

AN

✦ ILLUSTRATED ✦ WEEKLY ✦ MAGAZINE ✦

FOR THE

ARCHITECT, ENGINEER, ARCHÆOLOGIST, CONSTRUCTOR,
SANITARY REFORMER, AND ART-LOVER.

CONDUCTED BY

H. H. STATHAM,

FELLOW OF THE ROYAL INSTITUTE OF BRITISH ARCHITECTS.

"Every man's proper mansion-house, and home, being the theater of his hospitality, the seat of self-fruit, the comfortablest part of his own life, the noblest of his sonne's inheritance, a kinde of private principedome, nay, to the possessors thereof, an epitome of the whole world, may well deserve, by these attributes, according to the degree of the master, to be decently and delightfully adorned."

"Architecture can want no commendation, where there are noble men, or noble mindes."—SIR HENRY WOTTON.

"Our English word TO BUILD is the Anglo-Saxon Bylisan, to confirm, to establish, to make firm and sure and fast, to consolidate, to strengthen; and is applicable to all other things as well as to dwelling-places."—DIVERSIONS OF PURLEY.

"Always be ready to speak your mind, and a base man will avoid you."—WILLIAM BLAKE.

VOLUME LXII.—JANUARY TO JUNE, 1892.

OFFICE: No. 46, CATHERINE STREET, COVENT GARDEN, LONDON, W.C.

INDEX TO VOLUME LXII.

JANUARY TO JUNE, 1892.

Architecture from a Cosmical Point of View.

THE turn of the year, when one thinks what it really means, is an event that may very well draw our thoughts away beyond the mere daily necessities and fashions of architecture to a consideration of the subject in a wider and more abstract sense. To most of us, in our every-day attitude of mind, the New Year is a date merely, a marking off of a fresh division of our time, another milestone in the race of life (which in itself is a serious consideration enough, no doubt); also an excuse for a holiday, a little relaxation of business, a fresh interchange of friendly or neighbourly greetings and hospitalities. But when we think for a moment what it is which has marked out the interval for us,—the traversing by our planet of one more of its elliptical circuits round the sun,—we seem to be carried in thought somewhat beyond the annual amenities of New Year's Day. We are reminded thereby of our connexion with the great mechanism of the solar system, so vast to our perception, so small in comparison with the universe of suns on whose movements we can but partially speculate. Regarded from this point of view, the

earth is no more a surface on which cities may grow up, mansions and town-halls be erected, and land laid out for building estates; all these transactions become infinitesimal from the cosmic point of view; trivial and impertinent details, hardly perceptible at all in the general contemplation of our sphere as one among "flying synods of worlds."

There is only one sense in which architecture retains its dignity and importance even from this point of view; so far, namely, as it is the expression of an abstract thought or ideal. Amid the multifarious demands of practical life, and the limiting conditions of practical achievement, it is but seldom—in these hustling and hurrying modern days hardly ever—that architecture can rise entirely above utilitarian considerations and exist solely as an intellectual expression. But so far or so often as it can do this, it is in a certain sense independent of mere scale. Thought is not measurable by a material scale.

"A sphere is but a sphere;
Small, Great, are merely terms we bandy here;
Since to the spirit's absoluteness all
Are like."*

Ideal architecture in its purest form becomes not the mere construction of a shelter, however elaborate or picturesque, but the expression of an aspiration or a mood of the mind. It may even have a relation with the cosmic spectacle, if it is regarded as the effort of man to express in his own way something of the

grandeur and the hidden meaning which he has learned to discern in nature. In such a light the structures raised on the face of a planet by its inhabitants, infinitesimal as they are in comparative scale, may partake somewhat of the greatness and mystery of the scheme of nature which inspired them; and if we could imagine the various planets of our system to be in the same stage of habitability, and could visit them one by one, we might find it not the least interesting part of the investigation to compare the various ways in which mental thought and aspiration expressed themselves in structures raised solely for the satisfaction or emodiment of an ideal; to note, according to Wordsworth's fancy, how

"Swift Mercury resounds with mirth,
Great Jove is full of stately bowers."

As a matter of fact, probably, it must be many and many an age before the surface of Jupiter is contracted into ground solid enough for foundations; and an aqueous architecture is at all events beyond our present powers of conception. Nor indeed can we realise the least in imagination what entirely different possibilities of architectural expression may exist in planets of different conditions as to chemical composition and modulus of gravitation. Our forms of architecture seem varied enough: they may however be far more restricted in idea and conception than we are in the least aware of, in comparison with possible combinations which have never

* "Sordello," Book VI.

entered our human conception. Such as they are however, some of them may have a deeper significance than is commonly attached to them, where they have really been the outcome of the effort to give form to an abstract idea, to express a thought which may in a typical sense be indicated in architecture, although in a material sense, like Milton's gate of heaven,

"Inimitable on earth
By model or by shading pencil drawn."

If these are deemed profitless speculations, at all events it seems that we are not alone in indulging such, for with the New Year there comes to us a small book* specially concerned with "architecture, mysticism and myth," and by an architect who is no mere speculator, but one of the best draughtsmen and most artistic designers among the younger generation of English architects. The main point of Mr. Lethaby's fanciful but interesting little book, as stated in the introductory chapter, is that the usual history of Architecture, "with its theory of utilitarian origins from the hut and the tumulus," is rather the history of building; that architecture "is thought behind form, embodied and realised for the purpose of its manifestation and transmission."

"Of the modes of this thought we must again distinguish; some were unconscious and instinctive, as the desire for symmetry, smoothness, sublimity, and the like merely æsthetic qualities, which properly enough belong to true architecture; and others were direct and didactic, speaking by a more or less perfect realisation, or through a code of symbols, accompanied by traditions which explained them. The main purpose and burden of sacred architecture,—and all architecture, temple, tomb, and palace, was sacred in the early days,—is thus inextricably bound up with a people's thoughts about God and the universe."

The author goes on to urge that there is evidence of a "cosmical symbolism" in the architecture of the early world, and that the intention of the temple idea was "to set up a local reduplication of the temple not made with hands, the World Temple itself." Mr. Lethaby goes on to follow up this idea by tracing out the symbolism of various forms of ancient architecture; and though in his preface he disclaims the possession of the learning which may be thought necessary for the treatment of such a subject, he at all events brings together a great many curious facts and fancies from many writers, and brings out a great many curious resemblances and hints from ancient buildings of different styles and peoples. The relation of the placing and designing of ancient buildings to the sun and the sunrise, of which he gives many examples, is a study which has quite recently passed from the domain of fancy into that of scientific and historical investigation, and probably there are many more facts to be brought to light yet upon this interesting and suggestive subject. Among the chapters is one on "Pavements like the Sea," and a succeeding one on "Ceilings like the Sky." In regard to this last subject Mr. Lethaby observes that "it may be said that at great periods of architecture ceilings were always skies," i.e., studded with stars or with some similar suggestive decoration. This is going perhaps a little too far, unless we are to suppose that the author does not mean to include Greek architecture among great periods of architecture. Such an idea is not in keeping with the genius of Greek architecture; nor, we observe, does he bring forward any suggestion or example of such an idea from Greek buildings or literature. The idea is Egyptian, Byzantine, and Mediæval, but distinctly not Greek, though the placing or orientation of the Greek temples in regard to the position of the heavenly bodies appears likely to be more and more supported by evidence the more the question is looked into. This practice they very probably derived from the Egyptians. In regard to the Egyptian treatment of the ceiling Mr. Lethaby quotes from Champollion: "The Egyptians compared the

sky to the ceilings of an edifice, and those of the greater part of the temples are painted blue, powdered with stars. . . . The goddess of the sky is figured under the form of a woman, whose body, placed horizontally, and out of all proportion long, embraces a large space, circumscribed by the legs and arms, which are vertical." A sketch of such a figure is given; we are not told whence it is taken. In a less symbolical and more material, but certainly more architectural sense, it may be rationally supposed that the first idea of the dome, which is a feature more easily treated for internal than for external effect, was a derivation from the dome of the sky. All these ideas, as Mr. Lethaby does not fail to remark, belong essentially to a time when the earth was regarded as a fixed plane with the sky as a solid sphere extending over it, in which the stars were set. The modern scientific cosmogony has made sad work of all these old picturesque ideas of the universe, which lent themselves far better to typification or imitation in architecture than does the modern cosmogony.

In some chapters, as in that on the planetary spheres, the author rides his subject rather too far. The curious fact of the influence of the number seven on the mind of the ancient world is indubitable, but it is not easy to be sure whether it was the cause or the effect of some of the ancient fancies. To commence with the statement that "the number seven is written in the sky," that is, in the supposed seven planets, is a rather curious ignoring of the fact that all this is altered long ago; and in commenting on the fact that the Great Bear, "probably the first known and named of the constellations" is represented by seven stars, the author leaves us in doubt whether he means to imply that the collocation of these seven stars was one of the influences in giving importance to that number, or whether seven stars were selected to define a constellation in consequence of a previous attachment to the number seven. All this about the importance of the number is of course pure mysticism, which has nothing really to do with the typifying of abstract ideas on architecture, though it is interesting to study the various ways in which the worship, as we may call it, of the number seven can be traced. A more interesting subject, because less hackneyed, is that of ancient ideas as to the centre of the earth, by which of course the ancients meant the central spot upon the supposed flat surface of the earth. A diagram is given illustrating the fable of how the true centre of the earth was determined by two eagles being sent by Jupiter to fly, one from the east the other from the west, the spot where they met being the centre; but as in some other cases, the author does not make it clear whether the illustration is taken from any ancient representation or is merely his own way of illustrating the idea in drawing. The drawing, in outline, represents a kind of half-egg-shaped stone with the flat side downwards, and a bird on each side. It may be observed that Browning, whom nothing seems to have escaped, brings in this legend as an illustration in the sixth book of "Sordello"—

"So, says
About the world: where, in the midst, they met,
Though on a shifting waste of sand, was set
Jove's temple."

All this is merely mysticism, no doubt, and seems far enough from architecture in any sense; but it takes its part in what the author states is the central object of his book, to show "the influence of the known and imagined facts of the universe on architecture." The moral of this (for there is a moral in the book) is that architecture should still be designed, in its highest forms, under the influence of and with some relation to the known and imagined facts of the universe; in fact, that the highest significance of architecture is not attainable otherwise; that it must have a symbolism, immediately comprehensible by the great body of spectators. But of

what kind, and in what relation to the "facts of the universe" as at present "known," Mr. Lethaby does not offer to define. What he does say is rather negative than positive: "No terraced temples of Babylon to reach the skies, no gold-plated palaces of Echatana, seven-walled; no ivory palaces of Ahab, nor golden houses of Nero with corridors a mile long," all which were the production of the times of despotism and forced labour. That difference we can all see: architecture was once for the tyrant or aristocrat, and must in future ages be for the people, who have not shown hitherto much longing for architecture poetry and magnificence, for buildings designed in relation to and symbolical of the known facts of the universe. And one difference between the ancient and the modern life seems to be at present, that we have not even time to think of and contemplate architecture in the abstract and ideal spirit: everything is swallowed up in utility. As Matthew Arnold puts it

"We say that repose has fled
For ever the banks of the River of Time;
That cities will crowd to its edge,
In a blacker incessant line,
That the din will be more on its banks,
Denser the trade on its stream,
Flatter the plain where it flows
Fiercer the sun overhead;
That never will those on its breast
See an ennobling sight
Drink of the feeling of quiet again."

So one is often tempted to think now; but we do not know what higher and more widely-distributed education may bring forth in time, and whether the human race in the future may not still rise to the conception that there is something more in architecture than to afford work for the quantity-survivor and the contractor. Possibly it may be thought that, even in that case, the symbolism of nature is too fanciful and unpractical an element to find favour in these enlightened days. But the fact, which Mr. Lethaby's book reminds us of, that this semi-symbolical element and meaning once so largely permeated architecture, is significant in itself, and not without suggestiveness for the present day. Architecture at all events *once* meant more than meets the eye, and was connected in the minds of men with the order of the universe, as they understood it. It is as well to be reminded that such an ideal meaning, such a cosmic significance, was once recognised in architecture, and might again afford it, in a changed form, a new and higher significance than attaches to mere stone and mortar, and pilasters and colonnades. The possibility of the revival of such a higher symbolism in the art at all events forms a not unsuitable subject of speculation for the New Year, when our thoughts naturally turn towards the future developments which Time has in store for every phase of human craft or invention, Architecture among the rest.

OLD ST. PETERS, ROME.

BY MR. H. W. BREWER.

RAND as the modern Vatican Basilica undoubtedly is, yet the archaeologist and historian must always regret that the ancient church, the site of which it occupies, has so entirely disappeared. When one contemplates the fact that down to within four centuries of our own times there existed a vast, complete ecclesiastical edifice of the age of Constantine, very slightly altered from what that Emperor left it,—a building which preserved all the main characteristics of its original design, the largest ancient church of early Christian times, no architectural splendour, not even Michelangelo's glorious dome, can compensate for its loss.

It is a remarkable fact that all through the Middle Ages, down to the dawn of the Renaissance, it never seems to have entered into the minds of the Pontiffs to rebuild the old Vatican Basilica; even the glories of Venice, Milan, and Florence, to say nothing of the noble Gothic cathedrals of the north, could not tempt them to rebuild the great,

8. The Cantharus, or Fountain.

Key Sketch to View of Ancient Basilica of St. Peter, Rome.

rude, and somewhat barbarously-constructed old building.

Grimaldi, in his "History of the Vatican Basilica," refers to these facts.

Of course, various minor alterations and additions took place, from time to time, in the ancient Basilica, but the main fabric remained whole and entire as it had been constructed by Constantine, certainly down to the time of Nicholas V. This Pontiff has been usually accredited with the idea of the erection of the modern St. Peter's and the destruction of the ancient church, but there does not really appear to be any warrant for the statement.

Undoubtedly, in the time of Nicholas V. the old Basilica, which, Grimaldi says, had from the first been hastily constructed, and to a large extent from the materials of old classical buildings, had become decayed; in fact, some portion of it,—I am inclined to think the great apse or tribune,—had fallen down, and Nicholas V. had called in the celebrated architects, Leo Battista Alberti and Carlo Rossellino, who seem to have drawn up a report upon the condition of the building; what else they did is very doubtful. Either, however, in the time of Nicholas V. (whose pontificate extended from 1447 to 1455) or shortly after, the great transept of the church was pulled down, the altars, monuments, and other objects of art which it contained being rebuilt in the nave, evidently with the intention of replacing them in their original situations when the works of restoration or rebuilding had been completed. That this work was partially, if not wholly, carried out, is quite certain, because, on the reverse of a medal struck by Paul II. is a very interesting representation of the tribune or apse of St. Peter's as erected by that Pontiff. The inscription round it reads as follows: "Anno Christi MCCCCLXX has ædes condidit," and in the arch over the tribune is the inscription "Trihuna S. Petri," and below it the word "Roma." The tribune is here shown with a semi-dome above it, inlaid with mosaic, and a great baldacchino of a simple early form

below it. Evidently the whole thing was an attempt to reconstruct the old tribune. There are two very interesting early drawings showing the church at about this period. One has been republished by De Rossi and the other is engraved in the "Nuremberg Chronicle." Both of these show St. Peter's without transepts, but prove that in all other respects the church and its remarkable forecourt, or "quadruporticus," remained pretty much in their original condition. With the pontificate of Julius II., however, an entirely new state of things set in, and in 1506 Bramante commenced the present gigantic edifice, pulling down all the work which had been constructed by Nicholas V., Paul II., and other Pontiffs down to his own time. The great nave and aisles, the quadruporticus, and the lofty campanile were, however, not interfered with, and remained, with certain alterations and additions, down to the time of Paul V. (1605), who, with Carlo Maderno as his architect, perpetrated the terrible mistake of putting up the vast east front of the modern Basilica, which not only destroyed the symmetrical arrangement of Michelangelo's plan, but also necessitated the entire destruction of the old Basilica, which would not have been the case if Michelangelo's short nave had been adhered to.

There are a great number of drawings in existence showing the old church as it stood, with Michelangelo's dome and transepts rising up behind it. Amongst the most interesting are the following. The plan and views by Giulio Ballino (1567); by Marius Kartarus (1575); and a large view of the City of Rome, dedicated to Henry III. of France, by Antonio Lafrario (1577); also a view published in 1580, evidently taken from a much earlier drawing; also in the following works—Ciampini "De Sacris Edificiis a Constantino Magno Constructis," 1688; "Bonanni Templi Vaticani Historia," 1696; and "Fontana de Obilisco Vaticanani," &c.

In many of these views we see the quadruporticus and the great nave and aisles of the

old church, with the various additions that had been made to it from time to time. Although the eastern and western sides of the quadruporticus were unaltered yet, the north and south had been encroached upon by various structures. Upon the space marked C in our key-sketch, Paul III. (1503), had erected a large chapel with an elaborate Renaissance front projecting right across the south walk of the quadruporticus, and on the opposite side a large building called the "Auditorium Rotæ" was constructed by Innocent VIII. (1484-1492) which must have blocked up a considerable portion of the north walk.

The series of buildings forming the east front of the quadruporticus are shown in the earlier views, as represented in the drawing. To the extreme south-east (see I. in the sketch-plan) stood a quadrangular structure, with open arcades to the upper stories, which is described by Ciampini as the "Church of St. Appollinaris," but Bonanni, with greater probability, says that it was a Hospitium, erected by Leo III. for pilgrims. It was subsequently restored by Paul II., when, in all probability, the Renaissance doorway and windows, shown in the later drawings, were added. The arcaded stories above look like the old work of Leo III.

In the centre of the eastern front of the quadruporticus stood the great entrance gateway (fig. 2, sketch-plan), with three bronze doors. The arches and columns appear to have been Constantine's work, but the upper portion of the building had been covered by mosaic work, and Gothic windows introduced during the fourteenth century. To the north of this was a sort of open loggia (fig. 3). In the earlier views this is shown as a simple arcade with a balcony over it, protected by a penthouse roof, but in the later views, which are made from drawings executed by order of Sixtus V., a much more important structure is represented, with regular Renaissance pilasters and friezes; an alteration which was carried out between the pontificates of Sixtus IV., 1471, and

Alexander VI., 1503. There is rather an interesting question about this. The view in the "Nuremberg Chronicle," published 1494, shows this structure in its original condition, so that the drawing from which that very interesting engraving was made must have been taken at least a quarter of a century earlier.—I am inclined to think during the pontificate of Pius II. It is corroborated in nearly every detail by the Mediaeval view of Rome, published by De Rossi. Immediately behind this loggia rose the lofty campanile, called "Turris Cymbalaria" by earlier writers (fig. 4). Although this was, undoubtedly a lofty and beautiful structure, yet, surely, the old writers must have exaggerated its merits when we find Blondus affirming that "Talem Turrim Campanariam omnium primam in orbe terrarum fuisse!" Another writer, Angelus Rocca, states that "it was the loftiest tower in the whole world!" Ciampini, however, with his usual moderation, speaks of it as "Quidem non humilis Turris." The building is very carefully described in Bonanni, in a quotation from Tiberius Alphanus, who, in the reign of Sixtus V., collected together all the drawings and manuscripts relating to St. Peter's. In fact, as neither Ciampini nor Bonanni themselves saw the ancient church, most of the facts which they state are taken from Tiberius Alphanus, Turregio, and other earlier writers, whereas their plans and views are copied from drawings, either collected together or prepared under the direction of Tiberius Alphanus. It is but just to both writers to say that they acknowledge their obligations.

From Bonanni's description of the tower we gather that it stood four stories high above the roof of the quadriporticus, that in each story were eight two-light windows, with double columns and Gothic tracery, but Bonanni says that it was crowned by a dome and not by a spire, and undoubtedly the drawings executed in the pontificate of Sixtus V. agree with his description in every particular, but the earlier views agree in showing it crowned by a pyramidal spire; and as Tiberius Alphanus says, that the tower was restored in 1574, and there can be little doubt that the domical top, which has a very Renaissance appearance about it, was an addition of that date. The tower was constructed originally by Leo IV., in 1003, but, according to a writer of the name of Rutilius Albrinus, it was struck by lightning in the year 1333, when the bells were melted, and the whole was not restored until 1353. It may be a question whether there were not two towers attached to the quadriporticus, as built by Constantine, but there are no means of proving this point.

In front of the quadriporticus, and leading up to the great gate, was a platform (fig. 5) approached by an immensely wide flight of white marble steps, subdivided into five sets, each consisting of seven steps—(fig. 6). Passing through the great gate and entering the quadriporticus, we should have found in the centre of the court-yard, the great Pigna or pine-cone from the mausoleum of Hadrian (fig. 7), preserved beneath an elaborate and beautiful Gothic baldacchino adorned with mosaic work, and a few yards nearer to the church another pine-cone of brass which spouted out water and formed a fountain for the refreshment of pilgrims visiting the church (fig. 8).

The great east front of the church itself, though preserving the outline of Constantine's church, had been covered with mosaics, and its windows filled with Gothic traceries in the fourteenth century. Grimaldi speaks of these windows as being arranged "more Germanico," but they appear to have resembled most Italian Gothic windows of that period. Like all the others in the church, they were divided into three lights, and had three cusped circles in the head.

The church consisted of a long and very wide nave with four aisles. The clearstory was supported by forty-six columns, twenty-three on either side. The transept was not arranged as in Gothic churches, but formed a transverse nave at right-angles to the princi-

pal one, so that there was no "crossing." The great apse or tribune opened from the west side of the transept by a large arch called "Arca Triumphalis." To the west of the great apse was the Lady-chapel, erected by Probus and Proba (Prefect of Rome, and his wife), in the sixth century. It really formed a complete little basilica, having its nave, aisle, apse, and campanile, as is shown by the long section of St. Peter's in Fontana's work (see F).

The old basilica of St. Peter was surrounded by chapels and churches. Referring to our key-sketch, at G was the pontifical entrance to St. Peter's, used by the Popes when they lived at the Lateran Palace, and beyond it, at H, was a building called the "secretarium," in which they robed. Some writers have reversed the order of things here, and have created a confusion which seems to have very much troubled Bonanni, inasmuch as it makes the Popes enter the basilica through a chapel without an external doorway to it, and robe themselves upon a public staircase! All along this side of the nave were a series of ancient chapels, but Sixtus IV. destroyed all their symmetry and regularity by building what, from the view published in Bonanni, and made in the pontificate of Sixtus V., must have been a remarkably ugly chapel (J) for the use of the canons of St. Peter.

Two very curious buildings will be seen at figs. K, L. They are similar in design, forming large rotundas. Fontana appears to think that one, or both, of these were Pagan temples, which stood upon the spina of the old circus of Nero. Ciampini, however, says that the further one, dedicated to St. Petronilla, was erected by Honorius I. According to Fontana, these temples were dedicated to Venus and Mars; and what certainly is a strong argument in favour of Fontana's view is the fact that they stood close to the situation of the old obelisk called "La Giulia" (see M), from its having been brought over by Julius Caesar, which certainly was in its original position on the spina of the circus, before Fontana removed it to the front of the modern church.

The two rotundas, however, were dedicated under the titles of "St. Petronilla" and "Sta. Maria de Febribus." The former was pulled down before the time of Sixtus V., but a very interesting view in Bonanni's work shows the latter as it appeared in the time of that Pontiff, when it came to be used as the sacristy of St. Peter's. Uniting these buildings was a chapel and altar dedicated to St. John Chrisostom, see N, within which that great doctor of the Church was buried. On the opposite side of the basilica, at O, stood the chapel of St. Gregory the Great, containing the tomb of that illustrious Pontiff, and beyond it was a complete basilica church, P, which belonged originally to a monastery called Jerusalem, but after the removal of that monastery was dedicated to St. Vincent, and I cannot help connecting this building with the Jerusalem Chamber at Westminster Abbey. Its position is identical, and its juxtaposition to the tomb of St. Gregory the Great, whom Venerable Bede calls the Apostle of England (see book 2, cap. 1), seems too remarkable to be a mere coincidence.

On the opposite side of a narrow street, on the south side of the Basilica, stood the Campo Santo (Q), with its church dedicated to "S. Salvador de Osibus" (R), erected by Charlemagne. It had a lofty campanile, and is shown in Ciampini's plan as being very nearly square, standing north and south, and not east and west. It should here be noted that the Basilica of St. Peter itself was exactly orientated, but, of course, as in all the old Basilica churches, the Tribune and High Altar were at the west end, the latter having its back towards the congregation, so that when celebrating the priest and the congregation faced each other. So exactly due east and west was the Basilica that, on the vernal equinox, the great doors of the porch of the quadriporticus were thrown open at sunrise, and also the eastern doors of the church itself, and as the sun rose, its rays passed through the outer doors, then through the

inner doors, and penetrating straight through the nave, illuminated the High Altar.

On the right hand side of our view the old buildings of the Vatican are indicated, there is, however, considerable uncertainty about them. Nothing now remains of an earlier date than Nicholas V., except possibly the external walls of the Sistine Chapel, which look as if they might have formed a portion of a great hall or keep, which is shown in early views. Muratori says that Nicholas V. intended to rebuild the whole of the Vatican and St. Peter's. This statement seems to require corroboration, for, as we have previously noticed, his work at St. Peter's must be regarded rather in the light of a restoration than the commencement of a new building. The old Vatican was built, or re-built, by Innocent III. Bonanni, quoting from a manuscript file of Innocent III., says that "in 1200 he caused this house to be made anew, with chapel, chaplin's chambers, kitchen, stables, houses of the chancellors and chamberlains, elemosynarium, &c. He commenced the great hall (probably the building on the site of the Sistine Chapel), completed the loggia, enclosed the palace with walls and built the towers." It appears that Arnolfo di Lapo was one of the architects employed. In 1258 we find it stated that Nicholas III. ordered to be made the great hall, the palace, the chapel, and the ancient buildings to be enlarged. In all probability this hall was the one in the lower court of the Vatican, which is distinctly shown between the two great towers, one of which formed the "Orologium," or clock-tower. John XXIII. built the long gallery which connected the Vatican with the Castle of St. Angelo. It will be noticed at once that the Vatican and the Belvedere formed distinct buildings. It is to be regretted that the antiquarians and writers of the fifteenth and sixteenth centuries did not extend to the Vatican the same care which they exercised in preserving documents and drawings of the church and quadriporticus. As it is, anything like a careful restoration of the palace is impossible, as the views which show it are too vague to be implicitly relied on for such a purpose. As far as the palace itself is concerned, therefore, our restoration must be taken as being merely suggestive. H. W. B.

NOTES.

FROM our correspondence columns it will be seen that our friend Mr. T. G. Jackson continues to hammer away at the Institute and its examinations, and now concludes with the charge that the Institute is not offering "to a too confiding public" any guarantee of the artistic competence of its members. We do not understand that the Institute ever professed to be able to accomplish such an object by an examination test. What it professes to be accomplishing, or aiming at, is, in the interests of architects, to direct the studies of students to a fixed end, and to raise the general standard of knowledge and education among its members; and in the interests of the public, to ensure that members of its body shall have a competent knowledge of the technique of architecture. That is all the public could demand from it, or could expect to obtain. The question of an architect's artistic power, it has been over and over again pointed out (by "the memorialists" themselves among others), cannot be decided by any infallible test, any more than in any other branch of art. Cultivated public opinion settles that in the long run, as in every other form of art. Membership of the Royal Academy, a purely artistic body, does not settle such a question in the eyes of the public. People who know enough to distinguish between good and bad sculpture or painting are not influenced in their purchases or commissions by the consideration whether the artist is or is not a member of the Royal Academy. They judge the artist on his own merits and the testimony of his known works. The same test of free public opinion would operate

equally in deciding the artistic status of an architect. The Institute is not proposing to say to the public, "all our members are men of artistic power;" nor does the public want its advice on that point, any more than it wants that of the Royal Academy. What it proposes is to be able eventually to say, "all our members are men well instructed in the history and technique of architecture, and are up to a certain standard in general education" (the latter not so unimportant a point as some people think). More than this it is impossible that it could accomplish, since there is no infallible test of artistic power. Mr. Jackson blames the Institute for not doing what, in the nature of things, it is impossible that it could do.

THE dreadful catastrophe at Gateshead can hardly come under the chapter of accidents; even the word "catastrophe," which we substituted for "accident," is hardly the expression called for. The deaths unhappily caused by the rush for the exit should really be returned under the heading, "Suicide while in a state of unsound mind," always excepting that of the unfortunate doorkeeper who was killed while doing his best to bring a set of panic-stricken people to reason. It is with a melancholy sense of the hopelessness of average human nature that one has to read once more the discreditable story of hundreds of people losing all courage and presence of mind, and killing each other in a panic flight, because one hysterical woman screamed out "Fire!" The hysterical person, who is usually an element in these cases, has much to answer for, and has not always the excuse of feminine nervousness; and if the next person who started the cry of "Fire!" in such a case could be caught and given a year's imprisonment, perhaps other silly people would think twice before trying to upset the nerves of others on an occasion when coolness is the first requisite. In regard to the exit question it does not appear this has much to do with the matter when people once give way to a panic. The practice of keeping one leaf of the door closed after the house is full is very reprehensible, and may give rise to danger, or at least delay in exit, even when there is no panic; but it does not appear that it would have made any difference in this case if the doors had both been open. The real point in the matter, however, lies in the evidence the event gives of the danger and impropriety of wood-n construction in theatres, with hollow spaces where inflammable matter can lodge. Had the gallery been built of iron and concrete, with solid steps, there would have been no crevices in which papers could get lodged and into which matches could be let drop, and the hysterical person would have no temptation to begin his or her death-song. That is the moral of the whole thing from a constructor's point of view. Build the whole gallery of iron and concrete, and set wooden benches, if there are any, on solid steps, and the material for a fire-panic is reduced to a minimum, if not entirely removed. Here the whole material was, as it were, carefully prepared, and only required the match and the hysterical person to set it going.

THE three premiated designs for the proposed new parochial offices at Battersea have been for the past week on view at the new Free Library, Lavender-hill. Considering that this was a "limited" competition, we think it desirable that all the designs sent in should have been exhibited, and not only those awarded the premiums. Ample space was available in the room in which the drawings are hung for a selection at least of the other designs, and such a course would have been distinctly fairer to the other competitors, and would have allowed the general public to form an independent idea of the merits of the several designs submitted. The design sent in by Mr. Mountford, which was placed first, we have already noticed and illustrated (*Builder*, December 19, 1891). Of the various ways

which were open to competitors in the arrangement of the blocks (the details as to the arrangement of the various offices having been clearly defined in the conditions) two naturally presented themselves,—either of separating the public hall block from the official block, or combining them in one. Mr. Mountford has chosen the latter, which has the merit of giving communication between them by means of corridors without going into the open air, and is also the more economical of the two arrangements. The fall in the site was considerable at the northern end, and this has enabled Mr. Mountford to place the two smaller halls, which were required by the conditions, below the Public Hall. The Council Chamber is placed centrally, facing Lavender-hill, on the first floor, and the Coroner's Court is on the same floor at the back of the official block, and approached by a separate staircase, as shown on the ground-plan. The angle formed at the junction of the two blocks has been cleverly masked by the introduction of an octagonal vestibule to the public-hall, covered with a glass dome, with the reception-room and lavatories leading directly from it. The design by Mr. Cheers is somewhat unaccountable in its arrangement. On a site which was, compared with many, of a simple character, there is no obvious reason that we can see for the complicated arrangement of the various offices. The first thing that occurred to us on looking at the plans was that it would be apparently very easy to get into the building, and very difficult to get out. The central portion of the facade, which naturally suggested the position for a Council Chamber, has been unnecessarily frittered away in staircase and vestibules, and the Council Chamber finds a resting-place at the extreme rear of the building, where the quiet,—when it was reached,—would be its only recommendation. A large public hall, over 100 ft. in length, occupies the major portion of one side of the front block, although it does not appear on the front elevation. In short, this design is one of those unhappy instances of an exterior which gives no key as to its internal arrangement, and wants that element of simplicity and directness which should be characteristic of a good plan. Messrs. Reed & Macdonald, who were placed third, have adopted the "separate block" system, and the official block has a carriage-way completely surrounding it. The arrangement of the various offices is good. The Council Chamber and Coroner's Court are on the first floor, as in the design submitted by Mr. Mountford. The elevation to Lavender-hill is somewhat tame, and is not improved by the perspective view, which gives an even less satisfactory result than the elevation would lead one to expect.

THE resignation of Lord Lingen and Mr. Cohen of their positions on the Financial Committee of the London County Council has had one good effect, at any rate; it has drawn public attention to the principles of municipal loans. There are two clearly-defined parties in the Council on this point. The one to which Lord Lingen and all clear-headed men of business belong desires to see loans paid off in such a manner that the amount payable each year becomes less and less. The other party, headed by Mr. Charles Harrison, desires to see loans paid off on what is called the annuity principle, by which the amount of principal and interest to be repaid will be the same in the last as in the first year of the debt. It is clear that the first-named is the proper principle, otherwise—as it is certain that fresh improvements will necessitate fresh loans,—in a certain number of years the municipal debt must be largely increased. But when the amount payable diminishes year by year, if fresh loans are required, they can be procured without increasing the burden on the community. Moreover, each generation should, so far as possible, pay for its own work, even if the work should be a benefit to posterity. It is not possible, of course, for a community to

pay for extensive operations out of the revenue of a few years. But that is no reason why they should not pay off as much of the money borrowed during present times as is possible. Any other system of finance is both unsound and wanting in courage.

THE Bill which is brought forward by the Corporation of Birmingham for the purpose of obtaining a new water supply from the mountains of Wales is hardly likely to meet with any serious opposition. The principle that large towns are entitled to go to some distant district for the water supply has already been sanctioned in the case of Manchester and Liverpool. Hence the only questions to be set up relate to matters of detail. It has been supposed that a new Standing Order of the House of Commons may entitle the London County Council to oppose this Bill, on the ground that London may some day wish to obtain a supply from the same source. But it is doubtful if the Standing Order in question applies to such a case as this; even if it does give the London County Council a *locus standi*, it is equally clear that a possible, but uncertain, scheme for the supply of London from the mountains of Cardigan, Radnor, and Brecknock cannot be any real ground for refusing the demands of Birmingham. There is a legal and sensible maxim that the first in point of time is the first in point of right, and this principle clearly applies to such a case as this. The amount of the cost of the work, between six and seven millions, is very large, but it is an undertaking which, if successfully carried out, will supply Birmingham with water for generations, and it is well that such a work should, if done at all, be done thoroughly.

THE recent fogs have again drawn public attention to the way in which time, money, and health are lost in consequence of them. There was a time when they hardly caused inconvenience; the growth of London has increased their density and their injurious effects. In truth, they are the modern plague of London. It is annoying that no attempt has yet been made to obtain an authoritative and trustworthy report as to the means for their prevention. A Royal Commission, composed of scientific and practical men, might make a report, which might in its turn lead to beneficial legislation. These winter fogs have now become so great a pest that it is certain they will cause large numbers of persons who are not bound to the metropolis by business ties to leave it in the winter, and will prevent many from coming to London who would otherwise do so. The Metropolitan Members of Parliament should take the matter in hand; they are strong enough to force the matter on the attention of the Government, which, indeed, should not require much pressure to order an investigation into this affliction of the metropolis.

WE have received several samples of polished stone of grey, green, and red tints, and called "Bavarian granites," which the senders are desirous of more fully introducing to the English market. Now, we have nothing much to say against the materials, so far as their utility is concerned, but we do object to having them sent to us as coming from Bavaria, when we find that, as a matter of fact, some come from Sweden, and others from Saxony. Six of the specimens sent are unquestionably of Bavarian origin, and are quarried in the neighbourhood of Baysruth; these are grey, with the exception of one which is greenish in tint. The Swedish and Saxon samples are of rich red and deep green colours, and when these are interspersed with the true Bavarian stones they decidedly heighten the tone of the whole. A beautiful pink granite was also included amongst the samples, but in answer to an inquiry we find that this "has been withdrawn, as there is very great difficulty in getting any quantity of it." Why, then, was it sent to us? The real Bavarian

granites, although of grey tints and not so showy, perhaps, as the remaining specimens, required no holstering up. They are amongst the best granites we have ever seen; with one exception they are of warm tints, and will doubtless find a ready sale on that account. The nature of the minerals of which they are constituted, no less than the general structure of the stones, and their fine grain, place them at once above the average granites in point of durability. The greenish variety contains rather more iron pyrites than we like to see in a really first-class weather stone, and magnetite is found in small quantities in the more basic kinds, but these deleterious accessory features are more than compensated for by the fine condition of the essential minerals concerned, and do not materially detract from the value of the granites as a whole. The deep red stone from Sweden, which takes a good polish, is coarse-grained, its general tint resulting from the colour of the orthoclase felspar; the quartz is beautifully opalescent, and a dark mineral, resembling hornblende, is abundant. The dark green stone, apparently from Warberg, in Sweden, although handsome, contains such a large proportion of iron that we do not consider it would weather very well. It is not a stranger to the British market; we have seen it commonly in the yards of certain Aberdeen granite merchants. In the red granite from Saxony, alluded to, the orthoclase is pink, and the more or less rounded crystals of quartz which are "smoky" produce an effect much resembling our famous Peterhead granite. All these stones, from their nature and appearance, are eligible for competition in this country, and they will doubtless become conspicuous features in the market.

AT an adjourned meeting on Wednesday, the 23rd ult., the London County Council agreed (as reported in another column) to offer 5,000l. for the "Poor's Land," Bethnal-green, in pursuance of a clause in the Charity Commissioners' scheme of February last year:—

"The trustees shall, with the approval of the Charity Commissioners, and upon terms such as to secure a sufficient benefit to the poor of the parish of St. Matthew, Bethnal-green, forthwith grant to the London County Council, or any other public body, all the land held in trust for the charity, provided that the said land be secured and permanently maintained. . . . as a recreation-ground accessible to the inhabitants of the said parish."

This area of about six and a quarter acres is all that now remains of the fifteen acres, waste land of the manor, as conveyed under a deed of 1690 to "trustees for the poor" by certain persons who had bought the land and enclosed the greater part of it "for the prevention of any new buildings thereon, and to be for the yearly relief of the poor," &c. The trustees are empowered to lease the lands for terms of twenty-one years at the longest. Under special Acts they were paid 3,000l. Consols for sites for St. John's Church and vicarage, and the Museum, opened in 1872, with its adjoining pleasure-ground.* A lease of the remainder to Bethnal House (private lunatic) Asylum, for purposes of a garden, expired at Michaelmas, 1889. The Commissioners drafted three schemes,—one to carry into effect proposals by a majority of the twelve trustees for selling three plots of the vacant land for about 19,500l., to provide sites for a free library, an infirmary, and a new Vestry Hall, with conversion of 2½ acres into an open space. Those projects were opposed by, *inter alios*, the Metropolitan Public Gardens Association. The ultimate scheme was recently petitioned against,—in respect of its clause 30, quoted above,—by a majority of the trustees. They urged that whilst the deed of 1690 had, admittedly, two objects,—provision for the poor, and keeping the land open,—the latter is sub-

ordinate to the former, or eleemosynary, trust; and that such a sale would debar them from obtaining a full price for the ground. On July 23 Mr. Justice Chitty gave judgment in court in favour of the scheme, and declined to allow the petitioners' costs as out of the trust. His lordship is reported to have said that, looking to the deed, the contested clause formed, in his opinion, a lawful and *cy pres* appropriation of the property, for the deed, besides setting up a charity, had declared the land was to be kept open. Thus, we gather, a long out-standing question will now, in all likelihood, be determined.

ALL Saints' Church, Hertford, which, as we read, was entirely destroyed by fire last week, stands within a large graveyard in Fore-street, on the south side of the borough. As rebuilt, mainly of flint and chalk overlaid with rough-cast, early in the fifteenth century, it consisted of nave, chancel, transepts, and western tower. Two aisles were added since, and a leaden-covered spire. The interior was decorated, re-pewed, and repaired in 1872-3. This is one of two churches held, together with a house, by Peter de Valoignes, castellan of Hertford, *temp.* the Conqueror,* and assigned by Peter's son, Robert, to the canons at Waltham "for the health of himself and Hawise, his wife." The monks enjoyed this grant, confirmed by Richard I., until 26 Hen. VIII. when the Crown took the vicarage advowson, then rated, together with that of St. John, at 10l. 6s. 8½d. per annum. We gather that the organ (1750) and the fine peal of bells are destroyed. The bells were originally five in number. In 1674 William Wake cast the great bell into four smaller bells; the eight were recast 1771, by Pack & Chapman, at the cost of the Society of College Youths, Hertford, who, twenty years later, added two trebles, cast by Bryant, a townsman,—making ten in all. Here were many monuments and memorials of certain county families, including those of Dimsdale, Harrison, Townshend, Battell, Cherry, &c., with inscribed brasses to Isabel de Newmarch, maid-of-honour to Richard II.'s consort Isabella; William Wake, "sotmyng yeman of John Duc of Bedford's hors, And lat Surveyor with King Henry Sixt he was;" and John Prest, "quondam Janitor Hospitii Katharine nuper Regine Anglie,"—Henry V.'s queen. The registers are saved: an entry,—

"1665, Nov. 17th, Sir Richard Fanshawe, Lord Im Bassador, was laid in the Vault in the Chancell." cited in Turnor's "History of Hertford," shows Colley Cibber correctly says that Fanshawe, our Ambassador to Madrid, where he died, was buried in this church. A subsequent entry stands thus:—

"1671, May 18, Sir Richard Fanshawe, Imbassador, was taken out of this Vault, and laid in his Vault at Ware."

A tombstone in the burial-ground recorded the interment of "Black Tom" of the Bull Inn, Bishopsgate-street, in 1696. A view of All Saints', by J. & H. S. Storer, will be found in Lewis Turnor's volume.

AN interesting lecture on "The Development of the Pig-iron Manufacture in the United States" has been lately delivered before the Franklin Institute by Mr. John Birkinbine, and now appears in the *Journal of the Society for last month*. In 1863, the United States only produced as much pig-iron as Great Britain did in 1835, so that she was then thirty-one years behind this country. At the end of 1884, however, she was only twenty-one years behind, and if the same rate of progress of both countries continues, she will produce as much pig-iron as England in 1950. In the United States between 1830 and 1860, the production of iron increased twice as fast as the population, and between 1860 and 1890 it has increased four times as rapidly, the consumption at the

* For account of Hertford Castle see the *Builder*, December 23, 1882.

present day being at the rate of about 300 lbs. per head, the whole of which is produced in the country. Great Britain, on the other hand, makes more than she consumes, and during 1889 the production reached nearly 500 lbs. per head. As at present the production for the whole world is about 25,000,000 tons per annum, and during the next ten years this supply must be increased by at least 50 per cent., there is a bright future for those engaged in the manufacture of pig-iron and the allied industries.

THE same journal contains a paper on "Fuel Gas," by Mr. Arthur Kitson, in which he describes its production and distribution. The great value of gas for metallurgical work became evident directly Siemens introduced his regenerative furnace. The distinction that is made between fuel gas and illuminating gas arises chiefly from the difference in cost, since the latter makes excellent fuel gas providing it can be sold at a price sufficiently low to allow it being used for the purpose. Since it is possible to obtain about one-half of the total heat of combustion of gas, while only one-sixth of the heat contained in coal can be made serviceable for ordinary domestic purposes, the fact that gas generated from coal contains less energy than the coal itself does not prevent fuel-gas being economical. The author draws attention in his lecture to various methods of making the gas, and describes a producer he has designed, besides giving the results of several experiments he has carried out in connexion with this subject.

IT is extraordinary what vitality a scientific blunder possesses. More than twenty years ago Professor Tait, speaking before the British Association, said:—"Mark, however, that heat is not the mere motions, but the energy of these motions—a very different thing, for heat and kinetic energy in general are no more 'modes of motion' than potential energy of every kind (including that of unfired gunpowder) is a 'mode of rest.' In fact, a 'mode of motion' is, if the word motion be used in its ordinary sense, purely kinematical, not physical,—and, if motion be used in Newton's sense, it refers to momentum, not to energy." This emphatic protest ought to have killed the expression long ago, yet only the other day, not in a popular work, but in a singularly able leading article in the *Electrician*, on the question of the existence of electricity, we came upon the statement that heat is a "mode of motion." This strange persistence of error makes it very important to protest early against any abuse of scientific phrases. Already in [three] glossaries of electrical terms, we have found the "watt" defined as the unit of electrical energy, and a writer in *Lightning* who made, by implication, the same statement, while acknowledging the error, defends it, as "what in common parlance is done among engineers on every day in the week." If this be so, so much the worse for the engineers; they are preparing trouble for themselves in the future. What is the use of giving special names to definite scientific conceptions, if these names are to be regarded as interchangeable at will?

THE cable industry was threatened with extinction lately from the scarcity of india-rubber. Fortunately a large number of these valuable trees have been discovered in New Guinea, whence they can be transplanted and cultivated in more accessible portions of the globe. We shall, therefore, continue to receive from America early news of depressions, atmospheric and mercantile, and of the sayings and doings of that erratic genius, Mr. Edison.

WE have received a large quarto illustrated pamphlet got up by Mr. Franklin W. Smith, a wealthy inhabitant of Boston (with the help of Messrs. Renwick, Aspinwall, &

* Opened by the Office of Works in 1876. To it was added the Green, on the east side of which stood "Blind Beggar's House," built in 1570, it is said, by John Thorpe, the architect, for one John Kirby.

Russell, architects, of New York) containing the general idea for a great National Gallery of History and Art for America, proposed to be erected on the banks of the Potomac at Washington. The object of the publication is to arouse the public mind in America on the subject, and certainly the scheme proposed by Mr. Smith is magnificent enough to satisfy even a country which always wants to do something bigger than all the rest of the world has done. The idea apparently is that all the leading styles of architecture of the world are to be reproduced in the several halls and galleries; the domain is to be entered by a bridge over a small lake flanked by circular colonnades, and the climax reached at the further side in a kind of modern Acropolis with an imitation Parthenon (to a larger scale) surrounded by great double colonnades. The galleries, we presume, are to be filled with works of art of various types. We should very much doubt so ambitious a scheme being carried out, and fear it would look rather like an enormous museum of curiosities. If the American nation wish to have a National Gallery of Art, they will do more wisely to content themselves with attempting a more reasonable building in a modern style.

WE note the appearance of the third part of Mr. Goch's work on the "Architecture of the Renaissance in England,"* which includes illustrations and description of Kirby Hall, well known as one of the most interesting buildings of its class. The first two "Parts" of the book we have already noticed at some length. When the whole six "Parts" have been issued we will devote further space to a consideration of the remainder of the work.

IN the matter of the London Building Act Consolidation Bill, the Building Act Committee of the London County Council have suggested a number of amendments, and the Institute of Architects have issued suggestions for a "Draft Bill for the codification and amendment of the Metropolitan Building Acts," printing in double column the existing clauses with the proposed amendments and amplifications opposite. These we shall give full consideration to on another occasion.

THE *Daily News* says that in making the subway between the Great Northern Railway terminus and the King's Cross (Metropolitan) station, the men have found a solid block of concrete several yards square, 2ft. under the centre of the roadway, a few feet north of the Metropolitan tunnel. Our contemporary goes on to say:

"According to old plans, it is the foundation of the cross erected in 1290, by order of Edward I., as one of the resting-places of the body of Queen Eleanor, on its way from Hornby, in Lincoln (*sic*) where she died, to Westminster Abbey."

We have not seen the old plans referred to; and, at present, are inclined to suspect that, in view of the block's situation, and shallow depth beneath the present surface, it formed rather a foundation for the ridiculous structure, of brick cemented over, consisting of a watch-house (with a pair of Doric-fluted columns at each angle) and clock-tower, surmounted with George IV.'s statue, by Stephen Geary, architect, which was erected on the site (as we have read) of Cromwell's observatory at Battle-bridge sixty years ago. They took down the statue in 1842; the watch-house and tower, having served as a police-station, and then as a tavern with a camera-obscura in the tower, remained until 1845.† Crosses were set up in London to the Queen's memory at Charing-cross, where Charles I.'s statue now stands, and in Cheapside, by the end of Milk-street (or Wood-street). Of the latter there are views in Wilkinson's "Londina," after the Cowdry painting of Edward VI.'s

coronation procession, and an original drawing (1606) in the Pepysian Library, at Magdalene College, Cambridge, &c.

THE following paragraph, which appears in the *Times* of Tuesday last, ought to do something to further the movement in favour of an improved source of water supply for London:—

"POLLUTION OF THE THAMES.—At Staines Petty Sessions, yesterday, George and Robert Morgan and William Haimer were summoned by the Thames Conservancy for having emptied the contents of a cesspool into the Thames just above the intakes of the metropolitan water companies. The case was clearly proved by a Conservancy official, and the defendants were fined 50s. each."

We wonder how many cases of this kind escape undetected? The dangers to which London is thus exposed have often been pointed out, and it is appalling to think of the possible consequences in the event of the prevalence of typhoid fever in Staines or other places above it.

FROM a letter of the Rector of St. Mary Woolnoth, in the *Times* of December 26, giving some of the results of Mr. Mark II. Judge's examination into the condition of the building, it seems evident that it is nothing short of a public duty, independently of any consideration of the use of the church by the congregation, to remove from the centre of the city the festering mass of human remains which is enclosed in the basement of the church. That this may be done without permanent injury to Hawksmoor's remarkable building we have no doubt, and we hope we shall hear no more talk of anything so absurd as destroying the church.

IN reviewing a book on American railways some time ago we spoke strongly as to evidence given in it as to the deplorable want of the feeling of responsibility for the public safety, both in the construction of railways and in the performance of duty by officials, which was admitted in a book written by American engineers and railway officials. According to the New York correspondent of the *Times* (December 25) a crucial instance of this criminal light-heartedness on the part of American railway officials was given in the case of the collision between two trains on the New York Central Railway:—

"It is alleged that the brakeman who was sent to stop the St. Louis express reached Hastings Station in ample time to stop the train, but, believing it not to be due for some minutes, he stopped to take a drink with the stationmaster, and while so engaged the express dashed past."

Englishmen who are interested in railway working may be allowed to feel some pride in the reflection that such a deliberate dereliction of duty would be impossible and unheard-of among the humblest officials of a great English railroad.

LETTER FROM PARIS.

