scott.—The members of the Association had their annual excursion on the 4th inst. The destination this year was Drumlanrig Castle, in Nithsdale, permission having been obtained from the Duke of Buccleuch to inspect the building. A company of some thirty-five gentlemen proceeded by express train to Elvanfoot, and a drive was then commenced. A stop was made at the village of Durrisdier, where the party were met by the Rev. Mr. McKenzie. The old manse was first inspected, and Mr. McKenzie explained that it was supposed to be of pre-Reformation date. The church proper only dates from 1699, and is a very plain building. In the tower there are the notable "Queensberry marbles," and these were viewed with much interest. The sculptor of these works is unknown, but they date from about the middle of last century. The vault below is the burial-place of the

* Printed in extenso in last week's *Builder*. See pp. 437 et seq.

Dukes of Queensberry. After lunch the party proceeded to Drumlanrig, the pink sandstone pile which occupies such a commanding position above the right bank of the Nith. Mr. John McLachlan, who acted as leader of the excursion, gave some account of the castle and its history. The builder, he said, of Drumlanrig Castle was William, first Duke of Queensberry, and the erecting which began about 1680, lasted for over ten years. Regarding the building, the arrangement was simple and dignified. It consisted of a great square, 146 ft. by 120 ft. externally, with an inside space of 77 ft. by 57 ft. The double circular staircase to the front entrance was comparatively new, but a similar staircase formed part of the original design. The hollow square of the building had four staircases leading to the various flats, an arrangement somewhat similar to those of Linlithgow Palace, Caroline Park, and Heriot's Hospital. The architect of the building was unknown. The company subsequently went over the house and afterwards drove through the Drumlanrig woods and along the banks of the Nith. From Menock Bridge the drive was continued up the Menock Water to Wanlockhead and on to Leadhills, where the party dined.

GLASGOW ARCHITECTURAL ASSOCIATION.—The opening meeting of the season (1892-3) was held on Tuesday evening in the N.B. Station Hotel, George-square, the hon. President in the chair. Mr. Alexander McGibbon delivered his Presidential address, the subject being "Current Architectural Criticism." A few remarks by the hon. members present concluded the business meeting. The meeting then resolved itself into a smoking concert, during which Mr. Alexander McGibbon was presented with a handsome old Dutch cabinet and set of silver plate from the past and present members of the Association as a mark of their esteem of his long and faithful services as secretary. Mr. W. I. Anderson made the presentation on behalf of the members.

BRITISH ARCHEOLOGICAL ASSOCIATION

AT the meeting of this Association on June 1, Mr. J. V. Grover, F.S.A., in the chair, Mr. Barrett exhibited several sketches of various armorial bearings of old members of the Trinity House, and read an elaborate paper on the history of the Company, the materials for which he had obtained from various State papers, the archives of the Company having been burnt in 1714. The last history thus recovered referred to many onions points of sixteenth and seventeenth century history, including the establishing of light-houses along the coast of England, the Company having a patent for doing so. The origin was from a fifteenth-century guild, which was incorporated in 1573. The Company's arms were those of Sir T. Sport, the first Master, who died in 1541, and who is buried in Stepney Church. Enormous sums were spent by the Company in helping to man the fleet in times of national peril, details of which were rendered. In addition, many particulars were given of the Company's work in freeing captives from the Barbary corsairs, whose ravages round the coasts of England and Ireland is no creditable page of English history. Mr. Loftus Brock, F.S.A., exhibited some curious examples of neatly-turned alabaster fonos on the site of Cyzicus, of Greek workmanship. The chairman described several remarkable flint implements, of prehistoric date, one of which, found by him at Stoocheenge, was carbonated and white from long exposure. Mr. Earle Way exhibited several examples of bellarmine jugs found at Southwark, including some of earlier date than the middle of the sixteenth century. Mr. Barrett exhibited a very fine *Grès de Flandres* jug, dated 1691. A second paper by Mr. MacMichael was then read, entitled "The Greybeard." The author traced the origin of the once common brown ware jug from early times, and produced several examples, which showed the progress of the form to its full development, when, by the addition of the head and broad, square-cut heard, the shape was supposed to resemble the portly form of the obnoxious Cardinal. These vessels were made in very large quantities in almost every town of the Low Countries, and imported into England. A collection of the designs of the cartouches which decorate the sides were exhibited. These show, in almost every case, the arms of the various cities of manufacture.

Correspondence.

To the Editor of THE BUILDER.

ELECTION OF FELLOWS, R.I.B.A.

SIR,—It is proposed to alter the present system, and dispense with the ballot. I beg to suggest as an alternative that the existing system be retained, with the provision, however, that in the event of any candidate being blackballed, he shall have the option of a further chance with voting-papers, but only upon his own requisition.

The cost of the voting-papers and postage, addressing, &c., would in an isolated case be not much less than 10l.

A proposition has been made that the electors shall be by show of hands (unless three members should demand that voting-papers be issued).

In either case I think the cost of the voting-papers, &c., should be paid by the candidate only when unsuccessful.

"SUM CUQUE."

June 6, 1892.

HORNSEY MAIN ROADS ARBITRATION.

SIR,—It would no doubt prevent a good deal of misunderstanding, as well as needless litigation and expense in the future, if you would allow me, as the Chairman of the Highways Committee of the Middlesex County Council, to supplement the paragraph which appeared in the *Builder* under the above heading [p. 447, ante], by stating that the Hornsey Local Board claimed 4,098l. 18s. 4d., the total amount expended by them for the maintenance of about two miles and three-quarters of main roads for one year; and the award of the Local Government Board was, as mentioned, 3,221l. 5s. The important fact, however, is omitted, that the award is 877l. 13s. 4d. less than the amount claimed by the Local Board.

Without this explanation, local authorities throughout the country are likely to form a most erroneous judgment with reference to this case.

H. R. WILLIAMS.

6, Lime-street, E.C., June 8, 1892.

"A QUESTION OF BUILDING PENALTY."

SIR,—The letter under the above heading in last week's *Builder* should be carefully noted by all contractors, and replying to this we should say "A Contractor" had better refer to the contract he entered into, for from recent experience in a somewhat similar case, in which we were mulcted in a loss, we found that everything depended on this.

In our case delay was caused—1. By the carpenters' strike. 2. By additional work. 3. By our being unable to proceed for want of details and instructions.

The contract we had entered into allowed extra time for delay caused by "general lockouts," "strikes," or from any cause whatever which in the opinion of the architect was beyond the control of the contractor."

Now, this looked all right on the surface, but the fact was, the architect was brother to the employer, and we found to our cost that it was not a question of strikes, lockouts, or other cause whatever, but the opinion of the architect; and, having to choose between an action for fraud on the ground that the certificate was given contrary to facts,—and a loss,—we were advised not to throw good money after bad.

The lesson we have learned from this is, not to put ourselves into the hands of any one man or firm; and we think the conditions agreed on between the Royal Institute of British Architects and the master-builders of London are to prevent unfairness on either side, and that builders should not sign any other.

OTHER CONTRACTORS.

SIR,—In answer to your correspondent on p. 444 ante, I consider that the penalties in his case cannot be enforced, but before anybody could definitely decide all the points raised the whole of the documents should be inspected.

On the one question of the errors in the quantities it is necessary to know whether they were prepared by the architect or by an independent surveyor, and whether paid for by the builder or by the employers.

HENRY LOVEGROVE.

25, Bridge-rose, E.C., June 8, 1892.

FOURTEENTH AND FIFTEENTH CENTURY SCREENS.

SIR,—I shall be much obliged to any reader of the *Builder* who will inform me where I can see good specimens of church screens of the fourteenth or early fifteenth centuries.

The Student's Column.

WARMING BUILDINGS BY HOT WATER. XXIV.

EXAMPLES OF BUILDING WORKS.—Continued.

THE next example that may be suggested, is as fig 97. This is an apparatus extending away from the boiler in two different directions, for the purpose of heating two rooms of different size and in different manner. Taking the boiler first, this is shown having two flow pipes off the top, and each flow has a stop valve near the boiler, as shown.

FIG. 97

When it is convenient to have two flow pipes in this manner, it is as well to use them, although one flow, which is immediately branched in two directions, has no had features; in this latter case the single pipe should be a size larger. In an apparatus such as this, especially as it does not appear to be extending far in height, the main or general services should be 1½ in.; 1 in. might do in some cases, but is not recommended. The returns are usually brought right back to the boiler, although there would be no objection to their being branched into one, if they met at some distance from the boiler (this is not the case in the example given). If the two services terminate in a single return, it would be well to have this of a size larger pipe, as suggested with a single flow. An emptying cock and cleaning plugs must be provided to the boiler, and when placing the boiler there must be room enough in front of it for the cleaning and stoking tools to be used.

Each flow-pipe should have a stop-valve to it, so as to regulate the heat in either direction as occasion may require, and also to check the possible inclination one service may have to work more freely than the other. Hilberto we have suggested giving the longest service a greater rise (if possible) so as to equalise results, and this may be done in this case if convenient, but stop-cocks must be provided as well. We cannot suppose that both rooms want to be heated at the same time and to the same extent always, and on this account alone the stop-cocks are needed.

The service shown as proceeding to the left, goes to heat a large room, requiring three radiators,—a billiard-room, for instance. Speaking of billiard-rooms, let the reader be cautioned against putting pipes or coils under the billiard-table, nothing more improper could be done. If the pipes in question are sufficient to heat the

room, they will pull the table to pieces. The writer was once consulted respecting a billiard-room that some one had attempted to heat by a single radiator placed under the table. Fortunately for the table, the radiator was not a large one, it failed to heat the room and did no injury; but even with this insufficient heat the players complained of the heated air ascending from under the table, and coming directly to the face when in the act of resting on the board to play. No heating appliances should be under a billiard-table.

The illustration is intended to show the radiators placed around the room, in corners, or at most convenient points. They must not, however, be too near wainscotted or similar woodwork, or the heat will injure it. The radiators are shown of different shapes, but this is settled by the general conditions; the method of connecting them, however, requires a little explanation.

The nearest radiator is shown connected by a distinct branch flow and return from the main service; this is the best way to treat this one. The next, in the left-hand corner, is connected to the flow only as shown, and as described in Article XXII. The last radiator on the right has the main flow and return directly connected with it; it really forms a terminal to these pipes, as illustrated. Each of these radiators would need the usual air-cock on the top. There would be no need for a stop-valve to each, as although one may heat quicker than the other, the whole three would soon become of an even temperature. The mains with this apparatus should be $1\frac{1}{2}$ in., but the pipes or branches from the mains into the radiators need only be 1 in., or $\frac{3}{4}$ in. will do sometimes.

The service to the right may be supposed to furnish heat to a smaller room, but one of such a character that radiators, however good in appearance, would be objectionable. In this case the radiating media must be put out of sight, and this example shows it placed beneath the floor. In a new building, arrangements can be made for pipes to be carried whichever way may be most suitable, but such works as these are more often put in residences already occupied, but which have certain rooms that should have a regular heat, or which the ordinary fireplaces are not successful in heating. This latter trouble often occurs. There are numbers of rooms, even as large or larger than billiard-rooms, that have only one fireplace, which cannot heat the whole of the room, although it may be large enough to cause an intolerable heat at the end where it is situated.

The writer's usual plan when the heating-pipes have to be beneath a floor is first to see that the room below is an unimportant one,—a kitchen or servants' offices; then to cut away the plaster of the ceiling, and secure an ordinary pipe-coil with box ends up to the joists. Immediately above the coil, on the top side of the joists, a suitable sized hole is cut in the floor-boards, and a brass grating laid in. The pattern of the grating should be open, yet strong enough to bear being stood upon. Branch flow and return pipes enter the box ends of the coils as shown, but, with coils lying flat, it is best to let the flow-pipe enter at a point as far removed from the return as possible, so as to ensure the passage of hot water through all the pipes. (It is not as if the coils stood upright, when it is recommended to connect all pipes at the bottom only, as the heated water then readily finds its way through the top pipes without any special provision.)

Thus far the arrangement is sufficient to heat the room, as although the coils are on the ceiling of the room below, all the heat would come up through the joists and gratings, but there are two things further to consider. First, the coils would have an exceedingly bad appearance below, and secondly, and most important, all the impure air and possible odours (if a kitchen) will come through with the most undesirable speed imaginable. The coils must be boxed in below, this will totally hide them and will make the ceiling sound, and, when whitened, of ordinary appearance except for the square box projections that must exist. To do away with these boxes the joists would have to be cut through and trimmed to make a space for the coil; this would be a somewhat expensive and troublesome undertaking. Notwithstanding the box below, which quite shuts off communication between the room above and below, the spaces between the joists should be soundly stopped also, or air may be drawn this way from disagreeable sources. When this is done, the coil will heat the air of the room only, it will be practically a coil in a box, or well, sunk

in the floor, but, if convenient or desirable, a fresh-air conduit could be led to it from outside. There would be then a rapid inflow of

FIG. 98.

air, warmed by contact with the coil, and an inlet of this kind always goes to reduce the disagreeable draughts at doors and windows.

Air-cocks would have to be put upon the highest points of the coils, and when requiring attention could be got at by removing the gratings. If this is inconvenient, small tubes can be carried from the same points, but either up or down, whichever is best, and terminating with cocks.

With an apparatus like this, an expansion pipe should be provided; $\frac{3}{4}$ in. would do, and the proper point for it to start from, would be in the flow-pipe somewhere between the two stop-cocks. The cold supply would be provided for by a good-sized cistern fixed at any point from 1 ft. to 4 ft. above the top of the highest radiator. The supply-pipe might be led into any of the return-pipes with the necessary dip or syphon.

Doubtless many of our readers have heard that it is proper in some instances to connect all radiating pipes, coils, &c., to the main return service only. This is correct in some cases, but in none of the examples yet given is it necessary or desirable. The methods shown are as good as any. The idea of putting all radiating media on the main return, arises from the argument that the service-pipe which has the greatest weight of water in it, or connected with it, should be the one that has the water

FIG. 99.

descending within it when at work. In other words, if the flow-pipe had a greater hulk of water in connection with it than the return, it would tend to be an obstacle to the upward direction of the water when it goes to rise up this pipe, and having a greater amount of water to displace than there is in the return-pipe, it might bring about a reversed or retrograde circulation.

This theory is broken down a great deal now,

yet, at the same time, when an apparatus extends in a vertical direction a good height, and the engineer has any fear of such a result, he may put his coils all on the return, as fig. 98 for instance. This shows an apparatus with a boiler in the basement, but going to heat two corridors or rooms a floor or two above. If it was feared the upper coils (or pipes) would give better results than the lower, then the circulation to each could be equalised by running the services as in fig. 99. If it is not desired to make the connexions wholly with the

FIG. 100

return pipe, then it could be carried out as in fig. 100, which is, perhaps, the most customary way of doing it now.

GENERAL BUILDING NEWS.

ENLARGEMENT OF TULLIE HOUSE, CARLISLE.—On the 25th ult. the Mayor of Carlisle laid the foundation-stone of the enlargement of Tullie House, Carlisle. Tullie House, which dates from the end of the seventeenth century, is situate in Abbey-street, and will be used as a museum, and a new wing will be built at right angles with Abbey-street, to include rooms for the School of Art, the Public Library, with lending and reference departments, a general reading-room, a boys' reading-room, class-rooms for technical instruction, and a Fine Art Gallery. It is estimated that the cost will be 12,000*l.* The scheme was devised by Mr. C. J. Ferguson, who prepared sketches embodying his suggestions, and Mr. Howard Smith, the City Surveyor, prepared the detailed drawings. Upon the basement of the new building will be a boys' reading-room. On the ground floor will be the Public Library, class-rooms for technical instruction, and a lecture theatre to seat 200 students. Upstairs will be the School of Art, with its various elementary and advanced class-rooms, painting studio, and picture galleries. The chief contracts have been taken by Messrs. J. & W. Baty, for bricklayer's and mason's work; Mr. H. Court, carpentry and joinery; and Messrs. R. M. Ormerod & Sons, fireproof flooring. Mr. Howell is clerk of works. We published in the *Builder* of May 9, 1891, some drawings of Tullie House as proposed to be adapted for a free library and school of art, which were furnished to us by Mr. Ferguson.—After the foundation-stone of the enlargement of Tullie House was laid, the Mayor's drive on the boulevards round the Saucerics was inaugurated, and the new Recreation-ground in Botchergate was dedicated to the public. The Mayor's drive was commenced from plans prepared by Mr. McKie, the then City Surveyor, and has been finished by his successor, Mr. Howard Smith. It is a roadway formed from Eden Bridge round the Saucerics. It is about 1,200 yards in length, and along both sides of it are planted trees. There is a project for continuing the "Drive" round the Sheep Mount, and if this is carried out a bridge will be built across the river Calder, a short distance above its confluence with the Eden. The new recreation-ground is off Fusehill-street, and is over an acre in extent.

PUBLIC BATHS, SALFORD.—On the 2nd inst., the Mayor of Salford (Mr. Alderman Keeney) opened the public baths recently erected by the Salford Corporation in Regent-road. The baths are situated at the corner of Regent-road and Derby-street, and have been erected from designs prepared by Messrs. Mangnall & Littlewoods, architects, of Manchester. The design is Renaissance in character, the material for the elevation being red terra-cotta and the best pressed bricks from Bealton. The principal entrances are in Derby-street, the manager's residence over them forming a central feature to the elevation in that street. The first-class entrance is at the right-hand doorway, which leads to the first-class swimming-bath, the first-class gentlemen's slipper-baths, and the ladies' slipper-baths. The left-hand entrance is for the second-class bathers, and leads to the second-class swimming-baths and second-class men's slipper-baths. The first-class embraces vapor-baths, cooling-rooms, and shower-baths. The bath-rooms are 8 ft. by 6 ft. 6 in. There are ten first-class slipper-baths and eighteen second-class for

gentlemen. The ladies are provided with four first-class slipper-baths and eight second-class. The first-class swimming-bath has a water area of 58 ft. by 25 ft. The second-class swimming-bath has a water area of 75 ft. by 23 ft., the depth being 5 ft. 9 in. at the deep end, and 5 ft. at the shallow end in each case. The contractors were Messrs. Robert Neill & Sons, of Strangeways, and the total cost of the buildings is about 11,000.

BOARD SCHOOL, EDINBURGH.—On the 3rd inst., a new school for the Edinburgh School Board was formally opened by Lord Reay. The school is situated at Sciennes-place, and is the largest and most completely equipped of the schools erected by the Board. The total cost of the buildings was stated by the convener of the Building Committee to be about 21,620, and he claimed that in all its arrangements and equipment the Board had by no means neglected economy while securing the greatest efficiency. The accommodation of the school, including all the class-rooms and the lecture-room, he explained, was calculated at 19 square feet for juveniles and 8 square ft. for infants, and amounted to 1,682 places; but, including the swimming-bath and gymnasium, the total accommodation was 1,985. Taking the total accommodation as for 1,985 children, the cost per scholar was barely 10s. 17s. 11d. The building was designed by and carried out under the superintendence of Mr. Robert Wilson, the architect for the School Board. (We take the foregoing particulars from the *Scotsman*.)

MEMORIAL CHURCH, SUNDERLAND.—On the 18th ult. the Bishop of Durham (Dr. Westcott) laid the foundation-stone of St. Hilda's Church, Sunderland, which is being built as a memorial to the late Bishop Lightfoot. The church will be situated between the junction of Westborough and Clenny street, Millfield. It will be erected at an estimated cost of 5,072. The nave will be 62 ft. 6 in. long, by 21 ft. wide, and, in addition, there will be two side aisles, two transepts, and a baptistry. Twelve pillars will be erected in the interior of the building, the majority of them being subscribed for by various local societies. The glass for three lancet windows at the east of the church has been presented by the Misses Halcox, of Sunderland. The church will be surmounted by a spire, rising to a height of 134 ft. from the level of the ground. Accommodation will be provided for 505 persons, and there is to be a morning chapel running along the east of the south transept. The architects are Messrs. Hicks & Charlewood, Newcastle-on-Tyne.

GIRLS' HOME, BALLYSLYAN, BELFAST.—The opening of the Victoria Voluntary Homes for the Shamrock Lodge Girls at Ballyslyan took place on the 19th ult. The new buildings are approached from the Crumlin- and Oldpark-roads. The entrance lodge is situated on the Ballyslyan-road. The main buildings are arranged in a hollow square. In the middle of the front is placed a square tower, finished with a pyramidal roof and copper vane. The principal doorway is placed below. From the inner porch access is obtained to either of the principal schoolrooms. The west wing contains practically a distinct house, with the board-room, parlour, kitchen, and pantries on the ground floor. A corresponding wing on the south side for the industrial school department is arranged for 40 children. Behind it stands the hospital, complete with a separate kitchen, scullery, and yard. The upper stories of all these buildings form a series of dormitories, with bath-rooms and lavatories attached. The rear of the entire block is occupied by the laundry, smoothing and drying rooms, heated from the boiler-room adjoining. A dairy and general storehouses complete these offices. A small engine with a pump attached, is used for forcing up the water supply to a cistern placed in the tower. At a short distance from the central building stands the Forster Green Home. It is so planned as to be complete in itself, and accommodates thirty girls. On the ground floor access is obtained through a porch and hall, from which open the dining-room, mothers' room, and the playground. A bath-room, with lavatories, is attached to the last-named. Behind these are the kitchen, scullery, pantries, and yard. The upper floor is used for dormitories. The playground is arranged for use in wet weather. The buildings have been carried out in red brick, with Dumfriess mullions and sills. The plumbing has been executed by Mr. John Dowling. Mr. Robert Cory, Donegal Pass, has carried out the works, and Messrs. Young & Mackenzie, of Belfast, are the architects.

FOREIGN AND COLONIAL.

FRANCE.—At the Champs Elysées Salon this year nothing in the sculpture or architectural exhibits has been deemed worthy of the *grande médaille d'honneur*. On the other hand, in the section of painting, after three tours of inspection, the award has been bestowed on M. Albert Maigron, by 163 votes out of 324. The other awards have been distributed between MM. Vayson, Roybet, Henner, Benjamin Constant, Raphaël Collin, and Henri Martin. M. Maigron, who has exhibited an Apotheosis of Carpeaux, is a pupil of M. Lamoignon. He obtained a medal of the third class in 1874, one of the second in 1876, a first-class in 1879, and a

gold medal at the Universal Exhibition in 1889. He was decorated in 1883.—In architecture MM. Cordonnier and Charles Normand have obtained medals of the first class; MM. Chélanne, Lafargue, Hamoulin, and Gaidis the second; MM. Tisandier, Nizet, Trépy, Bailly, Boussac, Loyal, and Escalier the third.—In honours of mention has been awarded to MM. Béville, Bobin, Coulon, Dalmas, Desoues, Dzermann, Giroix, Guénot, Guyon, Lsgendre, Légonzé, Mauher, Mougenot, and Paul Normand.—At the Ecole des Beaux Arts the Fortin d'Ivry prize has been given to M. Bonis.

Several fires due to malevolence have destroyed a great quantity of wood in the most picturesque part of the forest of Fontainebleau.—In the Georges Petit Gallery an exhibition of 100 pictures has just been opened for a charitable object. They are works chosen from the most celebrated masters, from the time of Rubens and Rembrandt to Meissonier, Millet, and Corot. This exhibition is organised under the presidency of the Duc d'Aumale.—They have lately inaugurated a statue of Pascal Duprat, at Mont de Marsan (Landes). The statue is the work of M. Lalauze.

—Eugène Arago, recently dead, has left as a legacy to the museum at Versailles, two busts in terra-cotta, by Carrier-Belluse, of the astronomers Matthieu and Paul Langier.—M. Waldeck Rousseau has offered to the Luxembourg Museum a picture by M. Gervex, which was exhibited in the Salon of 1885, entitled "Meeting of the Jury of Painting."—MM. François, Bonnat, Jules Breton, Daumet, and Roty have been appointed to represent the Académie des Beaux-Arts at the ceremony of inaugurating the monument of Claude Lorraine at Nancy.—An exhibition of the works of the painter Antoine Richard is to be opened on the 15th inst. at Châlons-sur-Marne. It is announced that, on the occasion of the approaching visit of the President to Nancy, the corporation of sculptors of that town will offer to M. Carnot an architrave richly carved in walnut-wood and covered with a fine tapestry in which the arms of Lorraine are woven. This work has been executed by M. Donot, sculptor.—The death is announced of M. Frederic Grosclaude, portrait painter. He was born at Geneva, but had been naturalised many years. He exhibited at the Salons annually from 1872 to 1888 studies of heads and portraits in pastels, executed with a certain amount of talent.—The sculptor Bonmassieu, member of the Institute, one of the oldest professors at the Ecole des Beaux-Arts, has lately died at the age of 81. He was born at Baniassière (Loire), in 1810, and obtained the Prix de Rome in 1836. He then obtained a second medal in 1862, a first in 1864, a second in 1868, and a new first medal at the Universal Exhibition of 1855, at which time he was decorated. His well-known religious views made him the official sculptor of the Catholic clergy, and it is to him that we owe the colossal statue of Notre Dame de France, which commands the Vallée du Puy (Haute Loire). It was made from the bronze of the cannons taken at Sebastopol. He also assisted at the decoration of several of the Paris churches, notably that of St. Augustin. He has contributed nothing to the Salons for some time.—We have also to announce the death of the painter Jaumot, who died at Lyons at the age of 78. He received medals in 1855 and 1856.

BERLIN.—Hert von Forckenberg, who has been Lord Mayor since 1878, died last week. His funeral was one of great civic state. During the fourteen years he held office, Berlin has seen a marvellous development, and also great improvements in all matters relating to municipal management.—The value of the prizes to be offered for the coming competition for designs of the proposed Provincial Museum has had to be raised from 2500, to 4000, owing to dissatisfaction expressed in architectural circles as to the low figure of the premiums.—Some very interesting buildings for the Army Commissariat Department have been completed. In the main block there will be room to store 70,000 cwt. of oats. Owing to the great losses the force departments have lately had through fires in their store-houses, great precautions have been taken against the outbreak and spread of a conflagration. Each of the seven stories of the main building is divided into two separate risks, and each compartment has a separate system of sprinklers. It appears, however, that for some inexplicable reason wood has been used for all the floors.—On the recommendation of the sanitary inspectors the Police President will probably now prohibit ladies from kindly acting as voluntary street scavengers. There is to be a restriction as to the length of ladies' trains.—The historical Castle Church at Wittenberg, the restoration of which has cost some 45,000, will be reopened by the Emperor in the autumn. Professor F. Adler has had charge of the works.

MUNICH.—The International Art Exhibition, which has now become an annual institution, had been opened by the Prince Regent with the usual ceremony. The local press considers this year's show to be a good one.—The buildings for the Bavarian National Museum, which are to be erected on a fine site near the so-called "English Garden," will cover a superficial area of some 8,600 square metres. The new block is cost about 220,000, and some five years will have to elapse until the

halls will be ready for the reception of the exhibits (*Deutsche Bauzeitung*).

STUTTGART.—Again a competition has been opened with a great philanthropic object in view. This time it is a competition for designs of some large buildings, in which 400 or 500 railway servants and their families are to dwell. Each tenement,—consisting of two rooms, a kitchen, w.c., lobby, and a share of the staircase landing,—is to have an area ranging from 75 to 80 square metres; those with three rooms from 90 to 95 square metres. Much importance will be attached to the laying out of the ground which stands at the disposal of the authorities, as, besides the dwelling-houses, there are to be general washhouses, baths, stores, and a preparatory school to be found room for. The competition excites much interest throughout those parts of Germany where the artisans' dwellings question has been mooted.

SWITZERLAND.—Whilst at the past competitions for designs of new post-office buildings in Geneva and Lucerne the number of designs sent in was large, the assessors who have had to decide on the merits of the work tendered at the Zurich Post-office competition have only had twenty-seven to select from. They have not found any one of the twenty-seven deserving of the first prize, and have only been able to give five minor awards. The most valuable of these went to M. Eugen Meyer, a Swiss architect resident in Paris.

MISCELLANEOUS.

CHRIST CHURCH CATHEDRAL, OXFORD.—We are informed that the grave marked as Dr. Pusey's grave in our plan of Christ Church last week, in the external angle of choir and south transept, is in reality that of Philip Pusey, a son of Dr. Pusey. The latter was buried in the nave of the Cathedral.

FORTHCOMING SALES.—At the Mart, on the 21st instant, by order of the late Mr. W. B. Waterlow's trustees, various residential and building estates in the neighbourhood of Reigate and Redhill, comprising those known as High Trees, on the west side of Redhill Common,—the house built of stone in the Italian mode, for its late owner,—and, with frontages to the Common, Fairway, The Mount, Blackstones, and Earlswood Cottage; together with High Trees Park, and other lands adjacent. In July: The Barwhilant estate, of nearly 4,000 acres in the stewardry of Kirksendright, Galloway, and situated in the parishes of Parton and Crossmichael. The latter parish lies between the rivers Urr and Dse, to the north-west of its Parton—a district famous for its Celtic and Pictish remains. At Carlisle, on an early date, the Springkell estate, in county Dumfriess, just across the border, and about ten miles distant from Carlisle. It embraces an area of 14,000 acres, divided among fifty-one farms, yielding an annual rental of say, 11,000. The mansion house, built, we believe, about 100 years ago, for Sir William Maxwell, stands on the famed Kirkle water, which flows for some miles between Eskdale and Annandale. Gretna, or rather Grainy (*olim* Meg's-hill) is a farmstead, near to Springkell, a village established by Sir William Maxwell. One of the first inhabitants of that new settlement was Joseph Paisley, a tobacconist, often wrongly described as having been a Blacksmith,—whose memory is associated with the "Gretna Green" marriages since the passing of Lord Hardwicke's Act in 1754. Paisley died in 1814: his business, after that kind, was carried on here by his granddaughter's husband.

PATENT OFFICE REPORT FOR 1891.—According to the Comptroller-General's ninth report, for the year 1891, the general business of the Patent Office was represented by applications for 22,838 patents, being the highest total since the new procedure under the Act of 1883; designs, 21,950 (22,553);* and trade marks, 10,787 (10,258). Of the patents, 15,484 came from persons residing in England and Wales, 1,177 from Scotland, 134 from Canada, 1,466 from Germany, and 2,364 from the United States. Sales of the Office publications yielded a receipt of 6,142, 13s. 7d., and a surplus of 100,330l. 6s. 7d. is declared out of gross receipts amounting to 203,620l., the patent fees alone being 181,777l. 4s. 8d. The largest number of patents applied for under the old law was 6,241, in the year 1882, and of them two-thirds remained in force to the end of the fourth year. The ratio for the year 1880, under the new Act, is a little less than one-half. In virtue of a Royal charter dated August 11, 1891, the Institute of Patent Agents was incorporated; it had a total number of 236 names upon the register of agents on December 31st last. For the re-building of the Patent Office, as already begun in Took's-court, a sum of 21,703l. is taken on account in the estimates, for new works and purchase of premises.

SWEDEN AND THE CHICAGO EXHIBITION.—The Swedish Society of Engineers in New York is urging Swedish manufacturers to participate in the Chicago Exhibition, and has, to that end, offered a prize for the best essay, "Ought Sweden to Exhibit in Chicago," which is to be distributed in Sweden and America.

* The corresponding figures for the preceding year are enclosed within brackets.

COMPETITIONS, CONTRACTS, AND PUBLIC APPOINTMENTS.

COMPETITIONS.

Nature of Work.	By whom Advertised.	Prize.	Designs to be delivered.
*Public Baths	Walsh Corp.	50l. 30s. & 20s.	July 15

BRITISH MINERAL PRODUCTION.—The "Mineral Statistics of the United Kingdom" for 1891 show that the total value of the minerals raised last year was 91,228,024l., against 92,794,451l. in 1890, which is a decrease for 1891 of 1,566,427l., or 1.66 per cent.; the decline extending to nearly all branches of mineral production. The principal item of output was coal, of which were obtained 185,479,126 tons, or 4,264,836 tons (2.34 per cent.) more than in 1890, when the production was only 181,214,288 tons. The value of the coal output declined by 854,181l., or 1.14 per cent., the figures being 74,090,816l., against 74,933,997l. in 1890. Of iron ore, 12,777,689 tons were raised, valued at 3,355,860l., compared with 13,780,767 tons, valued at 3,926,456l. This shows a falling-off in 1891 of 1,003,078 tons, or over 7 per cent., in quantity, and of 570,585l., or 17 per cent., in value. Of the output of stone, the value only is given, amounting to 8,693,743l., against 8,708,091l. in 1890; decrease, 14,948l., or 0.17 per cent. The quantity of clays (excepting ordinary clay) obtained in 1891 was 3,222,035 tons (value, 943,896l.), against 3,908,214 tons (value, 899,166l.) in 1890. Thus, although the quantity raised in 1891 decreased by 86,179 tons, or 2.6 per cent., compared with 1890, the value increased by 44,707l., or nearly 5 per cent. The production of slates and slabs amounted to 415,029 tons, against 434,352 tons in 1890; the value was 937,000l. and 1,027,235l. respectively, the decline being 19,233 tons, or 4.4 per cent., in quantity, and 40,235l., or 3.9 per cent., in value. Of gypsum, 151,708 tons (valued at 60,038l.), against 140,293 tons (valued at 57,991l.), were obtained; decrease, 11,415 tons, or 7.55 per cent., and 2,047l., or 3.4 per cent., respectively.

"HYLONITE."—This material, some specimens of which have been forwarded to us by Mr. H. Brockmann, the London agent of MM. Schreiber & Co., is a preparation of wood pulp, to be used in place of plaster or stucco for decorations, or for wall covering. The special value claimed for it is that it is guaranteed to stand any amount of heat "without shrinking, bending, or losing its original shape." "Paper stucco" is another material of the same class claiming the same heat-resisting qualities. If this resistance to heat is realised under test no doubt this is a very useful material for lining buildings which are intended to be specially fire-resisting. As far as decorative effect is concerned, the examples of ornament appear to be very deficient in sharpness as compared with plaster or stucco. This deficiency may be met to some extent by designing specially for the material, as is often done for cast-iron. At all events, in a practical sense the material seems worth attention.

DEDICATION OF THE CATHEDRAL BELLS, NEWCASTLE.—On the 7th inst. the new peal of bells recently placed in the belfry of St. Nicholas's Cathedral, Newcastle, were formally dedicated. There are ten bells in the new peal, exclusive of the major or hour bell. Messrs. John Taylor & Co., of Loughborough, have had the casting of the bells and the re-casting of the major.

HOUSES FOR SAILORS IN THE EAST-END, LONDON.—A new branch institute, in West India Dock-road, of the British and Foreign Sailors' Society, of which the Duke of York is patron, is to be known as the

Albert Edward Sailors' Rest. The freehold of a disused public-house, called the "Jolly Sailor," with a message at the back, have been bought by the society, who appeal for contributions in aid of their work, both at home and abroad, which they began about seventy-five years ago, on board of H.M.S. *Speedy*. In 1856 the society's labours were greatly promoted by the late Prince Consort's active co-operation. On December 5, 1888, the Duke of Cambridge re-opened the institute in Mercers'-street, Shadwell. Of the Scandinavian Sailors' Home, by the East and West India Docks, we gave an account in our number of June 25, 1887. The Home in West-street, Wellingborough-square, stands, we believe, on the site of the Brunswick Theatre, which replaced the Royalty Theatre burnt in 1826.

CAPITAL AND LABOUR.

THE THREATENED STRIKE IN THE LONDON BUILDING TRADE.—As the outcome of the demands of the London bricklayers as to hours and rate of wages (published in the *Builder* for April 9, p. 296), the London Association of Master Builders, feeling the practical inconvenience that would arise if the men of the different trades had varying hours for commencing and leaving off work, at a conference held with the representatives of the bricklayers on May 25 announced that they could give no reply to the demands of the men until a conference could be held between the representatives of all the trades and of the employers, with a view of agreeing upon one code of working hours and rules. This conference has now been arranged, and will take place a few hours after these lines are published; the representatives of the masters having agreed to meet, at 2 o'clock on Friday, June 10, three delegates from each of the following trades, viz., bricklayers, masons, carpenters, plumbers, painters, plasterers, smiths (including filers and bell-ringers), and labourers. In spite of some rather wild talk which has appeared in some of the newspapers, we trust that both sides will exhibit a conciliatory spirit, and that a strike may be averted.

THE STRIKE IN THE CARDIFF BUILDING TRADES.—According to the *Western Mail*, the carpenters and joiners of Cardiff who have been concerned in the strike in the building trade there have agreed to accept the 5 1/2d. offered by the masters, and to eliminate their free labour clause. This action, however, does not affect the other trades, for from the first the carpenters and joiners have held aloof from the allied trades.

MEETINGS.

SATURDAY, JUNE 11.
 Architectural Association.—Visit to new Music School, Harrow, Mr. E. S. Prior, architect; and to other School Church at 3 p.m.
 Incorporated Association of Municipal and County Engineers.—Eastern Counties District Meeting at Peterborough.
 Junior Engineering Society.—Visit to the Works of the Patent Victoria Stone Co., Stratford. 3 p.m.

St. Paul's Ecclesiastical Society.—Visit to Chesham Bois and Chesham.
 Edinburgh Architectural Association.—The Sketching Class to meet at Royaton House, Carolina Park, Granton, to make measured drawings and sketches of the south front of the mansion. 3 p.m.

MONDAY, JUNE 13.

Royal Institute of British Architects.—Business Meeting.—(1) To receive the Report of the Scrutineers on the Election of the Council, Standing Committees, &c. (2) To receive and consider the Report of By-laws (Election of Fellows) Special Committee. 9 p.m.
 Society of Engineers.—7 30 p.m.
 Clerks of Works Association (Carpenters Hall).—Monthly meeting. 8 p.m.

TUESDAY, JUNE 14.

Incorporated Gas Institute.—Twenty-ninth Annual Meeting. 11 a.m.
 Society of Biblical Archaeology.—8 p.m.

WEDNESDAY, JUNE 15.

Incorporated Gas Institute.—Twenty-ninth Annual Meeting (continued). In commemoration of William Murdoch and the centenary of gas lighting, a "Murdoch" lecture will be given by Professor Vivian B. Lewis on "A Century of Work on the Development of Light from Coal Gas." 10 a.m.
 Builders' Foremen and Clerks of Works Institution.—Ordinary Meeting. 8 30 p.m.
 Royal Meteorological Society.—Two papers will be read. 7 p.m.

THURSDAY, JUNE 16.

Incorporated Gas Institute.—Twenty-ninth Annual Meeting (continued). 10 a.m.
 Society of Antiquaries.—8.30 p.m.

RECENT PATENTS:

ABSTRACTS OF SPECIFICATIONS.

7,229.—SELF-ACTING HOOK: G. Cooper.—This patent refers to an invention for retaining doors, gates, or for any other purpose where a self-acting hook is required, to fasten back and release when required. The inventor provides a circular plate with a barrel containing a buffer and spring. There is a slot in the sides of the barrel for the purpose of sliding screws, working a hook. There is also a screw below the slot for holding the hook in position. This part is fixed on the skirting or other position above the floor line. A plate with staple and releaser lets go the hook.
 11,175.—FLAP VENTILATORS: S. S. Robson.—This specification refers to an improvement in flap ventilators, the object of which is to produce a noiseless flap distinct from those now in use. The inventor uses asbestos paper, which is, of course, unflammable and noiseless. It is fixed to the ventilator in the same way as the ordinary flaps in use.
 14,608.—WINDOW-SASHES: J. Hanson.—This refers to an invention intended to be applied to carriage windows and the like, to prevent rattling or noise. One edge of the window-frame is provided with a corrugated slip corresponding in pitch to another corrugated slip contained by a metal case, and let into the groove of the door sash. To this case are attached inclined springs, upon which the loose slips work in such a manner that when the window is raised the corrugated slip slides up the inclined spring, so taking the grip off the window and allowing it to be raised without friction. When the window is stopped, the loose slips drop down the inclined springs and block the window.
 4,871.—PIPE CONNECTIONS: T. Robinson.—The object of this invention is to make a perfect air and liquid tight joint between the earthenware outlet-pipe of a water-closet basin, or other sanitary appliance, and the

LONDON.—For re-insulating, after Geo. Brandram's Wharf, Rotherhithe, S.E., for the Liverpool, London, and Globe Insurance Co. Ltd.:

LONDON.—For proposed new drill hall, offices, &c., Clapham, at Lieutenant-Colonel A. J. Bowen, Commanding. Mr. R. A. Briggs, architect:

LONDON.—For iron staircase at the Workhouse, Old Graveland Lane, for the Guardians of the parish of St. George-in-the-East. Messrs. Wilson, Son, & Aldwinckle, architects, 1, Victoria-street, Westminster, S.W.:

MAIDENHEAD.—For erecting Mr. May's new R.C. ch. for the Rev. John W. Ross, M.P. & K. A. White, architect, 4, Great Queen-street, S.W.:

PLASHEAT.—For painting and repairs at the Industrial Schools, Finsbury, for the Guardians of the parish of St. George-in-the-East. Messrs. Wilson, Son, & Aldwinckle, architects, 1, Victoria-street, Westminster, S.W.:

RIPLEY (Sussex).—For alterations to business premises, Ripley, Surrey, for Mr. Richard Green. Messrs. Peck & Lunn, architects, Guildford:

SWANSEA.—For the erection of two shops and premises, Alexandra-road, Swansea, for Mr. Jacob Jenkins. Mr. H. C. Portman, architect, Swansea. Quantities by the architect:

WALTHAMSTOWN (Essex).—For the erection of a new police station at Walthamstow, for the Receiver for the Metropolitan Police. Mr. John Butler, Architect. Quantities by Mr. W. H. Thurmond:

WIMBORNE.—For alterations and additions to stabling, &c., at Camford Manor, Wimborne, Dorsetshire, for the Right Honorable Lord Wimborne. Messrs. Bonnington-Walker & Tanner, architects, Cornish & Gaymer, 25, Abchurch-lane, London, E.C.4:

The Builder Cathedral Series.

Table with columns for issue number, date, and price. Includes issues for Canterbury, Lichfield, St. Albans, Peterborough, Wells, Exeter, Hereford, Chester, Ely, Llandaff, Oxford, and Southwell.

Post-free FOURPENCE HALFPENNY each, except Nos. 1, 2, 3, and 4, which are sent post-free; but the view, plan, and description of CANTERBURY, LICHFIELD, ST. ALBANS, and PETERBOROUGH, have been re-printed, and they can now be had, price EIGHTPENCE each; by post, 10d.

THE REREDOS, ST. PAULS. Reprinted from "THE BUILDER," January 29, 1888 (15 in. by 11 in.), on stout paper, unfolded, for framing, 6d.; by post, 8d.

PORTFOLIOS, for Preserving the Plates unfolded, 2s. 6d.; by post, 3s. London: Office of "THE BUILDER," 46, Catherine-street, W.C.

SUBSCRIBERS in LONDON and the SUBURBS, by preparing at the Publishing Office, 18s. per annum (or 1s. 9d. per quarter), can ensure receiving "The Builder," by Friday Morning's Post.

TERMS OF SUBSCRIPTION. "THE BUILDER" is supplied direct from the Office to resident in any part of the United Kingdom at the rate of 18s. per annum in advance. To all parts of Europe, America, Australia, and New Zealand, 25s. per annum. In India, China, Japan, &c., 30s. per annum. Remittances payable to DOUGLAS FOURDBRINER, Publisher, No. 46, Catherine-street, W.C.

PUBLISHER'S NOTICES.

Registered Telegraphic Address, "THE BUILDER," LONDON.

CHARGES FOR ADVERTISEMENTS. SITUATIONS VACANT, PARTNERSHIPS, APPRENTICESHIPS, TRADE, AND GENERAL ADVERTISEMENTS.

Six lines (about fifty words) or under 4s. 6d. Each additional line (about ten words) 0s. 6d.

TERMS FOR SERIES OF TRADE ADVERTISEMENTS, also for Special Advertisements on front page. Competition, Contracts, Sales by Auction, &c., may be obtained on application to the Publisher.

SITUATIONS WANTED. FOUR Lines (about thirty words) or under 2s. 6d. Each additional line (about ten words) 0s. 6d.

PREPAYMENT IS ABSOLUTELY NECESSARY. ** Stamps must not be sent, but all small sums should be sent by Cash in Registered Letter or Money Order, payable at the Post-office, Covent-garden, W.C. to DOUGLAS FOURDBRINER, Publisher.

ADVERTISEMENTS for the current week's issue must reach the Office before THREE o'clock p.m. on THURSDAY, but those intended for the front Page should be in by TWELVE noon on WEDNESDAY.

SPECIAL ADVERTISEMENTS IN STANDING ADVERTISEMENTS. ** MEN'S or ORDERS TO DISCONTINUE must reach the Office before TEN o'clock on WEDNESDAY morning.

The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to Advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

PERSONS Advertising in "The Builder" may have Replies addressed to the Office, 46, Catherine-street, Covent Garden, W.C. Free of Charge. Letters will be forwarded if addressed in envelopes are sent, together with sufficient stamps to cover the postage.

AN EDITION Printed on THIN PAPER, for FOREIGN AND COLONIAL CIRCULATION, is issued every week. Now ready. NINEPENCE EACH. (By Post, six-penny packed, 1s.)

HOWARD & SONS

25, 26, 27, BERNERS STREET, W., MANUFACTURERS AND CONTRACTORS. Deal Dadoes, from 1s. 2d. per ft. super. Oak Dadoes " 1s. 8d. Walnut Dadoes " 1s. 11d. Oak, 1 inch Parquet Floors, laid and polished, from 27s. 6d. per square. Solid 1-inch Oak, straight boards, laid and polished, at 4s. 18s. a square. Solid 1-inch Oak Parquet for covering Deal floors, laid and polished, from 45s. a square. Oak Wood Tapestry Dadoes, from 1s. per foot super. Walnut or Mahogany, from 1s. 3d. per foot super. Ditto with Heavy Mouldings, 4d. ft. extra. Ditto, ditto, with Carved or Painted Panels, prices according to sketches.

Prices given for all Interior Work, Doors, Architraves, Over-doors, Chimney-pieces, Stores, and Hearths. Architects' and Surveyors' attention particularly called to the above Quotations for

BILLS OF QUANTITIES.

Proposed Changes at the Institute.

HE discussion of a proposed change in the mode of election of members occupied a very crowded meeting at the Institute last Monday, the report of which is by this time in the hands of members.

The question arose in regard to the adoption of the report of the Special Committee which had been appointed to consider the present conditions of election as provided for under By-law No. 9. The By-law runs as follows:—

"Elections shall take place at Business meetings only, and, except as herein otherwise provided, by ballot, in which at least ten Fellows shall join; and the proportion of one black ball to six white shall exclude from election. At every election the meeting shall appoint two subscribing members as Scrutineers, and they shall superintend the ballot.

(a) In the case of candidates for the class of Fellows the election shall always be by ballot."

The two next sub-sections (c and d) provide for the occasions on which balloting may be dispensed with, the fourth states distinctly that no exception is allowed in the case of Fellows—

"(d) An Associate being eligible, and desiring to become a Fellow, must go through all the forms prescribed for the election of a Fellow."

The reasons for the appointment of the Committee were given in resolutions of the Annual General Meeting of May 4, 1891—

"That a Committee be appointed to inquire whether it is not possible under By-law 9 for a small body of members to exclude from the Fellowship of the Institute qualified persons approved by the Council, although a large majority of the members of the Institute approve of the election; and if so, to suggest steps for the amendment of the anomaly.

That it be left to the Council to appoint the Committee, such Committee to be a general one, and not exclusively composed of members of the Council."

The Committee consisted of Messrs. Frank T. Baggallay, James Brooks, Thomas M. Rickman, Lacy W. Ridge, R. Phené Spiers, Paul Waterhouse, Henry Cowell Boyes, Edwin T. Hall, Charles Henman, E. B.

L'Anson, J. G. Finch Noyes, and Wm. Woodward, with Mr. Arthur Cates as Chairman. They have reported that the present system of the election of Fellows is open to abuse, that it gives facilities for a small minority of members to enforce conditions of membership which have not been recognised by the majority, and takes up valuable time at a business meeting, and that the fitness and qualification of candidates can only be investigated by a confidential body of limited numbers, such as the Council; but the pith of the report, the essential point of the position taken up, perhaps lies most particularly in the following paragraph:—

"That, in the opinion of your Committee, the Royal Institute, in accepting a Royal Charter, placed itself under an obligation to admit to membership, in the class appropriate to their standing, all British subjects who, being willing to join, are duly qualified, and are prepared to exercise their profession in an honourable manner, in accordance with the conditions of membership imposed by the Charter and By-laws; and that herein the Royal Institute differs from any body of limited membership or from any club formed for private and social association among its members."

The recommendations of the Committee in detail are in the hands of all members of the Institute; we need only observe here that they amount to this: That after some special provisions for investigation of the claims of every candidate for election as a Fellow, the election shall ultimately be made at the general meeting by show of hands, unless a requisition be presented, signed by not less than three subscribing members (the majority of whom must be Fellows), demanding that the votes of the whole number of members should be taken by voting-papers. This is the proposal referred to in the letter of "Suum Cuique" in our last number.

At the meeting on Monday it was moved by Mr. Cates and seconded by Mr. H. C. Boyes that the Report should be received and adopted, and that the Council be requested to prepare modifications of the By-law in accordance therewith, and take the steps necessary to obtain the desired alterations. After a long discussion, this was carried by a large majority, a majority probably larger than it would otherwise have been, owing to an anonymous printed whip which was sent round to all those members who were

thought likely to support the new rule: we presume at least that this was the motive, as it was not sent to everyone. It seems to be unknown whence this circular emanated or by whose authority it was sent, but the sending round of a whip of this sort anonymously and on no one's specified responsibility is a piece of very bad taste on the part of whoever did it, and a line of proceeding which we hope will not be repeated, or will receive no attention if it is. If any members or any party in the Institute are desirous of supporting a special measure and of bringing together those whom they think likely to support it, let them do so openly and put their names to their document; then it is all fair and straightforward. In this case it was evidently circulated anonymously in the hope that those who received it would imagine it was official, and this is not a creditable piece of tactics.

We are not prepared to say that the proposed change is undesirable (nothing of course is final until the By-law in its new form is really passed), but we are of opinion that the resolution in favour of it was passed hurriedly at a meeting which was not duly representative of both sides of the question, and that the subject needs more consideration. The ostensible reason for the proposed change is that it is asserted that the ballot has been misused of late to keep out members who ought to have been elected, but who were obnoxious to a minority of persons who had combined accordingly to keep them out. One may say, as the senators did to Brahantio, "To vouch this, is no proof;" it is only common talk; nor, if we understand what is meant, are we by any means sure that those who are supposed to have been thus excluded were desirable members or would have been an honour to the Institute. Mr. Brydon, who, in a very able speech, moved that the consideration of the question should be postponed until the more important question of the conditions under which Fellows should be elected (to which we referred last week) had been settled, observed that out of two hundred and three ballots for Fellows during the past five years there had only been thirteen rejections, a proportion which does not look as if there had been any excessive use (or abuse) of the

power of black-balling. Mr. Brydon objected also to the theory propounded in the report of the Committee, that every person who was a *bona-fide* architect and prepared to carry on his profession in accordance with the requirements of the Institute had a right to election; he wished that election should be an honour only to be obtained by those whose works had shown them to be worthy of it, and that "F.R.I.B.A." should carry with it the same kind of testimony to ability in architecture which "R.A." is supposed to give to the possessor of that title. Here he was obviously illogical, in comparing two institutions which are not on the same kind of basis. The Royal Academy is a body of limited numbers, whose members are supposed to represent the *élite* of the artists of the day, admitted to membership on the ground of their special distinction; we do not say that it does as a fact represent the best of the artists, but that is the principle on which elections are supposed to be made. The Institute of Architects is a body unlimited in numbers, and which, besides being concerned with "the advancement of the art of architecture," is a body representing the interests of the profession, and which has the duty of considering and to some extent adjudicating on disputed questions of professional practice. It is therefore quite a different class of institution from the Royal Academy, and the reasoning which applies to the one does not necessarily apply to the other. It is desirable that all who are admitted to membership of the Institute should have given evidence of a certain standard of knowledge and ability; but, within that restriction, the position taken in the committee's report, that all *bona-fide* architects who comply with the requirements of the Charter and By-laws have a right to expect election if they desire it, is not unreasonable or illogical in substance, though it might perhaps have been more carefully and less comprehensively worded. It would hardly be right, at all events, that candidates who come under that category should lose election because a minority black-balled them from reasons, for instance, of personal dislike. That would be a sufficient reason for blackballing a candidate for a club, which is a social institution; but an institute of professional men, as the committee rightly observes, is not the same thing as a club, and reasoning which applies to the one case does not necessarily apply to the other.

At the same time we very much doubt whether the ballot has been used against candidates at the Institute for no better reason than personal dislike; at all events there is nothing to prove it. As Mr. Belcher (who supported Mr. Brydon's motion) observed, there may have been very good reasons for the not very large amount of black-balling which seems to have caused so much consternation. We should be inclined to go further than Mr. Belcher, and to add that there have been elections (we will not say many) which had better not have been made, and cases where candidates who received a large percentage of adverse votes would have been black-balled three times over if all who voted had known as much about them as some did. There may be such a thing, too, as a sense of general policy and fitness of things, to influence voting, apart from any personal feeling. One speaker at the meeting, who is exceedingly fond of posing as Indignant Virtue, inveighed against the idea of black-balling a candidate because he was a member of a certain Society which shall be nameless, and asked if that was not personal motive. It is nothing of the kind, not necessarily at all events. It appears to us that those who have been active members of a Society which includes all kinds of hangers-on to the skirts of the profession among its members, and which in its corporate capacity has done all it can to injure the Institute, have earned about as good a right to be black-balled in Conduit-street as any man could wish for, and though the present policy of the directors of the Institute in this respect may be very Christian (in the sense

of "if a man smite thee on the one cheek turn to him the other also"), it is a somewhat pusillanimous policy, and not the way to keep up the high standing and dignity of the central professional body.

The case between the system of election of Fellows as existing and the system which it is proposed to substitute for it may be summed up thus. At present the Council enter into inquiries as to a candidate and recommend him (if they are satisfied) for election; but the election depends on the vote of the general body. That appears to us to be on principle a very good and wholesome arrangement; the Council and the proposers of the candidate are supposed to do all they can to see that the candidate is a fit and proper person, but the possibly wider knowledge embodied in the general meeting has a chance of operating. The drawback to this is said to be that, according to the present arrangement of the ballot, a small minority have a power of excluding a man whom the Council wish to see elected, and moreover that this power of the minority may be and has been exercised from personal motives. We have seen no proof of the latter supposition, and we rather doubt it. If however, the minority has too great a power, it seems a simple matter to raise the proportion of "blacks" for excluding. On the other hand, we maintain that there may be and have been instances in which the adverse minority knew more or perhaps (even) were better judges than the Council. The best wisdom of the combined Institute cannot be supposed necessarily always to reside in the Council: figures and averages are against the probability of such a chance.

On the other hand the Council now propose to make arrangements for greater efficiency of inquiry into the status of any candidate, and having done so, merely to ask the general meeting to ratify their decision by a show of hands. That is now done in the election of Associates, but then Associates have passed a tolerably stringent and comprehensive examination, so that the cases are not parallel. This proposed regulation would no doubt do away with all opportunity for unfair frustrating of an election, but it has the disadvantage of constituting the Council a kind of irresponsible *Vehm-Gericht* with the election all in their own hands, the general body having only to take the candidates the Council give them. In a general way we have no doubt the Council would put forward the right men and keep back the wrong ones; but we do not know that members as a body will be altogether willing to part with their right of voting. And there are other features in the scheme open to objection. The Council propose, when a provincial candidate is not a member of his local Architectural Society, to enter into a confidential inquiry about him from that Society. As Mr. Pite very truly observed in the course of the discussion, is such a local Society likely to report fairly on a man who, from whatever cause, does not enrol himself with them? We certainly do not think such an arrangement would be popular with provincial architects, or would be likely to influence them towards wishing to be candidates for membership of the Institute.

On the whole therefore it appears to us that while the objections to the present system are not proved to have any ground in fact, and may be imaginary, the objections to the proposed system, so far as they go, are real and obvious, and that the minority who on Monday voted for postponing the matter for further consideration were in the right even on the merits of the case. But there would have been an additional reason for not coming to a resolution at the moment. The resolution which was to have been proposed by Mr. Chas. Barry, but which there was no time to go into, is really the key of the situation, and ought to have been considered first. The substance of this resolution, as we have already noted, was to the effect that for the future candidates for Fellowship should be Associates who had passed the examination

qualifying them for Associateship, in order to avoid the present anomaly by which candidates can avoid the Associateship examination altogether by waiting till they have passed the prescribed age of thirty, except in cases in which the Council might see occasion to abrogate the rule in consequence of the known standing and ability of the candidate. This, of course, practically amounts to the institution of the examination test for Fellowship, except in special cases; but it is not very easy to see how the Institute can stop short of this after laying so much stress on the Associateship examination. The candidates who would come up for election under this arrangement, we may safely conclude, would not include all those who under the present *régime* would be put up for election by the Council. At all events, it seems pretty clear that if this subject is to be seriously discussed, it should be discussed and settled before, and not after the proposed alteration of by-law 9. For if it were settled in the affirmative, all necessity for the other rather complicated machinery would be at an end, and Fellows could be elected by show of hands on the same principle that Associates now are. It is possible that when the alteration in the by-law, to which the vote of Monday night must naturally lead, comes to be finally laid before the meeting, there may be a requisition for a general vote of all members by voting paper. And in that case it may be found that the majority of members will take the view which has been already suggested, that the question involved in Mr. Barry's resolution should be settled before any further legislation is entered on. That would certainly be the most logical course.

THE COMPOSITION OF ANCIENT MORTAR.

THE chemical composition of the mortar employed in the construction of our old castles, abbeys, and churches has hitherto not received that attention which the subject certainly deserves, and which, moreover, in these days of scientific investigation it might reasonably have expected.

To the antiquarian and the admirer of old buildings it must be interesting to know how far the permanence of a structure is due to the massive character of its proportions, and how far to the superior quality of the mortar employed, while to the architect and the builder the subject must be of the greatest importance and of practical use.

In the former papers the writer has drawn attention to the inquiry, and in this communication desires to add the results of eight complete analyses of average specimens of the mortar authentically obtained from the buildings named in the table at the close of this article; also some illustrations showing the character and appearance of the sand employed in the mortar. The original photos were taken from microscopic slides by Mr. Albert Ashe, chief assistant to the writer, and in each case the sand was separated from the mortar by the removal of the lime and other salts with the aid of hydrochloric acid.

It should be mentioned that the analyses in the table represent, as far as possible, the average composition of the mortar, and not that of isolated pieces,—the samples analysed being prepared from the ground-up portion of a great number of small particles taken from different parts of the ruins, except in Nos. 2 and 4. In arranging the results the total amount of lime is first stated separately, and then, for convenience of reference, the proportions assumed to be present as carbonate, caustic, sulphate, and otherwise combined are added at the bottom of the table.

The largest quantity of lime (34.46 per cent.) occurs in specimen No. 6 from Glastonbury Abbey, and the smallest quantity (10.59) in No. 7 from Glendalough Church (in ruins), County Wicklow. A large proportion of lime, however, does not necessarily imply that the mortar is of the highest quality; for

Fig. 1.—Tintern Abbey.

Fig. 6.—Glastonbury Abbey.

Fig. 7.—Glendalough Church, Ireland.

Fig. 8.—Corfe Castle.

Illustrations of Sand used in Ancient Mortar.

instance, in specimen No. 2, from the leaning tower of Caerphilly Castle, Mon., there is only 13.39, yet the splendid character of the mortar is amply proved by the fact that it withstood the attempted destruction in the time of Charles II., and still remains in its leaning position.

Again, No. 4, representing the mortar used in the construction of the anicut of the Giant's Tank in Ceylon, more than 600 years ago, contains only 16.24 of lime; while in No. 1, from Tintern Abbey, on the banks of the Wye, the proportions of lime are 18.84. Both these specimens are certainly very superior in quality. Those who are acquainted with the beautiful ruins of the Abbey are aware that the four gable ends remain intact to the present day, and that this stability is not by any means due to the massive character of the walls; indeed, quite the contrary, for each gable carries a large window, so that the permanence of the gable

is due to the tenacity of the mortar in holding the fragile structure together, thus withstanding the force and action of the combined effects of wind and water for so many centuries.

On the other hand, No. 5, from Rochester Castle, represents, on the whole, an inferior mortar, though the lime amounts to as much as 28.67 per cent., while that from Corfe Castle, No. 8, with 31.05 of lime, is, on the whole, decidedly a superior mortar.

Indeed, the present appearance of these two old castles is a good indication of the quality of the mortar used in their construction.

Of Rochester Castle, practically only the keep remains, and that still stands by virtue of its massiveness rather than by any excellence of its mortar.

Of Corfe Castle, the late George Godwin, in his prize essay "On the Nature and Properties of Concrete," tells us that Smeaton visited it, and found that its solidity did not

consist in having been built with large hewn stones throughout, for the filling in of the walls consisted of rough rubble and fragments from the quarries, the interstices being entirely filled up with mortar poured in a fluid state, and the whole mass had in time become thoroughly cemented together. As a consequence, when the castle was destroyed in 1646, the walls when blown up did not fall into small pieces, but were split up into huge masses, which rolled bodily down into the moat below, where they remain still intact, the native builders finding it easier to obtain fresh stones from the nearest quarry rather than from these masses of cemented masonry.

As regards the actual proportions of lime, therefore, the requirements of good mortar would suggest that much more depends on the quality than on the quantity of the lime employed. Before passing on to other points, it may be remarked that, in all these analyses,

the proportion of caustic lime is practically unappreciable, and that most of the lime exists now as carbonate; also, that after allowing for the lime as sulphate, there still remains an excess of lime which is probably present in combination with gelatinous silica and alumina,—as existing in Portland cement.

The proportion of magnesia is very small in all these eight specimens, the amount being less than ½ per cent., except in that from Caerphilly Castle, where we find 1·87. It is interesting to hear this in mind after what has been written in reference to the presence of magnesia in some Portland cement used in the Aberdeen harbour works.

The proportions of oxide of iron and alumina are higher in the specimens of good mortar, such as Nos. 2, 6, 4, 1, and 8, than in Nos. 5 and 7, which represent the inferior quality, while No. 3 may be regarded as of medium quality, and has 1·35 oxide of iron and ·80 alumina.

Sulphuric acid is 1·37 in No. 1 and ·26 in No. 8, both specimens being regarded as of superior quality.

Chlorine varies considerably, the higher quantities being, doubtless, due to local circumstances, such as proximity to the sea or tidal rivers, but the variations are of no consequence in this particular inquiry.

The relative amount, however, of gelatinous silica soluble in a 10 per cent. solution of caustic soda is a point of considerable importance in determining the quality of a mortar. For the information of other investigators, it may be here stated that two grammes of the finely-ground mortar were first evaporated with HCl acid to complete dryness in a water bath, the insoluble residue was then treated with dilute hydrochloric acid, and the total insoluble matters filtered off, burned, and weighed. This was then hoiled for half an hour with 100cc. of a 10 per cent. solution of caustic soda, which dissolves all the gelatinous or amorphous silica, leaving the crystalline or coarser sand unaffected, and if this latter be weighed the difference between the original weight gives the amount of so-called soluble silica. It is in this form that most of the silica exists in Portland cement, the actual figures being from 20 to 22 per cent.

It will be noticed that this gelatinous silica is highest in specimen No. 2, namely, 9·85, which is very nearly half as much as occurs in the best Portland cement.

No. 8 comes next, with 7·50; then No. 4, with 7·10; and No. 1, with 6·20; also No. 6, with 6·10; afterwards No. 3, with 4·10; No. 7, with 3·90; and last, No. 5, with only 1·60 per cent.

In the analysis of limestone intended for

making lime for building purposes, it would be desirable to specially determine the amount of gelatinous silica present,—inasmuch as the best building limes no doubt possess to a considerable extent the properties of a cement.

We now come to the proportions of sand, which form the subject of the illustrations, and it will be noticed how very much they vary in quantity, in size, and general character, as observed through a microscope. No. 7 specimen contains 72·08, while No. 6 contains only 13·70.

Specimens 1 and 2 contain respectively 51·67 and 49·12; No. 4 has a little more, 55·45; while No. 5 has a little less, 45·62; then comes No. 3, with 34·78; and No. 8, with 29·51 per cent.

When we examine the size and character of the sand, the illustrations are particularly useful.

Fig. 5 is specially interesting, showing the smooth, rounded nature of the sand in the mortar from Rochester Castle; while in figs. 2 and 4 the variation in size of the particles, as well as the much sharper edges, are easily seen. In Raglan Castle, fig. 3, the granules are very small; while, in Glastonbury Abbey, fig. 6, and Glendalough Church, fig. 7, the particles are much larger, and present a more rounded appearance. The same power of magnifying was observed in all the specimens, and the sand was specially removed from the mortar without any grinding-up of the sample, in order to preserve the original appearance as far as possible.

Having now briefly reviewed the characteristics of the eight specimens, what are the practical conclusions to be drawn from these analyses?

1. That the actual amount of lime present in a mortar may vary very considerably, but that within certain limits the quality of the lime is of as great importance as the quantity,—indeed, a smaller quantity of well-prepared good lime is much more effectual than a larger quantity of a badly-prepared or naturally inferior lime.

2. That the proportions of sand may also vary considerably, even in really good mortar, and that while it is always desirable that it should be rough, irregular in size, and with sharp edges, rather than be smooth and round, still that, on the whole, the quality of the sand is not of so much importance as the quality of the lime.

3. That the presence of oxide of iron and alumina in a form readily combined with silica is not to be objected to in good building lime, indeed, that the purest limestones are by no means the best for making superior lime for building purposes.

4. That the higher the proportion of amorphous or gelatinous silica soluble in alkali, the better the quality of the mortar, and, as this kind of silica is associated originally with the lime, rather than with the sand, it becomes of the greatest importance that the character and composition of the lime intended to be used should be fully inquired into; and the best possible quality in the neighbourhood always selected by the architect and used by the builder.

JOHN HUGHES, F.C.S.

NOTES.

LARGE and influential meeting was held at Bristol on Monday last to consider the question of raising funds for the restoration of the Cathedral. The Bishop of the Diocese presided, and in the course of the proceedings a report from Mr. Pearson on the state of the Cathedral was read. Mr. Pearson reports the tower to be in a sound condition with the exception of the dilapidation of the exterior surface of the masonry, which could be refaced by taking out two or three stones at a time, retaining all the old ones that were good, except in the upper part of the tower, where the piers between the openings are so thin that it would be necessary to take this part down and rebuild it. The Lady Chapel required a considerable amount of repair, in renewal of parapets and pinnacles and repair of external walling generally, and internally the western archway into the north transept required to be opened out and restored to its original condition, with Purbeck shafts, caps, vases, &c. The floor should be taken up and a concrete bed formed under it and the old paving relaid. In regard to the re-arrangement of the choir we extract the following memoranda from Mr. Pearson's report as printed in the *Bristol Times and Mirror*—

"The choir still retains the arrangement necessitated when the nave was wanting, but which arrangement is now wholly inappropriate. Want of space led to the eastern Lady Chapel being included in the choir, with the altar-table against its eastern wall, and the stalls occupying a place so far eastward as to leave practically no space for the especial functions of a cathedral, such as ordinations and other gatherings of the clergy. The stalls themselves were enriched with the carvings of many a parish church; they were reconstructed some years ago, the old misereres and sundry other interesting fragments of ancient carving being re-used. Although it is impossible not to feel a certain amount of regret that this Cathedral should not possess more important stalls; still, as practically reproducing the ancient treatment and preserving to some extent the ancient carvings, my feeling is that they might be preserved, and take their proper place just east of the crossing. . . . It will be found necessary to remove the organ bay westward, in order to bring the organist into direct communication with the choir. As a part of this general scheme of re-arrangement, the holy table will be moved to what was obviously the position intended for it, i.e., one bay west of the Lady chapel. It should be new and much larger and more elevated than the existing altar table, which is so small and is raised so little above the general level of the cathedral that it adds no dignity to the east end. The removal of the altar table will render necessary the erection of a screen to separate it from the eastern part of the cathedral; this screen should be of sufficient height to give importance to the altar and its surroundings, and should be of stone, enriched with sculpture. The choir will need side-screens; these might be of metal, excepting those enclosing the sanctuary, which should be of stone. Sedilia and credence, also in stone, might be attached to these, with a seat for the Bishop on the north side. A western screen of open character would mark the entrance to the choir. The floor of the choir is at present on the same level as that of the nave, and the want of elevation is severely felt. I propose to raise the choir three steps at its western end, and by the addition of other steps eastward, to raise the altar three steps above the nave floor. The floor of the choir should be of marble, using up the old marble squares now in the choir. The steps, too, should be of marble. A new and sufficiently dignified Bishop's throne is especially required."

A resolution in favour of the schemes of restoration, as proposed by Mr. Pearson, was carried nearly unanimously.

THE second *soirée* of the Royal Society was held in the rooms at Burlington House on Wednesday last, the 15th inst., when the company was received by Lord and Lady Kelvin. It is generally the case that many of the exhibits at the second *soirée* have already been shown at the first, but this year there were a great number of new things, though but few were of such a character as would interest our readers. Amongst these few we may mention an instrument for drawing parabolas, exhibited by Mr. R. Inwards, which consists of a species of link-work, so contrived that a pencil attached to one part of it is always equidistant from a pivot representing the focus of the parabola, and from a steel straight edge representing its directrix. Mr. F. C. Penrose showed some water-colour drawings of Greek temples, &c., at Athens, as they appeared in 1847, illustrative of his investigations on the Orientation of ancient Greek Temples. There were eight drawings in all,—the Propylea, the Temple of Wingless Victory seen from the Propylea, the Parthenon seen from the north-west, sketch of part of the west front of the Parthenon, the east front of the Parthenon, the north portico of the Erechtheum, the Theseum,—east portico, and the Temple of Jupiter Olympus seen from the north-east. Mr. W. M. Flinders Petrie exhibited facsimile drawings from the pavement of the Palace of Chuenaten, at Tell-el-Amarna (1400 B.C.), which pavement was discovered by him during excavations last winter. It is the only one of the kind known in Egypt, and is especially remarkable for the realistic treatment of the plants depicted, not being in the conventional style familiar in ordinary Egyptian art. A number of additional proof plates to the first memoir of the Archaeological Survey of Egypt were shown by Mr. Percy E. Newberry, including drawings of the tombs of Chnemhotep I. and II., and of Ameni, unfinished lotus-hud column, &c., from Beni Hasan. We learn that four coloured "Goupi" plates will accompany each of the three volumes Mr. Newberry has in hand, in addition to the ordinary illustrations. There were a number of drawings representing wall-paintings, also from Beni Hasan tombs, which furnish us with the fullest, and by far the most curious, representations we possess of the daily life of the ancient Egyptians of the Middle Kingdom. There is hardly an incident in ordinary life that is not here delineated. Mr. W. Crookes showed an apparatus for producing the flame of burning nitrogen, proving that nitrogen is a combustible gas. There were a number of other electrical and natural history objects on view, but they were not such as to call for special comment.

AS will be seen by our report of the proceedings at the meeting of the London County Council on Tuesday, both Vauxhall and Lambeth Bridges are to be rebuilt in the course of the next few years. The former has quite outgrown its capacity to serve the traffic passing over it, especially since the new Vauxhall station of the London and South-Western Railway has been opened. Its numerous piers are also highly obstructive to the river traffic, and are not over-secure, the foundations being subject to a heavy scour at certain states of the tide. Lambeth Bridge it is proposed to rebuild first, owing to its greater insecurity. We shall not be sorry to see the last of this bridge, which is one of the ugliest on the river. That the creation of such an engineering commonplace should ever have been permitted at a spot just above the Houses of Parliament was not creditable to the authorities of that day, and we are not sorry that it has turned out to be a failure, although erected comparatively speaking only a few years ago. We trust that the London County Council will model their new bridges on such types as London Bridge and the new Putney Bridge, and not perpetrate a repetition of such architectural monstrosities as Blackfriars or (still worse) Hammersmith Bridge.

A REMARKABLE circumstance connected with the promotion of the Lancashire, Derbyshire, and East-Coast Railway, is the complete absence of anything like serious opposition to the scheme. It can hardly have been that a line upwards of 150 miles in length was looked upon as "not worth powder and shot," and if some of our existing lines had been as considerably dealt with, and had required as little ammunition of this sort, for clearing away obstacles at the preliminary stages of their existence, the shareholders would have been in a far better position than they are. Years ago it was estimated that the money wasted on the formation of railways in this country amounted to at least 12,000,000. The absence of opposition to the new line, will, it is supposed, allow of its being constructed at a total cost of about 43,000*l.* per mile,—a lower figure than that for most similar undertakings. The average for the United Kingdom is nearly 45,000*l.* per mile,—a striking contrast to the cost of colonial lines, which range from 6,868*l.* for South Australia, to 14,659*l.* for New South Wales. Of course there are certain easy sections of our own lines which were equally low; the York and Scarborough, for instance, which was constructed at a cost of 6,000*l.* per mile, and the Northampton and Peterborough branch of the London and North-Western, forty-seven miles in length, the total cost of which was 429,449*l.* The new east and west line will be more expensive from an engineering point of view, as thirteen tunnels and nine viaducts will be required. There is another east and west scheme, by-the-by, that we hear nothing about, although the connecting links have for some time been completed. There is now direct cross-country communication between the Midland main line at Bedford and their west branch at Broome (just above Evesham), over the East and West Junction lines *via* Olney, Towcester, and Stratford-on-Avon. The last section was completed a year or more since, and a regular service of goods traffic

this country. The fact of this demand being made, affords one more proof of the probable value that will attach to the new schedules of maximum rates, as compared with the antiquated jargon of the Acts which they supersede. Under the old *régime* a knowledge of the distances from station to station was of very little benefit to a trader, and very little more, perhaps, even to the railway companies' rate officials. Otherwise this information would have been pressed for and obtained long ago, but it was of no use whatever in the absence of a clearly defined classification and schedule. In the future, however, all this will be very different. There is but little doubt, judging from the remarks made at Tuesday's conference, that the railway companies will be allowed an extension of time for the publication of their new rates,—*i.e.*, from August 1 next to January 1—and it would be very convenient if the required distance tables could be compiled during the interval.

WE are very glad to see that, as reported in another column, the threatened extensive strike in the building trades of London has been averted, and that, as we ventured to hope would be the case, conciliatory councils prevailed on both sides. Let us hope that we shall go on smoothly now for some time to come.

THE various examples of wrought and other ironwork at South Kensington Museum have recently been re-arranged in an upper gallery between the two architectural courts. The fine gates from Hampton Court, and cases containing specimens of locks, keys, and bolts, chiefly foreign, are arranged down the centre, and on the balconies, and against the walls on either side, brackets, grilles, candlesticks, some domestic utensils, and one or two specimens of English ecclesiastical work. Of these latter the most interesting are the old hinges of late twelfth-

has been passing over the new route for months past, but it has not yet found a place in "Bradshaw."

A VERY sensible and practical proposal was made by Sir Alfred Hickman at the meeting at the Board of Trade on Tuesday, regarding the new railway rates. The suggestion was that the railway companies should publish, at a moderate cost, the distances between all their stations, to enable any one to calculate the legal rates between any two points without difficulty. Quite recently we noticed that the Educational Society of Bombay had just published a set of tables giving the shortest distance between any two railway-stations in India; and, upon inquiry, failed to find anything obtainable giving similar information with regard to

century work from the door which formerly led from the south transept to the slype at St. Alban's Abbey. This slype has now been removed, and we must be thankful, under the circumstances, that so interesting a relic has been preserved. There is also a portion of a hearse of fifteenth-century date from Snarford Church, Lincolnshire, and a screen of hammered iron from St. John's Church, Frome, but their proper place is distinctly in their several churches. While it is always good to see ancient work preserved in our national collection, it is still more important for objects of local interest such as these to be kept in the places to which they belong, and for which they have been designed. They are meaningless where they are, and the local interest which would otherwise surround them is gone. Amongst the other

examples of interest are two gondola prows—some good Italian grilles, several French and German candlesticks, a delicately-worked iron tripod in one of the centre cases, and another—English—dated 1662. There is also a quaint vane of German work, and two fine wrought-iron crosses. Some of the foregoing we herewith illustrate.

THE nights of June are shorter than those of any other month; and, therefore, the new departure in lighting omnibuses will not, for some months to come, be put to any severe test. If, however, the Litanode and General Electric Company and Messrs. Willing are able to accomplish the half of what they promise, their prudence in selecting the present time for their earlier installations is superfluous. We wish, and anticipate, all success to the undertaking. The problem of devising a battery of reasonable weight and low resistance, which shall not be interfered with by the jolting of an omnibus, does not seem insuperable, and Messrs. Willing and the Litanode Company appear to have solved it most successfully. A battery of five cells, weighing only 3 lbs. apiece, maintaining an e.m.f. of 10 volts for fifteen or twenty hours while a current of 1 ampere is being taken from it, is certainly something to be proud of; and the efficiency of the 5 c-p. lamp is also high, being 2 watts per candle. But even if the cell in practice is only used for twelve hours, and the lamp fall for part of that time to 4 c-p., few people will be foud to grumble, and all will be glad to get rid of the greasy, smoky oil or the flickering candle which is the rule in these not too luxurious conveyances. The first installation of the light will be with the Road Car Company's omnibuses. The L.G.O.C. will, doubtless, also take it up as soon as it has been proved a success.

ON Saturday last, the 11th inst., several members of the Junior Engineering Society availed themselves of an invitation to visit the new works of the Patent Victoria Stone Company at Stratford Market Station, E. They were conducted over the premises by Mr. Harry Rogers, the secretary and manager. The shed in which the washed, crushed granite is stored as it arrives from the Groby quarries was first visited. Near by were seen the machines designed for incorporating the crushed granite with Portland cement: the water used in the process is automatically gauged. A considerable part of the company's business consists of the manufacture of paving-stones, and this section naturally attracted the greatest share of attention. After being well mixed up, the concrete for making the stones is laid in slab moulds lined with zinc. The secretary and manager explained that the granitic concrete slabs, after setting, are turned out of the moulds, and steeped for about ten days in a solution of silicate of soda, by which process they become indurated. Considerable space is occupied by the large "silica-tanks," in which the slabs are immersed. The silicate of soda solution is made by boiling Farnham stone (quarried in beds of Upper Greensand age, at Farnham, in Surrey) with 70 per cent. caustic soda, previously made into a solution with water; the silica of the stone dissolves, and the solution is diluted for use to the required strength. The slabs when taken out of the solution are scoured with water and stacked in yards, where they are kept for some months before being sent away from the works. A large number of stair-treads, landings, and troughs were also observed in process of manufacture on Saturday; and several small tests as to the strength of the material were carried out. The visit concluded with the inspection of the cement store and engine, boiler, and solution houses, and after the usual votes of thanks, the members dispersed.

MR. C. DRURY E. FORTNUM'S second magnificent gift, this time in money as well as in kind, to Oxford University, as accepted in Convocation on the 7th instant,

The House of the Tradescant's (and afterwards of Elias Ashmole), Lambeth; as it appeared circa 1810. From the view in the "Fauvelroy" Pennant, Soane Museum.

will result in the erection of a new Ashmolean Museum, on, we presume, the ground near to the Taylor Building, and in the conversion of the existing museum into an extension, with a capacity, it is expected, of 100,000 books, of the Bodleian. The last-named was re-constructed in 1610 by Thomas Holt, of York, architect, for Sir Thomas Bodley, who further bequeathed funds for its enlargement with a third story, begun in 1613, the year of his death: the library had been founded nearly two hundred years earlier, by Humphrey, Duke of Gloucester. The Schools, built here in or about 1578, having been gradually absorbed by the library, are now replaced by the building planned and designed by Mr. T. G. Jackson, of which we published illustrations on August 9, 1890. The Ashmolean was built under, we believe, Wren's superintendence, for the Tradescant and Ashmole collections formerly housed in "Tradescant's Ark," South Lambeth, of which the site and once-famed botanical garden (four acres) were sold eleven years ago for 16,150*l.*, and converted into building lots.* Elias Ashmole's own collection consisted mainly of manuscripts and coins, but he lost part of them, together with his library of books, through a fire in the Temple, London. The contents of the Ashmolean, including the Arundel marbles, and the Etruscan antiquities presented by Chevalier Castellani, have lately been re-arranged. In 1888 Mr. Fortnum made a gift to the Museum of a considerable portion of his own collection,—gathered to exemplify the progress of art work from a remote period to the decline of the Renaissance, and stored in his residence at Stanmore. In a pamphlet published at Oxford in 1881, the late Rev. Greville J. Chester draws a heavy and detailed indictment against the University for ill treatment of the treasures in its keeping. There were grounds for his charge, albeit somewhat warmly expressed; but of late years the authorities, whose pecuniary resources in this direction are limited, have done much to dissipate the reproach. In our "Note" of October 25, 1890, upon the opening of the New Cast Museum, we referred to the signal advantages now to be enjoyed at Oxford by students of archaeology.

ON the 27th instant will be opened to the public, St. Anne's, Soho, churchyard, which is being laid out as a recreation ground by the Metropolitan Public Gardens Association, a faculty having been granted, in terms of the Open Spaces Act, by Dr. Tristram, Q.C., Chancellor of London. The church can be best seen from Wardour- and Dean-streets. It was finished in 1686, according to a stone on the west face, north side, of the tower. On the south side is Hazlitt's tombstone: he

* See also the *Builder* of January 8, 1881; and Smith's "Antiquities of London and its Environs." There is a view of the house in the "Fauvelroy" Pennant, Soane Museum.

died September 18, 1830; and, just above it, the monument, carrying an urn, that Walpole set up and inscribed in memory of Theodore, King of Corsica (and near to his grave), who died in the parish on December 11, 1756, a few days after his release from King's Bench prison. John Wright, an oilman in Compton-street, saved the King's remains from a pauper's burial. Here, too, was buried (1816) David Williams, founder of the Literary Fund that originated in a meeting, whereat Benjamin Franklin was present, of a small club at the Prince of Wales's tavern in Conduit-street, 1773. St. Anne's parish had been taken out of St. Martin's in 1678. Standing in what had been Kemp's-field, the church has a good interior and a fine east window. The original spire, shown in B. Cole's plate for Maitland's "History of London," 1756, consisted of a cupola carrying an octagonal lantern, with a heavy finial over it, and was removed in June, 1800. The present spire is surmounted with a singular spherical-shaped dial-piece. S. P. Cockerell, architect, rebuilt the tower about ninety years ago, in terms of an Act to that intent, of May 28, 1802. Malcolm, in vol. ii. of his "Londinium Redivivum," 1803, refers to the "monstrous copper globe;" in the "Dictionary of National Biography," the "ugly tower" is ascribed to Henry Hakewill, but is not cited under his name in the "Dictionary of Architecture." We read in Mackeson's "Guide" that Wren completed the church, which has been lately restored by Sir A. W. Blomfield. William Croft was the first organist; the later organ, by John Gray the elder, was rebuilt by Walker about twenty-five years since. In Dean-street, the home of Mrs. Thrale (Pozzi) when, as a girl, she came to the town, was "Jack's" coffee-house, since "Walker's" hotel. At the dispersal on April 19, 1888, of the late George Godwin's collection of historical chairs, with other relics, was bought, for two guineas and a half, "Dr. Johnson's banner-screen, from Jack's coffee-house, Dean-street, Soho."

WE learn that Mr. W. M. Flinders Petrie will most probably be appointed to the Chair of Egyptology recently founded by the late Miss Amelia B. Edwards, in University College. The foundation states that no official in the British Museum, and no one over forty years of age, shall be eligible for the post.

THE fourth part of Mr. Gotch's series of illustrations of "Architecture of the Renaissance in England"* is just issued, and includes illustrations and description of Cranborne Manor House, Canons Ashby, and other old places of much interest. As we have before said, we propose to consider the work more in detail when all the six parts have appeared.

* B. T. Batsford.

At the Fine Art Society's Gallery is to be seen Mr. Wyllie's large and very fine and interesting painting of the battle of Trafalgar, the most important work which this fine painter of marine subjects has produced. Near the centre of the picture the *Victory* is prominent, with the French ship *Redoubtable* locked to her by an entanglement in the rigging. Other historical ships are shown in the picture, which has been carefully studied from available records. The day was a sunny day with little wind, but a long heavy swell on the water, one can almost see the roll of the ships on it; the sea was even more finely given perhaps, in a small painting, perhaps a study for this, which the artist exhibited, if we remember right, at the Royal Academy a year or two ago. This painting of a great event in modern English history is well worth a visit. It is a curious coincidence that the room in which it is exhibited formed part of a house in which Nelson once lived. At the same galleries are also to be seen a collection of water-colour drawings of "Devonshire" by Mr. Henry B. Wimbush, a little too much of the "pretty vignette" order, but interesting nevertheless; and a small collection of "Early English Water-Colour Drawings," including examples of Barret, Morland, Gainsborough, Reynolds, F. Wheatley, Hamilton, Cipriani, and others. Among them is an interesting drawing by Kneller, on brown paper, the lights touched with white, called a portrait group, and showing Kneller's method of making studies for his pictures.

THE collection of small paintings of Venice by Mr. Mortimer Menpes, at Messrs. Dowdeswell's gallery, is perhaps the best thing this artist has done. The small studies of bits of Venetian architecture are painted with great force and truth of colour, and the larger view of the façade of St. Mark's under late afternoon light is a remarkably real and forcible piece of architectural painting. Among the small works specially noticeable are "A Vista" (7); "Santa Maria, della Salute" (16); "A Family Wash" (25), the white clothes hung out to dry contrasting with the sunlit walls behind; and "Humble Quarters" (28), the lower portion of an old crumbly marble palace.

THE Ameer of Bokhara is to be added, apparently, to the list of energetic sanitary reformers. He has ordered a cleansing of the city, described by the *Times*' correspondent as a nursery of disease and infection; and on hearing that there was a revolt against this order on the part of the dis-loving inhabitants, "His Highness at once commanded the execution of every subject who did not carry out the new sanitary regulations within a week." We ought to have the Ameer of Bokhara to deal with the landlords of insanitary property in London.

ARCHITECTURE AT THE ROYAL ACADEMY.—VIII.

(CONCLUDING NOTICE.)

1,817; "Pewsham House, Wilts;" Mr. C. E. Ponting. This drawing is published in the present number. It appears a very pleasing reminiscence of the style of the seventeenth century English country house, to which has been added the formal garden proper to the period, but not with entire copyism of old details. In the period to which the architecture of the house belongs, the garden would have been bordered by alternately clipped pyramids and little shock-headed round bushes; the less formally trimmed trees and the alternate vases are an improvement on this.

1,818; "Baroda Museum: Pavilion;" Mr. E. F. Chisholm. One of Mr. Chisholm's applications of the Hindin style to modern Indian buildings, of which some others have been seen in the Academy in former years. This is a brown shaded pen elevation with a central pavilion, or rather double pavilion with a recessed entrance between, with slender pillars and brackets in the form common in Indian architecture; an external stair in three flights leads

up to the entrance. The side portions are kept much lower, with an open arcade with segmental arches on brackets in the ground story, a frieze of figures and elephants above that, and a very high roof with two stories of dormers. Small pavilions form a stop to each end. It is an architectural which, being flat and destitute of mouldings, must depend very much on colour for its effect, which is not of course shown in this drawing, but the adaptation of the architectural style of the country to buildings erected there by English architects, though there may be a difference of opinion about it, is at all events an experiment of interest. It is contrary, of course, to the general precedent of history, which for the most part shows us the conquering nation imposing their own style of architecture on the conquered. As, however, we have no style to impose, there is the less to be said about that.

1,823; "Design for Bucharest Houses of Parliament;" Messrs. Williams, West, & Slade. A tinted elevation (no plan) in a rather French style of Renaissance with a large pavilion in the centre and a smaller one at each end, all covered by high domical roofs. Pilasters or engaged columns are run through both stories with a rather too perpendicular effect; the ground story has pedimented windows placed in the middle of each compartment or wall, with no architectural connexion, the upper storey large semi-circular headed windows, giving the impression that this is the principal storey. The authors may be credited with spirit in going so far afield in a competition, though we cannot think Bucharest has lost seriously by not having the building carried out.

1,824; "Proposed Gallery for British Art;" Mr. Sidney R. T. Smith. We have already illustrated the design for this. The architecture of the building, like that of the last-named, does not rise above the merest Classic respectability, and we may point out that the rather common-looking lean-to roofs of the loggie between the centre and the wings go far to deprive the façade of the one good quality, dignity, which it might otherwise boast.

1,826; "All Saints' Church, Penarth, Glamorgan;" Messrs. Seddon & Carter. Three cleanly-executed pen-drawings of a church in Early Gothic style, which is to be praised for the simple and unpretending character of its architecture, but we cannot like the effect of a row of small gables over the aisle, at right-angles with the centre roof of the nave. It is in contradiction to the spirit of three-aisled design, and has (we know not why) a kind of Dissenting-chapel look; not that we profess any sectarian prejudices, but Dissenting Gothic as a rule is not the best modern Gothic. The west end is the best part of the building.

1,827; "Design for a Timber Spire;" Mr. W. Percival. We believe we remember this drawing as one of a set which either earned the prize or a good place in one of the Institute Grissel medal competitions. It is a clever and picturesque piece of design, but perhaps has, for a timber spire, a little too much the aspect of masonry details slightly modified for wooden treatment, rather than of forms or treatment originally suggested by wood.

1,828; "Ferguslie Park, Paisley;" Mr. Hippolyte T. Blanc. A rather curious house, it seems a mixture of "Scottish baronial" with more English types; corbelled out turrets and corbie-step gables, combined with respectable-looking bay windows and a conservatory with Classic pilasters. It is not otherwise than effective, but the circular turrets seem intrusions and have not much meaning. No plan is given. The drawing is one in Mr. Raffles Davison's most "linear" style—rather too much so in this instance.

1,829; "Design for a Frieze;" Mr. A. Gwatkin. A holiday-designed scroll on a red ground, in which, as in other instances, the author has hit very happily the mean between realism and a too formal convention. The thin lines along the centres of the large leaves serve to define the scroll line well, and the edges of the serrated leaves are allowed a little freedom.

1,832; "Design for East Window, St. Margaret's Church, Lowestoft;" Mr. E. Frampton. A design for a Perpendicular five-light window of some originality. Two circles are formed in the centre, extending over the width of three lights, by rows of chern heads, the upper of which forms a framework for a figure of Christ; at the foot of the centre light is a figure of St. Michael weighing souls (we have before referred to this as a Medieval superstition quite out of place in

a modern window); in the side lights are groups of kneeling figures directed towards the centre of the window; the small upper lights of the tracery are treated as niches for small figures of saints. The drawing and colour are good, though the effect of the drawing is a little hard as a representation of stained glass.

1,836; "Temple of Mithras; the Vestibule;" Mr. W. Stirling. This is an interesting bit of imaginative work, an interior in pencil, belonging to no special style, showing a round-arched arcade on a pier surrounded by four small columns of a kind of quasi-Classical type, but with symbolic capitals of no recognised type; around the walls are has-reliefs, connected by a sculptured serpent which waves along the wall, and twists its neck into a circle in the foreground in which stands a female figure in alto-relief. On a little altar-like stand in the foreground four figures of boys support a fourfold candle-bearer with a symbol in the shape of an egg in the middle. This drawing looks as if it were a result of Mr. Lethaby's book on "Architecture, Mysticism, and Myth." It is a very original hit of work, only we cannot help thinking the door into the *penetrabilia* should have had more importance and a more mystic look about it; the conception rather breaks down at that point.

1,837; "Interior View of a Hall;" by the same artist as the last-named, also a pencil interior, with a plan, apparently a small hit of executed work. It shows part of a hall with a solidly-built fireplace and angle-nook, and part of a timber gallery over, of which the balustrade is decorated with delicate and prettily-designed floral ornament, apparently on successive squares of stamped leather tacked on. The author has a style of his own in handling the pencil.

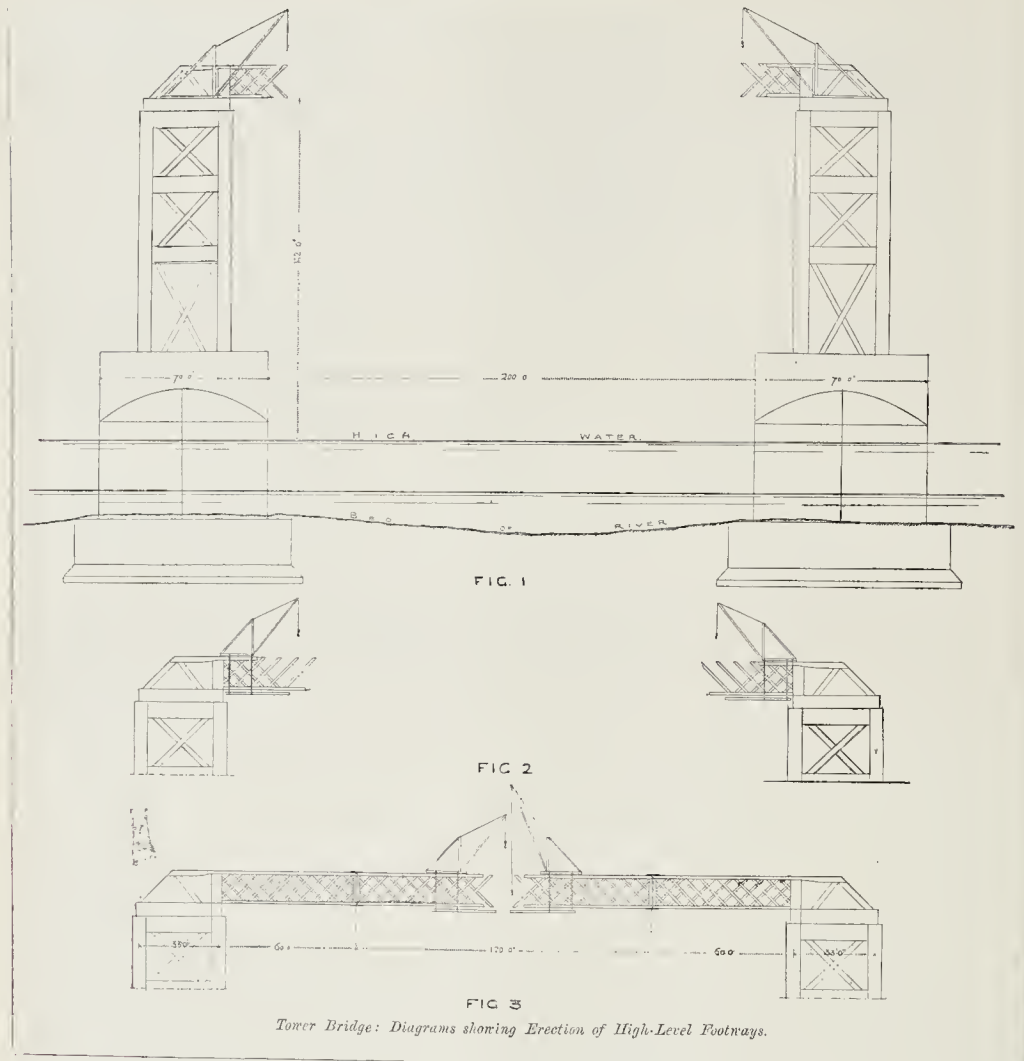

1,839; "Reredos, All Saints, Richards Castle;" Mr. R. Norman Shaw. There is not much architectural design in this, the interest of which consists chiefly in the paintings of saints on the reredos and the inner sides of the open doors: the paintings are divided by bars with a simple Medieval incised ornament. A wall diaper of Medieval design occupies the space below the doors, which appears too large in scale for the situation, and rather clashes with the scale of details and figures in the reredos.

1,840; "Selby Abbey Yorkshire; Restoration of Old Glass of great East Window, according to the original design;" Messrs. Ward & Hughes. The design of the glass of this great seven-light traceried window, as restored here, has a grand effect; it shows a series of small richly-coloured figures, imbedded in rich decoration, one above the other up each light; the design fills up the space well and produces a very fine total effect; according to a memorandum on the drawing the existing portions of old glass are distinguished by a red line, but the drawing is too minute, being a good deal above the eye, for this to be made out. At the base of the window a large-scale figure reclines, extending across the three centre lights.

1,843; "Design for West Window, Jesse Haworth Memorial Church, Walsbam;" Mr. William Pape. The general design only can be made out; the figure groups, which extend in hands across the window, seem not sufficiently supported by the lighter colour and detail above and below them. The design of the window itself is not very satisfactory; it looks like two three-light windows with tracery heads, divided by a single lancet-shaped compartment.

1,844; "Ambo, San Cesareo, Rome;" Mr. J. C. Horsley. This is the drawing published in the present number; a pencil drawing, with slight tinting to show the colouring of the inlaid marbles, red in the pilpit panels and green in lower ones; the panels of the pilasters are very delicately inlaid with coloured mosaic. The bold character of the twisted shafts in the pulpit is remarkable. The drawing is an admirable one, complete in effect, though not slightly executed.

1,847; "Mosaic Pavement at Murano;" Mr. A. C. Blomfield. A careful coloured drawing of a curious hit of pavement showing Byzantine influence; it is in two halves, and represents on one side what may be called we suppose a cockatrice, a half bird half best creature, on the other side two more harmless-looking birds drinking out of a vase. The birds and other parts of the design are outlined in black tessera, and coloured with yellow, two tones of red, &c. It is a curious and interesting piece of work.

Tower Bridge: Diagrams showing Erection of High-Level Footways.

1,848; "Kirklevington Grange, Yorkshire: additions;" Mr. E. J. May. A small plan shows the extent of the additions (Mr. May is one of the architects who never forgets the plan), which practically make a new entrance-front to the house, a long centre block with a projecting porch and room over, and return wings with large shallow bay windows carried through two stories and crowned with a balcony with small console-like brackets at the angles of the balustrade, which give a little special character. The work is in general a reproduction of the English seventeenth-century domestic style now so much in vogue, save that the windows are treated and spaced unsymmetrically on the central portion of the front. There is a restful feeling about this kind of house architecture, though there is rather a look of pretended archaism about it, which is increased by the architect's style of drawing, which is original and entirely his own, but gives a somewhat aged and time-worn look to the building in the illustration, which the actual structure would probably not bear out.

1,849. "Design for Stained Glass; Angels Appearing to the Shepherds;" Mr. A. L. Duthie. There is a refreshing originality about this hit of design for stained glass, in which we seem to get clear of the element of the "shop" which is too apparent in much stained glass work of the day, including a good deal of what is exhibited (in drawings) at the Academy.

The design is divided into two groups, the Angels above and Shepherds below, separated by conventional clouds forming a concave curve bending upwards towards the sides of the window. In both groups there is the same motif of action spreading, as it were, from the centre to the sides, the shepherd group starting apart from the centre, the lines of the angel figures taking the same general arrangement. The angel figures are designed with great boldness and freedom, in a manner quite distinct from the usual stiff and formal stained-glass angel (who seems kept in stock and cut out when wanted), and the colour effect is fine and unusual; the design is quite out of the conventional track.

In reference to the subject of stained glass we may observe that when our Royal Academy has come to recognise that there are other forms of art besides painting and sculpture, one of its efforts should be to endeavour to provide the means of exhibiting a certain quantity of actual stained glass by transmitted light, so as to represent the real work of the stained glass artist instead of a mere drawing of it on a small scale. There will have to be great changes at the Royal Academy, no doubt, before such a thing will be considered possible or come sooner or later, if the Academy is to keep its place as a true Academy of Arts, in the eyes of a generation becoming gradually more enlightened as to what Art means.

THE TOWER BRIDGE:

METHOD OF ERECTION OF THE HIGH-LEVEL FOOTWAYS.

THE great progress that has been made during recent years in bridge-building, is chiefly due to the introduction of mild steel, and to the adoption of the cantilever system of construction. In America and other countries where bridges have often to span wide and deep rivers, the cantilever system is very extensively used, but the bridges that are required in England are seldom of sufficient magnitude to render this form of design necessary. Occasions, however, sometimes occur, where it is most desirable to follow this principle, and few better examples of its application could be found than the high level footways of the Tower Bridge.

These footways had to be erected over the busiest part of the Thames, and the river authorities would not, of course, allow any staging being put up that would interfere with the shipping interests, even if it had been desirable for the building of the bridge. No experienced engineer would, however, consider staging necessary for such a purpose, because by designing these footways on the cantilever principle it would be almost as easy to build them out horizontally without any external support, as to erect them on the ground in the contractors' yard.

The clear span to be bridged over was only

about 240 ft., but the difficulties of construction were somewhat increased by the work having to be built at a height of nearly 150 ft. above high water, and immediately over a part of the river always crowded with vessels. The way in which the cantilevers were built out from their supports on either side of the river, and the central girders erected between them, was briefly as follows. After the steel columns on each of the large masonry piers were completed, cranes were placed on the top of them by which the first portions of the footways could be put into position (fig. 1). When this part of the work was finished and securely anchored down at the shore end, a travelling-stage, carrying a small hand crane, was placed on the overhanging portion (fig. 2). The lower part of this stage projected forward to form a platform upon which men could stand to bolt up the steelwork as it was put into place, piece by piece, by the crane above them.

The second length of the cantilevers being completed, the travelling stage, with its crane, was drawn forward ready to build another length in front of it. In this manner the cantilevers were soon entirely erected, and projected 60 ft. beyond the columns on each side of the river, and were ready for the end portions of the central girders to be attached to them. These girders, which are 120 ft. long, are suspended to the ends of the cantilevers by steel links, but during erection their top and bottom booms had to be temporarily connected to those of the cantilevers to allow them being built by the overhang method previously adopted. Before this could be done careful measurements had to be taken across the river, because the central girders, having been entirely finished by Messrs. Wm. Arrol & Co., the contractors, in their works at Glasgow, there was no place where any adjustment in the lengths could be made, and it was therefore necessary that the ends of the girders should be placed exactly in their right positions, to ensure the two halves just meeting.