SINCE our last letter the question of the Sèvres manufactory has been definitely settled. The Minister of Public Instruction, much embarrassed by the refusal of M. Braqueyemond to undertake the directorship, took the advice of the Conseil Supérieur des Beaux-Arts, which has decided a division of power between three distinct sections. The "administration" section will be placed under M. Baumgart, who will be responsible for the working of the manufactory. The section of "Travaux Techniques" will be placed under a distinguished chemist, M. Vogt; and that of "Travaux d'Art" under M. Jules Coutan, the sculptor of the monumental fountain of the great Exhibition.

M. Coutan's talent is well known; he is a conscientious artist in his own work, with a fine eye for form, but nothing in his past career seems to point him out specially for such a post as that at Sèvres. Ceramic art requires a special knowledge and experience, and a director of design in that art should have also knowledge of the practical processes employed; in fact there is or should be

a close connexion between "travaux d'art and travaux techniques" in this class of work. The future will show whether the young sculptor will be able to put any new life into the now rather superannated form of work put forth, not much to the national credit, from the Sèvres manufactory.

The Minister is also bent on transforming and developing the "Ecole de Sèvres." This institution is organised for giving instruction in ceramics for the benefit of private industry. Henceforward every citizen furnished with an official authorisation can obtain all the instruction he requires in design and manufacture; and funds are reserved for making all researches in regard to the fabrication and design of ceramic work. In short, the Sèvres institution will now be at once an artistic establishment, a centre of scientific research, and a school of advanced study in ceramic art. Such at all events, is the intention of the Minister of Fine Arts. It remains to be seen whether or not the good results anticipated will be realised under the routine system which always clings about a State establishment.

We have referred already to the projected "museum fund," to be furnished by the proceeds of payment on entry, a measure certain to be exceedingly unpopular. Such has been the opinion of the Budget Committee, which has pronounced itself strongly in favour of retaining the present free entry to National Museums. The Committee is, however, in favour of the increase of the annual credit for museums and art galleries, in order to facilitate the purchase of pictures and works of art. The authorised expenditure will probably be raised from 200,000 to 500,000 francs, and this is certainly the best solution of the difficulty, and there is little doubt that Parliament will ratify the proposal.

A good deal has been said in the press about a provincial shop for the manufactory of spurious Millet pictures, said to have been concocted by a former pupil of the artist. The fraud has been carried on for some time, it appears with profitable results. The police have put an end to an enterprise, which at all events showed that the "facture" of the celebrated painter of the "Angelus" was not difficult to imitate, and that the artistic perception of the majority of purchasers leaves great room for improvement.

Fraud however is very rife at present in connexion with artistic work; not only the fabrication of spurious works of art, but of the whole materials with which they are produced, such as pigments, oils, varnishes, &c. A number of painters, all members of the Institut, have felt this so strongly that they have addressed a memorandum to the Prefect of Police praying that all materials of painting offered for sale should be examined at the municipal laboratory and officially stamped.

We are in the season of small private exhibitions. To the usual number is this year added an exhibition with the pompous title of the "Exposition des Peintres Symbolistes." Under this title, perhaps destined to efface that of "Impressionist," are grouped a few young artists of talent, nearly lost in a crowd of mediocrities. Among those whose talents have been long recognised are M. Renoir, with a fine pastel; M. Willette, who has three exceedingly delicate drawings; and M. Leprie with an important landscape. Among those who promise well are MM. Bonnard, Maurice Denis, Anquetin, Filliger, de Toulouse, Lautrec and Seruzier.

The exhibition organised by M. Antocolski, a Russian sculptor, is also noticeable. He has a great reputation in his own country, and his score or so of statues exhibited enable one to appreciate his merits, but he shows a certain "preciosity" in the handling of the marble which is too much of the modern Italian school, and fatigues one by the *finesse* and multiplicity of detail. This pitfall at least modern French sculpture has avoided, and the exhibition of terra-cottas by the lamented Carrier-Belleuse which is now open forms a notable contrast in this respect with the work of the Russian sculptor.

It may be mentioned here that there is shortly to be an exhibition of the works of the late landscape painter Pelouse, as well as the ninth international exhibition of "Bianc et Noir," which will this year be transferred to the Champ de Mars, and will comprise an important retrospective exhibition of engraving to which many well-known collectors have promised to contribute.

* Published by B. T. Batford.
† *Vide* prints (1830) of the statue, and woodcuts (1842) of its removal, in the Guildhall Library, and the Grace Collection, British Museum; also Pugin's "Contrasts."

The exhibition of photographs collected by the Commission des Monuments Historiques, at the Trocadéro, should not be overlooked. There may be seen photographs of many of the most curious ancient churches in France: St. Oastriac, Rouan, Uzerehe, St. Calais, &c. This fine collection, organised by M. Miesement, shows the visitor also the Druidic monuments, dolmens, and menhirs, scattered about the districts of Charente, Maine-et-Loire, la Sarthe, and Brittany.

From historic monuments to "bâtimens civils" the transition is easy, since both are under the same administration, and it may be here mentioned that M. Yves Gyot has reconstituted the bureau of "bâtimens civils," which for 1892 will be thus composed: M. Jules Comte, President; MM. Charles Garnier, Daumet, Pascal, Moyaux, Bonvard, Marcel Lambert, Paulin, Vandremere, Sédille and Blondel.

It is announced that the Direction des Musées Nationaux has decided to put at the disposition of the public plans of large dimensions and variously tinted, to be hung at the two principal entrances of the Louvre, to enable visitors to find their way round without a guide; an excellent innovation, since to strangers the Louvre is a complete labyrinth of which it is difficult to find the clue. The Louvre has just acquired a curious bronze statuette of Dionysos, attributed to Praxiteles, and long reputed among archaeologists as one of the finest productions of that period of Greek art. It has also acquired five polychromatic stucco statues of the Italian school of the fifteenth century.

The State Committee of Fine Arts has recently examined the new model executed by M. Rodin for the monument to Victor Hugo in the Pantheon. In the first design, which was refused, the three figures symbolising the inspiring voices of the poet were placed above his head. In the second, the figure of Victor Hugo himself dominates the group. The new design is considered very satisfactory and M. Rodin is commissioned to commence the work.

Since December 25 the public has been admitted to examine the ninety-six designs, at the Champ de Mars, for the decoration of the Salle des Banquets at the Hôtel de Ville. The first selection will not be made till January 5 or 6, and the jury will have some difficulty, from among these ninety-six, in selecting the five who are to be worthy of entering for the final competition. The spaces for the decoration are three large ceilings and eight door-heads. The sum to be allowed is 49,000 francs, and the Committee charged with the work have set themselves against the eternal "still-life" subjects which form the recognised decoration of dining-halls. Some of the painters have endeavored to combine the figure with these materials of decoration, by paintings of fish-shops, fruiterers, &c.; but the result is not happy. Others have struck the patriotic chord, and one represents on the ceiling the fraternising of French and Russian sailors at Cronstadt! In spite of some pretentious or absurd work, however, the competition as a whole is up to a high standard.

The Académie des Beaux-Arts will be shortly occupied in filling the place of M. Alphand. M. Philippe Gille is said to be a candidate. He is a well-known journalist and dramatic author. His candidature can hardly be considered serious, yet it is more comprehensible than that of M. Roger Ballu, who is said to have already commenced the customary round of visits; but he is too young a man and with too little artistic achievement to show, to have any chance of entering an institution of which every member is a celebrity.

The Académie des Beaux-Arts will also have shortly to elect two foreign corresponding members in place of MM. Rosa and Vela. M. Fiorelli is a candidate "en première ligne," Mr. Alma Tadema "en seconde ligne;" MM. Hasenauer, Jacobi, and Cuyper are also spoken of.

Public works in Paris offer little of interest at this time of year. We may mention the formation of a new aghattoir on the left bank, similar to that of la Villette; and the works necessary for the isolation of the Sainte Chapelle. It is said that the Musée Galliera will soon be inaugurated. We shall have occasion to speak further of this elegant edifice, designed by M. Ginain at the cost of the widow of the Duc de Galliera, and the porticoes of which are adorned with sculpture by MM. Chapu, Thomas, and Cavalier. The art collection of the city of Paris will be infinitely better here than in the Musée d'Auteuil, built hurriedly in an out-of-the-way

quarter, and which is, in fact, no more than a store-room, almost unknown to the Parisian public.

The general meeting of the "Société des Artistes Français" was held a few days ago. It appears from the results of the meeting that in spite of the schism which led to the establishment of the rival Salon, the financial condition of the Society is most prosperous; it proposes to spend a portion of its funds in creating a "maison de retraite" for impoverished artists, and has already collected and set aside for this purpose a capital of 113,000 francs; and it will be able in the course of this year to distribute more than 22,000 francs in giving relief to artists or their families. It may be said therefore that the future prospects of the "Société des Artistes Français" are exceedingly satisfactory.

THE ENGLISH IRON TRADE IN 1891.

It would be vain to deny that 1891 has been a disappointing year to the iron trade. Prospects at its opening were not such as to give rise to sanguine expectations, but they warranted the hope that the coming year would be a fairly favourable one. This, however, has not been the case. The financial troubles towards the close of 1890, further disturbances in our trade relations with South America, the full effects of the tariff changes made in the United States, and a heavy falling-off in the shipments to the colonies, all tended to check our export trade. If it had not been for the comparatively sound character of our home business, the loss experienced by the English iron industry would have been still more severe than it actually has been. Taking things as we find them, and looking at facts broadly, we are confronted by a decline in our export trade such as it has not often been our duty to chronicle.

It will be fully a fortnight yet, from the time of writing, before we shall have the complete returns of our export trade; but the results of the first eleven months of 1891 form a safe indicator what the total deficiency in the year's exports will be. We shipped in the first seven months of the year now closing 3,018,025 tons of iron and steel, of a total value of 25,067,291*l.*, against 3,738,020 tons, valued at 29,313,214*l.*, in the corresponding period of 1890. The loss was consequently 719,994 tons, or over 19 per cent., in quantity, and 4,305,923*l.*, or 14.7 per cent., in value. Although the decrease is emphatic, it is, nevertheless, a source of comparative satisfaction that the decline in tonnage and value shows no great difference, an indicating that prices have not deteriorated greatly in the year, as will be seen further on. To this loss in iron and steel must be added a falling-off of nearly 9 per cent. in hardware and cutlery, of over 2 per cent. in implements and tools, and of 3.2 per cent. in machinery and mill-work. Unsatisfactory as this may appear, it is somewhat of a consolation to know that it might have been worse, considering all the conditions of business in 1891.

As in the case of our foreign trade, we shall have to wait some time yet before we learn the extent of our production of iron and steel in 1891. The estimated output of pig-iron in the north of England during the year is, in round numbers, 2,630,000 tons, against 2,846,089 tons in 1890, and from this preliminary statement of the production of the chief pig-iron making district in the country, some idea may be formed of what the total decline in the output of 1891 may be, bearing in mind the fact that the production of 1890 was the largest on record. It is an illustration of the changed conditions of the pig-iron trade that the price of Cleveland iron is no longer governed by that of Scotch pig-iron warrants. This is a healthy sign, and due to the fact that the pernicious speculation in Scotch warrants has been put a stop to by their successful "cornering" by what is known in the trade as the London syndicate, which body succeeded, in the course of the year, in getting hold of nearly the whole of the pig-iron warrants, the gambling in which has hitherto had such a baneful effect upon legitimate trade. What the ulterior objects of the syndicate may be is a matter of very little interest; but the good it has done is evident. The cash price of Scotch warrants at the beginning of 1891 was 48*s.* 2*d.*, at a time when the strike of the blast-furnacemen in Scotland had not yet collapsed, as it subsequently did. The London syndicate managed, owing to the strike

and the large purchases it was steadily making, to force up the price in January to 48*s.* 1*d.* It continued manipulating the market, to suit its own ends, throughout the year, the price falling to 42*s.* 10*d.* by the end of March, but rising gradually until 59*s.* was reached on June 1. Since then, the syndicate having obtained all the iron wanted,—that is to say, nearly the whole of the pig-iron warrants in existence,—the price has steadily gone down, and at the close of the year it stands at 47*s.* 11*d.*, or 1*s.* 9*d.* better than at its beginning.

Cleveland pig-iron stood in January at 42*s.* 6*d.* per ton, and December finds it at 39*s.*, which shows the decline on the year to have been 3*s.* 6*d.* per ton. The comparatively high price of Scotch pig-iron caused large shipments of Cleveland iron to be made to Scotland, the increase in 1891 amounting to over 160,000 tons, counterbalanced to some extent by decreased exports to the Continent, but leaving the year's shipments of Cleveland pig still about 80,000 tons above those of 1890. This fact, no doubt, contributed to the comparative steadiness of Cleveland pig-iron, notwithstanding a reduced consumption. The price of pig-iron in Lancashire has also been comparatively steady, although the tendency, owing to a lessened demand, has been downwards, the decline being about 2*s.* 6*d.* per ton, from 48*s.* 6*d.* to 46*s.* 6*d.* for Lancashire iron. What are known as district brands have been sold in Lancashire at reductions ranging from 1*s.* to 1*s.* 6*d.* per ton. Of all the pig-iron-making districts, Staffordshire has been the most favorably placed during the year. Cold-blast pig-iron was in January quoted 100*s.* per ton; it went up to 105*s.*, but now stands again at 100*s.* Hot-air iron fell from 65*s.* to 62*s.* 6*d.*, but is now again 65*s.* Part-time pig has risen from 42*s.* 6*d.* to 50*s.*, and common iron from 37*s.* 6*d.* to 40*s.* As the consumption in Staffordshire has been nearly throughout the year in excess of the output, this explains the firmness which prevailed. The hematite pig-iron trade has not been very active, and everywhere a decline on the year's prices has been reported. In the north-west of England mixed numbers of Bessemer pig were quoted by makers 54*s.* 6*d.*; they are now 49*s.* On the east coast hematites fetched 55*s.* in January, and 48*s.* in December. In Lancashire, good foundry hematites were at the beginning of the year at 64*s.*, and at present 57*s.* is the price. It only remains to add that Scotch makers, owing to the strike, sold very little pig during the first four months of the year, but even after the furnaces were in blast again, there was only a very quiet business doing, and the result has been a decline ranging from 2*s.* to 9*s.* per ton, according to brand.

The fortunes of the finished iron trade have varied greatly during the year and in the several districts. In the north of England, although pretty well engaged, makers have had to submit to reductions averaging 9*s.* per ton on the year. Scotch producers of manufactured iron were, during the first part of the year, employed badly, but they are now doing better, without any really good prospects, however. They had to reduce their prices for bars from 67*s.* 6*d.* to 6*s.* 5*d.*, and subsequently two other reductions, each of 5*s.* a ton, had to be made. Later on, however, the price rose to 57*s.* 11*d.*, at which it now stands. Finished iron makers in Lancashire were in about the same position as those of Scotland. The year opened dull with them, with bars at 62*s.* 6*d.*, to 6*s.* 5*d.*, hoops at 62*s.* 6*d.*, to 6*s.* 10*s.*, and sheets at 7*s.* 10*s.* to 7*s.* 15*s.* The close of the year finds bars at 62*s.* 6*d.*, hoops at the opening rates, and sheets at 7*s.* 7*s.* 6*d.* to 7*s.* 10*s.* The tinplate trade is now in a worse position than it was twelve months ago. The effects of the McKinley tariff did not make themselves felt until after June 30, but since that date the monthly exports have fallen to about one-half. The result has been stagnation in the industry, and a drop of about 4*s.* per box. Manufacturers of finished hardwares have not had much cause to complain. Their business was necessarily somewhat affected by the adverse conditions ruling in other branches of the iron trade, but there has never been any actual depression with them, and their prospects are better than they were a year ago.

The steel trade has not been nearly so well employed during the past year as in the two preceding ones, and wherever we look, we find a reduction of output and a lowering of prices. The production of steel ingots during the first six months of 1891 was over 100,000 tons less

than in the corresponding half-year of 1890, and this fact will explain the drooping tendency of the market. Those who suffered most were the railmakers; manufacturers of steel supplying shipbuilding material being far better off, owing to the generally healthy condition of the shipbuilding trade. In the north of England several works have had to stop from time to time, and the decline in rails has been as much as 10s. per ton, while ship angles and ship and boiler plates only receded 2s. 6d. a ton. In South Wales, where the illness has, perhaps, been most severely felt, rails have lost 17s. 6d. per ton, while another staple product, tinplate bar, has gone down 20s. a ton. The Scotch steelmakers have been fairly well engaged, and they have now their orderbooks quite full. The decline in ship plates in Scotland has been 5s. a ton, and in boiler plates 15s. a ton, the difference in the reduction of prices plainly showing what kind of material was most called for. The steel trade of Sheffield, especially the heavy branches, has not had much to complain of, and, notwithstanding keen competition, the year will probably prove a fairly prosperous one for most concerns. The steelmakers of the Furness district have been fairly active, but those of West Cumberland have been rather quiet. The decline for the various steel products manufactured in the north-west ranges from 2s. 6d. a ton for ship-plates to 17s. 6d. for rails and 27. for wire rods. Tinplate bars have advanced 5s. per ton, and hoops 20s. The Lancashire steel trade has been dull, and boiler plates, the principal product, have declined 10s. a ton.

As we pointed out above, the shipbuilding industry has been fairly well employed during the year. The total output amounted to 1,268,470 tons, compared with 1,272,263 tons in 1890, comprising 748 steam vessels and 209 sailing ships in 1891. The difference in the tonnage, it will be seen, is not large, but what is more remarkable is that in some of the more important centres there has been a heavy falling-off, while others, hitherto of less importance, have come to the front. The royal dockyards also increased their output considerably. The prospects of shipbuilders are now hardly so bright as they were at the end of 1890, the amount of work in hand being much smaller. Marine engineers, in consequence of the fair activity in the shipbuilding trade, have been very well employed; but it deserves to be noted that in the past year the proportion of sailing vessels built has been far larger than in previous years. Otherwise makers of marine engines would have secured a better business than they actually did. Nevertheless, they have been better off than other departments of the engineering trades, although most engineering firms will enter the year with a fair amount of work in hand.

Happily, there have been no very serious disturbances in the relations between capital and labour. The most serious trouble was that with the engineers in the north-eastern parts, who, not content with quarrelling with their employers, took to fighting amongst themselves. We refer to the dispute between the plumbers and fitters. This, however, was at last settled, as was also the long-pending strike of the Scotch blast-furnacemen, who were utterly defeated. Another passing cloud was the demand for a week of fifty-three hours by the engineers in Lancashire, which, after some resistance by employers, was finally conceded. Sheffield manufacturers of cutlery, owing to depression, had to ask their men for a reduction of 5 per cent. in their wages. Some resisted, and were out for a long time; but others, being endowed with more common-sense, accepted the inevitable. Although not directly connected with the iron trade, the action of the South Wales coal-owners in giving notice to the colliers of the termination of the sliding scale has a bearing upon it. We need not enter into the merits of the case, but we may express the hope that the pending negotiations will end in a compromise; in the contrary case, a very serious rupture and disturbance in the labour market and the coal trade are to be apprehended. We may add that the fictitious cry for an eight hours' working day for miners appears to find divided sympathy even with those most concerned, and when astute politicians decline to express their opinions on such a delicate question, we may hope for seeing it shelved indefinitely, for it ought never to have been raised, British workmen, and especially British miners, having shown by their unions that they are well able

to take care of themselves without interference by the legislature.

It is, as we know from experience, a very hazardous undertaking, at any time, to say much, either one way or the other, as to the trade prospects of a coming year. Appearances last year were so promising that we ventured upon a prognostication which would have come true if the unforeseen had not happened. As the unexpected is a factor which has to be reckoned with, all we dare venture upon is to say that not too much should be expected of the year we have entered upon. It may, however, be observed that there is a fair amount of work in hand in most branches of the iron trade, and that the good harvests in America ought to give a fillip to business. Should the South American Republics settle down to a more orderly state of things than have prevailed lately, a revival may also arise from that quarter; but great caution will have to be exercised in the immediate future in trading with those countries.

HOLMAN'S "SEWER-GAS EXHAUSTER AND DESTROYER."

MR. STEPHEN HOLMAN, M.Inst.C.E. (formerly of the well-known firm of Tange Brothers & Holman), has for the last few years been devoting his attention to a means of relieving sewers of their poisonous gases without resort to open grids (which are often a nuisance), or to stack-pipes carried up the sides or fronts of buildings, to which there are often strong objections. Mr. Holman utilises the ordinary street lamp columns as his extracting-shafts and destructors. In the base of the column is placed what is at once the extracting and the destroying apparatus, as shown in the accompanying section, in which A represents a

6-in. pipe leading from the sewer, projecting 3 in. above the brick foundation on which the column rests (such foundation being not less than 21 in. below the ground-line), and within the lower end of the column. B shows the connexion for the gas supply from the street main, C the brass regulating governor of the burner, D the brass atmospheric burner, and E Holman's patent wind-proof burner-protector—the bottom cup of this protector resting on the collar of the burner, the inner pieces being placed within that bottom cup, and the top part, E, above it. This cup is then surrounded and surmounted by a series of ribbed cones and chambers in cast-iron so arranged as to retain the heat of the burner in what is practically a furnace formed of a series of circuitous passages, through which the sewer air, drawn up the 6 in. pipe leading to the sewer, must pass and be rendered harmless, afterwards passing out by the upper part of the column through the lantern into the open air. After the burner with its protecting cups has been placed in position, the ribbed cones forming the body of the furnace are placed round it, commencing with the bottom cone which surrounds the burner; the flanged cone, F, is then placed on top of the

bottom cone, and inside the flanged cone are placed, one after the other, the three cones, G, G, G, after which the central pin is dropped in and the top cone, H, is superposed. The top and bottom cones are covered with asbestos to prevent the radiation of heat. These extractors are in use by the London County Council, the Richmond Corporation, the Hornsey and Acton Local Boards, and many other local authorities, with satisfactory results, according to the testimony of the respective Borough Engineers and Surveyors. The burners are made to consume from six to eight cubic feet of gas per hour, at a cost of from 4d. to 6d. per day of twenty-four hours. The apparatus, as tested by the anemometer, will extract from 40,000 to 60,000 cubic feet of sewer-air per day. Professor Wanklyn and other chemists speak very favourably of the efficiency of the "furnace" in rendering innocuous the sewer air which passes through it.

For use in connexion with the extractor and destructor at night, Mr. Holman has devised a very ingenious flash-light burner, by the use of which the gas can be lighted or extinguished without opening the lantern.

THE SALE OF WATER BY METER AT BERLIN.

At the fifth ordinary meeting of the present Session of the Institution of Civil Engineers, on the 5th ult., the President, Mr. George Berkeley, in the chair, the paper read was on "The Sale of Water by Measure in Berlin," by Mr. Henry Gill, M.Inst.C.E.

The author drew attention to the fact that the concentration of the population in cities, and the increasing severity of the tests for ascertaining the quality of water supplied to towns, made the difficulty and cost of obtaining sufficient and suitable water for domestic purposes greater each year. In addition, the enforcement of the laws for the protection of rivers against pollution added to the expense and difficulty of the disposal of the waste-water of town populations. These causes made it the interest of the municipalities, as owners of the water-works, not to restrict the supply, yet to prevent waste.

The fact was referred to that the water supplied to cities was far in excess of the actual requirements of the inhabitants, and that the excess not only served no useful purpose, but was wasted and was prejudicial to the community. The waste was not intentional, but was, in a great measure, the result of an imperfect system of supply and of the irrational method of charging for water. It was alleged that improvement could only be effected by the abandonment of the present system of assessment of the charges for water for domestic purposes, and the adoption of the system of sale by measure. The sale, exclusively by meter, as in the case of gas, would effectually prevent waste, and would reduce to a minimum the difficulty with reference to the disposal of sewage.

The condition of Berlin in 1865, when the tariff charge for water was a percentage on the rental, was then described, and how that system gradually gave place to the sale exclusively by meter, the transition being finally completed in 1878, with equal advantage to the purchaser and to the seller of the water. The nature of the meter employed, the place and method of its instalment, and the system of control, as well as the peculiar character of the Berlin houses, were detailed. The regulations and tariff charges were explained, and the effect of the system on the consumption per head was illustrated by tabular statements based on the Census of 1880, referring to a large number of houses in each quarter of the city. The effects on the expenditure and revenue were also illustrated by tabular statements for the financial year 1889-90.

The objections urged against the sale of domestic water exclusively by meter were referred to, and it was shown that these were not valid as regards Berlin, and that as to how far they might be valid for other cities could only be determined in each case by a consideration of the circumstances to be met. That these objections, however, did not prevent the adoption of the system in many cases in Germany, was shown by an official statistical table of the water supplies of 73 millions, the inhabitants of seventy-seven German cities, in 26 per cent. of which the sale of water exclusively by meter and the control by meter of a considerable proportion of the remainder had been adopted.

It was conceded that the great stringency with which the various Governments enforced the laws for the protection of the streams against pollution had promoted the adoption of the system which was first introduced in Berlin.

Illustrations.

ST. PAUL'S CATHEDRAL.*

IN the illustration given this week of the celebrated London Cathedral, the object has been to select a point of view which would realise something of the soaring effect which the composition of the two campaniles and the dome presents to the eye when they are seen in conjunction on the approach from Ludgate-hill. In the flank view St. Paul's has too much the effect of a long box with a dome seated on the centre of it. Seen from the western position, where the campaniles group directly with the dome, the defect of this long level line is kept out of sight, and the whole assumes more the aspect of a spontaneously conceived architectural composition, with a unity of effect and conception which certainly does not strike one in the flank view of the building. In fact, the dome, which pre-supposes a wide central area perfectly different in character from the narrow "crossing" of a Medieval cathedral with its central tower, is a feature much more fitted for the culmination of a plan of tolerably square proportions, a plan of the Greek cross type, than for a long narrow plan of the Medieval type; it requires a pyramidal rather than a longitudinal composition; and there can be no doubt that Wren's architectural instinct was true in leading him to prefer his former plan for St. Paul's (the one worked out in the well-known model now in the Cathedral), in which a nearer approximation is made to the Greek cross type of plan, and the whole composition has more distinct reference to the dome as its central motive. The same principle is illustrated in the plan and design of St. Peter's, which must undoubtedly have presented a much finer external effect, as a composition, when in the dimensions left by Michelangelo, and before Carlo Maderno had added the lengthened nave which throws the dome back and prevents it from taking its proper place in the composition. St. Paul's is, in fact, a Medieval plan treated as a Renaissance building, and the two elements do not harmonise.

A foreshortened view from the west realises this pyramidal effect of grouping which the dome seems to require, and affords an opportunity of throwing the more delicate and graceful treatment of the campaniles into contrast with the broad mass of the dome behind, the two features mutually assisting each other by contrast. There is no accessible point on the ground level, however, from which this combination could be shown in a drawing without distortion. There are photographs which give fine combinations of the dome and campaniles, but they are all taken from the roofs of houses, and even then the dome is in some cases either distorted or thrown too far back or too low in the composition, and loses its rightful predominance. We have therefore assumed a point of view sufficiently far back to allow the dome to be seen in its true proportions in combination with the campaniles. The assumed standpoint is distant from the building about two and a-half times its own length, and the proportions have been carefully worked out in perspective, from the plan and from Gladwin's careful engraving of the north elevation, made in 1828, a copy of which, in the possession of Mr. Penrose, he has very kindly lent to us for the purpose. Of this engraving we give with this number a zincograph reproduction, about two-thirds the size of the original, which may be of interest, as correct geometrical drawings of St. Paul's as a whole, and on a large scale, are not very plentiful or easy to come at; and Gladwin's engraving, though in the formal mechanical style in vogue at the time it was made, has the merit of being an exceedingly

correct representation of its kind, in every detail.*

The Queen Anne Monument, which should naturally have shown in the view, has been omitted intentionally, since it is no part of the building, and from this point of view it would have obtruded awkwardly in front of the cathedral. The peculiar effect of the weathering on the building, which has divided its two stages almost precisely, over most of the building, into a light-coloured story above and a dark and smoke-blackened one below, it may be said is also an accidental effect having nothing to do with the architectural design of the building; but it is too characteristic and picturesque an effect, and too much blent with every one's recollection of the building, to be omitted. The sharp line of demarcation between the upper and lower stories almost suggests the idea that a different bed of stone had been employed in the upper portion; but the result is due, we believe, merely to the greater effect of rain on the more exposed upper portions, coupled with the fact that the cornice of the lower order affords a protection from rain to the parts immediately beneath it, and thus gives that marked separation between the blackened and the cleaner portions. The plinth stones are whitened again where the drip from the cornice has fallen on them, and the angle pilasters at the exposed south-west corner have also got their share of cleansing.

St. Paul's occupies a very different position from any of the cathedrals already illustrated in this series, and from nearly all those which will follow, in the fact that it was built in the post-medieval period, and is the individual work of an architect whose name and history are well known. The building of St. Paul's followed, of course, upon the destruction of the Gothic cathedral in the great fire of London, but it is not popularly known, probably, that before that event the old Cathedral had been so much damaged by fire and neglect combined, that a complete scheme for its restoration had been formed, first entrusted to Inigo Jones, and latterly in the reign of Charles II. to Wren, who intended to add to the medieval cathedral additions in the Italian style, "after a good Roman manner, instead of the Gothic rudeness of the old design." It was in the consideration of the method of doing this that Wren first suggested the idea of the central space with a dome over it, which was eventually to form part of his new design. In 1666 the estimates for the work had actually been ordered, when the great fire broke out and (perhaps fortunately) put an end to all idea of this patchwork of Gothic and Renaissance, by destroying the old church completely.

The first stone of the present Cathedral was laid on June 21 1675, and the top stone of the lantern laid in 1710. Before the existing design was finally adopted, there had been (besides stray sketches) two other designs made by Wren. One of these is the Greek cross design already referred to, of which the model was made, and another is one which received the formal approval of the King, but with leave to deviate from it, fortunately for us and for Wren's reputation, for this officially approved design is unquestionably the worst of the three. The central feature is a kind of melange of a dome with a minaret on it, and it is difficult to understand how an architect capable of designing the dome as we see it could have ever thought of erecting such a barbaric affair. In regard to the first design to which we have already referred, on the Greek cross type of plan, while there is no doubt that the plan was the finer and the general conception of the whole broader and more dignified than the present building regarded as a whole, we cannot share the wish sometimes expressed that the design shown in the model had been carried out in place of the present building. The type adopted is far better, but the details are much inferior, especially of the dome, which is far more refined, more graceful, and better proportioned than in the "model" design.

The plan of St. Paul's is changed in axis from that of the old cathedral, partly to get rid of the difficulty which would have been caused by building on the site of walls whose foundations could not be depended upon, and which it would nevertheless have been a work of great labour to entirely remove. As matters are, the oblique position toward Ludgate-hill which the Cathedral assumes is hardly a disadvantage to

it, as it is so closely shut in by houses and so entirely devoid of anything like a grand approach that it seems better that it should have the element of irregular picturesque quality in its position, since that of stateliness is out of the question. It is greatly to be desired that the surroundings of the Cathedral should have been laid out in a more stately and spacious manner while there was the opportunity afforded by the destruction of those portions wrought by the fire; but in the natural eagerness of owners to repair their misfortune as soon as possible, the re-building of the adjoining houses had been commenced before anything was settled as to the plan of the Cathedral site, and Wren had to accept the position. As it stands, the Cathedral loses much of the dignity of effect it might have had on a better arranged site, and moreover there is no point where it can be seen as a whole. On the other hand it perhaps gains a certain effect of sublimity,—what we have called its "soaring" effect,—from the very fact of rising out the confined mass of inferior buildings so closely surrounding it.

The two chapels eastward of the western towers were added to the plan much against the will of Wren, in order to be used as chapels to special saints in case the Romish ritual could be restored, as James II. secretly wished. Internally they are an addition to the architectural variety of the church, but externally they are an excrescence and a detriment to its effect, fitting awkwardly against the base of the towers, and shortening the apparent length of the nave when seen in perspective.

Architecturally speaking, the campaniles and the dome are the making of St. Paul's. The design of the substructure is very commonplace, consisting of a double order of applied pilasters repeated in an almost mechanical and formal manner all round the building; and the windows are of poor and ineffective design. The worst thing about it all, however, is the fact that the upper half of the wall is for the most part a mere empty sham with nothing behind it, and when once this is known it is impossible to forget it, or to have the same feeling towards the building which a spectator might have, despite its defects of detail, who believed its external visible mass to represent its interior arrangement and contents. The floral ornament above and about the windows is in the artificial taste of the day, and cannot be called ornament, being merely sets of festoons with no design whatever, though with a certain boldness and freedom of execution. The sculpture is respectable, and nothing more. The double-storied colonnade of the facade has however a fine effect, partly owing to the deep shadow from the recesses behind the columns; this in fact just shows what it is that the rest of the building wants; it is all too flat. All these faults of the substructure, however, are forgotten when the eye rises to the campaniles and the dome. The former are most graceful and original in design, and as full of play of surface and light and shade as the substructure (except the portico) is destitute of it. The dome, with its fine colonnade, with the original and truly constructive treatment of the solid bay at every fourth inter-columniation (marking the main points of support of the dome), and the deep recesses between and behind the columns, is a noble piece of architecture of its kind; and the actual dome, with its fluently-curved outline, rises in a most effective and graceful manner above the main colonnade behind which it is recessed. The lantern also is a very graceful structure, though rather too heavy for its apparent situation; and here again we come on the drawback of want of architectural truth. The mere tyro in construction knows that the stone lantern could not stand on that timber dome; and the concealed cone to carry it (the line of which is partially discerned however, and not disagreeably, behind and between the main colonnade) only half reconciles us, by its ability and novelty as a constructive device, to the aesthetic sin which has been perpetrated. In a previous study for the dome Wren had adopted, like Brunelleschi, the device of a slightly-pointed masonry dome to carry the weight of the lantern, ingeniously counter-weighting its exterior thrust at the base by a cove hung inwards. It is a pity that he did not adopt this completely logical constructive expedient, which would have made the exterior dome a reality instead of a sham.

With all these drawbacks, however, St. Paul's

* This series of Illustrations of the Cathedrals of England and Wales was begun in our issue of January 3, 1891. A list of those already illustrated, with particulars of future arrangements, will be found on page 20.

† The plan of St. Paul's given here is based on a large scale and very carefully-engraved plan in the possession of Mr. Somers Clarke, who was good enough to lend it to us as a basis of operations. It has been supplemented by measurements and observations on the building.

* The steps to the west entrance are not as shown in the engraving, but they have been altered since it was made.

dome remains one of the great things of architecture, which has produced few structures at once so grand and so graceful, and we do not say that the popular admiration of it is at all more than it justly claims.

We may call attention to one aspect of the colonnade which architects and artists will enjoy, though it cannot be shown on a drawing in consequence of the conditions of perspective drawing. Go on a bright day into the southern enclosure of the railed space, stand near the remains of the old cloister and carry the eye up the re-entering angle of nave and transept. Over where the two cornices meet curves the colonnade of the dome, three or four bays only visible, the whole depth and solidity of the construction emphasised by the manner in which we look up between the columns to the very back of the soffit over them, and realise the scale and the projection of the colonnade, crowned by the sweep of its cornice against the sky. The effect is quite sublime. H. H. S.

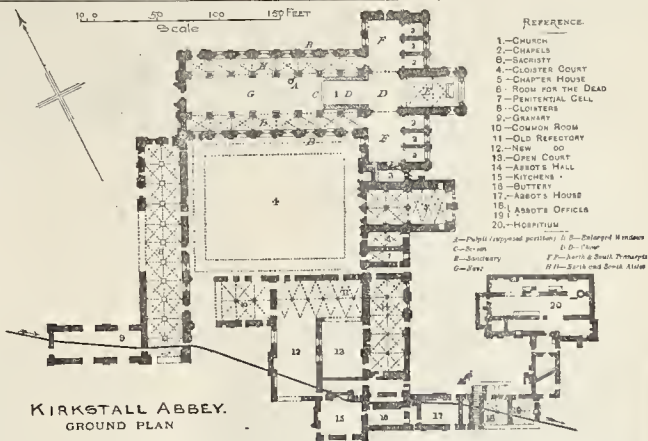

STAIRCASE, ST. PAUL'S CATHEDRAL.

This is a measured drawing by Mr. Stephen Ayling of the staircase in the south-west tower leading to the library. It serves to illustrate the style of the decorative detail within the building. The design of the ironwork is very good; the carved detail is in the usual style of the day. It may be a question, perhaps, whether Wren had very much to do with the design of these details; he was, in fact, an example of "that hybrid person, the Surveyor-Architect," of whom we have heard so much lately.

OLD ST. PAUL'S CATHEDRAL FROM THE NORTH-EAST.

As we have described Old St. Paul's Cathedral previously in a series of illustrated articles which have from time to time appeared in our columns, all we propose now to do is to say a few words about the drawing which we publish. In the first place, our readers will want to know what authorities exist for this "restoration." For this purpose the indications discovered by the excavations made under the direction of Mr. Penrose some years ago have been carefully studied. These show the form and the position of the east end of the church, the base of the respond at the south-east angle existing complete. It would appear from the foundations, which we have measured according to the indications marked out at the time the excavations were made, that the great east gable measured 36 ft. 6 in. between the buttresses; that the principal buttresses themselves were 7 ft. 2 in. wide; the aisles 15 ft. wide; and that the two buttresses at the angle of the aisle, which stood at right-angles to each other, measured together 14 ft., that the great preaching-cross was 30 ft. distant from this point, and that, including steps and parapet, it was 36 ft. in diameter. The eastern wall of the chancel appears to have been 7 ft. 2 in. thick, but the aisle wall, on the north side, seems to have been as much as 10 ft. thick! This is corroborated by Hollar's drawings, because he shows wall passages in the aisles and none to the clearstory; several of his illustrations also show that the aisle walls were thick enough to admit of monuments being let into them without cutting through the wall arcade. The tombs of King Ethelred and King Selba are cases in point.

Our view represents the church before the destruction of the spire in the year 1559. A drawing by Wyndgarde, the "Cowdray Picture," and a view by Hollar show the cathedral in this condition. The spire was of wood, and was, together with the parapet of the tower, erected in the year 1462, replacing one which was destroyed by lightning in 1444. Probably also at this time the flying buttresses at the base of the tower, were erected. They are shown by Hollar supported by plain, upright bars of stone, which look exceedingly ugly, but an earlier view by Vischer, 1616, shows these fillings-in as consisting of perpendicular mullions with ogee tracery heads between them. A very curious old picture of St. Paul's, from almost the same point of view as our illustration, is engraved in Wilkinson's "Londina Illustrata." It shows the preaching-cross, and King James I. attending a sermon preached therefrom. The gallery and Royal closet were then in existence; in fact, they probably remained until the year 1643, when the cross was pulled down by Lord

KIRKSTALL ABBEY. GROUND PLAN.

Mayor Penington. The Consistory-court, together with its shrouds and cloisters, would seem to have been perverted to secular uses, because a number of chimneys are shown, with smoke rising out of them, over which is the following inscription:—

"Views, O! Kings, how my wall-creepers
Have made me work for chimney-sweepers."

Another portion of the same painting is engraved in Nichol's "Royal Progresses of James I." This work is supposed to represent James I.'s visit to St. Paul's for the purpose of getting that monarch to restore the cathedral. There appears to have been some difficulty, however, about the matter, since, although the picture was painted representing the royal visit, James seems not to have gone until several years later, and, with his usual caution, appears to have suggested that so good a work should rather be the result of a "General Benevolence," than of a royal grant! The end of the whole proceeding is described by Dugdale as follows:—

"The collection of monies went so slowly forwards as that, though a good proportion of stone was brought in by the bishop, the prosecution of the work became wholly neglected, so that part of the said stone, lying useless, was after borrowed by the Duke of Buckingham for the building of the Watergate at York House, and there employed for that use." Of course this must not be confused with Laud's Restoration, which was not commenced until 1628.

The preaching cross was constructed of wood, and was rebuilt by Cardinal John Kemp. Dugdale appears to be wrong upon this point, as he attributes it to Thomas Kemp, Bishop of London. Kemp's arms were to be seen upon the leadwork of the roof. It was erected between 1422 and 1426. Sherrington's Chapel, Pardon-Church-Haugh, and the Charnel were pulled down by Protector Somerset, and their material used to erect Somerset House. The great campanile, called the clochier, is indicated in Wyndgarde and Vischer's views. Dugdale tells us that "within this clochier were four very great bells, called Jesus bells, in regard they specially belonged to Jesus Chapel, situate at the east end of the Undercroft of Paul's; and also, on the top of the spire, the image of Saint Paul, all standing till Sir Miles Partridge, Knight, temp. H. VIII., having won them from the King at one cast of the dice, pulled them down. Which Sir Miles afterwards, temp. E. VI., suffered death on Tower-hill for matters relating to the Duke of Somerset."

These isolated bell-towers seem to have been in frequent use in England during the Middle Ages, especially in the case of large and important churches. That of Chichester Cathedral still exists, and those of Salisbury, Westminster, and Worcester have only disappeared within the last two centuries. It is not quite known when the one belonging to St. Paul's Cathedral was finally destroyed; but, as it does not appear to be indicated in any view of a later date than Vischer's, and had entirely disappeared when Dugdale wrote in 1657, it is possible that, when the Duke of Buckingham "borrowed" the stone, brought for the restoration of the cathedral, he may have completed

the destruction commenced by Sir Miles Partridge by "borrowing" the stone of which the tower was built also. H. W. B.

ST. PETER'S DOME, FROM THE PIAZZA DELLA SAGRESTIA.

This is a reproduction of a drawing by Mr. Fulleylove, whose reputation as an artist dealing with architectural subjects is well known to our readers. It gives a rather unusual and little known view of the dome from a terrace, "Piazza della Sagrestia," high above the ground level of the Cathedral, and shows the dome and the upper part of one of the transepts; the angle of the façade is seen beyond.

OLD ST. PETER'S, ROME.

INFORMATION as to this drawing will be found in Mr. Brewer's article on an earlier page.

NORTH TRANSEPT, WESTMINSTER ABBEY.

This is such an exceptionally fine example of what must be called restoration, so completely in the true spirit and feeling of Medieval architecture, that we have wished to put it on record in a drawing worthy of its merits. Mr. Begg has taken special pains in the illustration of it, and as to the result we think there will be no difference of opinion.

THE KLINGEN THOR, ROTHENBURG, BAVARIA.

The fortifications of this interesting old town remain to-day in much the same condition as when they were completed and put in order for resisting the siege by Tilly in the thirty years' war. The town is of moderate size, completely encircled by walls, and each gate is guarded by an outer postern and tower; these are in each case intact. The Klingen or bell-tower is one of the largest and most interesting. The sketch shows the back of the tower towards the town, with the traces of the ancient clock-face. The galleries upon the walls are quite accessible as walks for visitors. The sketch shows the stairs to one section of them. Other views of Rothenburg have appeared in the *Builder*, by Mr. H. W. Brewer, and architectural artists in search of picturesque colour and old world scenes are to be recommended to try this quaint town, situated between Wurzburg and Nuremberg.

KIRKSTALL ABBEY.

The Cistercian community originally at Bernoldswic removed to the site of Kirkstall, near Leeds, in 1152, and the church was completed about thirty years afterwards. The building is one of the best known in Yorkshire, and is still a fine specimen of Norman transitional work. The central tower, the turrets flanking the gables, and also the tracery in some of the windows, are of Perpendicular date, the tower having probably been added by Abbot Marshall, 1509-1523. The situation of the Abbey must have been a very fine one. Its

St. Pierre, Coutances: Central Tower.

Scourished Church of St. Etienne, Caen: Central Tower.

picturesqueness has now, however, largely disappeared, owing to the close proximity of Leeds and its outlying suburbs.

The photograph, an unusually good one, from which the illustration is reproduced, was taken by an amateur photographer, Mr. William Brown, of Leeds, and was sent to us, with permission to reproduce it, by Mr. G. Atkinson, of the same town. The publication of an illustration of Kirkstall has some special interest at present, inasmuch as there has been a great deal of dissatisfaction expressed of late at the removal of the ivy from the ruins, and a good deal of paper warfare has ensued on the subject; and it may be of interest to those who loved the old aspect of the Abbey to have a memorial of its aspect before the ivy was removed.

We should add, however, that while admitting that an ivy-clad ruin is far more picturesque than one of which the walls have been laid bare, we are not by any means blaming those who were responsible for removing the ivy from Kirkstall. The preservation of the remains of a great monument of Mediæval architecture is, after all, of more importance than the picturesque effect of the ivy; and there can be no doubt that the growth of ivy over remains of this kind hastens their destruction as architectural monuments.

"LE TEMPS PORTANT LA RENOMMÉE."

"TIME brings Fame" to Delacroix is the idea which M. Dalou has adopted for the monument to the eminent painter lately erected

in the Luxembourg Gardens. Possibly the group may be criticised as being rather too full of movement for the true conditions of sculpture; but it has the great merits of boldness, spirit, and originality, and is one of the most striking works which French sculpture has recently produced.

Delacroix, who was born in 1799 and died in 1863, was one of the most remarkable of the distinguished French artists of the earlier part of the century, a painter of much originality of conception and great power as a colorist. His memory is celebrated in a monument worthy of his reputation.

TWO FRENCH TOWERS.

THESE illustrations of two characteristic French Mediæval towers are reproduced from sketches by Mr. R. A. Reid.

MEMORIAL STONE, KIRKINTILLOCH.—On the 19th ult. a memorial to the late Miss Beatrice Clugston was unveiled in the Old Aisle Cemetery, Kirkintilloch. The memorial, which is in the form of a red-stone monument of the English Gothic style, with a cast bronze panel inserted in the centre, stands at the head of the grave, and is 8 ft. broad at the base and 13 ft. high. The bronze panel is the work of Mr. Pittendrigh McGillivray, sculptor, Glasgow, and has in the lower part a group of figures representing charity, and above this a medallion portrait of Miss Clugston. The design of the monument was by Mr. W. F. Salmon, F.R.I.B.A., Glasgow, who superintended the work.

THE LONDON COUNTY COUNCIL.

At the special adjourned meeting of this Council held on Wednesday, the 23rd ult., Sir John Lushock, Chairman of the Council, presided.

The Bethnal-Green Slum Clearance.—The Housing of the Working Classes Committee reported as follows regarding this scheme:—

"The Council may desire to be informed of the progress being made in carrying the Boundary-street scheme into execution. The Provisional Order for the scheme was, after a local inquiry, confirmed by Parliament on July 3. The estimate of the cost of purchasing the lands and houses in the area, including trade and tenants' compensation, was 371,000*l.*; 129 claims have been received up to date, representing in the aggregate 414,850*l.* About forty-seven claims, it is calculated, remain to be received, the total amount of which will probably be about 90,000*l.* As regards the 129 claims received, negotiations are proceeding with respect to the greater number of them, and fifteen have been settled. The aggregate of the claims in these fifteen cases was 16,938*l.*, and the aggregate of the amounts at which they have been settled is 12,585*l.* Thirty claims have been referred to the Solicitor for submission to the Arbitrator, who will in due course be appointed, to decide the amount to be paid in all cases where agreements are not come to. There are in the area eleven licensed public-houses in respect of which claims have been received."

The Goldsmith-square Site.—The same Committee also reported with regard to the Goldsmith-square site in the following terms:—

"Before that portion of the Goldsmith-square site which is to be utilised for artisans' dwellings

can be put up for sale it will be necessary to carry out the widening of Goldsmith-row. Your Committee have issued instructions for the demolition of the existing buildings, and have directed the Engineer to carry out the necessary paving works in connexion with the widening of Goldsmith-row, and also the paving works in connexion with the widening of that portion of Goldsmith-square which is required for the line of frontage of the artisans' dwellings proposed to be erected on the site. It is estimated that the cost of these works will amount to £600. An estimate for this amount will be submitted by the Finance Committee concurrently with this report. Your Committee recommend,—

That the necessary paving works in connexion with the widening of Goldsmith-square and Goldsmith-row be carried out under the general contract at a cost not exceeding £600.

The recommendation was agreed to.

Rosebery-avenue.—The first paragraph of the Improvements Committee's report was as follows:—

"We have to report that the portion of the Rosebery-avenue improvement from Garnant-place to St. John-street-road, having been completed, was opened to the public by our Chairman, and the charge of the thoroughfare formally handed over to the local authority within whose district it is situated (the Vestry of Clerkenwell), on December 16. The Metropolitan Board obtained Parliamentary powers for this improvement in 1885. The contract for the works of the completed portion was entered into with Messrs. Mowlem & Co. in May, 1891."

Proposed Extension of the Chelsea Embankment.—The second paragraph of the same Committee's report ran thus:—

"On July 22, 1890, we reported to the Council in favour of continuing the river embankment from Battersea Bridge to Lots-road, Chelsea, on condition that the Vestry of Chelsea contributed one-half of the net cost of the work to be executed by the Council, such net cost being estimated at 62,000. After considerable negotiation, the Vestry declined to contribute more than 3,000, although it required to have possession, free of cost, of the whole land to be reclaimed from the river, about 3½ acres. The Vestry has asked that the question may now be re-considered by the Council, but, having regard to the resolutions of the Council of October 6 last, which were to the effect that the Council would defer further street improvements until some portion of the cost could be thrown upon the owners of property, we propose to give instructions for the Vestry to be informed that the Council is not at present prepared to entertain the matter."

After some discussion, the report was agreed to.

A Palm-house for Battersea Park.—The Parks and Open Spaces Committee's report began with the following:—

"We have had our attention called to the desirability of providing a palm-house in Battersea Park, not only for the accommodation of the palms which have outgrown the existing greenhouses, but also to be used as a winter garden and for the exhibition of chrysanthemums and other flowers. We submit a plan of the building, and propose that the central portion of it should be erected, leaving the wings to be added if necessary at some future time. We recommend,—

That, subject to an estimate being submitted to it by the Finance Committee, as required by the statute, the Council do authorise the expenditure of 1,500, on capital account, for the erection of a palm-house in Battersea Park, in accordance with the design submitted."

This recommendation led to a long discussion, but eventually it was carried.

Bethnal-green Poor's Land.—The seventeenth paragraph of the same Committee's report related to this much-fought-for piece of land, and was thus worded:—

"The Council will recollect that for some years the question of acquiring the land known as the Bethnal-green Poor's Land for the purpose of an open space has been before it, and the Council has already expressed its readiness to acquire the land, which is about 6½ acres in extent. According to a new scheme prepared this year by the Charity Commissioners, the trustees are to sell the land to the Council, and we consider that now is a fitting time for the Council to make an offer for the land. We therefore recommend,—

That, subject to an estimate being submitted to it by the Finance Committee as required by the statute, the Council do make an offer of 5,000, for the land known as the Bethnal-green Poor's Land, comprising approximately 6½ acres, in accordance with the terms of the new scheme prepared by the Charity Commissioners."