The distance between the ends of the cantilevers having been ascertained, the central girders were commenced on both sides of the river, the first portions being fixed in such a position that when each half was completed they would just touch, if the temperature was such as might be expected, in the middle of the day on which it was thought everything would be ready to make the final connexion.

When these temporary connexions were all made, the erection of the girders was proceeded with, and when completed, the two halves were found to be about $\frac{1}{2}$ in. apart at a temperature of 60 deg. Fahr., and so nearly opposite to each other both in elevation and plan that no difficulty was experienced in connecting them together on the first occasion when the weather became a little warmer. As quickly as possible after the booms had been bolted together the temporary plates which were connecting the ends of the girders and cantilevers were removed, and the central spans were then supported only by the suspension links at their ends, and free to expand or contract according to the variations of the temperature.

The total weight of steelwork in the footways is about 600 tons, and from the above description it will be seen that this was built and finished without any staging whatever being required to support it during the process of erection.

THE EXETER DIOCESAN ARCHITECTURAL AND ARCHÆOLOGICAL SOCIETY held its annual meeting on the 10th inst., at the College Hall, South-street. The chair was occupied by Canon Edmonds, and afterwards by the Rev. W. T. A. Radford. A paper was read on Domes, by Mr. E. Ashworth, commencing with that of the Pantheon, the work of Agrippa, so indefatigable a builder in the Augustan age of Rome. Other early domes were considered, and the progress of the cupola-covered churches of Byzantium under Justinian described, culminating in the Church of St. Sophia in the sixth century, which has been imitated in numerous mosques that adorn Constantinople. The introducing of Byzantine work into Italy, in St. Mark's Venice, and St. Antonio, Padua, and its appearance in the South of France, were illustrated. The domes reared by the Mogul Emperors in India as mausolea were next exhibited. The officers were elected, and a concluding part to Vol. V., Second Series, of the "Transactions," was issued.

THE ARCHITECTURAL ASSOCIATION'S VISIT TO HARROW.

THE first of the summer visits was made on Saturday, June 11, to Harrow-on-the-Hill, where Mr. Owen Fleming had arranged for the members to visit several of the school buildings as well as two private houses.

Assembling at 3 o'clock in the well-known churchyard, commanding perhaps the most extensive and beautiful views in Middlesex, a short visit was paid to the parish church. Unfortunately the vicar was prevented from meeting the party,—as he had intended,—so that no description or history of the church was forthcoming, but several items of interest were soon noted by the members. There is a good twelfth-century font, it is circular, with characteristic Norman decoration on the bowl, which is supported on a short base, having a shallow spiral decoration. The whole is of Parbeck marble, and in wonderfully good preservation.

Both the north and south doorways are examples of the Early Decorated period, with good labels and arch mouldings. That on the north still retains an original door with an oak lock of Brobdingnagian proportions.

The flat roof is an example of fifteenth-century work, having good detail in many parts, while a good effect is obtained by placing canopied figures under each truss against the walls. Unfortunately this roof has been somewhat lavishly varnished, with a result that can hardly be considered satisfactory.

On one of the nave piers is an original memorial brass to the founder of Harrow School, commencing thus:—

HEARE LYETH BURYED THE BODYE OF JOHN LYON LATE OF PRESTON IN THIS FISH YEOMAN DECEASED THE 11TH (sic) DAY OF OCTOBER 1522 WHO HATH FOUNDED A FREE GRAMMAR SCHOOL IN THIS FISH TO HAVE CONTINUANCE FOR EVER. * * *

On the wall of the south aisle are hung two brasses of sixteenth-century date. The mode of hanging them framed in oak suggested that they were "Palmbeests," and an examination of the backs proved this to be the case, as they were evidently both part of a much larger, earlier brass of rich workmanship and design, as portions of a border with small figures under canopies were easily recognisable.

The western tower shows signs of early work, the outlines of two round arches now blocked up, but visible internally, being apparently very Early Norman work, if not earlier. Externally, there are remains of a Norman doorway with zig-zag mouldings.

The clearstory windows are being gradually filled with stained glass, the subjects being chosen to illustrate events connected with the history of the parish. The first of these windows commemorates the restoration of church lands to Harrow, A.D. 825.

On leaving the church, a short visit was paid to the old schoolroom, which is now used for prayers only, and although Harrovians may consider it convenient enough for this purpose, the low, narrow, and worn seats (they cannot be termed benches) would probably be regarded with contempt by any modern School Board child. The wood panelling is carved all over with names of "Old Boys," in the traditional style, and the name of Byron, under the window, to the right of the headmaster's seat, is pointed out to visitors. The library, by the late Sir G. Gilbert Scott, was next visited. Externally it has plenty of colour, obtained by the use of variously coloured bricks and stone, and although, on close inspection, some of the detail is not quite in accordance with modern ideas, yet, seen from below, with its background of thick foliage, it groups well with its surroundings.

Crossing the road, a few minutes were spent in the speech-room, erected from designs by the late William Burgess. It is to be regretted that it is still unfinished, and also lacks the colour decoration, which it was presumably intended should be added, which gives the cast-iron columns and bare wooden vaulting a rather cold expression. Few of those who enter this building are aware that it contains an organ. The organist's seat and key-boards are below the front of the platform, but the instrument itself is placed along the straight wall, being principally below the level of the platform, along the back of which a plain wooden panelling extends, which hides all indications of its existence. Possibly the architect considered that the recognition of an

organ in the design would give to music undue predominance. If, however, music was not recognised in the speech-room, Harrow now possesses a building devoted entirely thereto in the new music school, designed by Mr. E. S. Prior. This building contains a lecture-room, surrounded by corridors, off which are placed the practising-rooms. These are all provided with double doors, double windows, and separated from each other by hollow walls. In the corridors are lockers for music and racks for violin-cases. Under the platform of the lecture-room a hand-room is provided. The rooms are warmed by hot water, and ample provision made for ventilation by means of flues, which, with the double doors and windows, is absolutely necessary.

On the hill above the Music School is the Museum and class-rooms in connexion with it, erected to commemorate the Headmastership of Dr. Butler. The building was designed by Mr. Basil Champneys, and is of red brick, with ornamental features and carving executed in bright "rubbers," which soft material has, unfortunately, already suffered at the hands of its constant frequenters, who could not resist the temptation when such an easily "worked" material was placed ready to hand.

An external staircase is carried from the ground level to the top story, and forms a pleasing feature in the design, being enclosed by an arcade carried by short carved brick columns. On the top floor the museum consists of two top-lighted saloons, side by side. The collections are not fully arranged yet, but an interesting feature is the collection of Egyptian and Grecian antiquities from the collection of Sir Gardner Wilkinson. A portrait of Dr. Butler, by Prof. Herkomer, hangs in one of the galleries. There are three floors below the museum, on each of which are two class-rooms fitted with modern desks and other appliances, and a waiting-hall, intended for the boys before the arrival of the Master. This, the custodian seemed to think, quite superfluous.

Opposite to this building, and near the speech-room, a house, by Mr. T. G. Jackson, was noticed.

Having completed the visits to buildings in connexion with the school, the party proceeded to a house designed by Mr. Prior for Dr. Stevens. There was an old house standing further back from the road; this was pulled down and the old bricks used for the facing of the new house, being, however, relieved by terra-cotta of a pinkish tint, which is used for window-dressings, cornices, balusters, &c. Internally, the house is conveniently arranged; the entrance-hall is a few steps lower than the principal floor, thus admitting of a consulting-room being placed so as to be easily accessible from the entrance, yet quite distinct from the family rooms.

Another example of Mr. Prior's work completed the programme. This consisted of a billiard-room recently added to a house on the Mount Park Estate, which, by the kindness of Mrs. Cator, the members were permitted to see. The room is a large one, and is end-lighted by two large windows in deep recesses at each end of the table. In addition to these there is a central glass dome internally, although externally only a steep tiled roof with the upper part glazed is the only indication of a top light.

The room is really more than a billiard-room, being devoted as well to the exhibition of a fine collection of Japanese and Oriental curios as well as to a collection of stuffed birds, &c., for which deep cabinets with glazed fronts have been arranged in each corner of the room. This being the last place to be visited, the party then broke up.

The next visit is announced for the 25th inst. It will be a whole-day visit to Canterbury.

WESLEYAN CHAPEL, CUDWORTH.—The Wesleyan Memorial Chapel was opened at Cudworth a few days since. The chapel, which is in the Renaissance style, is 39 ft. long and 35 ft. wide inside and capable of accommodating 200 persons on the ground floor. Preparation is made so that a gallery can be erected over the front vestibule; also an orchestra behind the rostrum at any future time. There are ministers' vestry, class-room, &c., provided at the rear of the building. The roof of the chapel, which is partly open-timbered, is of stained and varnished pine, the remaining inside woodwork is of pitch-pine varnished. Fresh air is admitted through inlet shafts, and the foul air carried away through an extract ventilator fixed on the roof. The work has been executed from the designs of Mr. Charles T. Taylor, architect, of Oldham.

DISCOVERY OF AN EARLY CHRISTIAN BASILICA AT SILCHESTER.

As we mentioned in a note last week, a highly interesting discovery has been made on the site of the Roman city of Silchester, in Hampshire, the excavation of which has this year been resumed. By the kind permission of Mr. St. John Hope we are enabled to give a plan of the foundations of the early basilica which has been found on the same *insula* as, and south-east of, the Forum—nearly in the centre of the city. Its apse or chancel faces west, and is flanked on either side by rudimentary transepts. Narrow aisles flank the centre portion of the church, and across its east end runs a narthex. The whole building is on a small scale, the total length being but 42 ft., outside measurement. The width of the nave is 10 ft., the aisles 5 ft., and the narthex 6 ft. 9 in. The whole of the centre portion of the church has been paved with inch-square red tile tesserae. In front of the apse is a square of finer mosaic, 5 ft. square, in black and white checks, with a border of coloured lozenges. There are some remains of paving in red tesserae in the northern end of the narthex. About 11 ft. east of the church is a foundation of the base of a fountain, in connexion with which the pit on its western side, lined with flints, was probably used. This discovery of what is generally supposed to be the earliest example we have of a Christian church in Britain will increase the interest already taken in the excavations at Silchester. Some notes on the results of previous excavations will be found in the *Builder*, January 10, 1891, and January 16, 1892.

THE ROYAL INSTITUTE OF BRITISH ARCHITECTS:

ELECTION OF COUNCIL.

At the business meeting of this Institute, held on Monday evening last, Mr. J. Macvicar Anderson, President, in the chair, numerous donations to the library and collection were announced.

The President, having read the report of the scrutineers appointed by the annual general meeting to direct the election of the Council for the year of office 1892-93, announced that the Council, consisting of thirty-six members, for the official year, and the auditors for the official year, were duly elected as follows:—

President.—Mr. John Macvicar Anderson [unopposed].

Vice-Presidents.—Professor George Aitchison, A.R.A., Mr. James Brooks, Mr. Henry Curry, and Mr. Campbell Douglas (Glasgow) [unopposed].

Hon. Secretary.—Mr. Aston Webb [unopposed].

Members of Council.—Messrs. Thomas Edward Colloutt, Ernest George, Arthur Cates, John Slater, B.A. Lond., William Emerson, Alexander Graham, F.S.A., Richard Phené Spiers, F.S.A., Thomas Blashill, Wyatt Papworth, John Alfred Gotch, F.S.A. (Kettering), Henry Louis Florence, John Belcher, Richard Herbert Carpenter, F.S.A., John Holden (Manchester), Lacy William Ridge, John McKean Brydon, Edward Augustus Graving, and Octavins Hansard.

Associate Members of Council.—Messrs. Paul

Waterhouse, M.A. Oxon., and Thomas Miller Rickman, F.S.A.

Presidents of Allied Societies.—Messrs. Thomas Harnett Harrison (Liverpool Society), William Hale (Birmingham Association), William Leiper, A.R.S.A. (Glasgow Institute); George Bertram Balmer (Leeds and Yorkshire Society), Charles John Innocent (Sheffield Society), Thomas Drew, R.H.A. (Royal Institute of Ireland); Robert Evans (Nottingham Society), Henry Crisp (Bristol Society), and Edward Salomons (Manchester Society).

Representative of the Architectural Association (London).—Mr. Herbert Osborn Cresswell.

Auditors.—Messrs. Lewis Angell, M.Inst.C.E., and William Woodward.

The result of the election of Standing Committees was next declared.

Fifteen Fellows, thirty-four Associates, and three Hon. Corr. Members were elected, and the meeting afterwards proceeded to discuss the question of the method of electing Fellows.

The meeting terminated at 11 p.m. with the announcement that the sixteenth and final meeting of the session will be held on Monday, June 27, when the Royal Gold Medal for Architecture will be presented to M. César Daly, Hon. Corr. Member.

THE INSTITUTION OF CIVIL ENGINEERS: ANNUAL REPORT.

THE annual general meeting of this Institution was held on May 31, Mr. H. Hayer (Vice-President) being in the chair, in the absence, from indisposition, of Mr. Berkeley, President.

The Report of the Council for the Session 1891-92 commenced by stating that the objects of the Institution were so widely known, had been so frequently referred to, and appeared to be so largely appreciated, that they might be passed over without comment. The constitution had remained unchanged since December 2, 1878, when the class of Associates was divided into two groups,—one being civil engineers, to whom corporate privileges were granted, and who were distinguished by the title "Associate Members," the other being non-corporate Associates, described as "persons able, from their connexion with science or the arts, or otherwise, to advance professional knowledge."

The Council had carefully guarded the admission of new members to every class, and the qualifications of all candidates had been subjected to rigid scrutiny. It was believed that a strict inquiry into each candidate's career was better than any system of examination. Members were again urged not to attach their names to the recommendation of any one for election or for transfer, unless thoroughly satisfied that the candidate was in all respects, professionally and socially, eligible. With regard to the changes in the roll of the Institution, it was stated that fifty-nine Associate Members had been transferred to the class of Member, and that there had been elected three Honorary Members, twenty-eight Associates, 321 Associate Members, and seven Associates, while four Associate Members had been restored to the register. These additions together amounted to 366. After deducting 145 names from deaths, resignations, and erasures there was an increase of 221, bringing

up the total number on the register to 5,371, as against 5,150 at the corresponding date last year.

This enumeration was irrespective of the Students, of whom 200 had been admitted during the year, as against 166 for the previous twelve months; but during this period 106 Students had become Associate Members, and 140 had disappeared from the list, so that the number now on the books was only 568, whereas last year the number was 914. Thus, including Students, the total number on the books was now 6,239, as against 6,064 twelve months ago.

During the financial year ending March 31, 1892, the receipts amounted to—Income, 20,070*l.* 17*s.* 3*d.*; Capital, 5,186*l.* 7*s.*; and Trust-Funds, 930*l.* 19*s.* 8*d.*, making a total of 26,188*l.* 3*s.* 11*d.*, as compared with 24,274*l.* 8*s.* 11*d.* for the previous twelve months. The disbursements were—General expenditure, 15,038*l.* 14*s.* 6*d.*; capital, 7,497*l.* 5*s.* 3*d.*; and trust-funds, 821*l.* 1*s.* 5*d.*; together, 23,357*l.* 1*s.* 2*d.* Capital expenditure extraordinary amounted to 1,612*l.* 13*s.* 9*d.*, mainly for the purchase of the lease of No. 27, Great George-street, against which there was a set-off for rents of 251*l.* 5*s.*, whilst there had been transferred from the current receipts 1,361*l.* 8*s.* 9*d.* to effect a balance. The purchase of the lease of No. 27, Great George-street was deemed advisable, having regard to the question of re-building, still under consideration. The capital receipts included a bequest of 500*l.*, free of legacy-duty, under the will of Sir John Hawkshaw, which, although unconditional, had been added to Capital. These several receipts had been invested in Dehture Stocks of British railway companies, of the nominal or par value of 7,000*l.* The balances to the credit of the Institution at the beginning and at the end of the financial year were respectively 6,755*l.* 2*s.* 8*d.* and 8,224*l.* 16*s.* 8*d.*

Allegation had been made on several occasions to the fact that, as the corporation included all classes of civil engineers, it must be expected that the "Minutes of Proceedings" would be gradually modified and developed, so as to meet the wants of its more diversified membership.

Having regard to these considerations, it would be found that, in Constructive Engineering, five papers have been read. Two of these,—"The Bishop Rock Lighthouses," by Mr. W. T. Douglass, and "The Illumination by Gas of Tory Island Lighthouse," by Mr. D. C. Salmon, referred to sea-coast works of supreme importance to every maritime nation. The three communications on "Portland Cement" and "Portland Cement Concrete," by Messrs. Bamber, Carey, and Smith, related to a material fast becoming indispensable to the constructive engineer. Two papers directly connected with Municipal Engineering were submitted for discussion, namely,—on "The Sale of Water by Meter in Berlin," by Mr. Henry Gill, and on "The Sewage-Farms of Berlin," by Mr. H. Alfred Roehling. Both bore witness to the advanced condition of sanitary matters in the capital of the German Empire.

The elaborate paper by Mr. Alex. R. Binne "On Mean or Average Annual Rainfall," must also be classed with this branch of engineering, as referring to one of the data upon which the Waterworks Engineer based his calculations. Mining and Metallurgical Engineering were represented by the paper on "Gold-Quartz Reduction," by Mr. A. H. Curtis. As the modern processes of ore-reduction were accomplished by the aid of machinery, the efficient conduct of the operations was directly dependent upon the engineer. In regard to Mechanical Engineering, the memoir on "Weighing-Machines," by Mr. Wilfrid Airy, opened up entirely new ground, while that on "Petroleum Engines," by Professor W. C. Unwin, was mainly an exhaustive study of a particular machine. Electrical Engineering was represented by a paper on "Electrical Measuring-Instruments," by Mr. James Swinburne. Finally, reference was made to some questions of importance belonging primarily to the domain of physics, and which required to be attentively studied by engineers; especially was this the case in respect to the operations connected with the Measurement of Light and of Heat, dealt with in the papers by Mr. A. P. Trotter, on "The Distribution and Measurement of Illumination," and Professor W. C. Roberts-Austen, on "The Measurement of High Temperatures."

To the Authors of some of the above communications the Council had had pleasure in

making the following awards:—A George Stephenson Medal and a Telford Premium to Mr. Alex. R. Binnie; Telford Medals and Telford Premiums to Mr. A. P. Trotter and Mr. W. T. Douglass; and Telford Premiums to Messrs. H. Alfred Roehling, A. H. Curtis, W. Airy, H. Gill, and Professor W. C. Roberts-Austen.

Among the papers which had been deemed suitable for printing without being discussed, those of Mr. F. Fox, on "The Hawarden Bridge," and Mr. Alfred W. Szlumper, on "The Widening and Improvement Works of the London and South-Western Railway," belonging strictly to Constructive Engineering; closely related were "The Building-Stones of Great Britain, their Crushing Strength and other properties," by Professor T. H. Beare, "Stresses and Deflections in Braced Girders," by Mr. A. D. Stewart; and "Practical Astronomy as applied to Land Surveying," by Mr. R. H. B. Downes. The description of "The Nagpur Waterworks Extension," by Mr. E. Penny, and of "The Southampton Waterworks," by Mr. W. Matthews, affected the municipal engineer, while Mechanical and Electrical Engineering were respectively dealt with in the papers by Professor W. C. Unwin, on "The Transmission and Distribution of Power from Central Stations by Compressed Air," and Dr. C. B. Shubiner, on "The Florence and Fiesole Electric Railway."

In respect of these communications, Telford medals and Telford premiums had been adjudged to Messrs. F. Fox and Alfred W. Szlumper, and Telford premiums to Messrs. Shubiner, T. H. Beare, W. C. Unwin, E. Penny, A. D. Stewart, R. H. B. Downes, and W. Matthews.

The Howard Quinquennial Prize had been awarded to Sir Isaac Lowthian Bell, Bart., F.R.S., M.Inst.C.E., for his treatise on "The Principles involved in the Manufacture of Iron and Steel."

The papers read at Supplemental Meetings of Students had shown in nearly every case evidence of having been prepared with care. Three, at least, were of high merit, and, with four others above the average, had been deemed worthy of publication, either in whole or in part, in the "Minutes of Proceedings." For the seven papers above referred to, the Council had had satisfaction in awarding,—the Miller Scholarship to Mr. H. B. Ransom, for his paper on "Fly-wheels and Governors," and Miller prizes to Mr. C. H. Worthingham, E. L. Hill, D. Carnege, G. H. Sheffield, J. E. Ball, R. J. Darley.

Understanding that there was a dearth of professional men in the Engineer Volunteer Corps, the Council expressed the hope that young civil engineers, whose education rendered them peculiarly fitted to fill the vacancies and to be of service to their country, would come forward in larger numbers than appeared to be the case at present, so as to prepare themselves by the necessary military training to give their aid in any National emergency.

The Report having, after discussion, been adopted, cordial votes of thanks were passed to the President, to the Vice-Presidents, to the Members of Council, to the Auditors, and to the Secretaries and Staff.

The scrutineers, to whom a vote of thanks was passed by acclamation, announced that the following gentlemen had been duly elected to serve on the Council for the ensuing year:—

President: Mr. Harrison Hayter.
Vice-Presidents: Mr. Alfred Giles, M.P., Sir Robert Rawlinson, K.C.B., Sir Benjamin Baker, K.C.M.G., LL.D., F.R.S., and Sir Jas. N. Douglass, F.R.S.

Other Members of Council: W. Anderson, D.C.L., F.R.S., J. Wolfe Barry, Alex. R. Binnie, E. A. Cowper, Sir Douglas Fox, J. C. Hawkshaw, M.A., Charles Hawksley, Sir Bradford Leslie, K.C.I.E., George Fosbery Lyster, James Mansergh, Sir Guildford L. Molesworth, K.C.I.E., W. H. Preece, F.R.S., Sir Edward J. Reed, K.C.B., F.R.S., M.P., William Shelford, and Francis W. Webb.

THE ENGLISH IRON TRADE.—There is little alteration to note in the English iron market. In Cleveland the works are slowly being started; there are now six furnaces in blast out of the eighty stopped for want of coke. Prices are easier. In manufactured iron there is still little doing; but in tin plates a fair amount of business is reported. Steel is in sluggish demand; but the prospects of new work are rather more encouraging. Ship-builders continue quiet, and engineers are only moderately employed. The coal trade remains fairly active.—Iron.

THE LONDON COUNTY COUNCIL.

The London County Council resumed its weekly meetings, after the Whitsuntide holidays, on Tuesday afternoon last, when the Chairman, Lord Rosebery, presided.

A Vacant Seat.—The Chairman announced that he had received a formal communication from the Clerk stating that the bankruptcy of Mr. Ernest Bowen Rowlands, one of the members for Central Finsbury, had been officially notified in the *Gazette*. It was therefore necessary to fill up within fourteen days the vacancy thus caused.

The Opening of Brockwell Park.—The Chairman referred to the sad death of Mr. Bristowe, M.P., on the occasion of the opening of Brockwell Park (as mentioned by us in a "Note" last week), and it was resolved unanimously to authorise the Chairman to communicate to the family of Mr. Bristowe the profound regret of the Council at the untimely death of that gentleman.

A Paucity of Tenders.—The third item on the agenda was thus stated: "To receive tenders for the erection of a school building at Crossness" (for the children of the workmen employed at the Southern Outfall Sewage Works), but the Chairman announced that only one tender had been received. Under the circumstances he thought it would not be advisable to open that tender, but that the whole matter should be referred to the Main Drainage Committee for reconsideration. This suggestion was agreed to, it being understood that the Committee were not to open the solitary tender sent in.

The Proposed Alterations at Shoreditch Town Hall.—One of the paragraphs of the Finance Committee's report was as follows:—

"The Vestry of Shoreditch recently applied to the Council for sanction to their borrowing 5,500*l.* for the purpose of carrying out certain additions and alterations to their Town Hall required by the Theatres Committee of the Council to comply with the regulations as to places used for music and dancing. It was pointed out to the Vestry by the solicitor that the Council could only sanction the cost of such additions to the offices of the Vestry as were required to meet the reasonable office necessities of the Vestry when acting under the Metropolitan Management Acts, and that the proposed expenditure did not appear to be within this limitation. The Vestry have since withdrawn the application. It occurs to us, however, that there may be cases in which it might be desirable to have the powers of vestries and district boards under the Metropolitan Management Acts enlarged, so that should occasion arise they may be able to build halls which could be used for meetings of the ratepayers for public and other purposes in which the inhabitants of the locality take an interest. We therefore recommend:—

"That it be referred to the Local Government and Taxation Committee to consider and report whether it is desirable that Parliament should be asked to amend the Metropolitan Management Acts, so as to permit Vestry and District Boards, where desirable and requisite, to provide for the erection of large halls for places of public meeting and other public purposes of the ratepayers and inhabitants of the district."

On the motion of Mr. Moss, it was resolved to add, at the end of the recommendation, the following words, viz., "and for the maintenance and alteration of such halls." The recommendation, as thus amended, was agreed to.

Decision to Purchase Hackney Marsh.—The Parks and Open Spaces Committee brought up a report in which they set out at length their report of November last,* recommending that the Council should offer 50,000*l.* for Hackney Marsh, including common, manorial, and other rights. That offer, it was now reported by the Committee, was declined by the vendors, but negotiations had since been entered into with the local bodies, and as the result, the lord, the commoners, and other owners of rights, who had combined for the purposes of selling the marsh, were now prepared to accept 75,000*l.*, which sum could be raised as follows:—The Council, 50,000*l.*; the Hackney District Board, 15,000*l.*; contribution by the lord of the manor, 5,000*l.*; and local and other contributions to be obtained, 5,000*l.*; making a total of 75,000*l.* "The question of the acquirement of Hackney Marsh," added the Committee, "is one for all London, and not for the East-end only, as, apart from the local use which can be made of it for games, it forms a splendid open space at the eastern boundary of the county." They accordingly recommended—

"That, subject to a supplementary estimate of 10,000*l.* being submitted to the Council by the Finance Com-

mittee, as required by the statute, and subject to the Hackney District Board entering into an agreement to contribute 15,000*l.*, and to the lord of the manor contributing 5,000*l.*, and to 5,000*l.* being raised from other sources, the Council do purchase Hackney Marsh for the sum of 75,000*l.*, such sum to include the rights of the commoners, the lord of the manor, and other owners, the Council's contribution of 50,000*l.*, being contingent on the necessary statutory authority being obtained."

After the discussion of an amendment (moved by Mr. Lloyd), to refer the whole matter back to the Committee with a view of obtaining further information, but which was rejected by a large majority, the recommendation was agreed to.

Recreation Ground at Fulham.—A further report of the Parks and Open Spaces Committee contained the following paragraph and recommendation:—

"The Council will remember that it agreed to contribute 2,625*l.* to the cost of purchasing ten acres of land for a recreation-ground at the corner of Crown-lane and Fulham-palace-road, such contribution being contingent on the Vestry of Fulham laying it out within twelve months from the date of the Council's vote. It was represented to us, however, some weeks ago, that the Vestry only obtained possession of the ground on March 8 last, and on that plea they asked for an extension of time for six months, which the Council on our recommendation granted on April 12 of the present year, attaching the condition, however, that no gravel should be removed from, nor dustbin or other offensive refuse deposited on, the ground. On visiting the place on May 18 last, we found that a quantity of gravel had been removed and sold, and that some very offensive material had been deposited in the hole whence the gravel had been taken. We at once communicated with the Vestry, to the effect that they were not complying with the terms of the Council's resolution granting conditionally an extension of time for the laying out, and received in reply an assurance that the sale of the gravel and the deposits of foul matter should be stopped. Provided that this promise is adhered to, we recommend:—

"That the Council do grant an extension of time to the extent of twelve months from March 8 last, to the Vestry of Fulham, to lay out the recreation-ground at the corner of Crown-road and Fulham Palace-road, on condition that no earth, gravel, or sand be removed from the land, and no dustbin or other offensive refuse deposited thereon."

Mr. Fred Henderson moved, as an amendment, that the matter be referred back, he and other speakers animadverting in strong terms on the way in which the Vestry had broken faith with the Council. After some further discussion, however, Mr. Henderson withdrew this amendment, and seconded the following, moved by Mr. Costelloe:—

"That the consideration of the recommendation be deferred, and that the Committee be instructed to require from the Vestry of Fulham an explanation of the removal of the gravel in breach of the agreement on account of its value, and to satisfy the Medical Officer of the Council as to the condition of the matter used to fill in."

This amendment was agreed to almost unanimously.

Proposed Re-building of Vauxhall and Lambeth Bridges.—The Report of the Bridges Committee contained the following paragraphs and recommendations:—

Vauxhall Bridge.—The question of the rebuilding of this bridge is engaging our attention, and the information that has been laid before us points to the fact that the bridge must be rebuilt. The bridge now requires to be repaired, the carriage-way being in a very unsatisfactory state. We have, therefore, had an estimate prepared showing what the cost of the works will be, pending the rebuilding of the bridge five years hence. The estimate reaches a sum of 2,400*l.*, which includes an amount for repaving the roadway with wood. We therefore recommend—

"That, subject to an estimate being submitted to the Council by the Finance Committee, as required by the statute, a sum of 2,400*l.* be expended for keeping Vauxhall Bridge in repair during a period of five years."

Lambeth Bridge.—The condition of this bridge is such that the Council will have to obtain powers in the next session of Parliament to rebuild it. The rebuilding will, it is estimated, occupy a period of two years, but it is necessary for the bridge to be repaired before the works are commenced. The works which now must be carried out are repairing the carriage-way and re-putting and painting the straws of the cables, which will cost about 170*l.* We recommend—

"That, subject to an estimate being submitted to the Council by the Finance Committee, as required by the statute, Lambeth Bridge be repaired, at a cost of about 170*l.*"

After some discussion, in the course of which exception was taken to the proposed paving of Vauxhall Bridge with wood, the gradients being so steep, both recommendations were referred back, and after transacting some other business, the Council adjourned.

* Printed in extenso in the *Builder* for November 21, 1891, p. 389.

Illustrations.

CENTRAL TOWER, IMPERIAL INSTITUTE.

THIS is the drawing of the tower exhibited at the Royal Academy, except that the sky has been re-sketched by the architect, as that in the original drawing failed to reproduce sufficiently in lithographing. The tower is now being erected, but as it is impossible to build more than about 2 ft. in one week, it will be some months before it is entirely finished.

The framework is in Portland stone, with occasional hands of red brick; the roof will be covered with copper. Besides a large tank to serve the fire hydrants, there will be a peal of ten or twelve bells.

The contractors are Messrs. Wowlm & Co., and the architect Mr. T. E. Colcutt.

DESIGN FOR A FRIEZE.

THE motive of this design by Mr. Arthur Gwatkin is the yellow horned poppy, and the foliage is evolved from its leaf forms.

The statement on the margin of the print, that it is in the Royal Academy Exhibition, is however only what ought to be the case and not the actual fact. The Royal Academy contains a drawing by Mr. Gwatkin entitled "Design for a Frieze," of the same shape and the same type of design as this one, and as we knew that this one was sent to the Academy, and had no occasion to examine the drawing at the Academy minutely till this week, we naturally concluded that this was the drawing. Mr. Gwatkin drew our attention to the mistake too late to alter the printing on the lithograph. Why we say that the statement "ought" to have been true is that this is a better and more elaborated design than the one hung at the Academy, and that they should have rejected the best design and hung the one which is certainly of less merit and interest, is only another of the eccentricities of hanging at the Architectural Room.

WALL DECORATION, CHAPEL OF ST. JAMES, SAN MINIATO.

THIS is from a drawing by Mr. G. C. Horsley. The lower part of the decoration is of marble, comprising a throue and panelling. The subject of the Annunciation is painted on canvas, and the picture is surrounded by a small gilt moulding; the trees and sky are painted in fresco on the wall.

PULPIT, SAN CESAREO, ROME.

THE pulpit is one of the most beautiful of the works of the "Cosmati" school remaining in Rome. It is of marble, carved, and inlaid with glass mosaic. The large disc of marble on the wall of the stair is of porphyry. The illustration is from a drawing by Mr. G. C. Horsley which is exhibited at the Royal Academy.

PEWESHAM HOUSE, WILTS.

THIS house is now in course of erection in one of the prettiest parts of Wiltshire. Externally it is faced with Cattybrook bricks, with Ham Hill stone dressings, and the roof covered with Raabon tiles.

The internal fittings are mainly of deal, the most notable exception being the principal staircase, which will be oak. The arrangements include a large top-lighted billiard-room on the first floor. The principal rooms on the ground level have their floors laid with wood blocks.

Stabling is about to be commenced. The work is being carried out by Messrs. Light & Smith, of Chippenham, from the designs and under the superintendence of Mr. C. E. Ponting, F.S.A., Marlborough.

The drawing is exhibited at the Royal Academy.

PRESENTATION FOUNTAIN FOR AYR.—On the 11th inst. the fountain presented to the town of Ayr by Mr. Steven, of Skeldon (of Steven Bros. & Co., architectural ironfounders, London and Glasgow), was formally handed over to the Town Council by that gentleman.

COMPETITIONS.

INFECTIOUS DISEASES HOSPITAL FOR WEST FIFE.—At a meeting at Dunfermline, on the 11th inst., of a joint committee appointed by the burgh and county local authorities, it was resolved to adopt the plans of Messrs. Charles S. Johnston and David B. Burnie, architects, Edinburgh, for an infectious diseases hospital for the district. There were seventeen designs sent in. The hospital is to be built on a site acquired from the Earl of Elgin at Milnesmark, and is, with furniture, to cost nearly £6,000.

COTTAGE HOSPITAL, GALASHIELS.—Some time ago, says the *Scottishman*, a scheme was set on foot for providing a Cottage Hospital for Galashiels and neighbourhood, for the treatment of patients suffering from non-contagious diseases. The Committee obtained plans and estimates, which were submitted to a meeting of the subscribers held on the 11th inst. in the Burgh Court-room. The Committee had selected, on the recommendation of Mr. Blane, architect, Edinburgh, the plan by Mr. Wallace, architect, Edinburgh, which will give accommodation for fourteen beds, with all the other accessories for an hospital such as that required for Galashiels. The estimated contract cost was £2,600 for building, without the fittings and furniture. It was agreed to proceed with the undertaking at once, on the plans selected, with such modifications as might be desirable.

THE ROYAL COMMISSION ON METROPOLITAN WATER SUPPLY.

WE continue our report* of the evidence tendered before this Commission.

The Kent Company.

This Company's statement began by citing the letters patent granted, in 1701, by William III., to certain persons, conferring on them for five hundred years the exclusive privilege of breaking up the streets in certain manors to lay water-pipes. The monopolists constructed the Ravensbourne Waterworks, which were in operation till 1808. Next year the Company was incorporated, and acquired the patent for £5,000. The manors included Greenwich, Deptford, and adjoining districts, which have now a population of 165,000. From time to time the limits of supply have been extended, till they embrace an area of 178 square miles, of which thirty are in the county of London and the remainder in Kent. About 1885 the available flow of the Ravensbourne proved insufficient. Then were sunk deep wells which yielded abundant supplies of good water. The river was superseded, and the district wholly supplied from the chalk wells in 1862. The supply, obtained from deep wells and borings in the chalk, is fed by rain falling on the North Downs, and on the chalk district lying between them and the river Thames. The mass of the chalk, which is from 500 ft. to 600 ft. thick, forms an immense underground reservoir, the overflow from which breaks out in numerous springs along the valleys of the Ravensbourne, the Cray, and the Darent, whilst many springs flow directly into the lower Thames at Erith, Northfleet, and elsewhere, where the river flows across the chalk formation. The chalk and other permeable strata which drain into it form a large catchment area, of which it is estimated that at least 110 square miles contribute to the supply in this Company's district. The rainfall on this area varies from 24 in. per annum in the Thames Valley to 36 in. on the North Downs, which rise to an elevation of from 700 ft. to 800 ft. above sea level. The heavy rainfall on the hills of the chalk escarpment may be assumed to give a percolation of 10 in. instead of 6 in., and this would give a daily discharge of 44,000,000 gallons. Beyond the chalk downs, there is a considerable area of lower greensand in the neighbourhood of Westerham, and this town is supplied from a well in that formation. The water from the greensand is excellent, and has been sought for in vain, and at great expense, by deep borings under London. This Company might obtain a large quantity either by borings through the gault or by wells in the out crop. Paragraphs on these supplies are quoted from the reports of former Commissions. That of 1869 said that this reservoir in the chalk did not feed the Lea or the Thames above Hampton, and that it would probably yield 30,000,000 gallons a day; that the water from the greensand was

soft and good, but there were then no means of estimating its quantity; and that the chalk wells might be increased in Kent without interfering with the springs in the valleys above London. The Company are assured that they can obtain from the old chalk area, from the new chalk area, and from the lower greensand 53,000,000 gallons daily. Large quantities escape into the Thames from the chalk, the Thanet sand, and porous Woolwich and Reading beds along a line from Deptford, past Erith and Northfleet to Cliff, and it has been estimated by Mr. Barlow and Mr. Anstead that 60,000,000 gallons a day from the chalk could be obtained by an intercepting tunnel along this line. The following are the Company's pumping stations and wells in use, their estimated daily yield in gallons, and the capacity of the pumping machinery (excluding the well at Westerham and a bore-hole in the chalk at Dartford available for use in those districts):—

	Yield.	Pumping power.
Deptford (3)	8,000,000	12,000,000
Crayford (3)	3,500,000	5,000,000
Shortlands (2)	2,250,000	2,250,000
Orpington (2)	2,500,000	3,750,000
Wilmington (1)	4,000,000	4,000,000
Plumstead (1)	800,000	1,200,000
Totals	21,050,000	28,200,000

Average daily supply for 1891	13,534,000
Maximum (January 28, 1891)	17,000,000
Number of houses and other supplies, 1891	76,754
Average population, in gallons	22½
Number of supplies under constant service (38 per cent.)	44,270
Company's area in square miles	179

Testimonies to the chemical superiority of the chalk water are quoted from the Chemical Commission of 1851, the Rivers' Pollution Commission, Professor Frankland, and Dr. Albert Bernays. The latter said he would recommend the adoption of any chemical process for the softening of the water. The Company's limits not being coterminous with registration districts, and many houses in rural districts not being supplied by the Company, an exact calculation of population to supplies is hardly possible. Tables show that since 1850 the average daily supply has doubled in seven, thirteen, and twenty years. The present supply may, perhaps, be doubled in thirty-six years. By 1912 another 6,500,000 gallons may be needed to make the total 20,000,000 gallons daily. Taking increase of supplies as a guide, and allowing 30 gallons a head, 6,000,000 gallons more would be required in twenty years. Add 6,000,000 gallons for a margin between average and maximum, and a possible maximum of 26,000,000 is reached. The present yield is 21,000,000 gallons, and by additional pumping machinery and mains, 8,000,000 gallons more could be provided without resort to other known and accessible sources. With improved fittings the supply per head could be reduced from 30 gallons to 28. The Company therefore claim to be able to provide abundance of water of the highest quality for the population in its district for many years to come, and, if necessity should arise, it could tap water-bearing strata estimated to yield from 50,000,000 to 60,000,000 gallons a day.

Mr. Alexander Dickson, the Secretary of the Company, called the attention of the Commissioners to the Company's monopoly in the supply of a portion of its district. After a long examination as to the method of arriving at the population, the number of houses or supplies, and the average supply per head per day, he expressed the opinion that with proper fittings and proper control, such as was exercised in Manchester and Liverpool, the average per head could be greatly reduced. Of the 30 gallons, 24 gallons were estimated to be for domestic use and six for trade, and, comparing these with several provincial returns, there seemed to be a very large margin for saving. The witness gave the maximum supplies (asked for in each case by the Chairman) for a week, a month and three months. The three months covered the drought of 1877, and the highest point reached was 16,180,000. The highest week and month were in the period. The prolonged frost of 1890-91 produced the highest day, the 28th of January, when the supply reached 17,000,000 gallons, the week averaged over 16,000,000 gallons; and the month nearly 15,500,000 gallons. The ratio of increase of supply was less now than it was five or ten years ago. A difficulty in basing estimates for

the future upon the past arose from the frequent enlargement of the Company's district, and this involved detailed explanations. Constant supply was being extended slowly, because difficulty was found in getting fittings altered, and the Company desired to avoid what had had to be done at Liverpool and Croydon,—turning off the water to avoid the waste. They thought steady advance was the best in the public interests; and, as far as it had gone, constant supply had resulted in a saving in some districts. The greatest difficulty occurred in times of prolonged drought and prolonged frost, when the public ran away with the supply and it passed beyond control. Cases of deliberate waste were very numerous, such as keeping open the valve of a closet, and there had been several prosecutions and convictions. Asked as to Dr. Bernays' discouragement of softening by chemical process, and Dr. Frankland's description of a method of doing it, the witness said the Company had met with no evidence to prove that water so softened was improved for domestic or dietic purposes.

Mr. Wm. Morris, Engineer to the Company, was pressed on the point whether the Company could, by any means get daily the estimated 44,000,000 gallons out of the chalk, and he said "possibly not the whole, but three parts of it." No doubt that would have a very considerable effect in diminishing the flow of the springs that feed the Ravensbourne, the Cray, and the Darent. No experiments had been made to determine what could be got out of the green-sand. The wells at Deptford were within 200 yards of each other, and pumping from one affected the level in the others, but not largely. No complaints had been received by the Company except with regard to shallow wells supplying houses in the immediate vicinity. Mr. Barlow's estimate of 60,000,000 gallons was given in evidence before the Commission of 1869. The storage capacity of covered service reservoirs was 10,500,000 gallons. A storage reservoir for 3,000,000 gallons had just been completed at Eltham, so that the aggregate was about a day's supply. At Deptford, working two wells continuously night and day, they had got 8,000,000 gallons a day. The witness was asked by the Chairman to supply the greatest quantities taken out of the wells consecutively in three months, six months, and a year. It was at the instance of this Company that the Lambeth Company was restrained in its Act of 1883 from sinking a well "in any part of the water lands" of the Kent Company. "Were you apprehensive that they might take water from you?" "Well, we have a very good supply, and we thought others might like to have as good."

This week the Commissioners have met twice. The greater part of Monday's sitting was devoted to an examination of Mr. A. R. Binnie, C.E., Chief Engineer to the London County Council; but the examination was confined to the statistical question of the relation between supply or consumption and population, in the past, the present, and the future. Tuesday was occupied with the evidence of the Secretary, the Engineer, and the Consulting Chemist of the Thames Conservancy; and the witnesses gave a good deal of definite information as to the relation between the Conservancy and the companies, the amounts of water that may be taken by them, and the measures adopted to prevent the pollution of the Thames and its tributaries.

Consumption and Population.

On Monday, Mr. W. B. Bryan, of the East London Company, was recalled, and handed in a statement of the water supplied for trade and non-domestic purposes, and it amounted to 21.06 per cent. of the total supply. He produced also a table showing for four parishes, wholly supplied by the Company, the number of "supplies" and the number of houses, according to the census of 1891. These are the figures:—

	"Supplies."	Houses.
London district:—		
Bethnal-green ...	19,141	17,109
Poplar.....	8,962	10,173
Country district:—		
Leyton	11,596	10,714
Walthamstow ...	8,799	7,977

He also furnished a table of the rainfall at six points for the years 1875 to 1891. In connexion with this table, he said the rainfall was not always followed by a corresponding discharge at Fildes' Weir, because much depended upon the time of the year when the rain came.

If much rain was to come now, with all the grass in the valley very long, it would scarcely reach the river at all. If the rain came in the early spring it would make a very considerable difference in the amount flowing over Fildes' Weir. Referring to the table of supplies and houses, Dr. Ogle stated that the census returns of houses were not yet published, and the number of houses at Poplar, instead of being 10,173, was 7,404. The Chairman wanted to know what allowance ought to be made for uninhabited houses, and the witness suggested that the Commission should wait until the census returns are published. Dr. Ogle stated that the population of Bethnal-green and Poplar was 185,515, which, divided by the number of supplies, gave 8.6 as the number of persons per supply. The population of Leyton and Walthamstow was 90,252, which, divided by the supplies, gave 4.4. It had been previously stated that the number of county supplies was 68,310, and of London supplies 104,000. Multiplying the latter by 6.6, and the former by 4.4, and adding the results together, Dr. Ogle arrived at a population for the whole district of 989,696, and the witness said, "That is evidently wrong." Dr. Ogle continued that the average daily supply in 1891 was 40,282,200 gallons, which, divided by the population, gave 40.7 gallons per head per day. The witness said that Poplar and Bethnal-green were not to be compared with White-chapel and St. George's-in-the-East, and therefore Bethnal Green and Poplar are not fair representatives of the urban parishes. After further conversation between Dr. Ogle and the witness, the Chairman said, "It is quite clear that this will require a great deal of investigation before we can usefully go on discussing the result. We must endeavour to get it as accurately as we possibly can in the face of the undoubted difficulties which exist." The witness offered, if time were allowed, to have every supply in the district counted,—that is, the number of persons for each ascertained,—and he said it would take a month or six weeks to do it. After consultation, the Chairman said the Commission thanked the witness for the offer, but would not accept it at present, but they must find some method of getting more accurate information on this important point of the number of supplies in a given district, and the number of people in the same district. They would take a little time to consider how it could best be done, and then probably ask the companies for definite information on a uniform basis.

Mr. A. R. Binnie, Chief Engineer of the London County Council, was then examined at great length in reference to a voluminous statistical compilation, occupying, with explanations, some eighty printed foolscap pages. He dealt with "Municipal London,"—the County Council area; "Greater London,"—that of the Metropolitan Police, 701 square miles; "Water London,"—the area supplied by the Water Companies, 514 square miles; "Registration London," practically Municipal London, without Penze. Municipal London was the "Inner Ring," the "Outer Ring" was that larger area which the Census returns called "Greater London,"—the police district. He had endeavoured to obtain accurate information as to population and the supply per head, and asked the Companies for data for 1861 and 1871, believing at the time that the data for 1881 and 1891 were in the official reports of the Companies. But now he doubted it. He found the same difficulty the Commission was finding in unravelling this question. He could not reconcile the populations with the number of houses supplied, and both with the quantity of water said to be supplied by the Companies. On the assumed accuracy of the populations of the Companies' areas, he had worked out calculations which he afterwards abandoned; and he embodied tables which reduced an assumed basis to an absurdity. To take an example from one table. In 1891, 182,456,905 gallons were supplied by the Companies. At 30 gallons per head per day 8,081,896 persons were supplied. It was clear that that population did not exist in Greater London, or any other district supplied by the Companies. At 32½ gallons per head, the population would be 5,614,059; but that was an impossible population, because Greater London contained only 5,635,000. At 35 gallons per head, we get a population of 5,213,054,—more likely to be correct. The fact that the Companies' districts and the registration districts

are not co-extensive, makes it difficult, if not impossible, to get anything but an estimate.

The Chairman remarked that from the average daily consumption for 1891 of 182,456,905 gallons, there would have to be some deduction made, in order to allow for slip in the valves, and short stroke in the pumps. Witness: There should not be.

Why not?

Because we have had for years past the statements made by water companies that they supplied so much as a total quantity of water, and I say, as an engineer, that they must have known that these quantities were either correct or incorrect. No engineer could make such a mistake as that.

Then the figures supplied to us were in the first instance, as we understand, without any such reductions?

Some of them, I am told, were so. The Chairman said that the East London claimed a reduction of 10 per cent., the Grand Junction, 7½, and one or two other companies, 5. The witness: The reduction is perfectly correct, and every engineer would make it. The only complaint I have to make is that all the returns that have been made to the water examiner have been hitherto false statements, and knowingly false statements.

The Chairman said he would prefer "incorrect statements," but the witness said "No engineer would return the quantity of water pumped without deducting the slip, which he must know. No pump discharges the theoretical quantity of water."

The Chairman consulted with the other Commissioners and said there might be some misunderstanding about this, and they wished to avoid any allegations of wilful misstatement.

The witness rejoined that he could not but remark on statistics on which he had had to base his calculations up to the period of the inquiry. Then followed a minute description and comparison of tables, without which the evidence would be unintelligible. Starting from a present population of 5,185,000 in Water London, the witness estimated that in 1941 the population would be 12,373,243, and that the consumption, at 35 gallons per head per day, would be 433,063,505 gallons. In Bradford he had been totally unable to reduce the amount per head per day to much below 35 gallons for strictly domestic purposes. The rates per head per day were much higher in some of the chief cities of France, Germany, and America. In Dublin it was 47, Glasgow 50, and Edinburgh 40. London was far behind in the appliances for the public distribution of water for ornamental, sanitary, and cleansing purposes, and compared with Paris it was deplorably in the background. Paris used about 18 gallons per head per day for public purposes,—twenty times as much as London. But for the fact that 35 gallons appears to be the present actual rate of consumption, he would have preferred to base his estimates on a total consumption of 40 gallons per head per day. In conclusion, the witness asserted that the West Middlesex and Chelsea Companies were precluded by statute from taking more than 20,000,000 gallons a day from the Thames.

The Conservators of the Thames.

The first witness for the conservancy was Mr. James H. Gough, secretary, and he was examined upon a carefully-prepared narrative which he explained and amplified by many details. The historical portion explains the successive relations of the Companies to the Corporation, and then to the Conservancy, and the present relation may be summed up in the following table:—

	A.	B.	C.
Southwark and Vauxhall...	£3,000	20 + 4½	
Lambeth	3,000	20 + 4½	
Grand Junction	3,000	20 + 4½	
West Middlesex	3,000	20 + (4½)	
Chelsea	2,500	20 + (2)	
East London	2,000	10	

The first column, A., gives the annual contributions of the Companies to the conservancy. The second column, B., in millions of gallons, the water that may be taken from the Thames under the 1852 agreement with the Corporation; and in the case of the East London, under the Act of 1867.

The third column, C., the extra quantities

under the Act of 1867.

which may be taken under the 1886 agreement with the Conservancy (the legality of which Mr. Binnie questions as to the West Middlesex and the Chelsea).

The following are the principal passages in the statement of Mr. Gough, which constituted the framework of his evidence:—

The condition of the works on the Thames above Staines, when handed to the Conservators, was so bad, and their reconstruction so costly, that the water income of 12,000*l.* was insufficient. A debt of 100,000*l.* had been incurred for the purpose of the works. After some negotiation the Companies consented to pay in the aggregate a further sum of 4,500*l.* One of the terms of the arrangement of 1886 was that the Conservators should enter into agreements with the five Companies, allowing them to draw 20,000,000 gallons daily in excess of the 100,000,000 permitted by the agreements of 1852, such additional quantity to be divided as in the table, or, in the aggregate, 120,000,000 gallons, which, with the 10,000,000 gallons allowed to the East London Company, makes a maximum draught from the river by these Companies of 130,000,000 gallons daily. The first payments under the agreements of 1886 became due in January, 1888, and, immediately after, the auditor appointed by the Local Government Board to examine the Water Companies' accounts raised a question as to the legality of the payments by the Chelsea Company and the West Middlesex Company. Sir Henry James was appointed to arbitrate, and he decided in favour of the legality of the agreements. Whilst the decision of the Arbitrator has set at rest the question of the legality of the agreements, it is worth notice that the two Companies in question have not reached the quantity of 20,000,000 gallons daily provided for in the original agreements, nor are they likely to do so for some considerable time. It has been found by gaugings taken at Teddington Weir that only in a few and most exceptional cases in the driest seasons known has the discharge at Teddington Weir fallen below 200,000,000 gallons in one day, and that after the abstraction of the water companies' supply. Even in these cases no detriment to the navigation or the amenities of the river has been experienced as a consequence of the abstraction of the water, which in dry seasons is at its maximum, exceeding, as it has done, 100,000,000 gallons in a day, and the Conservators are advised that no such detriment would ensue if the quantity abstracted were, even at those exceptional times, increased to the maximum of 130,000,000 gallons. In addition to the six Metropolitan Water Companies there are a few Local Authorities and Companies who are enabled by statute to draw water from the river; these are:—The Oxford Corporation, for the supply of the City of Oxford; the South-West Suburban Water Company; the West Surrey Water Company. In all these bodies are enabled to draw the following maxima supplies from the river:—

	Gallons.
Oxford Corporation	5,500,000
West Surrey Water Company ..	3,000,000
South-West Suburban Water Company	1,000,000
Total	9,500,000

And the grand total of water which by statute or under the agreements can be taken from the Thames is:—

	Gallons.
Metropolitan Companies	130,000,000
Other Authorities and Companies	9,500,000
Total	139,500,000

in respect of which the Conservators receive at the present time the sum of 18,115*l.* per annum.

The Conservators are of opinion that under existing circumstances this maximum quantity should not be exceeded. It has not escaped the Conservators' attention that the average daily supply of one Company to its consumers (the Southwark and Vauxhall Water Company), as reported by the Water Examiner of the Metropolis, has recently often exceeded the maximum of 24,500,000 gallons allowed to be taken from the river. The Conservators have called upon the Company for explanations, and are assured that the excess, if any, is taken from sources other than the Thames, and that the quantity taken from the river

has not reached the authorised maximum. The subject is continuing to receive the close attention of the Conservators. They desire to express their agreement with the views stated by the Committee of 1867 on the East London Water Bill, and by the Royal Commission of 1869, that it is quite possible to provide for a greatly enlarged demand by the storage of flood waters in reservoirs in the valley of the Upper Thames. They are prepared to adduce evidence on this point. In the year 1867 a Committee of the House of Commons on the East London Water Company's Bill reported that "if at any future period the increase of population should render it necessary to make provision for a greater supply of water than could be conveniently drawn from the Thames in a dry season, it could be adequately made by storing up in reservoirs in the valley of the Thames a portion of the flood water which now yields in a single day a sufficient supply for the whole year." The Royal Commission on Water Supply, 1867, 1868, and 1869, which was presided over by the Duke of Richmond, reported that when efficient measures were adopted for excluding the sewage and other pollutions from the Thames, and for ensuring perfect filtration, water taken from that source would be perfectly wholesome and of suitable quality for the supply of the Metropolis. The sixth report of the Rivers Pollution Commission, dated June 30, 1874, took a radically different view of the subject, and reported that the Thames should as early as possible be abandoned as a source of water for domestic supply, basing their opinion on the grounds that the Thames received the sewage of a large number of towns and other inhabited places, as well as pollution of other kinds. All opinions agree on one point, and that is, the necessity for the exclusion of pollution from the Thames; and the Conservators feel that they are able to show by facts that that exclusion is now accomplished, and that, whilst twenty years ago there was possibly room for a divergence of opinion on the subject, no such reason now exists. At first, after the passing of the Acts against pollution, difficulties in deciding between competing schemes, in raising the necessary funds, and in selecting suitable sites, confronted the Local Authorities in all parts of the river, and caused delays; but since 1874, difficulties have diminished, works by degrees have been completed, and year by year the Conservators have found the river improving in purity. Every town on the main river has taken steps to prevent the discharge of its sewage into the stream, and all, with the exception of Staines, which is now dealing with the question, and, to a limited extent the Chertsey District, have completed their works, and are passing into the river either no discharge, or effluents which are so free from pollution as to satisfy the rigorous analysis of the Conservators' Chemist, Mr. C. E. Groves, F.R.S. Of the towns which have so completed works there are, above the intakes of the water companies, on the main river, Oxford, with a population of 45,741; Abingdon, 6,557; Wallingford, 2,989; Reading, 60,054; Henley, 4,913; Maidenhead, 10,607; Windsor, 12,327; Eton, 2,499; total, 145,687. There are, on the tributaries,—Cirencester, with a population of 7,441; Old Swindon, 5,545; New Swindon, 27,295; Earley, 4,461; Wokingham, 2,060; High Wycombe, 13,435; Slough, 5,427; total, 65,664, thus making the total population of these towns above the intakes, 211,351. The following towns below the intakes of the Companies have, in consequence of pressure brought by the Conservators, diverted the sewage of their districts from the Thames or its tributaries:—On the main river,—Stratford, with the population of 10,052; Kingston, 27,059; Teddington, 10,025; Twickenham, 16,026; Isleworth, 12,973; Brentford, 13,736; Chiswick, 21,964; total, 111,835. On the tributaries,—Ealing, with a population of 23,978; Hanwell, 6,139; Willesden, 61,266; Acton, 24,207; Finchley, 16,639; Hendon, 15,835; Harrow, 5,725; Pinner, 2,519; Epsom, 8,417; total, 164,725, making a total population of these towns below the intakes, 276,560. No less than 683,100*l.* was the cost of the works executed by the towns above the water intakes, and 653,832*l.* below that point.

Owing to pressure on our space, we are obliged to defer, until next week, the concluding portion of our summary of Mr. Gough's statement on behalf of the Thames Conservators, as well as some notes of the evidence subsequently given by Mr. Gough,

Mr. C. J. Moore, the Engineer to the Conservancy, and Mr. C. E. Groves, Consulting Chemist.]

MUNICIPAL ENGINEERING AT PETERBOROUGH.

A VERY successful and well-attended Eastern Counties District Meeting of the Incorporated Association of Municipal and County Engineers was held at Peterborough on Saturday, the 11th inst. The members, to the number of about sixty, assembled in the Guildhall, where they were received by the Deputy-Mayor (Mr. Councillor Herbert), in the unavoidable absence of the Mayor. The Deputy Mayor, in the course of his words of welcome, said that while they did not profess to have anything remarkable in the way of sanitary works in Peterborough, they had nothing to be ashamed of, particularly in view of the fact that the borough was only incorporated nineteen years ago. The citizens of Peterborough were very much indebted to the public spirit of the original members of the Corporation, who found the city without any sewerage system and without any wholesome water supply, and at once set to work to provide both. The result of the energy and public spirit thus displayed by the members of the first Corporation of the borough had been to greatly improve the health and to lessen the death-rate. He hoped that on a future occasion the members of the Association would have time to visit the waterworks at Braceborough, some fourteen miles distant.

Mr. T. de Courcy Meade, the President of the Association, expressed the thanks of the members for the Deputy Mayor's words of welcome.

On the motion of Mr. Barber, seconded by Mr. Radford, Mr. Buckham, Borough Surveyor of Ipswich, was re-elected Honorary District Secretary.

Sewerage, Paving, &c.

Mr. J. W. Walshaw, Borough Surveyor of Peterborough, then read a paper on "Municipal Work in Peterborough," in the course of which he said:—

The Borough of Peterborough is situated on the banks of the river Nene, which divides it into two portions, the larger being in the county of Northampton, of which it forms the eastern extremity, and the smaller in the county of Huntingdon; it lies on the borders of the great Fen country, but is chiefly known on account of its grand old cathedral.

The population of the borough at the last census was 25,172, being an increase of 4,061 during the preceding ten years; the rateable value is 106,350*l.*

The main line of the Great Northern Railway passes through the town, and the Midland, Great Eastern, and London and North-Western Railway Companies have joint stations here.

The river Nene is navigable, and much timber and farm produce is brought by barges and discharged at the several railway wharves. It is due to the great railway accommodation that the town owes its prosperity. The trade is principally in malt, timber, agricultural produce and machinery, and the Great Northern Railway Company have engine-works, and employ a large number of men.

The town obtained a Charter of Incorporation in 1874; previously it was governed by Improvement Commissioners. Upon coming into office, the newly-formed authority found sanitary matters in a deplorable condition, especially in those parts of the borough which had not been included within the Commissioner's district; hundreds of houses were drained into cesspools, privies running into open vaults; and the water supply to the whole borough was taken from wells, many of which were not more than 8 ft. deep, and in close proximity to cesspools and privy vaults. There were twelve public pumps in the centre of the town, the whole of which, with one exception, have been left out of use; they are available, however, in cases of emergency. I am pleased to state that there has been no occasion to use them.

Upon coming into office the Town Council took immediate steps, both with respect to water-supply and drainage, and called in Mr. J. Addy, C.E., to prepare a scheme and report upon the subject; these were adopted, and the works proceeded with without delay. I may here add that at that time the sewage ran into the river, and that the authorities were threatened with an injunction to restrain them from permitting this to be continued.

The sewers are laid in straight lines, with

manholes at junctions and regular intervals; the inclinations are fairly good, with the exception of that of the intercepting sewer, part of which has a fall of 1 in 2,249, and requires periodical attention. All the old sewers, where practicable, have been retained for surface-water, and they are also used as storm overflows. The sewers are ventilated by open manholes at street levels; they are flushed by means of wooden discs, which are placed in the block on the outlet side of the manhole, and allowed to remain there until the water, which is run in from the town mains at various points, rises to a considerable height; the disc is then suddenly withdrawn and a good flush obtained. A large quantity of flush water is also run into the sewers which is not held up. Notwithstanding these arrangements, we have, especially in the autumn months, complaints of smells arising from the manholes; I suppose this is the general experience where similar means of sewer ventilation are adopted. Several cast-iron shafts, varying in diameter from 4 in. to 6 in., have been erected against buildings and trees; where these shafts are fixed near to the manholes they are often the means of preventing the escape of offensive smells from them, but this is not the case where they are more than ten or twelve yards away.

The sewage is treated by broad irrigation on a farm containing 300 acres, and situate about half-a-mile from the borough boundary; the whole of it reaches the farm by gravitation; that from the Huntingdonshire part of the borough, and from a low-lying portion on the Northamptonshire side of the river, has to be pumped. Upon reaching the farm the sewage runs into two small tanks with gratings fixed at the outlet end, to prevent paper and other solid matter passing on to the land; from the tanks it is carried through the farm by open concrete conduits, and distributed upon the land by slakers with sliding doors.

The straining tanks are emptied every three weeks; the mud is thrown into pits having earth sides; it is turned from one pit into another, and thus becomes stiff enough to cart away; as a rule I find a sale for the sewage mud at 3d. per cartload; occasionally it is given away.

About 100 acres of the farm are grass, of which 70 acres are let annually from April to December, at an average rental of 5l. per acre, and 30 acres are kept by the Corporation for grazing and hay for the horses belonging to the town. Willows are grown on 21 acres; some of them are sold on the land at 10l. to 11l. per acre; such as are not so disposed of are cut and peeled by our own workmen, and I always find a ready sale for them at a price of about 12l. per ton on rail here.

Rye grass is grown upon about 20 acres; much of this is cut green, carted to the Corporation yard, and sold at 4d. per sack; that not cut for sale is made into hay, but the hay so made is not of very good quality. The remaining portion of the farm is under cultivation, and we grow fine crops of wheat, oats, beans, mangolds, potatoes, &c. Our last year's farming operations were very successful; the profit, not allowing for interest on capital borrowed for the purchase of the land and the laying out of the same, was 1,030l.; this left a balance in hand of 145l., after paying all pumping expenses and for sewage distribution, &c. The farm cost 132l. per acre, and the sum of 6,000l. has been spent upon it in roads, laying-out, conduits, levelling, &c.

Roadways.—There are about 30 miles of roadway in the borough, of which 1½ miles are paved; 5½ miles are main road, the cost of maintaining which is paid by the County Council of the Soke of Peterborough. About forty-five years ago the central part of the town was paved with random granite setts laid on sand, with joints filled in with similar material. The paving was in a bad condition before the commencement of the drainage and waterworks excavations; but matters were made much worse by reason of the numerous disturbances of the old setts. For some years the Town Council were desirous of improving affairs, but their borrowing powers were exhausted, and the work had to be delayed. The first new paving to be executed was in 1841, when, as an experiment, about 600 yards of wood was put down in a narrow, busy street; the system adopted was similar to that at Norwich, viz., without a concrete foundation; the cost was 5s. 6d. per yard; the paving gave great satisfaction, and was renewed last year, after having been down seven years; the total quantity of wood paving here is about 2,500

square yards. In a portion of one of the streets so paved cressed blocks were used; I am of opinion that they are an improvement upon ordinary deals, but they have not been down sufficiently long to enable me to give a decided opinion. In 1888 powers were obtained for borrowing the money required for repaving the remaining portion of the then paved streets with 5 by 3 granite setts laid on 6 in. of cement concrete, grouted in with pitch and oil; the works were extended over a period of two years, and the sum expended was a little over 8,000l. The whole of the materials were contracted for, the paving done by the square yard, and the rest of the work executed by the Corporation workmen. The cost was between 10s. and 11s. per square yard. Those acquainted with the streets of Peterborough three years ago cannot but be struck with the altered appearance of them to-day. We have put down two short lengths of tarred macadam,—one with granite, the other with slag; that of the latter material has been the more successful, and I am about to extend it. A 12-ton steam roller is used on the macadamised roadways.

Footways.—Whilst the paving works were in progress, new footways were put down in the same streets; they are of concrete, with 12-in. by 6-in. granite edging. The bottom layer of the concrete is 2½ in. in thickness, and composed of 4 parts local gravel to 1 part Portland cement; the top layer is ¾ in. thick, and consists of 1 part Portland cement to 2 parts gravel; several materials have been mixed with cement for the top layer, viz., slag, granite, and gravel; that made with slag is the most durable, but its slipperiness is objectionable, and I have discontinued using it; I find the best material to be local gravel, free from sand, and granite sand in equal quantities. The work is carried out by our own workmen, and the cost is about 2s. 6d. per square yard. The main portion of the other footways is formed of tar and gravel, with 12-in. by 3-in. York edging; they cost 1s. 3d. per square yard. The Corporation have twelve horses in their town stables; these are supplemented by teams from the farm, and others are hired as required at 5s. 6d. per day for horse, cart, and man.

Building Bye-Laws.—Two years ago the "Model Building Bye-Laws" were adopted. They have effected a great improvement in the smaller class of dwelling-houses, both with respect to the thickness of walls and amount of open space required. A few of the clauses are felt to be stringent, more especially that with respect to the thickness of walls of houses where the space within the roof is so constructed as to be used as a box or lumber-room. It appears to me to be somewhat excessive to require the walls, for their full height, to be increased in thickness from 9 in. to 13½ in., when the space intended to be utilised in the roof does not necessitate the walls being of a greater height than they would otherwise have been.

House Refuse.—A periodical removal of house refuse is in operation in the borough,—there are two collections weekly in the centre of the town, and one collection elsewhere; the average number of loads collected weekly is 90, and the number is increasing. I regret to say that the disposal of the collected matter is not so satisfactory as the collection, for it is deposited in disused gravel pits, &c., a great part of which will some time or other become building land.

Cottage Hospital.—Eight years ago a cottage hospital for cases of small-pox only was erected on the sewage farm; during that period it has only been used on five occasions, one of them of recent date. The Rural Sanitary Authority have joint use of the hospital, for which they pay a yearly rental of 300l.; the cost of it was under 500l., and it will accommodate eight patients. We in Peterborough have great reason to congratulate ourselves upon our comparative freedom from this terrible disease. We have a Goddard & Massey's disinfecting stove at our store yard; it is used after all cases of infectious disease, free of charge.

Death-Rate.—The average death-rate of the borough for the past ten years has been 14.7, for the previous eight years the average was 20.7. The Compulsory Notification of Diseases Act is in operation here.

Public Library.—The Public Library Act has been recently adopted, a suitable building has been taken on a seven years' lease, and is now being fitted up at a cost of about 400l.

Public Lighting.—The gas-works are in the hands of a company; they supply and erect the public lamps wherever required, at a distance not exceeding 60 yards apart; the price

of gas for public purposes is 3s. 2d. per 1,000 cubic feet, for private purposes 3s. 4d. There are 642 public lamps, of which fifty-nine consume from 14 to 21 cubic feet of gas per hour; the remainder are regulated to consume 5 cubic feet each per hour; the charge for cleansing, lighting, and maintaining the ordinary lamps is 15s. each per annum, and the larger ones 20s. About two-thirds of the total number of lamps are not lighted during the summer months and moonlight nights, excepting when such nights fall upon a Saturday or other special occasion. Last year the bill for public lighting amounted to 1,347l.

Cattle Market.—The cattle market is owned by the Corporation; they purchased it about eighteen months ago, at a cost of 15,000l., and have found it a remunerative investment.

Municipal Buildings.—I cannot ask you to congratulate Peterborough upon the character of its municipal buildings; this is our Guildhall; our offices are scattered about here and there. We have expended all our means upon more urgent matters. I do, however, hope that when next the Association visits Peterborough,—which I trust may be at no distant date,—the meeting may be held in a building of a more pretentious character, and more befitting the dignity of a corporate town.

Water Supply.

Mr. John C. Gill, Assoc.-M.Inst.C.E., Water-works Engineer to the Corporation of Peterborough, next read the following paper on "The Water Supply of Peterborough":—

Peterborough was incorporated as a municipal borough in 1874, and previously to this date the water-supply, derived from shallow wells, was insufficient and impure. The Improvement Commissioners, as the Urban Authority before the town was incorporated, had been compelled to consider the advisability of providing an adequate supply of pure water from some extraneous source, but no active steps in this direction had been taken. In the meantime, outbreaks of zymotic diseases were frequent, and could be distinctly traced to the presence of organic impurities in the water used for domestic purposes.

The Corporation, with admirable promptness, determined immediately upon its establishment to introduce simultaneously an abundant water supply and a new system of drainage, and in August, 1874, within six months of the date of the Charter of Incorporation, instructions were given for the preparation of schemes for both purposes. The water-supply then introduced and since extended is the subject of this paper.

Summary of Works.—The works, which were opened in 1879, consist of:—1. A pump-well 63 ft. deep, 5 ft. 6 in. in diameter. 2. Three 6-in. tube-wells discharging into pump-well. 3. A pair of 120 horse-power rotary beam engines. 4. Four pumps of the hocket and plunger type. 5. Two "Lancashire" boilers,—shell 26 ft. long by 7 ft. diameter. 6. Buildings, consisting of engine-house, boiler-house, stores, workshop, and engineers' cottages. 7. A rising main from pumps, 7 furlongs in length. 8. A covered reservoir, of one million gallons capacity. 9. A delivery main, 18 in. in diameter and 14 miles long. 10. Thirty-three miles of distributing mains. 11. The necessary valves, hydrants, wash-outs, and fittings. The total cost of these works has been 91,115l.

The Water and its Source.—The water is drawn from wells sunk in a piece of land adjoining a branch of the Great Northern Railway, in the parish of Wilsthorpe, Lincolnshire, about three miles from Bourn, and fourteen miles from Peterborough. The original well from which the water is pumped is 5 ft. 6 in. in diameter, lined with cast-iron cylinders, and when the yield from this well became, through the increased requirements of the borough, inadequate for its supply, three 6-in. tube wells were sunk, from which the water is discharged into the original pump-well. The wells penetrate the colite formation and strike the water-bearing strata at an average depth of 53 ft. 6 in. from the surface. From this depth the water rises with considerable force; in one instance a stone weighing 6½ lb. was ejected from the top of one of the tubes. Before reaching the water a bed of argillaceous limestone, 8 ft. thick, abounding in marine fossils, was passed through, and between this rock and the water-bearing strata the estuarine clays, 27 ft. in thickness, were pierced. The first experimental boring was made in 1875, and on September 6 in that year the

water rushed up the bore-hole in large volumes, and was projected in the form of a fountain to a height of 15 ft. above the surface. The yield on September 21, fifteen days after being first tapped, was at the rate of 420 gallons a minute from the 4-in. bore, and gave a velocity of 770 ft. per minute at 3 ft. above the surface. The original pump-well, 5 ft. 6 in. in diameter down to the water-bearing rock, and thence continued by five 6-in. bore-holes, gave sufficient water until the year 1885, when, because of contracts entered into for supplying the railway companies, additional sources of supply became necessary. Three tube-wells were therefore sunk with a bore of 6 in. in diameter down to the water-rock, and continued to a distance varying from 9 ft. to 15 ft. in the different wells, with a diameter of 5 in. A solid drawn copper tube lines the bore down to the water-rock, into which it is sealed. At the top of each tube a stop-valve is fixed, and by this means the quantity of water drawn from the wells may be regulated according to the consumption in the town. When only one of these extra wells is required, the other two may be shut off entirely, thus preventing the water running to waste. The daily yield of these three 6-inch tube-wells, gauged on November 12, 1888, was as follows:—No. 1 well, 674,818 gallons; No. 2, 681,108; No. 3, 810,320; total, 2,166,246 gallons. The cost of the three wells, including all labour and materials, was 6492 13s. 11d. The total quantity of water drawn from all the wells during last year was 511,546,955 gallons, or an average throughout the year of 1,401,498 gallons a day.

The Engines, Pumps, and Boilers.—The engines are of the rotary beam type, with single cylinders 32 in. in internal diameter, and 6 ft. stroke of piston. The steam and exhaust valves are gun-metal, of the ordinary double-beat equilibrium type, the various grades of expansion being obtained by making the cams for operating the steam valves with an increasing tread, so that by sliding them on the shaft by means of suitable screws and gearing, which may be operated while the engine is in motion, the valves may be kept open for a longer or shorter period of admission of steam, and the speed of the engines thus regulated. Each fly-wheel is 20 ft. in diameter, and weighs 20 tons. The crank-shaft where in fly-wheel is 15 in. in diameter, and 12 in. at the necks. The throw of the crank is 3 ft. The beams are of wrought iron, 24 ft. in length, and 4 ft. in depth at the centres, the rolled plates of which the beams are formed being 1½ in. thick. To each beam are connected the rods of two main water-pumps, condenser air-pump, feed-pump for boilers, and air-pump for charging air-vessel. The main pumps, four in number, are of the bucket-and-plunger type. Each pump has a cylinder 1 ft. 5½ in. in internal diameter, with a stroke of 3 ft. The bucket is made of gun-metal, with a valve of the double-seated equilibrium type, with white-metal seatings. The diameter of the plunger is 1 ft. ¾ in. The pumps draw their water through two suction-pipes,—the two pumps on each engine being fed by the same pipe. These pipes are 1 ft. 6 in. in bore from the wells to the outward pumps, and 1 ft. 3 in. from the outward to the inward pumps. All the pumps deliver their water into the same delivery main which conveys the water direct to the town, the surplus over the consumption being accumulated in the reservoir. Two boilers of the "Galloway" type supply the steam for actuating the engines. The shell of each is 26 ft. long by 7 ft. in diameter. They are fed by water from the condenser hot well, which is at a temperature of 95 deg. to 100 deg. Fahr., when it enters the boilers. The engines, pumps, and boilers were made and erected by Messrs. Galloway & Sons, of Manchester, whose contract was 9,000l.

The Reservoir.—The reservoir is constructed on Otthorpe Hill, an elevation about seven furlongs from the pumping-station, having a summit level of 160·2 ft. above Ordnance Datum. It is a brick structure, encased in concrete, and made water-tight with an outer shell of puddle. The covering is formed by segmental brick arches, springing from transverse walls, built with arched openings upon piers. The floor is of concrete, finished smooth with cement. The reservoir is rectangular in plan, 120 ft. long inside by 89 ft. 6 in. wide, with a depth when full to overflow level of 16 ft., and a capacity of 1,000,000 gallons. The height of water in the reservoir is shown on a dial at the engine-house by means of an electrical water-level

indicator supplied and fitted by the Silvertown Company. The overflow level of the reservoir is 135·1 ft. above the ground level at the Guildhall, Peterborough. The cost of the reservoir and fittings was 7,356l. 12s. 9d.

Delivery and Distributing Mains.—The 18-in. delivery main, 14 miles in length, is laid in all the straight sections with pipes 12 ft. long, with bored and turned joints; in other parts the ordinary lead joint is used. The price per ton for the ordinary cast socket pipes was 5s. less than for those with bored and turned joints, yet the extra labour and materials used in making the lead joints caused the total cost of the finished main to be 1s. 4d. per yard run higher where the lead joints were used than in the lengths laid with pipes that were bored and turned. The bored and turned joints were used entirely throughout the delivery main, except at the bends, and have been eminently satisfactory during the thirteen years the main has been in work. The distributing mains, 33 miles in length, are of various sizes, from 12 in. down to 4 in., and are connected up in circuits so as to avoid dead ends as much as possible. Fire hydrants are fixed at an average of 90 yards apart, and sluice valves at all junctions and other places where required. The contract for supplying the pipes was let to Messrs. Cochran, Grove, & Co., of Middlesborough, and the sluice valves, hydrants, &c., were supplied by Messrs. Alley & MacLellan, of Glasgow. The total original cost of the delivery main was 36,456l. 13s. 4d., and of the distributing mains, 16,654l. 1s. 1d.

The district supplied by these works comprises several villages adjoining the main pipes, or the boundaries of the borough, and contains altogether a population of 29,300. The four railway companies who have works at Peterborough are supplied from these waterworks, and together consume about 750,000 gallons a day. The total daily consumption of water, taken on an average throughout last year, was 1,401,498 gallons. Excluding the water sold in bulk to the railway companies, this gives a daily consumption of twenty-two gallons a head for all purposes.

Mr. Isaac Stone next read a paper on "The Stone System of Town Drainage," but a summary of this, as well as a condensed report of the discussion which followed the reading of the three papers, we must postpone, for want of space, this week.

Owing to rain, only a few of the party visited the sewage-farm, under the guidance of Mr. Walshaw, the Borough Surveyor.

Correspondence.

To the Editor of THE BUILDER.

FOURTEENTH AND FIFTEENTH CENTURY SCREENS.

SIR,—The Rev. B. Ruck-Kee's query suggests a very tall order indeed!

Confining myself entirely to the county in which I write (Devonshire), of fourteenth-century stone screens there is—Bishop Stapeldon's (A.D. 1308-26) rood-screen in Exeter Cathedral; a screen of about the same date at Ottery St. Mary; and the beautiful fifteenth-century rood and parclose screens at Tolnes Church. The detail on these latter screens is so similar to those to the Lady Chapel and side chapels abutting it in Exeter Cathedral, that they are probably the work of the same hands. At Awlescombe and Paignton there are also stone screens of the same date.

Of oak screens, Devonshire stands well to the fore. Just to the left, on entering the Cathedral from the west, is St. Edmund's Chapel, now more commonly known as the Consistory Court. It is divided from the north aisle by a Decorated screen (A.D. 1340)—the oldest in the Cathedral. The screens that form lines of demarcation between the aisles of the nave and those of the choir date from a little later period. There are no fourteenth-century oak screens, so far as I am aware, in churches in the diocese. It seems that nearly all the county's efforts in the fourteenth century were directed to transforming our Norman-Transition Cathedral into a Decorated one. One hundred years later, however, people having had time to breathe, the wave of restoration went through Devonshire, from east to west and north to south. There are some very beautiful fifteenth-century oak screens in the cathedral choir. The city of Exeter only boasts of one other fifteenth-century oak-screen; it is now in St. Mary's Steps Church, but was formerly in (the now destroyed) St. Mary Major's.

There are fifteenth-century screens at Pinhoe,

Stoke-in-Teignhead, Poltimore, Littleham (near Exmouth), Broadwood Wilder, St. Saviour's (Dartmouth), Staverton, Bradinch, Cullompton, Feniton, Payhenbury, Plymtree, Colebrook (a very curious parclose), Down St. Mary, Lapford (rather late), Stookleigh Pomeroy, Atherington (late, and the only instance of an original rood-loft gallery in the county), Swinbridge, Sheldon, Halberton, Ashington, Chudleigh, Comb-in-Teignhead, Dunchideock, Hazcombe, Kenn, Kenton, Talator, Shirwell, Berry Pomeroy, Churston Ferrers, Broad Hempston, Ipplepen, Torbrian, Woolborough, Bovey Tracey, Isington, Manaton, St. Michael's (Honiton), North Leigh, Ashpington, Blackawton, Harburton, Rattery, Hartland, Kingsbridge, Aveton Gifford, North Bovey, Bow, Cruwys Morchard, Bampton, Bridford, Hocharton, Little Hempston, East Down, Donbury, Chumleigh, Chelvestone, Cornwood, Calverleigh, Buntingford, Burlescombe, Buckland Monachorum, Buckeral, Welcombe, Ugborough, Stokenham, Slapton, Sherford, Holne, North Huish, Kentisbeare, Sampford Peverell, Portlemouth, Rattery Plymstock, North Petherwin, Petertavy, North Molton, Mushury, Littleham (near Bideford), King's Nympton, South Milton, Dodbrooke, Marwood, and Buckland-in-the-Moor.

These names occur to me, but there are doubtless other churches in the county in which fifteenth-century oak screens, or portions of such screens, still exist.

Of all those now mentioned, by far the most beautiful and ornate is that at St. Paul's, Staverton, upon the banks of the river Dart. It consists of a continuous run of seventeen bays, in all 50 ft. long from north to south. It is groined on both sides, and there is a rood-loft the entire length, 6 ft. 9 in. wide. The gallery front, facing westward, is richly canopied. The height of the screen is 15 ft. It has recently been restored, at a cost of about 1,000l., by an anonymous donor, through the medium of the Rev. S. Baring-Gould, and under the direction of Mr. F. Bligh Bond, architect, of Bristol. The actual work itself was carried out by myself and sons.

HARRY HEMS.

Exeter, June 11, 1892.

LEWISHAM PARISH CHURCH.

SIR,—I learn from the minute-book of the trustees for rebuilding the parish church of Lewisham in 1774, that the architect of the new church was Mr. George Gibson, and that the builders selected were Oliver Burton & Co. I should be much obliged if any readers of the *Builder* could inform me whether representatives of the above are now living.

WARMING BUILDINGS BY HOT WATER.

XXV.

JOINTING AND SUPPORTING PIPES.—CHIMNEYS.

THE general method of jointing hot-water pipes, when there is a large number of joints to be made, is by what is known as the rust joint. For small works there is now a more general application of the rubber ring, or some of the different forms of expansion joints, these latter being now made in considerable variety and having many good features. Joints are also made with red and white lead and yarn, but this is a more expensive joint; it, however, is not so rigid as the rust joint, and fulfils a use in this respect as will be seen directly. It is a joint also used with small works, as the little extra expense is then trifling, and it is convenient both in application and in obtaining the materials. The rust joint is cheapest but not convenient, unless the works are on a large scale, or several jobs are being carried on at once. There are other different joints, workmen sometimes making a joint specially their own. The writer once saw a joint made with old tarred cord and nothing else, and this withstood a pressure of 30 lbs. per square inch.

There is a distinction between horticultural and building works in the question of joints, in the fact that the former, in having no height, produces no pressure, and almost anything will make a water-tight joint, if it does not make a lasting one. With building works, the pressure, if the height be anything to speak of, quite precludes the use of the plain rubber ring, and the other joints (rust, &c.) must be allowed to set thoroughly hard before the apparatus is charged. This, it is understood, applies to cast-iron heating pipes and coils; what wrought pipe may be used has screwed joints, and will bear very heavy pressures.

The rust joint is made by mixing iron borings (these can readily be procured at about 9s. per cwt.) with some sal-ammonia and sulphur in a powdered form. The addition of these two

latter materials to the borings causes a chemical action to set in, and the iron rusts into a hard and solid mass. The rusting process takes place quickly, but it is some days before the action entirely ceases, and this brings about very disagreeable results when the workman is not experienced. The borings, during the change they undergo by the addition of the two substances named, expand somewhat; that is to say, the mass of material exerts an expansive force while the chemical action is proceeding. The result of this is that, as the action chiefly takes place after the borings are caulked into the socket, there is every probability of the socket splitting if the joint is not made by a skilled man. There have been vast quantities of pipe spoiled in this way, and it is somewhat fair evidence of experience when a man makes rust joints which remain sound, and do not injure the sockets.

Workmen have different ways of caulking in this material. The socket is, we may say, never filled with borings only; there is always some yarn used. Some workmen caulk the socket half-full of yarn, the remaining half with borings; sometimes it is three-fourths yarn, just finished off with borings, or it may be the socket is packed with two or three alternate layers of the two materials. A good workman makes his joint quite watertight with the yarn alone, but this material needs sustaining with the iron borings which go to complete and make the joint permanent. Two-thirds yarn and one-third borings make a good joint.

The proportions of the materials added to,—say, 100 parts of borings, are one part powdered sal-ammonia and two parts powdered sulphur, the whole being moistened and thoroughly mixed. It requires to be made from one to two hours before it is used; but the weather will affect it in this respect. It cannot usually be kept longer than one day without becoming hard and unfit for use.

The red and white lead joint is made by taking the latter material, which is a sticky mass, and adding the dry red lead to it until the mixture is of the consistency of putty. Some of this mixture is taken, and has hotted oil added until it is quite liquid, and the ends of the pipes are painted with this, otherwise the putty material will not adhere. Usually the joint is made by caulking in alternate layers of yarn and lead, the yarn first, and finishing with the lead, and when dry it is a sound and durable piece of work.

The rubber-ring joint is now considerably in favour, as it has many good features, chiefly by its convenient application to certain purposes. A considerable trade is now done in small boilers, which are sent out for amateurs' greenhouses, complete with the pipes, &c., and are so constructed that the purchaser can erect the whole of the apparatus himself. The joints of these pipes, both with the hoiler and with one another, are commonly made with a plain rubber ring, and for this purpose it is a great convenience. Then, again, in some large works, temporary lines of pipes are sometimes needed, and for this purpose the rubber ring is a positive boon, as it can be used with any ordinary description of pipe. Occasionally permanent works of a large character are carried out with this joint, but it is not a usual practice.

The particular convenience of the rubber-ring joint is the expeditions way in which it can be used. It consists of a ring of round india-rubber, full 3/8 in. thick, the size varying with the size of the pipe, of course. This ring, which is a little smaller than the pipe, is stretched just on the spigot end of the pipe and this is then forced into the socket. Its passage in causes the ring to roll, and by the time the spigot is pushed home, the ring joint is half way up the socket, as fig 101 (section). Instead of stretching the ring on to the spigot, a ring expander can be had, which, when one

termed "expansive." What is really meant is, that it is elastic, and, considering that every variation in the temperature of the water brings about a movement in the pipes (expansion and contraction), the necessity of such a joint becomes obvious. With the rust and also the red and white lead joint, some provision is always made for this, if the pipes extend any distance. With short services no provision is needed. With the two joints named, a long, loose socket is provided here and there, and so packed that the pipes can move to and fro in it to a trifling extent. One firm of growers uses rust joints, but uses a rubber ring for every sixth joint. The expansive force is not extensive, that is to say in a 100-ft. run of pipe we may never get more than 1 in. total extension in length, but the force is certain and irresistible; so much so that brickwork has often been displaced by the thrust. The rubber joints allow for this, and act very successfully.

There are several forms of patented joints that have rubbers as the jointing material, and which possess the elasticity just spoken of. It is not necessary to describe them all, but Jones's patent, as fig. 103, can be described as

FIG. 103.

an example. This consists of two cast collars, A A, an iron ring B, two rubber collars C C, and the whole brought together with the bolts shown. This joint has the advantage of being used without socketed or special shaped ends to the pipes, any plain pipe can be jointed, and if the pipe was badly or roughly cut, a joint might still be well made. This saves waste of cut pipe, as some of the patented joints depend upon one of the ends being made to suit the other. A joint like this (fig. 103) permits of any length of pipe being taken out and replaced with new, if needed, without disturbing the remainder. This would prove very convenient if, after laying down a long run of pipe, a bad leakage was found somewhere in the middle. With the ordinary joints, a mishap like this is provided for by putting running,—i.e., loose,—sockets here and there. All kinds of rubber joints are more expensive than the rust joint; but if anyone wishes to compare the cost between the two, let it be remembered that a rubber joint can be made in an exceedingly short space of time.

PIPE SUPPORTS.—In nearly all horticultural works the supports are little piers of brickwork, and for such purposes nothing better is needed. It is essential that the brick piers be on a good foundation, or their own weight and the weight of the pipes may cause them to sink, with the most disagreeable results, even if the joints in the pipes did not become fractured. For those situations where the pipes are seen iron supports can be used, these (as fig. 104) being of better appearance and very safe; they are also exceedingly cheap, being mere plain castings.

FIG. 104.

FIG. 105.

When pipes are carried along a wall or woodwork they are sometimes strapped on as fig. 105. There is nothing unworkmanlike in this.

When the runs of pipe get somewhat extensive, then, in addition to elastic joints, there must be some provision on the supports themselves, to allow for the movement that takes place. With brick piers a piece of small iron pipe, or round rod-iron, will form a frictionless bearing, or if iron supports are used they can be purchased as fig. 106, or a smith can make something with

rollers for the pipes to rest upon. If such a provision is not made there is every probability of some harm ensuing; but, as just mentioned, this need not be thought of with medium and small sized works.

CHIMNEYS.—Reference has been made to these from time to time in the previous papers, and very little remains to be said. We have fully pointed out the necessary features with

FIG. 100.

chimneys in building works, but there needs to be given the rules usually followed in making the chimneys to boilers attached to glass-house works, those which stand away from buildings. In giving the following sizes it is supposed the chimneys are brick built, not sheet-iron pipe. Earthenware pipes, however, answer very well for this purpose as a rule.

The minimum height of chimney should not be less than the length of the flues that lead up and down the boiler,—that is to say, a 4-ft. saddle boiler, having flues once up and down its length, should have an 8-ft. chimney. If the boiler was one having the flues traversing its length three times, then it should have a 12-ft. chimney. Let it be clearly understood that these are minimum heights. If we made the chimney of less height than this, the draught in it would be insufficient to carry away the smoke or gases, and cause a proper degree of combustion in the furnace. Sometimes a chimney a little lower will work passably well, but it is best to calculate, as just described, for a minimum height.

Every opportunity should be taken to have a higher chimney wherever possible; better and more reliable results are attained; but of course in private gardens the chimney, beyond certain limits, is strongly objected to on account of its unsightliness in most cases. With professional growers, sightliness may probably be the last thing to be considered, profit has more consideration, and higher chimneys are the rule.

The area of the chimney should bear some relation to the size of the boiler, and the following sizes are reliable—

	Area of chimney in square inches.
For Trentham boilers 8 to 10 ft. long	400
„ Saddle „ 6 ft. long	300
„ „ „ 4 ft. 6 in. long	250
„ „ „ 3 ft. or smaller	200

These areas are for the minimum height chimneys just referred to. As the height is increased the area can be reduced. For low chimneys the area cannot be too roomy, it is essential; and at the point where the flues from the boiler enter the chimney, the passage should not be choked in anyway. It will be understood that as the height of chimney is increased, the draught is more keen and a less area will answer, but small area must be avoided with very low chimneys. If the height of chimney was double the minimum given, then the area could be reduced, say, one fourth.

SURVEYORSHIPS.

SALFORD.—At the monthly meeting of the Salford Town Council, held in the Salford Town-hall on the 1st inst., the Mayor, Mr. Alderman Keowney, as Chairman of the General Purposes Committee, as well as the Selection Committee, proposed the adoption of Mr. John Price (the Engineer and Surveyor to the Toxteth Park Local Board, Liverpool) as the Borough Engineer and Surveyor of Salford, at a salary of 500*l.* per annum, and that he devote the whole of his time to the duties of the office. Mr. Hunsley seconded. Mr. Alderman Walmisley proposed, as an amendment, that Mr. Joseph Corbett, of Broughton, be appointed the Borough Engineer and Surveyor. Mr. Alderman Bailey seconded the amendment. After some discussion the amendment was carried, 30 voting for it and 25 against. The recommendation of the General Purposes Committee was therefore rejected. The amendment then became the substantive motion, against which Mr. Snape moved an amendment that the name of Mr. H. C. Marks (the Borough Engineer and Surveyor of Dewsbury), one of the candidates, be substituted for that of Mr. Corbett. Mr. Hamblett seconded. On a second vote being taken, 25 voted for the amendment and 29 against. The substantive resolution was then adopted, appointing Mr. Corbett to the office.

FIG. 101.

FIG. 102.

end is placed in the pipe, permits of the ring being rolled up it, on to the pipe, and this prevents it being put on in an irregular manner or twisted. The tube expander is as fig. 102. This joint is totally wanting in rigidity, and the pipes need to be well supported.

This, and the following joint, are what is

GENERAL BUILDING NEWS.

MUNICIPAL BUILDINGS, CROYDON.—On the 9th inst. the Mayor of Croydon laid the foundation-stone of the Municipal Buildings, Croydon, which are being erected at a cost of £30,000. The principal front (we quote from the *Local Government Journal*) will be 285 ft. long, the side frontage being 170 ft. The municipal buildings block will extend for a distance of 100 ft. towards the High street. The entrance is in the centre, and leads to a large hall on the ground floor. From this hall staircases lead to the lower ground floor and to the first floor. Right and left on each floor branch corridors 10 ft. wide, lighted from two large open areas, giving access to the various departments as follows:—On the lower ground floor, Borough Engineer's drawing offices, plan and samples rooms, offices for the Building Inspectors, water and sewers foremen, offices for the Medical Officer of Health, Sanitary Inspectors and Clerks, Road Surveyor's offices, Inspectors of Weights and Measures offices, three waiting-rooms, and a muniment-room. On the ground floor to the left of the entrance are the public and private offices of the Borough Engineer, with access from the latter to the drawing office by a spiral staircase, to the right of the entrance are the rates offices of the borough, comprising the accountant's department. On the first floor is the Town Clerk's department containing a large public office, three small private offices for clerks and the Town Clerk's private room. The remainder of the Borough Accountant's department is on this floor, viz., his private office, a large public office, a small private office, and a room for auditors. On this floor will also be the Council Chamber, with galleries for the public and for reporters. Adjoining is the Mayor's parlour, a large ante-room, and two committee-rooms. On each floor are cloak-rooms and lavatories. There are also storage-rooms, and rooms for books and papers in connexion with several of the departments. Rooms for the hall-keeper will be on the floor above formed in a portion of the roof. The session courts are behind the municipal buildings. They will be on the ground-floor level. The court for the borough bench and quarter sessions is 50 ft. by 40 ft., the county-court is 40 ft. by 30 ft., both top-lighted. Near to the former are rooms for the magistrates, the magistrates' clerk's offices, and a large room for the grand jury at quarter sessions. There are also rooms for the county-court judge, barristers, &c., with cloak-rooms and lavatories. Beneath the courts are rooms for prisoners and police, which will connect, by a corridor and subway, with the police-station, to be built on the opposite side of the new street, and by a staircase with the dock in the large court. The public library forms a continuation of the Municipal Offices block towards the High street, but the front of the former is recessed 45 ft. from that of the latter; in the angle so formed stands the tower, about 150 ft. high. The lower part forms a vestibule from which a short flight of steps leads to a central-hall, on the left of which is the lending library, on the right the reading and news room, and opposite is the librarian's room. From the vestibule stairs lead down to the magazine-room, a workroom, stores, &c. Open areas, 12 ft. and 18 ft. wide, with retaining walls to the roads faced with ivory-tinted glazed bricks, will afford light to all rooms at this level. A corn market completes the group on that portion of the site nearest to the High street. It is proposed to warm the buildings by steam radiators fed with fresh air from the exterior, and to draw off the spent and vitiated air by the chimney shaft from the furnace of the boilers, supplemented by extraction fans in a shaft or trunk which will be connected by openings from each room. The style of the design is modern Renaissance, freely treated. The materials of the exterior are red bricks, with Portland stone dressings and green Westmoreland slates for the roof covering. Mr. Samuel Page, of Croydon, has undertaken the contract for the foundations and lower ground floor. The architect is Mr. Charles Heuman, of Croydon and London.

BOWES MUSEUM, BARNARD CASTLE, DURHAM.—The Bowes Museum, Barnard Castle, the foundation-stone of which was laid by the late Countess of Montalto, wife of the late Mr. John Bowes, of Streatham Castle, in November, 1839, was opened to the public on the 10th inst. by Sir Joseph W. Pease, Bart., M.P. According to the *Leeds Mercury*, the structure is in the style of the French Renaissance. The south, or principal, front is 300 ft. in length; the central dome and the two turrets are carried to a considerable height above the main building, which has an elevation of about 85 ft. East and west are wings the length of each of which is 130 ft., and the front is set back 33 ft. within these wings. The entrance-hall is 42 ft. square; the walls are of polished freestone, and the floor of marble mosaic. The main doorway is 24 ft. 6 in. high by 20 ft. 6 in. wide, and the doors are of iron. The steps of the principal staircase, which are 52 in number, are of polished Peterhead granite, and hang out of the wall 8 ft.; twelve polished red granite columns support this staircase, the landings of which are of stone from the Craigleith Quarries, Edinburgh. The

basement and top floors are appropriated to residential purposes. The rooms on the third floor are filled with collections of pottery and porcelain, glass, carved ivory, crystals, silversmiths' work, &c. On the second floor the rooms to the left form the library. In the large room on the right of the staircase, 42 ft. square by 25 ft. high, are hung a number of paintings, chiefly foreign landscapes, which were executed by the founders of the museum. The picture-gallery, which is entered from the first room, consists of a suite of three rooms, the entire length of which is 204 ft., and the width 44 ft. In the roof are three lights, each of which is 41 ft. 6 in. by 20 ft. The sculpture-gallery on the first floor is under the picture-gallery, and is of the same dimensions. The building was commenced in the spring of 1870. Mr. Joseph Kyle of Barnard Castle, was the builder; Monsieur Jules Pellechet, of Paris, and the late Mr. John Edward Watson, of Newcastle-on-Tyne, were the joint architects.

THE NEW FRUIT AND VEGETABLE MARKET IN THE CITY.—On the 13th inst. the Lord Mayor opened the new fruit, vegetable, and flower-market erected at the junction of Charterhouse-street and Farringdon-road. The new market has cost 70,000*l.*, exclusive of the value of the site, and of this sum 41,000*l.* has been laid out on the sub-structure and for basement works, under an agreement with the Great Northern Railway Company. The market has a frontage to Charterhouse-street of about 370 ft., and to Farringdon-road of about 184 ft. Of this area, representing about 54,000 ft., the building now erected occupies 30,000 ft. super., leaving ample room for extension when required. The main vehicular and footway entrance to the new building is in the middle of the Charterhouse-street front, and is 33 ft. wide. The avenue from this entrance, running parallel with Farringdon-road, and dividing the market equally, is of a like width; and a further entrance, 16 ft. wide, for carriages and pedestrians is placed at the north end of the Farringdon-road front. Two footway entrances, 8 ft. wide, are provided on the Charterhouse-street front, and one on the Farringdon-road front, all three affording access to gangways of a like width, traversing the market from south to north and west to east. The building is designed of iron and glass. The height of the building to the plate level is 23 ft., and to the ridge 46 ft. The basements under this and adjoining markets will be occupied by the Great Northern Railway Company, whose lines of rail and platforms will traverse the entire length from Charles-street to Snow-hill. The area of these basements is about 100,000 ft. Large hydraulic lifts are designed to raise the market produce brought by the railway companies to the markets above, and inclined roadways for horse traffic are provided as means of access from the basement to the street level. The late Mr. Alexander Peohles, City Architect, drew up the designs of the market, which has been constructed by Messrs. Rudd & Sons of Grantham, and Messrs. Perry & Co., of London. The execution of the work was carried out under the superintendence of the City Surveyor, Mr. A. Murray.

PRIMITIVE METHODIST CHURCH, GATESHEAD.—On the 6th inst. the foundation-stones were laid of a new church for the Primitive Methodists, Gateshead. The building is situated in Durham-road, and has a frontage also to South-street. There are three entrances, the two principal being from Durham-road. The church is 61 ft. in length and 42 ft. wide, with a gallery round three sides, and will accommodate about 620. The organ and choir are placed in a gallery behind the rostrum, and raised about 3 ft. above the church floor, with entrance from South-street. Under the choir gallery is a large church vestry, with ministers' vestry adjoining. There are two staircases to the gallery. The principal staircase leading from the entrance hall is so planned as to give communication with the schools and lecture hall adjoining. The church is being built with stone, and has been designed, to harmonise with the schools, in the Early English style, with a tower over the entrance porch, connecting the two blocks. The seating, rostrum, gallery front, and internal fittings generally are to be carried out in pitch-pine. The building is to be heated by hot water on the low pressure system, and are being carried out from plans and under the supervision of the architects, Messrs. Davidson & Bendle, of Newcastle, at a cost of about 3,250*l.* Messrs. Haswell & Waugh, Gateshead, are the contractors.

NEW YORKSHIRE PENNY BANK, LEEDS.—On the 1st inst., the foundation-stone was laid of the new Yorkshire Penny Bank in Leeds. The site is at the corner of Infirmary-street and Toronto-street, immediately behind the new General Post-office. The new bank, says the *Leeds Mercury*, will occupy an area of 1,315 square yards, with a frontage to Infirmary-street of 103 ft., and to Toronto-street of 115 ft. The designs are a treatment of Domestic Gothic. The tower at the angle of the building is terminated by an open stage, covered by a pyramidal roof of red tiles, surmounted by an octagonal turret. Inside the tower there is to be a stone staircase and a lift, giving access to the two suites of offices on the first and second floors. The basement will contain cellars, clerks' rooms, and other apartments, as well as the heating, ventilating, and lifting

apparatus. The business of the bank will be conducted on the ground floor, where there will be a large room, entrance to which will be obtained from Infirmary-street. The whole of the internal walls of this room are to be arched. On the same floor are rooms for the manager, clerks, inspectors, and other officials, and a safe-room. A large room for the use of the board of directors will occupy the east part of the same floor. The second floor will be let off as offices, and the third will be utilised as storage-rooms. The building, which is now above the ground, is to be erected entirely of Morley stone, with red-tiled roof. Special attention has been paid to the lighting and heating and to the sanitary arrangements. The lavatories and other conveniences will be disconnected from the sewerage system, and the supply of hot and cold water to all parts will be ample. The banking-room is to be heated by warm air, which will be driven inside by a fan, the same power supplying cold air in the summer season. The various lifts in the building will be worked on the high-pressure hydraulic system. Throughout the floors are to be constructed of iron and concrete, and the materials generally will be as far as possible fireproof. The architects are Messrs. Perkin & Baldry, Leeds. Messrs. Nicholson & Son, Leeds, hold the contract for the erection of the superstructure, including the masons', bricklayers', and joiners' work; and Mr. Evans has made the foundations and the basement. It is estimated that the buildings, including the land, will cost between 30,000*l.* and 40,000*l.*

MARCOSS CHURCH, GLAMORGANSHIRE.—We are informed that this very ancient and most interesting church, situated about the coast road, far from Nash Point, and St. Donat's Castle is about to be restored. The Norman chancel arch and porch doorway, together with the leper window in the chancel were the subjects of much interest to the members of the Archeological Society, who visited the church a few years back. The work of restoration has been entrusted to Messrs. Kempson & Fowler, architects, Glasgow. This restoration may, doubtless, be necessary, practically, but we fear it will greatly diminish the "interest" of archeologists in the church.