This recommendation was unanimously agreed to.

The Building Acts.—After a short discussion, the Council, on the recommendation of a special report of the Building Act Committee,

printed by us last week,* agreed that the Council do express a general approval of the Committee's suggested amendments† to the Metropolitan Building and Local Management Acts, and authorise the Building Act Committee to lay them before the President of the Local Government Board, and to confer with him as to any other amendments which may appear desirable during the progress of the Bill, and report the result to the Council from time to time.

Having transacted other business, the Council adjourned until Tuesday, January 19.

NEW BLIND FITTINGS.

MR. W. HENRY THOMPSON, of 147, Queen Victoria-street (son of the well-known contractor, Mr. John Thompson, of Peterborough), has brought to our notice a very simple though at the same time very ingenious Venetian blind-cord-holder. Fig. 1 shows the new holder with the cord secured, and fig. 2 shows the same with the cord released. Among other advan-

Fig. 1.

Fig. 2.

tages of this holder, which we have seen in action, we may mention the non-liability of the cord to kink, and the rapidity and facility with which the blind can be raised or lowered to any desired extent. The action is as rapid and as easy as that of a good spring roller blind. To raise or lower the blind the cord has to be held close to the window frame, and either pulled down or allowed to slide up, as the case may be. When the blind has attained the desired position, the cord is simply pulled away

Fig. 3.

from the window frame so as to raise the clutch, and the blind is instantaneously secured.

For roller blinds Mr. Thompson is also introducing a new and simple mechanical device for raising and lowering the blind, combined with a cord-holder. Amongst the small evils which householders have to bear, perhaps there is none more trying than the usual form of blind-cord-holder, which often either fails to hold at the proper moment, or wears out and cuts the cords prematurely. These defects appear to be entirely done away with in the cord-holder now under notice, which, as will be seen by the accompanying engraving, fig. 3, consists of

* See *Builder* for December 26, 1891, p. 457.

† We have received a copy of these amendments, but in the absence of the text of the Bill proposed to be introduced by Mr. Ritchie they are not very intelligible.

two small arms, pivoted on different centres, the outer end of the upper arm passing through a slot in the lower one, the cord to be held passing through the same slot. The holding power is obtained through the differential movement of the arms, any upward movement of the arms tending to close them on the cord. The greater the strain the greater the grip, but the pressure on the cord is only just sufficient to hold the blind, automatically increasing or decreasing as the weight varies, thus preventing the fraying and cutting and wearing-out of the cords. As will be understood from the engraving, the revolution of the roller, when the blind is descending, winds the cord round the reel or drum; by pulling the cord down it winds off the reel or drum, turning the roller with it, and so raising the blind.

Mr. Thompson is also introducing a very handy and ingenious little tool, named the "Eureka" tack-driver. It is chiefly suited for domestic use, and consists of a brass socket, fitted with a magnetised plunger, worked by a coiled spring. The plunger picks up the tack, head-first, and recedes with it into the socket. A smart blow with the palm of the hand on the knob at the top of the plunger-rod or handle compresses the spring and protrudes the plunger, driving the tack into the desired position. No hammer is required.

COMPETITIONS.

SCHOOL BOARD OFFICES, KEIGHLEY.—The designs for new School Board Offices, Keighley, submitted in limited competition by Mr. Leedingham, architect, Bradford, have been selected.

SCHOOLS, CHADSMOOR.—The Cannock School Board have selected the designs of Mr. Geo. H. Cox, architect, Birmingham, for the proposed schools at Chadsmoor.

Books.

The Mechanical Engineer's Pocket-book. By D. K. CLARK, M.Inst.C.E. London: Crosby Lockwood & Son. 1892.

ANY attempt to bring to a focus the vast accumulation of knowledge with which it is desirable that an engineer should be acquainted, so that its practical value may at once be evident, will always be welcome to professional men. So much information has now been published in technical works, and is to be found scattered through the proceedings of the various scientific societies, that it is becoming more and more necessary to have it condensed for actual use; and no one is better able to undertake such a work than the author of this book. The amount of information that it is possible to compress into a work of the pocket-book class is, of course, somewhat limited, as a considerable portion has to be given up to such mathematical and other tables as are so often needed, but Mr. Clark has devoted the chief part of his work to such formulae, rules, and data, as are required in the everyday practice of the mechanical engineer. In our opinion, the student who would study such a book as this in the same way as he would any other good technical work, and carefully read through it, committing to memory the more important formulae and data that the author has taken so much care to select and arrange, would, in a short time, have ready for instant use an amount of information which has only been discovered after years of hard work by men who have devoted their lives to scientific investigation.

The Pre-Norman Date of the Design and some of the Stonework of Oxford Cathedral. By JAS. PARK HARRISON, M.A. With illustrations. London: Henry Frowde. Oxford: Clarendon Press. 1891.

THIS is only a pamphlet, a reprint of a paper read at a meeting in the Chapter-house at Oxford some little time since, but it is of more than passing interest, as in his treatment of the subject the author takes up the general question as to the correctness of the date assigned to some supposed transitional carving, and gives illustrations from Saxon missals to show that ornamental details exceedingly like those of many such capitals are actually found in Saxon illuminated missals. The question in regard to Oxford Cathedral partly rests on a study of the stonework in detail, and without

making a special visit of inspection we could not undertake to pronounce on the validity of Mr. Harrison's views; but his paper is sufficient to show that the question is more open to discussion than has been generally supposed.

An Architectural Memoir of Old Basing Church, Hants. By the Rev. REGINALD A. CAYLEY, M.A. Basingstoke: C. J. Jacob. 1891.

This is a well-written description, in the form of a pamphlet, of a church which seems to have more points of archaeological interest than it is generally credited with, and which rather goes to persuade the reader, as Mr. Cayley suggests, that those who are interested in old churches would find it worth while to break a journey at Basingstoke and visit the church (two miles from the railway). Mr. Jas. A. Salter, F.R.S., adds some details as to the monuments and their heraldry.

The "Law Almanack" for 1892, edited by Frederick Herbert (London: T. Scott & Co., 1, Warwick-court, Holborn), is a very useful and clearly-printed sheet for the office wall.—Messrs. Shand, Mason, & Co., of Upper Ground-street, Blackfriars, send us a useful office-calendar, containing a spirited drawing, by Mr. Linley Sambourne, of firemen at work at the scene of a fire.—Messrs. John Ellis & Sons, of Leicester and Barrow-on-Soar, also send us a useful calendar, containing some very well-executed representations of fossils from the blue lias limestone at Barrow.

The General Manager of the Great Western Railway sends us a pamphlet entitled "Cornwall as a Winter Resort," which merits the attention of invalids and their friends. The pamphlet is published by Messrs. Waterlow Bros. & Layton, Ltd., Birchin-lane. With it come two small guide-books, entitled "The Winter Resorts of Cornwall," and "A Holiday Trip Round the Pembroke Coast." Both these are published by T. E. Longley, 39, Warwick-lane, E.C.

RECENT TRADE CATALOGUES.

The General Iron Foundry Company, Ltd., of Upper Thames-street, send us their new illustrated price-list (extending over more than 300 pages) of open, close, and self-setting ranges; tile and mantelpiece registers; overmantels; iron, marble, and wood chimney-pieces; rain-water pipes and gutters; socket-pipes, hot-water apparatus, laths, and sanitary ware; stable fittings, and general castings. The whole forms a very useful and comprehensive catalogue, and as it is well indexed, reference to any item in it is made easy.

Messrs. F. W. Reynolds & Co., of Southwark-street, send us a useful illustrated list of warming and cooking stoves and heating coils and radiators. The "Lacifer" slow combustion stoves, made in both square and round forms, and with large movable ashpans, appear to possess many good points. The same firm send us, from their other establishment, Acorn Works, Edward-street, Blackfriars-road, a sheet of very handy wood-working machines made by them. Both lists are well worth the attention of builders.

Woodhouse & Rawson United, Limited, Queen Victoria-street, send us two catalogues (List "B," Section 5, and List "B," Section 8) of electrical machinery and apparatus connected therewith, including engines, dynamos, accumulators, lamps, switches, fittings, instruments, &c. They are well worth attention, though the design of some of the electroliers and other fittings might be a great deal better than it is. Section 8 deals with steam and electric cranes, lathes, drilling-machines, tubewelders, &c.

Messrs. Taylor & Miller, of Argyle-street, Glasgow, send us an illustrated prospectus of "The Safety" Window, which presents many good points, though we have seen something very like it years ago. While retaining the ordinary sliding sash movement, both sashes can be opened into the room for cleaning, painting, or reglazing, without removing the parting-beads and without the jamming of weights. It is claimed that these windows are wind and water-tight.

BRITISH MUSEUM LECTURES.—Miss Millington-Lathbury is giving a series of four lectures on Greek Temples, Festivals, &c., at the British Museum, on January 28 and February 4, 11, and 18.

Correspondence.

To the Editor of THE BUILDER.

THE INSTITUTE AND ITS EXAMINATIONS.

SIR,—In your leading article of December 26, you refer to the passage in my letter, published in the same issue, where I speak of the surveyor-architect as "that hybrid personage of whom you think it unreasonable and impracticable that we [the memorialists] should want to get rid." Your reply is to the effect that when a man has been elected into the Institute as an architect it would be hard and un-Christian to turn him out because he earned an honest penny now and then, or habitually, by surveyor's work.

Very likely it would; but if I have rightly understood your reply, it does not meet my statement. When I said we wanted to get rid of the surveyor-architect, I did not mean to get rid of him out of the Institute. That is, of course, a matter of no concern to those who do not belong to that body. Our object is to get rid of the "surveyor-architect" altogether, and to get surveyors to stick to surveying, and architects to architecture. All we contend for is that the architect and the surveyor should stick each to his own last, and not be tempted by distracting, though possibly lucrative, invitations to follow two incongruous callings at once; because, if he does, it is certain that he will never make a good architect, and will probably make only an indifferent surveyor.

As regards the Institute, it may be, as you say, impossible for it to get rid of the surveyors within its ranks. I think it is. But at the same time this is a confession that, on its present lines, the Institute is not what it claims to be, a body of architects, and nothing but architects; and the five letters which denote membership, by this showing, only mean necessarily that he who owns them did at one time so far engage in architecture as to satisfy the very comprehensive conditions of the Charter. What then becomes of that protection which these five letters are supposed to afford to the confiding public?

T. G. JACKSON.

SIR,—In architecture, art and science are inseparable (as you very aptly illustrated in your reference to Peterborough last week). The two elements are so spun together into one thread that to remove either is to destroy the whole. Young men entering on a career may be materially helped by an organised system of teaching. Even the "little common sense" can be arranged and packed into the brain in a more accessible way with the aid of a teacher than without it; while the inherent art faculties of a youth, he they great or small, may be developed by good models and illustrations. It is true we cannot make a silkworm, but we can take care that the young grub is fed on mulberry-leaves as soon as it creeps out of the egg. It is perfectly idle to argue that a thorough system of education would prevent men of superior fibre from coming to the front. Occasionally, such a one may "ignore system" and survive, but to commend this example to the average youth is most pernicious teaching.

The Institute have thought fit to adopt an examination fence, which they are perfectly justified in doing, although, at the same time, examination without tuition is not a thing to be approved of in the abstract. Yet the step is so decidedly in the right direction that it should be accepted frankly, and the next step at once demanded,—namely, tuition. The Association, with the characteristic youthfulness of that evergreen body, have rushed into the gap, and exhibit the most commendable zeal in so doing,—but the field is wide, and London is not the whole Kingdom.

It is obvious architecture demands better educational advantages than it now possesses,—that its equipments should be at least equal to those of the other professions,—and that it should be placed with them on an equal footing in the great University centres of the country. The University authorities have the means and the opportunity to do a great deal for architecture if properly directed, and the needs of the profession properly put before them. While the Institute is not qualified to become a teaching body, it is fully competent to direct the training of the younger members of the profession. It could, with the voice of authority, point out to the Universities what is required and the form

it should take, and with their aid organise a general system of education for the whole country, and for the future exercise a supervising influence, seeing that the right materials were used in spinning the thread, otherwise it is possible the scientists may step in and try a new combination.

ARTHUR HILL,
Lecturer on Architecture.
Queen's College, Cork.

SIR,—As you were good enough to insert my letter last week, you will, I trust, allow me to finish my story.

I have told you of the benefits received from the Institute examination in the form of incentive and guidance. Let me tell you further of the tangible results. I commenced practice. I had no influence, no means. It would have been a hard struggle at first as an architect pure and simple in a provincial town, so I studied "quantities" and "surveying." These proved invaluable aids to myself, and of great service to my clients. When a client once found me at his stank like a limpet to a rock. Financially, I prospered.

But what of architecture? I do not deny that, had I bestowed all my strength on the artistic side of my work, capacity as a designer would have been increased. Such capacity, however, was not in demand. I had a wife and family to support, and others looked to me for help. I had the instinct of an artist, and nothing could rob me of it. My little works, if simple, are truthful; others say, "they are well-proportioned, dignified, and pleasing." Add to this, that I knew about every quantity, could tell of every "extra" and every deduction; that adjustment of accounts was consequently easy, that my clients' interests were conserved, and strict justice meted out to my contractors.

My work may increase so as to prevent this careful management of every detail; of that I do not concern myself. I would almost rather it did not; but if it does, then I must drop my "crutches" and soar to higher flights. I am still young.

Now, I should not have troubled you with further writing, had it not been to say what follows. If "the memorialists" do not see their way to join the Institute, and to help by precept and example to purify and better it, it is a matter which concerns themselves. Nothing shall prevent me supporting it, or make me afraid to join with any man doing honourable work. I say with confidence, Prepare for this examination. It is the way to success. The youth without guidance wanders aimlessly on, gets befogged, and often turns aside from all earnest effort. The Institute has marked out the path, you know that your perseverance and energy are rightly directed, and, working along the way with vigour and intelligence, you are certain of prosperity. You will also find that the stimulus given will grow with what it feeds upon, and that you will acquire noble lessons by the wayside.

Do the work that comes ready to your hand with your whole strength and soul. The fittest survive. Leave the immutable laws of nature to set everything in its due place.

EPICUREUS.

December 28, 1891.

ALL SAINTS' CHURCH, HERTFORD.

SIR,—This, the last building in Hertford possessing any remains of antiquity, was burnt down on Monday, December 21, at five a.m. Two of the other five churches were pulled down in the sixteenth century, and St. John's about a century ago, and St. Andrew's was rebuilt gradually about 1870-75. The spires of the town could be seen distinctly from Finsbury-park, a distance of sixteen miles.

The original building consisted of a nave, chancel and transept, and west tower. There was no east-aisle, and the nave was lighted by common domestic dormers.

The old portion appeared to have been built in the twelfth century, and had plain one-light lancet windows, and probably resembled Minster Church, near Margate. The tower formerly had a Decorated west window; the last remains of its tracery was removed in 1839 and restored in 1857. The south aisle was added about the time that the churches of St. Mary and St. Nicholas were pulled down. It is of unusual width, 32 ft., or nearly half as wide again as the nave. The north aisle was a stuccoed Gothic structure of the early part of the present century. The chancel aisle on the same side, built about 1875, was designed to match it in materials and style. The three lancet lights at the east end were replaced quite recently by a three-light window. The east buttresses, the only part not concealed by stucco, contained a considerable quantity of Roman

ricks. The leaded spire, about 40 ft. high, replaced one of double that height removed early in the present century. The churchyard is planted around all sides with a double row of large chestnut trees, as is the cemetery adjoining on the south side, which is simply an extension of the churchyard. These burial-grounds together make up about the finest churchyard in England.

Colchester, December 26.

WALTER SCARGILL.

ROOD-SCREENS.

SIR,—“W. S. B. H.” will find the rood-screen of Cullompton, Devon, fully illustrated, in the third volume of “Transactions of Devon and Exeter Architectural Society.” G. B. P.
Dec. 23, 1891.

SIR,—A correspondent in last week's *Builder* mentions the famous Caroline screen at Wiggenshall, St. Mary the Virgin. I fear it has been removed within the last five years. And it was doubly interesting, from its date, 1623, and also from its being erected just west of the medieval screen, which had been cut down to the stall level, so common in Norfolk.

There has been a correspondence lately on vandalism at Totnes Grammar School. And there, too, the great rood-loft in St. Mary's Church has been destroyed within the last three years. This was some 14 ft. wide, covering the first bay of chancel, the staircase being at the north-east corner; and had a stone screen west, and an oak one east. Meantime a hideous north gallery remains.

Perhaps the vicars of Wiggenshall, St. Mary the Virgin, and Totnes would explain. VIATOR.

Oxford and Cambridge Club, December 29, 1891.
We understand that photographs of the rood-screens of Devonshire and Cornwall can be obtained from J. B. Worth & Co., Cathedral-yard, Exeter. It may be a convenience to correspondents who are interested in the subject to know this.

The Student's Column.

WARMING BUILDINGS BY HOT WATER.

I.

INTRODUCTION.

THE purpose to which hot-water heating works may be put are both many and varied, but in dealing with methods, and the different forms of apparatus, it will be best to treat them under three distinct headings,—viz., horticultural works, building works, and works in which the heating is done by hot air alone. In the latter case the air is heated by pipes in a chamber specially provided, and differs from the two former methods by the absence of direct radiated heat.

From exposed pipes the heat is felt in two ways,—firstly, by direct radiation from the surface of the metal, that is, heat projected from the metal and being so transferred to surrounding objects; this warmth does not heat the air. Secondly, by the air being heated by contact with the pipes, which air instantly leaves the pipes and makes room for more air to come in contact and be heated, and so on. This is termed Convection,—i.e., heat absorbed and conveyed by the circulatory action of air. The difference between the two first and the third method mentioned is, therefore, that the former contribute heat by radiation and convection; the latter by convection only.

The object in treating these three purposes to which hot-water works are put separately, is that both the pipes and appliances generally differ to a considerable extent, and the actual phenomenon of circulation requires considering in different ways in each case. Before, however, proceeding with the description and examples of the work under discussion, it becomes necessary to say a word as to the manner in which heat operates.

Of course many readers may be conversant with the laws of heat, and, for the sake of those having this knowledge, we treat the subject as briefly as possible; but, on the other hand, so many following this calling have but imperfect ideas in this direction, that some description is really essential. No one erecting an apparatus can be certain as to the results it will give, unless the ways in which heat manifests itself are known to him. It is not sufficient that a man knows the principle of circulation of water only, as this deals with the action of the fluid by itself, and a hot-water apparatus, although it may be extensive, well constructed, and having a perfect circulation of hot water within it, is of no use whatever unless it freely parts with its heat and distributes it where required.

Heat.—Heat transmits or manifests itself to us in three different ways,—viz., by conduction, by radiation, and by convection. All these modes of action exist in connexion with every hot-water apparatus that is erected, and when once the principles are understood, it can be readily seen what description of apparatus is most suited for certain purposes and under certain conditions. There are other manifestations of heat, such as absorption, diffusivity, &c., which will be alluded to in due course. It is not proposed to deal with the theory of heat, as it does not come within the province of these papers; the action of heat, however, is all-important.

Conduction of Heat.—This is the way in which heat is transferred through or about a body. Every substance possesses this power of conduction to some degree, although there are many substances which are exceedingly slow in their action, and are frequently, though erroneously, termed non-conductors. It is in solids that we get the conductive power chiefly, metals in particular being mostly conductors of a very rapid character. In fluids, gases and liquids, the action is principally noticeable by its absence; but in these we get another more useful action, viz., convection, without which a hot-water apparatus, in its present form, would be a very useless contrivance.

It will be found in later papers that poor conductors of heat answer a very useful part in these works, when it is wanted to conserve the heat and prevent its loss. This happens when pipes have to be carried in very exposed places where the heat is not required, or wherever a waste of heat may occur.

For the purpose of these papers we have only to deal with the conductive properties of iron, this being, practically without exception, the only metal used in hot-water-heating work. If copper is ever used we may be content with the knowledge that it acts even better than iron. The following table shows the comparative conductive properties of various substances, and it will be noticed that iron, particularly that which is cast, stands high, and it possesses the important advantages of being inexpensive and durable. It has to be mentioned that there are several tables of conductivity compiled by different authors upon heat, and they vary considerably in the comparative powers of substances, but the materials in all the tables follow the same order as to precedence:—

COMPARATIVE CONDUCTIVE POWERS OF SUBSTANCES as given by M. Despretz:—

Silver	97.90
Copper	89.82
Brass	75.20
Cast iron	56.90
Wrought iron	37.43
Lead	17.96
Marble	2.36
Firebrick	1.14
Water	0.90

We shall have to refer to silicate cotton presently, when speaking of its low conductive properties. This material stands very much lower than the lowest figure upon the above table.

Although water is such a poor conductor, it stands high as an absorbent of heat. This peculiar property has to be considered, as some substances seem positively averse to heat in every way, which is, fortunately for these works, not the case with water. Those substances which absorb heat readily, also part with it freely; this water does in a very satisfactory method, and it may therefore be looked upon as the medium by which the heat is collected and conveyed to the points required; collecting it rapidly and diffusing it just as quickly where it has opportunity. It seems a drawback that water should have to be confined in pipes, as under the best of circumstances some of its good qualities are thereby lessened, sometimes lost.

As just mentioned, conduction, in these papers, has only to be considered as regards iron, that is, the boiler-plates and the substance of the hot-water pipes or radiating media. It does not apply to the fire which is around the boiler nor the water that is within it, but only to the materials that separate the fire from the water, and the water from the air, respectively. There are, however, other necessary features to be observed, particularly the radiative power of the surface of the pipes, &c. For instance, if we had silver pipes, the conduction of the heat would be nearly twice as rapid as with iron, but, by referring to the table of radiating powers in the next paper, it will be found that although

the heat is brought to the surface of the pipes, it would be very loath to dissipate, and the ultimate result might be worse than with iron pipe if precautions were not taken.

In concluding this brief explanation of “Conductivity,” attention may be called to a peculiar property closely connected with the same subject, which has very correctly been termed “Diffusivity.” Doubtless, all readers have seen “gilled” pipes, as figs. 1 and 2, and

FIG. 1.

FIG. 2.

have also heard of or seen “Gill stoves,” which are largely used, especially in public buildings. (The gills are a number of plates extending from the body of the stove, which is ribbed, so to speak.) It may not, however, be known to all what special use these gills fulfil. If we take a hot-water pipe and charge it with water at a temperature of say 200 degrees, the heat of the outer surface will bear a close relation to these figures. If, however, we add a number of gills to the pipe, as figs. 1 and 2, some of the heat will transport itself into these plates until the whole of the metal becomes of a fairly uniform heat, but it will be found that this heat no longer bears such a close relation to the 200 deg. In other words, we have the same quantity of heat distributed over a larger area, which reduces its quality, as we may say; a larger volume of heat at a lower temperature. We might almost liken the heat to an odour, which does not become lost, but weakened, as it spreads about. The utility of this heat diffusion is that we get an equal value of heat at less temperature in greater volume. The aggregate is the same, but a more agreeable result is effected by the greater distribution of heat thus brought about by the increased radiating surface, and, instead of being insufferably hot near the coil and cooler elsewhere, we may look for a more equalised temperature all around.

With hot-water pipes this result is, however, not noticed to the extent, nor is such a gain effected, as when the gills are applied to stoves. They are, then, a decided advantage, and there is hardly a stove-maker who does not make use of them in one way or another. Stoves that are in exposed places, are thus rendered practically safe should any one lean against or come in contact with them.

Radiation of Heat.—This is the term used to express the way in which heat is projected or diffused from the surfaces of heated substances. Projected is a better word than diffused, as radiant heat travels in direct lines from the source of heat. Although just within a certain radius around the heated object the heat appears to be general and equal in all directions, we find that immediately a screen or anything is interposed between us and the source of heat, we at that same instant discover that radiant heat is not diffused in a literal sense. It is not diffused like an odour.

Radiant heat distributes itself in a measure, its area becoming enlarged as the distance from the heated body increases, in the same way as can be noticed with a projected beam of light; but for the warmth that we experience behind or upon the opposite side of objects that may be opposite a source of radiant heat, we must look for a different cause. It is the re-radiation of heat and heated air that is accountable for this,—objects that have received heat redistributing it; and the air is heated by contact with these objects, and also by contact with the original radiating medium (assuming it is not an open fire). The air which is heated (that is, heated by contact with heated surfaces only) is distributed here, there, and everywhere by its property of convection, and screens and obstacles of a like character do not materially interfere with this means of heat distribution, as will be explained in the next paper.

A common example used to show that radiant heat does not heat the atmosphere, is to refer to the sun, which transmits heat to the earth by radiation, but leaving the outer or upper portion of the atmosphere, through which its heat has to pass before reaching the earth, in a state so devoid of heat as to cause death to aeronauts unless the utmost precautions be taken. The sun may be shining brightly all the time, and the heat at the earth very great.

OBITUARY.

MR. WILLIAM SMITH.—The death is announced of Mr. William Smith, City Architect of Aberdeen. According to the *Times*, Mr. Smith was born in 1817, and was educated at Marischal College, Aberdeen, where he graduated M.A. After travelling in Greece and Italy for the purpose of perfecting himself in his profession, he returned to Aberdeen in 1842, and ten years later succeeded his father as City Architect, an appointment which he held until his death. He erected many of the churches and public buildings in Aberdeen. When her Majesty and the Prince Consort determined upon erecting a new castle in the Highlands, Mr. Smith was chosen to design the building and to superintend its erection, and Balmoral was the result. Mr. Smith erected many other private mansions, schools, hospitals, &c., in various parts of Scotland.

MR. JOHN SHILLITOE.—The death is announced of Mr. John Shillitoe, contractor, of Bury St. Edmunds, in his fifty-ninth year. The son of a builder, and descended, it is stated, from a line of builders which can be clearly traced back for a period of three hundred years, he was born at Campsall, near Doncaster, in 1833. In 1867 he commenced business at Campsall with his brother-in-law, the style of the firm being "Shillitoe & Morgan." After residing for a time at Birmingham, Ham, Norwich, and other places, he removed in 1885 to Bury St. Edmunds. In the previous year he had taken his only son, Mr. Thomas Shillitoe, into partnership, the style of the firm becoming "Shillitoe & Son." He built and restored a large number of churches, and erected Truro Cathedral, the new King's Workhouse Congregational Chapel, Grosvenor-square, the additions to Westminster Hall, and many other important works. At the time of his death, amongst other works he had in hand the new National Portrait Gallery in Charing-cross-road, adjoining the National Gallery. He was much respected by his employes, and was a Town Councillor of Bury St. Edmunds.

MR. WILLIAM WILKINSON.—We regret to announce the death of Mr. William Wilkinson, head of the firm of Messrs. B. Cooke & Co., of Phoenix Wharf, Battersea. The deceased was well known in the railway and contracting world. The early part of his career was spent on works in connection with the Great Northern Railway, he having spent nine years as Resident Engineer on the Yorkshire district of that line. In 1872 he resumed this responsibility and joined the late Mr. Benjamin Cooke, and together they established the now well-known business at Battersea. The deceased was sixty-seven years of age, and will be interred at Wimbledon Cemetery this Saturday, January 2. He is succeeded in the business by his only son, who has been intimately connected with all contracts since 1875.

THE LATE MR. JOHN RINTZ.—We regret to record the death of Mr. John Rintz, which took place at his residence, Linton Lodge, Stoke Newington, on the 19th ult., after a short illness. Mr. Rintz was for twenty-one years an energetic member of the Metropolitan Board of Works, and accomplished much useful work. He was mainly instrumental in introducing the sanitary clauses into the Metropolitan Building Amendment Act, having gained considerable experience as chairman of the Hackney Board of Guardians during the last cholera visitation. He was keenly alive to the necessity of improving the thoroughfares of London, and the minutes of the Metropolitan Board can testify to the knowledge and activity he brought to bear in the numerous committees upon which he served. One of his favourite schemes was a 100 ft. thoroughfare from Somerset House in a direct line to the British Museum, this scheme, somewhat modified, has recently been under the consideration of the London County Council. It was he who promoted the Bill for the Freedom of the Metropolitan Bridges over the Thames and Lea, in conjunction with Sir William McArthur, which Bill afterwards became law, the freedom sought being acquired with the revenue of the Coal and Wine Dues. Mr. Rintz was, perhaps, best known for the active part he took in securing open spaces for the public,—Hickney Downs, Mill Hill Fields, Newington Green, Finsbury Park, and Beck, in conjunction with the late Mr. Joseph Baker, the acquisition of Clissold Park, by far the finest park in the north of London.

LONG-DISTANCE TELEPHONING.—The other Sunday a person at Cederslund, in Northern Sweden, was enabled to converse with another at Lund, in the extreme south, a distance of nearly 800 miles. The words were perfectly clear.

GENERAL BUILDING NEWS.

BISHOPSGATE GIRLS' SCHOOL, CHAPEL, AND RESIDENCE.—These new buildings, situate in Spital-square, Bishopsgate-street, were recently opened by the Right Hon. G. J. Goschen. They have been erected on the south side of Spital-square, to replace the school buildings formerly situated in Skinner-street and Primrose-street, Bishopsgate, these premises having been acquired by the Great Eastern Railway Company for the widening of their line. The buildings, consisting of the schools, chapel, and curate's residence, are grouped more or less on three sides of the open playground, which is entered by wrought-iron gates, and has a tar-paved surface. The new school buildings have been designed to accommodate 550 pupils, and are planned to meet all the requirements of a modern middle-class girls' school. The school building is approached across the playground, being set back from Spital-square, thus giving more quiet for the work of the teachers. The school building contains three principal floors, as follows:—On the ground floor one enters a hall with a wide corridor running parallel to the length of the building, and off which are placed the class-rooms for the younger children, also the head and assistant mistresses' rooms and the committee-room, and running along the east side of the building is the large dining-hall, measuring 55 ft. by 25 ft., which is divided from the kitchen department by a service-way. On the first floor are a series of class-rooms, varying in size, certain rooms being able to be thrown together, but all easily controlled and supervised by glazed pass-doors. On the second floor are the art and drawing class-rooms, the cookery kitchen, further general class-rooms; and in the east wing are a series of small and distinct music-rooms for practice, with a music library, &c. Special care, we are informed, has been taken with the ventilation and the drainage of the buildings. The heating is by means of open stoves, which emit warm fresh air into the class-rooms, and these are aided in the corridors and larger rooms with a low-pressure hot-water system, so as to keep the building throughout at an even temperature in cold weather. The range of latrines is placed in the rear outside the main building, having a direct access to the outer air. Externally the building has been erected in red bricks with buff terra-cotta dressings and enrichments, the style of architecture being based on collegiate buildings of the Jacobean period. Adjoining to the school, a chapel has been erected, with accommodation for upwards of 600 persons. This chapel, which is intended to be used for lectures, concerts, and other purposes, is 63 ft. long by 44 ft. broad and 34 ft. high, is largely lit by multilene windows, and has a panelled wooden ceiling with coiled sides, the main body of the building being divided from the aisle by polished granite columns. At the north end of the chapel a platform has been erected, and at the side the organ has been placed. The entrance is direct from Spital-square with a lobby, and there is also a further entrance from the schools at the rear. Adjoining the chapel and communicating therewith is a residence of three floors, with basement and attics in addition. Each of the principal floors contains a complete set of rooms, consisting of sitting, bed, and bath-rooms. The whole of the buildings have been designed by and carried out under the immediate supervision of the architects, Messrs. T. Chalfant Clarke & Son, Messrs. Woodward & Co., of Wilson-street, Finsbury, being the contractors. The cost of the buildings has been about 18,000*l.*, which is exclusive of the value of the land.

RESTORATION OF WIMBORNE MINSTER.—On the 21st ult. an opening service was held in Wimborne Minster, which has just been restored. At a vestry meeting held in November, 1890, Mr. Pevsner was appointed architect, and Mr. Fletcher was asked to act in conjunction with him in carrying out the work. The tender of Messrs. Merrick & Son, of Glastonbury, for the sum of 1,689*l.*, was accepted, and the work was commenced in May. Through the kindness of Mr. Walter Fletcher, who has been in charge of the work, we (*Dorset County Chronicle*) are able to give the following particulars of the principal work and the discoveries made:—The walls of the transepts have been raised about 2 ft., and thoroughly repaired. The dressed stone work, which was principally of Tisbury stone, and very much perished, has been renewed with Douling stone from Shepton Mallet. The roofs have been entirely reconstructed with good English oak, and raised to the original height of the short transept roof, as they existed in the Norman period. On the removal of the roof and timbers of the north transept the original line of the roof, as it was first constructed, was clearly to be seen where it abutted against the south side of the Norman staircase turret which in those days flanked the north-west angle of this transept. Why the fourteenth-century builders lowered the pitch of the transept roofs seems a mystery. Another peculiarity is that

the angles of the water tables on the north side of the lantern-tower do not correspond with regard to their rake, that on the east side being 9 in. wider than that on the west. The length of wall between the lantern-tower and the Norman turret on the west side of the north transept was found to be nearly 10 in. less in thickness than the rest of the wall. This difficulty has been surmounted by keeping the wall level at a higher level, which also gives additional head to the gangway leading from the turret to the triforium. On removing the thick plaster from the walls of the north transepts it was clearly seen various alterations had taken place from time to time. The masonry was finished with a rather rough face, which had been whitewashed over. A very thin coat of plaster had been added at some subsequent date, and various coats of white and colour had been placed on this, then a thick coat of plaster or stucco, which was the finish when the restoration was commenced. This has now been entirely removed, and a very thin coat of plaster put on the walls. It was also proved that the outside faces of the walls in the Norman period were covered with rough-cast, as the wall on the north side of the Norman turret was not bonded in on every course when the wall near the transept was lengthened in the fourteenth century, and the rough-cast had not been removed where it was not bonded. Another curious feature was that the stone string-course, which finished the wall, in the wall-plating was cut rough at regular intervals about 11 in. deep and 4½ in. wide, as if the Norman had had constructed with wall pieces coming below the string-course. These intervals had all been carefully filled up with stone-work. An altar recess has been discovered in the east wall of the north transept. The recess was originally 6 ft. 2 in. wide, and with a semi-circular Norman arch impost moulding on the north side, the corresponding impost being on the west and the arch on that side. The wall at this place has for some years shown signs of considerable movement, which is not to be very much wondered at, for the pier which remained to take all the weight of the superstructure was only about 10 in. thick. Added to this, it appears that when the gallery in this transept was constructed, early in the present century, it was approached by a staircase from the chancel aisle, and in forming a doorway at the top of the staircase the builders cut right through the centre of the arch of this altar recess. On removing the rough stone wall with which the recess was filled some very interesting frescoes were discovered. There appear to have been no less than three subjects painted on the inside wall at various times. The uppermost one represented the Holy Rood. The cross springs from the base of the carved stone-work to form a bracket which has at one time formed part of a shrine, and a piece of the same stone-work is walled in a little to the north under the figure of the Virgin Mother to form a small bracket. Since the recess has been discovered a typical fresco has in places been apparent, disclosing the figure of a Saint, evidently of a much earlier date, and also an *Arms Dei* over the head of St. John. The Holy Rood fresco must have been in its present position when the alterations in the archway between the chancel aisle and the transept were made, as they are not in the centre of the recess as it now exists. There are also indications of a third fresco, probably of a still earlier date, in several places. The stone altar has been restored, a line in the plaster showing its exact dimensions, and the defective pier rebuilt. The piscina, with corbel shelf over it, probably to take the figure which was found walled in the filling up of the recess, has now been placed on the north side, as there was not sufficient room, owing to the pier, to rub it in its original position on the south side. It might have belonged to another altar, as tradition assigns to this transept the site of Thomas de Brembre's chantry. The whole of the tracery of the west window of the transept has been restored, almost every vestige of it having been destroyed or removed. The wooden gallery, which rested on the tie-beams of the roof, and formed the means of access to the lantern-tower from the Norman turret, has been replaced with a handsome stone gangway, supported by a massive moulded arch, extending from turret to the lantern-tower, and finished with an iron railing. The north window is now being filled with stained-glass, the subject being the Te Deum. The window of the east side of the transept is a representation of the Virgin Dimitis. The window on the west side represents the Magnificat. The glass of these windows has been executed by Messrs. Clayton & Bell. The works in the south transept are somewhat similar to those in the north. The walls have been raised, and a new English oak roof of similar design restored to its original pitch and height. The remains of a single-light window were found in the east wall at the south end of this transept. The stone-work of this

has been restored as far as possible, but as the vestry and library over it project beyond the line of the opening, it cannot be used for its original purpose. It appears to have at one time contained the stairs leading to the chamber over the vestry, now called the library, as it is purely circular on plan, and the remains of the steps were found. The altar recess, occupying a similar position to the one in the north transept, has also been restored. The arch had been cut through when the gallery was found as in the north transept. The south window is to be filled in with stained-glass by Messrs. Powell & Sons, to the memory of the late Mr. William Drutt. It is the gift of his children, and whose generosity the cost of the repairs in the south transept is due. The repairs still remaining to be done are the making good of the masonry of the walls of the main aisles. Besides these alterations the heating apparatus of the church has been renewed, and an oak screen placed to shelter the western door.

HOSPITAL EXTENSIONS, WOLVERHAMPTON.—Extensions to the Borough Infectious Hospital, Green Lane, Wolverhampton, comprising an entrance-lobby, additions to the administrative block, and a hospital pavilion, were opened on the 23rd ult. by Alderman J. C. Major (Chairman of the Sanitary Committee of the Town Council). The pavilion is designed to accommodate sixteen beds; and has two main wards, each for eight beds, a nurse's duty room, and two single-bed wards, with bath-rooms for each ward, and other arrangements. The additions to the administrative block include doctors' or committee room, with dispensary and other conveniences, nurses' dining-room, eight bedrooms, bath-room, and other apartments. The building has been carried out by Mr. A. Lovatt, his contract price being 3,000*l.* The designs for the building were drawn up by the Borough Surveyor (Mr. R. E. V. Berrington), with the assistance of the Medical Officer (Dr. Malet), and the suggestions of the Sanitary Committee and its Chairman.

NEW BATHS, SALISBURY.—These baths have just been completed for the Salisbury Swimming Baths, Ltd. The site chosen is in Rolleston-street, and the building is about 94 ft. long by 50 ft. wide, with slipper-baths adjoining. The roof consists of iron principals with lantern ventilators, and is covered partly with slates and partly with glass. The bath itself is 80 ft. long by 34 ft. wide, lined with glazed bricks, and the water is procured from a well sunk on the premises, and warmed by steam injection to a temperature of 75° Fahr. A gallery runs along the two sides and one end of the building, under which the dressing-boxes are arranged, accommodation being provided for forty-one bathers. These dressing-boxes, as also the building, are warmed by steam-pipes. In connexion with the swimming-baths, and fronting on Church-street, a steam laundry has been erected, fitted with every modern improvement, and capable of turning out 60*l.* of work weekly. The hot water for baths and laundry is supplied by a 20-ft. Cornish boiler. The total cost of the laundry and baths, exclusive of the site, was about 4,500*l.* All machinery, pumps, laundry plant, &c. were supplied by Messrs. Thos. Bradford & Co., of London. The ironwork was supplied by the Redcliffe Crown Galvanised Iron Co., Bristol. The roofs were glazed by Messrs. Rendle & Co., of Westminster, on their patent "Acme" system. The contractor for the building was Mr. John Wort, of Salisbury; and the building was designed and carried out by Mr. Alfred C. Bothams, A.M. Inst. C.E., architect, of Salisbury.

FOREIGN AND COLONIAL.

BERLIN.—A competition has been opened for the design for an equestrian statue to the late Emperor Frederick III., to be placed on the battlefield of Woerth, in the Alsace, on which field he distinguished himself in the Franco-German war. Ten thousand pounds are at the disposal of the committee in charge of the erection. The statue is to be of cast bronze, and is to stand on a pedestal of some 3 to 4 metres high. The pedestal is to receive decoration in the form of bronze figures representing the companionship in arms of North and South Germany against France. The designs (models of some size) are to be sent in by April next, and will be assessed by a jury of four sculptors and a painter. Four prizes (of 200*l.* each) are to be given.—The competition for the design of the equestrian statue of the late Emperor William I., to be placed in a central position on the memorial monument in course of erection on the Kyffhäuser, has been decided. The first prize has fallen to the sculptor, E. Hündriesser (Charlottenburg). The number of competitors was thirty-eight, and four prizes were awarded. The average quality of the designs sent in was poor, quite two-thirds of the number having no artistic value whatever. The selection of Herr Hündriesser's design for the first prize meets with the approval of those who have seen the work sent in. It will be remembered that the Kyffhäuser monument is one of those large memorial piles in course of erection under the superintendence of the architect, Bruno Schmitz.—The competition for the large Government Travelling Studentship of Architecture by the Prussian Academy of Arts every

two years has this time again been a farce, only three architects applying for it, and of these three (who had passed the preliminary examination required of them) only one of them entering for the competition proper. The studentship was given to this one candidate, although his work was not considered very satisfactory. His name is Hartmann (Stetin). The country he will be expected to travel in is Italy. The value of the studentship is 1500*l.* a year for two years, together with 50*l.* extra for railway expenses.—Some activity apparently prevails in matters relating to the erection of some new buildings for the Prussian Upper and Lower Houses, referred to in a former number. The designs to be carried out are now settled: 10,000*l.* have been put at the disposal of the architect, "Baurath" F. Schulze, and the office at the works will be opened on the 15th inst. One of the two buildings will be commenced this year, but the other cannot be commenced for some years, the site on which it is to be placed being at present occupied by the premises of the Imperial Reichstag, which body will not vacate them until their new palace on the Koenigsplatz is complete.—The "programme" of the salon, to be held this year under the auspices of the Prussian Royal Academy of Arts, has been published, and from it we learn that there will at last be a stop put to artists exhibiting an unlimited number of works of art of the same class, as has been their wont on former occasions. Artists, as a rule, will not be permitted to exhibit more than three objects of the same class. Only a limited number of well-known men will be invited to exhibit more than three; and then, if possible, they are to exhibit a full collection of their best pieces of work, to be hung separately.—There is some talk of the Municipality of Berlin erecting a museum for modern sculpture, a house for this purpose having, apparently, been left to the city.—Some new regulations have been published relating to the erection of new buildings in the outer suburbs (independent villages as yet, lying outside the boundaries of the city). They are very stringent, and are causing much dissatisfaction.

MUNICH.—Herr Wilhelm Rettig has been elected to hold the post of City Architect, vacant since the death of Herr Zenetti. Herr Rettig, who will have the title of an "Ober-Baurath," made a name at the time of the great competition for the memorial monument to the deceased Emperor William I., at which he gained the first prize for a design made together with Herr Pfann. Since the year of this competition he has for some time been City Architect at Dresden, which post he had, however, to resign on account of a controversy with the authorities.

SWEDEN.—The Stockholm Building Association has just held its annual meeting, when all its officials were re-elected, the President being Herr C. A. Olsson, master builder, and the Secretary, Herr C. A. Flodquist, architect. A handsome building has just been completed at Copenhurg for the Gothenburg Bank of Commerce. The style is Florentine. The lower part of the façade is of roughly-hewn Swedish granite, whilst for the upper portion pressed Swedish cement has been employed. The architects are Messrs. K. Johansson & V. von Jergerfelt. The Gothenburg and Bohus Lån Sparbank has been rebuilt by Herr H. Cornelsen, architect.—The agent of the Swedish Export Association writes from Argentina that the import of timber villas from Sweden has almost entirely ceased owing to the high premium on gold and the low prices of bricks and wages, houses of stone being therefore as cheap. Owing to the low value of the notes in which wages are paid labour is as cheap as in Sweden. Several planning and carpentering factories have stopped from want of work.

SANITARY AND ENGINEERING NEWS.

POOLE SEWERAGE SCHEME.—The Corporation of Poole, Dorset, have recently instructed their Borough Surveyor to proceed with the scheme of drainage designed by Mr. Lewis Angell in 1885, estimated to cost about 30,000*l.*, and appointed Mr. Angell to act as consulting engineer therein; but in consequence of other official engagements, Mr. Angell has now been compelled to resign the position, at which the Council "express their regret," and have appointed Mr. James Lemon, C.E., Mayor of Southampton, in place of Mr. Angell.

SEWERAGE AND SEWAGE DISPOSAL OF KNARESBOROUGH (YORKSHIRE).—At a recent meeting of the Knaresborough Improvement Commissioners and Local Board of Health, Mr. D. Balfour, M.Inst.C.E., of Newcastle-on-Tyne, submitted report, estimate, and plans for a scheme of main sewerage and sewage disposal for the town, estimated to cost in execution 9,000*l.*, the sewage being disposed of on land. After the scheme, with plans, &c., had been thoroughly gone into by the Board, it was agreed to adopt the scheme as submitted, in preference to any chemical process of disposal, there being ample suitable land in the district available. The engineer was instructed to submit the plans to the Local Government Board for sanction to obtain the necessary loan for the works. A Provisional Order has already been obtained for the land purchase.

MISCELLANEOUS.

CARPENTERS' COMPANY'S PRIZES, KING'S COLLEGE.—On the 17th ult., the prizes given by the Carpenters' Company to the students of technical classes at King's College were distributed by Mr. Henry Harben, L.C.C., the Master and many of the past-Masters of the Carpenters' Company, Dr. Henry Wace, the Principal of the College, and many of the Professors being present. There were many members of the British Institute of Wood-Carvers at work in the wood-carving room, and there were microscopes in Professor Groves's room showing specimens of wood and stone. Line-light views of the various styles of architecture were given in the drawing-room, with explanatory notes by Prof. Baustier Fletcher. A fine collection of wood-carvings belonging to Mr. Rogers, and diagrams and instruments, were explained in the new Electrical Laboratory. The students' drawings were hung on the walls, and photographs, &c., in the Reference Museum and Architectural Corridor. The following is the list of prizes awarded:—*Building Construction and Architecture (Day Classes): Second Year*—A. E. Mullins, prize of 5*l.* and silver medal; H. P. Fletcher, 3*l.* and bronze medal; H. G. Leslie, 2*l.*; J. Howard and T. H. Coal, Certificates of Approval. *First Year*—H. T. Adlard, prize of 5*l.* and silver medal; A. T. Angeli, 3*l.* and bronze medal; E. C. Monson, 2*l.*; T. A. Watson, Certificate of Distinction; H. Alherry, R. C. Master, and H. C. Trimmell, Certificates of Approval. *Evening Classes*—J. Goddard, prize of 5*l.* and silver medal; C. M. Cobb, 3*l.* and bronze medal; E. C. Monson, 2*l.*; W. H. Lord, 2*l.*; J. Little, 1*l.*; J. Almond, 1*l.* 10*s.*; A. G. Hubble, 1*l.*; H. S. Craigen, T. J. Barrett, A. S. Brightly, and F. H. Pearce, Certificates of Approval. *Wood-Technical Drawing*—W. H. Lord and T. J. Barrett, bracketed equal, prizes of 2*l.* each; W. C. Pritchard, prize of 1*l.*; C. M. Cobb and H. S. Cregeen, Certificates of Approval. *Wood Carving: Evening Classes*—L. Aston, prize of 3*l.*; W. Watson, 3*l.*; C. M. Cobb, 1*l.* *Day Classes*—C. G. Money, prize of 5*l.*; G. Stevens, 3*l.*; E. R. Hine, 3*l.*; F. Ewan, 1*l.*; and J. Weeks, 1*l.* *Ladies' Classes*—L. Travers, prize of 2*l.*; and J. Stapleton, 1*l.*

THE MOVEMENT FOR NATIONAL REGISTRATION OF PLUMBERS.—A meeting of the Forfar, Perth, and Fifeshire District Council of the National Register of Plumbers was held on the 22nd ult. in the Burgh Court-room, Dundee. Lord Provost Mathewson presided, and there were present Dr. David Lennox, Dundee; Councillor Davidson, Perth; Councillor Smart, Perth; Mr. John Wood, Montrose; Mr. Thomas Kinnear, Dundee; Mr. P. Lorimer, Broughty Ferry; Mr. J. L. Warden, teacher of plumbing class, Montrose; Mr. J. J. Henderson, local secretary; Mr. W. Farquharson, local treasurer, &c. After the preliminary business, the Lord Provost said he felt that it was most important that every tradesman should have a scientific knowledge of the work to which he had devoted himself; but, above all, that plumbers should have a thorough scientific knowledge, so that they might, in every detail, understand their business. The plumbing trade affected not only the men employed, but the community at large to an extent that few trades did. In Dundee there was no excuse for any young man not having a proper scientific knowledge of his trade, for in the city there were the Technical Institute and the University College, both of which were splendidly equipped, and were doing excellent work. He thought he could say for the Police Commission that it was in favour of giving the 1,300*l.* grant to advance technical education. The Lord Provost then presented the prizes to the successful students during the year, the prizes consisting of volumes donated by the Worshipful Company of Plumbers. The prize-takers were (from Dundee) Messrs. Peter Edmonds (17 years of age), Thomas Kinnear (20), James Littlejohn (19), Alexr. Young (19), and Alexander Ferguson (20). From Arbroath there were two prize-winners.—Mr. Thomas Grant (17) and Mr. James Carr (20).—Mr. Henderson submitted a letter to the meeting which the District Council had prepared to forward to the various Town and County Councils in the district. The letter set forth the claims of the plumbers, and asked that a portion of the residue grant in the hands of the Corporations approached should be devoted to the technical education of plumbers.—Dr. Lennox moved.—"That this Council considers the technical education of plumbers a question of supreme importance, the provision of which is both difficult and costly, and approves of the proposed letter to the various health authorities in this district, recommending this question to their attention as one deserving substantial financial aid." He said it was perfectly obvious that the first requisite of technical education was to have efficient teaching, and good teaching, like good plumbing work, was a very costly matter. Plumbing was in reality a question for the community, and that trade, unlike others, specially affected the health and the well-being of the people in the town and district. Like the supply of water and other sanitary matters, it should be taken up by the sanitary authorities.—Mr. John Wood, Montrose, seconded the motion, which was carried.—Councillor Davidson, Perth, moved.—"That this Council considers it

CONTRACTS AND PUBLIC APPOINTMENTS.

CONTRACTS.

Table with columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, and Tenders to be delivered. Includes entries for Station Improvements and Bridges over Railway and Stream, Slaters' and Plumbers' Works, Alarm Posts and Calls to Firemen, etc.

CONTRACTS.—Continued.

Continuation of the Contracts table, including entries for Congregational Church and School, Private Railway Line, Street Paving Works, etc.

PUBLIC APPOINTMENTS.

Table with columns: Nature of Appointment, By whom Advertised, Salary, and Applications to be in. Includes entries for Architect and Surveyor, Dublin District Surveyors, etc.

Those marked with an Asterisk (*) are advertised in this Number. Contracts, pp. 17, vi., viii., & x. Public Appointments, p. xxii.

desirable at the present opportune time to call the attention of every registered master in the district to the valuable assistance he may give to the registration movement by employing only such journeymen as are registered, and such apprentices as will attend classes in theoretical plumbing work if such be within their reach." Councillor Smart, Perth, seconded, Mr. Lorimer, Broughty Ferry, supported, and the motion was adopted.

TELEPHONES.—Messrs. Nussbaum have recently made a complete installation at the "Adelphi" Hotel, Liverpool. The installation comprises three floors, and on each floor a switch board for seventy directions is fitted. The total number of stations being 210. Each room is fitted with a call-box and double "Ader" instrument (magnetic transmitter), a separate call-bell and a three-contact pear push, which is suspended near the bed, so that the visitors can ring in the usual way or communicate through the telephone. The visitors are able to communicate through the telephone. The visitors can communicate with one another and with the staff of the hotel. This effects great saving of time both for visitors and staff.

THE PHOTOGRAPHIC LENS.—Messrs. R. & J. Beck, of Cornhill, send us a useful pamphlet they have issued, giving a simple description of the principles and method of application of the photographic lens, mainly with a view to assisting amateur photographers.

ENGINEERING EDUCATION IN THE BRITISH DOMINIONS.—Under this heading, a pamphlet of about seventy pages is issued by the Institution of Civil Engineers, giving a statistical statement as to the various educational institutions in the British Dominions where instruction is given bearing on the profession of civil engineering. The book also contains the regulations of the Council as to the admission of students, and a list of public examining bodies and examinations recognised by the Council.

PROPOSED RAILWAY THROUGH SIBERIA.—The Institution of Civil Engineers publishes in a pamphlet form the paper on this subject read before the Institution by Mr. W. M. Cunningham. The paper contains a consideration of the proposed routes, and a map containing special information from materials furnished by the author.

THE PUBLIC HEALTH (LONDON) ACT.—An abstract of clauses of this Act, reprinted from the "Metropolitan Local Government Journal," is issued by Messrs. S. Edgewcombe-Rogers. It is a useful guide to the Act in the shape of a small pamphlet summarising and classifying its provisions.

VENTILATION, MUNICIPAL BUILDINGS, ALLOA.—The Town Council of Alloa have entrusted the ventilating and heating of the municipal buildings of that town to Messrs. Baird, Thompson, & Co., of Glasgow. The County Council have also instructed this firm to examine and report upon the heating of the County Buildings, and to prepare plans.

CHRISTMAS FESTIVITY AT EXETER.—Mr. Harry Hens gave his twenty-third annual Christmas dinner to poor old people on Christmas day, when sixty *twelves* sat down to table. On Monday last Mr. and Mrs. Hens entertained at tea seventy children from St. Martha's Orphanage and other places.

FAILURES IN THE BUILDING TRADE IN 1891.—The supplement to *Kemp's Mercantile Gazette* for December 30, in its statistical abstract of failures, &c., during the year 1891, states that the number of failures in the building and timber trades was 525, as compared with 561 in 1890, showing a decrease of thirty nine.

"THE 'BRITISH ALMANACK.'"—In reference to our notice of this, we have received the following: "Parson any pointing out the 'British Almanack' on 'Engineering,' in the 'British Almanack' for 1892, was not written by Mr. J. S. Shedlock (who writes on 'Music'), but by your obedient servant, R. L. C. (the writer of the 'Architecture' article)."

VENICE AT "OLYMPIA."—We are informed that most of the houses forming modern Venice at Olympia were executed in fibrous plaster by the Plastic Decoration Company, Limited, Wellington-street, Strand, from photographs of buildings taken on the spot. The architectural features have, it is stated, been closely followed. The company have also carried out about 10,000 square yards of stib-plastering throughout the buildings to meet the requirements of the London County Council.

THE SANITARY INSTITUTE'S EXAMINATIONS FOR INSPECTORS OF NUISANCES.—At an examination for Inspectors of Nuisances, held at Manchester on December 18 and 19, fifty-three candidates presented themselves. Questions were set to be answered in writing on the 18th, and the candidates were examined *visu et voce* on the 19th. Thirty-seven candidates were certified to be competent, as regards their sanitary knowledge, to discharge the duties of Inspector of Nuisances.

TERRA-COTTA AS A FIREPROOF MATERIAL.—The *Southampton Observer* of the 19th ult. contained an account of an experiment made two days before with the view of showing the value of terra-cotta as a fireproof material for the erection of houses and other buildings. The experiment took place at the works of Messrs. M. H. Blanchard & Co., successors to Coal's original Terra-Cotta Works, Lambeth (established 1759), and the scene for the experiment was at their works at Bishop's Waltham, Hants. The object of the experiment was to show that there need be no more burning floors, walls, staircases, or roofs if constructed of terra-cotta, even were ever so intense a fire to break out, that the conflagration broke out in one room it could not possibly extend to the next apartment, nor could the means of escape from the upper to the lower part of the house be cut off through the burning of the staircase, which has been the occasion of many fatal disasters. This result, it is claimed, ensured by using Mr. M. H. Blanchard's patent fireproof terra-cotta chambered blocks, slabs, and tiles, which are described as suitable for all building purposes, and artisans' dwellings, warehouses, residential flats, from the humblest dwelling to the palatial mansion. The experiment was made in a little building of the dimensions of one room of an ordinary house, with brick sides, and a terra-cotta floor above, the pieces being so dove-tailed as to render it almost hermetically sealed. This floor was reached by means of a wide staircase, with an ornamental balustrade resembling that of carved oak. In the room below fagots of wood were piled up to the ceiling. Round these at the bottom were placed tar barrels, with a layer of straw. The mass was set on fire, and the fire burnt with great intensity. While this was going on most of the visitors ascended the staircase, and stood on this floor, feeling the slabs from time to time to see if the heat was making any impression on them, but throughout the whole trial they maintained almost the same temperature, being quite cold. By-and-by the fierce flames lapped themselves round the staircase, cutting off retreat by that way, and had it been composed of wood short work would have been made of it. However, beyond being slightly blackened by smoke, it remained as impassive as the floor above. The room was one

mass of white heat, resembling in colour molten lead. Had the floor fallen in at that time promotion would have been the fate of those on it. The party remained on the roof from half to three-quarters of an hour,—a sufficient period to put the experiment to the severest test,—and so little had they felt the heat below that many shivered with cold. Immediately the visitors descended, a large number of the workmen and boys ran up the stairs and jumped about on the floor, which apparently had not in any way been affected by the great heat, though the fire continued to burn for a considerable time afterwards.

SOCIETY OF ANTIQUARIES OF SCOTLAND.—The first monthly meeting of this Society for the present session was held in the Society's Library, Queen-street, Edinburgh, on the 14th ult., Sir Arthur Mitchell, K.C.B., in the chair. The first paper read was on tracing the human skull in pre-historic times, by Dr. Munro, secretary.—The second paper was entitled "Notes on examples of old heraldic and other glass existing in or having connexion with Scotland, with special reference to the heraldic rondel preserved at Woodhouselee," by Mr. J. M. Gray, Curator of the National Portrait Gallery, F.S.A., Scot. The author showed the progress which had been made in our knowledge of the existence of examples of stained glass in Scotland since Mr. George Seton submitted a paper on the subject to the society in 1878, and he pointed out how the result of the recent Heraldic Exhibition had been to add considerably to the list then made up by Mr. Seton. Having referred to some fragments of stained glass from Dundermilne exhibited by Sir J. Noel Paton, and to the heraldic shields and other fragments in the windows of Stobhill, the fine rondel at Tyrie Castle, and the missing St. Bartholomew of the Magdalen Chapel, Mr. Gray exhibited a full-sized outline lithograph of a glass panel and border in the possession of Mr. Albert Hartsborne, F.S.A., the panel representing a traditional event in the life of Sir Alexander Stewart, great grandson of Walter Stewart, Seneschal of Scotland, and the border including a Stewart family tree, the panel, however, being manifestly modern work, probably of the present century, although the border is, doubtless, of the date with which it was inscribed, viz., 1574. The rondel from Woodhouselee, it was explained, shows the Royal Arms of Scotland impaled with those of Anne of Denmark, Queen of James VI., with a decorative border of a conventional Renaissance arrangement of fruit and leafage.—The third paper was a notice of a submarine deposit of Sarnian ware from the Pan Rock, off the coast of Kent, by Mr. John T. Beer, F.S.A., Scot.

CHOIR STALLS, CHRIST CHURCH, CLIFTON.—The new choir stalls in Christ Church, Clifton, which have been placed there in memory of the late Rev. Edward Young, were used for the first time on the 26th ult. The stalls are of oak, in the Early English style of carving. The work has been carried out by Messrs. Cornish & Gaymer, of North Walsham, from the designs of Mr. Basset Smith.

THE NEW GOTHENBURG WATERWORKS.—The water supply of Gothenburg having for some time proved insufficient, it has been decided to obtain an additional one from the Göta river. The works which are now being carried out will cost about 70,000.

TELEPHONE BETWEEN STOCKHOLM AND CHRISTIANIA.—The Parliaments of Sweden and Norway have voted £90,000, each towards establishing telephonic communication between the capitals of the two countries.

LONDON.—For pulling down and rebuilding the "Langdon Arms" public-house, Newgate-street, St. Luke's. Mr. H. Roberts, architect:—
 C. Cox £1,664
 Outwater & Son 2,447
 Ashby & Turner 2,347
 F. & F. J. Wood 2,418
 W. Gladding £2,577
 Shewin Bros. & Co. Clap.
 Sun (accepted) 2,295

LONDON.—Accepted for the erection of stables and other works in connection with the Highgate Lodge, for Mr. H. Kogman, Mr. R. J. Beale, architect:—
 Percival Hart, Station Works, West Green, N. ... £195 0 0

LONDON.—For alterations, new shop, and showroom, 124, Tottenham Court-road, for Messrs. T. W. Thompson & Co. Mr. Ernest H. Abbott, architect, 4, Warwick-court, W.C. Quantities by Mr. A. Johnson, 59, Imperial-buildings, Ludgate-circus:—
 T. W. Smith & Son £1,246 0
 A. J. & C. Hosking 545 5
 F. & H. F. Higgs 537 0
 Hall, Beddall, & Co. £892 0
 Surprenant & Co. 759 0
 Scharian & Co. 730 0

LONDON.—For building new falling-school at Gloucester-gate, Regent's Park, for Mr. Parry. Mr. Horace Dove, architect, 4, Tottenham-buildings:—
 Gould & Brand £2,489
 Surprenant & Co. 2911
 Martin, Wells, & Co. 2,369
 Williams 2,268

WIGLEY.—For the creation of a new infants' school, Talbot-street, Wigley. Mr. John Grossett, architect:—
 J. T. Clark £2,294
 G. J. Muirhead 1,209
 C. Laird 1,167
 A. P. Whitstone 1,173
 S. Watton £1,113
 Thomas Mason, Holbeck 759 0
 Ford (accepted) 1,092

SOUTHAMPTON.—For alterations, additions, and improvements at the Eastern District Board School, for the Southampton School Board. Mr. J. H. Billard, architect:—
 Jackson £2,298
 J. Dyer 2,373
 Silvester & Co. 2,199
 J. Crook & Sons 2,190
 Roe & Co. 2,305

The Institute Suggestions for a Building Act.

HE Institute of Architects, as before noted, has issued a series of suggestions for a draft Bill for the codification and amendment of the Metropolitan Building

Acts. These suggestions were prepared in 1890-91 by the Practice Standing Committee, and were considered and adopted by the Council of the Institute on the 30th November, 1891. The existing building regulations are printed in one column and the proposed amendments or insertions in a parallel column, for more convenient reference and comparison.

In the course of some introductory remarks, it is suggested that the details of construction, which are subject to variation from time to time from different causes, but more especially on account of new inventions in building material or new methods of construction, should be omitted from the body of the Act and placed in schedules as bye-laws which can be altered from time to time as may be thought desirable, without interfering with the general working of the Act or necessitating fresh legislation. This suggestion is so entirely in accordance with common sense, and the necessity for such a provision has already been so decisively shown in various instances, that we may almost regard it as a foregone conclusion in connexion with any fresh legislation on the subject of building. Another general suggestion which is made, not in the introductory sentences, but in its place in the draft Bill, is that the new Act should not be divided into parts—"The first part relating to the regulation and supervision of buildings; the second part relating to dangerous structures" &c. (Act of 1855), as such division "serves no useful purpose." This we do not feel so sure about. The more an Act for very multifarious provisions is classified, the easier is it for those who have to obey it to find out what is required of them in any special case, and that is certainly a "useful purpose."

Coming to the detailed suggestions of the draft, of which we only propose to notice a

few of the most important, we are reminded on the second page of one of the curious oversights in our existing legislation, viz.: the absence of any direct or authoritative definition of a "building." "Building owners" are referred to, but with no definition of what it is that they own; "public buildings" are defined in reference to the qualifying adjective "public," but not in reference to the noun which it governs. The Institute of Architects therefore has the honour of attempting the first definition of a building for the purposes of legislation. This is the definition:—

"Building includes every erection comprising a cubical space defined by walls, piers, posts, or other structures, and a roof or other covering, whether such erection is wholly enclosed or not, and whether it is fixed on permanent foundations or not, and of whatever materials it is constructed, and for whatever purpose it is used or constructed or adapted (but so that this interpretation be not construed so as to exclude from the application of the term building as used in this Act any erection that would have been determined to be a building according to the true construction of this Act if this interpretation had not been inserted in this Act)."

The first part of the definition seems well worded and sufficiently comprehensive, and by the sentence "whether fixed on permanent foundations or not" any dispute about the nature of the foundation is no doubt barred. Still, as there is a distinct reference to "permanent foundations" and the reverse, we should have looked to find under the proper heading some definition of "permanent foundations," an expression which does not in itself convey a very distinct idea. But all we find under foundation is,

"Foundation shall mean that on which the walls piers and other supports of any building or other structure rest."

This is better than the sentence of 1878—"The term foundations shall mean the space immediately beneath the footings of a wall," which is very loose, inasmuch as a foundation is certainly not a "space." The word "other," however, is superfluous, because in the Draft Bill "structure" is already separately defined from "building" as follows:—

"Structure includes any wall or other erection and anything affixed to or projecting from any building wall or other erection."

It should have been "any building or

structure," not "or other structure." That is only a detail of wording. Still, such inaccuracies of wording sometimes lead to disputes. And we should certainly wish to understand what a "permanent foundation" is, or rather what a "not permanent" one is.

But there is a more serious discrepancy between the above definition of a building and another clause in the draft; page 12, "Foundations and Sites of Buildings." We there read that

"Every building shall be enclosed with walls constructed of brick, stone, or other hard and incombustible substances, and the said walls shall rest on the solid ground, or upon a bressumer of fire-resisting material, or upon other solid sub-structure."

If every "building" shall be enclosed with walls constructed of brick, stone, &c., what becomes of the definition of a "building" as an erection "comprising a cubical space defined by walls piers poste or other structures, whether such erection is wholly enclosed or not?" The framers of the draft seem to have forgotten on page 12 what they had said on page 2. We presume what they meant to provide is that a building, when it is enclosed, should be enclosed "with walls constructed of stone, brick, &c; i.e., it should not be enclosed with timber or lath and plaster walls. But as the wording stands the two sentences are contradictory.

What again is the value of that cunning-looking parenthesis appended to the clause defining a "building"? The clause aims at exactly defining a "building," and then follows a caveat that nothing should thereby escape being considered a building because it does not come under the terms of the definition. Then what is the use of the definition? Such cautionary clauses are only necessary when an Act is worded in loose and broad terms; but where there is an intention to define accurately, it is a confession of failure to fall back upon a vague expression about the "true construction of this Act." The definition is the "true construction" if it is a full precise definition. In this case we think it is; only some other clauses do not agree with it in terms.

To the original definition of "public building" the Draft adds some other classes (public

hath-house, public gymnasium, &c.), but covers the whole, like the 1855 clause, with a general phrase, "constructed or adapted to be used ordinarily or occasionally for any other public purpose." "Ordinarily or occasionally," it will be seen, is an important and indeed necessary addition.

"Sky-sign" is retained as at present in the definitions, but there appears a new definition of "wall sign," which will include the monstrous lettering often fixed upon buildings; and in a clause on page 15 we find it provided that no advertisement shall be set upon the face or in front of the external wall of any building in any street "except on frames or other construction of fire-resisting material," in accordance with by-laws to be made by the Council in pursuance of this Act; and the wholesome clause is added that "no such advertisement should be fixed to diminish the light from any habitable room." That would put an end to the 18th Mr. Darnum's compliment to us, that England was the only country he had been in where people were content to shut out the daylight from their dwellings for the sake of advertisement.

To return to the definitions, that of domestic building (a difficult expression to define) is well considered:—

"Domestic building shall mean (Class A) a building used, constructed, or adapted to be used wholly or principally for human habitation; (Class B) an outbuilding or stables appurtenant to a building of Class A or C whether attached thereto or not; and (Class C) a building used or constructed or adapted to be used wholly or principally for business offices or shops or any other building, not being a public or a warehouse or domestic building of Classes A or B."

A "habitable building" is a room in which a person passes the night, as distinct from a "living room," "used for human occupation by day," which includes kitchen, scullery, and pantry (not larder). A separate definition of a "flat" is also given, and a definition of the often contested word "storey," which is full and satisfactory. The suggested definition of "site" is also better than that of 1878.

"Fire-resisting," in relation to material might perhaps have been relegated to a schedule. The definition includes concrete and allied materials, brick, terra-cotta and natural or artificial stone; iron, steel, or bronze, and "other material of similar character which the district surveyor may approve; and, for bressumers and posts, wood beams" of not less depth and width in any part than 10 in. Should there not have been a difference made as to some kinds of woods? An oak post in this respect is a very different thing from a fir post for instance. And it may be questioned whether stone should be included under "fire-resisting materials." It does not burn, it is true, but it is one of the first things to crack and become thereby useless for any purpose of upholding the structure.

In the list of buildings to be exempted from the operation of the Act one or two important modifications are suggested. The Bank of England is left exempt, but the exemption "shall not include any branch of such Bank erected in any other part of the metropolis." The Draft proposes the entire omission of the clause which exempts "the Inner Temple, the Middle Temple, Lincoln's Inn, Gray's Inn, Staple Inn, Furnival's Inn, or the close of the collegiate church of Saint Peter, Westminster."

The clause of 1855, which exempts any building "not exceeding in height 30 ft. . . and distant at least eight from the nearest street or alley, and 30 ft. from the nearest buildings," has an important addition providing that no such building shall be exempt where it is erected on any estate laid out for building where it is intended to erect other buildings or to let or sell any ground "other than to the owner of such building" (not quite grammatical) "within the said distance of 30 ft." The exemption of greenhouses is proposed to be limited to those which do not exceed in area 300 ft., measured to the outside of the framing.

Another section of exemptions is to

apply to the roofing over of open yards enclosed on one or more sides by buildings, and no yard so roofed over shall be deemed to be a building within the meaning of this Act. Then follows another clause which appears to clash with the definition of a "building" before referred to: "Sheds open on one or more sides may be erected if the roof be covered with fire-resisting material," &c. Now we look in vain for any definition of a "shed," and the words here used are equally applicable to a "building," considering that by the previous definition a building may be supported by "posts" and need not be enclosed at the sides to come under the definition. In that case what differentiates a "shed" from a "building"? Following this is a provision that external metal flue-pipes exceeding 10 ft. in length shall be inspected by the district surveyor every five years, and if in his opinion they are safe, a licence shall be granted for another five years.

A clause in regard to the alteration of buildings is suggested, providing that any exemption or privilege of building shall remain in force only so long as the building is retained for the special use on account of which or in respect of which it was exempted; and another important one follows in regard to the restoration of old buildings, which provides that when it is necessary to take down an ancient building and re-erect it in a more secure manner, then with the written consent of the Council such building may be re-erected as it was before, even if in contravention of the terms of the Act: it remains, in short, legally an ancient building, though newly erected: a provision which might certainly become necessary occasionally.

Clauses are suggested in modification of the existing clauses as to recesses in party walls, which define better what was probably intended but not properly expressed by the framers of the 1855 Act, stating distinctly not only that the backs of such recesses shall not be of less thickness than thirteen inches, but that "in no case shall the back of such recess be within four inches of the centre of the said wall." The loose wording of the old act in this respect has been the cause of much dispute and of much licence by builders who chose to construe it the way that suited their convenience. The clause as to chases in party walls is re-worded to a similar effect. Considerable additions are suggested to the clauses as to carrying up party walls above the roof; one dealing with a point hitherto overlooked, that where eaves or gutters not of fire-resisting material project beyond the face of the building, the party walls shall be corbelled out to an equal extent, and carried up to the height required by the Act as to other parts of the wall.

The most important additions after this are in regard to provision against danger from fires, one clause suggesting that the floors of every corridor, hall, or passage, as well as the stairs, in any building having a floor area exceeding three thousand six hundred square feet or containing more than fifty thousand cubic feet, shall be of fire-resisting material, which may however have wooden flooring on it "without an air space between." There follows on this an important clause on "egress from certain buildings," applicable to any building containing flats which has a greater floor area than five thousand feet, or where the greatest distance from the end of any corridor to a staircase in such building exceeds sixty feet, or wherever any warehouse contains any flat or other habitable rooms,—in all such cases the staircase shall be carried up to the roof and a portion of the roof, in no part less than 6 ft. wide, laid flat and with a railing for safety, to give access to another staircase of fire-resisting material; both such staircases to have communication with the street to afford means of egress in the event of fire. This is an important suggestion, and if carried out would make a great difference in the percentage of deaths from fires in inhabited buildings.

The portion of the Draft Bill now printed

and circulated among Members of the Institute is that which deals with construction. The Practice Committee are still, we understand, at work on the subject, and in the further portions of the existing Acts many changes will be required "consequent on the foregoing revision of the first part as well as on the merits of the sections themselves." The "first part" means, we presume, the portions of the existing Acts which refer to the regulation and supervision of buildings, which formed the "First Part" of the Act of 1855 but it is not very clearly expressed. As far as the Institute revision has gone it appears to contain many excellent suggestions and to form a very good groundwork for a new Act, but like the existing Acts it fails sometimes from lack of clear definition in wording, which is a very important point in legislation dealing with a very complicated subject. The definition of a "building" certainly requires either revision or the modification of those clauses which at present clash with it. As the draft now stands there is room for a good deal of misunderstanding on the subject.

THE ARCHITECTURE OF THE TEUTONIC ORDER OF KNIGHTS IN PRUSSIA.

BY THE BARON DE GEYMULLER.

Medieval castles, on the Continent at least, have been hitherto far less than other classes of monuments of the past the object of investigation by architects as well as by archaeologists; no doubt, besides the ruined state to which wars and revolutions have generally reduced them, because, as dwellings and as fortifications many centuries old, they differ too much from the requirements of modern civilisation to be very suggestive to those who are in search of some inspiration for their own works.

But as documents for the history of architecture and civilisation, these habitations of a pre-eminent class of the nation are certainly important and worthy of consideration. It may, therefore, also interest some readers of the *Builder* to have their attention called to some recent German hooks treating of these subjects. An attentive examination of the two volumes published by Herr Steinbrecht,* a Prussian Government Architect, will soon show that even from their architectural merit, in the strict sense of the word, the buildings of the Teutonic Order offer not only considerable variety, but form an unexpected manifestation of Mediæval architecture, the importance of which, if I dare to judge from my own case, has not been suspected hitherto, even by the few who might have visited the celebrated Marienburg. The strict rules of a congregation and Power, at once military and religious, soon lead to a system and order which make their monuments differ considerably from the strongholds erected for the abode of feudal families.

The Teutonic Order was the third of the Christian Orders of Knights. Its origin was in 1190, during the siege of Acca, when citizens of Bremen and Luheek, under the protection of Count Adolph, of Nassau, united with the brothers of the German hospital, which since 1128 existed at Jerusalem. Their object was twofold; the nursing of sick pilgrims and the defence of the Holy Land. Acca was the first home of the Order which received the same rights as the Templars and Knights of St. John. It had two classes of members; Knights and merciful brothers, later also priests. The Order under the fourth master, Hermann von Salza, the greatest statesman of the thirteenth century, became very powerful, had numerous possessions over Germany, Hungary, Italy, and Sicily. Its help was then requested by the Duke Konrad of

* Thoru im Mittelalter. Ein Beitrag zur Baukunst des deutschen Ritterordens. Berlin: Julius Springer, 1885. In folio, 45 pages of letterpress, with 33 illustrations and 14 plates on copper.

† Freussen zur Zeit der Landmeister, Beiträge zur Baukunst des deutschen Ritterordens. Berlin, 1888. In folio, 129 of letterpress, and 184 illustrations.

assovia, against the heathen Prussians. The Pope and the Emperor Frederic II., being favourable to this design, and the Culmerland having been assigned as the seat for the order, the Landmaster, Hermann Balk, was sent (1230) with about ten knights to begin the contest, which ended 1283 with the victory over the Prussians and their conversion.

If this undertaking did not, like those of the Orders in the East, meet with a resultless end, it is due, to the merits of the Teutonic order, which completed the conquest, directed the colonisation of the country, founded towns and villages, and understood, for a long period, how to direct and order wisely the inner and outer affairs of their dominion, which, at the time of its greatest power, extended from the Oder to the Gulf of Finland. To them so Prussia is indebted for the embankment of the Vistula and Nogat.

Some buildings, it is true,—for instance, the celebrated Marienburg in Prussia, the ruins of Königsberg and Franenberg, the castle of Heilsberg,—had been the object of study as well as more recent publications. The latter, due to Herr von Quast, had the merit of suppressing, by the minute examination of the Marienburg, the prevailing erroneous opinions. One serious and important error continued, however, to mislead opinion,—viz., that the principal architectural activity of the Order was not anterior to the middle of the fourteenth century. This idea remained at the bottom of all criticisms, and led to the belief that no remains of earlier buildings of any importance were to be found any more.

Professor Töppen, however, lately provided by a series of documents concerning the castles of the Order, as well as those erected by bishops, that if the knights made a considerable use of temporary constructions of wood and earth, wherever they had obtained solid footing, it was stone, and consequently monumental architecture, that they employed. Calling the attention to an apparent contraction existing in the remarks of Herr von Quast, according to which the oldest parts of the Marienburg anterior, as generally admitted, to the year 1300, were far superior, architecturally as well as technically, to the parts that had been added since by Dietrich von Aldenburg (1335-41), he expresses the confident hope that a proper study of the hitherto neglected residences of the Order would lead to the discovery of important remains of that earlier period, history teaching that the oldest settlements of the order are to be looked for on the border of the country on the right of the Vistula and on the shore of the Haff, but, above all, in the Culmerland and in the city of Thorn.

It must, therefore, be considered as a very happy idea of the senate of the "Technische Hochschule" at Berlin to propose in 1881, as a theme for the Louis Boissonnet Prize, an extensive study of the buildings erected by the Teutonic Order in East and West Prussia, and principally those of the town of Thorn. These countries have been hitherto little explored.

But before undertaking the minute study of the monuments at Thorn, Herr Steinbrecht thought it advisable to visit throughout the country the remains of the principal establishments of the Order, drawing their plans and details, obtaining thus a precious source of instruction.

These preliminary informations form part of the first volume, whilst the second volume contains a closer investigation and the exact drawings of the more important of these monuments erected during the period of government of the Landmasters. Among these, Culmsee has a Duomo of considerable effect, and a rich choir, partly of Romanesque style. Culm in its fortifications and by the importance of its churches reminds us of Thorn; its celebrated castle, the Althaus, distant one hour, was the first residence of the Landmasters, demolished in the last century.

Schwetitz in the low country, accessible to the inundations of the Vistula, with a fine round angular tower and battlements.

Grändenz, from its elevated situation, was

one of the strongest and most important castles; of this, one tower, the interesting Kilmnek, alone remains.

From Grändenz, the three castles of Engelsburg, Rheden, and Roggenhausen are easily visited. The second of these, from its picturesque outline, its artistic value, its origin in the best period of the Order, and its never having been "disfigured" by later additions, is one of the principal places for the study of the architecture of the Order.

Riesenburg and Schöneberg are castles of the Bishop and the Chapter of the Duomo of Pomerania. Golub, situated very much out of the way, has changed little, offers numerous wood houses with low flat-arched arcades or loggias.

At Soldau begins the territory of the ancient Duchy of Prussia, and its buildings bear a different character. They belong to the later period of the Order, show a cheaper and more common art, have generally been transformed for modern use, and thus offer less interest to archaeologists, but, on the other hand, by their often well-preserved general appearance, give an idea how grand an impression was produced in former days when the country, once possessed by the Order, was covered by many hundreds of such castles.

The Neidenburg, though erected for a mere bailiff, rises like a gigantic residence over the country. Heilsberg, in the heart of Ermland, is picturesque like a Thuringian place. Its castle, principal residence of the Bishop, has been sufficiently illustrated by one of H. von Quast's publications, and, though since then several changes have taken place, it is the castle in Prussia, which inside and outside, and by the preservation of the outer castle and surrounding parts, has best retained the noble and striking features of an "Ordensburg." The inner court has a beautiful Medieval double-storied cloister.

The castle of Rastenburg is only small, but its St. George church rises like a citadel on the highest point of the town.

Barten, of considerable extent, well preserved in its general features, is of a late character, and from its chapel and other parts seems never to have been quite finished. More to the east one castle rises close to the other. Their transformation has seldom left more than the general plan, as is the case at Tapiau and at Tilsit, or some mere details or vaults, of archaeological interest. Ragnit at least shows, besides its great extent, the energetic design of the facades.

In the border of land extending along the Frische Haff, once distinguished by a series of magnificent castles, such as those of Elbing, Brandenburg, Frauenburg, Balga, Königsberg, everything has been destroyed. At Lochstedt alone a group of small rooms, elegantly vaulted, most likely the dwelling of its former lord, is left, likewise a chapel of extreme delicacy in design as well as care in execution; the terra-cotta ornaments of the old door can only be compared to those of the "golden gate" at Marienburg.

This exploration clearly proved that the castles of the south-east region belong, without exception, to the same and more recent epoch,—the second half of the fourteenth century. But in the oldest settlements, in the "Culmerland," along the Vistula and the Haff, differences of style corresponding to a period of about a hundred years backwards could be observed. Generally, it was not possible to fix the dates of the monuments in an isolated situation, on account of the want of documentary information. On returning to Thorn, a remedy was found for this latter deficiency. The monuments of this town unite all the features observed separately in the castles of the places, and a rare abundance of documents given by the archives at the Town-hall enable one to fix the dates of building even unto the very details, and thus fixed points, of comparison for dating the monuments all over the country were safely obtained, and an important step made concerning the historical as well as material knowledge of the architecture of the Teutonic Order.

In former times the valley of the Vistula was a broad, marshy, impracticable ground. In one single spot the higher banks approach on both sides of the river, an island rendering the passage easier. Here the knights founded their castle, and the town of Thorn, as a base of operation for the conquest of the Culmerland. It was their first settlement beyond the Vistula.

From the very beginning the Order aimed at establishing a solid territorial dominion. For this German immigrants were necessary, the rights of the colonies settling under the protection of the castles were fixed 1233. Thorn and Culm, the two first towns, received the Magdeburgh municipal rights. Already (1264) the number of new colonists was so considerable that a new town (the "Neustadt") had to be founded outside the existing one, henceforth called the "Altstadt."

In the course of the fourteenth century Thorn became the first town of Prussia, the point of transit between Poland and the Baltic, and a member of the Hansa, and was called "The Queen of the Vistula." The old parish churches, the town-hall,—no more sufficient to satisfy the new circumstances,—had to be modified as well as amplified. After the defeat of the Order at Tannenberg (1410), and forty years of subsequent struggle, West Prussia was subsequently lost, and Thorn, after the so-called "war of the towns," renouncing its ties with the Order, became the chief head-quarters of the Prussian League, and put itself under the protection of the King of Poland. The peace of 1467 freed it from the hated yoke of the Order. From this period date the greater elevation given to the nave of St. John, and the building, called "Junkerhof," erected on the place occupied until 1454 by the "Burg."

The return of Thorn to Prussia in our century has given new importance to this city, now the chief bulwark of the German Empire towards the east, a singular illustration as to the judicious choice made by the Teutonic Order of Thorn as a strategic situation.

The fortifications of Thorn are the oldest of the lower Baltic region, and are remarkable from the exceptional dimensions of their profile, gates, and towers. Herr Steinbrecht attributes this fact to the habits contracted by the Order in Syria. This opinion seems confirmed by another constant disposition in all the buildings of the Order. The ditch does not begin at the foot of the principal wall; it is separated from the latter by the "Parcham." This name is given, in the buildings of the Order, to a somewhat lower terrace all around the walls, protecting these against mining. Its battlements command the ditch and form a first line of defence. It comes from the *προτειχισμα* of the Byzantine engineers, which had been adopted in Frankish buildings in Syria. It was only by means of ancient views of the town that Herr Steinbrecht was able to restore the main features of this important castle. It rose on the right bank of the Vistula, at the upper end of the town, and outside its walls, beginning at the broad ditch of the Altstadt. Since the creation of the Neustadt, with its fortifications, the castle came to be partly situated between the two towns, preserving, however, an open space on the banks of the river, forming a new outer fortified precinct of considerable extent. The only parts of the castle actually existing are the "Danskier,"—a peculiar sort of tower, the explanation of which will be given further on,—and the building erected across the ditch containing the weir and all the contrivances for maintaining the water of the small river. Bache in the ditch around the town and castle, when risen to the desired level. This castle contained seven outer courts or "Vorburgen," and, as Mr. Steinbrecht rightly observes, the Neustadt itself can be considered as a sort of outer "Burg." It was the first castle erected by the Order, begun in 1236, when the town of Thorn, founded five years before, was removed to its present site. When the war between the allied towns broke out, after a brave defence, it was

stormed by the citizens on February 7, 1454, and burnt down. This was the signal for the rising of the whole country.

The other buildings of Thorn which are the object of a complete description are the parochial church of St. John-in-the-Altstadt, its successive transformations being illustrated by four woodcuts, and St. Jacob-in-the-Neustadt, erected at the cost of the Order. In the former the three naves are equally high. A chromo-lithograph shows the effect of the green and yellow glazed ornaments of the choir of St. Jacob, with a frieze composed by an inscription with ornamental letters. St. Mary, the church of a Franciscan convent, shows original specimens of brick architecture.

The Town-hall (Rathaus) of the Altstadt, and several private houses, combine to give a very interesting idea of the buildings, which, like the whole town, owed their erection to the Teutonic Order, or to the impulse it had given.

In his second book, Mr. Steinbrecht describes twenty-two castles of the Order, in the districts of Culm, Pomerania, Natangen, and Samland. He deserves special credit for the clear and easy way in which he gives us, first, such historical and geographic information as are necessary for the intelligence of the reader, the greater number of which are likely to feel otherwise strangers in the centres described.

The principal events of the history of the Order, before and since the conquest of Prussia; the state of the country before the arrival of the Knights; the history of the conquest, accompanied by two maps, are given in short, well-written chapters, and the volume finishes with two very interesting tables, the first giving the chronological succession of their foundation as strongholds of a temporary character, in earth and wood, and the dates of their transformation into permanent buildings of brick and stone. The second gives a comparative view of the composition of each castle, its superficial area, the dimensions of its most important elements, the character of its principal tower, and the position of the Dansker.

In some cases the outlines of the three castles, which generally composed the residences of the Knights, are preserved, or at least well recognisable, as is the case with Egelsburg and Balga. The outer castle, Vorburg, is the largest, then comes the middle castle (Mittlere Haus), finally the upper castle (Oberste Haus, Convents Haus).

The castles, according to their importance, were commanderies, district commanderies, and residences of the Landmeister, or governor of the whole dominion. Unfortunately, the palace of the latter, in the castle of Elbing, and since 1281 the principal of the Order, has totally disappeared. Since 1309 the "Hochmeister" of the Order established his residence in Prussia, instead of the Landmeister, and Marienburg became his abode. This celebrated castle is intended by M. Steinbrecht to form the subject of a separate monograph.

The strongholds which the Order erected in the conquered countries were destined, besides their strategical intent, to offer a shelter to the colonists. Under the protection of its walls, towns arise, the castle becomes the citadel of these cities, and it was the interest of the Knights to further order and prosperity of the new communities.

The flat configuration of the country certainly facilitated the development of the regular plans which are one of the striking features of these castles. Some are situated on the very shore of the sea, others on rivers or near lakes. When the position chosen for the castle offered an elevation of the ground, the outlines of the three different castles are quite irregular, following the lines of the ridge of the plateau. This is the case, for instance, at the Egelsburg, at Balga on the shore of the Frische Hafl, and at Roggenhausen. In this latter case the area of the Schlossberg was sufficient to contain the second castle, and in it the upper house, which could receive a regular square plan; we see

the same disposition at Mewe and Popau. This fact, combined with the circumstance that out of the twenty-two castles twelve show regular plans in the shape of a square, clearly illustrates that this disposition was considered by the Order as the best, whenever circumstances permitted its adoption. The square plan of Reden, preceded by two outer castles of less regular form, confirm this idea. At Lochstedt, the upper and the middle castle each are on a square plan, separated by broad ditches from each other.

Generally inside the walls the four sides are surrounded by the different buildings, leaving a court-yard of regular form in the centre; buildings seem to have occupied only the two opposite sides of the square, being connected by lower galleries and the upper battlement.

In many cases the angles of the square are strengthened by four square towers, only slightly projecting, but rising to a moderate height above the battlement. Besides these towers sometimes a principal more important tower is added. At Reden it is octagonal and situated in one corner just behind one of the angular towers, which it commands by a far superior height. At Strasburg and at Mewe it takes the place of one of the four angular towers, whilst at Golub it was circular, and situated outside the square, in a diagonal position, quite close to one of the angular towers.

These hesitations as to the position of this tower, which may be considered as the donjon of the upper castle, in itself a sort of donjon, are worthy of notice. A very interesting example of such principal towers is that of Strasburg in the district of Culm. It is octagonal, of more than 10 metres in diameter, 55.5 metres high, with eleven stories inside, crowned by two terraces with battlements, the upper one of lesser diameter disposed around the conical roof. Strasburg shows another tower of an entirely different character erected over the Neumarker Gate in the town wall, showing above two storeys with windows one of those high gables frequent in Northern Germany, with several retreating storeys, separated by buttresses, ending in pinnacles, and dividing interspaces decorated like high and narrow windows. Roggenhausen exhibits another type of towers over a doorway. It is square, of imposing dimensions, of a simple but noble architecture. From what remains of the principal tower of Grandenz Castle, called "Der Klimek," it must have been interesting example of the round type.

Another disposition considered as belonging exclusively to the castles of the Teutonic Order is the so-called "Dansker," consisting in an isolated square tower, at a certain distance from the walls of the upper castle, situated on the slope of its eminence, or in the lowest part of the neighbourhood, opposite the side of the principal attack, and sometimes (as at Thorn) built on four piers, between which passes the running water coming from the water-mills. This tower is connected with the castle by a narrow corridor between battlements passing over lofty arches. For a considerable time the exact use of these "Danskers" seems not to have been fully understood. It was believed that they were intended to permit a final escape by the chimney-like descent they contain, or to attack from behind the enemy fighting near the foot of the castle-walls. But Mr. Steinbrecht tells us that their real use was much more prosaic, and that Professor Töppen† has proved them to have contained the privies destined for the numerous inhabitants, which the Knights were desirous of isolating as much as possible from the dwellings. Various examples of this disposition are those at Thorn, Lochstedt, Marienburg, &c.

In the second publication we notice, amongst the most interesting features, the plan of the town of Culm, showing all the

streets at right-angles and equidistant, like many ultra-modern cities.

In considering the composition of the upper castle in the greater number of these strongholds, we feel that their architectural fundamental idea is similar to the peculiar character of their builders: warriors and monastic brothers at once. Unless admitting that the generally square form of the outer walls be some reminiscence of the Roman Castrum, it seems more natural to derive it from the square form of the cloister of the convent around which are grouped chapel, chapter-room, refectory, dormitories, the dwelling of the commander, and so on. And considering the similitudes of composition existing between a great number of these castles, and forming, if we do not misunderstand the illustrations of Herr Steinbrecht's volume, a type of peculiar character, we feel inclined to ask whether the architects who built them did not belong themselves to the Order, following precise rules and principles of their own, and of experience far superior to what could be met with in the architects of Northern Germany.

The system of decoration of the monuments erected by the Teutonic Order is closely connected with the style adopted in the marches of Brandenburg, and illustrated many years ago by the publications of Professor F. Adler. However, if we are not mistaken, the monuments of the Order, besides the special types of its castles, generally show a nobler and more powerful scale of proportions with greater elegance and signs of a more refined taste, which very likely are due to Southern and Arab influence which some way or other the Order contrived to preserve in the earlier period, at least, of its monumental creations. This seems to be also Mr. Steinbrecht's opinion, and he considers the examples of inscriptions with ornamental letters employed as decorations as a reminiscence of Arabian art hardly met with in Western Europe, except in the buildings of the Teutonic Order. (Vol. i., pl. ix., and Vol. ii., figs. 166 and 168).

The materials in which these monuments are erected, generally speaking, are bricks and terra-cotta. Popau, however, is built in random blocks of granite in layers from 50 centimetres to 1 metre in height, with ornaments of hewn stone. In many cases the walls are decorated by various courses of glazed bricks.—Reden, Strasburg, Mewe, and, particularly, the Marienburg show examples of this system. The details of terra-cotta are generally obtained from moulds, and similar to those adopted in the marches of Brandenburg and northward, generally red alternating with green or yellow. Some of these forms, according to their disposition, permit of various patterns, for instance, in the village church at Balga. In other cases, according to Mr. Steinbrecht, the beautiful details of the Marienburg and some at Lochstedt have been obtained by a process described by him on a previous occasion,† consisting in artificial blocks of clay in which the ornaments are sculptured when dry and before being burnt.

These Italian and Arabian features can, we believe, nowise astonish if we reflect that the conquest of Prussia was begun under the Grand-Masterdom of Hermann von Salza. This high-minded and noble statesman and warrior was the friend and constant counsellor of the Emperor Frederic II. Both it is well known, resided more in southern Italy and Sicily than in Germany. Their constant intercourse with the East, and Frederic's Body Guard of Saracens, suffice to explain the source of such influences which may be supposed to have been even stronger in the earliest monuments, the Althaus, Culm; and Elbing, the capital of the New Dominion and the first Residence of the Landmaster. Their total destruction must be considered as an irreparable loss, the more to be regretted since it becomes evident

* As at Popau, Leipzig, Schonneke, Golub, Reden, Strasburg, Elbing, Mewe, Brandenburg.

that, besides all the remarkable features alluded to, the superior qualities displayed in the composition of all the dispositions of the plan of these convent-castles are, perhaps, an unique phenomenon in the architecture of the Middle Ages, and, as such, may be considered as partly monuments of the genius of that extraordinary and unique Prince, Frederic II. of Hohenstaufen.

All these qualities, rarely found, I am inclined to believe, to such an extent in German monuments, seem united in the noblest way and with a superior degree of artistic skill in the north front of the Upper Castle at Marienburg.

It measures about 52 metres length, and may be called majestic. Besides the tall corner towers, of Italian or Arab elegance, rising three stories above the battlements, with delicate tracery windows and arched friezes, the facade shows three unequal divisions in its length, corresponding to the chapel, the chapter-room, and the entrance. The latter, from its considerable height of above 14 metres, reminds one somewhat of the imposing entrance-gates of Indian and Persian mosques. The large windows of the chapter-room, the still larger ones of the chapel, contrast beautifully with the broad surfaces of unbroken wall, the far smaller and rare windows of secondary rooms, and the regular openings of the crenelles (creneaux) of the battlement, decorated with shields. The monotony of the high brick-walls is cleverly avoided by a moderate use of glazed and coloured bricks, with dispositions reminding one in some places of oriental influence.

Herr Steinhilber intends to close the exploration of these interesting buildings by a special monograph of this important residence, the restoration of which, if I am not mistaken, has been confided to him. By the way in which he has accomplished the task that was put into his hands, he has brought to our notice monuments of remarkable and, I dare say generally, unexpected qualities, well deserving the attention of those who, besides the mere architectural interest, are accustomed to read in the character of its monuments the reflection of the great deeds of history. He thus exhibits in a new light some of the characters of that once mighty Order, which, far weaker at its origin than the Templars and the Order of St. John, finally achieved results of a far more lasting and important nature, since, with the Margraves of Brandenburg, they are considered now as the founders of the Kingdom of Prussia.

H. VON GEYMÜLLER.

OLD MASTERS AT BURLINGTON HOUSE.

THE twenty-third loan exhibition of "Works by the old masters and by deceased masters of the British School," at Burlington House, is very unequal in interest, and betrays the difficulty which for the last few years has evidently been felt in keeping up these exhibitions to anything like their old level of interest, without repetitions. As we have before suggested, when the twenty-fifth exhibition has been held, and one generation may be said to have passed away, it is to be hoped that a new generation of owners will be asked and will consent to lend their greatest possessions in painting, already exhibited five and twenty years before, for the delight of a new generation of visitors who have had no experience of the glories of the earliest loan exhibitions of this series.

A good deal of the interest of the present exhibition resides in the landscapes, the comparison of which suggests besides some reflections as to the intellectual ends of landscape-painting, and the nature of the pleasure to be derived therefrom. Opposite to each other in the first room, for instance, hang a landscape of Müller's "Eel-backs at Goring" (11), and one of F. Walker's, "Sunny Thames" (32). Are either of these two really like nature? And are they scenes on the same planet? We

might allow an affirmative to the latter question, but certainly not to the former. Müller's picture (which at a first glance might be taken for a Constable) is a tremendous sketch of wonderful vigour, on the hack of which we are told the painter has written "Left as a sketch for some fool to finish and ruin." Müller was right from his point of view; the picture is a most powerful piece of "impressionism," and the effect of it on the spectator arises in great measure from the sense it gives of the artist's power and freedom in recording his impression. As an actual representation of nature it is exaggerated in general effect and coarse in detail; it does not represent the scene, but the effect the scene produced on Müller's mind. Walker's painting is unlike nature in a totally opposite sense. Müller's scene is cold in tone and with a violent opposition of lights and shadows. Walker's is suffused by a warm quiet light in which the sky, the banks, and the stream are all harmonised. Walker never really saw bank and water and figures all in that suffused kind of pervading glow, but he saw them so in his sentiment, and the painting is the effect of the scene on his mind. So with Cotman's grand landscape (35), a poetic composition made up on the basis of an effect in nature. Bonington's "Coast Scene" (18) is far more like a real scene than any of these; it is managed nicely no doubt; the lights and shadows and half-tones are obsequiously in their places as regards the general composition; but still it is like an actual scene of the kind; it is real, not transcendental. Yet it must be admitted that it is a weak work in comparison with any of the three previously mentioned, and the pleasure it gives, is weak also. There are more materials in the room for a "Philosophy of landscape-painting." Look at Richard Wilson's "Snowdon from Nantlle" (40), cut out of cardboard, as it were, and painted up like a theatre "flat." What a lesson on the dehilitating effect of a constant course of "classical landscapes."

Both (48) and Hobbema (66, 67, 71) give their views of landscape also, the reduction of a landscape painting to a single recipe. Mr. Morrison's Paul Potter, "Carriage at a Roadside Inn" (89), is a nice little picture worth attention as a curiosity, being so unlike the typical Paul Potter, who is represented a few feet off by a very typical work, the "Young Bull" (94) from the Buckingham Palace collection. In the large room one of the places of honour is occupied by a landscape, Constable's "Opening of Waterloo Bridge" (137). As far as the foreground is concerned Constable, too, is here seen as an impressionist; he gives up the prosaic details of the sentinals and the caparisoned people in the barges, but raises the whole into a rich play of colour; and what a rich texture, too, in the architectural details of the foreground, and what a broad and airy light over the middle distance and the famous bridge. It is not like the real event probably, but it is worth a great deal more than any realistic transcript could have been. In the same room is a remarkably fine Turner, "The Lake of Geneva" (108), in his best period; his "Petworth House" (133) is one of the "pretty" Turners, not to be despised in their way; his "Seapiece," (131) lent by Lord Leonfield, is another matter; "agitated sea" it is described in the catalogue, and so indeed it is—"agitated" in a way no sea ever was except in a picture of Turner's. One must not how down blindly before even a great painter when he misrepresents nature in this way. As to the colour and texture of the waves, too, interrogations might be made; but we do not know how the present aspect of the canvas represents its original state.

Of the figure pictures the portraits are (as usual of late years) the strongest part, excepting the Earl of Dudley's Raphael, "The Crucifixion" (151) in Gallery IV. This is one of the pictures which makes one comprehend the feeling expressed by Ruskin and others as to the "Paganism" of Raphael. In this graceful composition we have the tragedy

of the Crucifixion of Christ treated "in a decorative manner"; the Magdalene and St. Jerome kneel on each side in symmetrical pose, St. John and the Virgin stand behind in the same symmetrical manner, the cross in the centre; two small angels flutter in conventional attitudes beneath the arms of the cross, and their long fluttering ribands help to fill up otherwise empty space in the composition. In colour and grace of drawing the picture is a fine example of Raphael's work, but it is an extraordinary instance of the subordination of feeling and pathos to mere decorative effect. The painting by Lucas van Leyden opposite to it, "The Adoration of the Magi" (171) from the Buckingham Palace collection, is a fine and powerful work in its combination of gorgeously-clad figures with strange and abnormal piles of architecture in the background. Among the other works in Gallery IV., where as usual the older Italian paintings are collected, are to be noted Lucas Cranach's "Virgin and Child" (174) exquisite in the soft though formal beauty of the faces, which however have surely been freshened up to some extent; Da Vinci's "Virgin and Child" (165); and Sandro Botticelli's profile portrait of a girl in a red dress (144), a beautiful example of this type of art. Piero della Francesca's "Virgin and Child with Angels" (149) shows an interesting study of Renaissance architecture as a background.