FOREIGN AND COLONIAL.

FRANCE.—It is announced that, on account of the opposition to a certain number of architects named in the section of architecture in the Concours Elysée Salou, and who have not received the summons for the vote of the Medal of Honour, the sub-committee has resolved to cancel the negative ballot of May 30, and proceed with a new election this week.—The Society of Fine Arts of Departments has just held its annual reunion at the Ecole des Beaux-Arts, under the presidency of the Minister of Public Instruction.—The special commission charged with the awarding of the three prizes called "de l'Institut," at the Salon des Champs Elysées, has given them as follows:—M. Henri Royer, the Henri Lehmann prize, for the encouragement of good classical studies; M. Moleya, the Brizard prize, for landscape or sea painting; and the Maxime David prize, for the best miniature painting, has been awarded to Madame H. Richard. The competition instituted by the National Society of French Architects for young French architects, between the ages of eighteen and twenty-four, has just been decided in the Palace of the Bourse du Commerce. The competition was for a lodging-house in the Batignolles quarter, which was to contain all the latest inventions for comfort and hygiene. Out of thirteen interesting designs, the jury decided to give the first prize to MM. Colas and Daudanne; the second to M. G. Madaule, and the third to M. Paul Martin, of Moulins; a first mention to M. Bierry, and a second mention to M. Déjan.—Ninety-two painters have taken part in the open competition for the decoration of the *Mairie* of Montreuil-sous-Bois. The exhibition is open at the *Hôtel de Ville* in Paris, and the judgment will be given in the course of next week.—We hear of fresh fires in the forest of Fontainebleau, principally in those parts which are planted with pines, and covered with heather.—The Government has just offered to the Museum of Troyes a beautiful picture by M. Adrien Moreau, entitled "In the Park."—At Marseilles a monument has just been inaugurated to the memory of the Abbé Dassy, who founded the schools for the blind, and the deaf and dumb. The monument, which has been paid for by subscription, is the work of M. Fabre. On the suggestion of M. Charles Garnier, the committee for the monument which is to be erected by subscription to the memory of Alphonse, has chosen the environs of the Bois-de-Boulogne, and more especially the great avenue which leads to it. M. Formige, the architect who is to execute the work, has been instructed to study the spot, and choose the best site.—The death is announced of M. Villiers-Hussosier, painter and engraver, pupil of Paul Delarocbe. He received medals at the Salons of 1806-1834 and 1839.—On Sunday last in Paris there was a solemn inauguration of the new Roumanian Church, which was founded to be the old chapel of the Dominicans of the Rue Jean-de-Beauvais. This edifice, which

had been abandoned by the order from the time of their expulsion from France in 1882, has been entirely transformed and richly decorated.—The Minister of War has given up the idea of having a military hospital in the park of St. Cloud.—August is the last day for sending in designs for the competition for the erection of a Lion on the Square Jussieu, of the monument to the memory of Achille Testelin, who, during the Franco-German war, organised the national defence in the North of France.

VIENNA.—The municipal authorities have opened a competition for plans for the future arrangement and improvement of the city, including the extension of the drainage system, the regulation of the canal, the erection of warehouses, the building of railway lines, &c. The time granted to competitors is twelve months. Premiums will be given not only for "whole designs," but also for parts of the general scheme, points of detail, &c. The competitor does not require so much knowledge of the locality as outsiders might be led to believe. The plans obtainable with the "programme" would suffice.

CAIRO.—A competition for designs for a new drainage system has been opened. Some thirty candidates sent in work, and a jury consisting of a French, a German, and an English expert, after coming to the conclusion that none of the schemes submitted could be adopted unaltered, have now made a rough sketch of what they consider desirable. An Egyptian Government Department will now work out the proposed scheme in detail, and it is hoped that the excavators can be put into motion this winter. Some 12,500,000 francs are to be spent.

THE NEW MUNICIPAL BUILDINGS, BOMBAY.—The *Bombay Gazette* of the 7th ult. says that, with the exception of the central tower and dome, the masonry work of the new Municipal Buildings, Bombay, has long since been finished, and now the decorative work is being proceeded with. The general ornamental work is all Indian, being composed of Indian animals, birds, and foliage, all worked into fanciful designs in relief. The balcony over the main porch is flanked by two-winged Vanastha lions, rampant and holding between their paws weather vane, while over the council chamber a rampant lion holds between its paws a shield bearing the arms of the Corporation. (These lions, we understand, were carved by Mr. Harry Hens, of Exeter.) From the terrace over the third floor, the central gable on the front tapers to a point from which rises an allegorical female figure, 13 ft. high, representing "Urbs Prima in India," the latter being a circular panel bearing the arms of the Corporation. The lions are now all in position, and the statue of "Bombay" will soon be in position over the main structure with outstretched wings and holding aloft in her raised hand a full-rigged ship. It is intended to plant small gardens in front of the eastern and western wings of the building, facing respectively the Hornby and Churchwarden's roads, while the ground between the wings will be laid out with shrubs and flower-beds and will have a fountain playing in the centre. Almost all the carved work in the buildings was designed and modelled at the Bombay School of Art and executed by skilled Telugu carvers. The architect of the buildings is Mr. F. W. Stevens, C.I.E., F.R.I.B.A., of Bombay.

STAINED GLASS AND DECORATION.

WINDOW, NORTON CUCKNEY CHURCH.—A stained-glass window has just been placed in Norton Cuckney Church, Mansfield. It is the eastern window of the church, and contains subjects of the Baptism, Crucifixion, Resurrection, and Ascension of Our Lord. The work was designed and executed by Messrs. Warrington & Co., of London.

MEMORIAL WINDOW, MANCHESTER CATHEDRAL.—A new stained-glass window, which has been placed in the south side of the nave of Manchester Cathedral, to the memory of the late Dean Oakley, was formally presented to the Dean and churchwardens at Manchester Cathedral on the 26th ult. The window is a representation of the "Magnificat." It has been executed by Messrs. Barlow & Grylls, of London.

DECORATIONS AT HAWORTH CHURCH.—This church was re-opened on the 29th ult., after having been temporarily closed, chiefly for extensive mural, &c., decorations, which have been designed by Messrs. Powell Brothers, of Leeds. The whole of the walls of the chancel, nave, and aisles are painted in warm yellow tones, dispersed richly in colours and in intricate, but significant designs,—the cross, crown of thorns, Lily, &c. borders, and other ornaments being also carried around the arches, and other salient features in the architecture. In addition to this general ornamentation, the upper portions of the chancel walls are further enriched with groups of angels, some of which and some of the mural instruments; and similar angel attendants follow on above the large eastern window, whilst the spaces to right

and left of this window are devoted to the Evangelists. At the west end of the church a large wall space has been painted with a representation of Our Lord's entry into Jerusalem, and above the arch leading into the chancel is the final event on Mount Calvary. The spaces of this picture are almost life-sized upon a "flat" or "dead" gold background. Some considerable colour has also been introduced into the wooden roofs throughout, chiefly in the form of spots and hands of brilliant colour, with lines of pure gold. In most cases the girders and the principals end in shields, and advantage has been taken of this to introduce here a scheme of heraldic embellishment, embracing the arms of the principal sees, and of the colleges and halls of Oxford and Cambridge.

MISCELLANEOUS.

SALE OF BOOKS UPON ARCHITECTURE AND OTHER ARTS.—The library of Mr. Wyatt Papworth, together with other collections, was sold by auction a few days since by Messrs. Puttick & Simpson. The lots realised, as a rule, but low prices. Amongst those that fall within our own province may be cited the following:—Octavo size: J. Fergusson's "Illustrated Handbook of Architecture," 2 vols., and a volume of his "History of Architecture," 12. 6s. (George); J. G. and H. of Ruskin's "Modern Painters," 1831, 11. 4s. (Newton); the *Archaeological Journal*, 1844-91, in the original numbers, 5l. (Sotheman); vols. i. iv. of the "Antiquarian Itinerary," large paper, 1816, and others, 1l. (George); Jackson and Chatto's "Treatise on Wood Engraving," 1838, 1l. 1s. (Edwards); Violette-Duc's "Dictionnaire Raisonné," &c., Paris, 1854-68, 7l. 5s. (Quaritch); Ackermann's "Repository," the large series, 4l. vols., 1809-28, 9l. (Parsons); T. H. Turner's "Domestic Architecture in England," 4 vols., 1851, 2l. 11s. (Lugsher); Fergusson's "History of Indian and Eastern Architecture," 1876, 1l. 8s. (Batsford); and Knight's "Cyclopædia of London," 1851, Shepherd's "Astrolonch Improvements," with views, 2 vols., with other similar volumes, fourteen in all, 4s. (Farker). Quarto size: W. Smith's "Particular Description of England in 1588," with views, edited by Wheatley and Ashlee, a subscriber's copy, 12s. (Harris); two sets of Stothard's plates to illustrate the "Pilgrim's Progress," 1l. 11s.; J. O. Halliwell's "Ancient Inventories of Furniture, Tapestry, Plate, &c.; Illustrative of Domestic Manners in England in the Sixteenth and Seventeenth Centuries" (twenty-five copies, privately printed), 9s. (Harris); Morant's edition, being the third, of T. D. Whitaker's "History and Antiquities of the Deanery of Craven," 1878, 10s. (Bull); R. Ackermann's "Westminster Abbey," 2 vols., coloured plates, 1812, 1l. 10s. (Fawcett); his "Microcosm of London," 3 vols., 104 coloured plates by Pugin and Rowlandson, 1808, 5l. 7s. (Fawcett); R. & J. Brand's "Analysis of Gothic Architecture," 2 vols., 1847, 1l. 4s. (Batsford); A. Pugin's "Gothic Ornaments," with Harding's illustrations (and an autograph letter of Pugin inserted), 1831, 15s. (Massey); J. B. Papworth's "Select Views of London," coloured plates, scarce, 1816, 2l. (Fawcett); and C. Clarkson's "History, &c., of Richmond, Yorkshire," 1821, 1l. 10s. (Quaritch). Folio size; vols. 1. to 4. of the names of the "Verona Galleries of British Art," large paper, 2l. 17s. (Roche); J. Walker's "Minerant in Great Britain and Ireland," first edition, 180 engravings, 1799, 1l. (George); T. Chippendale's "Gentleman and Cabinet Maker's Directory," 160 copper plates, a fine copy of this scarce work, 1754, 14l. (Forrester); D. Wyatt's "Metal Work and its Artistic Design," many coloured and plain plates, 1852, 1l. 6s. (Quaritch); F. T. Dollman's "Priory of St. Mary Overie, Southwark," 1881, 6s. (Parsons); J. Gibbs's "Book of Architecture," 150 plates, 1728, 1l. 4s. (Batsford); A. Basso's "Compartmenti di Camere per uso degli Amatori," &c., 1827, 1l. 13s.; J. Fergusson's "Rock-cut Temples of India," and "Illustrations of Ancient Architecture in Hindostan," in one volume, tinted plates, 1845-8, 3l. 14s. (Batsford); "Diæl et Corvinius: Erste und Zweite Fortsetzung Herrlicher Garten und Furstgebäude," 92 plates, Augsburg, 6l. 17s. 6d. (Quaritch); the Domesday Survey, Record Commission Publication, 2 vols., 1783, "Inquisitio Eliensis, Liber Winton," &c., 4l. 10s. (Jobb); and "Churches of Moscow," some of the plates coloured, letterpress in Russian, an incomplete copy of a rare book, Moscow, 1850, 1l. 1s. (Batsford). Six pounds were bid for eighty-one original plates of Morland's sketches, with ten of Craig's landscapes, with animals, 1824; and a copy of Ainsworth's "Jack Sheppard," with portrait and plates by Cruikshank, 3 vols., first edition, 1830, was bought for 6l. 1s. (Horn).

EFFECTS OF THE ZONE RAILWAY TARIFF.—From an official report just issued on the working of the Zone tariff in Hungary during the two first years of its introduction, viz., August 1, 1889, to July 31, 1891, as compared with the two preceding years, we learn that in the former period 35,325,300 passengers were carried, yielding receipts amounting to 25,041,400 florins, as against 12,752,300 passengers and 19,660,700 florins respectively in the two preceding years. Thus there was an increase in the number of passengers of 177 per cent., and

in the receipts of 27 per cent. Of the former, 3,500,700 passengers fell upon the period August-December, 1889; 11,716,400 on the year 1890; and 7,358,900 on the seven months January-July, 1891. These increases show that further increases may be calculated upon. The directors of the Kaschau-Oderberg Railway, too, have issued a report, showing that even on this short line, running through poorly-inhabited districts, there is a marked increase of passengers and earnings since the adoption of the zone system.

PETERBOROUGH CATHEDRAL.—Mr. Hitch, whom we named last week as the sculptor of the pulpit at Peterborough, writes to say that the carving on the bishop's throne was his work also, as well as most of the figure work on the stalls.

PROPOSED DOCK IMPROVEMENTS, LIVERPOOL.—At the weekly meeting of the Mersey Dock and Harbour Board, held in the Revenue buildings, Channing-place, Liverpool, on the 2nd inst., commendation of the Committee of Works, to spend 180,000l. extra in the improvement of the Canada, Huskisson, and adjoining docks, for the accommodation of Atlantic liners and other large vessels, was again under consideration. Mr. Kennedy, Chairman of the National Steamship Company, said that, with regard to the width of entrance, he thought it desirable to give 100 ft. He was informed that the difference between that and the lesser width would only be 5,000l., and this, in an expenditure of 180,000l., was not worth considering. That ships of the future would be longer and broader he had little doubt, but that they would be deeper in proportion he had very grave doubt, and he thought it would not be well to spend more money on depth than was absolutely necessary. Ships would be deeper, but not in proportion to the increase in length and breadth of beam, and while he would be quite prepared to vote for the proposed expenditure, he should like that if the Committee, after further consideration, found the extreme depth unnecessary, they should have power to revise their opinion. The recommendation of the Committee was adopted unanimously.

MONUMENT TO COLUMBUS, NEW YORK.—The monument to be erected in the Central Park, New York, by the Italian residents of the United States, in commemoration of their countryman Columbus, is, we learn from the *Il Progresso Italiano*, almost completed. It has been executed at Rome, from the designs of Gustavo Russo, and will be conveyed to America in an Italian war-ship some time next month. The monument to be erected in the Central Park, New York, by the Italian residents of the United States, in commemoration of their countryman Columbus, is, we learn from the *Il Progresso Italiano*, almost completed. It has been executed at Rome, from the designs of Gustavo Russo, and will be conveyed to America in an Italian war-ship some time next month. The monument is 77 ft. high. The pedestal, consisting of terraced steps with four octagonal buttresses, is of red Italian granite. Against the second or die portion of the pedestal rest, on opposite sides of the monument, two figures, each 10 ft. in height, consisting of a winged statue of the Genius of Columbus contemplating the globe, and a carving of an Alpine eagle in an attitude of defending the top of the die springs a shaft of the same red granite, terminating in a capital of white Carrara marble, and surmounted by a statue of the great navigator, chiselled from red granite, and 12 ft. high. On the main base of the monument two bronze bas-reliefs, 10 ft. long by 2 ft. wide, represent "The First Sight of Land," and the "Landing on San Salvador Island." The shaft is ornamented with bas-reliefs in bronze of the prows of Columbus's fleet,—the *Pinto*, *Nina*, and *Santa Maria*,—and bears the inscription, "A. Cristoforo Colombo," also in bronze. The ceremony of unveiling the monument (the cost of which is not stated) will take place on October 12 next, fittingly to celebrate the 400th anniversary of the discovery of the New World; and also, we are glad to hear, in grateful acknowledgment of the Italians who have begun life anew, and made homes for themselves within the borders of the great Republic.

REREDES, BERROW, SOMERSET.—An oak reredos has been erected in the parish church here to the memory of the late Vicar, the Rev. C. R. Jervis Pearson. The architect, Mr. J. Houghton Spencer, sends us the following remarks on the symbols employed:—"The centre portion, which is raised above the sides, is divided into five arch-shaped enspiced compartments bearing early Christian symbols, carved in boxwood, standing in advance of diapered oak panels. The centre symbol is taken from the catacomb of St. Agnes, and is formed of the small-corned St. George's and St. Andrew's crosses combined, with the bow of the Greek letter 'rho' attached to the latter. The St. Andrew's and St. George's crosses, respectively corresponding to the Hebrew letters 'aleph' and 'tau,' occupy the extreme right and left panels, and the 'alpha' and 'omega' the panels next to the centre; the former alluding to the saying of the Rabbin, 'Ab Aleph Alpha and Omega, the beginning and the end.' The central symbol of the interlacing crosses before described, with the bow of the 'rho' attached to the St. Andrew's cross, or 'chi,' combines the Hebrew with the Greek idea by the evident allusion in this symbol to the Greek name of Christ, 'Christos.' Three equal-armed crosses, referring to the name of Christ, were employed in the centuries of the Christian era, and were continued in use by the Eastern Church, and preferred to the

* Two of 10,000 florins, three of 5,000, three of 3,000, and a number of minor ones having a total value of at least 23,000 florins.

form known as the Latin cross, which the Latin, or Western, Church, afterwards insisted upon employing, as being, so it is stated, a probable form of the instrument of His water-work.

SHERBORNE WATERWORKS.—The Local Board of Sherborne, Dorset, upon the recommendation of their Engineer, Mr. Thos. Farrall, have decided to adopt Jennings & Brewer's electrical apparatus to indicate and register in the engine-house of the waterworks pumping station the varying levels of the water in the storage reservoir.

CAPITAL AND LABOUR.

SETTLEMENT IN THE LONDON BUILDING TRADES.—We are glad to learn that at the conference between masters and men, representing all trades, held on Friday, the 10th inst., and to which we referred in our last, after a discussion of five or six hours it was agreed:—1. That the working hours in summer shall be fifty per week. 2. That during fourteen weeks in winter, commencing on the first Monday in November, the times for the first three weeks shall be eight and a half hours per day, during the eight middle weeks eight hours per day, and the three following weeks eight and a half hours daily. 3. That the present rate of wages for skilled artificers and labourers shall be advanced 1d. per hour. 4. That overtime, when worked at the request of the employer, but not otherwise, shall be, from leaving-off time until 8 p.m., time and a quarter; from eight p.m. until ten p.m., time and a half; after ten p.m., double time. No overtime shall be charged until a full day has been made, unless time has been lost through stress of weather. On Saturdays the pay from noon until four p.m. shall be time and a half, after four and during Sundays double time. Christmas Days and Good Fridays to count as Sundays. 5. The employers shall give one hour's notice, or pay one hour's money, on determining the engagement. All wages to be paid at the expiration of such notice, or walking time if sent to the yard. 6. That men who are sent to the shop or yard, or sent to the country, shall be allowed for their expense 6d. per day for any distance or for their expense from shop or job, exclusive of travelling expenses or lodging money. 7. That payment of wages shall commence at noon on Saturdays and be paid time at the rate of three miles an hour to be allowed so as to get to the pay table at noon. 8. That employers shall provide, where practicable and reasonable, a place to have meals in on the work, and a labourer to assist in preparing them. 9. That the wages earned after leaving off time on Fridays and Saturdays only, shall be kept in hand as back time. 10. That the term "London district" shall mean a twelve-mile radius from Charing-cross. 11. That six months' notice on either side shall terminate the foregoing resolutions, to expire on the first Monday in November. The foregoing resolutions shall come into force on the first Monday in November next, but the increase of pay to bricklayers shall commence on July 1 next.

THE STRIKE IN THE CARDIFF BUILDING TRADE.—The arrangements made between the Master Builders' Association and the carpenters and joiners, through the general secretary, have fallen through, the masters refusing to discharge men who were employed by them during the strike, and who do not belong to any union. The masters have now withdrawn their offer of an advance of 3d. per hour.

MEETINGS.

- MEETING, JUNE 18. Liverpool Engineering Society.—Excursion to Thirlmere Aqueduct. Glasgow Architectural Association.—Visit to Largo. Dundee Institute of Architecture.—Excursion to Perth and Stone Palace. TUESDAY, JUNE 21. Society for Preserving Memorials of the Dead.—Tenth Annual Meeting, Bishop's Stortford. WEDNESDAY, JUNE 22. Society for Preserving Memorials of the Dead.—Tenth Annual Meeting (continued). FRIDAY, JUNE 24. Institute of Certified Carpenters (Carpenters' Hall).—Monthly meeting 7.45 p.m. SATURDAY, JUNE 24. Edinburgh Architectural Association.—The Sketching Class to meet at Royston House, Carolina Park, Granton, to make measured drawings and sketches of the south front of the mansion. 3 p.m.

RECENT PATENTS:

- ABSTRACTS OF SPECIFICATIONS. 10,177.—DOOR-SPRINGS: T. & W. A. Starkey.—This specification refers to an improvement in springs for closing doors by means of an ordinary spiral spring, with suitable ends attached, which may be of any metal adapted for the purpose. The inventors take an ordinary spiral spring, one end being fastened firmly to the door-jamb, the other end fitting to a circular collar or disc, having ratchet teeth formed on its face, which closely fit into another disc fastened to the door, and by means of a lever in the form of a wire pin placed in holes on the side, the upper disc is turned so as to uncoil the spring. Thus the teeth, by rising over each other, pass round and increase the pressure the spring exerts on the ends which are attached to it. 10,152.—DOOR-FASTENINGS: A. Hodge.—This patent relates to an arrangement of the key to act on, also available for use by means of a bolt, having no metal. The invention comprises:—firstly, the arrangement, or teeth suitable for friction or gearing surfaces, in or on which the key or pin fits; secondly, the addition to the hearing frame or case of the bolt of bearing parts, or one or more journals, formed at the part or parts where the key or pin fits; thirdly, the addition to the hearing frame or case of the bolt of a device, as above mentioned, that involves the bolt as alternately to free and replace the turning or revolving the key in or on its bearings, and in fact as a gear or pinion to slide the bolt longitudinally.

10,994.—PORTABLE BUILDINGS: G. Epitaller.—The object of this invention is a new type of building, constructed entirely of cardboard, cellulose, or other compressed substances, with the introduction or insertion into such substance of a sheet of metal, thus increasing the rigidity, and requiring that the thickness of the various substances should be only a few millimetres. This new type of building, while presenting the various advantages of similar structures, is said to be capable of being very easily moved in consequence of the lightness of its parts and the facility with which it can be erected.

6,091.—SEWER VENTILATION: H. E. Newton.—The object of this invention is to ventilate sewers from their lower grades, and at the same time destroy by heat any deleterious sewer gases and the germs contained therein. This is effected by means of an appliance of peculiar construction, fully described and figured in the specification, placed near the base of an uptake shaft, by which the objectionable gases are drawn by the action of the apparatus. The uptake shaft is bulbed at a certain height, so as to form a chamber containing the ventilating apparatus. Within this chamber is placed a perforated spherical shell constructed of firebrick, or other material that will resist intense heat, its upper part being formed as a lid. A perforated false bottom covers the bottom part of the interior of the shell, forming a chamber below the false bottom, to receive a Bansen or other gas-burner, the air being supplied to the burner from without the shaft. The space within between the false bottom and the cover is loosely packed with asbestos.

6,654.—ROOFING TILES: O. R. Westhead.—This invention relates to roofing tiles having a free surface of a symmetrical shape in the longitudinal direction of the tile. The free surface can, therefore, be either of regular hexagonal, elongated hexagonal, square, or rhombic form, the longitudinal direction going along a diagonal. The tiles do not lie loose upon each other, as has hitherto been the case, but are provided at the under side with ribs along half their periphery, the ribs being adapted to engage in corresponding grooves near the upper edges of the tiles placed beneath.

NEW APPLICATIONS FOR LETTERS PATENT.

- May 30.—10,256, J. Gordon, Sash-fasteners.—10,245, J. Vocs, Lead Lights.—10,253, J. Turner, Seasoning or Preserving Wood.—10,272, W. Oxford Municipal Buildings Competition.

THE erection of new Municipal buildings in a city like Oxford,—a city of such special character and association both in a historic and an architectural sense,—is an event of more than usual interest. Although the project is solely that of the Municipality, and does not in any way directly concern the University, one cannot but desire that so important an addition to the old and stately University town should be such as will be in harmony with its surroundings, and be not merely a convenient building for the transaction of municipal business, but an architectural addition to one of the most architecturally beautiful cities in the world. It is gratifying to find that the final competition for the Municipal buildings at Oxford shows at least a possibility of the combination of both elements, the practical and the architectural.

As our readers will remember, this is a competition on the dual system, a sketch competition first and a second trial of strength among a limited number of selected competitors afterwards, which is so much the fashion in France, and has lately been adopted in a good many instances in England; the architects in the second competition, in this as in most similar cases, receiving each a fee for his work. The present competition suggests the question, on which it is worth while to say a word, whether this duplicate system presents sufficient advantages to render its adoption desirable as the normal system of architectural competition. A good many architects object, and not without reason, that it is in reality inflicting double work on the best competitors. This objection would hardly apply, perhaps, if the word "sketch" were interpreted in a more literal sense. If the first set of plans were no more than is generally understood by that word, no doubt a large number of competitors would be saved the vexation, inherent in the ordinary form of competition, of having thrown away much time and labour on getting up a com-

plete set of drawings on a chance which has brought them no return. But competitors themselves will hardly allow of this interpretation. Each competitor hopes to attract attention to his first set of plans, and possibly to surpass others, by putting a good deal of work into them, and turning out a more or less finished set of drawings on a small scale. In the present competition the original sets of drawings in the first competition are (very rightly) hung along with the completed sets. We have thus a direct opportunity of comparing them, and it is obvious at once that the plans at all events might just as well have been selected on the basis of the first as the second competition. The scale is the same in both ($\frac{1}{4}$ in. to the foot), and except that the second set are in most cases rather more neatly and carefully drawn than the first, there is little difference between them, and either would do equally well as a basis for classifying them according to merit. One or two of the plans have, it is true, been materially altered and improved in the second edition (the competitors having been allowed full liberty in this respect), but these improvements do not affect the relative merit of the different plans, and could just as well have been developed (as they no doubt would have been) in making the working drawings; so that as far as plan goes the result is merely that the selected architect has to make out his plans three times instead of twice. In regard to the elevations the matter is different. In the first competition the elevations were to the same scale as the plans, in the second they are to double the scale; and the comparison of the two sets of elevations shows forcibly how much easier it is to produce a decent and attractive-looking elevation on a small than on a large scale. Among the five designs there is only one (No. 5) in which the small scale elevation does not produce a far more favourable impression than the large scale one; an elevation which seems picturesque, well-filled, even rich in effect, on the small scale, looking comparatively thin and hard on the large scale, and the detail in some cases not bearing out the promise given by its rougher indications on the smaller scale. Perspective drawings, from a point of view fixed by the instructions, are required in

the second competition; but there is only one instance (No. 2) in which the perspective gives a better or more favourable idea of the design than was afforded by the first set of sketches. The small-scale sections of the first set show all that was required to form an opinion as to the treatment of the interior; and therefore the conclusion is that the whole competition might have been as well settled on the basis of the first set of small scale plans and sections and one large-scale elevation, and would have come probably to the same result in the final selection. The Corporation could still of course have remunerated the five best competitors, and 100%, or 2 per cent. on the estimated outlay of 50,000*l.*, is certainly not an extravagant premium for any set of sketch plans which merit serious consideration, without the extra labour of preparing a second set.

The Corporation undertook to select from the first set of sketch-plans a number not exceeding five for the second competition, and have selected the maximum number. The scheme of the required building includes a large Town-hall or music-room; a smaller Assembly-room to be used for meetings for which the Town-hall is too large, or as a supper room when the Town-hall is used for a ball; a police department, with a large parade room in addition to charge-room, cells for prisoners, and other usual requirements; a Sessions Court with its necessary rooms for judges, jurors, barristers, witnesses &c.; Municipal Offices, Council Chamber, Mayor's Parlour, Committee-rooms, and offices for City Engineer, water, rates, Medical Officer, pay office &c.; and the usual offices, kitchen, scullery, porter's room &c. The scheme also includes a public library to form part of the building architecturally, but to be separate from it and self-contained in regard to plan. The site is a difficult one to treat, as it presents only two street frontages, a principal one to St. Aldate-street and a side one to the narrow Blue Boar-lane; the rest is hemmed in with houses and a good deal encumbered with rights of light, so that the use of internal courts for light is a necessity. The principal entrance must naturally be in St. Aldate-street; and as the existing Town Clerk's offices at the north-west angle of the site are to be retained and to communicate

with the new buildings, this approximately fixes the position of the Council-chamber and Mayor's parlour, which ought to be within easy reach from the Town Clerk's office; while the library site is fixed, by the instructions, at the south-west angle; at least it is strongly recommended that it should be there, and all the competitors have adopted the suggestion.

We will offer a few remarks on the designs, taking them in the order of numbering. No. 1 arranges the parade-room and police department on the ground floor in a large central block running west and east (i.e. at right angles to the principal front) and the Town-hall partly over the parade-room; the library forms a long block along Blue Boar-lane with the assembly-room over it. This lane forms an obtuse angle with St. Aldate-street, so that there is a little contrivance desirable to make a good joining of the two façades; in this case the oblique line is stopped short before reaching the angle and set back to a line at right angles with St. Aldate-street, the re-entering angle being filled up with a staircase turret. Between these two blocks is a long irregular courtyard with an entry from the street, from which courtyard is the entrance to police department, Sessions-court, and stairs to the Town-hall gallery; the Sessions-court is on the first floor in the rear of the Town-hall. This courtyard loses a good deal of space and is not otherwise a good arrangement. There are two entrances in St. Aldate-street, one near the library, beside which is the stair to the assembly-room, the other near the other end of the front, and a corridor runs parallel with the front, with a cross corridor from the entrance, leading to the principal staircase. The Council-chamber is properly placed, internally and near the Town-clerk's offices, on the first-floor; the principal committee-room opens out of it in the interior part of the building. But though the main departments are arranged in good relative positions as regards one another, the whole plan wants system and has mistakes in detail; e.g. the position of the ladies' and gentlemen's cloak-rooms, with the doors close to each other and directly facing the assembly-room doors on the other side of the corridor, is absurd. The engineer's drawing-office faces St. Aldate-street and has a west light (slightly south-west) which is not good, but three out of the five competitors have made this mistake. The design is of a late Gothic character: the Town-hall front or end is somewhat recessed and has a large traceried window, with lower buildings forming a screen in front of it; the small scale elevation is very prettily sketched and looks well, but the large one shows but commonplace detail, and the perspective is almost puerile in manner and execution.

No. 2 is far superior, and we should rank it as the second best of the five, in design if not in plan. Here the library is treated also as an oblique block parallel with Blue Boar-lane, but wider than in No. 1, and the Town-hall placed over it; the assembly-room is on the first-floor in the middle of the principal front, that and the large committee-room giving three large windows as the main feature in the central block parallel to St. Aldate-street. The connexion between the oblique blocks and the front is well managed, the library block being returned at right angles to its flank, but provided with a very large segmental bay window the lines of which serve to divert the eye from the change of angle between the two portions of the building. The principal entrance is in the middle of the St. Aldate-street front, and from this a long corridor runs as a backbone to the very back of the building, leading on the first floor to the Sessions-court block in the rear, the public entrance to which is from Blue Boar-lane, behind the library. The parade-room is on the basement under a glass roof, over which on the other stories is a large area for light. In respect both of areas and corridors the plan is wasteful, and the aforesaid front-to-back corridor is a promenade which might have been avoided, and makes the Justice's room (if he is supposed

to enter at the principal entrance) a kind of *ultima Thule*. A broad cross corridor runs parallel to St. Aldate-street, and on the first floor a fine use is made of this, which is treated as a state corridor lined with columns and connecting the council-chamber and Mayor's room at one end with the Town-hall at the other, while the assembly-room and large committee-room also open out of it, so that for a large fête the whole are connected by this columned corridor. Unfortunately, the ladies' and gentlemen's cloak-rooms also open direct out of the same corridor; a great blunder. The front also is not the best place for a committee-room, nor, as before observed (though for another reason), for the engineer's offices. The design is a freely-treated Gothic, with a mingling of classic feeling in some details: the effect is got mainly by the arrangement and treatment of the windows, with little decoration. The end of the Town-hall facing St. Aldate-street is treated as a large gable with an effectively designed window, and a very good feature is the treatment of the flank of the library and Town-hall. On the elevation the library front appears a mass of large windows, but these are grouped under lofty wall-arches in such a manner as to have a satisfactory and sufficiently solid effect in perspective. Corresponding to the piers of this large wall arcade are internal buttresses which serve as nuclei for bookcases, and the inner ends of which carry the columns of the side galleries of the Town-hall above, and a kind of clearstory wall which rises above and behind the library wall, and is connected with it by deep buttresses with bold scroll consoles at the top. This treatment of the flank is a very good bit of subsidiary architecture. The perspective, a pen and ink drawing touched with a light and free hand, has an exceedingly picturesque and characteristic effect.

No. 3 covers the ground very much, leaving very small areas for light; in other respects the interior lighting is cleverly managed, but the areas would be very like wells. The Town-hall is arranged parallel to the principal front, with complete corridor communication all round it, but the advantage is rather discounted by the fact that the principal staircase is not sufficiently central, in relation to the Town-hall, for access to these corridors, being near the north-west angle of the Town-hall, and visitors would have to circulate all round the corridors to get access to the further side of the large room. The Sessions-court stairs from Blue Boar-lane would no doubt afford an additional access, but it is not convenient at a large gathering to have two different street entrances for the same portion of the audience. The provision for internal communication by this arrangement of corridors is very complete but somewhat circuitous in character, and the corridors run away with a good deal of space. The author has divided the levels on his section, placing the Council-chamber and Sessions-court on the principal front, half-way above the Town-hall floor level, and divided by the principal committee-room, which projects in the centre of the front, and is connected with both so as to make a suite. This might be convenient on occasion, but the rooms are too high up in the building; the placing of the assembly-room on a different level from the Town-hall would materially interfere with its proposed use as a supper-room in connexion with a hall, and the council-chamber and assembly-room are too distinct in their uses and functions to be properly placed as pendants to one another in either plan or design. Moreover, the front to the principal thoroughfare is not the place for council-chamber and committee-room, in which quiet is especially desirable. The Mayor's parlour, on the other hand, might better have been placed facing the street, so as to have an outlook, instead of looking only a small interior well. The Sessions-court department is arranged behind the Town-hall, with external access from Blue Boar-lane. On the ground-floor is marked a gentlemen's lavatory and cloak-room for Town-hall receptions, which is well placed, but we failed to discover

any similar provision for ladies. The elevation is Gothic with a character of detail which seems to have been intended for terracotta; if so, we have another example of the fact that the contemplation of terra-cotta is a temptation sometimes to the use of a rather exuberant character of detail; the heads of the window-lights, for instance, are decorated with small inverted carved scrolls or consoles, one on each side, with a pendant in the centre, which is rather too much for the situation; it makes a bad line for the head of the light, and has rather a pie-crust appearance. The perspective is carefully but somewhat heavily executed, and does not aid much in recommending the design. The author has made a considerable change in the disposition of the plan since the first competition, in which the Town-hall was placed east and west, and is now turned round, as observed, parallel with the principal elevation; the alteration is a distinct improvement. The space allotted to the library seems rather small.

The author of No. 4 has been evidently aiming at a design of "Oxford character," as shown especially in his short square staircase tower with heavy pinnacles at the angles and a lantern connected with them by flying buttresses; the upper portion of the tower is decorated with blank tracery. The entrance, however, is badly managed; for some inexplicable reason the actual entrance, to north of this staircase tower, is masked by a screen wall ending in a pier like a gate-pier, and the actual setting-down place in the street is at some steps in front of the staircase tower, so that people alighting from carriages would have to walk from what may be called the entrance gate, round the angle of the staircase tower, to get under cover in the entrance. Imagine how people would bless the architect for this when there was a large entertainment on a rainy night! The library is placed to the south of the staircase tower, turned more towards the principal front than in the other designs, the parade-room behind it, with the end towards Blue Boar-lane, and the Town-hall over the parade-room. As the platform of the Town-hall room is at the inner or north end of the hall, this brings the main staircase and the platform end in close contiguity, which is not what is wanted; the main staircase should adjoin the public end of any large entertaining-room: the platform should have been put at the Blue Boar-lane end, with its own entrance from the street for those whose place is on the platform. The council-chamber and Mayor's room are well placed, the former within the building parallel with the main front, the latter on the other side of the corridor, on the main front; the principal committee-room is cleverly got in off the corridor which leads to the Sessions-court at the back of the building, but it is thus a long way from the Town Clerk's offices, which is not convenient. The engineer's offices are placed with a north light, looking towards an internal area to the north of the new buildings. The assembly-room is on the second floor, reached from the central staircase tower, and with a small reception or ante-room between it and the stairs: in view of the point in the instructions already referred to, as to the use of the assembly-room in connexion with the Town-hall, this is a worse position than in No. 3, as it is a whole story above the Town-hall floor instead of half a story. The design may be called Collegiate Gothic, with mulioned windows, with niches between them on the principal floor; there are some characteristic bits of detail, such as the treatment of the roof-balustrade, but the details generally seem rather large and coarse in character, and show an uncertainty as to scale; for instance, the traceried window in the lower part of the tower, which lights the staircase, gives the impression to the eye of being much smaller than the scale shows it to be by measurement. The perspective is a slight but cleverly executed pen sketch which looks well, but in which detail is merely indicated in the roughest manner.

No. 5 is the only really first-class plan of the set, and is one of the best arranged plans

we have ever seen in a competition. The arrangements for internal communication are admirable and most compact, with no waste of space in needless corridors; indeed, almost the only fault we should be disposed to find with the plan is that one or two of the corridors (or at all events one,—that leading to the Sessions-court department from the central cross corridor) are insufficient in width; they are barely five feet in width by scale. This only applies, however, to a small portion of the plan. The central entrance in St. Aldate street leads to a square central staircase hall with a staircase with a central lower flight and side return flights above, the ladies' and gentlemen's cloak-rooms are placed on the ground floor with their respective entrances on either side of the lower flight of the staircase, which projects slightly into the hall: this is the only plan in the collection in which this important detail is properly arranged. The water and rates offices are placed in the front to left of the entrance, the latter close to the entrance, as it should be; the engineer's offices are cleverly planned in the same position as in No. 4, with a north light for the drawing office. The ground plan is cut in two by a corridor separating the front from the back portion and entered from Blue Boar-lane, which corridor forms the public access to staircases to the public galleries of Town-hall, Sessions-court, and Council-chamber, which are thus contrived so that one street entrance serves for all. The entrance to the library is at the south-west angle, with an angle turret over it making a feature in the design. This corridor runs at right angles to Blue Boar-lane and therefore obliquely across the building, and behind it the line of building is turned obliquely to the line of the principal frontage. The central portion of the ground floor here is occupied by the parade-room. On the principal floor the Town-hall occupies the position over the parade-room and extending forward over the public corridor before mentioned. The entrance wall of the Town-hall room is very cleverly treated with projections and a large alcove towards the central hall, so as to mask the turn in the line of building and bring the rear side of the central hall parallel with the front side. The Sessions-court department is between the Town-hall and Blue Boar-lane, and connected with the central hall by a corridor, the one which we referred to as being too narrow; but as after all this corridor is only for official communication with other parts of the building (the Sessions-court having its own access from the street), perhaps it is sufficient for its real purpose; it looks rather cramped on the plan. The Sessions-court has its own small central hall out of which the various rooms open, and the justices' room is reached by the other narrow corridor running towards Blue Boar-lane from the central hall, leading to a private room overlooking the lane and outside the Sessions-court department, but opening into the court. The assembly-room is in the centre of the main front, opening from the central hall, and adjoining it a short corridor leads to another small square lobby from which open the doors to the council-chamber (over the engineer's offices), the committee-room in front of the building, and the corridor leading past the door of the Mayor's office (in front) and to the Town Clerk's office, (the Town Clerk and Mayor thus being in immediate contiguity, and the council-chamber department arranged *en suite* in connexion with its own lobby or vestibule, shut out from the more public part of the building but easily reached from it. The central hall is not over large and runs away with no unnecessary space, and the manner in which everything is grouped in connexion with it cannot be too highly praised. There is a little drawback in having the committee-room facing the street, that is the only criticism that can be made. Another committee-room opens out of the passage to the justice's-room, and this being intended also to serve as a grand jury-room when wanted, its door faces the passage to the Sessions-

court department. The manner in which almost everything seems to have been got just into its right place on this difficult and confined site is a triumph of planning, and must have cost the author no little trouble and thought.*

The elevations are in a style partaking a little both of the Jacobean and Elizabethan manner; the St. Aldate-street front is symmetrically treated; the centre block has three large windows between pilasters which mark the assembly-room; the corbelled-out bay-windows of the Mayor's-room and principal committee-room are balanced by similar windows to the library on the other side. The Blue Boar-lane front is simply treated, but a pleasing architectural point is made by an arcade of three large arches on the ground story, the wall behind being set back a little; through one of these is the public entrance to the Sessions-courts, &c., through another the entrance to the basement. The principal front is finished with gables over the bay-windows, decorated with colonnettes and ornamental features belonging to the style, and a larger gable in the centre treated in a similar manner; the feature in the centre of this is too *rococo* in style, and would bear paring down a little; it is in character with some old work in Oxford, but we do not see why old detail which is in a corrupt taste should be repeated now. The gables on the side portion also, though they have windows which light attics, have a little too much the appearance in the perspective view of being carried up for ornament only, in the upper portion at least; for which also, no doubt, there is plenty of precedent.

The front of this design looks rather costly in comparison with others; but apart from that point, which of course will have to be considered, there can be no question between this and any other set of drawings sent in. As far as plan is concerned no other can be considered in the running with it; as far as design goes No. 2 has the merit of producing a very picturesque building at probably less cost, and is a design which we should be very glad to see erected, as architecture, though it cannot have the dignified effect of No. 5. We may add that the drawings in the latter set are beautifully executed, but we do not know that they owe any special advantage to that fact; the incontestable superiority is in plan, in which drawing does not count.

The promoters of the competition made one mistake, in not attaching the architects' reports to the drawings; on which account it is impossible to understand what the several architects propose in the way of ventilation, which cannot be sufficiently indicated on plans and sections except when detailed to a larger scale. This is a serious omission; the architect's report should always be appended to competition drawings when public criticism is invited. On the other hand we must praise the Corporation for their commonsense in putting up the designs for public criticism before they had made their final selection. Generally speaking, one is only invited to criticise competitions after the selection has been made, and when in consequence it is too late for criticism to be of much practical value. As at present intended, the final decision will be made at the Council meeting to be held on the 29th of this month.

THE ENGLISH IRON TRADE.—The approach of the General Election, and the uncertainty which generally precedes the usual quarterly meetings, are not conducive to a considerable augmentation of business in the English iron market, and the condition of trade shows but little amelioration. In Cleveland there is a slight improvement noticeable in the demand, and most of the furnaces are again in blast. The hematite pig-iron trade is also a trifle brighter, on account of an increase in the consumption by steel-makers. Generally, however, the crude-iron branch remains quiet, and manufactured iron continues dull. The steel trade is a trifle better, and the inquiry for tinplates is still fair. Shipbuilders and engineers exhibit little alteration. The coal trade is fairly brisk.—*Iron.*

*There can be no doubt of the authorship of this design; but we do not choose to suggest names as long as they are still officially private.

THE FURTHER REPORT OF THE COMMITTEE ON TOWN HOLDINGS.

IT is to be regretted that the final report of the Committee of the House of Commons on Town Holdings, which was appointed for the first time in 1886, and has been reappointed during succeeding sessions, has been issued when the country is interested in little else than the General Election. Politicians who should study this report will be wholly concerned with the register of electors, and a document of considerable value is likely to be passed over without the full attention which should be given to it. The main point to which the present report refers is that portion of the reference to the Committee which was concerned with "the question of imposing a direct assessment on the owners of ground-rents and on the owners of increased values imparted to land by building operations and other improvements."

A primary reason for taxing any kind of property is that it has hitherto escaped taxation, and is a proper subject for taxation. It has been shown over and over again that things should not be taxed if the obtaining of the money is a cause of difficulty and annoyance. As regards ground-rents and ground landlords, it has been contended by all reasonable men that they are indirectly taxed; that is to say, though the occupier is the person who pays the tax to taxgatherer, yet, in consequence of the law of supply and demand, the ground landlord pays his share indirectly. In other words, it has been contended that he is already taxed. The Committee agree with this view, as will be seen from the following extracts from their report:—

"The idea that ground-rents are a class of property which at present escapes assessment for the purposes of local taxation is, of course, quite erroneous. The basis of all rating is the whole annual value of the building and of the land on which it stands, regarded as one entire property. In the ordinary case of a house subject to a ground-rent, and let by the owner to the occupier at a rack-rent, the several interests of the ground landlord, of the owner of the house, and of the occupier, constitute together the subject-matter of an assessment which is made upon the property as a whole. There appears to have been a popular impression that ground-rents constitute a subject-matter of assessment hitherto untouched, and that a new fresh source of revenue for local purposes would be "tagged" by imposing a direct assessment on such ground-rents, in addition to the present assessment of the whole property. But this view was found not to bear examination. It was soon seen that the assessed value of the house includes that of all the various interests above enumerated, and that to put a direct assessment on the ground-rent in addition to the existing assessment of the house, would be to rate a certain portion of the value twice over. This would result in an obvious inequality in the burden of taxation as between different properties. Thus in the case of two houses of equal value standing side by side, if one were leasehold and the other freehold, the leasehold would bear a larger share of local taxation than the other, as, in addition to the rate on its entire value paid by the occupier, there would be a further distinct rate levied on the ground-rent."

The actual conclusion is, perhaps, more concisely stated in the following paragraph from another portion of the report:—

"Upon the whole, the conclusion we have arrived at is that in the inception of the ground-lease allowance is made on account of the existing and contemplated rates, and that the amount of such allowance is deducted from the ground-rent, which might otherwise be charged, and that to the extent of such allowance the owner of the ground-rent indirectly bears the burden of rates, in the sense that if this burden were remitted he would be able to obtain a ground-rent increased by the amount so allowed for. Similarly, the house-owner gets from the occupier a lower rent than he would have obtained if it had not been for the obligation undertaken by the tenant to pay the rates."

The Committee then proceeds to consider whether the present occupiers have to bear new and unexpected burdens, that is to say, whether they are burdened with charges which were not contemplated when they became tenants. The result is thus stated, "from these various considerations we conclude that the number of present occupying tenants who entered into their bargains here

the rates now said to be new and unexpected burdens were first imposed must be very small." The result of the inquiries of the Committee thus shows that occupiers are not the illused persons which some individuals are continually declaring them to be, and it is equally clear that the case for any taxation of ground-rents and ground landlords wholly fails. But with a considerable want of logic the Committee, nevertheless, propose a change, for they recommend in their summary that, "Under all future contracts, local taxation shall be equally divided between occupiers and owners, and that each owner should have the right of making a proportionate deduction from his superior landlord." We have already pointed out that the Committee find that the ground landlords at present bear a share of local taxation. Why, then, is the recommendation made? Because, say the Committee, "it is desirable that the real and apparent incidence of local taxation should be as far as possible identical." This reason does not, in our judgment, warrant the making of so large a change which is thus described in greater length.

"We are, however, of opinion that it possessed some advantages of great practical weight. It will impose a portion of the rates, in the first instance, and ostensibly, on the persons who already bear a part of the real burden; it will reduce the importance of the difficult questions arising in connection with the 'shifting of taxation,' and the still more difficult question how far such doctrine is limited by the various causes known as 'economic friction.' It is not easy to make the abstract reasonings of economists, however well founded, clear to the minds of the great masses of those who have to pay rates; and, in our opinion, the change would do much to remove the sense of injustice which, whether rightly or wrongly, is no doubt at present very widely entertained, by making it clear that at least some share of the local rates is paid by owners."

The change will necessarily involve owners of ground-rents in uncertainty as to the annual amount which they will receive, and it will cause many practical inconveniences. Moreover, the Committee admit that when a new class of direct ratepayers is created they must be represented on local bodies administering rates. They pass airily over a difficult question by stating that, "We see no insuperable difficulty in framing a scheme by which the right to vote could be claimed by those owners who are liable to pay their share of the rates under the new system." The difficulty may, indeed, not be insuperable, but it is a substantial difficulty, and one not easy to overcome. Surely, therefore, seeing that this change is only proposed to remedy an imaginary and not a real grievance, the game,—to use a colloquial expression,—is not worth the candle. The change is not required in the public interest, and we do not believe that the Legislature will ever sanction it, having regard to the fact that the Committee, on their own showing, are unable to prove that there is any real sound and pressing reason in its favour. To enter into the reasons advanced by the numerous witnesses for and against the change would be useless; what we are concerned with is the finding of a semi-judicial body; a finding which has also been arrived at by the great bulk of reasonable and clear-headed men. It has further to be borne in mind that, in some senses, the ground-landlord and the receiver of the rack-rent by no means benefit, except infinitesimally, in the result of the expenditure of rates. "It is difficult," say the Committee, "to point out the pecuniary benefit conferred upon owners by the ordinary current expenditure of the community on such purposes as the cleansing, lighting, and watering of streets, the relief of the poor, or public elementary education."

"On the other hand, speaking generally, expenditure upon public improvements of a permanent or remunerative character, such as the construction of new thoroughfares or new systems of drainage, the erection or freeing of bridges, or on other similar works, undoubtedly benefits owners as well as occupiers, but the extent to which all such owners derive a benefit from this expenditure varies greatly according to the proximity of their reversionary interests. The owner of a reversion ninety years distant or more (and consequently of no actuarial value) would derive no appreciable advantage from a great public work, whilst the

same work might confer a substantial pecuniary benefit upon the owner of a reversion falling in within twenty years or less, and, of course, all sorts of cases intermediate between these two may and do occur."

Therefore, seeing that both the rack-rent and the occupier have, in making their bargains with their respective lessors, taken into consideration the general incidence of rates in calculating the ground rent and the rack-rent respectively, it would appear from the foregoing extract that, if anything, it is the rack-renter and the ground landlord who have reason to complain, rather than the occupier. Upon no single ground, at any rate, does the Committee find any reason for a change in the present system of taxation, except upon the purely sentimental one of making the actual incidence of local taxation more plain to the community at large.

We have said enough to make this portion of the report plain to all our readers. It is time to say a word on another part of it, which touches on the taxation of vacant building land. This is one of these specious proposals which, until they are submitted to a close examination, appear to have some merits. The Committee analyse the arguments and reasons, pro and con, with so much levity that it is impossible to give anything like a *precis* of them. It must suffice to state that the proposal to tax vacant building land is rejected in its entirety. It is said that by taxing vacant land of this kind more of it must be forced into the market, so that the rent of town houses would be lessened by the supply being enlarged. But the answer to this is that as soon as land is really "ripe," the owners put it on the market. There is no advantage in keeping it vacant longer than is necessary. Moreover, there is an initial difficulty. Before vacant building land can be taxed, the question has to be answered,—viz., "What is vacant building land?" A moment's thought will show the difficulty of the question. For example, is a pleasure-ground or large garden vacant building land? Again, say the Committee, "Great difficulties must arise, as all land near towns grows imperceptibly into building land," and thus it is difficult to define the time at which land can be said to become building land. Again, also, the Committee can see no distinction between vacant land and empty houses, and if a measure to tax the former becomes law, it must be followed by one to rate the latter. In the result we therefore have these conclusions arrived at:—

"As regards the argument drawn from the benefit to vacant building land from public local expenditure, it does not appear to us that so much of the expenditure as is devoted to current purposes can have any direct effect in increasing the value of such land, nor is such expenditure undertaken with any such object. The purpose of such local expenditure is, as it appears to us, the benefit and convenience of the inhabitants. As regards permanent improvements, it must be borne in mind, as pointed out by some of the witnesses, that streets and sewers are generally constructed at the expense of the persons interested in the land they are designed to develop, and, as regards improvements of a more public character, such as embankments, bridges, and parks, although, no doubt, they benefit the immediate locality, we do not think that the vacant land within the municipal limits can be said generally to derive any appreciable benefit, such as to form a valid ground for imposing special taxation."

Further, the Committee point out that such taxation would not benefit the working classes by enlarging the supply of houses; they show that it is a tax on capital, and is at variance with all received axioms of taxation, and would be most difficult to levy, and they, therefore, reject the proposal. Thus they throw over the suggestions, of which a good deal has of late been heard, to tax the "unearned increment," a principle which could not be confined to one species of property, and upon which economists of high authority differ. Moreover, it is important to bear in mind that what may be termed extraordinary methods of raising money for the purpose of local expenditure can at the best only be justified,—if, indeed, they can be justified,—because there are either no other more legitimate means of taxation or because the in-

crease of taxation is very great. But a return procured by the Chairman of the Committee shows that out of the fourteen most important towns in the country the rates have risen in the pound in seven, and fallen in six. In London the rate has risen, but if in Manchester and Newcastle it has fallen, has its rise been legitimate in the Metropolis? In other words, the true course for municipal and local bodies to pursue is to endeavour by economical and efficient administration to keep down the increase of rates, rather than to seek new methods of raising money. Be that as it may, the report, of which we have given some of the most important points and conclusions, shows clearly that many of the methods now suggested for raising fresh local taxes cannot be justified.

OLD PICTURES AT THE BURLINGTON CLUB.

THE collection, at the Burlington Fine Arts Club, of pictures "by Masters of the Netherlandish and allied schools of the XV. and early XVI. centuries" is a really remarkable one in regard to the interest and power of many of the works contributed, some of them bearing the names of artists who are at all events not popularly known, and some of whose works will surprise many to whom the names of the painters are not very familiar. But in another sense the collection ought to be interesting to those who are interested in architecture and decoration, for many of the paintings contain, in the costumes of the figures, splendidly-executed designs for textiles, and not a few of them illustrate the architectural ideas of the day in the buildings which form backgrounds to the scenes represented.

Among the paintings which are remarkable for their adjuncts none is more so than the painting of "St. Jerome in his Study" (7A) by Antonello da Messina, of whom the catalogue note says, "date of birth unknown, but may have been early in the fifteenth century." This is a truly remarkable little painting, not only in regard to the fine painting of the figure seated in the back part of the interior with side face to the spectator, and the light fall upon his expressively and powerfully-painted head, but also in the extraordinary elaboration of all the detail surrounding the central portion of the scene. On the right we look through a door into a vaulted hall with two rows of columns, though which ball rooms the traditional lion which was the companion and attendant of the saint. Through two windows in two portions of what we may call the back scene (for the whole very much resembles a set scene on the stage) is seen a distant landscape and figures on the most minute scale and painted with the most careful exactness. Concerning the interior itself, the catalogue quotes Sir J. E. Robinson to the effect that "the two-light window, divided by a slender central shaft, is known in Spain as the *ajimez* window. The type is quite peculiar to the districts of Spain in question. . . . There cannot be a doubt that the interior here depicted with so much verisimilitude, was carefully copied from an existing building, probably the house of one of the rich merchants of Valencia." In the picture of the holy women at the Sepulchre (11), attributed, though we should think very doubtfully, to John Van Eyck, we see in the background the painter's idea of the houses and towers of Jerusalem, with the mosque of Omar doing duty for the Temple. In the two curious Madonna pictures labelled "Early Flemish School" (13 and 16), we see a peculiar feature in the shape of low stone walls with crops of flowers on the top; on one of these, in 16, the Virgin is seated. No. 13 presents a study of Renaissance façade of rather curious detail on the right. In the centre of the wall, over the fireplace, is a little gem of a painting in its way, a "Virgin and Child Enthroned" (14) labelled on the owner's frame "Mabuse," but reduced in the catalogue to the more modest and doubtful

claim of "School of Roger van der Weyden." The small figure is seated under a Late Gothic canopy so forcibly painted as to seem almost in relief; the Virgin has an elaborate crown, the jewels in which still make tiny points of light in the picture; her flowing and luxuriant hair has been painted with the greatest care, and seems still fresh from the brush. The architectural canopy is decorated in the upper part with sculptured figures only about a quarter of an inch high, but in which the features and details of drapery are all quite sharp and distinct. The whole picture is less than six inches in height. It is hard and formal of course, but one cannot help contrasting the conscientious labour bestowed here with the easy fame won in these days by painting "impressions" and "nocturnes." Near this is one of the most splendid pieces of costume painting in the collection, "S. Victor with a Donor" (17), by Hugo Van der Goes. The armour of the saint, the blue velvet vest, the cloak with fur collar, are painted with marvellous truth and force, and the cope of the ecclesiastic who kneels beside him is painted with equal power, and is a fine and sumptuous piece of design as well. In this case there is dignity too about the face and figure of the saint; in others of the paintings, as in Nos. 13 and 16, it is curious to note how the whole skill of the painter, the whole feeling for beauty, seems to have gone away into the accessories, leaving the faces of the figures utterly devoid of grace or expression, and the figure of the Holy Child, which is the centre and supposed object of the whole painting, looking more like a monkey than a human infant. This is the same puzzle that we see in Japanese art up to the present day; the power to paint decorations and inferior forms of life highly developed, while the painter's capabilities and his sense of beauty alike seem to desert him as soon as he comes to deal with the human face and form. It is a curious paradox in art, and might form a subject for inquiry as to the causes, social or philosophical, which lie behind it.

In the picture labelled as of "The School of Hans Memling" and representing "Virgin and Child Enthroned" (23), the design of the throne is of some interest. It is described in the catalogue as of "red and white marble," which we think is a mistake; it is wood and white marble; if the other material were taken to be red marble we can only say it shows much worse painting of material than is usual in pictures of this school. The artists of the Netherlands School were very fond of painting wood and carefully showing all the details of the grain, as will be seen in other paintings where the object is undoubtedly of wood; the same kind of execution is seen in the more massive portions of this throne, and the compilers of the catalogue seem to have been misled into describing it as marble merely because the combination of wood with marble seemed an odd and unusual one. The upper (marble) portions of the thrones are finished at each side by a curious finial bent round and with a bunch of grapes sculptured as if hanging from it, while a small angel figure stands on the upper side of the scroll. Altogether this throne is a curious and interesting piece of work.

The picture of the school of Roger van der Weyden (29) should be noticed for the remarkable painting of the distant town and cathedral seen through an open window, and which is almost like a view through a telescope; notice the minute but carefully-painted figure, so small as to be only just discernible, of a man on a ladder painting the wall of one of the houses. Lucas de Heers's portrait of Lady Jans Grey should not be passed over (32). The Virgin and Child by Mabuse (39), a splendid example, is interesting architecturally from the curious design of the throne, with its short thick pilasters and large capitals, and the four stone consoles in the front on which the floor of the picture seems to be supported. Another painting, called "Mabuse" on the frame but denied as such in the catalogue (41), has a most

elaborate architectural background of Roman and Renaissance detail. The genuine Mabuse, No. 42, a triptych, with the Virgin enthroned in front of a landscape, gives an elaborate Mediaeval stone castle in the middle distance, contrasted with the half-timber houses of the peasantry adjoining it, and (strange feature in a Dutch picture) we see a garden with winding walks and a rustic bridge. In the picture described as of the "School of Geeraert David" (46) the student of decorative design will find a "cloth of estate" covering the virgin's throne, which furnishes a splendid wall-paper design. Among the paintings of more purely artistic interest may be mentioned the fine portrait of a man by Bartel Bruyn (52), and the portrait of a lady by Nicolas Lucidel "called Neuchâtel" (53), a beautiful face in which the sweet mouth and bright eyes are all the more expressive, perhaps, from the subdued and rather flat and delicate manner in which the rest of the face is painted. The costume of this half-length figure is a perfect study for artistic design and patience and refinement of execution.

The whole exhibition is one for which we ought to feel real gratitude to the Burlington Fine Arts Club.

NOTES.

WE give in another column some particulars as to the work done at the Imperial Institute, which seems now to be considered to have reached a certain recognisable stage on its road to completion, to be marked by receptions and other such formalities, though there is a great deal to be done yet, both externally and internally. From the architectural point of view there is little to criticise in the interior treatment of the rooms and corridors, which, without being ornate or disproportionately expensive, is substantial in construction and agreeable in appearance, except in the case of the large plaster pendants to the ceiling on one of the principal rooms, a piece of gimcrack which we regret to meet with in a building of this importance. In the corridors and in others of the rooms the plaster decoration is kept of a tolerably flat character, in low relief and refined in detail; the mosaic pavements of the corridors have a good appearance, the Hopton Wood stone with which the lower portion of the walls is lined looks very well and shows a finish almost like marble. The doors are well designed, though simple, and everything is in good taste. The large brackets under the principal stairs form a good architectural feature, and a welcome exception to the fashion of sticking stone stairs and landings out from a wall with no support in an architectural sense, and not quite enough in a constructive sense. The front entrance is decorated, as we have already had occasion to remark, with some bas-relief sculpture of a higher class than is usual in what is somewhat cynically called "architectural sculpture." Mingled with this prominent sculptured detail we notice a small repeating ornament formed of conventionally indicated boy figures with the extended arms crossed. Is this the last reduction to commonplace of Blake's sublime design of the morning stars singing together? We constantly meet with this motif now, and it seems to be taken from Blake, but we have never seen it reduced to a mere pattern before. In regard to the exterior generally, it may be said that it is a graceful and elegant building on a large scale, but not a grand one; which, with its dimensions, it might have been. The reason for this appears to reside to a great extent in the character of the detail employed, which is not of the most truly masonic character; there is an undefinable appearance about it as if all the parts were fitted together like joinery, as if it were a piece of cabinet-making on a colossal scale. The deeply-recessed arches on the ground floor, in the portions between the centre and wings, have a fine effect, and this portion will look much better when the intended

sculpture in the now bare spandrels and panels is executed. That a building is entirely refined in detail and that there is absolutely nothing of bad or tawdry taste in it, is indeed much to say, and this praise the building fully merits; but we cannot call it a great or striking piece of architecture.

THE soirées given by the President of the Institute of Architects and Mrs. Macvicar Anderson at South Kensington Museum on Wednesday were very well attended; the precise number of guests was, we are informed, 1,145. Among the guests present was M. César Daly, to whom the Institute Gold Medal is to be presented on Monday evening. The string band of the Royal Artillery discoursed music in the Italian Court, and in the theatre a musical entertainment of a less every-day order was given by the Royal band of Hand-bell Ringers, whose performance was a remarkable display of the apparently easy execution of music under difficulties, by the manipulation of bells which have to be continually changed, lifted, rung, and put down again to lift the next pair. The Elizabethan dress of the ringers (we presume a tacit claim for the antiquity of the institution) gave an element of picturesque in the performance, which was increased by the graceful and easy and practised action with which the manipulation of the hand-bells was carried on. From a musician's point of view, no doubt, the result is not of much importance, but the performance is a very pretty and pleasing one, and an example of the manner in which difficulties can be vanquished by practice. The Elizabethan costume, with the ruff, and the beard cut in fashion to match, showed how easily and completely the man of the present day may be transformed into the semblance of another age by judicious treatment: the group of bell-players might have come off Shakspeare's stage.

THE last quarterly report of discoveries in Greece, issued in the *Mittheilungen* of the German Institute at Athens (1892, XVII., 1), contains a good deal of interesting news. In the recent excavations at Epidaurus, an inscription has come to light which promises to be of great architectural importance. Mr. Stais is to publish it very shortly; he believes it to contain the statement of accounts for the building of the famous Tholos of Polycleitus; he further claims that the inscription settles not only the precise date, but also the purpose of this hitherto very enigmatical structure. It has been a fascinating problem for so long, that the solution will be eagerly looked for. Besides this, Mr. Kabbadias, who directed the excavations at Epidaurus, has cleared out the greater portion of the gymnasium, and also the small Roman theatre. The great theatre of Polycleitus is now completely cleared, and the seats have been built up again wherever the original stone slabs could be found.

AT Mycenæ, Mr. Tsountas has made considerable progress with his excavation of the second great "beehive tomb," and it bids fair to be as impressive a spectacle as the better known "treasury of Athens." The *aromos*, or entrance passage, is, however, built of much smaller blocks. Sufficient architectural fragments have been found to restore conjecturally the façade of the entrance. To the right and left of the gate stood half-columns, the one remaining capital of which shows a marked resemblance to that of the Lion Gate. The architrave consists of a frieze decorated with circles, and a cornice in which runs a spiral ornament. Photographs of the façade in its present state, and of the various architectural fragments, have been taken by the German Institute, and are now available to the public. Excavations have been begun to the north of the Lion Gate, but, so far, nothing of much importance has come to light. The same number contains a valuable paper, far too detailed for summary,—

by Dr. Bruno Sauer, on ancient Naxian sculptural art. Since his paper on the disposition of the Partenon pedimental figures, Dr. Sauer's name may be held as a guarantee of the ability of his work. He here pursues the same method,—a method too long neglected,—i.e., a close and careful analysis of the technical procedures of sculpture, and he succeeds in dating, with a high measure of probability, many Naxian monuments hitherto vaguely classed as "archaic." Another paper by Dr. Paul Wolters will be read with special interest in England, for it settles, we trust for ever, the vexed question of whether the colossal Melos head in the British Museum be Zeus or Esculapius. Dr. Wolters publishes a statuette found at Epidamur, representing an unquestioned Esculapius, for the god leans on a snake-entwined staff, the type of face, *mutatis mutandis*, is precisely that of the Melos head; in fact, the pose of the Melos head can only satisfactorily be explained by supposing it to have belonged to a statue standing in the attitude of the Epidamur statuette. The analogy is made clear by a plate showing the two heads side by side, reduced to the same scale.

THE account given in the *Times* of the deputation to Mr. Gladstone last week on the subject of "the eight hours" question is truly edifying reading. One knows not whether to admire most the preposterous nature of the proposals made by the representatives of labour, or the scarcely veiled insolence with which the veteran statesman who received the deputation at his house was made to understand that the representatives of labour had it in their power and intention to injure his immediate political prospects, if he did not accept their terms. With politics, of course, we have nothing to do; but we are glad to observe that a statesman who has shown himself only too ready to make promises to the constituencies who could bring him into power, in this instance at least refused to be bullied, or to put common-sense and logic on one side to secure the support of the representatives of labour. The deputation, however, has had one good result; we know now in unmistakable language what the advocates of an eight hours movement really want. We have it on their own statement that they wish for an enactment to interfere with the private life of employes after they have left the workshop, and to make it penal for them to take work home and pursue their trade there in order to make a little more money. The trades represented in the deputation do not wish to work more than eight hours; consequently no one else shall do so. After this, the opinion that an employer would make more money out of eight hours work than out of ten hours seems only a mild form of eccentricity.

THE case of *Henthorn v. Fraser*, which is reported in the current number of the *Law Reports*, contains a decision of some practical importance in regard to the sale of property. These were the short facts. H., who lived in Birkenhead, called at an office in Liverpool to negotiate for the purchase of some houses belonging to S., who handed him a note giving him the option of purchase for 750l. within fourteen days. Next day, between 12 and 1 o'clock, S. posted to H. a letter withdrawing the offer. This letter was received after 5 p.m. Meanwhile, H., at 3.50, had posted an unconditional acceptance of the offer, which was delivered in Liverpool after office hours, and not received by S. until next morning. The question, of course, arose, Was the acceptance or the withdrawal of the offer binding. The Court of Appeal answered that the acceptance was binding, for two main reasons. In the first place, the Court held that a person making an offer must be considered as continuously making it; or, as we should prefer to say, not withdrawing it until the withdrawal is brought to the mind of the person to whom the offer was made. Here, when the offer was accepted, the with-

drawal had not come to H.'s mind. The second reason was thus stated by Lord Herschell:—"Where the circumstances are such that it must have been within the contemplation of the parties that, according to the ordinary usages of mankind, the post might be used as a means of communicating the acceptance of an offer, the acceptance is complete as soon as it is posted." Testing the facts by this rule, it is clear that H. had made a binding and valid acceptance, and that the withdrawal of the offer by S. was too late.

THE Salford County Borough Council seem to have perpetrated what is commonly called a "job" in the election of their new Borough Engineer. They advertised for applications and referred them to a sub-Committee, whence they came before the General Purposes Committee, which selected Mr. Price, of Liverpool, and passed a resolution recommending his appointment, at a salary of 500l. as Borough Engineer and Surveyor. At the Council meeting the Mayor proposed the adoption of the recommendation, remarking that it had been a constitutional usage that the action of the Committees should be supported, and that Mr. Price was head and shoulders in front of all the other candidates; in fact, the Selection Committee thought there was no other candidate in the running. Upon which a member of the Council proposed Mr. Corbett, of Broughton, a candidate who had not been either first, second, or third in the selection of the Committee, and thirty Councillors voted for him and only twenty-four in support of the Committee's choice. Now Mr. Corbett was an ex-Councillor. The gross unfairness of such a proceeding, after inviting public candidature, and after the best man had been practically appointed on his merits, it is unnecessary to point out. We really thought the time had gone by when such a method of proceeding would be tolerated in any important public body; but Salford seems to be a survival of Little Pedlington.

TRINITY COLLEGE, the three-hundredth anniversary of which will be celebrated at Dublin in July, was founded under letters patent issued on March 3, 1591, by Queen Elizabeth, who about the same time fitted up the Castle as a residence for the Lord Lieutenants, who had formerly occupied Thomas Court. But as early as 1311 John Leck, archbishop of the See, had obtained a Bull from Rome for the establishment of a university school in Dublin; his successor, Alexander de Bicknor, accomplished the design, and set up a school of learning in St. Patrick's Cathedral, which, however, gradually declined. For a new site the mayor and citizens gave the dissolved monastery of All Hallows on Hoggins, since College-green, granted to them by Henry VIII. The present buildings consist of three quadrangles, erected in the Classic styles, chiefly after Sir William Chambers's plans and designs. The outer quadrangle, known as Parliament-square, and with a principal front along the whole east side of the Green, has an interior area of 316 by 212 ft.; on its north and south sides stand the chapel and the theatre. The next court is the Library-square, 265 by 214 ft., having the library on one side. To the east of Library-square was built the printing-office, in the Doric style, as founded by Dr. Stearne, Bishop of Clogher.

A PROSPECTUS is issued from the Leadenhall Press of "London City Suburbs," designed for a companion volume to "London City," by the Rev. W. J. Loftie, F.S.A., which we noticed on November 29, 1890. As in the earlier book, the illustrations will be engraved from original drawings by Mr. Wm. Luker, jun. Mr. Percy Fitzgerald contributes the letter-press. Whether he drew up the prospectus we know not; its writer makes us somewhat apprehensive as regards the text. Of the specimen views now printed one shows the pond by the old mile-

stone at the top of Heath Mount, an elevation which geologists tell us was laid before the Right mountain had been formed under water. In the background we see a glimpse,—more should be rendered visible,—of "Upper Bowling Green House," literally the "Upper Flask" tavern, memorable to readers of "Clarissa," and a resort of the Kit-Kat Club. In 1750 it was converted into a private residence, and has been inhabited by George Stevens the commentator on Shakespeare, and by Coleridge. Another view at Hampstead shows the block of wooden cottages which stand near to Wildwoods, by the "Bull and Bush." The scene, "In Regent's Park," requires amendment: the hirers of boats are excluded from the narrow waters there, and are not allowed to land and lie about on the banks. The picture of Greenwich Park presents the Hospital and the Royal Naval School, the latter occupying what used to be the Palace of Delight, built by two queens,—Anne of Denmark and Henrietta Maria,—of which there is a scarce plate, dated 1637. A succeeding generation may turn to this book if desirous to learn what was the aspect of the suburbs at this day.

THE Census Report published on July 10 last gives the London population as 4,211,956, compared with 3,815,544 in 1881. Four little maps published by the *Lancet* a fortnight since demonstrate in a striking shape how an increase of almost a million in the past twenty years is distributed. The diagrams show an increase at Battersea, and at Fulham, of nearly twice the former population; whilst the populations are more than doubled at Hampstead, Wandsworth, and Camberwell. The change of foot-paths and walks into roads, the covering of gardens with houses, go on apace: they who, taking thought, look around and forward, discern the necessity for open spaces here and there to break the continuity of London's monstrous growth. In one of her powerful, yet temperate, appeals, printed in the *Times* some months ago, Miss Octavia Hill pleaded that surely the landless should be enabled to derive some enjoyment from the land.

WE have no wish to say hard things of railway officials who make a blunder after perhaps long years of good service, but we certainly think the signalman who was unquestionably responsible for the accident at Bishopsgate has been remarkably fortunate in finding a jury to return a verdict of accidental death under the circumstances. The accident was confessedly the direct result of the omission of the signalman in the north box to signal a train, and the line being left consequently unblocked. This is one of the curious eccentricities of justice in such cases. There may have been plenty of extenuating circumstances to urge in palliation of the signalman's neglect, but it was a clear and admitted case of neglect of duty, and a verdict of manslaughter has not infrequently been returned on less decisive evidence than this. In sympathy for the signalman, the jury seem rather to have forgotten sympathy with the victims, and care for the safety of the public.

THE question of providing some means for the safety of persons falling into the water near the Thames Embankment, by providing something along the face of the Embankment which they can catch hold of, has been again before the County Council. The Engineer had suggested life buoys with ropes attached, placed on the Embankment; but unless these were fixed so that there was considerable difficulty in getting them loose, they would quickly be stolen, and if they were not easily got at they would be useless in an emergency, so the suggestion does not seem a very practical one. The Committee have ordered that lines of steel wire with wooden floats should be placed in three bays of the Embankment, and "if

found useful for the purpose of saving life" the method should be extended to the whole Embankment; but it is not very apparent how this is to be tested. Is an employe of the Council to be thrown into the Thames to ascertain if he can save himself by the wire? Or does any member of the Council intend to make the experiment in the public interest? It is time that something were settled and carried out about this matter, for the long bare wall is a hopeless barrier to any one who falls into the river, and is not a good enough swimmer to reach one of the steps; and the matter has been talked of for years and nothing done.

ABOUT ten years ago, a movement was set on foot for the purpose of erecting a monument in Edinburgh to John Knox. The model of a proposed statue was prepared by Mr. D. W. Stevenson, R.S.A., which was afterwards exhibited in the Glasgow Exhibition, but sufficient funds were not subscribed to enable the project to be carried out. After paying expenses, including the cost of the model, a sum of about 90*l.* remains, and it is now proposed that this amount should be augmented to 200*l.* wherewith to provide a statue of the Scottish Reformer to be placed in one of the niches of the National Portrait Gallery. A Committee has been formed for furthering the project.

THE weekly journal called *Invention* is a very interesting miscellany of news, but we must protest against the rather free use which it makes of matter taken from our columns, without a word of acknowledgment. On two recent occasions it has appropriated matter from our pages, not very great in amount, it is true, but if the matter was worth taking its source should have been acknowledged.

THE annual exhibition of the Home Arts and Industries Association, which has been open from the 16th to the 20th of this month, at the Royal Albert Hall, is more interesting as an exposition of the excellent work which this society is doing than as a show of art workmanship. To those who are not well acquainted with the Association and its work, we may say that it endeavours to nourish home arts and industries as a source of recreation and pleasure by encouraging the work of the many handicraft classes which are springing up all over the country, chiefly with the object of employing to advantage the leisure time of the youth of town and country. By means of grants of money, as funds allow, and by furnishing good designs for execution, this work is carried out, and it certainly deserves the success which seems to attend it. The exhibition does not, and can hardly be expected to, contain many exhibits of real excellence. The objects seem to show that efforts have been made to copy, sometimes slavishly, good designs, and the workmanship is apt to be cramped and devoid of that simplicity, freedom, and vigour which should be a characteristic of art-workmanship. We are probably right in thinking that the work having been done to good designs is due to the Society's care. Amongst the many schools, representing all parts of the United Kingdom, may be mentioned the Ruskin Linen Industry, the Balmoral School, the Alexandra Technical School at Sandringham (in which the Princess of Wales is so keenly interested), and Mrs. Alfred Waterhouse's brass school at Yattendon. The Langdale Linen Industry has an interesting exhibit of their material, embroidered with good conventional designs and capital workmanship in coloured wools, whilst Bangor was represented by slate plaques and other useful articles. We noticed a carved hard-wood panel by J. Phillips, of Altrincham, which for execution and design was much above the average in quality; it was exhibited in connexion with the Sandhach School. The list of schools exhibiting is a long one, but the exhibition is extensive in its range,

and includes articles of carved wood, leather work, *repoussé* and hammered metal work, wrought-iron baskets, pottery, and furniture, all of which testify to the excellent work the Association is doing, in which we wish it all success.

THE IMPERIAL INSTITUTE.

On Saturday, the 18th inst., what may be called a "Press view" of the buildings of the Imperial Institute, as far as they are at present completed, took place. Although we have from time to time during the last five years described the progress of the building,* the following particulars may here be placed on record.

The building has a frontage of about 750 ft. towards Imperial Institute-road, one of the new roadways which have been cut from east to west across what were the Royal Horticultural gardens,—of late years the scene of the very popular and useful exhibitions known briefly as "The Fisheries," "The Healtheries," and "The Colonies," or Indian and Colonial Exhibition. It was indeed, we are told, in consequence of the great interest excited throughout the British empire by the display at the Colonial and Indian Exhibition of 1886, which illustrated the vast wealth in natural products and the commercial and industrial resources of our various colonies and of India, that the idea was conceived of a permanent institution, designed firstly to afford a thorough and living representation of the progress made in the development of those resources, and, secondly, to serve as a national memorial commemorative of the fiftieth year of the reign of her Majesty. With that end in view, the buildings include, or will include, conference-rooms, reference libraries, exhibition galleries, and a large central hall. These features of the Institute will be supplemented by reading, writing, smoking, and refreshment-rooms for Fellows, who will practically have a club-house for their convenience.

The principal entrance is in the centre of the *façade*, and the portal is 17 ft. wide by 23 ft. 6 in. high. Above it, and for some distance each side of it, will stretch a frieze sculptured by Mr. Pegram in low relief consisting of emblematical figures, with the Queen in the centre. Entering this portal, the visitors were received by Sir Frederick A. Abel, the Secretary to the Institute, and by Sir Somers Vane, the Assistant Secretary, and by them were conducted over the building. The apartment seen through the stone casements on the right as one enters is a general waiting-room for the lifts, cloak-room, &c.; that on the left is the post-office, telegraph, telephone, and inquiry office. The shaft for carrying on the building operations of the central tower at present intersects the main structure. The large unfurnished room at the back is the shell of the vestibule to the proposed great hall. The vestibule will be temporarily used as a general conference hall, and was used on Saturday last as a luncheon-room.

The principal floor is that first reached from the entrance. In the west corridor are the British-American and British-Anstralian Conference Rooms (these Rooms are nearly finished), the Council Chamber, and the Secretarial and clerical offices. In the east corridor are the British-Indian and British-African Conference Rooms, the writing, reading, and news rooms, and the temporary library. The windows at the end of each corridor respectively indicate the interior approaches to the contemplated Conference Hall and Library.

The east stairway, by which access is gained to the upper floors, is nearly completed. The walls are lined with Hopiton Wood stone, polished (the largest use yet made of this stone in one building, probably), the balustrade and rail being of polished Belgian marble. This stairway gives a very good idea of what the grand stairway on the west side of the vestibule will be like; the latter is intended to be more richly ornamented. The arms of various colonies, and a record of the objects and date of founding of the Institute, are introduced into the coloured glass of the windows.

The first floor has the Fellows' Dining Room as the first apartment to attract notice. The

rooms in the east corridor are for the present assigned to the Exhibition of Indian Art Metal Work; they will eventually be used for the Commercial Intelligence Department and commercial conferences. The rooms of the west corridor will be adapted for use by various societies whose objects are kindred to those of the Imperial Institute. Here also will be the conference rooms of the groups of Crown Colonies. The Fellows' Dining Room is paneled in English oak which was carved and worked at Danmow, in Essex, and is pointed to as a practical illustration of the feasibility and advantages of village industry; the artisans engaged upon it share the profits. Above this room on the second floor is the Public Dining Room and Restaurant (this room will eventually be decorated in a similar manner to the Fellows' Dining Room); and above that again are the kitchens and serving rooms.

On the second floor, the rooms in the east corridor will probably be occupied for some time by certain societies who are seeking the accommodation which the Institute affords for carrying on their work. The rooms in the west corridor and on the south side will be mainly used as sample examination rooms. The two large rooms at the south-west corner will be a map-room and the Fellows' smoking-room. The balcony which leads to the west tower will also be a pleasant smoking lounge in fine weather.

The ground floor will be principally devoted to the storage of samples in bulk, the portions underneath the main entrance being arranged for certain offices, &c. The two colonnades which are eventually to connect the main building with the side galleries (the old arcades which flanked the Horticultural Gardens) will bring this floor, the arcades, and the lower floors of the central and north galleries to a uniform level. The stores in bulk on the ground floor of the main building will be arranged to be as near as possible to the location of the Index Collections in the galleries.

The engine-room, boiler-house, and dynamo-chambers for providing the heating and lighting of the buildings are at the rear of the central gallery, and immediately underneath what will be the floor of the Great Hall. The steel boilers are Galloway's make, and the whole of the electric-light machinery and fittings are the work of Messrs. Allpress & Belshaw. When fully developed the Institute will be in a position not only to supply motive and dynamo-power for its own wants, but also those of the surrounding institutions. All the gas, water, and sanitary main-pipes are carried along a walking snhway in the basement. There are over fifty hydrants throughout the building, and there will always be ready a large supply of water from the tanks in the towers, exclusive of that obtained from the water company.

The Central Tower is now approaching the stage when it will present an effective appearance (see illustration in last week's *Builder*). It has been built without the aid of any exterior scaffolding whatsoever. The plain shaft-like portion indicates the position of the water-tanks. The lantern-chamber now rising above the first balcony (about 200 ft. from the ground) is that where the suggested peal of bells would be accommodated. The Prince of Wales has accepted the offer of an aged Australian lady to provide and completely equip a perfect peal, which is to be rung on the Queen's Birthday and Accession-day, and on the birthdays of the immediate members of her Majesty's family. The alarming statements lately current to the effect that a subsidence of this tower had taken place were grossly exaggerated; the fact is that the compression on the clay bed of this vast weight,—now over 5,000 tons,—is only half an inch, and less than what had been naturally expected.

The Lower Floor Intermediate Gallery has been allotted to the Australian and African and other Colonies. Several of the Colonial Governments are only waiting for the clearance of this gallery by the builders, to commence the work of fitting the cases and installing the collection.

The installation of the British Indian Court,—including Ceylon,—(formerly known as the East Arcade) is sufficiently advanced to afford an appreciable notion of the manner in which this important branch of the Institute's work will be carried on. In accordance with the views which have from time to time been indicated, it has been decided that the scheme to be adopted in the arrangement of the

* The following illustrations of the building have appeared in this journal, viz., Mr. Collett's design as submitted in competition, *Builder*, July 2, 1887; plans and detail of *façade*, July 9, 1887; large perspective view, January 5, 1889; and view of central tower, last week, June 18.

collections representing the economic products of India and the Colonies should have a commercial and industrial, rather than a scientific, bearing. It has consequently been arranged to adopt, in the arrangement of the Collections, the system of grouping economic products which has already been pursued in the preparation of similar collections for exhibition in the Indian Section of the Institute, under the auspices of the Department of Revenue and Agriculture of the Government of India; the following being the general headings of the groups:—1. Foods and Food-Stuffs; 2. Stimulants, Beverages, and Narcotics; 3. Oil Seeds, Oils, Soap, and Perfumery; 4. Drugs, Medicines, and Chemicals; 5. Gums and Resins; 6. Dyes, Tans, Mordants, Pigments, and Paints; 7. Fibres and Fibrous Plants; 8. Hides, Leather, and Horns; 9. Canes, Bamboos, and Grasses; 10. Timbers; 11. Minerals; 12. Domestic Products. Each of these groups is, naturally, subject to subdivision into sections, according to the system which was pursued in the Economic Courts of the Colonial and Indian Exhibition of 1886. This system of grouping renders it, of course, unavoidable that certain products which are applied to more than one use should appear more than once in the collection; thus turmeric receives application as a condiment, as a dye, and as a medicine; hence, specimens of turmeric have to be included in three different groups. Following this system, the form of the collection will be two-fold, *i.e.*, there will be the "Index Collection" (as seen in the court and galleries) on the one hand, which will be illustrative of, and correspond to, a complete Catalogue or Dictionary of Economic Products, and the "Commercial Collection" (stored on the ground-floor of the main building), on the other hand, which will consist, in part, of samples in bulk—corresponding to the specimens included in the Index Collection, and, in part, of products of known or anticipated commercial utility in all stages of preparation and manufacture.

The general method in which the Index Collections are to be arranged is as follows:—(a) In air-tight receptacles with glass fronts, and also vessels entirely of glass, in which the samples will be well displayed, and the form of which admits of their compact arrangement and exhibition. The receptacles will bear efficiently descriptive labels, with reference numbers to the "Dictionary" and to the "Commercial Collection;" (b) Cases in which these specimens will be conveniently exhibited, and which are so arranged that any one of the receptacles may readily be abstracted for closer inspection. These cases are so constructed as also to afford accommodation for larger samples, or for small models, and to admit of the display, in connexion with the specimens, of diagrams, maps, or other auxiliary means of illustration and explanation.

The space available in the Institute renders it out of the question that many of the samples in bulk (forming the Commercial Collection), should be openly exhibited, or that they should even be stored in packages in the same locality where the Index Collection is situated; they are therefore to be stored in the commodious rooms on the ground-floor of the main building, close to the galleries containing the Index Collections, and communicating by means of a lift to the second floor of the Institute, where the "Sample Examination Rooms" are situated. The samples are to be stored in air-tight canisters of sheet tin, each tin being marked with the scientific name and Dictionary Number of the sample it contains; in addition a supplementary "Store Number" will be instituted, that number being repeated on the labels of the samples in the other division of the collection, so that any person desiring to closely inspect and to handle a particular sample in bulk would only have to take note of its "Store Number" in the exhibited collections.

In order to render the establishment of this representation of products of continuous service to India and the Colonies, and to those engaged in commerce with them, or practically interested in the application of such products to industrial purposes, every facility will be given to merchants, manufacturers, and scientific workers, to examine samples and to be supplied with specimens of those which interest them, and with all available information concerning them.

It is stated that the authorities of the Imperial Institute are fully alive to the importance of combining, with a comprehensive

and progressive representation of the economic resources of India and the Colonies, systematic arrangements for the submission of samples to valuation, and for the analytical and other chemical or physical examination of products which are either new or else but imperfectly known, and also of making arrangements, from time to time, for practical experiments with a view to ascertain the adaptability of new products to practical purposes. When the operations of the Institute are sufficiently advanced, its regular income adequately increased, and its equipment fairly developed, it is intended that the latter should include an experimental department, where commercial valuations and scientific investigations connected with products displayed in the collections can be efficiently carried out.

Another very important branch of the operations necessary for a thorough utilisation of the collections of natural products, which will be taken in hand as soon as the supply and arrangement of these are sufficiently far advanced, is the holding of conferences in connexion with particular groups of products, with a view of considering existing commercial, scientific, and technical knowledge relating to them; the directions in which it needs development; the results of scientific or technical experiments which are new or little known, and other subjects of commercial and industrial importance connected with the development and utilisation of the natural resources of the Colonies and India.

The large quadrangles will lend themselves to a variety of useful purposes. Musical afternoons and evenings will probably be arranged. In the east quadrangle, and adjoining the Indian Court, will be erected the Indian Pavilion (the gift of one of the Indian Princes), in which tea, coffee, and other light refreshments will be served.

As our readers know, the general contractors for the building are Messrs. John Mowlem & Co., of Grosvenor Wharf, Grosvenor-road. The marble mosaic pavement of the principal floor was laid down by Messrs. Burke & Co., of Newmarket-street, who also executed the marble work of the staircase and the marble chimney-pieces in Rooms 18 and 19. Other mosaic work was executed by Messrs. De Grelle, Houdret, & Co., and by Messrs. Rust & Co., Ltd. The lifting machinery, designed and erected by Messrs. Archibald Smith & Stevens, consists of eleven hydraulic lifts with pumping-engines and power storage plant. There are two passenger lifts running from the ground to second floors, three lifts for reception and distribution of coals and general stores, three appropriated to the kitchen department, one for delivery of refuse from the engine and boiler house, one heavy machine capable of raising a ton up the central shaft of the east tower, and designed for dealing with stores and large objects for the museum, and, finally, a three-ton lift for raising extra large exhibits to the upper floor of the great gallery running east and west. All these are supplied by water at 700 lbs. pressure per square inch. This water is pumped by an engine into a weighted receiver or accumulator, wherein it is stored at the required pressure, and drawn off as required by any of the lifts. Immediately this occurs the accumulator by automatic mechanism starts the pumps, which run till the accumulator is again full, when it automatically stops them till more water is required. All the water employed is returned by the lifts to the pumping machinery for re-use, and is therefore not wasted, but kept constantly circulating. The cost of working the system is consequently only that of the coal burnt, and the labour of stoking, no other attendance being required. In its outlines the system is similar to that adopted by the London and other hydraulic power supply companies, and to that on which the lifts for the Electric Railway are worked. The fire-protection of the buildings has been provided for by the installation of a powerful stationary steam fire-engine with quick-steaming boiler, which will be used in conjunction with a tank in one of the towers, to supply the large number of hydrants fixed throughout the buildings. A new and improved method of running out the fire-hose has also been adopted. The whole of the fire arrangements are being carried out by Messrs. Shand, Mason, & Co., of Upper Ground-street, Blackfriars. The stained glass has been executed by Messrs. Clement Heaton & Co. The casements and stoves were supplied by Mr. Thomas Elsley, and the grilles and ornamental ironwork by Messrs. Potter & Sons. Mr. C. F. Murray

Painted the panels of the staircase ceiling, and Mr. Julius Sax has provided the electric bells and speaking-tubes.

The architect of the buildings is Mr. T. E. Collcutt, F.R.I.B.A.

ARCHITECTURAL SOCIETIES.

LIVERPOOL ARCHITECTURAL SOCIETY.—Classes have been held during the session which has just concluded, for the benefit of the student members, the subjects bearing directly on the Institute examinations. The classes were well attended, and the students have by their interest shown that the Committee's efforts have been appreciated. The following are the subjects, with the lecturers:—Sanitation, Dr. D. Harrison and Mr. T. Harnett Harrison, F.R.I.B.A. (President). Mouldings, Features, and Ornament, Mr. C. E. Deacon, F.R.I.B.A. History of Architecture, Mr. H. W. Kee, F.R.I.B.A. Building Construction, Mr. G. Ware. Specifications and Quantities, Mr. H. L. Beckwith, F.S.I. By-laws and Public Health Act, Mr. J. Dod. An examination was held at the close of the session, in which Mr. Lawrence Hobson, to whom the Council will award the prize, distinguished himself most highly. Meetings have been started, and will be continued every week during the summer months, conducted by Mr. C. E. Deacon, at Bevington, for the purpose of preparing measured drawings of the old church.

MANCHESTER SOCIETY OF ARCHITECTS.—The second of the summer series of sketching visits was paid on Saturday, the 18th inst., to Prestbury, under the leadership of Mr. H. E. Stelfox, A.R.I.B.A.

GLASGOW ARCHITECTURAL ASSOCIATION.—A party of about twenty-two members of this Association visited Largs on the 18th inst. On arriving, the party was met by Mr. T. G. Abercrombie, architect of the new U.P. church now being erected by Mr. John Clark, of Curling Hall. Mr. Abercrombie conducted the party over the church, which is still unfinished. Thereafter he kindly showed the members through Curling Hall, to which he lately made a large addition. The company then proceeded to the half timber lodge and gardener's house, recently erected for Mr. E. Philippi, from designs by Mr. A. J. Fryers, architect, Paisley. The new parish church was next visited. Mr. Balfour, of Messrs. Steel & Balfour, the architects, kindly went over the building with the party. After tea, some sixteen of the party visited the Montgomery monument in the Skelmorlie aisle, situated in the old churchyard. This concluded the excursion, and the party returned to town, having spent a very enjoyable day, despite the unfavourable weather.

COMPETITIONS.

NEW BUILDINGS FOR THE STAFFORDSHIRE COUNTY COUNCIL.—In this competition, in which Mr. J. Macvicar Anderson, President R.I.B.A., was the assessor, 63 sets of plans were submitted. The premiums were awarded by the assessor as follow:—First, "M," 150*l.*, Mr. Henry T. Hare A.R.I.B.A., London. Second, "Expert," 100*l.*, Messrs. Treadwell & Martin, London. Third, "Acoustics," 50*l.*, Messrs. Cooksey & Cox, London. The architect has yet to be appointed by Council. All plans are retained at present, as under the conditions, the Council have power to exhibit the same. Meantime the names of all the competitors, except the three whose designs have been selected for the premiums, remain unknown.

WESLEYAN CHAPEL, BARNABY CASTLE.—In the competition for this chapel, the design by Messrs. Morley & Woodhouse, architects, Bradford, has been selected. The chapel will cost about 3,500*l.*

WALSLEY PUBLIC BATHS.—By a printers' error in an advertisement which appeared in the last two issues of the *Builder*, the date for sending in designs in this competition was given as July 10 instead of Saturday, July 16.

FREE LIBRARY, BIRMINGHAM.—On the 5th inst., the Mayor of Birmingham opened the new Branch Free Library at Bloomsbury, Birmingham. The building has been erected at a cost of 3,700*l.*, from designs by Messrs. Cossins & Peacock, on a triangular piece of land abutting on the Saltley-road. It has a terra-cotta front, and, in addition to the news-room and lending library, a reference library on a small scale has been provided.

North Transept, Christchurch Priory, Hants.—From a Drawing by Mr. J. A. Pywell.

CHRISTCHURCH PRIORY, HANTS.

The north transept of Christchurch Priory is a curious and in the highest degree interesting example of Norman decoration. On the north-east angle is the Norman turret, the whole surface of which is occupied with arcading interlacing, and other methods of decoration.

The lower story is occupied by the wall-arcading, which also runs round the transept, the spandrels over the arches being filled with fish-scale ornament. Above the string-course is a second arcade, the stone of which is much decayed. The arches of both arcades are moulded, and the lower ones contain a herringbone ornament between the mouldings on the

front face, and traces are also to be seen of it in the upper arches.

Springing from these is a lattice ornamentation which forms a net of large rope-like hands girding the masonry and seemingly holding it together, though in reality carved from it. A third arcade runs round the top story, above which is a dog-tooth string moulding.

The drawings of capitals (see next page) show those to the lower arcade. The shafts are also ornamented, two of them by interlacing, the rest being fluted. The flutings are of four different kinds, which are again varied by being continued spirally round the shafts or by being mitred in front or on angle. Portions of the lower arcade have been carefully restored; the upper portions are 800 years old. J. A. P.

THE INCORPORATED ASSOCIATION OF MUNICIPAL AND COUNTY ENGINEERS.

In the course of the discussion which followed the reading of the papers read at the Peterborough meeting of this Association,*

Mr. Buckham asked whether the manholes in Peterborough were constructed so as to be made use of as flushing-chambers? In his own district he had found that a very convenient

* See page 483, ante, for two of them, viz. "Municipal Work in Peterborough," by Mr. Walshaw, the Borough Surveyor, and "The Water Supply of Peterborough," by Mr. J. C. Gill, Waterworks Engineer to the Corporation. For the substance of the third paper, by Mr. Isaac Shone, on "The Shone System of Town Drainage," see succeeding columns of this issue of the *Builder*.

and economical course. He should also like to ask Mr. Gill whether, in laying his pipes for the water supply, he had tried any other methods of jointing besides those mentioned in his paper? As to Mr. Shone's paper, he begged to express his thanks to that gentleman for so kindly acceding to his request to read a paper on his system of drainage, which he (Mr. Buckham) was prepared to say, from his experience of it at Ipswich, was particularly applicable to the drainage of towns in the Eastern counties, because it was peculiarly fitted to cope with the low levels and flat districts which there abounded, and could be applied to the lifting of sewage in certain situations with more satisfactory results than any other system with which he was acquainted. Moreover, with its aid, the engineer would be able to provide his sewers with adequate and necessary gradients, and could get his sewage lifted without having to buy land for pumping-stations. It had been said by many people that Shone's ejectors were, after all, nothing more than pumps. True, but they were pumps which would do what no other pumps could do, and they were perfectly automatic in action, and the cost of their maintenance was very little.

Mr. C. F. Gower, M.Inst.C.E., Ipswich, said that as a visitor, not being a member of the Association, he should like to bear his testimony to the success of the Shone system as applied at Ipswich. Mr. Shone, in his paper, had referred to the "separate" system. In theory he (the speaker) greatly approved of the "separate" system, and had carried it out in practice, but he found that it entailed a great deal of trouble and difficulty in actual working, and as far as his experience went he could only advise engineers to stick to one system of sewers.

Mr. R. A. MacBrair (Lincoln), referring to footways, said that Mr. Walshaw had referred to slag concrete as being the most durable, but as being objectionable from its slipperiness. His (the speaker's) experience was that the paving slabs made with slag were the least slippery of any. It struck him that the price named by Mr. Walshaw for horse, cart, and man (viz., 6s. 6d. a day) was very low.

Mr. E. J. Silcock (King's Lynn), in moving a vote of thanks to the readers of the papers, said that the best testimony to the efficiency of the works which had been carried out in Peterborough was the striking diminution in the death-rate from 20.7 to 14.7.

Mr. Robert Godfrey (King's Norton), in seconding the motion, referred to the vexed question of sewer ventilation, and the best method of effecting it. He strongly urged that the only real solution of the question would be found in an alteration of the law so as to compel every house or other building which used a sewer to contribute to the ventilation of that sewer by a ventilating-pipe or shaft. Let all the houses by all means be safeguarded against the admission of sewer-air, but do not let them escape their share towards ensuring that the sewer shall contain no foul air. The system of relying only upon ventilating grids in the surface of the roadway had been tried and found wanting. Such grids were, and must necessarily be, comparatively few and far between, and in undulating towns, those at the low level would become inlets, and those at high level outlets. Even when there was no nuisance from these grids, people whose houses were near them were always nervously apprehensive of harm, and fancied it existed when perhaps it did not. No man liked to have a sewer ventilating grid directly opposite to his door, and the only real solution of the difficulty would be found in a law compelling every house to do its part towards the ventilation of the sewers.

Mr. Barber having read a few words in support of the motion,

Col. Jones, V.C., referred to the sewage system of Berlin, in which, he said, a great deal of difficulty had been overcome by the adoption of the radial system, whereby the sewage was taken out into different districts. It seemed to him that the Shone system was particularly applicable to a radial disposition of the main outfall sewers.

Mr. O. Deacon Clarke, late Municipal Engineer at Rangoon, testified to the success of the Shone system in that town. When the works were designed they had a population of 150,000, which had since increased to 180,000, and it had been found quite easy to provide for

the increased population much more economically than would have been possible in any other system.

The vote of thanks to the readers of the papers having been carried,

Mr. Walslaw briefly replied to some of the questions raised during the discussion. He said that the manholes were not constructed so as to be used as flushing-chambers. The daily flow of sewage was about 750,000 gallons. As to the cost of carting, 6s. 6d. a day was a low figure, and it was due to the fact that Peterborough is in an agricultural district. The reduction of the death-rate which had been alluded to was undoubtedly entirely due to the sanitary works which had been carried out. Before those works were executed, there used to be 600 cases of typhoid fever treated in the infirmary alone every year.

Mr. Gill, in replying, said that no other joints for pipes had been tried. Bored and turned joints were often regarded as very good in theory, but not in practice: here was a case in which their success in practice was unqualified.

Mr. Shone also replied, and the meeting terminated.

After luncheon, some of the members visited the sewage farm, as mentioned by us last week.

A very successful meeting of the Northern Counties and Yorkshire District of the Association was held at Scarborough on Saturday last, when the members were received by the Mayor. Papers were read (1) by Mr. Joseph Petch, the Borough Surveyor, on "Scarborough, its Progress and its Public Works in Recent Years," and (2) by Mr. William Millhouse, Water Engineer, on "Scarborough Waterworks." Subsequently the members visited some of the public works of the town. We are obliged for want of space to defer a report of the proceedings until next week.

THE SHONE SYSTEM OF TOWN DRAINAGE.*

ALTHOUGH much has been written, printed, and spoken about this system, yet it is feared that there are still to be found municipal engineers, surveyors, architects, Medical Officers of Health, and others interested in sanitary engineering works, who are more or less imperfectly acquainted with its principles and *modus operandi*. The inventor of the system is, therefore, much obliged to your Honorary Secretary for the Eastern Counties, Mr. E. Buckham, M.Inst.C.E., for inviting him to read a paper on it at this meeting. The author assented all the more readily to prepare this paper because he is satisfied that Mr. Buckham (having investigated the system for himself, and having, as the result of that investigation, recommended the Corporation of Ipswich to adopt it, in connexion with the drainage of Stoke, which is a part of Ipswich, and for which it was deemed by him to be specially suitable), as an honest conscientious engineer, became anxious that the merits of the system should be communicated, if possible, to his co-workers in this Association through the medium of a short paper upon it.