Among the more modern pictures Reynolds's "Death of Dido" (105) occupies the centre position at the top of Gallery III.; a composition fine in colour and tragic in feeling, but undeniably theatrical. The curious decorative picture by Rubens and Snyder which hangs opposite to it, "Cupids, Fruit, and Flowers" (126), is a very fine work of its kind; the cupids by Rubens form an admirably painted group seated on the ground in the centre, Snyder's "swags" of fruit &c. hang across the upper part of the picture, and are painted with great force; the whole is a very fine piece of colour. Tintoretto is represented by two portraits of senators and by his "Apollo and Marsyas" (117), in which the figure of Apollo, with laurel branching round his head, and his right hand extended with the bow ready to commence playing his viol, is a figure of remarkable beauty and a kind of godlike energy, which, indeed, seems to strike Marsyas, who is holding his own pipe away from his mouth, and anxiously awaiting Apollo's performance. Andrea del Sarto's "Virgin and Child" (121) is a charming example of that finish and balance of colour and composition which distinguished him who was called "the perfect painter." Mr. Beaumont's Giorgione, "The Adoration of the Shepherds" (112) is interesting more from the quaintness of the conception and the treatment of the landscape and buildings than from the qualities generally most characteristic of Giorgione.

Of the Dutch pictures, collected as usual in the second room, the finest is Teniers's "Man and Woman in a Cowhouse" (82), which is painted with great delicacy in every detail and is a fine specimen of Teniers in one of his "finishing" moods. The other Teniers near it, "Old Woman Consulting a Doctor" (87): lent, like the last-named, by Mr. Morrison, is admirable for the character of the two figures, especially in the scrutinising countenance of "The Doctor"; the picture is interesting also as illustrating an old superstition of the doctor's craft, mentioned in Shakspeare, but about which the catalogue is necessarily silent, and we must imitate its reticence. The picture by Maes, from the Buckingham Palace collection (85), is, like some others of the Dutch selection, a kind of second-best edition of what the painter has done better in other works; this part of the collection is not up to its usual level of interest. A Watteau in the same room, "L'Accordée du Village" (43) is curious for its resemblance

* Not "cithara," as stated in the catalogue. A cithara was played by snapping the strings with the fingers; "cithar" is the modern form of the word. What Apollo is playing in the picture is the viol, an early form of the viola.

to the grouping and even the colour of Stothard (or Stothard's resemblance to it).

Among the portraits Gainsborough's "Mrs. Portman or Bryanston" (9) is a noble specimen of his powers: the lady is seated in an ample "white dress trimmed with lace," as the catalogue has it, but in reality the very point of the matter is that there is no real white in it; Gainsborough knew better than that. The head is relieved against a crimson and flowered screen or curtain behind in half light; the "white" dress is just warmed sufficiently to harmonise and not clash with this; the whole has a grand unity about it. Raeburn's bust portrait of "Mrs. Smith of Jordanhill" (5) is a charming work; so also Romney's "Hon. Charlotte Clive" (36), in a pale yellow dress and reclined in a beautifully composed attitude. Romney's "Countess of Derby" (27), in a white dress and with a hand touching her chin, is still more delicate and graceful, though not so striking in colour as the former. Perhaps Romney's finest work here is "Mr. and Mrs. Lindow" (132), the husband seated and the wife standing by him, grouped so as to compose admirably without the slightest look of posing, and admirable also for the harmonious treatment of rather subdued colours in the two costumes; "a blue dress" Mrs. Lindow's is called in the catalogue, but it is something a great deal more subtle than that. Of a very different kind of power is Van Dyck's superb full-length of "The Earl of Portland" (123), one of the most remarkable impersonations of manly and aristocratic dignity ever realised even by Vandvck. A good Frank Hals is hung near this (124), and Rubens's remarkable portrait of the "Marchesa Isabella Grimaldi" (125) in her bridal dress; she married the Doge Doria, and her appearance and attire are worthy of so resplendent a match; the work is a superb example of what may be called the sumptuous or decorative order of family portrait.

The Water-colour Room and Black and White Room contain a fine series of water-colours, some of them well known (such as Cox's "Welsh Funeral"). There is a beautiful collection of William Hunt's works, especially fruit and flower subjects. A number of Turner's sketches and original drawings for vignettes and book illustrations are there, including the curious but certainly imaginative illustrations which he made for Egerton Brydges' edition of Milton; also a large number of sketches and studies by Cotman, which show him in the light of an architectural as well as a landscape artist. Turner's large and beautiful water-colour of "Bonthill" (19) is the culminating point of what is certainly not the least interesting section of the Old Masters Exhibition.

DAILY LIFE IN THE ANCIENT WORLD.

THE translator of Becker's "Gallus" says in his preface, "The idea of making an interesting story the basis of his exposition, and of thus 'strewing with flowers the path of dry antiquity,' is most judicious. We have here a flesh-and-blood picture of the Roman, as he lived and moved, thought and acted, worth more, a thousand times more, than the *disjecta membra*, the dry skeleton, to be found in such books as Adam's 'Roman Antiquities,' and others of the same nature, which, however erudite, are vastly uninviting." What Becker, with so much applause from his contemporaries, did for the daily life of ancient Greece and Rome, M. G. Maspero, the distinguished Orientalist, and late Director of Archaeology at Cairo, has essayed to do for the daily life of ancient Egypt and Assyria.* Whether the method of writing employed by the French, as well as by the German author, is the best which could be chosen for imparting knowledge, is a subject on which a word must be said later on, but if the method be accepted, much praise may be given to M. Maspero for the able fulfilment of his task.

*"Life in Ancient Egypt and Assyria" from the French of G. Maspero. London: Chapman & Hall, 1891.

We have here presented to us in one small volume the essence of a vast amount of widely-ranging investigation, including much original research, as well as comparison of the work of other labourers in the same field, and its publication ought to add considerably to popular acquaintance with two of the most remarkable nations of the ancient world. New and striking historical revelations are not, indeed, to be looked for here; the general aspect, both of Egyptian and of Assyrian society, is too well known for anyone to be able to astonish us by fresh accounts of their peculiarities, but any attempt to spread and render easier the acquisition of accurate knowledge of the ordinary conditions of life in former states of civilization is of great educational value. There are few phases of modern life, with which correspondences, often very instructive, may not be found in the pages before us, and without venturing into the deeper questions of religious and political organizations, a few matters of social interest may be noted, to give an idea of the variety of information which M. Maspero has brought together.

Few subjects will have been so frequently in the minds of readers of this journal during the last few months as strikes of workmen, but neither the organisers nor the victims of our strikes need either flatter or hemoan themselves that they are better or worse off than were the citizens of Thebes three thousand years ago. We may read here,—

"Suddenly a great noise is heard at one end of the street, the crowd is violently opened, and about a hundred workmen, shouting, gesticulating, covered with clay and mortar, force their way through, dragging in the midst of them three or four frightened, piteous-looking scribes. These are the masons employed on the new buildings of the Temple of Mut, who have just gone on strike, and are now on their way to lay their grievances before Psaou, governor of the city, and general superintendent of the king's works. These small riots are not rare, they spring from misery and hunger. The greater portion of the wages consists of wheat, flour, oil, and rations of food, which the masters usually distribute on the first day of every month, and which ought to last until the first of the month following. The quantity allotted to each man would certainly suffice if it were economically used; but what is the use of preaching economy to people who reach home in a famished condition, after a day of hard work in which they have only eaten two cakes, seasoned with a little muddy water, about twelve o'clock? During the first days of the month, the family satisfy their hunger without sparing the provisions; towards the middle the portions diminish, and complaints begin; during the last week famine ensues, and the work suffers. If we consult the official registers of the scribes in the workyards, or simply the books of the overseers, we shall find notes in the end of each month of frequent idleness, and, at times, of strikes produced by the weakness and hunger of the workmen. Is their pay insufficient, or have they eaten their supplies unreasonably quickly? According to their own accounts, the scribes give them short measure, and enrich themselves by the robbery. On the other hand, the scribes accuse the poor fellows of improvidence, and assert that they squander their wages as soon as they receive them. No one could be astonished if both scribes and masons were found to be right."

It is often imagined that in ancient monarchies the occupations of soldier or priest were the only roads to riches and greatness, but in Egypt, at any rate, the "Civil Service" was highly esteemed, and its members often very prosperous; indeed, the attainments of an ordinary clerk might bring a man quite to the top of the social scale, as, after bearing of the education of a "scribe," we read:—

"His children will follow in the same path, and their children after them; there are whole dynasties of scribes, the members of one family having succeeded to the same posts for a century or more. Sometimes one of them, more intelligent or more ambitious than the others, makes an effort to rise above the usual mediocrity; his good writing, happy choice of words, activity, obligingness, and honesty,—perhaps, on the other hand, his prudent dishonesty,—attract the attention of his superiors and secure his advancement. Cases have been seen of the son of a peasant or of a poor citizen, commencing by booking the delivery of bread or vegetables in some provincial office, and ending, after a long and industrious career, by governing one-half of Egypt. The rooms of his barn overflow with corn; his storehouses are full of gold, valuable stuffs, and precious vases; his stable 'multiplies

the hacks' of his oxen, and the son of his first protector dare only approach him with his face bent to the ground, dragging himself upon his knees."

A curious parallel between the customs of modern London and ancient Thebes may be traced in the illustrations representing the royal chariot-horses, which have their heads as cruelly tied-in by tight hearing-reins as any unlicky horse to be seen now in a fashionable carriage; another, from which drier morals may be drawn, is shown by the statements that "beer-shops drove an excellent trade," and "beer has always been the favourite beverage of the people," in spite of "the moralists who cannot find words strong enough to express the danger of it."

Building, except in the case of temples, is described as being in Egypt a very simple and inexpensive operation. After an account of a disastrous hurricane, which has utterly wrecked every house in the district, we are told that:—

"Elsewhere such a catastrophe would entail utter ruin; here one or two weeks of labour suffice to repair it all. As soon as the rain has ceased, the whole population,—men, women, and children,—exert themselves, and hasten to draw from the rubbish the wood, provisions, and utensils that have resisted the inundation, then from the dilapidated mass of the old buildings they make new huts, which the sun quickly dries and cracks in all directions. Two days later no traces of the accident remain. A little more time and labour are required to rebuild the houses of the better classes. Two or three labourers go down to the nearest pool, and collect pallets of mud from the bottom, heap it upon the bank, knead it, mix it with gravel and finely-chopped straw, and press it into wooden moulds, which an assistant carries away and empties out into the sunshine. In a few hours the bricks are ready for use, and the building is commenced. No one thinks of clearing the ground or of digging foundations; the people are satisfied with levelling the rubbish, and placing the first bricks loosely upon the kind of bed they have thus prepared. A fortnight later the ground-floor is closed and roofed in, the family re-enter the dwelling with their cattle, and live in it whilst the upper story is being completed."

Turning to Assyria, we get some glimpses in the second portion of the book, of the architecture of that country, from which it appears that private houses, just as in Egypt, were not built in a manner calculated for long endurance, and were also studiously devoid of any outward show. The art of building was evidently thought much of by the ruling orders of the Assyrians, for we read that "the bricks destined for public buildings are holy, and can be made only at certain seasons. They are prepared under the auspices of a particular god, Sivan, lord of foundations, and only during the month to which he gave his name;" and also that before beginning a new palace, the king, after sacrifices, and with great solemnity, prayed that "Sivan and his father, Bel, the architect of the universe, would consent to direct the works." But their architecture was almost entirely confined to palace-building, for their temples, unlike the great independent establishments of the Egyptian priesthood, were only what might be called chapels-royal, included in the general group of palace-buildings, and occupying a comparatively small corner of the inclosure; of which, however, they were often very conspicuous features, being built of tower-like form, and decorated with lavish wealth of ornament.

The Assyrian, or as it might more properly be called, the Chaldean, method of land transfer, is well known as having been brought to a system of elaborate completeness, and a specimen is given of a deed of conveyance of an arable field, though some other extant documents, relating to the purchase of town-property, are still more interesting, and show that surveying must have been an important profession amongst the inhabitants of the father-land of geometrical science. The plan adopted in these transfers for recording the particulars of sale and for guarding against subsequent attempts at fraud was extremely ingenious. The documents were inscribed on clay tablets, which, when sealed both with the seals of the contracting parties and the judge before whom all such transactions had to be performed, were placed in an oven and converted into

almost indestructible bricks. But to prevent any tampering with them, besides taking the precaution of making three copies, the third of which was deposited with a royal notary, "the tablet, once sealed, was covered with a second layer of clay, upon which they traced an exact copy of the original deed. The latter thus became inaccessible to forgers, and if a dispute arose, and some alteration was suspected in the visible text, the enclosing tablet was broken before witnesses, and the deed was verified by the original writing preserved inside."

The translator's work (by Miss Norton) is very well done, and is not disfigured by those too literal interpretations of French phrases which make many translations look so awkward; but a few curious words, some of them probably only printer's errors, should be noted for correction, e.g., "which respond to our cardinal points," "have faith in formulas and talismans," "the head of a cynophelus," "the Phœnician merchant-ships have at many points stable establishments," "rising with bowed spine and drooping arms," ("spine" is frequently used for "back") and "the experience acquired in navigation upon soft water, enables them to dispense with a long apprenticeship upon the sea," a most original use of the word "soft" as applied to water. The illustrations, though rather roughly executed, are all to the point, and greatly add to the interest of the book, which will probably achieve some success, although there already exist many others on the same subjects which might be thought better suited for English readers. It belongs to a peculiar, nondescript class of writings hitherto more popular in France than in this country, a good deal resembling the "architectural novelette" of Viollet-le-Duc, and, like that, being neither plain history nor an antiquarian treatise, nor yet a real story, but attempting to combine all three, having enough air of fiction to spoil the reality of the historical portion, and enough antiquarian detail to make it unreadable as a tale, and unconnected as a chronicle. The student of history or antiquities would probably prefer to enjoy his facts without the uncomfortable feeling of unreality which the method of presenting them gives him at every turn, while the ordinary reader, who cannot endure a book unless it contains a story, could not possibly be beguiled by such a thin film of narrative into wading through what is practically a dictionary of antiquities, heavy with the minutest erudition. We believe that the enthusiastic student will still prefer to go straight to the works of Wilkinson and Layard, which in popular editions are now easily accessible; while the more numerous class of readers who for a picture of Roman life would turn rather to the pages of "The Last Days of Pompeii," than to those of "Gallus," will still find their best realisation of the ancient world in such books as Ebers' "Urarda," or Whyte-Melville's still more romantic "Sarchedon."

NOTES.

WE regret to hear of the death of the venerable M. Bailly, Member of the Institut de France and President of the "Société des Artistes Français," and long an honoured name among contemporary French architects. He was eighty-two at the time of his death, and in spite of his great age, and of the illness which finally carried him off, and which two months ago prevented his attendance at the annual meeting of the Académie des Beaux-Arts, he pursued his studies almost to his last hour. Antoine Nicolas Bailly was born at Paris in 1810 and was a pupil of Debret and of Duban, and in 1834 was attached to the municipal administration as an Inspecteur. Ten years later he was appointed "Architecte du Gouvernement," and then diocesan architect at Bourges, Valence, and Dignes, and restored the churches in these ancient towns with great ability and erudition. He was subsequently appointed "Architecte-en-chef des travaux d'entretien" to the Paris municipality. At the close of

the Empire he retired from this post with the title of "Inspecteur-Général Honoraire." Independently of the work which he carried out at the Hôtel de Ville under Godde and Lesueur, he also carried out the Mairie of the Fourth arrondissement, and the Lycée St. Louis at Paris, the Tribunal de Commerce, the restoration of the house of Jacques Coeur at Bourges, &c. He was a Commander of the Legion of Honour and received medals at various exhibitions. He replaced Labrousse as member of the Académie des Beaux-Arts. He took an active part in the foundation of the "Société des Artistes Français," where his zeal, impartiality, and amiability of character secured him general regard, and his loss is regretted by a large circle of friends.

IF ever a peerage is the fit reward for scientific eminence, never was that distinction better bestowed than on Sir William Thomson. The days are past when a man could say with Bacon, "I have taken all knowledge to be my province"; nor is it now possible even to so take all science, but Sir Wm. Thomson may justly claim to have taken all physical science as his province, and there are few who can rival him in any one branch of it. Go where you will, we find traces of his restless activity. Every telegraph office is stocked with instruments of his invention; a large part of London is lighted by dynamo machines which are modifications of one of his; and in the test-rooms of all the installations in the world the most accurate instruments are his also. We go to sea, and we find the means of taking soundings without stopping the ship, designed by Sir William Thomson; we arrive in port and find the height and time of the tides predicted by Sir William Thomson's tidal clock. Perhaps we are interested in questions of speculative science,—the age of the earth,—the constitution of matter, and the size of its ultimate molecules,—the origin of life on the earth and its probable duration,—none of these questions can be adequately discussed without mention of his name, and on some of them he is the only authority. In collaboration with Professor Tait he has written what is generally accepted as the text-book on Natural Philosophy, and some of the most brilliant mathematical investigations we have ever seen are due to him. When the history of science in the nineteenth century comes to be written, three names will stand out pre-eminent, those of Faraday, Darwin, and Sir William Thomson.

THE new volume of the *Transactions* of the Institute of Architects forms certainly one of the best practical answers which could be supplied to the charge brought against that body recently of being indifferent to the artistic side of architecture. With the exception of the paper, "A tour in the United States," by Mr. Cox (who, as holder of the Godwin Bousary, was under a special undertaking to direct his attention to practical construction), the whole volume, with its copious and in many cases beautiful illustrations, deals entirely with architecture in its artistic aspect. The volume includes Mr. Phéné Spiers's copiously illustrated paper on "Sassanian Architecture"; Baron de Geymüller's essay on "The School of Bramante," one of the most valuable recent contributions to the study of the architecture of the Renaissance; Mr. Starke Gardner's paper on "Wrought Ironwork" of the Mediæval period; Mr. Simonds's paper on "Some Aspects of Sculpture considered in relation to Architecture"; Mr. W. Simpson's paper on "Origin and Mutation in Indian and Eastern Architecture"; and papers by Mr. Brydon, Mr. W. B. Richmond, and Mr. Westlake, on "Decorative Painting." Mr. Somers Clarke's paper on the "Fall of a central Pillar at Seville Cathedral" may be said to partake both of archeological and structural interest, and is of value as coming from an architect who had special opportunities of studying the results of the catastrophe on the spot. Some of the authors are not members

of the Institute, but that they should be invited to read papers on branches of art with which they were specially acquainted certainly does not argue indifference to the art of architecture on the part of those who invited them. The whole volume is one of the best and most interesting which the Institute has put forth, and the illustrations alone should give it a high value to all students of architecture.

IN the *Times* of the 6th Mr. Holman Hunt writes to call attention to a matter which may well make the whole artistic world feel a shiver of apprehension. Visiting the Campo Santo at Pisa the other day, Mr. Hunt saw an erection evidently raised for some painter's convenience, and on inquiry found it was not for the harmless exercise of copying the frescoes, but for an artist engaged in re-painting the figures! Mr. Hunt says—

"I was able to see that this meant the blackening of the celestial purity of colour, and the mauling of every delicate form in the innocent drawing of the figures. It is not disrespectful to the painter to say this, for surely no living master could trust his hand to improve a surface on which time, where he has been able to weaken, has had no power to unspiritualise the traits.

It is true that the work remaining has to risk peril of effacement, but this danger would surely be more wisely met, and it has been in other cases in this country, by covering the surfaces with sheets of glass, or even by glazing all the open spaces in the cloister. Should it be urged that the original strength of colour should be renewed, surely this might best be done on copies carried first to the existing pitch of strength and then enforced at discretion."

If there were no alternative, it would be better to take copies for preservation and let the originals die out, as in the long run they must. What is their value, artistically or historically, when "repainted"? It is one of the saddest and most hopeless pieces of news of the kind that we have heard of for some time back. Mr. Holman Hunt's letter, we may add, merits all the more attention because it is written calmly and judiciously, and without that hysterical kind of exaggeration in which those who deplore restoration are too often wont to indulge, and which tends to defeat its own end.

THE various trading associations in Ireland are hesitating themselves, and have put in an appearance at the Board of Trade in opposition to the proposed rates for Irish lines. With a view of coming to some agreement whereby a protracted inquiry would be avoided, conferences have been arranged between the parties interested. At the first of these meetings, which was held last week, and which was well attended by representatives of the railway companies and the trading community, Mr. Courtney Boyle presided; and on his recommendation an adjournment was made in order that figures might be obtained in support of the statements made as to the effect of the proposed changes. This, each party will doubtless be able to do to their own satisfaction; while the Board of Trade will probably, as before, steer between the two. Some of the English traders are still hoping to obtain amendments to the classification,—notably the timber merchants, who desire to have the term "timber" defined as embracing all rough and unmanufactured wood, whether round or squared. All are awaiting with some anxiety the appearance of the revised rates, and many supposed that alterations would be made on the 1st inst. As far as we can learn, however, the old rates generally remain in force; and, as has been previously intimated, it is very improbable that any important changes will be introduced until much later on in the year.

FOR the first time for many years the Railway Clearing House are not issuing a fresh edition of their Classification with the new year. It has always been the rule for a revised list to be published on January 1, incorporating the various additions and alterations which the previous year's experience has shown to be necessary; but on this occasion

the revision is deferred pending the completion of the new rate-books, upon which the railway companies are still busily engaged. It is probable that a fresh edition will be published later in the year, remodelled on the lines of the Parliamentary classification settled last session, and possibly some of the provisions of the Act will be set forth.

THE agreement arrived at between the Great Northern Railway Company and the Manchester, Sheffield, and Lincolnshire Railway, by which the former company on certain terms has withdrawn its opposition to the extension to London of the latter, is likely materially to improve the chance of the passing of the Bill which was thrown out last Session. That the Bill will be modified in some form is pretty certain, but it is difficult to believe that the opposition of the inhabitants of St. John's Wood can prevent the passing of the Bill. That a new trunk line can be financially successful is, however, very improbable, but if the localities through which it passes desired, and there is no strong opposition, Parliament will hardly concern itself with the possibility that the shareholders may lose their money.

IN a "Note" on June 27 last we adverted to the Government scheme for an enlargement of the Record Office. Three weeks ago the materials of Nos. 6 to 20, on the eastern side of Chancery-lane, were sold at auction, and the fifteen houses are now being pulled down. The demolition includes the stone gateway, having a side footpath, which leads into Rolls-yard, and situated directly opposite to the chapel's western end. The old houses we speak of have for some years past been filled with Record Office stores, papers, &c., but being very unsuitable for that purpose will, as we understand, be replaced with a more commodious and fireproof structure.

By their recent vote of 3,476 $\frac{1}{2}$, as half of the purchase-money, the London County Council secure the addition of 3 $\frac{1}{2}$ acres, finely wooded, of the Bedford-hill estate, to Tooting Bec-common. This, and the adjoining Tooting-common,—being 207 acres in all,—their predecessors rescued from further encroachment and spoliation in 1875. The manors of Tooting, Estreham (Streatham), and Belgeham (Balham) are cited in Domesday survey; the former two as held of the Abbot of St. Mary de Bec. By an escheat of 8 Edward II, it appears that the priory of Ok-bourn, Wiltshire, an alien cell of Bec, held the two manors, by service of a knight's fee, of Gilbert de Clare, Earl of Gloucester, who fell at Bannockburn. At the seizure of alien priories, 2 Hen. V., the consolidated manor became vested in the Crown. In 1441 Henry VI. assigned it as part endowment to Eton College; but his successor, who resumed some of the grants to Eton, gave it to Lawrence, Bishop of Durham, for life. According to Rymer's "Fœdera," the priory or manor of Totyngbeke, as parcel of Ok-bourn, reverted, with the advowson of Streatham, to the King, who settled them upon John Tiptoft, Earl of Worcester, master, and the wardens of St. Mary's Guild, in All Hallows, Barking, Church. In 1599 it was bought by Sir Giles Howland, Knight, who is supposed to have built the manor-house at corner of Streatham-common, on the Croydon-road.* Elizabeth, heiress of John Howland brought the property in marriage to Wriothesley, second Duke of Bedford, who in 1695 was created Baron Howland, of Streatham. Their descendant Francis, fifth Duke, conveyed the house and grounds to Lord William Russell, and in June, 1816, John, sixth Duke, sold the manor, according to Brayley's "Surrey." Streatham Place, close to Tooting Bec-common, the home of the Thralls, has been quite dismantled. The house and its contents were sold in 1816;

* The home of Lord William Russell, who was murdered by his valet, Convoisier (1819), and rebuilt by Lord Deechurst, seventh Earl of Devon.

amongst the portraits being those, by Sir Joshua Reynolds, of Sir Robert Chambers (80 guineas), Goldsmith (127 guineas), Dr. Burney (80 guineas), Sir Joshua (122 guineas), Burke (240 guineas), and Dr. Johnson (360 guineas). A woodcut of the house is in the *Monthly Magazine* of July, 1823.

THE usual correspondence in the papers about fogs and the wickedness of scientific men who do not stop fogs, has followed the recent fogs in London. We have the same thing every year, and indignant people write letters to the *Times* speaking as if the authorities of London had only to give the requisite orders to shut off fog at once, and that it is only through pure "cussedness" that they do not do so. One correspondent, "Lucifer," who unfortunately does not give his name, but who says that he is a chemist, seems to be possessed with a somewhat more reasonable spirit. He observes—

"What we need for the formation of an ordinary mist is a chilled vapour-charged atmosphere and minute, solid particles to serve as nuclei for the condensation of this vapour into the droplets of water of which mist is composed. This mist may be aggravated into a fog if from any cause it is made abnormally dense, and it happens that such conditions exist in towns. . . . In towns these conditions are the existence in the air of an abnormally large supply of solid nuclei—which are quite independent of smoke—and the prevalence of sulphurous acid, which, likewise, is independent of smoke. This sulphurous acid comes from coal, and, as you justly remark, will come from coal whenever and however that coal is burnt. The amount of this gas sent into the air of London in one day is prodigious, for it will weigh about one-fiftieth of the total coal consumed. That the intensity and pungency of town fogs are due to this is a view which has been confirmed by so high an authority as Helmholtz (the Sir William Thomson of Gornatny), and it is idle to talk of the reduction of fog to mist by the smokeless burning of coal. It is no doubt true that the dirtiness, flavour, and unpleasantness of fog are much increased by the admixture of smoke, and no effort should be spared, in fair weather or foul, to mitigate the smoke nuisance. It acts, too, as an intensifier of fog, as has been shown by Dr. Frankland, by retarding the evaporation of the droplets of water of which the fog is composed.

Scientific men are continually being called upon to invent some means of dissipating or preventing fog. Professor Oliver Lodge has shown that fogs may be dispersed by means of a continuous discharge of electricity into them; but he would, I feel sure, be the last person to anticipate that such a method could be applied outside Utopia to the smallest town in the kingdom."

We commend these remarks to the attention of those enthusiastic persons who are constantly urging that we can prevent London fog at will. "Lucifer" goes on to observe, truly, that the general adoption of gas for heating and electricity for lighting would be "a solution of the fog question"; but in saying that he himself goes too far, it would remove the excessive darkness and irritating character of the fogs; but would still leave them as white fogs. The recent fog of London extended over a considerable tract of country, only it had not the same character in the country as in London. And it would remain to be considered whether this change from a smoky brown fog to a white one would be a sufficient good to compensate for the permanent exchange of gas fires for the warm and cheerful coal fire. Some people would probably think otherwise; but of course the majority have the right to decide the point, and if coal fires are condemned the minority must give way. But we rather doubt it really coming to that. People may think so while a fog lasts, but when it is gone they will sigh over the loss of their comfortable fire.

THE fog correspondence has produced complaints also, as usual, from passengers by the railways. Some of these are perfectly reasonable, and some of the delays might have been prevented. At Euston it is extraordinary that the Board of the North-Western Railway have not introduced a more efficient system of lighting. In foggy weather the delays on that line are chiefly produced by the difficulty experienced in

sending trains from the terminus. Strong lights will not altogether prevent difficulties from severe fogs, but they will do a good deal to alleviate the trouble.

SOME NOTES ON THE HISTORY OF ENAMELLING.

BY J. STARKIE GARDNER.

THE art of enamelling is very ancient, and consists of fusing a coating of glass upon metal. Metal, however, being tough and malleable, and in many other respects the opposite of glass, and the two bodies having different measures of expansion and contraction, skill and experience are needed to unite them. When the metal to be enamelled is thick its surface is divided into cells, in order that its expansion and contraction may not shiver the glassy skin; but when the metal is thin, it is usually coated all over by the enamel, which acts as an envelope and protects it uninjured by ordinary changes of temperature. This difficulty has probably gone far to determine the various forms of enamel known to art, and which may be grouped into cellular and glaze enamels. The cellular group is divided into those in which the metal surface is gouged out, called *champlevé*, and those in which cell walls are added to its surface,—*cloisonné*. Fusion in these was, and is usually, accomplished under the blow-pipe, while glazed enamels were fused in the muffle or closed oven.

The enamel is simply a more or less fusible glass which is transparent unless mixed with tin, when it becomes opaque. The colours used are of course only such as will stand heat, and practically are oxides of different metals,—copper, cobalt, iron, gold, manganese, &c. The range of colour is almost unlimited.

There is some difference of opinion as to whether the Egyptians ever fused the enamel paste they produced on to metal, or whether they merely used it as an inlay. There is none as to its very sparing use by the Greeks in jewellery. It seems to have been unknown to the Etruscans, Romans, or any other civilised nation previous to the Christian era.

It was, however, known to one barbarian nation, our own, in prehistoric times. It can never be known exactly, but as all British enamels are stanniferous, the discovery must have been due to some smelting of tin and bronze. Until the Roman colonisation, enamelling seems to have been confined to small trappings for man and horse, but later highly decorated vases and howls were made and exported. The ivy was much used in their decoration, and the classic laurel-leaf border is often introduced. The Gallo-Romans seem to have practised the art to some limited extent, and the Italians appear to have produced a bastard enamel by mixing the *maître-bleu* and other glasses in jewellery, and fusing them sufficiently to unite to the metal.

It is unlikely that this art was connected with enamelling as practised at Byzantium, many centuries later. On the other hand, there is sufficient evidence that it was never lost in the British Isles. A kind of *champlevé* process had been handed down from time immemorial, the metal being cast, and the cells filled with yellow, red, green, white, and blue. Several vases of British manufacture have been found in France, Germany, and Denmark. In Ireland also, the art of enamelling was known in very remote times. The exquisitely beaten shields and helmet found in the Thames, and now in the British Museum, and the horns of the same workmanship in Dublin, are alike decorated with small blood-red enamels, and many of the Celtic brooches are set with enamels. The Ardagh chalice, which dates probably from the eighth century, is of peculiar interest, as being perhaps the earliest enamel in existence made for a sacred purpose, and as having served as a type on which others were fashioned. It is decorated with three kinds of enamel, all of them showing a marvellous amount of thought and skillful manipulation. The Irish enamels present indeed processes such as the inlay of one coloured enamel in another, and the pressing of the metal filigree into hot enamel, which are quite peculiar, and should enable us to recognise them wherever met with. While tin appears to have been a necessary ingredient in British enamels, it is not present in some of the oldest from Ireland, which are translucent; and the coarse British variety of

champ-levé is abandoned for the more delicate *cloisonné*.

The next step in our history was a very important one, the introduction of pictorial representations in enamel, and this step also was taken in England. In the well-known Alfred jewel found in Athelney, and inscribed with the words, "Aelfred mec heht geortan," we have a most beautiful example of *cloisonné* on gold bearing a portrait, and rich in translucent enamel of fine hue. No piece of *cloisonné* enamel, bearing such strong intrinsic evidence of its date, is to be met with which can compare with it in antiquity.

But it does not stand alone. An exquisitely worked brooch found on Dowgate-hill bears a delicate *cloisonné* portrait of a royal person, supposed to represent Alfred or his father. Like the Alfred jewel, it is rich in translucent green and blue, the flesh tints being opaque, with a golden-yellow crown, and with pearls and black enamel rosettes set in its filigree gold border. An equally beautiful brooch of the same workmanship reposes beside it in the British Museum, in the centre of which is a highly decorative cross in deep translucent blue and ruby. These superb specimens of *cloisonné* jewellery are linked to the older British enamels by a curious unfinished plaque, also in the British Museum, and found in London, enamelled in blue, red, yellow, and white, which has a somewhat Medieval feeling; and still more so by the ring of King Ethelwulf, of blue and green *champ-levé* on gold, inscribed with his name and two eagles, or perhaps ravens. A ring of not dissimilar style, but filled with niello in place of enamel, is inscribed with the name Ahlstan, supposed to be the Bishop of Sherbon, 823-67.

These enamels have not hitherto been universally admitted to be of English manufacture, but the inscriptions on them, and their refined style and execution, are strong arguments in favour of their native production at the time when England occupied the leading position in the arts and sciences. We may admit, if necessary, that the introduction of portraiture may have been due to the journeys that Alfred and his father made to Rome. Those who find it difficult to admit an English origin for these enamels, regard them as of Byzantine origin, but there is no clear evidence of the production of enamels in Byzantium prior to the tenth century, and none exist which can be attributed with certainty to a date earlier than about its close. The pectoral crosses, of which there are two in the Kensington Museum, appear to be the oldest. The designs are fashioned in delicate gold filigree, and in color and technique they are not dissimilar to our portrait enamels. The beautiful series of plaques discovered in a field, and now in the National Hungarian Museum, are typical Byzantine work, and their date is known to be between 1042 and 1054. They probably formed a crown like that of Charlemagne in form. The most famous Byzantine enamel in the world is the Pala D'Oro, the golden altar-piece of St. Mark's Cathedral, Venice. None of the enamels which enrich it are, in the opinion of Mr. Franks, older than the figures of the Empress Irene and the Doge Faliero, about 1105, while others are as recent as 1209. The equally remarkable golden altar at Milan, known as the Paliotto, is not believed to be Byzantine, and being executed by one Wolvins, an unmistakably Saxon name, at a time, 835, when it cannot be shown conclusively that enamelling was practised except in England, there is some slight (*a priori*) ground for hoping that it may prove to be an English work. Small enamels, set as jewels, abound in works as old as this, such as in the crown of Monza, about 625; the reliquary of St. Zeno, 720; that of Pepin, in the crown, sword, and gloves of Charlemagne; the A of Charlemagne and many other objects preserved in the Treasury of the Abbey of Conques, &c. Some of these may be English and Irish, and their origin may be as various as those of the gems which accompany them. The strongest evidence in favour of the antiquity of the art of enamelling in Byzantium is the fact that we find the art transported to Germany soon after the marriage of Otto with Princess Theophanie in 973. The enamels at Essen, inscribed with the names of Matilda, Abbess 974-1013, and Theophanie, Abbess 1014-1054, are generally regarded as the oldest of German origin. The former are of the finest work, being perhaps executed by Byzantine workmen. The Germans soon resorted

to the *champ-levé* process on copper, very frequently combining it with gold *cloisonné* for the more delicate details. A few Byzantine enamels are known of this mixed kind, but in these the copper is beaten out to form the design, instead of being chased out as in the *champ-levé*. The seat of the manufacture seems to have been at Cologne, and nearly all the large shrines and reliquaries preserved in Germany are of Rhenish production, and nearly thirty of them still exist in the diocese of Cologne. Among the most important is the shrine of the Magd at Cologne, of the Virgin at Aachen, Saint Servais at Mästricht. German enamels are characterised by somewhat rude drawing and the use of many colours, which are generally shaded and sometimes blended. As we have seen, *cloisonné* decoration was frequently, almost habitually, used for small details on the base of *champ-levé* work. We possess in the Solitkoff reliquary at Kensington one of the finest specimens of early German enamel in existence.

In addition to the Rhenish production we have evidence of an important seat of the industry on the banks of the Meuse, in Lorraine, in the twelfth century, Abbot Suger having taken his workmen from thence to St. Denis in the years 1143-47. The splendid altar front of Klosterneubourg, consisting of fifty-one plates of *champ-levé* enamel, was made by Nicolas of Verdun, 1181. Enamelling was also carried on at Mästricht in the thirteenth century, but the style of Limoges was followed.

The German and other enamels, about which little is really yet known, deserve most careful study, as many enamels are referred to a German origin, which in refinement of design, delicacy of detail, and general style, in no way resemble the ordinary expressions of German art. Still less do they resemble Byzantine or Limoges work. It is significant that most of these have been found in England, whilst much evidence can be brought forward to show that enamelling was an important art in England during the twelfth to the fourteenth centuries, when English enamels were prized on the Continent. Instances of this are the enamelled clasp in the inventory of the Duke of Normandy, 1363, the enamelled gold goblet and ewer given by Henry IV. to Charles VI., the fine specimen taken as a souvenir of his visit to this country by Charles V., &c. We possess, moreover, a few acknowledged enamels of English production, such as the Lynn cup and Wykeham crozier, which are of fine workmanship; and, if we wish farther to gauge what English enamellers were likely to produce, we have only to look at the thirteenth-century glass remaining at Canterbury or York, to feel convinced that it would be of high quality, both in refinement of drawing and beauty of colour. It is interesting to notice that Richardin, an enameller from London, was one of the first of the craft established in Paris, 1292.

Among the most beautiful examples are those in which the surface is divided into small panels in the fashion of the contemporary stained glass. The dividing lines are generally ribbons bearing leonine verses remarkable for their erudition and thought. The compartments are round, lozenge shaped, or polygonal, and contain exquisitely-drawn groups of figures, either biblical or allegorical subjects. To this unfortunately rare group belong the Meyrick crozier, the Warwick bowl, the Bruce bowl, the Saverlake horn, and the chalice of Wilten in Tyrol, and, perhaps, a curious enamelled flask in the Berlin Museum. That this panelled or diapered treatment was always a favourite one in England there is abundant evidence to show. We find it in all sorts of examples, such as the beautiful Fair Rosamond ring, the painted roof of Peterborough Cathedral, and many of the early cups belonging to colleges and corporations.

The triptych from Alton Towers, as pointed out by Mr. Franks, is not dissimilar in its style, being divided into nine compartments, with scriptural subjects and leonine verses. Another triptych, also in the Kensington Museum, which might be claimed as English, was found in Essex, formed part of the Arundel collection, and figured in the "Archæologia." It is remarkable for the fine drawing of the subjects in the eight compartments, and for its translucent enamels. A very similar specimen is in the Kensington Museum. The beautiful Lynn cup of the time of Richard II. is also divided into compartments, on which are small and delicately drawn figures on translucent enamel.

Part of a very beautiful cup, 1276-1316, at All Souls' College, and the binding of the Bodeleian Psalter, are also enamelled in brilliant translucent colours, and are undoubtedly English. The English origin of the Wykeham and the Limerick croziers and mitres, the latter inscribed by Thomas O'Carty, 1418, has never been questioned, and both are superb examples, not only of the goldsmith's, but of the enameller's art. When we remember that the goldsmith's and other artistic work produced at Ely, Glastonbury, Durham, York, Colchester, St. Albans, &c., was celebrated from the eleventh to the thirteenth centuries, and that vast treasures of this work were frequently accumulated, it would, indeed, be matter for surprise if our country were as destitute of examples of its ancient art as is generally supposed.

When we can place the English origin of a few more enamels beyond doubt, the study of the rest will be greatly facilitated. They seem to have been much more varied than those of other countries, and hence require particular care in distinguishing them. Armorial bearings are enamelled on the shields to the tombs of Edward III. and Richard II., and on the shields and belt of the effigy of the Black Prince, while a sword of Edward III. has a handle enamelled with his arms. A few caskets, like that of De Valence in the Kensington Museum, a small shrine with St. George and the Dragon, with a few other objects, and the armorial bearings on the herse and tomb in the Beauchamp Chapel, belong to the same group. Of great interest, too, are the Garter plates at Windsor, beginning in 1368, and extending over a period of 500 years. The inventories of the jewels belonging to Edward II. and III. mention 200 distinct enamelled vessels.

The name of Limoges is first connected in a definite way with enamelling towards the third quarter of the twelfth century. The celebrated enamelled brass of Geoffrey Plantagenet, father of Henry II., is still preserved at Le Mans, and is especially interesting from its heraldry. This Prince died in 1151. The enamel, however, is very unlike any work of Limoges, and the proofs of its origin advanced are quite inconclusive. Among the earliest undoubtedly authentic works of Limoges are the two plaques from the Abbey of Grandmont in the Cluny Museum. One bears an inscription claimed to be in Limousin patois, and the date assigned them is prior to 1188. A still more characteristic specimen is the fine chalice of Mozac. Authentic twelfth century specimens of Limoges work are, however, extremely rare, the vast mass of Limoges enamels belonging to the thirteenth century. At this time they enjoyed an extraordinary popularity, and were exported far and near. One of the best known, and a signed work, is the pyx of Alpaïs in the Louvre. We possess an almost corresponding piece in the British Museum. The most important objects are the reliquaries in form of ecclesiastical edifices with high pitched roofs. Other objects are croziers, crosses, missal covers, pyxes, &c. These are nearly always decorated with figures representing the Adoration of the Magi, the Flight into Egypt, the Martyrdom of St. Catherine, St. Valerie, St. Thomas a Becket, &c. The figures on the reliquaries are stiff and without much movement, often badly drawn, and are either outlined on a gold ground on an enamelled field or enamelled on a gold field. The heads, or sometimes the whole figures, are often embossed in high relief. Gems and filigree are rarely used to enrich the effect. The tone of colour used is decidedly blue, and the effect brilliant. The ground is almost universally a deep ultramarine; but a darker blue, as well as turquoise and sky blue, are also used. Red, purple, light and dark green, white, yellow, and black are used sparingly. Ultramarine draperies are bordered with light blue or white, and green is bordered with yellow. There is great sameness about the work, which is often exceedingly coarse, as if the objects had been produced in quantities for export. Very highly finished Limoges work is rare, and the pedigree of several unusual examples claimed by French writers requires careful examination. It was, no doubt, partly owing to its inferior and monotonous execution that it fell into complete disfavour in the fifteenth century.

French writers claim that all the enamelled tombs and effigies, formerly abundant, but now excessively rare, were produced at Limoges, which held a monopoly of such work. A list of them is given in Ernest Rupin's "L'Œuvre de

Limoges." Many are only known from de Gaignères's drawings, and notes preserved in the Bodleian. The tombs of Blanche and Jean, children of St. Louis, who died in 1243 and 1248, are now in the Abbey of St. Denis, and the effigy of Blanche of Champagne, 1283, is in the Louvre. Other tombs, presumably of Limoges work, are preserved in Spain. That of William de Valence, made in 1296, is still in an extremely perfect condition as regards the effigy. It shows a pillow, belt, and shield, emblazoned all over in the richest way with the arms of Valence. The enamel is on plate copper, fixed to a rough wooden core. There is no record as to where it was made, and there is no other tomb resembling it in England; but an enamelled tomb was ordered from Limoges in 1277 for Walter de Merton, Bishop of Rochester. Enamelling was carried on in other parts of France, particularly in Paris, but hardly any pieces can be identified, and the study of Medieval enamels, notwithstanding the hooks that have been written, is still in a very imperfect state.

Illustrations.

SELECTED DESIGN FOR THE MUNICIPAL BUILDINGS, BATH.

WE have already in a review of the Bath Municipal Buildings Competition (page 178 of our last volume) given a description of the main points of this design, by Mr. J. M. Brydon, which has been awarded the first premium and, we understand, accepted for execution. We give the principal elevation and the plans of the two principal floors.

We have nothing to add to the remarks we have already made on the plan and design; but the following summary, communicated to us by the architect, may be given as setting forth his view of the objects and treatment of the building:—

"In describing the general arrangements of the proposed new buildings, it will be noticed that the accommodation provided divides itself into two main sections.

1. The administration of justice, comprising the new Sessions Court and the rooms connected therewith. These are located on the ground floor.

2. The public services, comprising the new Council-chamber and the offices of the various departments for the business of the municipality. These are principally located on the first floor.

In working out the details of these two sections, the additions have been so arranged with reference to the present Guildhall that, though each is distinct in itself, together they form a complete scheme, in the consideration of which the old and new buildings may be taken as a whole. With this view the present entrance in High-street is allotted to the courts and the banquetting-hall, and a new entrance is provided at the Orange-grove corner for the Municipal offices. Spacious and amply-lighted corridors connect these two approaches, while a new municipal staircase is provided near the latter.

The new court is placed at the back of the building, away from the noise of the street traffic, and immediately around it are rooms for witnesses, jury, solicitors, barristers, and others connected with the business of the court, so arranged as to serve the purposes of both courts. The new Council-chamber is also placed in the rear, and over the court below. Near it are grouped the Mayor's parlour, the committee-rooms, Town Clerk's and Treasurer's offices, &c.

A special feature is made of the connexion between the old and new buildings on both floors,—on the ground floor by a new inner hall from which the court corridor opens; and on the first floor by a circular vestibule with a domed light, at the junction of the Council corridor and the present staircase. From this vestibule a new entrance is made into the banquetting-room, bringing it into suite with the Council-chamber, &c. Access for the public to the galleries of the court and Council-chamber is provided by a separate entrance and staircase from the proposed new market approach.

As will be seen from the view, the additions take the form of wings on each side of the Guildhall with rounded corners at the return ends, marked by low flanking towers, and it is proposed to increase the importance of the centre block by crowning it with the low dome so characteristic of the style. Indeed, the whole question of style demanded the most special study and attention, it being considered of the first importance that the additions should so harmonise with the existing work that any impression of an after-thought should not only be avoided, but that the building, as a whole, should appear as if it had been so designed from the first, and, if possible, infuse the spirit of the old work into the new, while at the same time the importance and the dignity of the former should

be increased rather than lessened as the central features of the whole composition.

The southern wing contains the new Municipal offices, and the northern wing the School of Science and Art, the sculpture in each rounded angle indicating the purposes to which they are devoted. The interior of the building will be carried out in harmony with the style of the exterior, and with the rooms of the existing Guildhall. It is, therefore, confidently hoped the result will be a work which, without any meretricious ornament, will, from the dignity of its treatment, proclaim itself essentially a public building not unworthy the architectural traditions or the civic home of such a historic city as Bath.

MOSAICS IN ST. MARK'S, VENICE.

THESE sketches represent St. Athanasius and St. John Chrysostom, two of the four Greek Fathers of the Church in the Baptistery of St. Mark's, at Venice. They were executed in mosaic by Greek artists of the twelfth and thirteenth centuries. In Mrs. Jameson's work on "Sacred and Legendary Art," she says:—"When they are introduced collectively as a part of the decoration of an ecclesiastical edifice, we may conclude in general that the work is Byzantine, and executed under the influence of Greek artists." They occupy the four spandrels of the vaulting, filling the same places here which are usually occupied by the four Latin Fathers in church decoration. Each has his name inscribed in Greek characters, and holds in his hand a scroll bearing some remarkable passage from his work in Greek. Thus St. Athanasius has "Often and anew do we flee to thee, O God," while St. John Chrysostom has, "God, our God, who hath given us for food the bread of life." St. Athanasius, the eldest of the Fathers, was born at Alexandria, A.D. 298, and died A.D. 372. St. John Chrysostom was born at Antioch, A.D. 344, and died A.D. 407. The tympan between the spandrels are filled with mosaic work depicting scenes in the life of John-the-Baptist. The sketches are by Mr. Arthur C. Blomfield, M.A., and the original drawings were exhibited at the Royal Academy Exhibition of 1891.

THE "JEW'S HOUSE," LINCOLN.

THE illustration of this well-known and interesting old house at Lincoln (why called the "Jew's House" no one seems to know) is from a drawing by Mr. A. H. Powell, which was included in the exhibits of the Architectural Room at the Royal Academy last year.

"A MOUNTAIN CHURCH."

THIS is a study for a church in a mountainous district; the fall of the ground towards the east suggests the position of the heating-chamber, the vestry being placed over, reached by an external staircase. The accommodation is for 300.

The drawing was exhibited in the Royal Academy of 1891. G. L. M.

MAGAZINES AND REVIEWS.

THE *Art Journal* commences with an article on "An Etcher of Architecture," by Mr. C. Lewis Hind, the etcher in question being Mr. A. W. Haig, who well merits a post of honour in any artistic journal. The article is illustrated by reductions from some of Mr. Haig's etchings. We learn from it that Mr. Haig commenced with shipbuilding or making designs for and drawings of ships, and subsequently was a designer of buildings in the usual way of architectural draughtsmanship, before he took to the career which has given him fame. Mr. Hind rightly notes the special quality of Mr. Haig's etchings of buildings as giving breadth of effect without overlooking accuracy and minuteness of detail. The first of a series of articles by Mr. Aymer Valance on "The Furnishing and Decoration of the House" deals with floors and ceilings. In regard to some very good (and well-known) ceiling papers which are illustrated, the author rightly points out that a ceiling decoration should have no tendency of line in one direction. "Sir Joshua Reynolds and his Models" is an interesting paper by Miss Frances A. Gerard. The first example of the promised stories, "The Sculptor's Mistake," is not very attractive *quâ* story; the illustrations are the best part of it.

In the *Magazine of Art* Mr. Reginald Blomfield starts what we presume is to be a series of articles on "Artistic Homes," illustrated by his

own sketches of his friends' houses, and containing many good and pointed remarks as to house-designing. An article on "Book-edge Decoration," by Mr. S. T. Pridéaux, touches a subject which has been rather overlooked, and gives several interesting illustrations from examples in the British Museum. We certainly cannot agree with him in thinking that landscapes painted on the edges of the pages form "the most attractive form of edge decoration;" on the contrary, nothing could be more out of place, in spite of old examples. An article on John Russell, "the Prince of crayon 'portrait-painters,'" is illustrated by a frontispiece from one of his works, a portrait of a lady. Russell was born in 1711; the article, by Mr. G. C. Williamson, is mainly biographical, and contains a good deal of interesting information. The whole number is a very good one.

Among things in *The Antiquary* which will interest our readers are "Latest Discoveries at Mycenæ" by Professor Halbherr; "Notes on the Lights of a Medieval Church," by the Rev. F. W. Weaver, and "A List of the Inventories of Church Goods made temp. Edward VI.," by Mr. W. Page.