The author contends that by the aid of this system, house-drains and sewers can be laid in low-lying, flat, and tide-locked habitable areas, on the most perfect hygienic principle which it is possible or necessary for the practical sanitary engineer to carry out. Not only can drains and sewers be laid down by hydraulic and sanitary rules in low-lying, flat town areas, but they can also be so laid, by the aid of this system, in undulating town areas, in an endless variety of ways.

A few engineers in the past, strange to say, treated the Shone system as if its object was simply to lift sewage in opposition to the most economical pumps extant; and, accordingly, these gentlemen entered into elaborate calculations to try to prove, to their own satisfaction at least, that lifting sewage by compressed air was less efficient than lifting it by steam power direct in the ordinary way. The inventor remonstrated, too often in vain, with these engineers who elected thus to regard the system. But, happily, the discussions which have arisen from time to time between its advocates and opponents have greatly helped to

elucidate the intrinsic merits of the system. The process, however, of silencing prejudiced and incompetent critics, and converting opponents into supporters, has been as long as it has been painful and laborious. But the author is now thankful to say that at last he is no longer under the necessity of defending the system against the attacks of opponents. The fact is, they have all caved in and disappeared before the indisputable evidences which have been afforded from time to time by the numerous and various works carried out on the system, in support of the claims originally set forth, in its favour.

The primary object aimed at with the Shone system, is to get as high a degree of sanitary efficiency in connexion with the every-day working of house-drains and sewers as it is possible. The question which relates to the difference between the cost of lifting water by steam pumps, and ejectors worked by compressed air, is one of secondary importance. The ejector system may in certain cases involve you in the purchase of a little more fuel per annum than a steam pump, but, on the other hand, comparatively large and deeply-laid sewers, discharging into one steam pumping station, would be more costly initially and annually, and they would involve you in a larger number of sewage-gas nuisances, and withal a larger number of preventible deaths, than would obtain by dividing a town or district into a number of separate automatic drainage districts on the Shone system. The author regards his ejectors more in the light of life-saving apparatus than as economical sewage lifters; because we are told by the highest medical authorities, that decomposed putrid sewage, whether it be in vertical or horizontal cesspools, gives off gas which is prejudicial to public health; that foul drains, sewers, and cesspools cause an incalculable number of preventible deaths and cases of sickness. No sanitarian will attempt to contradict this statement in these days; and yet it is surprising to observe with what comparative indifference even professional sanitary engineers occasionally treat those who venture to propound simple, scientific, and practical remedies for the prevention of unsanitary drainage and sewerage works. You all know that the only effectual way to place house-drains and sewers in a satisfactory sanitary condition, is to cause them to be self-cleansing and to be properly ventilated. You also know that, in order to render drains and sewers carrying sewage self-cleansing, they ought to be adjusted in size and inclination to suit the volume of sewage which they are intended to carry, so that the velocity of the sewage when the period of maximum flow obtains shall be, if possible, 2.5 ft., but never less than 2 ft. per second. If we call the 2.5 ft. 100 per cent., then it is evident that 2 ft. would only be $(\frac{2.0 \times 100}{2.5}) = 80$ per cent. In

other words, no drains or sewers should be designed or carried out which would permit of the velocity efficiency being less than 80 per cent. of the 2.5 ft. per second—the velocity now universally considered to be necessary to render drains and sewers self-cleansing. Drains and sewers thus designed, if they are also efficiently flushed and ventilated, will be as reasonably perfect, from a sanitary point of view, as it is possible and necessary for the practical municipal engineer and surveyor to make them. If drains and sewers are not thus designed, they will become drains and sewers of deposit, and consequently unsanitary.

The velocity of 2.5 ft. per second, however, applies only when drains and sewers are used for the carrying of sewage proper, on what is called the "separate system." When drains and sewers are used as the carriers of sewage and rainfall, on what is called the "combined system," a greater velocity than 2 ft. 6 in. per second must be insured, to preserve them in a self-cleansing condition; because the rainfall carries with it road *debris*, and this adheres more or less tenaciously to the drains and sewers, and, by degrees, consolidates on their inverts, rendering the process of self-cleansing impossible, even by the most systematic and liberal use of flushing water.

Mr. Julius Adams, C.E., Chief Engineer to the Board of City Works, and Consulting Engineer to the Board of Health, Brooklyn, U.S.A., states in his book, on "Sewers and Drains of Populous Districts" (after acquiring considerable experience of town drainage on the combined system):—"As easily carried in memory,

* From a paper by Mr. Isaac Shone, read at the Eastern Counties' District Meeting of the Incorporated Association of Municipal and County Engineers at Peterborough, on the 11th inst., as elsewhere mentioned.

the following will represent about the falls which will preserve circular sewers free from deposit, provided they run half full":—

For 6-inch diameter a grade of	1 in 60
" 9 "	1 in 90
" 12 "	1 in 200
" 15 "	1 in 250
" 18 "	1 in 300
" 24 "	1 in 400
" 36 "	1 in 600
" 42 "	1 in 700
" 48 "	1 in 800

Here we see Mr. Adams's practical experience tells him that a sewer which is used for both sewage and rainfall, even in comparatively well scavenged towns, must have a grade which shall be sufficient to give a velocity, when the sewer is half full, equal to about 3.75 ft. per second, which is 50 per cent. more than we consider necessary to render sewage sewers self-cleansing.

It will be interesting, not to say instructive, to compare the gradients at which Mr. Julius Adams considers the following sized sewers should be laid, on the combined system, with the gradients at which they might be laid, to insure a velocity of 2.5 ft. per second, on the separate system, i.e., according to the author's improved Hydraulic Sewerage Tables, which are now in the press, and which will shortly be issued to the public.

	Combined Separate	
	System.	System.
	1 in.	1 in.
6-inch sewer.....	60	150
9 " "	90	248
12 " "	200	350
15 " "	250	458
18 " "	300	570
24 " "	400	805
36 " "	600	1309
42 " "	700	1575
48 " "	800	1849

The foregoing comparison shows that the difficulties in the way of an engineer draining a low-lying, flat town of any extent, of its sewage and rainfall discharges combined, in one set of drains and sewers, to one outfall or pumping-station, so that the drains and sewers may be maintained in a self-cleansing, and consequently sanitary condition, are physically insuperable, i.e., at a reasonably permissible cost. Equally insuperable would be the difficulties, if he had to drain such a town on the separate system, were the whole of the sewage conducted to one outfall or pumping-station.

For scientific, sanitary, and economic reasons the author has long advocated the adoption of the separate system, in preference to the combined system, in all new drainage projects, providing, of course, that the works are carried out throughout on sound sanitary principles, and providing the drainage of the sewage proper cannot be conducted, say, to a sea outfall, through drains and sewers which will carry the sewage separately, or in combination with the rainfall, at a perfectly satisfactory self-cleansing velocity. But some of you may be disposed to say what other engineers have said in effect before, viz., that all sanitary engineers nowadays lay down sewers at gradients which will secure "self-cleansing" velocities. This we know they do to the best of their abilities; but we also know that many engineers call sewers designed by them self-cleansing sewers if they are laid at gradients suitable to their size, regardless of the volume of sewage available to them. We have known engineers, for example, advise sanitary authorities to the effect that a 24-in. sewer laid at a gradient of 1 in 805 was laid at a self-cleansing gradient, which was literally true, if only the volume of sewage estimated to be available to the sewer had been sufficient to half-fill it; but, inasmuch as the sewage available was barely sufficient to half-fill a 6-in. pipe laid at a gradient of 1 in 150, the velocity of that volume of sewage flowing on the invert of the 24-in. sewer would not exceed 1.16 ft. per second, giving only 46 per cent. efficiency, instead of 100 per cent. In this case, as in many others, the engineer laid the sewer at the best inclination at which he was able to lay it owing to the natural configuration of the ground! It is in this way that the so-called English water-carriage system of sewage removal from houses and towns has wrought so much unsanitary mischief all the world over.

A 24-in. sewer is $\left(\frac{24^2}{6^2}\right)$ 16 times more capacious than a 6-in. pipe, and consequently, all things being equal, it will hold sixteen times more

foul air, and it will require sixteen times more water to flush it, than would be required to flush the 6-in. sewer. Moreover, the 24-in. sewer would cost roughly five times more than the 6-in. sewer! These statements tend to show that we ought in all cases reasonably possible, to recommend the adoption of the separate system of town drainage. Again, the cost of treating sewage conducted to the outfall on the separate system is reduced to a minimum. The value of sewage discharged on the Shone system,—where the separate system of drainage is adopted in connexion with it,—if it is utilised as liquid manure upon land suitable for irrigation purposes, must necessarily be much greater than it can be when it is discharged into drains and sewers on the combined system.

But it would be impossible for the author to explain his views fully on these matters, in the compass of a paper like this, without taking up much more of your time than he is entitled to do. He will, therefore, content himself by saying that the most important part of the work of a sanitary engineer is to drain houses of their sewage discharges in such a way as to cause the minimum unsanitary nuisance en route to the outfall. And the way to do this, as he has already stated, is to lay down all drains and sewers by hydraulic rule. If the hydraulic rule cannot be acted upon by trusting to natural gravitation drainage, then recourse should be had to artificial or mechanical means,—such as can be obtained from the adoption of the Shone system.

The following towns have applied the Shone system, more or less, in its entirety, viz.: Henley-on-Thames and Beaumaris (at these places automatic flush-tanks and the author's new system of ventilating sewers, were not used), Rangoon, Hampton Wick, and Wallingford. The improved system of ventilating sewers was not applied at Rangoon, for the reason that it was not invented at the time when those works were designed. But at Wallingford is to be found the most complete example of drainage works on the Shone system. There the public sewers have automatic flush-tanks and air inlets at their heads, and there also all the manhole covers are sealed, and the nozzle sewer ventilators are connected with each ejector station.

You all know that complaints of sewage-gas nuisances arising from perforated manhole covers over street sewers are all but ubiquitous, and these nuisances are intensified when house connexions are being formed with new drainage works. At Wallingford, however, such nuisances have been rendered non-existent, not a single case of complaint having been made up to the present time. . . .

But, occasionally, objections are raised to the system on the score of first cost. The following statement, which may be relied upon, will, however, serve to show that, even in point of first cost, the Shone system is to be preferred to the ordinary gravitation drainage. For example, the following towns were drained on the ordinary system, viz.: Margate (where hydraulic pumping is resorted to), Southport, and Llandudno, and the cost per head amounted to 4l. 7s., 6l., and 7l., respectively; or an average of 5l. 15s. 8d. At the following places, drained on the Shone system, the approximate cost per head has been as follows:—

	Cost per head.
Beaumaris.....	£. s. d.
Henley-on-Thames.....	3 0 0
Wallingford.....	3 15 0
Hampton Wick.....	3 9 0
	3 7 6
Average.....	3 7 10
Rangoon.....	2 2 4

The chief object in view in giving you these costs is to show your Association that high-class sanitary drainage works, on the Shone system, may be carried out at home and abroad, at fairly low prices per head of the population. In point of fact, the author knows cases where the ordinary gravitation plan has been carried out at prices which are more than double those at which the same extent of sewerage work could have been carried out on the Shone system.

[We give elsewhere a brief report of the discussion which followed.]

REMOVAL.—Messrs. Pugin & Pugin, architects, have removed their offices to St. Hubert's, Brook-green, London, W.

COMPETITION DESIGN FOR THE GLASGOW ART GALLERIES.

WHEN criticising the various designs submitted in this competition, we took occasion to comment on the vagueness of the instructions issued by the Committee, which left competitors to find out, or guess, important particulars which ought to have been clearly specified. A comparison of the plan by Messrs. John Honeyman & Keppie, which we now publish, with that selected, well illustrates the consequent perplexities of competitors. The authors of this design understood the Committee to mean that the central hall was to be a "concert-hall,"—as it is called in the conditions,—provided with the usual accommodation for orchestra or other performers, and capable of being used apart from the rest of the building without any interference with the access to the museum and art galleries. They also understood that the floor area of this Hall was not to be less than 10,000 superficial feet,—that minimum being clearly specified.

In order to gain their object, Messrs. Honeyman & Keppie run spacious corridors along each side of the hall, connected at the south end by the entrance-hall, and at the north end by a cross corridor. These side corridors are 22 ft. wide, and are divided by arches into a series of domical bays, each lighted from the centre. Three of these on each side are open to the hall, from which direct access is thus obtained to the art galleries on the one hand and the museum on the other. These departments have also independent entrances, and are so arranged that they may be kept entirely isolated from each other or otherwise, at pleasure. It now appears that the Committee did not wish any such classification, and it is a pity they did not say so distinctly at first. As will be seen from the elevation, there are no side windows in the galleries on the first floor. These extend right round the building, and are lighted from above. As there are no corner pavilions or other excrescences above the roof line, there is nothing to interfere with the proper lighting of all the galleries, and the whole space is utilised. We understand that this design cost less per superficial foot of area covered than any of the others.

Though this design was formally sent in as Messrs. Honeyman & Keppie's, we believe that practically it represents Mr. Honeyman's idea of the treatment of the problem, and as such is an interesting example of the taste and predictions of the older Classic school of Glasgow architects, among whom Mr. Honeyman has long held an honoured position. The design is at variance with recent architectural proclivities, but it is a fine and dignified building in itself, and, if erected, might possibly have commanded more permanent appreciation than some public buildings which are more in accordance with the latest architectural fashions.

MOSAIC PAVEMENT, HOUSE IN CHESTERFIELD-GARDENS.

THIS is a pavement of black and white mosaic for the staircase hall of Lord Leconfield's mansion in Chesterfield-gardens. The large panel at the foot of the stairs is filled with floral ornament in white on a black ground, with a border of black dolphins on a white ground. The parts at the sides of the first flight are powdered with circular and oblong panels filled with red and green porphyry, bordered with black and white mosaic. The corridor to the morning and business rooms has red mosaic grounds in addition to the black and white.

The balustrade to the staircase is entirely of hammered copper, burnished, and consists of openwork panels of floral ornament between turned copper balusters. The balustrade finishes against copper newels on the ground floor, and runs into marble pedestals on the first floor. It contrasts well by its lightness with the marble lining of the well-hole, the marble columns, and the marble balustrade; and its colour is heightened by contrast with the green Genoa marble of the cornice and capping of the marble balustrades.

its size, great care was necessary in the planning to obtain the necessary accommodation. The walls are faced with red bricks, and the dressings up to the 1st floor are of Portland stone; the large roof cornice and quoins, being of cement, were proposed by the architect to be painted white. The roofs are tiled. Mr. R. A. Briggs prepared the designs, which were carried out by Mr. J. Douglas, under his superintendence.

The drawing is exhibited at the Royal Academy.

THE ROYAL COMMISSION ON METROPOLITAN WATER-SUPPLY.

WE resume our report* of the evidence given before this Commission by continuing our summary of Mr. Gough's statement on behalf of the Thames Conservators. It had been urged, he said, that in times of very high flood the sewage farms become over-taxed, and that they do not work efficiently, with the result that impurities find their way into the river. The Conservators have had this consideration under their notice, but remark that, in floods of the description referred to, the river flow is twenty times greater than in dry weather, and that consequently the increased pollution is relatively hardly appreciable. The Conservators employ two Chief Inspectors, two Assistant Inspectors, and four River-keepers, who, although they have other duties to perform, devote a very large proportion of their time to the inspection of the sewage works referred to before, and to the detection of any cases where the law as to pollution may be infringed. In the course of the year these officers make as many as 2,900 inspections in the aggregate, and it is very rarely that cases are found where steps, even by way of correspondence, have to be taken by the Conservators. On the tributaries there are five smaller towns at some distance from the river, which have not diverted their sewage; these are:—Highworth, $\frac{3}{4}$ miles from the river, with 3,302 inhabitants; Faringdon, 3 miles from the river, with 3,141 inhabitants; Witney, 7 miles from the river, with 3,110 inhabitants; Eynsham, $\frac{1}{2}$ mile from the river, with 2,076 inhabitants; and Uxbridge, on the River Colne, 8 miles from the River Thames, with 8,206 inhabitants. In the case of Faringdon, the Local Authority disclaim all responsibility in connexion with the pollution. Notices have, therefore, been served on the householders. In the four other cases the Conservators have taken proceedings, but the justices have refused to convict, presumably on the ground that the pollution was not likely to reach the Thames. It is an offence only to pass sewage into a tributary in such a manner that the same is carried, or is likely to be carried, into the Thames. Great difficulty has been experienced in satisfying Courts of Justice that the sewage is so carried into the river, and the Conservators submit that it is necessary the law should be so amended as to make it penal to discharge sewage or offensive or injurious matter into any tributary of the Thames without qualification. There are three authorities, Hampton, Hampton Wick, and Richmond, below the Water Companies' intakes, who, although they are now executing works, have not finally completed them. In consequence of pressure used by the Conservators, the Sanitary Authority of Guildford, with a population of 14,319, which is beyond the Conservators' jurisdiction, is about to execute works to divert the sewage of that town from the River Wey, at an estimated cost of 27,325. There are a considerable number of places which are within the jurisdiction of Rural Sanitary Authorities, and in the great majority of instances the sewage of these places has been diverted from the river. The efforts of the Conservators have not been confined to the discovery of drains from towns or centres of population, whether large or small, but have also been directed to the prevention of sewage contamination from isolated houses, mills, and farms. There are a considerable number of paper-mills on the tributaries, but it is most rare to detect any discharge from them, and on the few occasions when a discharge has been detected, it has not been of a serious kind. The Conservators have caused the diversion of pollution from 750 scattered houses or farms, and at the present time their officers have difficulty in finding any fresh cases to

report of the kind. Although it may be doubted whether suds and sink-water are pollution within the meaning of the Act, the Conservators call upon owners and occupiers of the premises to stop the discharge without delay. In the great majority of instances, earth closets are used on houseboats and on those launches which have any conveniences of the kind. In ordinary circumstances, the owners of the vessels deposit the contents of the closets on land, under arrangement with landowners, and at Hensley Regatta, when a large number of these vessels are brought together on a comparatively small section of the river, and it would be difficult to find a place of deposit, the Conservators specially provide four punts to go round at night to collect excreta and refuse of all kinds, and thus guard against any pollution of the river on that occasion. No clear case of pollution from houseboats has been detected, and there is every reason to believe that the law is generally observed. In January, 1884, the Conservators gave instructions that no inhabited houseboat should be allowed to lie in the river between Chertsey Bridge and Hampton Ferry; that is to say, within a distance of from five to seven miles above the intakes of the water companies. Offensive substances falling or thrown into the river are removed before they putrify and pollute the river. With some inappreciable exceptions, the river is no longer contaminated by sewage, and the principal objection to the use of river water for dietic purposes can now no longer be urged against it. During the last twelve or fourteen years the weirs have been much improved, their sectional area increased, and mode of construction modified so as to admit of the greatest possible aeration of the water and its consequent improvement in quality. During the past year the Conservators had a large number of samples of river water, taken under different meteorological conditions at various points of the stream, not the most favourable for yielding samples of the best quality. The samples were analysed by Mr. Groves, who reported that they were all samples of a good potable river water. It is the view of the Conservators that the Thames forms a source of water supply perfectly suitable in quality for the Metropolis, and that it has not failed in quantity in the driest seasons, whilst, even in those seasons, it is capable of being supplemented by storage to an extent quite sufficient to meet the necessities of London for any measurable period in the future. These are considerations affecting the maintenance of the river which are of great importance to the public who use it. The charge of the river above Staines was not devolved upon the Conservators at their own instance, but, in the year 1866, that part of the river being in an insolvent condition, the President of the Board of Trade invited them to undertake its control, in addition to that of the district below Staines, which was already vested in them. Until recent years, when the contributions were increased, the Conservators have conducted their operations above Staines under the strain of constant financial difficulty. Every available shilling has been expended in the restoration of the river, and much important work remains to be done by degrees, as the state of the funds each year will admit. Difficulty has always been found in balancing the income and expenditure on the upper river, and the Conservators have frequently been compelled to forego the construction of works which nothing but shortness of funds would have made them consent to delay. The revenue received by the Conservators independently of the water companies has, fortunately, during the past twelve or fifteen years increased in amount, owing to the fact that the river has become one of the most important pleasure grounds of the Metropolis, but the traffic which has thus grown up has not proved itself equal to support the river independently of extraneous aid, nor in the opinion of the Conservators is it likely ever to do so. If no funds were left to the Conservators besides the river tolls and the few minor sources of income, there would be barely enough to pay the charge for the debt and the lock-keepers' wages. No further improvements could be contemplated, and it would not be within the competency of the Conservators to prevent the present works from falling, in a very short time, into decay. The staff of Inspectors could not be retained, and the inevitable consequence would be that the provisions of the Acts for keeping order on the river would become a dead letter. The

necessity of keeping the river pure from pollution for drinking purposes would indeed have ceased, but as a resort for health and pleasure, the river ought to be maintained in its present satisfactory condition, and without proper supervision there would be great risk of losing very much of what has been gained in this respect during the past twenty-five years. Thus the abandonment of the river as a source of water-supply, if accompanied by the corresponding loss of revenue without compensation elsewhere, would practically entail the abandonment of the river as a playground for the metropolis, and the Conservators urge upon the Commissioners the importance, or rather necessity, of some provision being made in this event, to enable them to continue the work they have carried out during the past quarter of a century for the benefit of the public.

Mr. Gough also handed in the following particulars respecting the sewage works of towns and other places on the Thames and its tributaries, above the companies' intakes and below them. After the name is given the population; then the description of works, with their area in acres. Where three figures are given, the first is the highest level of the farm, the second the lowest, and the third the level of the river at the nearest point. Lastly is given the geological formation of the farm; but the latter details are omitted in respect of places below the intakes:—

Above Intakes, on Main Stream.

Oxford, 45,741; irrigation farm at Littlemore, about 334 acres; 224, 189, 177; coralline oolite. Abingdon, 6,557; irrigation farm, 44 acres, $\frac{1}{2}$ mile south of the town; 169, 164, 162; Kimmeridge clay. Wallingford, 2,689; Shone's system, 10 acres, $\frac{1}{2}$ mile west of the town; 154, 152, 141; upper green sand. Reading, 60,054; irrigation farm, about 700 acres, $\frac{1}{2}$ mile south-west of the town; 128, 124, 121 (River Kennet); chalk. Henley, 4,913; Shone's system, 5 acres, $\frac{1}{2}$ mile north of the town; 145, 135, 101; chalk. Marlow, 4,764; no sewage works; cesspools in use; chalk. Maidenhead, 10,607; partly irrigation and partly filter-heds; a large amount is pumped up to Horst's land adjoining, and is used over the land; about 20 acres and Horst's land; close to town; 105, 75, 70; chalk. Windsor, 12,327; A, B, C system, about 20 acres at Ham Island, above Old Windsor Lock; 58, 55, 48; chalk. Eton, 2,499; irrigation, about 30 acres at Eton Wick; 67, 64, 61; chalk. Staines, 5,000; drainage chiefly into cesspits; no works; subject under consideration; gravel. Chertsey, 9,215; no sewerage works; drainage into cesspools and tubs, which are emptied by the Rural Sanitary Authority, and contents taken to sewage depots, and subsequently used as manure. Weybridge, 3,027; no sewerage works; contents of tubs, &c., taken to sewage depots; Bagshot sands. Sunbury, 4,297; no sewerage works; drainage into cesspits; gravel.

Above Intakes, on Tributaries.

Cirencester, 7,441; irrigation, 57 acres, 3 miles south of the town at Tudmore; 310, 305, 270 (Thames or Isis); cornbrash. Old Swindon, 3,543; irrigation, about 200 acres, 1 mile south of the town; 350, 340, 335 (river Ray); Kimmeridge clay. New Swindon, 27,295; irrigation, 50 acres,—farm comprises 100 acres, but only 50 used; 305, 295, 290 (river Ray); Kimmeridge clay. Wokingham, 2,060; irrigation, 8 acres, 500 yds. from the town; 10 acres, $\frac{1}{2}$ mile north-west of the town; 3 acres, at back of union; 171, 165, 133 (river Loddon); London clay. Wycombe, High, 13,435; 100, 188, 150 (river Wye); chalk. Slough, 5,427; irrigation; 10 acres at Dorney; 71, 70, 61 (Thames); chalk. Highworth, 3,302; no works; two large cesspools, which are emptied when full and sewage distributed over land. Witney, 3,110; no works; drainage into river Wenwash, above 5 miles distant from Thames. Faringdon, 3,141; no works; drainage into stream ditch, about 3 miles from Thames. Uxbridge, 8,206; precipitation and filtration; 6 acres; 100 highest level; 95 level of river Colne; chalk. Guildford, 14,319; chemical filtration and irrigation; 13 acres (works in progress); distance, 12 miles from Thames. Watton, 6,572; irrigation; 60 acres; 35 highest level; 27 level of river; gravel.

The following places drain into cesspools:—Shrivenham, 721; Binsey, Wytham, Littlemore, Headington, Cowley, which are on coralline oolite, and calcareous clay; Steventon, 924, on

* See *Builder*, pp. 418, 436, 456, 480, ante.

† *Ibid.*, p. 481, ante.

gant; Sutton Courtney and Eynsham, on the Oxford clay; Wargrave, 1,882, Remenham, Cookham, 6,851, Datchet, and Chalvey, on the chalk; and Shepperton, on gravel. At Steventon there is one farm which drains into a brook which runs into the Thames, but the provision of a cesspool is promised. A small amount of drainage from Datchet runs into a ditch which flows into the Thames near Wrayshury.

Below Intakes, on Thames.

For the following places the levels and geological formations are not stated as they are below the intakes and do not affect the water supply—

Kingston, 27,054; Surbiton, 10,052; and Hampton Wick; works on the A B C system, 3 acres.
 Teddington, 10,025; works, precipitation, filtration and irrigation, 22 acres.
 Twickenham, 16,026; works, filtration, 4 acres.
 Richmond, 22,684; Petersham, 566; Kew, 1,670; Mortlake, 6,330.
 Barnes, 6,001; works, precipitation and filtration, 11 acres; outlet at Mortlake.
 Isleworth, 12,873; works, Candy's process and irrigation, 22 acres.
 Brentford, 18,736; works, precipitation and irrigation, 3 acres.
 Chiswick, 21,964; pumping station, precipitation, 5½ acres.
 Hampton, 5,322; drainage at present into cesspool (scheme lately adopted and to be carried out).
 East Molesey, 4,693; cesspool drainage at present; scheme for drainage under consideration; waiting Local Government Board's report.
 Ealing, South, 3 acres, precipitation and special.
 Acton, 24,207; 5½ acres; Candy's process, discharge into the River Thames at Chiswick.

Below Intakes, on Tributaries.

Ealing North, 23,978; 22 acres; pre., fil., and irr., r. Brent.
 Hanwell, 6,139; 12 acres; pre. and irr., r. Brent.
 Willesden, 61,266; 18 acres; pre., fil., and irr., r. Brent.
 Finchley, 16,639; 72 acres; chemical p. and irr., formerly into the Brent and now into the Lea.
 Hendon, 16,833; 23 acres; International Water and Sewage Purification Company's system, into the Brent.
 Harrow, 5,725; 25½ acres; two irrigation farms, into Brent.
 Pinner, 2,310; 6½ acres; irrigation farm, Yeading Brook and River Crane.
 Uxbridge, 8,417; 120 acres; irrigation field, Hogg's Mill river.
 New Malden, 3,437; 9 acres; p. and irr., Hogg's Mill river.
 Cranford, 503, 2½ acres; farm, f. and irr., river Crane.
 Alperton, 8½ acres; farm, p. and irr., river Brent.
 Stanmore, 1,312, 8½ acres; irrigation farm, river Brent.
 Southall, 3,784, and Norwood, 6,681, 11 acres; irr. and f. works, river Brent.
 Esher, 1,193, Clarendon, Thames Ditton, 2,956, and Long Ditton, 2,313; 20 acres, p. and irr. works; river Mole.
 Tolworth and Hook, 9 acres; p. and irr. works; Hogg's Mill river.
 Harmondsworth, 1,812; tank, sewerage; solids used as manure; Duke's river.

In the course of his evidence, Mr. Gough said that the Companies that were unlimited by Act were the Southwark and Vauxhall, the Lambeth, and the Grand Junction, and the Companies that were limited were the East London, the West Middlesex, and the Chelsea. The Conservancy considered that the effect of granting the extra 20,000,000 gallons would not prejudicially affect the river. The actual amount taken from the river at the intakes varied from about 90,000,000 to 105,000,000 gallons. The quantities taken were furnished by the Companies; and the Conservancy had no check. In the return of sewage farms, the geological formation was taken from the geological map, which did not show what the top soil was; but that he could supply. The Conservators' local officer reported that there was no pollution whatever coming into the Thames from Marlow. Three or four years ago the effluent from Oxford was not satisfactory; this was represented to the Oxford Corporation, and they improved it at once. If the inspecting officer of a district observes that an effluent is at all of a doubtful character, he reports it, and sends up samples. A sample is sent to Mr. Groves for analysis, and if on analysis it is found to be of an indifferent character a representation is made to the authority under whose jurisdiction the farm is. Oxford was reported in September, 1887, again in August, 1888, as "not good" and "had"; in December, 1889, as "good;" and in February, 1891, as "fair." There are from thirty-six to fifty inspections

a year of the same places. A total of about 2,900 inspections are made in the year. There are two inspectors. The upper navigation down to Staines is under Lieut. Bell, assisted by Mr. Green, who is a land surveyor; the district from Staines to the western limit of the Metropolis is under Mr. Little, with Mr. Drummond as assistant, and each is helped by two river-keepers. The officers go up the tributaries to a distance of ten miles measured in a direct line from the Thames. Abingdon works very satisfactorily. Wallingford has given trouble; the sewage was stopped, but not in a satisfactory manner; but lately the authority has completed a system since which there have been no bad reports. When asking about the Reading works,

The Chairman said: We should like to know exactly how many inspections have been made of the effluent, how many times it has been reported upon unfavourably, and what the results of any communications have been. We should also like an estimate of the amount of time the staff of the Conservators can really devote to inspections consistently with the discharge of their other duties.

Speaking of Windsor, the witness said that Ham Island had a lock out on one side and the river on the other; the sewage was treated chemically in tanks by the A.B.C. process; and in the last five or six years the effluent had not been sufficiently bad to be reported upon and to be analysed.

The Chairman: Who judges as to whether it is what you call "sufficiently bad?"

Witness: The inspector, if he observes anything which he thinks it his duty to bring under the notice of the Conservators, takes a sample and reports it, and it is sent to the analyst at once; I send it on.

Do we understand that no effluent is analysed unless you get a bad report upon it?

The Conservators have not regularly analysed the samples until the samples are reported upon by their officer as being of such a character as to require analysis.

Then, for five years the works of Windsor have gone on absolutely without check? They have not been analysed.

I mean absolutely without check beyond the test of the eye?

Yes, and the observation of the officers. Mr. Mansergh: And of the nose, probably? Yes, and of the nose.

In the case of each town above the intakes, the witness continued, there was an actual effluent into the river. In the case of High-worth, the Conservators took proceedings, but they were not able to obtain a conviction. It is now reported that the sewage is distributed over the land, so that no pollution is coming into the Thames. Farringdon is situated on a hill; the sewage passes into a tributary of the river, which is called a stream ditch. The Conservators have had a great amount of trouble with this case. They have corresponded with the local authority, who disclaim any liability. They say that the drains are private drains, and they quote the decision of the High Court with regard to Staines, — that they have no power to compel the individual owners of drains to divert their sewage. The Conservators have accordingly obtained a list of all persons who have sewage drains and who discharge their sewage drains into the stream ditch, and have served notices, after analysis of samples taken, upon those various individuals requiring them to divert the flow of the sewage from their drains into this stream ditch. These notices will shortly expire, and thereupon the Conservators propose to take proceedings before the magistrates to enforce compliance with the law as to pollution. In the case of Windsor, five miles from the Thames, the Conservators have taken proceedings and have failed to obtain a conviction. In the case of Eynsham, cesspool drainage was general, but there was a small discharge into the ditch at Lynsbam Wharf. The Conservators have proceeded against the Rural Sanitary Authority, and were not able to obtain a conviction, but they are watching with the view of obtaining a sample which will enable them to try again. It is not always easy to obtain a conviction by local magistrates. The Conservators several years ago twice took proceedings against Uxbridge for the pollution of the Colne. The magistrates refused to convict, and on the second occasion imposed all the costs upon the Conservators, on the ground that it was not proved that the pollution was likely to reach the Thames at a distance of 8½ miles. On more than one occa-

sion the Conservators have been met by scientific evidence that pollution was not likely to be carried into the Thames. The Conservators have often felt that it ought to be an offence to pass any pollution into a tributary within the watershed of the Thames. The Conservators have watched Staines from the commencement in 1866. They have taken samples and obtained convictions, but the convictions led to no useful result, and they decided to proceed against the Local Board in the High Court. The Judges decided that the Local Board were not liable, because there was a prescriptive right for the individual owners of drains to discharge into their drains. Counsel then advised that the only step to take was to serve notices on the individual owners of the drains. This was in 1888, so that it took twenty-two years to get to that point. Drains had to be broken open and samples taken at the discharge of the small drains into the large drains. On the expiry of the first set of notices proceedings were commenced, and on June 20, 1891, the Local Government Board received a petition from inhabitants praying the department to hold an inquiry. The magistrates adjourned the summonses. The inquiry was held on September 26, and on December 15 the Local Government Board issued an order requiring the Staines Local Board to provide sufficient sewers within six months. The Local Board propose to comply with the order by having a system of cesspools, and they will have carts to empty the cesspools and convey the material away, unless the Local Government Board should interfere, and say that that is not a sufficient dealing with the question. The only power of the Conservators was to say that there should be no pollution passing into the river. Some years ago Weybridge proposed to have sewage works, but the Conservators opposed, on the ground that the sewage was likely to be washed out of them into the river. Paper mills are most carefully watched, and the slightest impurity is easily detected and reported at once. There are some thirty or forty above all the intakes. There are a fellmonger's works at Wokingham, from which blood occasionally passes into the river. The 750 scattered houses or farms have also to be watched. They discharge into tributaries or drainage ditches. In dry weather there is no discharge, but at flood times there is risk of pollution being washed into the river. If the inspectors see a possibility of pollution, occupiers are called upon to divert it, and they do it mostly by cesspools, sometimes by sealed tanks, from which it is pumped out in dry weather and distributed over farms. The Conservators have prohibited inhabited house-boats lying between Chelsea Bridge and the intakes of the Companies. There are 167 vessels registered as house-boats, and 47 as dressing-places and storage for boats' gear. There is a mark outside a house-boat which shows that it has been registered. There is no power to go on board house-boats to inspect them, but it is made a condition of their having places at Henley Regatta that they shall allow inspection. They have on board earth pans and patent closets, the contents of which are taken on shore and dug into the soil. There are 393 registered steam-lanchnes, and on the majority there are no conveniences of any kind. Out of the total amount paid by the water companies, about 3,500*l.* may be apportioned as fairly chargeable in respect of inspection for pollution purposes. The thirty-seven villages or towns named are all that have at any time been suffered to pollute the river. The County Council map shows many places that have been actually dealt with, and which are no longer sources of pollution.

Mr. C. J. Moore, Engineer to the Conservancy, produced a table showing for the nine years 1883 to 1892 the daily flow at Teddington Weir after the water had been abstracted by the companies. The following abstract gives averages, *maxima* and *minima* :—

	Millions of gallons.	Millions of gallons daily.
Average Annual volume of discharge.....	447,041·9	
" Monthly " " " " " " " " " "	37,253·5	
" Daily " " " " " " " " " "	1,224·0	
Maximum volume of discharge :—		
In a year (1883).....	659,837·4	= 1,807·3
(a) 6 months " " " " " " " " " "	466,639·3	= 2,578·1
(a) 3 months " " " " " " " " " "	367,235·0	= 4,080·3
(a) 1 month " " " " " " " " " "	174,575·0	= 6,234·8
(a) 7 days " " " " " " " " " "	60,865·0	= 8,395·0
(a) 24 hours " " " " " " " " " "	9,640·0	

Minimum volume of discharge —	Millions of gallons.	Millions of gallons daily.
In a year (1890)...	261,915-6	= 717-6
(a) 6 months	76,925-6	= 420-3
(b) 3 months	26,215-2	= 234-9
(c) 1 month	6,517-3	= 210-2
(d) 7 days	1,253	= 179-6
(e) 24 hours	153-3	

(a) All in 1888. (b) June to Nov., 1890. (c) July, Aug., and Sept., 1887. (d) Aug. 1885. (e) Aug., 1885, and Sept., 1887. (f) Aug., 1887.

Having regard to these minima, the present authorised maximum abstraction of 150,000,000 gallons could not be safely increased in dry weather. If 500,000,000 gallons were coming down the river and 100,000,000 gallons were taken out, he estimated that the abstraction would lower the surface about 4 1/2 in.; the abstraction of 150,000,000 would make a further difference of about 1 1/2 in. The effect would diminish as you went down the river, and at Hammersmith would be lost. A half-tide weir is being built at Richmond, and that will maintain a level of about half-tide up to Teddington. The Richmond people have complained of the exposed foreshores, the low-water level having been considerably lowered. This was due to the removal of bridges and obstructions in the lower part of the river, and to dredging for the removal of shoals and the improvement of the navigation. Reminded by the Chairman that the figures he had given were smaller than those adopted by the Commission of 1869, the witness said he thought it had always been assumed until lately that there was more water in the river in dry seasons than was actually the case. The witness handed in a table showing the volume of the discharge at Teddington Weir for the years 1813 to 1891 inclusive, with the addition of the quantities abstracted by the companies, and the equivalent rain-fall for the drainage area of 3,766 square miles above Teddington. The yearly averages were: Gangings at the weir, 447,042,000,000 gallons; abstraction by the companies, 80,896,000,000 gallons; actual volume of discharge, 477,937,000,000 gallons. This discharge is equal to 347,335 gallons per square mile of the water shed per diem; and that is equivalent to a rainfall of 3-7 in. per year. In this way the volume of discharge seemed to vary from a maximum rainfall of 12 1/2 in. in 1883 to a minimum of 5-4 in. in 1890. The minimum could be partly accounted for by the fact that there was not the full average rainfall, and that there was a very severe frost, during which the river ran very low. For the three driest consecutive months in every year of the nine years there was an average flow of 429,000,000 gallons per day, which might be called the ordinary summer flow. This was what was left after the companies had taken their quantities.

The Commission then proceeded to take the evidence of Mr. Groves, Consulting Chemist to the Conservancy; but we must break off here for the present.

SANITARY SAMPLES AT HIGHGATE.

THERE is now approaching completion, at the Highgate Depot of the Hornsey Local Board, situated on the great North road of the old coaching days, what is intended to be a permanent exhibition of sanitary appliances, together with a standard reference museum of samples of materials and fittings. The establishment of this useful exhibition and museum is an interesting event, and reflects much credit on the Hornsey Local Board, whose enlightened policy in regard to sanitary administration generally has been noticed on previous occasions in these pages. Under section 18 of the Public Health Acts Amendment Act of 1890, the Board, in common with other local authorities, have power, under certain conditions, to execute, by their own officers and staff, any works necessary to put a dwelling-house into a healthy and habitable condition, and to charge the cost upon the owner. It is not proposed by the Board to adopt the course of doing such works themselves except under very special circumstances, as they have a wholesome desire to refrain from unnecessary interference with ordinary traders, but in all cases they will closely inspect and carefully test the efficiency of such works. The increased attention that has been devoted to sanitary matters of late years is, it seems (in the district of the Hornsey Local Board, at any rate), beginning to tell, and people are showing a

laudable desire to feel assured that the houses in which they live are in proper sanitary condition, and that the appliances in use are adapted to their various purposes. In their anxiety for information, inhabitants of the district are constantly writing to the officials of the Board to know what are the best types of appliances and the best modes of fitting them; and as numerous have these demands become that the Board determined to make the experiment of establishing a typical exhibition of the best sanitary appliances and samples, and to confide the direction of the work to their Engineer and Surveyor, Mr. T. De Courcy Meade. A couple of advertisements in the *Builder*, inviting the co-operation of manufacturers and others willing to exhibit, elicited a very large number of offers of help, and a selection having been made, the result is that four large rooms, having an aggregate floor-space of 325 square yards, are now devoted to an exhibition to which nearly all the leading firms of manufacturing sanitary engineers are contributors of appliances of all kinds. Not only is the floor-space well filled, but the walls and division screens are well covered with exhibits. No charge is made for space, but the exhibitors will no doubt be expected to keep their stands always "up to date." An exceedingly useful feature of the exhibition consists not only of standard stamped samples of lead-piping and other materials, but of full-size sections showing the proper construction and sanitary arrangements of a healthy house. By way of negative teaching, showing what to avoid, a number of horrible examples of bad plumbing work are shown in section; and D-traps and other bad old contrivances filled with hard deposited matter, and 9-in. drain-pipes completely choked with tree-roots which have entered at the joints made with clay instead of cement, convey lessons likely to be impressed upon the memory of all beholders. The exhibition (which will be open free of charge to visitors on every working day) cannot but prove of great educational value to the residents; and it is even hinted that many builders and their workmen,—and possibly some architects,—may there learn not only how to produce good work, but how to avoid bad work. We have not space now to attempt a detailed notice of the exhibits; that we must reserve for another occasion; but we must congratulate the Hornsey Local Board upon their excellent idea, and Mr. Meade and his assistants upon the way in which it has been carried out. The exhibition is now practically filled up, but Mr. Meade would nevertheless be glad to hear from anyone who has anything new and special that might be deemed worthy of a place in the collection, which is now being catalogued.

SOCIETY OF ENGINEERS:

FOREIGN SEWAGE PRECIPITATION WORKS.

At a meeting of the Society of Engineers held at the Town Hall, Westminster, on the 13th inst., Mr. Joseph William Wilson, jun., President, in the Chair, a paper was read by Mr. Albert Wollheim, on "Foreign Sewage Precipitation Works." In the introduction to his paper the author compared and traced the development of sewage precipitation works in this country and abroad, and stated that as yet there were only very few works of the kind in existence abroad. Then taking for the first part of his subject the works of Germany, he reviewed and detailed the existing legislation for the prevention of river pollution. Unlike England, Germany possessed no statutory legislation for preventing the pollution of its water-courses. There are only in existence Ministerial decrees, rescripts, and reports of scientific bodies.

The most important precipitation works of Germany are those at Frankfort-on-the-Maine (population 160,000). Ever since the year 1885, when the canal works and port were completed, the trade of the town has increased to an enormous extent, and a thorough system of sewerage and sewage disposal is therefore of the first importance to the town. The system of water-closets, drains, and sewers was commenced over thirty years ago under the late Mr. W. H. Lindley, and completed by his son, Mr. W. Lindley, the present city engineer, who has also designed the precipitation works. These are situated on the left bank of the Maine, the sewage from the right bank being conveyed across by two wrought-iron siphons, 2 ft. 6 in. diameter, with a total discharging capacity of

800,000 gallons per hour. The precipitation tanks are covered in, and will consist of two groups of six subdivisinal tanks each, but only four subdivisions are as yet constructed. They are each 270 ft. long by 17 ft. average width, and 6 ft. 10 1/2 in. average depth of water. Each sub-division holds 250,000 million gallons, and as the present daily dry weather flow is 6,000,000 gallons, the existing tank capacity is 16 per cent, of the total daily flow. The whole volume gravitates to the works, and in dry weather overflows continuously at the outlet-end. But as the high-water mark of the river is considerably above the ordinary water level in the tanks, special adjustable high-water dams have been provided at the tank outlets, which enables the sewage to be backed up in the tanks and sewers for some hours without, however, causing floodings in the town. During exceptionally heavy floods, when there is danger of backing up the sewage too high in the town, two powerful centrifugal pumps with 20-in. sections can lift the effluent into the river, and thus keep down the tank water level. The sludge is pumped up periodically into sludge drying pits capable of holding an aggregate of 1,000,000 gallons of liquid sludge. The precipitants used are lime and sulphate of alumina, and the quantities are adjusted by means of Lechner and Spohr's patent automatic electric gauge, which continually transmits to the precipitant house, and records on a revolving drum the height of the sewage in a bay formed at the tank inlets where the chemicals join the sewage. In concluding his description of the Frankfort works, the author drew attention to some important experiments carried out by Mr. Lindley, bearing on the displacement of water in tanks. These tend to show that in summer the incoming sewage slides along the top, in winter it immediately falls to and slides along the bottom towards the outlet end. In both cases the body of water in the tank remains more or less undisturbed. To remedy this Mr. Lindley has devised a falling dam to be fixed in front of the outlet, which has the effect of deflecting and diffusing the incoming stream throughout the tank.

The Roekner-Rothe system of circular upward flow tanks, as distinguished from the rectangular longitudinal system was next described. The Roekner-Rothe system has been somewhat simplified by Herr Kniebuehler, City Engineer of Dortmund. His tanks are huge circular brick wells sunk into the ground, the sewage being led into the conical bottom where it deposits the sludge, the clarified effluent rising and overflowing continuously all round the top. The sludge is pumped up periodically without disturbing the continuous working. A complete installation on this system is at work at Dortmund.

The author concluded his paper with a brief résumé of what has been done in the United States to prevent river pollution. It would appear that the States, with their vast area and innumerable rivers and streams carrying large volumes of water, have not experienced any difficulty from the discharge of raw sewage until a short time ago. The country is just now beginning to stir in the matter. This accounts for the fact that only three precipitation works have been constructed. The largest are those at Worcester (Massachusetts). In the Worcester works, which were designed by Mr. Allen, the City Engineer, well-known English types have been followed, the tanks having been planned somewhat after the Coventry tanks. The tank walls are constructed of small rubble heddled in Portland cement, and faced with vitrified bricks, the copings being composed of granite chippings and cement. The chemicals used are lime and sulphate of alumina. Only a portion of the city drains to the works at present, the daily flow being about 3,000,000 gallons. In this connexion the author gave a table showing the number of gallons of water per head supplied to various towns throughout the States, from which it appears that 100 gallons per head is by no means an uncommon figure. An intimate acquaintance, he said, with American home and industrial life was necessary in order to comprehend how such high figures could be reached.

The paper was illustrated by a large number of diagrams.

VISIT TO THE SOUTH METROPOLITAN GAS-WORKS.

The excursion which the members of this Society made down the river on Tuesday last,

June 21, was more particularly interesting on account of the visit to the South Metropolitan Gasworks at East Greenwich, where the largest gasometer in the world is now being erected. The party were landed at the great coal stage, where in the hydraulic room they were entertained at luncheon, Mr. Tysoe, the Superintendent of the works, presiding, in the unavoidable absence of Mr. George Livesey. Inspection was thereafter made of the engine-house and the machinery therein for exhausting the gas from the retorts and passing it on under pressure to the washers, scrubbers, and purifiers, and finally through the meters into the mains. The order, quietness, and efficiency were greatly admired. The retort-houses were next taken, and here the process of gas-making was seen carried on by hand at the floors, and by staging for the tiers of retorts one above the other. Mechanical means, too, of charging and of drawing were shown. Other departments were also inspected, and high appreciation invariably expressed. The marked peculiarity of the East Greenwich Works is that they are fundamentally based upon the most modern knowledge and experience, and have not been built up successively from foundations laid in former stages of the general progress of gas manufacture. The South Metropolitan Gas Company possess several large works which originated in such earlier circumstances, and have been kept in touch with advances by modifications and improvements,—namely, Vauxhall, Bankside, Old Kent-road, and Rotherhithe, but East Greenwich is an entirely new station. When the amalgamation of the Phoenix Company with the South Metropolitan took place in 1880, the whole of Blackwall Point was acquired, with an area of over 110,000 acres, of which something like 100,000 acres have been retained for present and future works, and which latter can adequately provide for a long series of years complete extension of gas supply to meet increased demands. Another important feature of this site are the advantageous facilities for the supply of coal,—the raw material of the manufacture. Vessels of from 1,000 to 1,500 tons burden can discharge at the landing-stage, whilst on the other hand the surplus coke from the manufacture can be tipped from the waggons on the railway by the river wall direct into the barges for sale.

The immediate interest of the day, however, centred on the large gasometer erecting in the marshes. The storage of gas is one of the most important considerations, not only in regard to the skill of the engineer in the required constructions, but still more so in the fact that the larger the gasholder the less the cost in proportion to the quantity stored within it. The material, however, must be thin, because the gasometer must not be heavy, as it has to be raised by the very moderate pressure of the gas within it. Nevertheless, the gain of economy is so great as to have tempted one very practical and prudent man to carry magnitude, in this instance, far beyond any previous attempt. The Vauxhall works have a gasometer of 3,000,000 cubic feet capacity, and the existing gasometer of the East Greenwich works will contain 8,500,000 cubic feet of gas. The new gasometer will store 12,000,000 cubic feet, and its diameter is no less than 300 ft. The tank in which it will float is raised above the marshland by a circular embankment of concrete, and is 303 ft. 6 in. across; its depth at the internal wall is 32 ft. to the rest-blocks. Its thickness is 4 ft. 6 in. at the bottom, and 3 ft. 6 in. at top. The gasometer is of telescopic type, and will rise to a height of 180 ft. in six lifts. The surface of such a gigantic and lofty object presented to the wind is enormous, and a mere ring of independent columns, as employed by the old engineers would be utterly inadequate for its support. In the first place, there is no cohesion between the loose columns, and under strong winds the pressure is concentrated on one or two of them alone at the rear, whilst the lateral columns have no stress brought upon them at all. The bracket system of supports, extending from the gasometer to the vertical standards in the surrounding ring, was introduced by Mr. Livesey some years ago at Rotherhithe, and these may be well seen from the decks of the river steamers. This primitive idea has been now developed at East Greenwich into a remarkable engineering structure of enormous strength and coherence. The columns have given place to wrought-iron standards, with their bases firmly embedded in the concrete wall of the bank. A projection on

the face of each standard is bevelled on either side, and the two rollers attached to the end of each of the gasometer brackets,—which are set somewhat diagonally instead of directly radially,—run against these faces; and thus is distributed some of the wind pressure upon every standard in the whole series. A wrought-iron coping or continuous circular girder, 22 in. in breadth, surmounts the whole circle of standards, and combines them in perfect mutual and united support. The inter-spaces between the standards are finished with strong open wrought-iron lattice-work, so that the final condition is that the wind's pressure on the gasometer will be transferred to a surrounding enormously strong and rigidly fixed wrought-iron cage, built up to the height of 60 ft. from the ground, and above which two-thirds of the gasometer will extend skyward.

The strength of wind which has thus been provided against is 56 lbs. to the square foot, the highest reliable strength of wind record obtainable by the ordinary anemometer, and notably in excess of the 45 lbs. to the square foot usually taken as maximum storm-pressure. There is no doubt that in hurricanes and cyclones there are pressures beyond this, but they occur so rarely, and even then along such limited lines, that, for practical purposes, they may be neglected.