The Architectural Review, of Boston, which is a successor to or expansion of *The Technology Architectural Review* to which we have several times referred, commences with an article on the late J. D. Sedding, by Mr. Ralph Adams Cram, which is sympathetic and enthusiastic, but errs in the way so common among a certain school of writers on architecture, of speaking with contempt of architects who are not, like Sedding, seekers after originality at all costs. Mr. Cram must be very ignorant of the subject to say that Barry was an architect of mere archeological exactness, and refer to his Parliament houses as therefore an anachronism. Has he never heard that the style of the building was imposed upon Barry by the Government? Barry was a very original architect, using Renaissance materials after his own fashion, and American critics had better learn something more about his works before they sneer at him. And we would also suggest to the editor to take the trouble of getting English architects' and artists' names correctly; we find references to "Mr. Bigg's" drawings of Lincoln in our pages, a design for a frieze by Mr. Arthur "Gwatke," and a "Beaford" grammar-school by Mr. E. C. "Robbins." Apparently the writer of the article cannot even read print correctly. He also describes an Academy drawing of Mr. Batley's as by Mr. "Bailey," and shows his perception by describing the panel, published in the *Builder* of November 21, as "a perfect orgy of design," "bad taste," &c., &c. The design, a pretty little unpretending relief in gesso, will be remembered by many visitors to the Architectural Room of the Royal Academy, who will probably be rather astonished to hear of its being an "orgy of design."

In *Harper's Magazine* Mr. Besant's "London under Charles the Second" is the most interesting of these historical articles that we have seen. It is confined to the city and popular life, leaving on one side the manners of the Court, which Mr. Besant thinks had little effect on the general life of the middle classes. He has got hold of an old housekeeping account-book of a middle-class family from 1677 to 1679, from which most realistic details are obtained. Details as to the Plague and the Fire of course occupy a good deal of the article, which is also illustrated by some very pretty sketches of bits of the London of the period. An article in the same number by Mr. Julian Ralph, on "Our Exposition at Chicago" gives a good idea of the immense and ambitious scale on which this great show is being carried out. The manufacturers' building itself is one-third of a mile long. The combination of water with the architecture will, no doubt, add much to the effect of the scene. According to the writer, the English section is to include a reproduction of some notable English mansion or manor-house.

Scribner devotes an interesting article to some "Correspondence of Washington Allston," the American artist of the early days of this century, whose name is probably little remembered among English lovers of art at present, but who was a man worth to be had in remembrance on account of his general intellectual culture, as well as the beauty of his sketches in figure and subject; some of his sketches are given as illustrations; one of the heads of angels from a picture of "Jacob's Dream," is notable for its Raffaellesque grace of outline.

SELECTED DESIGN FOR MUNICIPAL BUILDINGS, BATH.—Mr. J. M. BRYDON, F.R.I.B.A., ARCHITECT.

PLAN of ALL SAINT'S CHURCH, HERTFORD DESTROYED BY FIRE DEC. 21, 1891.

Allston visited and remained some time in England. His remarks on some English painters of the time are curious to read now, as instances of the different manner in which artists are seen by their contemporaries and by posterity. Northcote was a great painter then; and of Fuseli Allston observes that his picture of Hamlet and the Ghost was "alone sufficient to immortalise him." Haydon had a great admiration for that picture also: we know not where it is now.

The only paper in the *Century* dealing with art is Mr. Stillman's on Andrea del Sarto, in continuation of the series of articles on Italian old masters. The article is a short one, and gives a fair estimate of Andrea's powers and weaknesses. Mr. Stillman also reminds us that Andrea del Sarto was one of the artists who produced the model of the facade for the Duomo of Florence at the time of the visit of Leo X. It was produced conjointly with Sansovino, and one may naturally think that the latter had the most to do with it; Mr. Stillman observes however that "the masterly knowledge of perspective shown in some of his frescoes would suggest such a knowledge of architecture as most of the painters of the period possessed." The article is illustrated by engravings from two of Andrea del Sarto's works.

The *Nineteenth Century* of this month contains an interesting article on the "Electrical Transmission of Power," by the Earl of Albemarle, which repeats, quoting from M. Fignier, the pleasant fable that the reversibility of the dynamo was accidentally discovered. The article will give to the general reader a vivid idea of how a dynamo is a source of power, and when power can be transmitted electrically over a long distance. It is singularly free from technicalities, and is written in a powerful and graphic style. We feel particularly grateful to the Earl for the epigrammatic phrase, "vested interests and invested cash." Unfortunately the author resuscitates the notion disposed of by Mr. Swinburne two years ago, that a motor should have a relatively large armature. Small field magnets may be a necessary evil in motors for driving electric launches and tramcars, but the advantage in weight is gained at the cost of diminished electrical efficiency.

The *Portfolio* for this current month contains the first of a series of articles by the Reverend

W. J. Loftie, upon a somewhat well-worn subject,—the Inns of Court. In reviewing Mr. Loftie's "History of London" a few years ago,* we had occasion to point out the absence of any logical principle of architectural thought or criticism from that work. In inveighing against the mischief which followed upon the first outbreak of the great Gothic revival, he would adopt,—

A recent suggestion, namely, that in writing or speaking of modern, or mock, Gothic, as distinguished from the real thing, the term Vandal or Vandalic might be used.

He triumphantly asks what name can he more appropriate for Mr. Pearson's use of what he would persuade us is Gothic at Westminster? As he says that "even ordinary Gothic only exists in the Savoy and at Westminster," we infer that by "Westminster" he means the Abbey; in which case we are sorry for one who would stigmatise as Vandalism the recent work by that architect upon the exterior of the north transept. Possibly, however, he means to refer to the treatment of Westminster Hall, in which case we are with him. The "kind of garret," by the way, into which, as Mr. Loftie complains, some monuments have been removed at the Temple is, in fact, the triforium of the Round Church there. The article, however, is mainly concerned with topographical matters, in respect whereof Mr. Loftie treads upon surer ground. The complex story of Portpoole,—site of Gray's Inn,—is dismissed in thirty lines. It begins with a derivation for the name, thus:—

But the "port" which means, in this connexion, rather an extra-mural market than a gate, may be found, perhaps, in the neighbouring Staple Inn . . . and the pool,—well, what can be more natural than that a horse pond adjoined the market-place? (1)

It ends by saying that the manor came to the crown at the Dissolution, but Henry VIII. renewed the lease,—which must now be taken as correct; and that "the Treasury still pays the rent to the Crown." It is quite clearly set out in Mr. W. Ralph Douthwaite's "Gray's Inn,"† that the society bought, in 1733, their fee farm rent (6*l.* 1*s.* 4*d.*) from parties deriving title from Sir Philip Matthews' co-heirs, and have

held the property free from any rent or charge ever since.

The *Health Record* (Dublin) is a new Irish Journal of Sanitary Science, to which we wish success. The short articles on various sanitary subjects are written in a sensible spirit. We learn from it that the Corporation of Dublin have adopted the report of the Main Drainage Committee, and the *Health Record* recommends the Dublin authorities, to economise, if they like, in other matters, but to lose no time in carrying out a main drainage system for Dublin.

PLAN OF ALL SAINTS' CHURCH, HERTFORD.

We are indebted to Mr. Scargill for the above plan of All Saints', Hertford, the destruction of which was referred to in our "Notes" and in Mr. Scargill's letter last week.

FIXING PORTABLE RANGES.

We are here speaking of kitchen ranges which have all the flues constructed in iron and made part of them, and which are sometimes called independent, or self-setting, or more commonly called "American" ranges. This style of range was introduced from that country, where it was found of the utmost service to pioneers and settlers, being independent of brickwork fixing, ready for use almost at a moment's notice, and being made of light metal they could be treated as an article of furniture. They are used in great quantities exactly in this manner at the present day.

In bringing this range into towns or cities, as was a matter of course when they were introduced into England, many new circumstances were encountered, the chief of these being the chimney opening and the brick chimney, and, strange as it may seem, these ranges which are so very simple to put up, and need so little labour in so doing, are as great sufferers as our brick-flue Leamington ranges in working badly through incompetent work in fixing.

Doubtless these portable ranges suffer through its being considered that they need no fixing, as the flues are already made. This is correct so far as the flues around the ovens and hollers are concerned, but unfortunately many workmen have a very imperfect notion as to what

* See the *Builder*, February 2, 1884.

† Reviewed in our columns on April 17, 1888.

the "draught" is which impels the flame and heated gases through these flues in question; and, unless the range is in sound and proper communication with the chimney, the flues in the range will be of little use in assisting efficiency.

As every skilful range-fixer knows, the "draught" (without which every close fire-range would be utterly useless) is created in the chimney, and no range has ever been known to act correctly without a chimney of some sort, and they must be in proper connexion with each other.

To illustrate to what an extent carelessness enters into the fixing of these little ranges, it has been no uncommon thing to find one simply thrust into the chimney opening, with, say, two or three feet of flue-pipe placed on the nozzle, which is at the back of the hot plate, and nothing else done except cementing the opening round to make it tidy. In such a case as this the range proves the worst of failures, as the up-current of air, the draught, all passes in the open mouth (or throat, as it is more commonly called) of the chimney, and none passes through the fire to carry the flames, smoke, &c., around the flues, and, in fact, it is found difficult to keep the fire alight.

There is one necessary feature in fixing any and every description of close fire-range. That the range must be fixed air-tight, so that every particle of air which passes into the chimney, and which constitutes the draught, must first pass through the fire; there must be no openings, crevices, other flues, or passages leading into the range chimney so that air can pass in without being heated by first passing through the fire. A copper flue running into the range chimney is permissible, provided it has a well-fitted damper in it, so that when the copper is out of use the damper can be closed; when the copper is in use no ill result occurs, as it is adding its proportion of hot air to keep up the draught.

The range just spoken of as an illustration failed for want of a covering-in plate,—a plate extending across the top of the opening from side to side and front to back, a hole being cut in it to fit tightly round the flue-pipe, and a door being provided for the sweep to operate through and for ventilation or other purposes. The addition of this plate would have caused the pulling power (as it may be called in this instance) of the draught to exert itself wholly through the fire, and instead of the fuel being in a state of half combustion, it would burn fiercely as in a furnace, and the flame will be travelling through the flues at great speed with a roaring noise, which, however, can be instantly checked by the damper.

This is how every range should work if the conditions are normal, particularly iron-flue ranges which are expected to work a little more sharply, as there is no separation between parts and consequent leakage of air, as between the brick and iron work of brick-flue ranges. If a range does not work in this manner then there must be something wrong, but it does not follow that the range-maker is to blame, though no doubt some makes of ranges need a more complex method of fixing than others.

It is not very common for portable ranges to be fixed so that they will not work at all, as the majority of workmen know the need and use of the covering-in plate spoken of, but it is quite common for these ranges to be found working sluggishly, that is, taking an unnecessary long time to cook what is put in the oven, or on the hot-plate, the fire being rather dull, and the flues being quickly full of soot, which collects under the hot-plate in festoons, and the flues need sweeping almost daily instead of once a week. In a case like this it can with every confidence be stated that there is a leakage of air into the chimney somewhere, that is, the draught in the chimney is not wholly coming up through the fire.

If the range is newly fixed, it may be caused by the covering-up plate not fitting tightly round the edges, or the hole in it for the flue-pipe is badly cut, or it may be a copper or other flue running into the kitchen chimney, or a hole or aperture somewhere. It will undoubtedly be found that there is an opening at some point more or less easy to find that is causing the mischief. If the range has worked well, and then suddenly fails, it may be some of the soot-doors left out of place, the door in the covering-in plate left open, or some such oversight, unless some accident has occurred. The best way to discover leakages is with a lighted taper; by holding this to suspected places, the flame will be drawn in if there be an

in-current of air. Sometimes a range will work well when a leakage is known to exist, but this only happens when the chimney is high and very efficient, and can work the range well with its draught somewhat reduced.

Frequently these ranges are fixed standing out in front of an existing range,—one of the old pattern open ranges most probably; in this case it is much the best plan to carry the flue pipe from the portable range through the chimney-breast above the mantelshelf, and have the original chimney opening stopped across the top with a covering-in plate, as described before; if, however, there is a positive objection to carrying the flue pipe through the breast, then it can be carried up through the covering-in plate; but, in any case, everything must be air-tight. This cannot be too strongly insisted on. The joints in the flue pipe, and the joint where the pipe fits on the hot-plate nozzle, must be made sound. Common glaziers' putty is the very best article for jointing purposes, but the surfaces should be painted or Brunswick-lacked before the putty is applied, to make it adhere. Putty hardens with heat, and makes a really successful joint for all purposes like this.

Sometimes the front of the old existing range and the opening is entirely covered over with a large iron sheet, and the flue-pipe is just carried through a hole in this. This is a very inefficient method, as it is next to impossible to make this large sheet tight-fitting round the edges, and then no provision can be well left for the sweep, except by moving the sheet, which the sweep will not trouble to replace so secretly as it should be. If the front of the opening containing the old range must be covered, let a loose covering be used, but have a covering-in plate fitted inside as recommended.

If a portable range is fixed in front of an existing close-fire range or kitchen, there is a little feature which needs attention, and which may very readily be overlooked. This is the possible bad state of the brickwork flues behind the kitchen. If these are out of order, it is possible that the chimney will manage to draw air through this direction, to the prejudice of the small range, and it becomes very desirable to see that the range behind the portable one is air-tight everywhere before good results can be expected. In the same way, if a portable range is fixed in an opening from which a kitchen has been removed without pulling down the old brick flues at the back, these flues should be filled up solid with concrete or some such material.

In alluding to the frequency with which portable ranges may be found working sluggishly, let it be clearly understood that this is never, or hardly ever, connected with the height or build of the chimney. What has been spoken of is a sluggishness, that is, perpetual, no one day giving better results than another. If the range should work well sometimes and badly at others then the trouble cannot be overcome by any of the suggestions yet made; the fault will be most probably due to the chimney itself, which will be found to be subject to down-draught with more or less intensity at certain times when the wind blows from certain quarters. Of course, irregular results are oftentimes occasioned by irregular attention in cleaning the flues.

When a portable range is worked out in the open-air, as in military camps where there are no high surroundings, it is astonishing what a short length of pipe will act efficiently as a chimney. The writer saw some at Hounslow which were fitted with handles for convenience of removal from spot to spot, and these were working their very best with 10 ft. of 8-in. iron pipe for a chimney, but to do this it must be seen that all the joints in the range itself as well as in the pipe were well-made and sound.

Iron pipe flues for these ranges should be 7 in. for 30 and 36 in. size, 8 in. for 42 in. size, and 9 in. for 48 in. size or larger. Some may consider these sizes too large, for there is a strange notion prevalent that very small pipe flues will answer. These sizes are none too large, for the largest mentioned is smaller than a 9-in. square brick chimney, and no builder would think of building less than a 9-in. chimney for the smallest cottage range. Every joint in a pipe chimney must be made perfectly tight.

If desired two of these ranges can be worked into one 9-in. chimney, and will work perfectly, provided each has a well-fitting damper that can be tightly closed when either range is not in use.

THE SANITARY INSPECTORS' ASSOCIATION.

The annual presidential address to this Association was delivered on Saturday evening, the 2nd inst., at Carpenters' Hall, before a large audience, by Dr. Richardson, the main subject of the address being the change which during the past year has taken place in the constitution of the Association. The Association must be congratulated on having, at so early a period in its existence, become practically an incorporated society, or, to speak more exactly, a society limited by guarantee. Very rarely has any society so young been so greatly honoured. But the change brought with it increased responsibilities, and in carrying out the powers given to them in their articles he thought their first efforts should be to make a school—a thoroughly practical teaching school. Lecturers might be got and work commenced by next October. The President thought the programme of studies should include six subjects, but two of these were not of immediate necessity. The four necessary subjects were in order (1) Physiology,—not the teaching of the dissecting-room, though it should be of a serious, if popular, character; (2) Natural History, with microscopical studies; (3) Chemistry, with a well-fitted, if small laboratory, where research would be practicable independently of the school programme; and (4) Hygiene, their own proper study, the laws of health. The two eventual subjects were "The Theory of Hygiene," which presents the philosophic side of the matter, and lastly, what had been called by Dr. Despiné, of Marseilles, "Moral Hygiene," for which they could at present probably get no teacher and no class, but which might in the end prove to be the most beneficial of all. It might, perhaps, enable them to go so far as to undertake the cleansing of the world from all uncleanness. The lecture concluded with a retrospect,—a stock-taking of matters hygienical. English people often reproached the Continentals with neglect of practical sanitary measures, and we had now the French throwing back upon us the reproach, and retorting that we had done nothing to reduce the fatalities from disease, and had not touched epidemics. Whether the charge was true or not, could not be certainly known until we got the complete statistics of the last census, which would not be for another year. From an analysis of the statistics of the previous census, made by Sir E. Chadwick and himself (Dr. Richardson), it was found that in two classes of causes of death there had been no progress, but retrogression, although in the remaining classes improvement was shown. Taking each 1000 deaths from 1847 to 1880, there were from zymotic diseases of all kinds 23.26 in the former year, and only 20.09 in the latter,—an important reduction. Deaths from consumption had also diminished from 12.67 per cent. in 1847, to 9.12 per cent. in 1880, and from diseases of the digestive organs, from 5.82 to 4.74. There was also a slight diminution in all other classes of causes of death, except the two already mentioned, viz., "brain and nervous diseases," and "respiratory diseases other than consumption." The latter, which stood at 12.14 per cent. in 1847, had risen in 1880 to 17.78 per cent., and the former had risen from 11.54 to 13.12. This reduction in the case of the spreading diseases was no doubt due to improved sanitary drainage, and water supply, and the cases of consumption to the fact that people were better housed and better fed. Why there had been an increase in the case of the other respiratory diseases he could not tell, but that due to brain disorders was easily enough accounted for. Would there be an improvement for the decade 1880-1890? He would say Yes, with regard to consumption, not on account of improved methods of treatment, but because people were able to get better food, and because they had better sense. The increased numbers of those who played lawn tennis, and particularly of those who practised cycling, had been the most fruitful causes of progress; and the chief cause of the retrograde movement was, in his opinion, that *typhus fatuus*, the germic theory,—or rather the search for germs in all diseases. Good minds were led astray from seeing the paramount importance of cleanliness, from the principles established by the Board of Health, from the necessity of rapidly getting rid of excreta, of removing all obstacles from our streets, of systematising our methods of road-making to save man and horse, both great sufferers by

finding here wood, there stone, and in other places macadamised roads, instead of one general system of pavement. It was possible that the retrogression might be found to have gone on during the last decade, and with regard to the unfavorable movement in other respiratory diseases, there was much room for doubt. Some people believed insanity to be on the increase; suicides certainly were, and it appeared that cancer was becoming more and more fatal. The greater activity in political and literary matters, the increase of ambition, and the race for wealth obviously introduced severer strains, and accounted for the retrogression in the class of nervous disorders. One respiratory disease,—influenza,—which was baffling all the doctors and sanitarians, might perhaps be due to cosmic causes. Here they must all bend low and look for more light. The members of that Association could be depended upon, in the meantime, to go where it was their duty to go, and do what they thought best to be done to check disease, and, in conclusion, he wished them every success in their important work.

A discussion followed on the proposal of a vote of thanks, in which Mr. Perry (Hon. Member), Mr. Conson (Inspector, Chelsea), and Mr. Hugh Alexander (the Chairman of the Council) took part.

The vote of thanks was passed with warm acclamation, and Dr. Richardson briefly replied, explaining in doing so that he wished not to be misunderstood with regard to his remarks upon the germic theory. He did not deny the existence of germs nor their influence in one or two small classes of diseases, but he regretted that these discussions led to little practical result, while much practical good that might be done was neglected in theoretical discussions which absorbed energies that would be prolific in good results if devoted to the real battle against disease, and to improving our drainage and increasing public cleanliness.

During the proceedings, the death of Lady Chadwick (widow of the late President) and the cremation of the body at Woking were mentioned, and a resolution was carried asking the President to continue negotiations which were already in progress for a four days' visit to Paris at Whitstable, to hold the annual conference of the Association in that capital on the invitation of the most important Sanitary Association of France, namely, that presided over by the veteran sanitarian, Dr. Pietra Santa.

THE POLYTECHNIC INSTITUTION.

THE annual Industrial Exhibition of the Polytechnic Young Men's Christian Institute, which has been open since the first of the month at 309, Regent-street, and will remain open until the end of this week, admirably shows the wide extent of the work of this institution, under the guidance of Mr. Quintin Hogg, who generously devotes many thousands of pounds annually in furtherance of the objects of the Institute. The exhibition appears to show the work of the students in the various classes during the past year, and to this is added many specimens of the work of members who, though they may have been students once, are now more advanced. Though a distinction is made in the catalogue, it would have been more interesting if the arrangement of the exhibits had more distinctly marked this difference. Of the technical exhibits, the most interesting is undoubtedly the mechanical engineering work, and, considering that much of this has been done by students of eighteen or nineteen years of age, under the guidance of one technical instructor, Mr. Rogers, the result is an exceedingly good one. The exhibits include pumps, lathes, dynamos, engines, and tools of various descriptions. The lead-work shows the usual difficulties of bossing and soldering lead work successfully overcome; and adjacent to this exhibit is an example of oak and rubbed brickwork, showing a niche head and various capitals carefully expected, though somewhat lacking in vigour of design.

The exhibits of hootmaking, tailoring, harness-making, and carriage-building are interesting, though they cannot here be alluded to in detail. The furniture is entirely by members, and not by students, and is an interesting collection, in which the workmanship far exceeds the design. On a screen in this room are some most interesting sketches by Messrs. Herbert Ralton, J. Pennell, C. W. Wylie, and Alfred East, and others, which have been lent for exhibition by Messrs. Cassell & Co. The

joiners' and carpenters' woodwork exhibited are the usual specimens of joints and hand-railing which are set as exercises for the students. There is a large collection of drawings prepared in the building construction classes, upon which an immense amount of care seems to have been bestowed, and the construction is clearly shown. One case, however, of a cornice-stone, shown in section, appears to be sadly lacking in "bed," and would inevitably over-balance itself were it constructed as it is shown. There are several sets of designs submitted in competition for the Spencer Chadwick prize, the subject being a block of flats; but there is a singular lack of artistic conception displayed throughout. Though the exhibition is mainly the work of students, and as such must not be judged from too high a standpoint, we would call attention to the fact that there seems a great deal of room for improvement in the designs displayed, especially in the architectural drawings and in the furniture, jewellery, and other articles where, with every advantage, beauty of form might be allied with precision of workmanship. It appears that at present more attention is given to the latter than to the former, and we would commend this point to the careful consideration of Mr. Quintin Hogg and his colleagues who are interested in the capital work which this Institute is no doubt doing. One of the most interesting portions of the exhibition is the collection of steel and iron work and goldsmiths' work, lent from the South Kensington Museum collection.

Correspondence.

To the Editor of THE BUILDER.

THE FUTURE BUILDING ACT FOR LONDON.

SIR,—It is understood that among the many and extensive modifications in the Building Acts suggested by the County Council, there is one which affects the vacant space to be left for the use of buildings for light and ventilation. As this is not simply a proposal for allotting more space, but also introduces a new system of determining that space, it ought to be very carefully considered by all interested in London buildings. Its results are sure to be to some extent a surprise, and it appears likely to be far-reaching in its operation.

The new principle is that an imaginary plane is to be drawn from the back of the site at an angle of 45 deg. to the horizon (our old friend the angle of forty-five having lost credit of late with lawyers, has found some one fresh to take it up), and this plane of 45 deg. is to form a limit which the building is not to pass. Circumstances have caused me to consider what the effect would be on a good class of property,—say houses approaching 100% a year rent, and it appears that it is likely to excite an injurious influence directly by the alterations which would have to be introduced into the design, and indirectly by the changes that might be made inside to avoid the pressure of the enactment; and when I say an injurious influence, I mean an unsanitary one.

It will, of course, be remembered that by this rule no part of a building can be higher than its distance back from the starting point,—e.g., 20 ft. back allows 20 ft. high, and no more. Now, *primò facie*, it appears inconsistent that the same Act should allow the *fronts* of houses to be as high as they are distant from the points of opposite buildings, while the *backs* (supposing two rows of houses parallel and back to back) will have to be twice as far apart as they are high. Yet this would be the result.

Let us suppose a house of a basement and four stories planted, as many good houses are, so that the basement-floor is level with the back-yard or garden, the front road being on arches. If the house is 55 ft. high at the back, and the back land 45 ft. deep or less, the top rooms at the back would have to be entirely dispensed with, yet these would be the best-lighted and best-ventilated rooms in the whole house; but for sanitary reasons (1) they must go. If the room or rooms cannot be spared, they will have to be added above the back addition, with the result that they themselves will be less well ventilated and worse lighted; that they more or less must overshadow windows of other rooms at the back, making those rooms less healthy; and that they will

turn a back staircased window into a door, darkening the staircase, and depriving the lungs of the house of part of their supply of air.

Supposing a "tight fit," the method to which a builder of such houses could have resort in order to get his building into his site, would be diminishing the height of his stories, sinking his house into the ground, diminishing the width of his front area, and keeping up the level of his back-yard or garden. Every one of these expedients would diminish the healthiness of the house. I hardly think the Building Act Committee of the County Council can have foreseen all this, which, however, follows naturally from this proposal.

A DISTRICT SURVEYOR.

TOTNES CHURCH.

SIR,—“Viator” in his reference to rood-screens in last week's *Builder*, through a want of accurate information as to the details of restoration of the above church, has conveyed an incorrect impression. He says: “The great rood-loft has been destroyed within the last three years”; makes mention also of an eastern screen of oak as though that had been demolished at same time; and adds, “Meantime a hideous north gallery remains.”

An acquaintance of over thirty years with the church,—one of the handsomest in the west of England,—enables me to give reliable facts in this matter. The works of restoration, under the superintendance of Sir Gilbert Scott, and latterly of his son, which extended over a period of twenty-two years, were completed in 1888, nothing at all having been done to the fabric in the last three years. The beautiful rood-screen of stone is the most conspicuous feature of the interior, traversing its full width, an elaborate network of tracery, but lightly proportioned so as to present the least possible obstruction to the view of the chancel beyond. I well remember a gallery with high pews which, previous to 1870, bridged the church, topping this screen and resting on iron supports in the chancel; its floor may have been identical with the original rood-loft, but was quite a wreck after seventeenth-century “vandalism”; if an eastern screen of oak ever stood here it was at a period beyond the memory of any living inhabitant. This gallery shared the fate of the other galleries with which the building was encumbered; for all were removed in or soon after the year mentioned. The stair to the rood-loft still remains, though closed up with an ornate entrance; and to north and south there is a parlous state. A considerable sum was spent on the screen itself, the dilapidated stonework being repaired and re-instated, and the whole decorated in harmony with the old colouring which could still be seen. As to a “hideous gallery remaining,” the only ground for such a mis-statement can be that in an outer north aisle, built at the time of the restoration, a small gallery was placed to provide needful accommodation; it is not in any sense prominent, and the front panelling, which corresponds with the architect's other designs, is quite the reverse of unsightly.

Your correspondent says, “Perhaps the Vicar of Totnes will explain.” My reason for sending these few lines is that the late Rev. J. W. Burroughs, who was the animating spirit throughout the very arduous undertaking of restoring so large a church, was well known to me. The fifty years during which he was vicar have indeed left their mark, and he will long be remembered as one who exhibited in himself a happy combination all too rare,—faithfulness in the discharge of parochial ministrations and unwavering loyalty to evangelical principles, with a zeal that could not allow neglect of the “earthy sanctuaries,” but by reverent care must make it worthy of its sacred purpose. It is fitting that his devotion to this object should thus be put on record in your journal, especially as his sympathies were ever with “conservative” restoration. He entered into rest in 1888, and the towering walls of his old church overshadow his grave.

DEVONIENSIS.

SOFT TILES.

SIR,—Can any reader tell me of a preparation to render the surface of soft paving-tiles hard and incapable of forming a fine dust, which finds its way from the kitchen throughout the house?

DUST-HATER.

THE ENGLISH IRON TRADE.—After the holidays, the English iron market is naturally quiet, and the unfavourable character of the Scotch and Cleveland ironmasters' returns will retard any forward impetus. Prices, however, do not exhibit any material reduction. There is a hotter demand noticeable in the hematite iron trade of the north-west. Manufactured iron is still in moderately good inquiry; and in steel rails there is a slightly better tone, but the steel trade generally is quiet. Tinplate shows an improved tendency. Engineers and shipbuilders are fairly well engaged. The coal trade, on the whole, is moderately busy; and in South Wales fair shipments have been made, in spite of the stoppage of the pits which was threatened, the crisis, however, being fortunately averted.—Iron.

The Student's Column.

WARMING BUILDINGS BY HOT WATER.
II.

HEAT: RADIATION (continued).

THE following table shows the comparative radiating powers of substances. The absorbing and radiating powers of materials are equal, so that the table applies either way. The reflective powers of surfaces are in exact inverse ratio to the above; for instance, lampblack, which stands highest in radiating power, is practically devoid of reflecting power, as everyone knows. Polished metals, however, stand high as reflectors, but would give poor results as radiating media. A homely illustration is the copper kettle, which loses heat rapidly when dirty (the metal being an excellent conductor), but when polished the loss is reduced to a minimum.

Radiating and Absorbing Powers of Substances.

Lampblack	100
White Lead	100
Glass	90
Cast-iron, untouched	70
" polished	32
Wrought-iron, polished	30
Lead, tarnished	45
" clean	19
Zinc	18
Brass, clean, rough	12
" highly polished	7
Copper	7
Silver	3

Lampblack answering so well as a radiating material has led to the belief that colour affects the radiating power of substances, but this is not the case with dark rays of heat, such as we get with all hot-water works, and from all non-luminous bodies.

The radiating power of a body is not due to its substance, but to its extreme external surface, we may say, its skin. Lampblack, painted on, is very perfect as just mentioned. If this material composed the whole substance of the pipes, the effect would be bad, as being a poor conductor, the heat would not get through to its outer surface to be radiated. The high radiating efficiency of white lead points conclusively to paint being a very suitable material to apply to any exposed radiating surface which cannot be left untouched or coated with lampblack. All paints, particularly those whose colours consist of metallic oxides, answer exceedingly well, but they should be laid on thin, for the materials of pipes are not all good heat conductors, and no barrier, however slight, should exist to prevent the free escape of heat where it is desired. Undoubtedly lampblack, applied as a water colour, gives the best results if appearance has not to be studied; an application of this material to the silver pipe referred to would overcome the trouble mentioned.

There is a fancy for bronzing pipes and radiators, especially the latter, but although the effect may be liked as regards appearance, the results in regard to radiation are bad. All bronze powders, also gold leaf, and metals electrically deposited, are practically bright metallic surfaces, which have been already pointed out as being bad radiators. They are less efficient than varnished or painted surfaces. If a radiator or coil which is in use be half-bronzed and half-painted black, the difference in heat radiation from the two different surfaces will be actually perceptible to the hand or face, if tested at about 12 in. distance. In making an experiment like this, however, it must be first ascertained that the actual temperature of the radiator is alike all over; this is not always the case.

From the table quoted it will be noticed that glass is a good radiator of heat; whatever heat it absorbs, it parts with readily. This by itself might bring glazed porcelain and Donlon ware radiators into use, and which would be exceedingly pretty; but there is another point to be considered in the fact that the material of the pipes and the glazed surface itself are all poor conductors of heat, and would, therefore, give but little chance for the outer surface to show its radiating efficiency. Probably something of the sort may be successfully brought into use some day. It would be worth doing, for radiators, although decided improvements upon coils, are capable of being improved upon also, and to a considerable extent. Stoves are made in earthenware, and have a very handsome appearance; but the higher temperature of fire heat can be more easily dealt with than that

which we get from hot water. The former is retained, subdued, and tempered by the interposing poor conductor.

Before quitting the subject of radiant heat, special attention must be drawn to its non-effect upon the air. The radiant rays, as before mentioned, pass through the air without raising its temperature, and they only have effect upon whatever they come in contact with and impinge upon. From these objects that they encounter, there proceeds a re-radiation of heat, which also goes on without heating the air. The particular advantage of this is that human beings, as also most living creatures, benefit, and are also made comfortable by their bodies being kept at a good warmth, but at the same time breathing a cool or cold air,—air at a much lower temperature than the body enjoys. The extremes that this can be carried to are very great; this can be judged by the pleasure experienced in breathing the cold air of a bitter winter day, the body at the time requiring to be thickly clothed and of a temperature that is registered quite at the other end of the thermometer. Radiant heat, which is the most natural heat, fulfils this requirement by affording warmth to the surroundings, but without affecting the air.

There is, however, another good feature connected with radiant heat which, as it does not alter the temperature of the air, does not interfere with its proper degree of moistness. The moistness or saturation of the atmosphere has always to be considered in warm or hot-air works, and it has often to be provided for in works with exposed pipes.

It has to be explained that the air with every difference in temperature has a different capacity for water. The cooler the air the less water it requires or can hold in suspension, but in direct proportion as it gains in heat, it will imbibe moisture. If air has not a sufficiency of moisture in it, it is, to say the least, disagreeable, sometimes injurious, especially affecting those with throat troubles (as an east wind does, which also lacks moisture). Air, when saturated, contains water vapour as follows:—

Temperature of the air (Fahrenheit)	Quantity of vapour per cubic foot (Grains weight)
20	1.52
30	2.16
40	2.92
50	3.93
60	5.25
70	7.00
80	9.50
90	12.75
100	17.00

The capacity of air for water is about doubled by each increase of 27 deg. F.

As explained earlier, a hot-water apparatus with exposed pipes furnishes heat in two ways, viz., by radiation, and by heating the air which has contact with the pipes, &c., and not by radiation only, so that, properly speaking, some provision should always be made to add moisture to the air which is warmed. This, however, is seldom done, and as seldom needed, for with exposed pipes, the chief of the heat is radiated; the little increased heat to the air can readily supply itself with moisture from many sources. It is usually sufferers from bronchial affections who can instantly discover a dryness of the atmosphere. In this case moisture can be furnished by pans of water placed on the radiators; some radiators have the top castings capable of holding water which permits of the air helping itself, and the water itself also evaporates slightly with the warmth.

CONVECTION OF HEAT.—This is the way by which heat is conveyed (actually transported) by fluids. This action is almost of greater interest to the hot-water engineer than either of the others treated, as it really accounts for the existence of his calling. Water and gases—in fact, all fluids, are composed of elements existing in the form of minute molecules, grains, or particles. It is very necessary to understand that fluids are composed of atoms, to account for the action of convection. There is not the slightest friction or cohesive property existing among these particles—in fact, there is supposed to be a slightly repelling influence amongst them, for gases and water will spread great distances if unconfined and experiencing no restraining influence. It is to be assumed that the molecules of water are spherical to account for the very free motion amongst them; and a point to be impressed upon the reader is, that the utter absence of friction permits of an exceedingly rapid motion being attained. It is

sometimes a little hard to grasp this theory, but there are no solid and visible substances that act with a freedom any way approaching this.

There is a simple means of experimenting to ascertain and become familiar with the process of convection. Take a medium-sized glass jar or a wide-shaped bottle, and nearly fill it with water; then place or suspend it over a lamp,—spirit lamp gives the greatest heat, but the action is quite sufficient if the vessel is held over the glass chimney of an oil lamp. Before, however, any visible results can be obtained, we must put some substance in the water that will make the motion obvious. The best material to put in the water is amber, which must first be reduced to a dust, a fine powder. This should be stirred in. Amber most nearly approaches the gravity of water, and it will be found that a good proportion of the dust particles will remain suspended in the water without motion unless agitated. By watching the movements of these particles we may ascertain exactly what is happening with the water, for every movement is indicated by the amber.

Fig. 3 shows the motion of the water, if the heat is applied to the centre of the bottom of the jar; if the heat is applied nearer the side the action is more as fig. 4. The exact cause of the action is as follows:—

Before the heat is applied to the jar we may consider that the particles constituting the mass of water are stationary. Upon application of heat to the bottom we cause those particles which are in contact with the bottom surface to become warm, and as they absorb heat, they, like every other substance, to a greater or less extent, increase in size; that is, they expand, where heated. When a material expands with heat it does not, of course, increase in weight, consequently it may be looked upon as a lighter substance while it is hot. This is the case with the molecules of water as they become heated; they increase in size but not in weight, and, consequently, are, hulk for hulk, lighter than their colder neighbours.

The result of this difference in weight is that the particles being so mobile and free from friction, the heavier ones instantly force their way below the lightened ones and cause them to rise. This is just the same action as takes place if we take a piece of wood or cork and plunge it into a vessel of water and release it at the bottom; it instantly ascends to the top, it being a lighter material than the water. Therefore, we may understand, and experiment will show, that immediately warmth is imparted to the water at the bottom, a circulatory action sets in, the warmed particles rising and cold particles taking their place, which also become warmed, and rising, give place to more, and so on. The circulatory action of water, and its application to hot-water pipes, will be dealt with in the next paper.

SOCIETY FOR THE ENCOURAGEMENT OF THE FINE ARTS.—The thirty-third annual report of this Society, for the year 1891, briefly chronicles the proceedings of the year, and appends the programme for the coming year. The *conversations* will continue to be held in the galleries of the Royal Institute of Painters in Water Colours, Piccadilly. It has been customary to hold the first *conversations* in the month of January, but owing to the inclement weather which usually prevails at that time, the Council have decided to hold this *conversations* at a later date.

BELLS, NORTHWOOD CHURCH, STAFFORDSHIRE.—Messrs. Charles Carr, of Southwick, have secured the contract to recast and rehang the bells (weight, 22 cwt.) at Northwood Church, near Bucknall, Staffordshire.

GENERAL BUILDING NEWS.

HORSHAM GRAMMAR SCHOOL.—The Governors of the Grammar School being about to erect new school buildings and residence, eight architects of repute were nominated, from whom they have selected Mr. Arthur Vernon, of London and High Wycombe, as their architect to carry out the new buildings, which are to be commenced in the spring.

SCIENCE AND ART SCHOOLS, HIGH WYCOMBE.—New science and art schools are about to be erected at High Wycombe, from the designs of Mr. Arthur Vernon.

NEW BUILDING ESTATE AT BIRMINGHAM.—The first portion of a large building estate, situated at Sparkhill, a suburb of Birmingham, has now been completed. The builders were Messrs. Hughes & Son, of Sparkhill. At Edgbaston, another large suburb of Birmingham, a number of villa residences of somewhat similar character to the preceding, but with wider frontages, have also been completed. The builder was Mr. Edward Airey, of Gilchrist-road, Birmingham. The architect of these was Mr. John Statham Davis, also of Birmingham.

RESTORATION OF WOODLEIGH CHURCH, DEVON.—For the past seven or eight months the Church of St. Mary, in the parish of Woodleigh, has undergone restoration, at a cost of £1,220. The tower has been coped with granite, as it was found that the stones at the top were quite loose, and all the mortar was washed out. It has also been re-roofed, leaded, and pointed with cement. All the roofs of the building have been renewed, the inside showing oak boarding on a circular sweep, with oak purfin and ribs and bosses at the intersections. Inside the chancel roof has been treated the same way. The walls have been stuccoed with blue lime, these being previously covered with curious paintings in distemper. An attempt was made to preserve these, says the *Exeter Morning News*, but they have been so whitewashed over and over again that this was found to be impossible. Wood-framed windows have been replaced by granite, while those of stone have been renewed and pierced, the whole being filled with cathedral glass. What was known as the Hendham organ has been given up for use as a vestry and organ-chamber. The space underneath the tower, which formerly served for this purpose, is now converted into a baptistry. All the floors are tiled, and the pews, which have a flooring of Farris patent wood blocks, are of red deal, stained and varnished. The chancel arch has been rebuilt, and quoined with granite. On the north wall of the chancel, a window, which has been walled up for years, has been opened, and the spalls built with leaders and stretchers resting on granite sills. Within the chancel a rise is made by three steps of white Sicilian marble and encaustic tiles. In the north wall of the chancel there is an old eastern sepulchre, which has been preserved. Mr. G. H. Fellowes Pryme, London, was the architect; and Messrs. Farr & Sons, of West Alvington, were given the contract for the work.

COTTAGE HOSPITAL, HIGH WYCOMBE.—The High Wycombe Cottage Hospital has been recently enlarged and endowed with a sum of about £5,000, granted by the trustees of the East of Beaconsfield Memorial Fund from the surplus at their disposal. The new buildings consist of a large operation and convalescent room, bath-room, heated linen-chamber, and other conveniences, costing, with additional pieces of land, about 800. The new buildings were opened by Mr. Coningsby Disraeli, the heir of the late earl, on the 19th ult. Mr. Arthur Vernon was the architect, he having been the architect of the new buildings which were erected in 1875; and Mr. H. Flint, of High Wycombe, was the contractor.

NEW BOARD SCHOOLS AT PERCY MAIN.—The formal opening of new schools, erected at Percy Main by the Tynemouth School Board, took place on the 30th ult. The site, purchased from the Duke of Northumberland, is in one of the most prominent thoroughfares of Percy Main, namely, in John-street, and containing 2,500 superficial yards, with a frontage of 134 ft. 6 in., and a depth of 123 ft. Provision is made for 172 children in Standards I. and II., and for 166 infants, with arrangements for future extension to accommodate 108 more children. The main school is 60 ft. long by 22 ft. wide, with a central recess 22 ft. by 16 ft., and class-rooms at each end 20 ft. by 18 ft. At the west end are two infants' rooms, the larger one (fitted with desks) 27 ft. 6 in. by 22 ft., and the smaller one (with gallery) 22 ft. by 20 ft. Care has been taken to supply the largest amount of light and ventilation. The desks and fittings are all of oak. The playgrounds are cemented throughout, and the children will have the advantage of covered sheds for wet weather. The contractors for the whole of the works were Messrs. J. & W. Simpson, of North Shields and Elyth, and the buildings, which include a caretaker's house of four rooms, have been erected from the designs and under the superintendence of Mr. F. R. N. Haswell, F.R.I.B.A., of North Shields.

NEW COTTAGE HOSPITAL AT LEDBURY.—Mr. Michael Biddulph, M.P., has given to the town of Ledbury, in commemoration of the coming of age of his eldest son, Mr. John Biddulph, a cottage hospital, at a total cost of about £3,000. The new building is erected in a most commanding position

in the town, and immediately opposite a dwelling-house in which the Ledbury Cottage Hospital was opened nearly twenty years ago. The new building is of the Elizabethan style, and in addition to offering all the requirements of a cottage hospital, there is attached to it the residence for a town nurse. Mr. Hadden, of Malvern, is the architect, and Mr. George Hill, of Ledbury, the builder.

THE BUILDING TRADE IN SCOTLAND IN 1891.—The *Aberdeen Free Press* reports that the building trade in that city during the past year has been "fully more prosperous" than during the preceding twelve months. "Fewer new buildings have been erected, but the operations have been all over, on a larger scale. This will be fully seen when it is mentioned that with an addition of about 170 new houses and cottages to the city, as against nearly 250 in 1890, there is an increase in the valuation of the town through the erection of these new buildings alone of 6,308*l.* 7*s.*, as compared with 5,470*l.* for 1890. As a consequence, both the mason and joiner departments of the trade have been very fully employed. In the latter branch business was indeed exceptionally brisk during the summer months, and men were in great demand. This naturally led to a demand for a rise in pay. About the middle of May, therefore, and after the matter had been discussed by the trade "Board of Arbitration," the standard rate of pay was advanced from 6*d.* to 6*½d.* per hour, with 7*d.* and even 7*½d.* for very superior men. With the rise in wages, however, there was no corresponding rise in prices; competition has been tending, indeed, to become keener than ever, and as a result the profits of the employers continue to diminish. In fact, as one large employer in the city puts it, the masters begin to breathe an air of satisfaction when they find themselves clear on a job. The working day in the joiner trade, as among the masons, continues at the nine hours, and there appears to be no disposition towards a change on the part of either the masters or men. There is a feeling among the men, however, that another rise in wages might fairly be demanded about the beginning of the year; but it may be assumed that, before anything of the nature of strong measures are taken, the matter may be referred again, in the first instance, to the jointer Arbitration Committee."

The *Dundee Courier* says that during the past year the building trade of Dundee has been exceptionally brisk, it being estimated that over 200,000*l.* has been expended in the erection of dwelling-houses and public buildings or on making additions to works in different parts of the city. From a public point of view, the principal undertaking has been the new Parochial Hospital in Mains Loan. The Old Asylum grounds, it may be mentioned, have been the centre of activity, some blocks of shops and dwelling-houses having been reared on the site acquired from the Asylum Directors in Park-avenue, Morgan-street, Cardean-street, Albert-street, and Balmore-street.—The *Edinburgh Evening News* says that the year, on the whole, has been a satisfactory one from a labour standpoint. "Unskilled labour has been in far demand, the work carried on in connexion with the Water of Leith Purification Scheme and railway extension having given regular employment to a large number of men, but our survey concerns workers of a superior grade, and it is gratifying to note that, in the main, the position of the artisan has rather improved than otherwise. With one of the most important classes, masons, a reduction of wage had recently to be endured, following, however, a previous increase. In the early autumn the standard wage was lowered from 8*d.* to 8*½d.*, but notwithstanding, the masons are financially better circumstanced than they were twelve months ago, and that thing seem to have an upward tendency seems to be shown by the statement of one of the leading firms in the city that if they were asked to estimate for fresh contracts the possibility of increased expenditure in this department would be taken into account. The distinguishing feature of the past year from the builder's outlook has been the comparative absence of fluctuation, no congestion having occurred, in the first instance, because the openness of the weather at the beginning and end of the year has enabled the work to proceed unobscured. As has already been shown, speculative builders have not played so pronounced a part as in past years, and as private beneficence and commercial enterprise have alike provided, and will continue to provide, material for building operations, the year closes with the promise that in the succeeding twelvemonths matters will stand about their present level."

DISSOLUTION OF PARTNERSHIP.—We are informed that in consequence of the retirement of Mr. W. Frederick Simpson from the firm of W. B. Simpson & Sons, of 100, St. Martin's-lane, a dissolution of partnership takes effect from December 31st. The business will be carried on by Mr. Edward Henry Simpson under the style of "W. B. Simpson & Sons," as heretofore.

PARTNERSHIP.—Mr. Charles H. Beloe, M.Inst. C.E., of Liverpool and Westminster, has taken into partnership Mr. Frank E. Priest, Assoc. M.Inst. C.E., a former pupil, and for several years past the manager of his Liverpool office.

SANITARY AND ENGINEERING NEWS.

SEWERAGE WORKS, HAYES (MIDDLESEX).—A Local Government Board inquiry was held on the 31st ultimo with respect to the application of the Uxbridge Union Rural Sanitary Authority for the sanction of the Local Government Board to their borrowing 10,500*l.* for the purposes of sewerage and sewage disposal for the Parish of Hayes. Details were given in connexion with the application, of which the Inspector, Col. Ducat, R.E., took notes, and promised to report thereon in due course to the Local Government Board. The engineer to the scheme is Mr. Frederick Beesley, M.Inst. C.E., of Westminster. The system proposed for dealing with the sewage is that known as the International Purification Company's process.

EAST BROOK AND DYNAS POWIS WATER-SUPPLY.—The Cardiff Rural Sanitary Authority have now, after a considerable amount of opposition, supplied these important and growing villages with an adequate supply of wholesome water. Dynas Powis was formerly supplied by springs from a catchment area, gravitating into a reservoir having a storage capacity of 100,000 gallons, thence the water, after passing through a filter, gravitated to the village of Dynas Powis by 3-in. cast-iron socket-pipes for a distance of half a mile, where lately, owing to the increase of population, the supply had to be worked on the intermittent system, which proved both wasteful and injurious to the health of the inhabitants. In the meantime East Brook was supplied with water from some fifty shallow wells sunk in the neighbourhood of cesspools and surrounded with highly-manured garden land, resulting, as might be expected, in causing a great deal of sickness, arising from the effects of polluted water. The Rural Sanitary Authority, after the consideration of several schemes for augmenting and improving their own existing supply, so as to extend the same to East Brook, eventually agreed with the Cardiff Corporation to extend their mains from Llandough, through East Brook, to Dynas Powis Bridge, levying their own water-rates at East Brook, and discharging a supplementary supply in bulk into the mains of the Rural Sanitary Authority at Dynas Powis Bridge. For this purpose the Cardiff Corporation have laid about 2,500 yards of cast-iron 4-in. socket-pipes, together with lead service-pipes laid to the external walls of each dwelling house, and hydrants for fire-extinguishing purposes laid 100 yards apart on the 4-in. main, together with all necessary stopcocks, sluice and air valves complete. This work was effectually carried out under the superintendence of Mr. Priestly, Assoc. M.Inst. C.E., Deputy Borough Water Engineer, Cardiff. The Rural Sanitary Authority have also extended their mains at Dynas Powis, having laid 1,000 yards 3-in. and 500 yards 2-in. cast-iron socket-pipes, with all necessary sluice and air valves, stopcocks, hydrants, and water-meters complete; also 300 yards 3-in. and 200 yards 4-in. wrought-iron pipe, and 200 yards 3-in. and 300 yards 4-in. lead pipes, with all necessary fittings complete. The excavation for this work was carried out almost entirely in rock by Mr. Edmund Lewis, contractor, Dynas Powis. The contract for the supply, laying and fixing all mains and fittings, was carried out by Messrs. Cross Bros., of Cardiff, and William Fraser, Assoc. M. Inst. C.E., Surveyor to the Rural Sanitary Authority, was the engineer.

WATERWORKS AT AVINGTON PARK.—A new water-works have recently been constructed for Avington House, the seat of Sir Charles Shelley, Bart., which not only supplies the domestic requirements of the mansion, but make provision with a view of protection from fire, both at the house and at the stables. The supply is obtained from the Tohen at the waterfall in the Park, and close to the high road, the water being filtered through a small gravel filter bed before passing to the hydraulic rams constructed in a small building on the opposite side of the road. There are two 5-in. "Vulcan" high duty rams, each worked by a separate drive pipe, the effective working head being 7 ft. Each ram uses about 50 gallons of water per minute, and together they force upwards of 3,000 gallons per twenty-four hours to the reservoir, which is on a hill at a distance of 1,080 yards, and at an elevation of 126 ft. The rising main from the rams to the reservoir is of cast-iron socket-pipes, the spigots and sockets being turned and bored to ensure satisfactory joints, and is in two sections. The first section, from the rams to the mansion, distance 1,400 ft., is 3 in. internal diameter; the remainder from the mansion to the reservoir, distance 1,340 ft., is 6 in. internal diameter. The rising main is led into the bottom of the reservoir, and is used both as an up-cast and down-cast, thereby obviating the necessity of two separate lines of pipes. The fire hydrants round the mansion are five in number, and are placed in the most advantageous positions to gain complete command of the entire building. The reservoir is situated on top of a hill in Chalkdale Field, the elevation, as stated above, being 126 ft. above the hydraulic rams. It is excavated out of the hill, and is divided into two compartments by a longitudinal wall, each compartment being 50 ft. long by 14 ft. 6 in. wide by 8 ft. 6 in. deep. The reservoir contains, when full, 60,000 gallons. It is constructed of brickwork laid

COMPETITION, CONTRACTS, AND PUBLIC APPOINTMENTS.

COMPETITION.

Table with 4 columns: Nature of Work, By whom Advertised, Premium, Design to be delivered. Entry: Family Hotel, Clacton-on-Sea, J. Gilders, £100, No date.

CONTRACTS.

Table with 4 columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, Tenders to be delivered. Entries include: Wards at Fever Hospital, Belfast Union; New Road, Colver, Landaft High, Bld.; Water Supply Works, Nalston, N.B.; Water Supply Bore Hole, Armagh U.S.A.; Concrete Extension Works, Rugby Local Board; Joining and Laying Cast-iron Pipes, Municipal Ash (Giam); Broken Granite, Paddington Vestry; Granite Kerb, York paving, etc.; Roadmaking and T.P. Paving Works, Lewisham Rd. of Wks.; Hoisting Board's Offices, Hornsey Local Bd.; Kitchens, Boilers, &c., Electric Light Station, Dickinson Street, Manchester Corp.; Iron Castings, Lead Board; Making-up and Paving, Fulham Vestry.

CONTRACTS.—Continued.

Table with 4 columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, Tenders to be delivered. Entries include: Alterations to St. Stangerton Manor; Pierpont Foundry, &c., at Public Works; Palace Station, &c., Harrington; Works for Men's Club, Metchley, near Leeds; New Branch P.O., Manchester; Public Conveniences, &c.; Alterations to Sanitary Arrangements at Works; Works and Repairs to Public Buildings, &c.; Waterworks; New Engine and Well House; Erection of School Buildings; From Bazaar, or Hallway, Hull; Granite Sills, Curbs, and Channelling; Sewerage Works, &c., Birkdale, Southport; Western Chapel, Telford's, Haulley; Two Pairs of Office Quarters, Devonport; Wesleyan and Baptist, &c., Upper park; School of Craftsmen; Corn Law Commission; W. H. W. & Co.; C. H. Cox.

PUBLIC APPOINTMENTS.

Table with 4 columns: Nature of Appointment, By whom Advertised, Salary, Applications to be made. Entries include: Engineer's Assistant, Reigate Corporation, £150; Public Health Inspector, Civil Service Commrs.

Those marked with an Asterisk (*) are advertised in this Number. Competitions, p. iv. Contracts, pp. iv, vi, & viii. Public Appointments, p. xviii. & xix.

in cement, the floor being of concrete, and the roof is formed of wrought-iron girders, placed at distances of 5 ft. apart, the spaces being filled with shallow arches of solid concrete levelled on the top. This portion of the works has been carried out by Mr. W. Shearman, builder, of Winchester. The hydraulic rams were manufactured by Mr. H. P. Vacher, of the Vulcan Ironworks, Worthy, near Winchester, who contracted for and carried out the entire installation.

STAINED GLASS AND DECORATION.

MEMORIAL WINDOW, ST. JAMES'S CONGREGATIONAL CHURCH, NEWCASTLE.—A stained-glass window has just been placed in St. James's Congregational Church, Newcastle, by Mrs. Scott, in memory of her late husband. The work has been executed by Messrs. Heaton, Butler, Bayne, & Co., of London, and represents the incident in the Gospels of the meeting of Our Lord and Nathaniel.

STAINED-GLASS WINDOW, PARISH CHURCH, IDLE.—A stained-glass window has just been unveiled in the Parish Church, Idle, in memory of the late Vicar of Idle (the Rev. Henry Harrison). The window, which is the work of Messrs. Kayll & Co., of Leeds, has been erected under the supervision of Messrs. Kendall & Bakes, architects, of Idle and Leeds. It is divided by the gallery into two equal parts. The upper portion is filled in with painted glass, geometric in design. The lower half of the window consists of a representation of the "Good Samaritan."

WINDOWS, GIGGLESWICK CHURCH, YORKSHIRE.—Mr. T. W. Camm, of Smetwicks, has completed two windows for Giggleswick Church, Yorks. The east window contains the subjects of the Crucifixion and the Ascension, occupying the whole of the six lights, with their canopies and bases. The west window of the north aisle contains the subject of the Presentation in the Temple, in three lights. They are memorials to the Hartbury family.

FOREIGN AND COLONIAL.

DENMARK.—For a considerable time one of the leading questions in Copenhagen, as testified from time to time in our columns, has been the provision of better and safer accommodation for the valuable national museums.—viz., of Norse Archaeology, the People's Museum, the Ethnographical Museum, the Numismatic Museum, &c., which are now located in the so-called Prince's Palace, and one plan was to erect a couple of large new buildings for the storage of these treasures between Gøttersgade and Osterbro, where the new great Museum of Arts is in course of erection. But recently it has been considered whether, after all, the use of the Prince's Palace might not be continued by rebuilding it, and buying up certain properties around. An influential commission of savants and architects was appointed by the Government, and that body recommends that this plan should be carried out. It is proposed to buy up all adjoining properties, and by the making of a new street, to form a square complex of museums, isolated on all sides. The cost of this great undertaking is estimated at 87,000*l.*, the work occupying some five years. Professor Sterk has already prepared a preliminary design for the new building, which has been approved by the com-

mittee. The style naturally will be the same as that of the old building, viz., late Renaissance. It was built at the beginning of last century. The properties referred to around the Palace have already been acquired by the State.—In the neighbourhood of Vindrup, in Southern Jutland, Dr. Henry Peterson, of the Museum of Northern Antiquities, has excavated some barrows from the Bronze Age, in which a large number of oak coffins, made by hollowing out the trunks of trees, have been found, similar to those already found in Denmark, and being several thousand years of age. Some objects of bronze and wood were also found. Denmark is the only country possessing perfect examples from the Bronze Age. Those of men are all alike, but not so those of women. Of female costumes only one has hitherto been found perfect in Denmark. The discovery is, therefore, of some interest in an archaeological sense.

STUTTGART.—The new National Museum for Science and Art in course of erection is to have a central hall as a memorial to the late King of Württemberg. 6,700*l.* have been set aside for this purpose, and a competition has been opened for designs. The very detailed programme of requirements published shows that eight prizes are to be given, having a total value of 500*l.*

VIENNA.—On the grounds of the so-called "Music and Theatre Exhibition" to be opened next summer a "model" theatre is in course of erection, at a cost of some 65,000 *florins*. There will be 1,500 seats, and standing room for 500 visitors in the place. A large concert-hall is also being built on the grounds.

MISCELLANEOUS.

LECTURES ON ARCHITECTURE AT THE ROYAL ACADEMY.—Professor Aitchison, A.R.A., is announced to deliver six lectures at the Royal Academy on "Saracenic and Turkish Architecture." The dates are January 25 and 28, and February 1, 4, 8, and 11.

THE SLATE TRADE DURING 1891.—During the past year there has been a marked improvement in the demand for all sizes of slates, but more especially in one or two of the large sizes, orders coming in more briskly as the season advanced, so much so that the close of the year found the quarries with smaller stocks and better orders than they have had for the last fifteen years. The foreign and colonial trades have been very brisk, the home trade fairly so, but the present state of affairs is caused principally by the stoppage of over-production and the supply having been reduced so that it does not exceed the demand. When prices were low, quarries endeavoured to make up for diminished profits by increasing their make. This, in many cases, was forced to the utmost capacity of the quarry, and without any corresponding dead work being done, and with the inevitable result that the make cannot now be kept up without considerable expenditure, and in some cases the quarries are nearly worked out. The process of the "survival of the fittest" has been going on, so that most of the weak quarries have been closed, and only three new slate quarry companies have been registered. All old quarries re-opened, as there is practically no undeveloped ground on the Bangor or Festioug

voins. There have been no strikes or labour troubles, and the men are earning fair wages.

THE HARD-WOOD TRADE.—Messrs. C. Leary & Co.'s annual circular, dated January 4, 1892, on ship-building, furniture, and other hard woods says:—"The total imports of timber and plank [during the past year] are 1½ per cent. below those of 1890, whilst the deliveries show a reduction of 14½ per cent. The stock standing at an increase of 14½ per cent. There are 2,800 loads landing, as against 1,500 loads a year ago, the tonnage allowed is 9,985 tons, as compared with 18,826 tons, and that under charter but not yet loaded is 29,354 tons against 25,302 tons at the close of 1890. Timber.—The volume of business has been fairly satisfactory, but during the first half of the year prices steadily declined until very low figures were established. A decided improvement afterwards set in when it became evident that the supplies for the new shipping season would be light, in consequence of insufficient rains for floating operations. Prices have advanced about 20 per cent. from their lowest point, and the present position of the market is satisfactory. For the present the demand for the tonnage allowed to be more than moderate, the tonnage engaged for loading during the year is very reasonable, and a steady and satisfactory market may be anticipated. Plank.—The import has been heavy, the largest, we believe, on record; the deliveries show a falling off of 10 per cent., and the stock is more than doubled that at the beginning of 1890. The market was favourable during the first quarter of the year, after which the constant arrivals began to tell, and prices quickly declined about 10 per cent. The demand has been languid during the last six months and prices remain depressed, but with moderation in the supplies we see no reason why there should not be a steady recovery to more satisfactory values."

RESULTS OF AUCTION SALES IN 1891.—According to "Extracts from late Exchange Registers," the total of sales reported from January 1, to December 31, 1891, amounted to 4,174,915 *l.*, as compared with 4,447,840 *l.* in 1888; 4,304,954 *l.* in 1889; and 4,287,111 *l.* in 1890. There has thus been a continued decline during the past four years.

A MAIN ROADS ARBITRATION.—A dispute between the Hampshire County Council and the Bournemouth Town Council respecting the cost of maintaining main roads through Bournemouth, was decided a few days ago. The length of road was three and a half miles. The Town Council originally claimed 1,868 *l.*, which was refused by the County Council, on the ground that it was exorbitant. The County Council offered 1,400 *l.* This was refused by the Town Council, on the advice of the Borough Surveyor, Mr. F. W. Lacey, by whom this claim was amended. The matter was finally referred to the arbitration of the Local Government Board, and in July last Mr. T. Coddington, M.I.C.E., attended at Bournemouth for that purpose. Besides Mr. F. W. Lacey, the Borough Surveyor, Mr. C. Jones, of Ealing, Mr. J. William Weaver, of Kensington, and Mr. J. J. Strachan, of Brentford, gave evidence for the Town Council, and Mr. Jas. Robinson, County Surveyor of Hampshire, Mr. Fletcher, County Surveyor of Dorsetshire, Mr. Charles Meads, of Bournemouth, Mr. Charles Meads, of Bournemouth, Mr. Robert Phillips, County Surveyor of Gloucestershire, and Mr. Charles Tomes, Borough Surveyor of Eastbourne, for the County Council. The award has now been settled at 2,600 *l.*, nearly 800 *l.* in excess of the original claim.

LONDON.—Accepted for decorative works at No. 5, Upper Hamilton terrace, N.W., for Mrs. Platon..... £260
Grosvenor & Co., Limited..... £250 0 0

LONDON.—Accepted for alterations and sanitary improvements and decorations at No. 5, Chester-place, W., for Miss Jones.—
Grosvenor & Co., Limited..... £175 0 0

TWICKENHAM.—For sanitary and decorative repairs to "Cherry-bank," Cambridge Park, for Dr. J. Compton Burnett, M.D. Mr. Alfred Broad, surveyor, 27, Dinehall road, Croydon.—
E. Soper & Co., Limited, 1, E. J. Somers-street..... £238
Harcourts & South..... 348 E. P. Baint, Croydon..... 225
* Accepted.

WALLINGTON (Surrey).—For the reconstruction of small shop property in Manor road, Wallington, Mr. Henry Gough, architect, Bank-consultant, North Road, Croydon..... £224 0
Stewart..... £274 0 Owen..... £220 0
Andrews..... 238 0 Bournes..... 220 0
Clark..... 279 0
* Accepted.

WIMBLEDON.—For paving work in the Hill-road and High-street wharves, for the Wimbledon Local Board. Mr. C. H. Cooper, A.M.I.C.E., Engineer and Surveyor—

Table with 2 columns: Name of contractor and amount. Includes Patent Portland Stone Company, Malcolm, Woodcock & Co., A. J. Phillips & Co., etc.

SUBSCRIBERS IN LONDON and the SUBURBS, by depositing at the Publishing Office, 19s. per annum (or 4s. 3d. per quarter), can ensure receiving "The Builder" by Friday Morning's post.

Nature in Ornament.

WE fear that Mr. Day is not far wrong in his remark, in the introductory chapter to the book before us, that "even in these days of supposed interest in things decorative, the Englishman generally speaking neither knows nor cares anything about the subject. He is in most cases absolutely out of sympathy with it. . . . The forms of ornament he most admires are those most nearly resembling something in nature, and it is because of that resemblance he admires them: abstract ornament is quite outside his sympathies and beyond his understanding." Mr. Day, indeed, thinks that the bias of the natural man is in the direction of nature; it is only by thought that he arrives at the perception of the necessity for treating nature in such a manner as to render its suggestion subservient to the true office of ornament. The reason why the Englishman, of all Europeans, is most out of touch with the art of ornament, is probably that he has never been accustomed to regard it as a subject worth serious thought. If he could be got to give his mind to it, he is as intellectually capable of comprehending it as most other people.

There are, however, many more people in England who understand the subject now than there were fifty, or even twenty years ago, and it is at all events a satisfaction to consider that there is sound teaching to be had in this country for those who care to look for it. Mr. Day's beautifully-illustrated little works on "The Planning of Ornament," "The Anatomy of Pattern," and "The Application of Ornament," may be named among text-books which are at once sound in principles and attractive in style and manner, and which may we hope have already exercised some influence. The present work, belonging to the same series of "Text Books of Ornamental Design," is naturally a larger work

than its predecessors, for it deals with a much larger subject, the whole relation of natural forms to ornament; a subject which demands serious thought on the part of the artist himself, and on which a certain degree of difference of opinion may be expected and allowed for even among those who are entirely at one as to general principles in the design and application of ornament.

The subject of nature in ornament leaves on one side a whole division of the subject of ornament; all that kind, namely, which comes under the head of mere pattern-making, the arrangement of lines and squares and circles and other such geometric forms according to a certain order. The tendency to pattern-making of this kind is perhaps, after all, more inherent in the uncultivated mind of man than the tendency to the imitation of natural vegetation; at least we find it the predominant influence in most ornament of uncivilised peoples. In the earliest archaic Greek pottery, even, the ornament consists mostly of mere lines, marks, triangles, and other such forms, arranged in a more or less systematic manner. In a higher stage of culture these materials are refined into very effective forms of ornament, but the variety of designs to be made from geometric forms does not seem to be very great; at all events the actual variety developed and used in ornament has not been very great; they fall into a few well-known types, which have been used over and over again with little variety in the motive. The Japanese and Arabic puzzle-designs, as they may be called, look very intricate, and the Arabic forms have a good deal of variety in appearance, but an analysis of them rather reduces our respect for them; the method is simpler than appears at first sight, and the variation less. We cannot get very far in the elaboration of diaper ornament without introducing forms that are not geometric, and that bear some relation to physical nature, unless with the aid of colour. With that assistance the variety of permutations is no doubt much enlarged, as we can see in such a mere toy as the kaleidoscope, which has a practically endless range of patterns. But the production of patterns on that principle could perhaps hardly come under the category of

design in the true sense; it is rather ingenuity.

But if geometric forms are rather limited in number, this cannot be said of the forms of physical nature, which are practically endless in variety; and it is, as Mr. Day remarks, somewhat curious to consider how few of these have really been used in ornamental design. Most schools of floral design have kept to a very few types or examples in nature. But in spite of this, even this small volume gives us evidence in its illustrations of an immense variety of ornament more or less directly connected with nature. And this variety, if we examine into it, we find arises to a great extent from variations of treatment suggested by the varieties of material or method of execution. Woven ornament on textiles is entirely different from carved ornament based on the same natural form; stencil ornament again is different from either; varieties of light and dark in treating the same type are endless. No one could even turn over Mr. Day's book without being struck by this immense variety in the illustrations; and this fact is certainly hopeful for the future. When we regard the variety of actually existing ornament, and the few natural types which have supplied it, and reflect what an amount of suggestion there is in nature which has never yet been pressed into our service in this way, we ought to feel that there is still a very large field open for the designer in ornament. If we have run in certain tracks, and repeated a great deal of what has been done before us, this is rather from want of enterprise, purpose, and thought, than from want of material supplied to us by nature.

"Material supplied to us by nature:" that is the true position in the relation of nature to ornament. However we may try to escape from this prison-house of the intellect, we are brought up, whichever way we turn, by the fact of the incapacity of man to absolutely originate form. Even if we regard such an ornament as the Greek "honeysuckle" as in reality "brush-work," and not imitation of floral form, we cannot help admitting that it is suggested and permeated by the recollection of floral form, unconsciously if not consciously. That is the true relation in which natural

* "Nature in Ornament." By Lewis F. Day. With 123 plates and 192 illustrations in the text. London: R. T. Batsford. 1892.

forms stand to ornament: they form the material on which to work by adaptation to the methods and materials employed.

And this consideration has something to do with the desire of the ornamentist for conventionalism. There is of course the fact to be taken into account, that we cannot, in the materials mostly used for ornament, really imitate and reproduce the infinite variety and delicacy of nature. If we could, there might be more excuse for naturalistic treatment. But naturalistic treatment really means flower-painting for its own sake, not the production of ornament suited to a special material and a special situation. The things which we ornament are in themselves artificial, and we have to suit the natural forms to their artificial position and employment,—to make them part and parcel of what they decorate. But beyond this is the desire to make them in a sense our own. We cannot originate form but we can originate treatment, and thereby render the form to that extent a new creation of our own. When we stop short of this, we have stopped short of inventing. "Nature" says Mr. Day, "is very ready to suggest, as the Pompeian bronze-worker realised when he went to the river side for a reed as 'motif' for the ornamentation of his candelabrum." But the fault of the candelabrum in question, as illustrated in cut 4 in the book, is that the Pompeian artist did not take it merely as a suggestion to work out his own idea from. The stalk of the candelabrum is too close an imitation of the original, too naturalistic; the artist contented himself with imitating, instead of working out his own treatment from the suggestion of nature. Hence this particular illustration is misleading, which cannot be said of many in the book.

The stalk is in fact one of the greatest difficulties in the adaptation of nature. Leaves and flowers mostly fall into forms which have more or less of the quality of artistic design in them; some of them require little conventionalising to fall into their place as ornament, others require a great deal; some are so deficient in grace and definiteness of form that they will hardly lend themselves to ornament in any recognisable form. This is the one drawback to the hopefulness of the prospect for the future, contained in the inexhaustible variety of nature. Not all the forms of natural foliage or flower will equally lend themselves to adaptation as ornament, and it cannot be denied that those already used (if not used up) are among the most suitable for this treatment. The instinct of men in past ages has led them to the best available forms. Still there are many left unused for us to try our hands upon.

But it is difficult to treat the stem conventionally except by conventionalising away most of its natural characteristics. Mr. Day remarks that the thickening of the twigs where they join on to the central stem is an incident which has been rather overlooked, and little or nothing been made of it. But it is rather difficult to see how it can be retained without retaining too much of the natural appearance. How often do we find, in wrought-iron work for instance, the stem the one blot on a design; the leaves sufficiently and finely conventionalised, the stalk half naturalistic, striking a false note in the combination. It would be an interesting subject of study to note the manner in which the generating stem of design founded on foliage has been treated in various styles of ornament. The Greek and the Hindu alike treat it in scrolls, with cleanly-defined artificial lines, and similar treatment is seen in the best periods of Gothic work. In some of the carved foliage of the Transition period it is partly naturalistic, and (what is worse) angular in its lines or crippled in its curves. In the later Decorated Gothic we meet with this vice of naturalism in the stalks again. In the Roman scroll there is no naturalism of detail, but there is too often the crippled curve which destroys the æsthetic balance of the design. How

different from the Greek scroll, in which the central stem is an almost geometrically-designed curve, from which sprout foliage having a closer alliance with natural form. That is the true treatment; the central portion from which the details spring should be the most highly-conventionalised; the nearer we get to extremities, to minuter details, the more freedom we may allow ourselves. The want of this perception is the one defect in the well-known and in some respects splendid piece of Indian perforated tree ornament of which a portion is given on Plate 77 in the book. The minor details are fully conventionalised, but the twisting eteme from which they spring are too naturalistic, and bring us too close to the actual nature of a tree, which should only have been more distantly suggested.

Mr. Day commences with a chapter, after the introductory one, on "Ornament in Nature," notes on the ornamental character shown in natural objects, as a prelude to the reverse view of the subject, "nature in ornament." In the latter chapter the author emphasises somewhat the idea that apparently natural ornament may not always have been derived direct from the study of or from any desire to imitate nature; it may have been hush work with unconscious reminiscence of nature. He gives examples of the Greek and Roman acanthus leaf, and a classical scroll of his own, translated into brush work, but the illustrations will hardly be taken as supporting the view that the brush-work was the first form. They are interesting rather (the two forms of scroll especially) as examples of the entirely new effect which may be given to the same decorative idea, in a sense in fact the same design, by varied methods of execution. We then have two further chapters on contrasted subjects, "the simplification of natural forms," and "the elaboration of natural forms." Simplification is in a certain sense one form of conventionalising, generally adopted because certain details of the original object will not lend themselves to the process or material employed; sometimes because breadth and simplicity are gained by this means; but there is a danger in this simplification of losing the essential character and suggestiveness of the original; and indeed, as Mr. Day does not fail to point out, some of the distinctive character in natural foliage depends on such slight details that the simplification process may very easily result in destroying character and reducing several different types of nature to similarity. On the other hand, he gives an admirable example from a panel designed by G. E. Street, in which the thistle is simplified out of nearly all its smaller details and yet the character of it is fully preserved—it is a conventionalised thistle and nothing else. The elaboration of natural form, adding to it a greater multiplicity of detail than in the original, is a process which is justifiable or not chiefly in relation to the nature of the material in which the work is executed. To do it in carving would in most cases, perhaps in all, be the worst form of mistake. To do it in silk embroidery, where a highly enriched surface effect is desired, by filling in the surface of leaf forms with delicate ornamental work, is a perfectly suitable and even necessary kind of elaboration, without which embroidered design founded on natural forms would be but a poor and ineffective affair. In such a case the natural forms are the framework only of the design; in carved work they form the essential element. "Consistency in the modification of nature" forms the subject of the following chapter, a very important point which certainly receives more attention from designers now than it used to receive. That ornament which simulates or recalls growth should follow the natural laws of growth is now generally recognised. There are other forms of inconsistency however, not so obvious but equally important to avoid; such as inconsistency in character. Mr. Day gives two instructive examples of this in treatment of design derived from oak-leaves, with a delicacy

and symmetrical character of the leading lines quite foreign to the character of oak growth. Such examples might be multiplied, no doubt; and another form of inconsistency, of which Renaissance ornament is full, is that of the combination in one design of details from plants which have no kind of relation to one another either botanically or in a decorative sense. "One of the most irritating things," as the author remarks, "is to see flower-like catherine-wheels, or other such prim rosettes, on stems suggesting growth, or to find naturalistic flowers springing from quite arbitrary and mechanical lines."

In two chapters on "Parallel renderings" the author gives a number of very interesting and instructive examples of the different rendering of the same plant in different styles and materials. A student of ornament would find it very good practice to extend these experiments, and see how many different treatments of the same flower, distinct in effect but each suitable to the circumstances, can be suggested by the various conditions of different materials.

"Animals in Ornament" forms the subject of a separate chapter, with some very good examples of conventionalised animals, and a warning against the rash employment of animal forms in too realistic a manner. We presume that the odious wall-paper with snails (Plate 98: German we are glad to say!) is a warning and not an example, though it does not appear to be condemned as heartily as it deserves. In regard to "The Element of the Grotesque" the author is apologetic, admitting that it has been much abused, but claiming that it has its rightful place in art provided that the designer can put as much of consistency, anatomical and otherwise, into his creation as to give a certain possibility of existence to it. Here we quite concur with him, though we cannot concur in thinking that even any half apology is possible for the monstrous panel by Sansovino given on plate 104. Such things are unpardonable under the shadow of whatever great name.

We may conclude with a very good paragraph, from the chapter on "Consistency," in regard to the general question of the manner in which the ornamentist should make use of his studies of nature:—

"The designer can hardly make too many studies from nature, but he can easily make bad use of those he has made, and easily encumber himself with them. A man can design quite freely, only when the burden of natural fact is so familiar that to him it ceases to be a burden. Refreshing as it may be to refer to his studies, or to nature herself, he cannot design with either in front of him. The actual thing is not malleable enough for his purpose, whereas an impression or a memory of it accommodates itself in the most surprising manner to the conditions of the case, and the necessary modification occurs as though it were a matter of course."

SILCHESTER.

BY MR. G. E. FOX, F.S.A.

It may be remembered that an account appeared in the *Builder* in January of last year of discoveries made in the course of the year 1890 at Silchester, near Reading, the site of the Roman city of Calleva Atreburum.

The excavations on the site, undertaken in that year under the auspices of the Society of Antiquaries, were continued during 1891. Within the last fortnight, the antiquities then obtained have been exhibited to the public in the rooms of the Society at Burlington House, together with plans of such further portions of the city as were uncovered in the course of the last summer and autumn.

The discoveries of the second year of exploration do not yield in interest to the first and our knowledge of the character and arrangement of the ancient Roman city has been considerably extended.

The examination of the remainder of the first Insula, a block, begun in 1890, formed part of the work last year, and two more of these blocks, formed by the intersection of the streets lying west of the *basilica*, were undertaken and thoroughly investigated. A

Excavations on the site of Silchester: some of the objects of interest discovered during 1891.

the south-west corner of Insula I. occurred traces of a large house. From amongst the ruins of the foundation was dug up the curious disk of bronze here figured (see sketches). The inscription surrounding the eagle, its central ornament, has been read as COH. OPTIME. MAXIME, the missing letters being made out from another specimen, exactly similar, found in the station of Bremenium, beyond the Roman Wall. The use of the object has not yet been determined. Close by a drum of a column was dug out, and a fragment of a fine Corinthian capital which had once formed part of one of the columns of the colonnade of the neighbouring basilica. A large piece of a wall-slab of foreign marble was also turned up near the same spot.

The examination of Insula II., to the west of the basilica, showed the former existence of a large house at its north-east angle, and along the east side an almost unbroken line of buildings. The mosaics here given came from a series of chambers. The centre of one floor was successfully raised, and was placed in the Society's exhibition this year. The mosaics formed the ornamentation of the rooms of a wing of the house just mentioned, and though of interest as revealing alterations made in the house at a late date, were but of simple character and design.

More fruitful, however, were the results obtained by the excavation of the south-west corner of this insula. There were found the foundations of a perfect house. The plan showed a small dwelling of four or five rooms, to which was attached a long line of shops and store-rooms. Access to these, from the

house, was given by a long corridor at the back. Only one of the rooms of the house was warmed by a hypocaust, which was of a composite character,—i.e., partly formed of piles of brick, partly of masses of masonry. A detached chamber, its use could not be determined, lay a few feet east of the house. It had a well-laid floor of brick tesserae, and in one corner stood the little base, of which a drawing is given.

Insula III. showed as many traces of buildings as Insula II. did. It lay to the south of Insula II., and the houses in it had been much ruined. Traces of baths, or what may have been baths, were found in the south-east corner, and from among the foundations there came a fragment of the inscription cut in a slab of Purbeck marble, and figured here, and two bases of half columns also given. The plan of a small but very complete house could be made out in the centre of the south side, perhaps in some way connected with these baths.

The interior of both insulae showed open ground dotted with rubbish-pits, but in both the houses were close together, and the open ground of smaller area than in Insula I., examined in 1890. Another fact worthy of notice was the presence of many hypocausts in the buildings, the house at the north-east corner of Insula II. having as many as five or six. Why this was is readily accounted for. The city stood on high ground, and was exposed to heavy gales from the south-west, bringing much rain, whilst the land to the north of it was open heath.

The rubbish-pits afforded a rich harvest of all kinds of objects, but mostly of pottery,

specimens of which, illustrating leading divisions, are here given. The contrast between the strictly Classic ornamentation, as seen on the fragment of so-called Samian ware, No. 1, and the long, bean-shaped scrolls of thoroughly Celtic character on the pot-shaped vase, No. 2, is well worthy of remark.

The forms of the bronze fibulae found were mostly those of the two illustrated, the front of one of which has been ornamented with enamel. These might afford to our jewellers some of the hints which they are so much in need of.

It would be quite possible to combine thin, graceful lines, full of character, with that display of the precious stones which seems to be the one thing sought after at the present day.

The exhibition at the rooms of the Society of Antiquaries closed on the 14th. The contents, like those of the former one, will be deposited in the museum at Reading, by the desire of the Duke of Wellington, to whom the site of the Roman city belongs. As the excavation of the site, under the auspices of the Society of Antiquaries, will be continued as long as public subscriptions are forthcoming for the purpose, as it is hoped they will be, the collection may become, in course of time, an exposition of the Romano-British period scarcely to be equalled in England.

G. E. F.

WESLEYAN CHAPEL, & CO., HARRGATE.—We are asked to state that, in a limited competition for the Wesleyan chapel and schools, Harrogate, the design submitted by Messrs. Morley & Woodhouse, architects, of Bradford, has been accepted.

NOTES.

Our readers will concur with us in our expression of deep regret and sympathy in regard to the sad loss which has fallen upon the Royal family of this realm by the lamented death of the Duke of Clarence, an event so national in its interest that it must come home to all classes and professions. There would in any case have been a universal feeling of sympathy for the bereavement of the Prince and Princess of Wales, who have endeared themselves to the country by their general courtesy and kindness in public life, and who are known to be affectionate parents in private life; but in this case we have to deplore not only the loss of a son of the Prince of Wales but of a future heir to the English throne, while the event is rendered still more sad from the fact that the young Duke was in a few weeks to have entered into a marriage which had the good wishes of the whole nation, irrespective of creed or party.

THE Crystal Palace Electrical Exhibition was supposed to be open to the public last Saturday; those, however, who went there on that date in expectation of seeing the Exhibition were soon undeceived. The machine-room, generally the most interesting, was closed altogether, and the nave was redolent of paint and encumbered with ropes and ladders, while everywhere the sound of hammers was unceasing. Some few stalls, especially those at which light and portable articles were exhibited, were in a state approaching completion, while others were entirely empty, and in the galleries this latter state of things predominated. Special attention seems to have been paid to the question of electric fittings, and a good deal of taste and ingenuity is displayed in devising novel and artistic lamp supports and in pleasantly screening the light; but we regret to see that the heavy and ugly supports inherited from the gas decorators have too often survived. The exhibits of the General Post Office are nearly ready, but are not yet all numbered; most of them are very interesting historically, and, whether designed or not, the earliest and roughest of these are in close proximity to cases containing highly-finished specimens of Sir William Thomson's latest instruments, as though to mark the advance in the science within less than sixty years' time. There is a catalogue moreover, "First edition under revision," as we are informed on the back. We trust the revision will be thorough: it is certainly required. If anyone wants to find a particular exhibit and chances to know the name of the exhibitor he may be able to find it; if he knows only the name of the instrument the index gives him no help; nor can one even walk conscientiously round, catalogue in hand, and trust to numerical order; the exhibits seem arranged in the catalogue quite at random. Thus we find on page 73 (we opened the book haphazardly)—"No. 208 South Gallery, No. 76A Machine-room, No. 68 Machine-room" as consecutive entries. "The Court would be obliged to you, Mr. —, if you would arrange your facts in some sort of order; chronological order is the best, but any order will do—alphabetical order," a witty judge once said to an embarrassed junior. The G.P.O. part of the catalogue adopts the judge's "best" chronological order, but this is unsuited to the rest of the exhibition, which is not historical, and we find on looking more closely that there the alternative is "alphabetical order." The exhibits are divided into sections lettered from A. to P., and in each section arranged according to the alphabetical order of the exhibitors' names. To each section there is an introduction, with a fair sprinkling of the usual blunders of popular science, but we must postpone further notice of the exhibi-

tion and its catalogue until the former is really open and the latter has been revised.

WE have to thank many correspondents who were exhibitors in the Architectural Room of the Royal Academy last year for their very cordial letters in regard to the "Builder Album of Royal Academy Architecture," which contains in a folio volume the illustrations published in this journal of drawings exhibited at the Royal Academy and lent by their authors, either before or after the exhibition, to be lithographed for our pages. Although some extra copies of the Album are available for those (non-contributors) who may wish to possess it (as will be seen from the publisher's announcement on another page), the main object in issuing it has been to present to the many architects who paid us the compliment of wishing their Academy drawings to be illustrated in the *Builder* a return for their courtesy in the shape of a collection of these drawings, which, besides being of interest for the moment, may in time have a certain historic value. The collection of a number of the Royal Academy exhibits in one volume in this manner may also have a value, as our contemporary the *Athenæum* has observed, in showing that the "Architectural Room" exhibits of the year "merited a great deal more attention than they had received." We refer to the subject here chiefly to point out that, as one of our correspondents says, "it will be the fault of architects themselves if the future volumes are not of equal interest to that now published." We desire to render these Albums a valuable series of permanent records of the Academy architecture of each year; but we can only hope to do so by the hearty cooperation of the exhibitors themselves.

THE Abbey Church of Notre Dame, at Fécamp, in Caux, totally destroyed by a fire which broke out in the liqueur distillery last Monday night, stands in the middle of the town on the river Fécamp. It had been founded in 666, by, as some say, St. Ouen, Dagobert's Chancellor, and Archbishop of Rouen, founder also of St. Wandrille, Jumièges, Saint Sésens, and Fleury. William Longue-épée supplanted the nuns with some canons regular. His son, Richard I., Duke of Normandy, rebuilt and richly endowed the church, in honour of its relic of the Holy Blood, in 988; his grandson, Robert the Devil, the Conqueror's father, bestowed it upon a band of Benedictine monks from Dijon. To such wealth and extent did the monastery increase that when suppressed about 100 years ago, it covered 13 acres, including the gardens, and had a revenue of about 6,500*l.* per annum, with jurisdiction over 36 parishes, 11 priories, and 14 cells. The buildings, though unfinished until the sixteenth century, consisted mainly of fourteenth-century work: two round-arched apsidal chapels at the east end being earlier in date, the south side of the choir, and the Chapel of the Virgin, marked with its wolf and fox gargoyles, being later. By the Virgin chapel stood the tombs of Richard I., Ssns-peur, and Richard II., le Bon, Dukes of Normandy. The nave, about 460 by 160 ft., had an arcade of ten piers carrying a smaller arcade, and above that a triforium. The tower (which has altogether fallen) at the crossing, and rising 210 ft., was of the eleventh century. The monk Chardon's remarkable group of the death of the Virgin stood in the south transept; in the north transept the seventeenth-century big clock. Some of the abbey remains were adapted to purposes of the mairie, and the municipal library.

THE abolition of the second class on railways is slowly but steadily becoming more general, in spite of the protests raised

by some of the Great Northern passengers who were "evicted" in consequence of the adoption of this policy by that company. The discussion which followed upon the Great Northern announcement proved that the main objection to the change was that it deprived a certain section of the travelling public of an "almost indispensable refuge" from the rough company sometimes, unhappily, encountered in third-class carriages,—a difficulty which, it will be remembered, was met on the Midland by reducing first-class fares to the figure charged on other lines to second-class passengers. Among the contributors to the discussion was the Chairman of the London and North-Western, who expressed a determination on the part of his company to continue their present policy, and not to throw their intermediate class overboard. Some surprise has, therefore, been expressed at the announcement that no second-class carriages would be run on the branch of the London and North-Western Railway opened this month between Mold and Coed Talon. Certainly this is a line upon which there cannot be many passengers of any class, seeing that it was made some time ago, but has been closed for passenger traffic for many years. Neither is it by any means a long branch, for the journey only occupies a quarter of an hour, and but two trains are run per day in each direction. Still, if the London and North-Western Company ever give way on this question, the little Flintshire line may be pointed to as the thin edge of the wedge.

THE tenth Building Exhibition is to be opened at the Agricultural Hall on March 14, and is to remain open a fortnight. It is two years since the last similar exhibition, and no doubt the discontinuance of the practice of holding the exhibition annually will render it more easy to make it worth holding, though we think an interval of three years would be even better than two. We are informed, however, that there is to be a considerable effort made to render this year's exhibition a successful one, and to give it some new interest, and among other things there is to be an "Art-work Branch" open to workmen, apprentices, or amateurs, for building and the allied trades. There will be eight groups in these exhibits viz.: Carpen-try, Carving, Furniture, Painting and Decorating, Metal-work, Building Appliances and Materials, Building Facilitators, and Invention and Design. The last two are rather vague. One does not see very well how art is to come into "Building Facilitators" (as far as one can attach any definite meaning to the term), while "Invention and Design" is far too comprehensive a title. What is meant, we presume, is, drawings of work not executed otherwise than in the drawing stage; but it should have been more explicitly worded.

THE interim report of Mr. Rogers Field in regard to the sanitary arrangements of Wellington College is of too brief a character to require detailed notice at the present time. It states that there are defects of a grave character, but it does not state in detail what these defects are. Important sanitary work was done in 1883, that is, not ten years ago, and yet that work is now imperfect. The fact shows very strongly the necessity of periodical inspection of all buildings and drains which belong to colleges and schools. No other course gives real security, and it is in the long run the most economical system. Whether or not the diphtheritic epidemic at Wellington College was caused by these defects is by no means proved. On the contrary, it would appear to have been brought into the college from outside. It is probable, however, that even if this were so, the sanitary defects have made boys more liable to the disease than otherwise would have been the case. It is to be hoped that a thoroughly detailed report will in due time be issued by Mr. Field, for it would be of use as a warning to other schools and colleges,

* See the Encyclopédie Méthodique, 1782: Paris: Dictionnaire Général de Géographie et d'Histoire, 1889; and Larousse's Grand Dictionnaire Universel du XIX^e Siècle, 1872.

and throw light on the defects of our public schools. Another point which cannot be passed over is the ascertained fact that the gas at the large school was very impure, and that there were many escapes. At the beginning of the winter we called attention to the negligence which apparently exists in regard to the lighting of many of our public and private schools. Here we have a glaring and clearly ascertained instance of the fact which we ventured to assert in a general form, though not without particular grounds. The authorities of every college and school in the country should without delay set this matter right.

IN the last issue of the *Transactions* of the American Society of Civil Engineers we observe that Mr. Latham Anderson, a member of the Society, is putting forth as a new idea what he calls "the single-trap system of house drainage," the principle of which consists in cutting off the outer drain from the house by a single trap, and using no other trap to any closet or waste-pipe, &c., in the house, but arranging an upcast ventilating pipe, with suction induced by a gas-jet or other means, to exercise a steady draw upon all the soil-pipes in the house and merely produce a constant suction of air from the interior of the house to the drain, rendering (as is supposed) traps to the water-closet unnecessary. This may be new in the United States: it is not new here; it was set forth and illustrated in our columns ten years ago at the instance of the late Sir Henry Cole, who was employing it in his own house, and a considerable correspondence on the subject followed. There is a beautiful simplicity about the system, provided one can always rely on the exhaust-shaft to act, and no doubt there are advantages in getting rid of traps to water-closets, the best flushed of which must collect deposit in the dip to some extent: but it does not appear that experience of the system has led to any great increase in its adoption in this country. It is an excellent system as long as it acts exactly as intended; but if anything gets out of order with the exhaust ventilator and its working power, people would very soon find that there was plenty of smell from the deposit on the sides of the pipes, even with the outer drain trapped off; and most people will feel safer from annoyance and danger to health by having the soil-pipes trapped off than by a system to prevent the air ever travelling up them. Still it is of interest to note that the system has been advocated in America, and we should like to hear what is the result, and whether it finds any favour there.

DYSART HOUSE, Fifeshire, together with the mansion-house portion (about 85 acres) of the estate, and lying along the shore of the Firth of Forth, is offered for sale by private bargain. The property to be sold includes Ravensraig, or Ravenshaugh, Castle, that stands upon a high promontory washed on three sides by the sea. This and Morton, Rait, and Tullyallan Castles are peculiar instances of a kind, since they present examples of a design and plan intermediate between those of the keep for refuge or defence, and of the castle with an inner quadrangle to serve as a residence. A work that we have recently reviewed* contains plans, sections, and views, with details, of Ravensraig. Built by James II.'s widow, Mary of Guelders, and being, for most part, of one age, its leading features comprise a rounded keep towards the mainland, containing the principal private rooms, and joined by a curtain about 53 ft. long to a salient circular tower, 44 ft. in diameter, which stands on lower ground at the north-eastern angle,—the site is a rocky plateau, rising up 100 ft. above the water. The top story has been modernised, and the

crow's-rest gables of the roof are regarded as a later addition. Shortly before the king's death, Walter Ramsay, and Janet his wife, vassals to the Earl of Fife, assigned Dysart to the queen for lands near to Linlithgow. Some accounts of Mary's lands and fermes, 1462-3, show payments of 600*l.* to Master David Boye, Master of Works, for directing the building, and of various sums for materials,—including 14 great timbers, "joists," from the woods by Allan-water: the payments cease with her death. Her son, James III., bestowed the castle and lands, 1470, upon William St. Clair, fourth Earl of Orkney, in exchange for his castle of Kirkwall and "his hall right to the earldom of Orkney." It subsequently passed to the Earls of Rosslyn, of Dysart House.

THERE have been so much talking and writing about the desirability of making the national treasure-house of the British Museum better known to the public, and especially the working-classes, that we are glad to see something definite is about to be done. The trustees have given their consent to a course of evening lectures on "Greek Art and Life," as illustrated by the contents of the Museum, the first of which is to be given on January 19, at 8.30 p.m. The Keeper of Greek and Roman Antiquities will take the chair, so the movement has ample official countenance. The first five lectures are to deal with Greek sculpture in the fifth century B.C., and especially the Parthenon marbles, and are given by Miss Eugénie Sellers, who devotes part of her first lecture to the history of the Classical Collections in the Museum. There is an admirable paper on this subject by Sir Charles Newton in his *Archæological Essays*, but the spoken word will, we hope, reach many to whom the "written word is a dead letter. The originators of the scheme have wisely decided to divide the course between Greek art and Greek life, and this other branch of the subject is confided to Miss Millington Lathbury, our first *certificated* lady archæologist. She is to deal in five lectures with all those topics which to some minds come so much nearer home than any questions of art, e.g., "Greek Festivals and Games," "Daily Life of Men and Women in Greece," "Greek Dress and Greek Armour Temple Services," and last, though not least, "Greek Grave-reliefs and Funeral Customs." The scheme has been set going by the two indefatigable honorary secretaries of the Chelsea and Whitechapel centres of the London Society for the Extension of University Teaching.

WE read in the *Times* that new premises for the Parcel-Post Service are to be erected in Paddington, and,—as in the case of Coldbath-fields,—upon the site of Tothill-fields Prison, Westminster. The latter prison was pulled down and the ground cleared in 1883-4.* Having latterly served as a female penitentiary, it was built, after Robert Abraham's designs, in 1830-4, for 800 prisoners, upon a plot of ground near to the then Palmer's village. The plan consisted of several wards, including 42 day and 348 night rooms, arranged round a garden; the governor's house, with chapel above, being in the front. The entrance, south-east, had a handsome elevation of granite with a porticulis, and the whole building was considered to form one of the finest pieces of brickwork in London. Ashley-gardens and Amhrosden-avenue now divide the site into two portions, whereof one is reserved for the proposed cathedral (R.C.): see the *Builder*, of March 8, 1884. The old Bridewell, first built in 1618, along the northern side of Green-coat School and Hospital, on Tothill-side, stood until 1836, when its gateway, with the keys, were removed, as relics, to the new position. The narrow stone portal, with its inscribed stone above, were afterwards set up against the north wall of the Sessions House, which

is about to be enlarged at an estimated cost of 20,000*l.* The inscription stands thus:—

Here are several Sorts of Work
For the Poor of this Parish of St.
Margaret's Westminster:
As also the County, according to
LAW, and for such as will Beg, and
Live Idle in this City, and Liberty
of Westminster, Anno 1655.

IT is seldom that a freehold area of nearly one acre and three-quarters (75,000 feet superficial), with vacant possession, within the City of London, is offered for sale. Last April the Court of Common Council decided to sell the site and buildings of Farringdon Market, whereof certain existing rights are about to expire. Tenders were invited, for deposit on October 7 last. But it seems that none of these proved satisfactory, since the Corporation are now resolved to sell the property by auction early in the coming spring. The several frontages are to Shoe-lane, Farringdon-street, and Stonecutter-street, with a decline from west to east. We gave a brief account of the market and its site in a "Note" on July 2, 1887.

THE necessity for a public hall in Edinburgh, suitable to the requirements of the city, has long been felt and commented upon. The Music Hall, in George-street, the largest in the city, although admirable as regards situation, does not contain accommodation for an audience of 1,500; and, at this season of the year especially, complaints are continually cropping up as to the high prices charged for admittance to good concerts, oratorios, &c., as compared with those charged in cities where suitable provision is made for large audiences. The site occupied by the Music Hall is sufficient for a building adequate to accommodate at least 3,000 persons, without galleries, and, were they included in the plan, an additional 1,000 would find room. The present building contains, beside the Music Hall,—which is situated in the rear,—a suite of rooms appropriated to dancing assemblies, and on the ground-floor are two shops. The site is one which deserves to be occupied by a more attractive structure than the present building, which is of very little architectural merit.

WE have received a copy of a country newspaper, published not far from London, containing an advertisement which certainly exhibits "that hybrid personage the Surveyor-architect" in all his glory. It runs thus (omitting name and address):—

"Mr.—
(Associate Royal Institute British Architects),
ARCHITECT, SURVEYOR AND SANITARY
ENGINEER.

[here follows the address].

"In matters of Quantity Surveying, Arbitration, Settlement of Building Disputes, Compensations, Valuations, the General Sale or Transfer of Properties; also Drainage, Ventilation, &c., Mr. — can be consulted daily by appointment.
Preliminary Sketches, Plans, &c., prepared, and the approximate cost of proposed works ascertained free of charge."

The name of the person making this tradesman's advertisement is not in the list of members of the R.I.B.A. recently issued. If he has become a member since the issue of the last "Kalendar" of the Institute, he must have been admitted through the Examination, we presume; which would, at all events, show that the Examination is no protection against men getting into the Institute who have no sense of professional or artistic dignity, or of the self-respect proper to gentlemen. We have enclosed the original advertisement to the Secretary of the Institute of Architects, from whom the advertiser will probably hear, in one sense or another, according as he is, or is not, a member of that body.

THE *Scientific American* (Architects' and Builders' Edition) for December, 1891, we observe, gives two plates from drawings

* "The Castellated and Domestic Architecture of Scotland, Twelfth to Eighteenth Centuries," by David Macgibbon and Thomas Ross, architects. See the *Builder*, December 25, 1886, and January 19, 1889.

* The materials were sold at auction for 5,300*l.* including, we were told, 2,300*l.* for 190 tons of lead.

"Lanterne des Morts," Ciron, Indre.

"Lanterne des Morts," Cemetery at Pers (Deux-Sèvres).

by Mr. Alexander Graham of the Triumphal Arch at Tim-gad, Algeria, as existing, and restored. Reproductions of these drawings, from the originals lent to us for the purpose by Mr. Graham, were published by us as plates in the issue of the *Builder* for October 4, 1890. The illustrations in the *Scientific American* are obviously bad reproductions from our plates, reproduced without permission and without acknowledgment of the source from which they are taken. It is apparently useless, in the present state of literary law and literary morality in the United States, to expect common honesty in these matters from American journals; but they will at all events not be allowed to plunder from our pages without the fact being duly noted and made public.

SOME OLD FRENCH CEMETERY ERECTIONS.

The erections described and illustrated here are taken from old churchyards in Brittany, where especially there has been kept up what may be called the "cult des morts." Besides the stone cross which was a common object in Medieval graveyards or cemeteries in connexion with a church, there is found frequently a small isolated tower, in the form of a hollow column and terminating in a kind of lantern. These erections, the use of which can be traced in France to a remote antiquity, have been called "Lanternes des Morts." Some of them have at their base a large stone, serving appa-

rently as an altar; and a lighted lamp is said to have been placed every night in the "lanterne." It appears to have served the double object of indicating to strangers that they were in a burial-ground, and of keeping away, as was believed, evil spirits, vampires, "long-garons," &c., which used to be a terror of the populations of the north and west of France.

In Brittany the little cemeteries surrounding the churches were quickly filled, and from time to time the good people exhumed their ancestors to make room for their descendants. But in place of re-interring the remains in a pit, the bones were piously preserved in ossuaries. Generally the ossuary formed a little chapel in a portion of the burial-ground, in close proximity to the church, with compartments arranged for the storing and exhibition of the remains. Often families, at the exhumation of the remains of their relatives or predecessors, would demand the skull as a memorial, and enclose it in a small box surrounded by a cross which was placed in the ossuary, or sometimes in some part of the church. Inscriptions, sometimes in French sometimes in Latin, were painted on the boxes; sometimes they are in the old Bretonne dialect, and in some villages are found constructions specially formed for the exhibition of these boxes.

As an example of these a sketch is given of the ossuary of St. Pol de Léon in the department of Finistère (see page 46); it is set against the wall of a cemetery, and divided into bays or niches to receive the boxes. This is one of the most curious and characteristic which I have met with.

I have thought also that it would interest English readers to see some representations of the old crosses and "Lanternes des Morts" which are still to be found in the cemeteries of the ancient provinces of the west of France. Sketches of four of these are given, two crosses and two of the characteristic "Lanternes."

Photographs of these and others are to be found among the fine collection of photographs of ancient remains made by M. Miesement for the department of "Monuments Historiques."

ADOLPHE GULLON.

ARCHITECTURAL SOCIETIES.