On the return journey, the party landed at the north pier of the Tower Bridge, and were conducted over the works by Mr. Cruttwell, the resident engineer for Mr. J. Wolfe Barry, and by Mr. Tait, the representative of the contractors, Sir William Arrol & Co. We published some particulars of the construction of this bridge, illustrated by diagrams, in last week's *Builder*.

THE LONDON COUNTY COUNCIL.

THE usual weekly meeting of this Council was held on Tuesday afternoon, at Spring gardens, the Chairman, Lord Rosebery, presiding.*

Finance: The Council's Accounts for 1891-92.—The Finance Committee reported that Mr. H. Lloyd Roberts, the Auditor appointed by the Local Government Board to audit the accounts of the Council for the year ended March 31, 1891, completed his audit and gave his certificate on May 21, 1892. The Committee append a copy of his report, which they regard as very satisfactory, and as calling for no special observation, the alterations required by the auditor involving questions of book-keeping only, and not allowance or disallowance of any item. Two paragraphs from the Auditor's report may be quoted, as showing the extent of the Council's financial operations and obligations:—

"The balance in the hands of the Council at the commencement of the year was the sum of 92,693, 16s. 9d.; their receipts within the year amounted to the sum of 3,332,399, 10s. 6d., and their expenditure to the sum of 3,608,770, 1s. 1d.; leaving an available balance of 648,043, 6s. 2d. in their hands at the end of the year.

"The amount of the Metropolitan Consolidated Stock issued by the late Metropolitan Board of Works and by the Council outstanding at March 31, 1891, was 25,834,925, 10s. 11d., and the balances of loans outstanding at the same period were, in respect to loans contracted by the late Metropolitan Board of Works, 163,532, 6s. 8d., and in respect of loans contracted by the former counties of Middlesex and Surrey and taken over by the County of London, 539,260, resulting in a liability of the Council as to stock and loans of the sum of 26,577,110, 3s. 7d."

Proposed Widening of the South End of Tottenham Court-road.—On the recommendation of the Parliamentary Committee, it was resolved, after some discussion,—

"That we be authorised, in conjunction with the Improvements Committee, to endeavour to arrange with the promoters of the Hampstead, St. Pancras, and Charing-cross Railway, for the clearance of the site of Butler's-court, on the understanding that the Council will contribute a sum not exceeding half the net cost of such clearance."

An Additional Assistant Medical Officer of Health.—On the recommendation of the Public Health and Housing Committee, it was resolved:—

"That an additional Assistant Medical Officer of Health be forthwith appointed, at a salary of £500 per annum, rising to 600, per annum by two annual additions of 50, each."

Alterations of Claybury mansion-house.—The Asylums Committee's report contained the following paragraph and recommendation:—

"We have further to report that the tender of

* Lord Rosebery has since resigned the Chairmanship, the reorganisation of the Council's Committees, &c., having now been effected.

Messrs. Reed, Blight, & Co., of Plymouth, for alterations to the mansion-house, which the Council on April 12 last authorised us to accept, amounting to 8,955, and that the sum authorised by the Council, on our recommendation, to be expended on this work, viz., 10,000, (7,500, for building, and 2,500, for furniture, &c.) will therefore be insufficient. The explanation for the estimate being thus exceeded is, we think, that the labour market is at the present time in so unsettled a state. We recommend—

"That, subject to an additional estimate being submitted by the Finance Committee, we be authorised to expend a further sum of 2,000, not exceeding 12,000, in all, in converting the mansion-house into an annexe to the main asylum for the accommodation of fifty male paying patients."

This was agreed to without discussion.

Additions at Cane Hill Asylum.—The same Committee's report contained the following paragraphs:—

"On May 17 last the Council authorised us to accept Messrs. Reed, Blight, & Co.'s tender, amounting to 15,410, for the above, provided that they agreed to the insertion in the contract of the condition that they would 'pay the London rate of wages, and observe such hours of labour as are generally accepted in London as fair in the trades they employ.' Messrs. Reed, Blight, & Co. intimated their willingness to agree to such a condition being put in their contract, if by that it was understood that the rate of wages recognised at the time of the acceptance of the contract were to be paid during its continuance, and that in the event of an increase of the union rates of pay, they would be compensated by the Council for the extra amount they would consequently have to allow their workmen. We saw Mr. Reed, and informed him that our resulting of the Council's resolution differed from his, and that the rate of wages paid and hours of labour observed were to be those which are from time to time accepted in London as fair in the trades employed. Mr. Reed thereupon respectfully declined on behalf of his firm to complete the contract. We accepted this decision, and informed him that his firm would not be prejudiced thereby, inasmuch as the condition was not in the form of contract to which they tendered, but was imposed subsequently.

"Though it is most pressing that the buildings and works under this contract should be at once proceeded with, we think, looking to the difficulties that may arise, it advisable not to again issue advertisements until the terms of the 'wages' clause have been definitely fixed by the Council."

These paragraphs gave rise to considerable discussion, and eventually the matter was referred back to the Committee to re-advertise for tenders as soon as possible.

Contracts for Work at Asylums.—The same Committee also reported,—

"We are unable to proceed with the provision of infirmary accommodation at Banstead Asylum, and the installation of the electric light at Claybury Asylum, as, though the forms of contract have been prepared by the Solicitor, he cannot complete them until the terms of the 'wages' clause have been definitely settled by the Council. This, we understand, may take some time, and, as it is most urgent that both these works should be commenced at the earliest possible moment, we recommend—

"That we be authorised to obtain tenders for the provision of infirmary accommodation at Banstead and for the lighting of Claybury Asylum by electricity, conditionally upon clauses being inserted by the Solicitor in the respective contracts binding the contractors to pay the trades union rates of wages and to observe such hours of labour as are generally accepted in London as fair in the trades they employ."

Lord Monkswell moved, as an amendment, to omit the words "trades' union," and to insert, after the words "rates of wages," the words, "agreed upon between employers and the recognised trades' unions." This was ruled out of order, however, and the recommendation of the Committee was agreed to.

Further Works at Claybury Asylum.—The concluding paragraph and recommendation of the Asylums Committee were as follow:—

"We have further to report that we have approved estimates for making roads, draining land, preparing airing-courts, building a mortuary, cow-houses, piggeries, stabling, cottages, fences, and greenhouses, and extending electric lighting to mortuary and farm buildings, amounting (together with the commission to architects and salaries of clerk of works and incidental expenses) to 25,000. We have also approved the sketch plans submitted of the cowhouses, piggeries, stables, and cottages. The whole of these works are essential to the completion of the Asylum, and we therefore recommend—

"That, subject to the usual estimate being submitted by the Finance Committee, and to the approval of the Home Secretary being obtained to the plans of the farm buildings, we be authorised to provide at Claybury Asylum the buildings and works above enumerated, at a cost not exceeding 25,000."

The recommendation was referred to the Finance Committee.

Proposed Residential Chambers at the Westminster End of the Victoria Embankment.—The first paragraph and recommendation of the Building Act Committee's report were as follow:—

"We have had before us an application of Mr. Keeling, on behalf of Mr. J. Sarl, for approval by the Council of an amended plan for consent to the erection of a block of residential chambers on the Victoria-embankment, and adjoining St. Stephen's Club. The site now vacant was sold and conveyed by the late Metropolitan Board on July 2, 1880, for 3,500*l.*, to Messrs. Hansom & Widdowson, who covenanted with the Board not to build or erect any erection or building whatsoever of which the front next the Embankment should be in advance of the line marked "line of building frontage" on the plan in the conveyance (which is a continuation of the line of frontage of St. Stephen's Club), or any erection or building whatsoever, except such as should be faced with stone or marble, or such also as should be in strict accordance with such elevations and plans as should be submitted to and approved by the Board, or their successors, before such erection or building was commenced. The Solicitor advises that the Council can insist that the buildings shall not be erected in advance of the line of frontage marked on the plan on the conveyance, and can also insist that no building shall be built except in accordance with the elevations and plans submitted to and approved by the late Board, provided the Council exercises its powers reasonably, and not in such a manner as practically to prevent the land being utilised to advantage as building land. Your Committee have also had before them a letter from the Receiver of Police, strongly urging that the buildings proposed to be erected on this site should be kept back to the line of frontage of the police offices recently erected. The First Commissioner of H.M. Office of Works also expresses an opinion that if the building as proposed is erected, it will have a detrimental effect upon the Houses of Parliament, and further that the height of the Club building was reduced considerably below that designed by that department, and that it would be a great satisfaction to the Office of Works if the highest part of the new building could be kept down to the top of the level of St. Stephen's Club. In this view your Committee concurs, and under all the circumstances we see no reason to approve of any deviation from the line of frontage shown on the plan in the conveyance of the property by the late Board, more particularly as the building as now designed would be higher and in advance of the adjoining club-house, and would in our opinion spoil one of the finest views in London. We recommend,—

"That the application be not granted."
This was agreed to without discussion.

Proposed School Building at the Crossness Outfall Sewage Works.—The Main Drainage Committee's report contained the following paragraph in relation to a matter mentioned by us last week in our report of the Council's proceedings:—

"At the meeting of the Council on Tuesday last the Chairman suggested that as only one tender had been received for the erection of the school building at Crossness, although the work had been duly advertised, the tender should not be opened, but that the subject should be referred to us. That suggestion was acted upon, and the matter has accordingly been under our consideration. We think in view of all the circumstances, and after conference with the Solicitor, that, before deciding to take any other step, it will be best to open the tender which has already been sent in. We therefore recommend,—

"That the tender be opened by the Council, and referred to us for consideration and report."

This was agreed to, and the Chairman accordingly opened the tender, the amount of which he stated to be 2,270*l.* The name of the tenderer was not announced.

The London Water Question.—The Special Water Committee presented the following report and recommendations:—

"The Royal Commission on Metropolitan Water Supply having expressed a wish to be furnished with some indication of the views of the Council on the subject of the inquiry, the accompanying memorandum has been prepared by the Deputy-Chairman of the Council, and carefully considered by us in conference with him. It is based on resolutions passed by us after consideration of tables prepared by the Engineer, with reference (a) to the number of years upon which estimates, having reference to the future water supply of London, should be based; (b) the population for which provision should be made; and (c) the quantity of water which should be supplied per head per day. The views which we entertain on these points would, no doubt, have greater weight with the Commission if the matter were considered

by the Council. We therefore append the Deputy-Chairman's Memorandum to this report, and recommend,—

"That the Council do confirm and adopt the opinions and conclusions expressed therein:—

1. That in making any estimates having reference to the future water supply of London, such estimates should be based on a period of fifty years from the present time.
2. That in dealing with the question of a source or sources of water which shall meet the requirements of London and its neighbourhood for fifty years provision should be made for supplying a population of at least 12,500,000.
3. That in calculating the quantity of water required per head per day, the amount at present supplied by the companies should be increased by at least 10 per cent., and in no case should it be less than 35 gallons."

With reference to the progress of the inquiry before the Commission, we report, for the information of the Council, that the Commission has now held seven sittings, and that, in addition to witnesses on behalf of the Water Companies and from the Thames Conservancy, the Chief Engineer of the Council was examined on Monday last, and scientific witnesses on behalf of the Council as to the quality of the water will be examined on Monday next."

The recommendations of the Committee were agreed to after some discussion, and having transacted other business, the Council adjourned shortly before six o'clock, the paper having been cleared an hour earlier than the usual time of adjournment.

Correspondence.

To the Editor of THE BUILDER.

THE STATUS OF THE ARCHITECT AT THE R.I.B.A.

SIR,—In your issue of last Monday's meeting at the R.I.B.A., and of the meaning of the result obtained (I venture to think not in the most straightforward manner), I would suggest that the time has come to discuss the desirability of the R.I.B.A. availing itself of the clause in its Charter giving it power to create new classes of subscribing members, on the following lines:—

Two new classes should be created, the first to be called "Architect Fellows," or some similar title, the qualification for this class being mainly the architectural beauty, refinement, and skill they show in their executed works. This, I consider, would be acceptable to very many, for until the body that should represent the mass of gentlemen practising as architects and surveyors in these kingdoms honours the leading men who practise the art of pure architecture, how can it expect to hope to raise the status of the general practitioner? The other new class, to be called "Surveyor Associates," and to be open to gentlemen who are trained to, and follow the calling of, quantity surveyor, but who "practise in bricks and mortar" (that most felicitous term which we owe to one of our eminent Fellows). The qualification of these gentlemen to be the skill in planning and common-sense excellence shown in their works.

A reform like this, I think, would do much to improve the situation at the R.I.B.A. and raise the status of the architect.

SYDNEY VACHER.

CHANGES AT THE INSTITUTE.

SIR,—Will you permit me to emphasise the opinion expressed in your article of last week upon the election of Fellows of the Institute,—that they should be nominated from the ranks of examined Associates? I cannot but consider that the examination scheme, if it is to be supported with the same determination that has hitherto been directed towards it, demands this. I would maintain that no distinct examination for Fellows can be established. Candidates would not present themselves. The examination for Associates is valuable, inasmuch as to pass it, affords a *bona fides* that the candidate is an architectural student who has elected to follow architecture as a livelihood, and is, therefore, a fit person to become a member of a guild representing the craft. Without such a test it might be that he was only a surveyor, say, if he resided in London, or an auctioneer if in the country. To show that you possess some knowledge of materials, and would not treat stone, iron, and wood in precisely the same way, is to give some assurance that you may one day be an architect. This a student should be able to give at the end of his articles. But when seven years has elapsed, to ask a man to furnish a sample of his maturer skill and

how the Institute could avoid that conclusion.

proficiency, towards no end whatever, is what no modest craftsman would do. Neither is it likely that he would possess so little respect for himself as to display his wares to be turned over by he knows not whom, and thrown back to him. I am not sure that it would not be less inviting were the Fellowship altogether abolished, and Membership only remain. But, things remaining as they are, it is clear that the member who has rendered himself eligible for Associateship after the manner prescribed, is the fittest, I had almost said the only possible person, to become a Fellow. At least let him have a voice as to who shall be elected over him.

AN ASSOCIATE.

IS THE PROVISION OF WARMTH AND VENTILATION COMPULSORY IN WORKROOMS?

SIR,—In addition to the above question, I would like to ask,—if compulsory, who is responsible for their introduction? I am induced to ask these questions, as I have been informed that at a certain West-end establishment some two dozen girls have to perform their daily work in a room in which there is no chimney, and therefore no means for providing warmth and ventilation, either by the usual open fire, or by other and more modern means. Ventilation is sought to be obtained by a skylight and a hole in one of the side walls; but generally these let in cold draughts, especially in winter, and are, therefore, more frequently closed than open. To obtain some little warmth in winter the gas is often lighted, as also a couple of gas stoves (without flues), and naturally the ventilators are closed. The influence upon the health of the workers, hoked up in such an apartment, can readily be imagined; one of them has just had to leave, her ailment having, no doubt, been aggravated by spending many days and evenings in this modern building, which has now been in existence over eighteen months. Are there many workrooms of this class in the metropolis? M. R.

["* By perusing the Factory Acts and the Public Health Acts, our correspondent will probably be able to answer his own question. It is the duty of factory inspectors to see that the provisions of the law are obeyed by owners of factories and workshops, and information of any clear infringement of the law should be given to them.]

DEVONIAN SCREENS.

SIR,—Mr. Hems, in his letter of last week calling attention to these interesting relics of wood-carving, enumerated the chancel screen at Holbeton as a fifteenth-century work. Knowing the screen well, I would point out to him that this is a unique Devonshire example of a particularly ornate description, and is of sixteenth-century date. It never had a cove, and was never intended to have one; but, apart from that, the original treatment in the upper portion, usually filled with tracery, but in this case filled with bunches of foliage of singular boldness, makes this screen of great architectural value, if only as a link between fifteenth-century and Jacobean screens. Plymouth.

The Student's Column.

WARMING BUILDINGS BY HOT WATER.

XXVI.

IRREGULAR FORMS OF APPARATUS—CONCLUSION.

TO carry the pipes of an apparatus in any way contrary to the principles laid down is, of course, never recommended, yet at the same time it is very commonly permissible if there is no possible means of doing otherwise. As an example, we can refer to the occasional practice of dipping a pipe, in greenhouse work, if a doorway has to be passed. In the ordinary way, the pipes are carried round the house some 12 in. above the floor level, and to pass beneath a doorway opening means a dip in a pipe of at least this distance. This would be effected as in fig. 107.

FIG. 107.

Instead of carrying a pipe beneath the path tiles, a special pipe of square design can

be obtained, and this would lay flush with the floor.

Now, a dip in a pipe creates an obstacle to the free circulation in a way that will be described directly, and considering the low speed of circulation or motive power that we get in horticultural works, it is very little indeed that we dare attempt in this direction. With building works the circumstances are different, for the speed at which the water moves is so much greater. It will be seen that with works extending up only 2 ft. or 3 ft. the circulation is sluggish enough to be an objection at all times if the services extend any distance and a fair degree of heat is required at the further extremities; and if we introduce anything to make the circulation still slower, trouble will most probably ensue, even supposing the dip does not entirely destroy efficiency.

According to the present accepted theory, the circulation of water in any apparatus depends upon the difference in weight of hot and cold water; the water in one pipe being heavier than the water in the other, and causing the latter to ascend. With an apparatus as fig. 108,

FIG. 108.

which we may suppose is a single pipe carried all the way round a house, we should have to pass a doorway somewhere, and the dip necessary to effect this is shown. (Let it be clearly understood that this is quite an imaginary arrangement, to illustrate the subject under discussion).

This apparatus can be carried, and would work in quite an ordinary manner, to the point marked A, and so it would to C if it did not have to rise again; but from C to D the water is colder and heavier than it is between A and B, and consequently it would tend to bring about a retrograde movement,—a movement in the contrary direction to what the water takes from the boiler to A. It is plain that the farther the water travels from the boiler the cooler it becomes, owing to its losing heat, as it is required to do; consequently the column of water C, D must be colder than that from A to B, and its greater weight naturally opposes the movement of water in an upward direction. A very well-known writer upon heat, in dealing with the circulatory action of heated water, adopts an ingenious method of making the subject clear, by spacing off the pipes in lengths of imaginary temperatures, as figs. 109 and 110.

By allowing a certain difference in weight to each space the theory can be very clearly dealt with.

With fig. 109 we have a difference in mean temperature in the two columns of water of 33 deg. This may be called 33 grains (the water in the return-pipe bringing about the circulation by its being thus much heavier than the water in the flow. By increasing or decreasing the height of the pipes the motive power will be increased or decreased pro-

portionately. If we plan an apparatus as fig. 110 and space it off, we find in theory that we get an equal weight in each pipe, and we may suppose that the water would fail to circulate either way. By the same reasoning, we may expect a circulation more or less efficient by putting more pipe above the boiler than in the last cut, or, a reversed circulation if we carried the pipe further down below. This makes the theory plain, and in making dips in pipes it will be seen that, if of no great depth, they would prove no serious obstacle in building works, but in the average glass-house apparatus they are better avoided. As before mentioned, if, in these latter works, a dip did not actually stop the circulation, it would render the circulation more sluggish, and in long runs of pipe this is a great drawback.

Occasionally a boiler has to exist between two houses, which, being on rising ground, may bring one house a trifle lower than the boiler itself. This being the case, the more common plan adopted, to permit of the pipes in this

FIG. 111.

house being so low, is to use a tank as fig. 111. The further use of the tank is to act as a feed cistern and air exit. The service from the right of the boiler is supposed to go to heat the house that is of sufficient height, the service to the left is carried as shown, the flow to the tank by the most direct route, and the return acting as the radiating media. By thus circulating up to a higher point than usual, we get a more efficient circulation, a higher motive power, which is always sufficient to make the apparatus work well if the rise of the return-pipe to the boiler does not exceed, say 18 in. It will be understood that the tank shown is not absolutely necessary. If we carried pipe up to this height with a feed-cistern beside it, it would amount to the same thing, but would not have such a workmanlike appearance. The tank should have a cover to keep dirt from entering, as it fulfils the purposes of a supply-cistern as explained.

Occasionally, when a boiler is fixed somewhat centrally to the work, a tank is made use of, having a flow-pipe to it from the boiler, but having several returns running in different directions. The flow would be carried to the tank by the most direct route, as just explained, the returns acting as the radiating pipes. It is said in favour of this plan that it allows of the freest possible escape of air, and it is further suggested by those who recommend the plan, that by the use of wooden plugs in the return pipes where they leave the tank, the need of stop-cocks is dispensed with. Certainly by the use of a tank, placed in the highest position it can be, we get a better or stronger circulation, as will be understood.

The chief trouble experienced in works that depart from the regular form, is air dislodgment. It may appear an easy matter to many to get rid of air that, it is admitted, does get in the pipes, and which must exist in the pipes before they are first charged, but every man with experience knows that air dislodgment partakes of the nature of a problem sometimes, and the solution is not discovered in a moment. In the illustration, fig. 111, the return would descend to the point A, and then take an ascending direction all the way to the boiler, and, at first glance, there would be, apparently, no need for an air-pipe at all. This, however, is not the case, an air-pipe should be provided at B, not that there would be much use for it when the apparatus was once full and working well, but when charging the apparatus with water, there would be every probability of air being locked in the lower pipe between A and B, with ill results. In the same way an air vent would have to be provided both sides of the dip in figs. 107 and 108. It has to be particularly remembered also, that although an apparatus may perhaps be filled easily when first charging it, it does not follow that it can be filled as easily after it has had water once in it, for when emptying it will be practically impossible to get the water out of any dips there may be in the pipes, and these collecting points will

prove obstacles to the free escape of air as the water is filled in again, unless, of course, air vents are provided.

This completes the papers upon "Warming Buildings by Hot-water," and our last suggestion to those who have the giving out of these works, is to ascertain that the people entrusted with the work are capable and experienced; and to those who execute the works, let it be an ambition to be master of the subject. This advice is, of course, good in all cases, but with hot-water works it is especially good, for it is really wonderful what perplexing difficulties a little want of knowledge may bring about, and what expense and trouble may be incurred in remedying such errors.

GENERAL BUILDING NEWS.

NEW THEOLOGICAL COLLEGE, EDINBURGH.—On Wednesday of last week, being the centenary of the repeal of the penal laws affecting the Episcopal Church of Scotland, a new Theological College in connexion with that church, was opened with fitting ceremony. The building is situated within its own grounds, in an appropriately retired spot about 100 yards to the westward of St. Mary's Cathedral. The nucleus of the building consists of a mansion house, called Coat's Hall, which was designed by the late Mr. David Bryce in the Scottish Baronial style, for the late Mr. Napier, sheriff of Peebles-shire. Considerable additions have been made to the original structure, including a beautiful little chapel. The college contains accommodation for twenty resident students. The adaptation of the original building, and the additions thereto, have been carried out in a thoroughly satisfactory manner by Messrs. Sydney, Mitchell, & Wilson, architects, Edinburgh.

BOARD SCHOOL, BALDON, YORKSHIRE.—A new Board School, built at a cost of 2,750l., including site, by the Baldon School Board, at Tong Park, was opened on the 11th inst. by Mr. Edward Holden, of Baldon. The new buildings, for which Messrs. W. & J. B. Bailey, of Bradford, have prepared the plans, are to accommodate 220 scholars.

SCHOOLS, DARNALL, YORKSHIRE.—On the 4th inst. the Archbishop of York opened the new schools which have been erected in connexion with Darnall Parish Church. The new school building has two stories, the lower one for boys, the upper one for girls, while the infants are in the old school, which has been remodelled so as to give the requisite accommodation in an improved way. The rooms in the new building are arranged for Sunday-school purposes as well as for large parish meetings, &c. Accommodation for day-school purposes has been provided for 240 boys, 240 girls, and 212 infants. Block flooring of teak has been laid, and movable partitions have been placed between the school-room and the class-rooms, by which 600 persons may be seated in one room for meetings. The architect is Mr. C. J. Innocent, of Sheffield, and the contractors Messrs. George Longden & Son, Neepsend. All the buildings are of stone, walled in courses, and with ashlar dressings. The amount of the contract, including asphalted yards and boundary walling, is 3,927l.

CHURCH AND SCHOOLS, POOLSTOCK, WIGAN.—On the 4th inst. the foundation-stone of the Mission Church and Schools of St. James's, Poolstock, Wigan, was laid by Mrs. B. Brown, Shelley House, Wigan. They are to accommodate about 250 children, and will cost 1,500l. The architects are Messrs. Heaton & Ralph, of Wigan.

NEW CHURCH, BONANE, CO. KERRY.—On Ascension Day the dedication of the new Church of Bonane took place. The church was designed by Mr. Daniel O'Connell, Derrynane House, and built by Mr. Daniel Foley, Sneem. The church consists of a nave, 79 ft. by 21 ft., and a sanctuary terminating in a pentagonal apse.

CONGREGATIONAL BUILDINGS, SOUTH SHIELDS.—On the 6th inst. the foundation-stone was laid of a new Congregational school and hall, to be built adjoining the Ocean-road Church, South Shields. The building will be raised upon the vacant ground on the east side of the church, and completes the original scheme. The ground floor will contain the hall, 74 ft. by 36 ft. 6 in., and 20 ft. high, with raised platform and ante-rooms at the far end, and having tea and holler rooms beneath. On the first floor, which will be approached by a stone staircase from the main entrance, is an infants' school, 30 ft. by 25 ft., and eight class-rooms. The heating is to be by hot-water piping, with ventilating coils for the admission of warm air. The contract for the work has been let to Mr. George Goddard, Westoe, and Mr. J. H. Morton, South Shields, is the architect.

TOWER, WADDESDON CHURCH.—On Wednesday was dedicated the rebuilt tower of Waddeyson Church, Bucks. It is an unusually fine tower of the fourteenth century, of massive proportions, and contains a peal of eight cast steel bells. It had been in a critical condition for some years, and when taken down, it was with difficulty that the accident was avoided. The interior of the walls was disintegrated throughout, having been built with earth and rubble for mortar. Enormous buttresses had been erected, which, however, failed

to afford support to it, for the foundation of the tower, though 6 ft. deep, rested on 2 ft. of soft, wet clay. The tower has been rebuilt as nearly as possible upon its old lines, but with new western doors upon the window under the old curtain rib, and a turret staircase at the south-east corner. In the pulling down, portions of an old turret staircase were found embedded in the wall. The turret and tower alike are finished with battlements. The old rane is fixed in the centre of the lead roof. The total cost has been about 1,900*l*. Two hundred tons of lime were used in the work. Great care has been taken to protect and preserve the weathered surface of the old stones as far as possible. The new stone for dressed work is from the Hornton and the Ham-hill quarries, with local limestone for walling. Mr. Sherwin, a local builder, who has been clerk of works at Baron Rothschild's mansion in the same parish, obtained the contract, the architect being Mr. William White, F.S.A.

CONSERVATIVE CLUB, FAILSWORTH.—The foundation-stones of the Failsworth Mowbray Conservative Club, which is to take the place of the "Mowbray" Conservative Club in Failsworth, were laid recently by Sir John Mowbray, Bart., M.P., Mr. R. G. C. Mowbray, M.P., and other gentlemen. The new building, apart from the furnishings and extra items, will cost 1,450*l*. It will be faced with Accrington plastic bricks on the two principal entrances, interspersed with stone and red Russian terra-cotta dressings. The contractors were, for excavating and brickwork, Messrs. S. & J. Smethurst; masonry, Mr. Joseph Clough; carpenter and joiners work, Mr. J. W. Kent; slating, Mr. J. Jackson; plumbing, glazing, and painting, Mr. J. White; plastering, Mr. J. Hall. The whole was supervised from the designs, and under the superintendence, of Mr. Charles T. Taylor, architect, of Oldham.

WORKMEN'S DWELLINGS, BIRMINGHAM.—Plans have been prepared, and building operations will immediately be commenced, for the erection of three shops and sixty-eight workmen's dwellings at Vauxhall, a densely populated district of the city of Birmingham. The erection of these houses at the present time will be a much-welcomed relief, as a great number of dilapidated and insanitary buildings have recently been demolished in this locality. A new street is in course of formation which will form frontages for a portion of these residences. The total cost of the buildings is estimated at about 11,000*l*. The contractor is Mr. Williams, and the architect, Mr. J. Stabham Davis, both of Birmingham.

NEW CHANCEL, POPLAR CHURCH.—On the 5th inst. the newly-formed chancel of Poplar Church was opened. The work just finished forms one of the six sections of the work of restoration now being carried out in the church. In the sanctuary the east window has been covered over and new hangings have been formed. A new dorsal and hangings surround the walls at the end of the chancel, and a new altar table with restable of marble has been provided. The old choir stalls have been added to, and the chancel floor has been raised above the floor further westward. The new floors are of marble. The old wooden pulpit has been removed, and an open pulpit of bronze and mahogany has been placed in its place. The cost of the works just finished will be about 600*l*. The general contract has been carried out by Mr. J. Kemp Coleman, of Poplar. The pulpit was executed by Messrs. Strode & Co., of Regent's Park, from the designs of the architects, Messrs. J. & S. F. Clarkson, Great Ormond-street, W.C.

THE NEW ADMIRALTY BUILDINGS.—Messrs. Mark Ewbank & Co. inform us that their fireproof and ventilating floors have been selected for the above buildings, and that the contract for the whole of the floors, ceilings, roofs, domes, &c., with the constructional steel work, conducted therewith, has been placed with them.

SANATORIUM, LADYWELL, NEAR ECCLES.—On the 16th inst. the Mayor of Salford (Alderman P. Keeney) opened the new Ladywell sanatorium or hospital for infectious diseases, which has been erected at a total cost of 50,000*l*, at Ladywell, near Eccles. The hospital is situated on the Eccles New-road, and has been erected by Messrs. R. Neill & Sons, Salford, from the designs of Messrs. Maxwell & Tuke and Messrs. E. & F. Hewitt, of Manchester. The hospital is divided into isolated blocks and pavilions. The three pavilions include six centre wards, each being 45 ft. by 26 ft., containing six beds each, and six convalescent wards, 120 ft. by 26 ft., containing eighteen beds each. There are thirty-three nurses' bedrooms. The hospital is heated with steam, and steam is applied to all the disinfecting, washing, and cooking apparatus; also to work the laundry engine, electric-generators, and pumps. A hydraulic lift is provided to raise patients to the upper stories. There are verandahs and gardens for the convenience of patients, and space is left for an extension of the sanatorium.

PROPOSED PUBLIC BUILDINGS, BATH.—At the Barb Guildhall, on the 14th inst., Mr. S. J. Smith, C.E., Local Government Board Inspector, held an inquiry into the application of the Corporation to borrow 6,000*l* for purchasing three houses in the Abbey Churchyard, for the site of a proposed extension of the Pump-room, and to borrow 35,000*l* for the

purpose of erecting new municipal buildings. With regard to the first application, evidence was given by Mr. Radway, chairman of the Baths Committee, as to the increased number of bathers and takings at the baths, and the need of providing additional accommodation for the visitors. Alderman Gibbs objected to the proposal as unnecessary, though he agreed that something should be done to protect the Roman remains. The application with regard to the municipal buildings was supported by Alderman Murch (ex-Mayor), Alderman Gibbs, Colonel Ford (senior magistrate of the city), Mr. Stone (town clerk), and others, the plans being explained by Mr. J. M. Brydon, the architect. With regard to the objections to the new buildings encroaching on the pavement near the Abbey, the inspector said he would have the building-line shown on the pavement in chalk.

WESLEYAN SUNDAY SCHOOL, HARROGATE.—On the 16th inst., the memorial-stones of a Wesleyan Sunday school were laid at Grove-road, Harrogate. The cost of the chapel and school will be about 5,000*l*, but the chapel will not be proceeded with yet. The architects are Messrs. Morley & Woodhouse, of Bradford. The contractors are—masons' work, Alderman Simpson (Harrogate); joiners, Mr. Cheekley (Harrogate); and plasterer, Mr. Laycock (Harrogate).

SANITARY AND ENGINEERING NEWS.

THE PLUMBERS' REGISTRATION BILL.—At a special meeting of the Glasgow Master Plumbers' Association, the Plumbers' Registration Bill, as amended by the Select Committee of the House of Commons, and the Blue Book containing the evidence taken by the Committee, were submitted. The Association entirely approved of the amended Bill, and resolved to petition Parliament in its favour.

GRAVEN ARMS WATER SUPPLY.—This matter has occupied the attention of the authorities for the last seven years. Various schemes have been proposed, but, from unforeseen difficulties, none of them could be carried out. It is hoped, however, that a satisfactory solution of the difficulty has at last been found. A trial boring has just been completed, and pumping from it kept up day and night for a fortnight. The quantity pumped was over 50,000 gallons a day, more than three times the quantity required for the present supply of the district. Mr. Wyatt, of Shrewsbury, is the engineer, and Messrs. Timmins, of Runcorn, the contractors.

FOREIGN AND COLONIAL.

FRANCE.—We mentioned last week that, on account of some disputes, the voting at the Champs Elysees Salon for the awarding of the medal of honour in the architectural section was postponed. Another election was held last Saturday, and, after two tours of inspection, the medal was awarded, by 98 votes out of 103, to M. Louis Marie Gordonnier, artist of the Palais de la Bourse at Amsterdam. This young architect, who lives at Lille (Nord) is a pupil of his father and M. André.—The jury of the Ecole des Beaux-Arts, in the superior competition of anatomy, has awarded the Huguer prize to M. Gullmant, pupil of MM. Bouguereau and Gabriel Ferrer. The Raigecourt-Goyon prize has been awarded to M. Maurice Perrot, for his picture, "Départ des Pirogues pour la Pêche," which was exhibited at the Champs Elysees Salon.—The Institute have not been able, on account of poverty of materials, to award the Bordin prize this year, the subject for which was "Developpe the National Characteristics of French Sculpture from the Thirteenth Century to the Revolution."—A curious exhibition of the geographical documents of the sixteenth century has just been opened at the National Library, on the anniversary of the fourth centenary of Christopher Columbus.—The assa painter Léon Heakman has just opened an exhibition of his works at 39, Boulevard des Capucines, under the title "L'Épopée de la Mer."—The monument to the memory of Stendhal has just been inaugurated. The monument, which is in the Montmartre Cemetery, is of grey granite, decorated with a bronze medallion of Stendhal by David Angers, &c.—A petition has lately been addressed to Government for the removal of the Lycée Lakanal at Bourg-la-Reine, near Seaux.—Ninety-two artists have taken part in the open competition for the decoration of the "Salle des Mariages" of the Town Hall of Montreuil-sous-Bois. The decision will take place next week.—M. Maurice Vuy is nominated architect of the French Colonies at the International Exhibition at Chicago.—A propos of the recent inauguration of the statue of Claude Lorraine at Nancy, the German journals remark that it is a long time since a commemorative monument has been raised to this painter in the environs of Munich.—A company of engineers and learners, Frenchmen is shortly to start for Sardes in Asia Minor, for the purpose of excavating.—Last week the bust of the satirical poet Crinon was inaugurated at Vraignes (Somme). The bust is the work of M. Georges Tattetrain, and the model was exhibited in the Salon des Champs Elysees this year.

—July 15 is the last day for sending in designs for the open competition for the statue of Joan of Arc in the town of Chinon.—It is announced that an artistic exhibition will be opened at Nice on January 10 next, and closed at the end of March.

—The spire of the Church of the Bourne has been completely destroyed during a storm.—The town of Vichy is organising an industrial and artistic exhibition to be held in the buildings of an old hospital; it will be opened on July 1.—The town of Périgueux (Dordogne) has just acquired a beautiful mosaic, which was discovered in the environs last year, and which is of a pure style of Archaic Greek. The mosaic is composed almost entirely of geometric designs.—M. J. Blain, political draughtsman, attached to several Parisian journals, especially the *Caricature* and the *Pilori*, has just died at the age of forty-five years.—M. Alcide Loron, landscape painter, has just shot himself. The suicide is attributed to unhappiness. He was thirty-nine.—We have also to mention the death of M. Jean Francis Delarue, member of the Central Society of Architects, who died in Paris at the age of seventy-two. He was a pupil of Moreau and Heurteault. To him we owe the church of St. Cloud, that of Croissy, the gate of Randon at Grenoble, the restoration of the chateau of La Saunzière, at Nantes, and numerous other works. He was a Chevalier of the Legion of Honour.

MISCELLANEOUS.

THE "TUFFEL" STAIR TREAD.—This is a leader: stair tread crossed by firrows leaving raised squares arranged diamond-wise, the special feature of which is that whilst the lead is in a molten state numerous small lengths of iron, brass, steel, or white metal tubes are inserted vertically in the thickness of the lead and finishing level with it. The surface of the lead affords a good foothold when new; as it is worn down and more or less polished by the traffic the rings of harder metal are left protruding slightly above the surface, and keep up a roughened surface. The sample of the tread submitted to us seems a thoroughly sound thing, the harder metal being firmly incorporated with the lead, and the invention is worthy of attention as a means of preventing the slippery state to which stair-treads, which are satisfactory when first laid down, are often reduced when worn. Mr. F. Fitton, of Rochdale, is the inventor.

PETERBOROUGH CATHEDRAL.—Mr. Hitch writes to us again to say that he did not claim the carving *en masse* on the Bishop's Throne as his work, but only the figure sculpture, the decorative carving being by Mr. Thompson's workmen.

CUTTING OFF THE WATER SUPPLY.—The President of the Local Government Board and the Home Secretary have under their notice a question of serious moment, which has arisen since the Public Health (London) Act, 1891, has been put in force. Since the new Act came into operation the Chelsea Water Company has increased its "cutting-off" action nearly sixfold, and during the past two months the District Medical Officer of Health, in his report to the Chelsea Vestry, states that no fewer than twenty-one occupied houses have had their water supply cut off. The Public Health Act, section 49, provides that a water company which has cut off the water supply from a house for non-payment of rate or other cause is required to give notice thereof within twenty-four hours after cutting off the supply to the Sanitary Authority of the district. Section 45 of the same Act provides that an occupied house without proper and sufficient supply of water shall be a nuisance liable to be dealt with summarily under the Act, and, if it is a dwelling-house, shall be deemed unfit for human habitation. The water company, therefore, in exercising the power it has under the Waterworks Clauses Act, 1847, creates a nuisance, liable to be dealt with summarily under the Public Health Act. This is an anomalous state of affairs, for it is one which might seriously affect the public health.—*British Medical Journal.*

THE NEW CENTRAL ELECTRIC STATION IN COPENHAGEN.—The central electric station, erected by the municipality of Copenhagen, has been opened. At present it can only supply about 17,000 lamps, but it may be enlarged so as to supply 40,000. The cable run, on the trolley wire system, is 90 kilometres in length. At present the steam-engines are three,—one 330 and two of 550 h.p. each. Each engine works two dynamos. There is also a battery of accumulators, capable of supplying 3,000 lamps for three hours. The electric plant has been delivered by Messrs. Siemens & Halske, and the steam-engines and boilers by Messrs. Babcock & Wilcox, London and Glasgow. The cost of the establishment is 142,000*l*.

BUILDING LAND AT HASTINGS.—As will be seen by an advertisement in another part of this week's *Builder*, Messrs. E. & H. Linsley will offer for sale on Thursday next, the 30th inst., fifty plots of building land on the St. Helen's Park Estate, Hastings.

NEW PARK AND STREET IMPROVEMENTS AT DEWSBURY.—The Corporation of Dewsbury has just received the Local Government Board's sanction for the borrowing of 41,250*l*. This sum is to be expended in the purchase and laying out of

COMPETITIONS, CONTRACTS, AND PUBLIC APPOINTMENTS.

COMPETITIONS.

Table with 4 columns: Nature of Work, By whom Advertised, Premium, and Date to be delivered. Includes entries for Public Baths, Town Hall, and Infectious Diseases Hospital.

CONTRACTS.

Table with 5 columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, and Tenders to be delivered. Includes entries for Hires of Steam Boiler, Buildings, and various engineering works.

CONTRACTS.—Continued.

Table with 5 columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, and Tenders to be delivered. Continues from the previous table with entries for Servoir Reservoir, Construction of Embankment Wall, and various other works.

PUBLIC APPOINTMENTS.

Table with 4 columns: Nature of Appointment, By whom Advertised, Salary, and Application to be made. Lists appointments for Clerk of Works, Engineer Assistant, and others.

Those marked with an Asterisk (*) are advertised in this Number. Competitions, p. iv. Contracts, pp. iv., vi., viii, ix, & xxiii. Public Appointments, p. xx.

public park, and in street improvements. The park is to cost 33,250l., and will be laid out in accordance with the design prepared by Mr. Henry C. Marks, Assoc. M. Inst. C.E., the Borough Engineer and Surveyor, which includes ornamental waters, lodges, and three miles six furlongs of drives and promenades.

NEW LANDING STAGE, HOLYHEAD.—The new landing-place erected at Holyhead, at a cost of about 2,500l., was declared open by Commander E. Scobell Clapp on the 20th inst. The pier is about 220 ft. long, with an "L" arm 60 ft. long. It is 22 ft. high from low water spring tide, and 12 ft. wide from the corner of the Navy yard, and 9 ft. from there to the shore end. The pier is paved on the top with stone pitching, having a hand-rail of red iron on the side, and a wall at the extreme end, with cement coping, about 4 ft. high. It has a double landing-place. Mr. Corton was the engineer, and Mr. Williams was the contractor.

THE SOCIETY OF ARTS.—The Council have awarded the Society's Silver Medal to the following, among other readers of papers during the Session 1891-2:—At the Ordinary Meetings: To Prof. Silvanus P. Thompson, F.R.S., for his paper on "Measurement of Lenses;" to Mr. G. H. Robertson, F.C.S., for his paper on "Secondary Batteries;" to Prof. Vivian B. Lewes, for his paper on "Spontaneous Ignition of Coal, and its Prevention;" to Mr. Robert S. McCormick, for his paper on "The Trade Relations of Great Britain and the United States;" to Captain W. de W. Abney, C.B., F.R.S., for his paper on "Colour Blindness;" and to Mr. F. E. Ives, for his paper on "Composite Helicograph." In the Applied Art Section: To Mr. William Morris, M.A., for his paper on "The Woodcuts of Gothic Books;" to Mr. C. Purdon Clarke, C.I.E., for his paper on "English Brocades and Figured Silks;" and to Mr. William de Morgan, for his paper on "Lustre Ware." Thanks were voted to Mr. James Dredge, for his paper on "The Columbian Exposition at Chicago, 1893." Mr. Dredge being a member of Council, and, therefore, under the usual practice of the Council in such cases, not eligible for the award of a medal.

RENOVATION OF THE ROUND ROOM OF THE MANSION HOUSE, DUBLIN.—According to the Freeman's Journal, the historic Round Room of the Mansion House, Dublin, has recently undergone renovation. The work was entrusted to Messrs. Sibthorpe & Son, of Dublin. The ceiling of the room has been remodelled to a considerable extent. Immediately below the ceiling is the new cornice, which is formed of fibrous plaster. There are sixteen circular windows, underneath which are

fitted leaded lights of tinted cathedral glass. On either side of these windows are thirty-two circular shields, representing every county in Ireland, and in which are shown the arms of the four provinces and principal towns, with wreaths of shamrock. The architectural details below the original and larger cornice have been coloured in white and gold.

The architrave is supported by several new pilasters in enamelled wood, coloured in red and gold with festoons. The walls and railings of the balcony are stained in old gold with ornamental gilding. The drapery hangings of the balcony are new. The date has also been improved. Mr. C. Ashlin, architect, afforded a good deal of assistance in the carrying out of the details. The whole alterations were carried out under the plans of Mr. Spencer Hart, Borough Engineer.

STAINED GLASS WINDOW, CHRIST CHURCH, CHILTON.—The large west window of Christ Church, Chilton, Gloucestershire, has been filled in with stained glass, the gift of Mr. W. A. F. Powell. The window is a triplet of lancet-headed lights, the central one being more than 25 ft. in height. The subject selected illustrates "The Te Dium." The window has been designed and executed by Messrs. Joseph Boll & Sons, of Bristol.

MEETINGS.

SATURDAY, JUNE 25. St. Paul's Ecological Society.—Visit to the Churches of Crayford and Dartford. Edinburgh Architectural Association.—The Sketching Class to meet at Rouston House, Carolina Park, Granton, to make measured drawings and sketches of the south front of the mansion. 3 p.m.

MONDAY, JUNE 27. Royal Institute of British Architects.—(1) Presentation of the Royal Gold Medal to Mr. Cesar Daly, Hon. Corr. Member. (2) Reading of a description of the collection of architectural drawings by Palladio and others, originally obtained by the Earl of Burlington, and now lent by the Duke of Devonshire. 8 p.m.

WEDNESDAY, JUNE 29. Builders' Foremen and Clerks of Works' Institution.—Half-yearly meeting of the Directors. 8 p.m.

THURSDAY, JUNE 30. Dundee Institute of Architecture.—Annual Business Meeting. 8 p.m.

SATURDAY, JULY 2. Edinburgh Architectural Association.—The Sketching Class to meet at Rouston House, Carolina Park, Granton, to make measured drawings and sketches of the south front of the mansion. 3 p.m.

RECENT PATENTS:

ABSTRACTS OF SPECIFICATIONS. \$,500.—BRICK MAKING: P. & C. Koper.—This invention relates to improvements in dies or moulds for making bricks, and has for its object to provide an improved means for forcing the clay into or around the die, and also a self-acting contrivance for moistening the clay and die near the outlet. The invention consists in the construction of tapering guide frames for use in connection with the die, which, when the clay will pass with greater ease and regularly into the die, without being broken by contact with clay left in the angular recesses. Also in the construction of metal frames for use with the adjoining tapered rods for the purpose of moistening the clay, by a small supply of water on its passage to the outlet. The inventor sets perforated rods for making holes in bricks, in perforator bars placed at such an angle that the rods will maintain an uniform converging direction towards the centre of the outlet, and the clay pass smoothly over them. 11,203.—BRICK, &c., PRESERVATIVE: H. Aiken.—An invention that prevents or lessens the destruction or deterioration of stone, brick-work, plaster, mortar, or stucco, or the like. It consists in the use of corrosive sublimate or bicarbonate of mercury, preferably in the form of a strong solution. The inventor considers that the deterioration in the above materials arise from living organisms, and gives various substances to destroy the same.

IMPROVEMENTS IN BUILDING BLOCKS: F. W. Holloway.—The object of the invention is to form from stone, concrete, or other suitable materials, blocks of such uniform shapes of their respective class as by the aid of key blocks, comprising the same, or wall decorations, materials, arches without any cutting. Each block or voussoir being a repetition in shape formed respectively with upright or sloping joint beds, with ledge or hearing, so that the work will be self-acting, and the claim is set out in the specification as follows:—First: Blocks or voussoirs, for use in building arches, or horizontally bridging openings in brickwork, being moulded or formed, so that the angle of sloping joint beds, the depth of such blocks, or voussoirs being made to correspond with any required number of courses of brickwork. Secondly: In blocks or voussoirs, the formation of funnels, frogs, or other indentations in the joint beds, by which to bind the work in a manner more effectually to resist lateral pressure.

5,967.—TILES: H. Miralles y Angles.—This invention consists in imitation tiles to be used in place of porcelain, faience, or other tiles, or wall decorations, and like purposes, the imitation tiles having the same size and general aspect as the ordinary tiles in the same designs, colours, and lustre, but made of paper, or card cut to the proper size, so that the imitation tiles may not differ in appearance from those they are desired to resemble. They are covered with any suitable transparent varnish.

6,745.—CEMENT: V. F. L. Smith.—The object of this invention is to manufacture from ordinary cements, especially portland, a cheaper cement, from which can be prepared mortar having the high quality of cement mortar, but being in cost of production equal to, or lower than, ordinary lime mortars. The inventor grinds together ordinary cement and a quantity of the same admixture as that which is generally used in the preparation of cement mortar to produce a powdered sand cement, of a similar degree of fineness as that of ordinary cement. This sand cement is then to be used in the same manner as ordinary cement mortar, but prepared by mixing one part of sand cement with one or more parts of the ordinary admixture. By grinding together, e.g. one part of ordinary cement and three parts of sand, in four parts of admixture are produced, and from these a mortar can be prepared in the proportion of one part of sand-cement and three parts of sand, so that out of the one part of ordinary cement six parts of mortar are prepared, when under ordinary circumstances, only four to five parts of mortar would have been prepared out of one part of cement.

NEW APPLICATIONS FOR LETTERS PATENT.
June 7.—10,717, J. Short, Chambers for Frying Bricks, &c.—10,718, C. Judson, Doors, Grates, &c., Shutters, the Improvements being specially applicable for use in connection with elevators. 10,724, W. Wheeler, Water-waste Preventing Cisterns for Flushing Purposes.—10,755, W. Ward & Sons, Limited, and W. Ward, Brick Presses.—10,801, S. Croft, Machines for the Manufacture of Tiles, and for the Manufacture of Mortar and Concrete. 10,812, J. C. Glasson, Sash-weight and Method of Hanging Sashes.
June 8.—10,831, E. Buller, Guard for Preventing Fire from Spilling, being placed between the Inside of Doors and Frames.—10,837, S. Jenkinson, Attaching Table Tops to the Frames thereof.
June 9.—10,911, O. Hays, Harmonical Clocks for Domestic Use, and for Hanging Bells.—19,918, V. Aston, Balancing Window-sashes.—10,927, H. Birbeck, Process for Preparation of a Material for Building or other purposes.
June 10.—10,963, J. Day, Drainage and other Sockets to Facilitate Joining.—10,964, W. Smryk, Sash-fastenings.—10,974, A. Walker, Buttons for Doors, &c.—11,001, A. Selig, Bakers' Ovens.—11,009, V. Winter, Cowl for the Chimney of a Boiler.—11,022, E. Winter, Cowl.—11,025, J. Blanc, Wooden Blocks for Covering Floors, &c.

PROVISIONAL SPECIFICATIONS ACCEPTED.
 9,912, H. Fenning, A new T square and Drawing-eyes for the use of Architects, Engineers, and Surveyors.—7,224, H. Thompson, Grates or Stoves.—7,892, H. Keppelie, Spirit-level.—7,900, J. Major, Domestic Sewing Machine.—7,924, W. Wheeler, Water-waste Insulator.—8,847, W. John, Facing Bricks or Tiles.

COMPLETE SPECIFICATIONS ACCEPTED.
(Open to Opposition for Two Months.)
 11,102, J. Parker, Window-sashes, &c.—11,617, J. Stearn, Kinds of Heating Pottery, &c.—6,800, G. Sparling and F. Solomon, Lock or Fastener for Securing Window Sashes.—8,359, C. Borgner, Bricks.—8,381, C. Behn, House Drains.—8,725, G. Moelckel, Arches for Ceilings and Vaults.

SOME RECENT SALES OF PROPERTY:

ESTATE EXCHANGE REPORT.

June 13.—By G. A. Wilkinson & Son: "The Wheat-sheaf" Public-house, Rochester, L., s. 507, 755; 238, 300, 334, and 335, Rochester, L., s. 521, 38, 80, 6; 6,800, 6,801, 6,802, 6,803, 6,804, 6,805, 6,806, 6,807, 6,808,