THE ARCHITECTURAL ASSOCIATION: DISCUSSION SECTION.—The fourth meeting for the session 1891-92 was held at the rooms of the Association, on Wednesday, the 6th inst., when Mr. Cecil A. Sharp read a paper on "Work-house Planning and Construction." The discussion which followed the reading of the paper was opened by Mr. A. W. Saxon Snell, F.R.I.B.A., and sustained by Messrs. Hall, Stockdale, Pywell, and the Vice-Chairman, Mr. S. Beale. Mr. T. Aldwinckle gave some excellent hints, and Mr. Gordon Smith's summing up was full of valuable information. The special Visitors for the evening were Mr. P. Gordon Smith, F.R.I.B.A., Architect to the Local Government Board, and Mr. Thomas Aldwinckle, F.R.I.B.A.

CARLISLE ENGINEERING, ARCHITECTURAL, AND SURVEYING ASSOCIATION.—At the usual meeting of this Society, on December 29 last, a paper upon "Sewerage and Sewage Disposal"

Cemetery Cross, St. Georges du Roc (Deux-Sevres).

Cemetery Cross, Aiffres (Deux-Sevres).

was read by Mr. Arthur Turley, Civil Engineer, Carlisle. The most approved system of main sewer construction was described and illustrated, the lecturer explaining the mode of procedure for the preparation of a complete scheme of main drainage and sewage disposal for a district having a population of 20,000. The question of disposal of heavy rainfalls was dealt with, various forms of storm-water overflows being illustrated and described. The hydro-pneumatic system of sewerage was exhaustively dealt with, the lecturer having prepared explanatory plan, sections, and other details of that system as laid down at Henley-on-Thames. The ventilation of public sewers was fully gone into, and the use of factory chimneys to assist in this work was strongly advocated, wherever such facilities could be obtained. The various systems in vogue for the treatment of sewage were treated at great length, the cost and result of each being given. The systems dealt with were those of broad irrigation, intermittent downward earth filtration, various chemical processes, combinations of chemical precipitation and laud filtration, and several patented processes, viz: the Iron Process, the Ferronox and Polarite Process, and others. The lecturer stated that these patented systems were worthy of careful consideration by those interested in the subject of sewage purification, and he thought it unfortunate that opposition to them should be offered by the Local Government Board by their insisting upon the purchase of land for the treatment of the effluents obtained from these systems, such supplementary process being, in his opinion, quite unnecessary.

LIVERPOOL ARCHITECTURAL SOCIETY.—A special meeting of this society was held at their Library on Monday last, under the presidency of T. Harnett Harrison, F.R.I.B.A., when a paper was read on "Cement and Cement Testing," by J. A. Berrington, A.R.I.B.A., fully illustrated by practical tests of specially-prepared briquettes, by a Michele machine, and also by the use of Vicat's needle; and the methods of sifting, weighing, mixing, &c., in order to ascertain the quality of the cement, were fully gone into. All the briquettes tested yielded very good results,—as much as 1,000 lbs. tensile stress being registered on the area of 2½ in., four days' old, dry mixed. Special attention was directed to the method of mixing in favour with manufacturers, i.e., very dry mixing,—some of the tests being with briquettes mixed with 16 oz. of water to 48 of cement, and others with 10 oz. of water to 48 of cement,—the latter giving much better results; but it was pointed out that cement mixed so dry as the latter could only be used for such purposes as foundations for roadways, carefully rammed and consolidated (and the same method had to be adopted to fill the moulds for the tests). If used as mortar, or for other building purposes, 25 per cent. of water was as little as could practically be used, and this proportion was considered the legitimate test. The paper and the experiments were much appreciated by the members, as giving them a practical insight into the modes of testing and the best manner of judging of reliable cements, which are not always open to the investigation of architects.

SHEFFIELD SOCIETY OF ARCHITECTS AND SURVEYORS.—The monthly meeting of this

society was held at the School of Art on Tuesday last. The departure from Sheffield of Mr. G. Alsing, C.E., for Glasgow, was considered, and the following resolution, moved by Mr. F. Fowler, seconded by Mr. E. M. Gibbs, was carried unanimously:—"That this meeting of the Sheffield Society of Architects and Surveyors desires to express to Gustave Alsing, Esq., C.E., on his leaving Sheffield, its high appreciation of his courtesy to the members of the society in carrying out his duties as Chief Engineer of the Sewerage and Rivers Department of the County Borough of Sheffield, and to assure him of the best wishes of the society for his future prosperity and happiness." Mr. F. R. Farrow, F.R.I.B.A., Vice-President of the London Architectural Association, then read an interesting and instructive paper on "The Ventilation of Public Buildings." He commenced by defining the principles on which ventilation depends, being the substitution of fresh air for foul air, which to be successful must be without draught. Foul air is air vitiated to a certain definite extent; fresh air, air in a normal state of purity. Draught is the unpleasant contact of moving air with the person, and air is a fluid and a gas, and therefore heated air is lighter than cold air of equal purity, and foul air is heavier than fresh air of equal temperature. In elaborating these points he gave figures as to and formula for the calculations of proper temperatures, speed of incoming air to avoid draught, size of flues, engines, &c., and described the proper means for effecting the purposes required, either by natural or artificial ventilation, showing the superiority of the latter over

Ossuary, St. Pol de Léon (Finistère). See page 44.

the former. He gave several examples of different forms of ventilating apparatus, and their application to different classes of buildings, including some of the large public buildings of Vienna, the Rathaus, University, Bourse, and Grand Opera House, which are ventilated on elaborate systems. He showed what to avoid in planning-out systems, and the essential points to be provided. The lecture was well illustrated by drawings and diagrams.

Illustrations.

ARCHITECTURAL STUDY BY BRAMANTE.

THIS is a reproduction from an engraving by Bramante in the British Museum, of which only a very few copies are known to exist in Europe. It was specially alluded to by Baron de Geymüller in his paper on the School of Bramante read before the Institute of Architects last year, when a copy of it was exhibited. It is a striking example of the class of ideal architectural composition in which the leading architects of the Renaissance not unfrequently indulged. The treatment of the foreground arch in section is a characteristic feature, as also the introduction of the bust turned from the spectator, in the circular opening on the left. The figures are in the usual costume of the day, looking oddly out of keeping with the ideal design.

While on the subject we may refer to another composition "attributed to Bramante" and published in the *Builder* for March 21, 1891, about the authenticity of which Baron de Geymüller expressed himself, in the paper referred to, as somewhat sceptical. It may be of interest to note that we have recently heard from Baron de Geymüller that he has found reason to think that the design referred to is very probably an authentic design by Bramante.

SEASCALE CHURCH.

THE church at Seascale occupies a fine site on a little hillock above the rising seaside resort of Seascale in Cumberland; it is built of the local red sandstone from St. Bees' Head, an ancient quarry on the seaboard, from which

Windsor Castle is recorded to have been repaired in the times of the Edwards. The church is from the designs of Mr. C. J. Ferguson, F.S.A., architect, of Westminster and Carlisle, and is so arranged that it may be added to if the increasing requirements of the place demand it. The drawing, by Mr. R. W. Paul, was exhibited in the Academy of 1890.

HYMERS' COLLEGE, HULL.

OUR illustration shows this building as it is now being carried out, some slight modifications having been made in the competition design, which was placed first by the assessor, Mr. E. C. Rohins, F.S.A., and which we illustrated on June 28, 1890.

The building consists of sixteen class-rooms, eight on each floor, grouped around a central hall 92 ft. by 45 ft., in such a manner that every class-room is entered directly from the hall, or from the galleries which surround it on three sides. The Classical School, on the ground floor, consists of six class-rooms for thirty scholars each, and two for twenty-four each, the floor area being twenty superficial feet per scholar. The corresponding class-rooms in the Modern School (first floor) accommodate respectively forty and thirty-two, the floor area being fifteen superficial feet per scholar; the total accommodation thus being 532. Dadoes of cloak-lockers around the central hall, galleries, and corridors, provide accommodation for both schools, each scholar having a separate locker. The administrative offices are placed in the lower building along the principal front, beneath the large windows of the central hall. The principal entrance is in the centre, with the head-master's room and porter's room on either side. Beyond these are the secretary's room and the assistant-masters' common room, with lavatory and cloak-lobby. The principal staircase is directly opposite the main entrance, and communicates with a wide gallery behind the hall arcade, a narrow gallery at one end, and a wider gallery at the other end, with seats for the accommodation of some fifty persons. Two short and straight corridors lead from the central hall to the side entrances. The class-room doors will be glazed, and inspection windows provided. It will thus be seen that the whole building, with its entrances and exits, is

brought directly under the supervision of the head-master and porter. It is intended to add, at some future time, Science and Art blocks at each end of the building, the corridors being extended for that purpose. Until these additions are carried out, class-rooms in the main building will be temporarily fitted for instruction in science and art. The latrines and lavatories are arranged in separate blocks on the east side of the main building. The external facing is of red brick, with Ancaster stone dressings; the central hall and corridors being finished in the same manner; the roofs will be covered with red tiles. The total cost of the main building, with the lavatories and latrines, will be about 12,900*l.* Messrs. Botterill, Son, & Bilson, of Hull, are the architects.

STUDY FOR A COUNTRY HOUSE.

THIS study, which speaks for itself, is by Mr. J. H. Sellers, and was exhibited in the Architectural Room of the Royal Academy last year. The plan is a peculiar one, with a flight of stairs direct from the entrance-porch, rather more suggestive of a club perhaps than of a country house. The kitchen presumably is on the lower level. The exterior design is treated with commendable simplicity.

THE CONDITION OF GLOUCESTER CATHEDRAL.

WE have received a copy of a recent report of Mr. F. S. Waller, the consulting architect to the Dean and Chapter of Gloucester, on the state of the building, which shows that an effort is necessary on the part of all who are interested in the Cathedral if it is to be kept in an adequate state of repair. It must be presumed that there is no "fabric fund" for the Cathedral, and it is stated in the circular accompanying the architect's report that twelve years ago the revenues of the Cathedral were more than double what they now are, and the Dean and Canons have, therefore, suffered a loss of more than 50 per cent. of their incomes. The Chapter have to the best of their ability laid out upon the fabric more than should rightly be spared from the maintenance of the services and the stipends of the staff. This expenditure on the fabric has been mainly in-

in the constant employment of a body of skilled workmen, who, under the supervision of the architect, have executed such repairs as were from time to time absolutely necessary for the safety of the building. They are now, however, totally unable to exceed their present outlay upon the fabric (and it is a very inadequate outlay) without external aid. They have, already, during the last few months incurred a special expenditure of £124 on the reparation of one of the Norman turrets, and £50 on the reconstruction of the lightning conductors on the best modern system. These works could not be delayed, if positive disaster were to be averted.

They have also put forth an appeal for the Cathedral bells, which, owing to the state of the framework and partial wear of the metal, at present cannot be rung.

The following is Mr. Waller's report, which we give in full, as it must be of interest to many of our readers whom it would not otherwise reach:—

“Gloucester, December 1, 1891.
To the Very Rev. the Dean and Chapter of Gloucester.

Gentlemen: I gladly avail myself of your instructions to report upon the present state of the Cathedral and on the buildings attached thereto, excluding of course the residential houses; and, as from conversations I have had with some of the members of your Chapter, I am led to believe that an appeal to the public is contemplated, to ask for assistance in doing works of repair which must, failing such help, remain entirely neglected, I may, perhaps, be allowed to preface this paper with a few explanatory facts, relating to the past, which are requisite to make the whole subject more readily understood, but which are not generally known.

Previous to the agricultural depression (now of many years duration), not only was there no difficulty experienced in finding the funds necessary for the ordinary repairs of all the Caputal buildings, but there was a considerable surplus for structural restorations; amongst the last and most important of which may be specially noted, the partial rebuilding of the north façade of the north transept, with its turrets, and also the entire reconstruction of the parapets and cornices, together with the four large pinnacles of the great central tower, the whole completed at a cost of several thousand pounds, derived solely from the Chapter funds.

These works were finished in 1879, since which time the depreciation in the value of landed property, then hoped to be only temporary, has continued to increase, resulting in a reduction of at

least 50 per cent. in the Chapter revenues, whereby the funds for even the most ordinary annual repairs are necessarily reduced to a minimum, leaves absolutely nothing to arrest the great and steadily increasing structural dilapidations of the Cathedral and the interesting buildings by which it is surrounded.

To fairly understand your great liabilities as custodians of the Cathedral and the numerous buildings and grounds attached thereto, it will be necessary also to speak of these, which may be thus briefly described:—

BUILDINGS.

The Cathedral, the Library, and Chapter-house, and minor rooms connected therewith, the great and little cloisters, the organist's house, and college school, and out-buildings attached thereto. The old gateways and Abbey walls, and other remains of the Monastery, the College-green, roads, and gardens, these latter now used as a public resort (for which one man is constantly employed), and the whole area of which occupies a space of about six acres.

The foregoing list represents a formidable and grave charge for any public body, even if the buildings were in good repair, and under such circumstances the average annual outlay of several years past would be too small to keep them in sound and good condition; they are, however, very far from being in good condition,—indeed, in many parts they may be said to be in an absolutely ruinous state; a strong assertion, it is true, and one that many people may appear almost incredible when taking into consideration the very large sums known to have been expended on the Cathedral during the last thirty years.

This, however, admits of easy explanation when we refer to the report made by the late Sir Gilbert Scott in 1866, and see how much of that which he then spoke of, as being necessary, has been left entirely untouched, remaining in the same condition, especially as regards the roofs and parapets, as when he inspected the Cathedral, excepting that

REMARKS.

These buildings consist of an immense pile of masonry, more or less ornamental, with buttresses, pinnacles, parapets, paneling, niches, copings, and other decorative and constructive work, constantly requiring attention and care, with the windows, doors, floors, drains, gutters, &c.; also a vast and costly extent of lead, stone tiles, and slate roofs, nearly two acres by admeasurement, all the above requiring more or less annual repair, added to the everlasting contingent works pertaining to old buildings, to which must be added the serious dilapidations hereinafter detailed.

the lapse of time has necessarily created still greater dilapidations.

Large sums have been expended on the choir and on internal fittings, and on windows for the reception of painted glass, and the external repairs have also been very considerable, including the north and south transepts, the south porch, the nave and choir; the pinnacles and parapets of the tower, and some other portions of the building; but many more remain to be done, as stated in the said report, and estimated therein to cost several thousand pounds.

In speaking of some of the most pressing of these works, I may mention especially the walls, windows, parapets, pinnacles, and roofs of the north and south aisles of the choir; the roof and gutters of the south aisle of the nave, and the condition of the great tower also, which, excepting the pinnacles, parapets, and chief cornice (which are in perfect condition), sadly requires pointing and general repair. Indeed, pointing alone would be the means of staying further decay, and of preserving the stonework for many years to come.

For these items alone and the repairs of the roofs a considerable immediate or annual outlay is now required, the present expenditure, as before stated, being wholly inadequate to stay the very serious dilapidations of which I have spoken, and which get decidedly worse year by year.

All of the foregoing are not only most important structural works, but they are absolutely essential for the preservation of the Cathedral; they are, in fact, simple repairs, due to the effects of old age. Unfortunately, when executed, they will be little seen, and therefore it is not probable that they will find favour with private individuals for memorial purposes, as is sometimes the case with the more conspicuous and ornamental parts of the building.

As regards the probable cost of the most pressing of these dilapidations, I am of opinion that 2,200*l.* will be sufficient to complete all that will be required for the walls, parapets, and roofs of the choir aisles and chapels, and the worst parts of the roof of the south aisle of the nave.

What may be required for the pointing and repair of the stonework of the Tower can only be known when the scaffolding is erected; the cost will vary on each face, and so much must depend upon the condition of the weather mouldings, and other dressed work, some of which appears to be very bad. I am quite sure the work must be attended with considerable outlay, probably not less than from 1,000*l.* to 1,500*l.* The other roofs spoken of by Sir Gilbert Scott are estimated by him to cost upwards of 2,250*l.* It will, therefore, be seen that between 5,000*l.* and 6,000*l.* is now required to simply repair and reinstate where necessary the most important of the dilapidations I have alluded to.—I beg to remain, gentlemen, yours very faithfully,
FREDK. S. WALLER.

P.S.—In this statement the subject of the restoration of the Lady-chapel has not been entertained, as it is altogether too grand a work to connect with the absolutely necessary repairs of the fabric, but as the windows are known to be in very bad condition, often admitting wind and rain from all quarters, and the millions are in some parts so dangerously decayed that a ladder cannot with safety be placed against them, it would be very desirable to restore these as early as possible for the better preservation of the interior of the building, and so that the chapel may then be thrown open to the rest of the Cathedral and be properly warmed, which in its present state is impossible. The cost of this would be about 1,200*l.*, and one of the most expensive and important structural repairs of this chapel would then be completed, the decorative works remaining for future years."

It is not surprising that under these circumstances the Dean and Chapter have felt compelled to appeal to the public for assistance, and we hope that many unconnected with the Gloucester Diocese, but who feel that the cathedrals of England are a great national possession, will be willing to contribute towards the task of putting the fabric of Gloucester Cathedral into a satisfactory condition. Subscriptions to the amount of something over 2,000*l.* have already been promised, the Bishop, the Dean, Earl Ducie, the Archdeacon, and Mr. Dyer Edwards being among the largest subscribers. Subscriptions will be received either by the Dean, the Archdeacon (who is treasurer of the fund), or Canon Bowers, the secretary.

BRITISH ARCHEOLOGICAL ASSOCIATION.

At the meeting of this Association, held on Wednesday, January 6, Mr. C. H. Compton, V.P., in the chair, a large number of antiquities belonging to various members were exhibited, among which the following may be noted: Mr. B. Winstone, a very fine milk-white glass medallion of Sir Hans Sloane, Bart. Mr. Winstone also showed to the meeting one of the office books of the Commissioners of the River Stort, containing early minutes of proceedings. The Chairman described some interesting brasses in the Church of Ringwood, Kent, of which rubbings were submitted for inspection. Mr. J. M. Wood produced some hard Roman mortar from Colchester, and he also described some of the original lead piping used by Sir Hugh Myddelton at Sadler's Wells. The metal is $\frac{3}{8}$ in. thick, formed of plates hammered into shape, and jointed in a remarkable manner without soldering. Mr. Watling showed drawings of curious Elizabethan paintings on the pillars of St. Clement's Church, Ipswich; and Mr. Earle Way, Roman and Medieval remains, recently found at Southwark, including a large number of fine blue spherical Roman beads. A paper by Mr. Andreas E. Cockayne, on the "Antiquities of Derbyshire," was then read by Mr. W. de Gray Birch, in the author's absence. It treated for the most part of the evidences of the existence of man in pre-historic times, and the recent discoveries were passed in review. The Chairman read a note on the date of the foundation of Furness Abbey. The concluding paper was on a "Find of Roman Remains at Caerleon." These consist of the remains of former buildings. Roofing-tiles, stamped with the Legionary mark: "LEG II. AVG.," pottery, coins, &c. They have been found in excavating for a house for Mr. T. Parry, on the Common.

THE MERSEY TUNNEL RAILWAY.

On Monday last the new station of the Mersey Tunnel Railway, at the bottom of Bold-street, Liverpool, was opened for traffic. The *Liverpool Daily Post* says that "probably as a feat of engineering the construction of the new station at Bold-street is not inferior to any part of the scheme advanced. Under very singular and perplexing difficulties it could only be proceeded with in its first stages from midnight until six o'clock the following morning, it being, of course, essential that the traffic at the Central Station should not be interfered with. During these hours, night after night, trenches were cut at intervals of 10 ft. across the roadway connecting the arrival platforms at the station, and into these were placed strong banks of timber, across which planks were laid as a temporary roadway. Beneath these planks, which were taken up and put down as required, the rock was excavated to a depth of 9 ft., and the banks supported upon stout props. Then from the driftway or rough boring beneath

well-holes were bored to the upper excavation, and through them the strong upright iron pillars designed to support the roof of the new tunnel station were passed, bedded, and securely fixed in position. No sooner were they *in situ* than the most troublesome part of the task was entered upon, for the banks had then to be removed in order to allow to be placed in position the girders running the length of the new station, and resting on the tops of the upright pillars. From these longitudinal girders cross-girders of great strength were placed, and between these were built brick arches, packed above with concrete. This formed the roof of the new station. One portion of it passed under the rails in the station above, and had to be constructed without stoppage of the traffic. The rails had consequently to be supported on a temporary steel bridge of ingenious design, constructed by Mr. C. A. Rowlandson, the resident engineer and manager of the company, under whose personal supervision, as representing Sir Douglas Fox, the work has been carried out. With this device the men were enabled to go on in safety, although locomotives were passing immediately above their heads. After the completion of the roof the station below was excavated by what is technically called "plug and feather" work,—that is to say, by drilling bores, into which powerful wedges are driven to split the rock.

Entering the new station by the convenient access under the Lyceum, the visitor proceeds through a wide vestibule on the street level to a spacious booking-hall lighted by windows. From this a short flight of steps, some 20 ft. in width, conducts to a broad corridor, which forms the entrance to a gallery overlooking the station. At the opposite end of this gallery are the steps leading to the booking-hall and entrance from the Central Station; and at one side, equally distant from either end, are some ten or twelve stairs leading down to the platform. The platform itself is an island 270 ft. long and 20 ft. broad; whilst the station is 50 ft. in width, and 27 ft. high. To avoid the shadows cast by the pillars supporting the roof and placed along the platforms at distances of 30 ft., Mr. Rowlandson has hung two rows of lamps, one over either side of the platform. The edges of the platform are thus thrown into relief, and passengers do not stand in their own light when entering the trains; while the effect of this double row of lights, and the entire absence of shadow, is remarkably pleasing. For the purpose of handling luggage, there has been erected on the platform a small lift leading to a hanging gantry, along which luggage can be passed to the Lyceum booking-hall on the street level. As to the important matter of ventilation, a fan, similar in design to those already in use, and 12 ft. in diameter, has been erected by Messrs. Walker Brothers, of Wigan, for the purpose of ventilating the station apart from the tunnel. The ventilation is, in consequence, excellent. The contractors for this work are Messrs. John Waddell & Sons, who have carried out the entire tunnel scheme at a cost of nearly 2,750,000*l.*"

Books.

K. K. Oesterreich Museum für Kunst und Industrie. Die Sammlung Antiker Vasen und Terra-cotten im K. K. Oesterreich Museum. Katalog und Historische Einleitung. VON KARL MASNER. Mit 10 Lichtdruck und 1 Steindrucktafel; 36 Abbildungen im Text. Wien: Gerold. 1892.

PRIMARILY a catalogue of the collection of vases and terra-cotta in the Vienna Museum, the hook before us is incidentally much more. It is, in fact, in some respects a model that it would be well if the directors of all our public museums would imitate. Why, we are inclined to ask, is there for our collection of vases at the British Museum, a collection incomparably richer, no such book,—a book which, while it is a register of scientific facts for the specialist, is also so written and illustrated that for every educated art-lover it opens up a new field of delight? Of course, the answer is in part that the Vienna collection is a small one, and, therefore, can be dealt with succinctly without sacrifice of completeness,—this, with the large collections of our own Museum, of the Louvre, Berlin, Munich, and the Vatican would be impossible. Still, surely, a selection might be made, and some insight into the treasures of national storehouses facilitated to the general educated public. At present we have

our large official catalogues,—too often quite unnecessarily bulky and out of date. We have, in some cases, a small popular "guide," both dull and superficial; but we have no book that stands between, scientific in basis, yet lucid and readable, and, above all, illustrated in the accurate fashion that modern processes permit.

What strikes us at the outset in the Vienna work is the due subordination of material. The writer has not, through long living in a museum, dimmed his sense of intellectual perspective. Every vase is registered, and with adequate completeness for identification; but practically a duplicate, will be settled with in three lines, whereas a unique specimen, or one the subject of which is mythologically interesting or debatable, will get a column to itself. Then, further, two sorts of print are employed. The large print tells all that the ordinary visitor will need of explanation; the small print that follows is addressed to the specialist, and gives him not only a description that in the absence of the original is a substitute as adequate as possible, but also full reference to all the literature of the subject. The phototype plates (from photographs taken direct) give admirably what so often is neglected in illustrated books on vases,—the actual decorative effect, the massing of light and shade, and the spacing out of the subject in the vase itself; while, whenever this process shows the subject inadequately, and this is of interest and unpublished, the phototype plate is supplemented by a woodcut in the text. Many of the Vienna vases are, of course, already known through chance publications, but some will be new to most. One of the most noticeable (No. 92) is, we believe, the subject unique, and certainly most curious. Hermes holding his key-keel, leads to an altar a large pig, obviously for sacrifice. On closer examination, the apparent pig is seen to be no pig at all, but a disguised dog. A dog is masquerading as a pig, and the paws that protrude below the pig's skin clearly betray the fraud. The Greeks were certainly not narrow in their conception of the character of their divinities if they can thus represent one Olympian god playing the fool at the expense, or, rather, for the amusement, of another. The detection of the concealed dog is due to the acuteness of Dr. Studniczka, who is going to publish a monograph on the subject.

The catalogue proper is preceded by a short and very useful "history of the collection." Anyone who knows how tiresome it is to be referred to *e.g.* "Coll. Scaramanga," and not to have the faintest idea where the "Coll. Scaramanga" has gone to, will appreciate the value of this. Nowadays most of the large private collections have gone piece-meal to the various public museums of Europe, and a tabular view of their present distribution would be a great boon. This "history" is, however, a short, but much to the point, history of Greek and Roman art, the best we know within a limited space. The account is, of course, mainly based on the specimens in the Vienna collection, but where this suffers from lacunae they are filled up from other museums. The early local types, Trojan, Mycenaean (the author, he it noted, does not seem to be acquainted with Mr. Flinders Petrie's recent investigations as to the dating of Mycenaean art), Dipyron, &c. are well traced out, and everywhere common-sense prevails. The student is told why the Dipyron and other vases are so called, with a few words of clear, straightforward explanation. The transition from black to red figured styles is particularly clearly made out, and the dominance of particular forms, *e.g.*, the clyx at particular times. Herr Karl Masner is a name new to us in archaeology, but he must have been trained in a good school. Indeed, with Drs. Benndorf and Klein behind him, at Vienna he could scarcely fall of a good tradition. Irresistibly the wish returns that our own Museum might furnish a book at once as practical and beautiful.

Historic Towns: Boston. By HENRY CABOT LODGE. London: Longmans & Co. 1891.

THIS, which is one of the "Historic Towns" series, is a well-written history of the rise and development of the United States city which may be said to be the most interesting to Englishmen, as the most English in feeling and the most closely connected in its rise and traditions with the old country. The history is almost entirely on political lines, and therefore out of our proper province; there is however a

useful map given in which the extent and configuration of old and new Boston are indicated by colouring, and there is a description of the aspect of the city about the middle of the last century, which we may quote:—

"As seen from the harbour, Boston was formed of an amphitheatre of houses, rising gradually one above the other from the water's edge. There were many wharves built out with much industry, and conspicuous among them was the Long Wharf, esteemed a prodigious work at the time, which was two thousand feet in length and covered with handsome warehouses. From Long Wharf ran King-street, then the principal business street, through the heart of the town; and at its head was the Town House, where the State Government in all its branches met, and beneath which the merchants held their exchange, and booksellers their stalls. The streets were sufficiently wide, but crooked and irregular, paved with cobble stones, with gutters in the middle, and side-walks marked off by a line of posts and chains. They were clean and well kept; and although not lighted with any sufficiency before the year 1773, were quiet and orderly. . . . There were also public buildings of no little pretence in size and appearance, and solidly built in the fashion of the eighteenth century. One of these was Faneuil Hall, which had been presented to the town by the rich merchant whose name it bore; another was the Town House, which still stands, like Faneuil Hall, practically unchanged; still another was the Province House, a handsome building where the Royal Governors resided, and there were besides not far short of twenty churches, the majority belonging to the Congregationalists, who were of course the prevailing sect. The harbour was always busy with shipping; and the Long Wharf, and its companions with their rows of warehouses, stretched far out into the water."

The Practical Catechism. By ROBERT GRIMSHAW, M.E., Ph.D. New York: John Wiley & Sons. London: Gay & Bird. 1891.

THE above little book is a collection of miscellaneous questions on technical subjects, each of which is followed by its answer. The work contains a large amount of information, and covers a very extensive field of inquiry. Mr. Grimshaw informs us in his preface that he is not responsible for the selection of the questions, but only for the replies, so that it is really not his fault if he is compared on one page to give some useful remarks on the preparation of beef-tea, and on another a method of estimating approximately the weight of the earth. Between such limits as these what questions might not be asked? There is, however, an excellent index at the end of the book so that even such a variety of information is reduced to order, and the clear and precise manner in which the answers are given make the little work a desirable one to keep in readiness for reference.

Sketches of Village Buildings. From designs by Jas. Williams, architect. With Notes. London: Richard Bentley & Son.

THIS small oblong volume is really a collection of reproductions from brush sketches of designs for village buildings by the author, without plans, however, and done solely for the sake of picturesque effect. The obvious aim, admitted indeed in the introductory essay, is to suggest the idea of imitating old cottages and villages more closely in building new ones. It might be better to do this, perhaps, than to build the mere brick cube with a blue-slate roof which is so often the new form of addition to the village architecture in these days; but in other respects we do not think the recommendation to copy old cottage buildings a wise one. Some of the sketches in the book are very pretty, though some are rather careless in perspective; but we do not see what object the book can well serve except to call attention to the author's facility for making old-fashioned cottages, or to furnish matter for "cribs" to those who prefer to make use of the sketches in that way without troubling the author. He has handicapped the amateur in this respect, certainly, by giving no plans.

Sell's Dictionary of the World's Press, 1892. London: Sell's Advertising Agency, Limited.

THIS bulky and in other respects notable volume now makes its twelfth annual appearance. It not only contains a directory of all the English, Welsh, Scotch, and Irish newspapers, periodicals, and magazines, and of the principal Indian, Colonial, and foreign newspapers and periodicals, but a fund of useful information which ought to prove interesting to all who read, write for, or advertise in, newspapers, and in the aggre-

gate that is, of course, a very large class. Mr. H. R. Fox Bourne contributes an article on "The World's Press of to-day," tracing how, from very small beginnings, the newspaper press has become what it now is, and describing the organisation and division of labour which are brought into play in the production of a daily paper. We are glad to see that Mr. Fox Bourne deprecates the apparently increasing tendency to purvey personal gossip. If, as he says, much and perhaps most of this idle-tattle is harmless, and though some of it may be even useful (which we are inclined to doubt), "there is nothing dignified in the pandering to idle curiosity, the indulgence in small spites or small flatteries, of which it gives evidence." A feature of this publication is the large number of well-executed portraits of prominent journalists which it contains. The work is well printed, but is not free from mistakes.

Sprague's Pocket Diary for 1892. London: Sprague & Co.

THE above consists of a nicely-made pocket-book of convenient size, containing a diary, in which, besides all the ordinary information generally given in almanacs, there is to be found much useful information on technical subjects. As the space that could be devoted to such matters is necessarily limited, great care has evidently been taken to select such rules and tables as are most frequently needed by those engaged in the architectural and engineering professions.

No. 5 of "The Local Government Handy Series" (London: S. Edgcombe Rogers, Dorset House, Salisbury-square, E.C.) is devoted to an abstract of the clauses of the Public Health (London) Act, 1891, with an index. It has been reprinted from the *Metropolitan*, and is a very cheap and handy synopsis of a very important piece of sanitary legislation.

"Dutton's County Almanac and Essex Gazetteer" for 1892 (Chelmsford: John Dutton) is a very useful publication of nearly 200 pages, and is sold for the small sum of 2d. Besides a variety of information as to local institutions and organisations, it contains a very handy "County Gazetteer," originally compiled by Mr. Edward Smith, F.S.S., and now revised and considerably amplified by Mr. R. Burch. So far as we have tested it, the information given is correct and reliable. Probably nothing of a similar character has ever been issued before at so low a price for Essex or any other county. The undertaking deserves success, and is worthy of imitation in other counties.

Trade Diaries, &c.—Messrs. William Sugg & Co., Limited, of Vincent Works, Westminster, send us their very useful "Gas Engineer's Pocket Almanac and Lighting Table for the year 1892." It contains a great deal of information concerning gas-testing and other matters of interest to municipal and local authorities and their officers.—Messrs. Hayward, Bros. & Eckstein, of Union-street, Borough, send us a useful diary, interleaved with blotting-paper, combined with a catalogue of their well-known specialities.—The Electrical Power Storage Company, 4, Great Winchester-street, E.C., have sent a blotting-pad and diary designed so as to keep the "E. P. S. System of Electrical Distribution" always in mind.

RECENT TRADE CATALOGUES.

Mr. W. G. Sutherland, of St. Ann-street, Manchester, sends us a "A Selection of Designs for Stained Glass Windows" executed by him at St. Peter's Works, Gaythorn, Manchester. Part I. includes designs for windows in houses, business premises, and secular public buildings, together with some heraldic and other special devices. Some of the designs are very suitable for their intended purpose. Part II. contains designs for church windows. The catalogue is worthy of the attention of architects.

Messrs. Charles Winn & Co., of St. Thomas' Works, Birmingham, send us the fifth edition of their catalogue of plumbers' goods. It fully describes and illustrates a great many practical appliances used in sanitary work in every-day practice, and is exceedingly convenient in arrangement; a plumber requiring one class of goods will find on adjacent pages the materials and appliances he will need for use therewith, and the various descriptions and qualities of any particular item are arranged in such a form that the buyer can see them all

at a glance. The catalogue includes some excellent valve and other closets, urinals, sinks, baths and bath-fittings, traps, brasswork, and Messrs. Winn's now well-known and admirable "Aeme" and "New River" flushing cisterns. The portable screwing-machines for wrought-iron bolts and tubing, illustrated and described at the end of the book, are well worth attention.

Messrs. Young & Co., of Victoria-street, Westminster, send us a useful catalogue of their iron fittings for stables and cow-houses, saddle and harness-room and coach-house fittings, &c. The catalogue, which is very comprehensive and well-illustrated, should be looked at by architects who may be called upon to carry out works of this character.

Correspondence.

To the Editor of THE BUILDER.

BUILDING ACT AMENDMENT.

SIR,—Might not the forthcoming Building Act provide as follows?

1. That no works shall be begun until the written authority of the District Surveyor has been obtained.

This would stop many irregular works *in limine*. The onus of justifying them would fall on the person proposing to do them, who could, of course, summon the District Surveyor in case of wrongful refusal. At present, the builder generally makes a start and the District Surveyor has to summon him.

2. That the person giving notice deposit with the notice the sum of, say, 5*l.* in the case of alteration works, or 10*l.* in the case of a new building. The difference between the authorised fee and the sum deposited to be returned to him when the District Surveyor has become entitled to payment.

No one who has not had (I have) to assist a District Surveyor in the management of his district can form any idea of the time lost in collecting the fees. And this time could be so well devoted to looking after the buildings, instead of running after the builders. I am sure that half my time went in fee-collecting.

I believe that the District Boards of Works insist on a deposit before any interference with public pavings. The amount to be deposited is fixed by their Surveyors, and the balance, if any, is returned when the Board has taken up and made good the footway or roadway.

The deposits which I suggest need not be made with the District Surveyor, or at Spring-gardens. Suburban banks are now very numerous, and would be glad enough to hold them.

January 7, 1892.

L. C. R.

SIR,—As there is no definition of the word "building" in the present Act, on several occasions when proceeding against wrongdoers I have been asked to define a "building," and the following has been my definition:—"A structure or edifice for the purpose of trade, manufacture, occupation, use, or convenience." I think that a sufficiently inclusive drag-net.

I would suggest that "sheds," *i.e.*, slight buildings roofed in and supported on piers, or iron or wood posts, should be erected to the satisfaction of the District Surveyors. "Public building" should mean every building used for a public purpose, and should include banks, colleges, and schools. I had to contest the question of school construction, and lost the case because schools were not mentioned, yet the corridors and stairs were of wood, and numbers of boys in the school in question sleep on the premises. The Press took it up and commended me.

"Domestic building" should include every building, from a cottage to a palace, not otherwise described or defined.

"Warehouse" should include all buildings use for storage purposes, manufactories, breweries, distilleries.

Some years ago I had to contend with Mr. Dayman, police magistrate, who said that the ground floor was the floor next the ground. Finding he was about to decide against me, I applied for an adjournment for a fortnight that I might ask the world what it understood by the phrase "ground floor." I received some thirty replies, and some of the sketches were very ingenious, especially that by the late Mr. E. W. Godwin, who sketched a house next a bill and from it an entrance to each floor (the Yacht Club, Gravesend, is an illustration). Mr. Dayman was a little

taken aback by it; however, he said he did not care what we all agreed on, the ground floor was the floor next the ground; but when I asked him to what floor cellars and underground rooms belonged, he said he couldn't say, and gave me my case.

I have a number of decided cases pasted in a copy of the 1855 Act, opposite to the section to which they apply. I will look them through and send on, as they may be instructive.

Let the definitions be as clear as may be, some omissions are sure to occur, and I would recommend that, in the absence of definition, the dictionary meaning should be adopted, say, the "Imperial," "Walker," or "Webster." The judges have adopted this course. I give a case in point: "South African Bank v. Stokes." Stokes wanted to go down below the level of strong-room floor. The Bank, scared for the safety of its money-bags, resisted, on the plea that the Act gave only power to raise a party-wall, and that being so, Stokes could not underpin. Sir George Jessel, Master of the Rolls, tried the case, referred to the dictionary, and found to raise meant "to enlarge, to extend, to increase, to advance." He said that means making the wall deeper, higher, longer, and does not mean simply putting a piece on the top; Stokes can underpin. To underpin should be defined. T. E. KNIGHTLEY.

106, Cannon-street, E.C.,
January 13, 1892.

ROOD-SCREENS.

SIR.—I never said the stone screen or parclose at Totnes had been removed. "Devoniensis" admits the rood-loft is gone, and that it was co-extensive with the original one is clear from the position of the staircase, one bay east of chancel arch. This staircase now leads nowhere, though it may be "closed up with an ornate entrance." If the ugly north gallery is erected in a new aisle, there is still less excuse for it than I thought.

No doubt the late vicar was an excellent man; but his school are notoriously opposed to rood-screens. Your readers will know that during the last years of Archbishop Thomson, no new screens were permitted in his diocese, and many disappeared. That in Beverley St. Mary was stowed away over the vaulting of the north chapel. (The new one in the minister merely replaces another, and is rendered necessary by the returned stalls.) At Chesterton (Cambridge) the vicar swept away the fifteenth-century screen at the recent "restoration"; at North Pethers, the squire (who has a Quaker name), during a vacancy of the living, removed the screen to a neighbouring barn. And similar instances will occur to many of your readers. January 9, 1892. VIATOR.

TOTNES CHURCH.

SIR.—Will you allow me to correct an error in the letter of "Devoniensis" in your last week's number?

The repair of the stone staircase of the rood-loft and the new paled and carved oak roofs throughout the church—which brought the work of restoration to a close—were carried out under the direction of Mr. C. R. Baker King, of London.

EDWIN G. S. LUSCOMBE.
Exeter, January 11, 1892.

THE OLD WATCH-HOUSE AT KING'S CROSS.

SIR.—In reference to your paragraph on page 7, *ante*, I well remember passing the old watch-house at King's-cross, when my then very infantine mind was delighted at seeing an individual conveying some fluid to a friend, who was incarcerated in the basement, by pouring it into the bowl of a tobacco-pipe, and so by the stem through an iron grating to the mouth of the recipient.

The foundation just discovered only 2 ft. below the surface could not, therefore, I think, have served for this structure.

S. J. NICHOLL.

TAR ON SLATES.

SIR.—Can I learn from any of your readers how to remove tar from a roof of slates without displacing them? IGNORANCE.

ALTAR AND REREDOS, ST. KATHARINE'S, FELTON, SOMERSET.—The new altar and reredos given by the vicar (Rev. H. G. Phillips) and his sister, in memory of their father and mother, were dedicated on the 24th ult. in St. Katharine's Church, Felton. The altar and reredos were supplied by Messrs. Jones & Willis, and are of oak. The panels are filled in with paintings, the centre one in the reredos representing the Crucifixion, and the side one the Virgin Mary and St. John. The centre panel in the front of the altar shows the Saviour in the act of blessing; and adoring angels are represented upon the side panels.

The Student's Column.

WARMING BUILDINGS BY HOT WATER.

III.

THE CIRCULATION OF WATER.

THE previous paper dealt with the convection currents of heated water, as they are manifested in an open vessel. This is not sufficient to illustrate how the motion is utilised for heating purposes in a system of pipes. If we take the glass jar mentioned in the last paper, and stop the mouth with a tightly-fitting cork, we can make use of it as a boiler in the following way. Get a few feet of $\frac{3}{4}$ in. or $\frac{1}{2}$ in. glass tube, which is easily obtainable at a glass-worker's or dealer's, and after cutting two holes in the cork of the bottle, fit up an apparatus something like fig. 5. This tube can be easily bent in the flame of a spirit lamp or over an ordinary gas burner, and by marking it round with a small file it can be cleanly broken at any point. The tube is jointed where required by short pieces of rubber tube, a size smaller, and stretched on. Tee-pieces can be made from zinc or copper tube.

From a little apparatus like this very many useful results can be noted. Usually results are only attainable by feeling the pipes of an existing apparatus, and it is not always that any degree of certainty can be experienced in solving problems. With a glass model, filled with water containing amber dust, the causes of difficulties can be readily noted, and its simplicity of construction enables many things to be tested which might have to be guessed at otherwise. Sometimes, however, a certain allowance is necessary for the smallness of the apparatus.

The first and most important thing to be described as regards this little appliance is the reason for the different levels at which the pipes terminate in the boiler. It has been explained that immediately heat is transferred to the water particles at the bottom ascend, and the cooler particles, those not yet affected by the heat, descend to take their place, and this brings about the circulatory motion or direction of the water. By having the opening of one pipe at the top of the boiler and the other at a lower point we can with certainty rely upon the heated water ascending the former and not the latter, and by this means the current is carried in the required direction. If, on the other hand, we terminated both pipes at the top of the boiler, we should still get as rapid and as efficient a circulation, but we should quite lose the feeling of certainty as to which pipe the heated water would pass up, or which would have the cold water descending in it. In other words, we could place no reliance in one acting as the "flow" pipe and the other as the "return" regularly and unfailingly.

There is a commonly-accepted idea that if pipes were thus terminated, at exactly level and equal points in a boiler, no circulation would take place in the pipes; that is, the water in neither pipe would give to the other, and consequently, both columns would remain stationary. This is incorrect; the little apparatus illustrated can be easily made to demonstrate how readily the circulation sets up, but with the pipes level it is impossible to say which will be the ascending column, the "flow," and which the reverse. Strange to say, the pipe which acts as the former one day may very likely take upon itself the duties of the latter the next day, although no interference with or alteration to the disposition of the pipes be made meanwhile. It is not, however, necessary to inquire further into this phenomenon, as it is never necessary, and never proper, to terminate the pipes at points level with one another, and if terminated at different heights irregularities of this kind cannot very well happen.

It will be now understood that the action which takes place when heat is transferred to

water enables us to bring about a transference of the heated water from the boiler to any point we may require. There is no reasonable limit to the distance at which this can be effected, for the fluid is so free from friction amongst its particles, so exceedingly mobile, as to have a very rapid movement, and travel a considerable distance in a short space of time. This is supposing certain necessary features are observed in the construction of the apparatus.

In the first place, it will have been gathered that the point at which the heat is applied to the water, that is, the position of the boiler, must be the lowest of all, and from that point the pipes should be disposed so as to give the water every facility to proceed in the ascending direction the heat causes it to take. This would at the same time give the descending column of cold water (the "return") every opportunity to take its downward course towards the boiler and effect its downward pressure, which is an all-important feature, as will be described directly. In horticultural works, unfortunately, the ascending and descending pipes are very limited as to length, as from the top of the boiler to the highest point of the system of pipes is seldom more than a few feet, and this tends to minimise the desired effect. In building works, however, the reverse of this is usually the case, the height of the apparatus being everything that could be desired, and permitting of such an effective circulation as even to need the introduction of means to divert and check it. An apparatus extending in a horizontal direction, without height, has the least motive power; one that extends vertically and has little horizontally has the highest motive power. By motive power is meant speed of circulation; there being features which conduce to a free and high speed in the movement of the water.

In concluding the actual description of the circulation of water it has to be pointed out, as it was when describing the action of convection in an open vessel, that it is the weight of the cold water, in displacing the lighter warmed particles, that brings about the motion. It is decidedly essential that this be understood, for the prevailing notion that warm water has an inclination of its own to rise has led to very many strange conclusions in solving problems in these works. There can be no more peculiar idea than this, and a moment's reflection shows everyone that hot water does not rise of its own accord. If we put some heated water in a vessel it does not instantly rise up and flow over the sides, but if we put precisely equal quantities by measure of cold and very hot water in the opposite pans of an accurate pair of balances we should find the pan containing hot water would rise, not by any effort or will of its own, but because the cold water by its greater weight caused it to do so. The hot water, in a system of pipes is quite a helpless element; the cold water by its superior gravity is the active force. It has been remarked:—"Were there no gravity there could be no convection. Were it not for gravity it would be of no consequence what part of a vessel we heated, the effect of the heating would be always the same."

It will be found, when examining the processes in a glass apparatus, that when a movement takes place it is instantly transmitted everywhere, or it would be better to say the movement takes place everywhere at the same instant. It might be supposed that when the lamp is first placed under the boiler that the circulation might set up in the boiler itself for a short period before affecting the water in the pipes. This is, however, not the case, for directly the faintest motion is observable in the boiler, the water in the pipes will be seen fulfilling its duties. This is due to the non-elasticity of water. We might almost compare it to the movement of a solid substance, if it is given a motion at one end we expect the opposite extremity to move at the same instant.

From all this we gather that the circulation of water in pipes is brought about by the different degrees of gravity of the water in the flow and return services,—that is, the ascending and descending columns of water; that, by increasing the vertical length of the pipes we increase the strength of circulation, or motive power, and that the water in horizontal pipes cannot aid circulation, but only go to retard it, action, more or less, according as the length is great or little.

In horticultural works, as just mentioned, the vertical pipes are quite in the minority, for, as a rule, the services have to be carried horizontally, or very nearly so, almost immediately

they leave the boiler; and to examine the action that takes place in this instance we should have to construct a little apparatus, as fig. 6. In this case we cannot very well see

FIG. 6.

any glass vessel for the boiler, in consequence of the return-pipe having to enter its side as shown; but, as the other experiments with glass boilers give a very clear idea of what action takes place within them, we can get along very well with a zinc or copper one in this case. It is what takes place in the pipes that is of greater interest now.

It has now to be explained that when speaking of horizontal pipes in these works it must be understood that they are not perfectly horizontal, but have a slight ascent from the boiler to the furthest extremity or extremities. In all hot-water works for heating purposes a perfectly horizontal pipe is looked upon as a bad feature, and this applies with the greatest possible force to horizontal works, which have such a low motive-power at all times. The upward inclination of the pipes, however slight, aids the circulation, and there is rarely an instance in which a rise is not obtainable, even if only an inch in ten feet. Then there is another reason of fully equal importance why pipes should have a regular rise to their furthest extremities, viz., to admit of the air escaping freely from within them, not only when first changing, but at all other times. Air-vents, pipes, or cocks are always situated at the extremities, these being the highest points, as stated. This subject will be fully dealt with in due course.

SURVEYORSHIPS.

BELFAST.—The Belfast Corporation have increased the salary of Mr. J. C. Bretland, M.Inst.C.E., City Surveyor, to 800*l.* per annum; that of Mr. Jas. Munce, Assoc.M.Inst.C.E., the Assistant City Surveyor, to 350*l.* per annum; and that of Mr. G. A. Boyd, third assistant and Superintendent of Buildings, to 150*l.* per annum.

DIOCESE OF LINCOLN.—On the 12th inst., at a meeting of the Archdeacons and Rural Deans at the Old Palace, Lincoln, the Bishop of Lincoln presiding, Mr. J. C. Traylen, architect, Stamford, was elected an ecclesiastical surveyor for the diocese of Lincoln.

GENERAL BUILDING NEWS.

NEW BOARD SCHOOLS AT BARKING, ESSEX.—The new schools in Gascoigne-road, erected by the Barking School Board, were opened on the 7th inst. The site is one and a half acres in extent, and each of the four frontages of the school faces a roadway 40 ft. in width. The schools provide accommodation for 1,408 children, viz., 545 infants on the ground floor, 432 boys on the first floor, and 432 girls on the second floor. The infants' department consists of one class-room for 110, and five class-rooms for sixty-four each, all fitted with Kindergarten dual desks on raised floors; and a hallies' room for 115, also fitted for Kindergarten teaching, —the desks in this room being fixed on galleries. The boys' and girls' departments, on the first and second floors respectively, have each two class-rooms for eighty-six each, and five class-rooms for fifty-two each, all fitted with dual desks on raised floors. On each floor is a central hall, 64 ft. long and 32 ft. wide, the seven class-rooms from each department opening from the central halls, which will be used for assembling the children of each department at the commencement of school-hours, and for physical drilling, examinations, singing, and other purposes. They will also serve as corridors for access from the various class-rooms to the staircases, entrances, &c. An entrance is provided at both ends of each floor, so as to enable each department to empty at both ends at the same time, the first and second floors having separate staircases leading from them for that purpose, thus obviating the inconvenience and danger of crowding a large number of children at one part, as would be the case if only one entrance for each floor were provided. The staircases have easy-going short flights

of granolithic stone steps. Cap and cloak rooms for the use of the children are provided at both ends of each department, and the lavatories are placed in these rooms. A cookery class-room is provided on the second floor, and fitted with cooking-ranges, dresser, sink, and other appliances necessary for the purpose of teaching the girls plain cooking. A separate private room is provided for the head teachers and assistants for each department, and is fitted with an "Eagle" cooking-range, and furnished so that the teachers need not necessarily leave the building between morning and afternoon school. Separate and distinct cloak-rooms, latrines, and lavatory accommodation for the teachers are also provided within the building. The schools are well-lighted, and fifteen out of the twenty-two class-rooms have a direct north light. The whole of the class-rooms are warmed by open fireplaces fitted with fire-lump stoves, with wrought-iron fronts of a special character, the two large class-rooms on each floor having, in addition, a hot-water radiator. Each of the central halls is warmed by five hot-water radiators, three of which are made ventilating, the cold air being drawn in at the bottom from the outside, and discharged warmed on the inside at the top. Each of the cap and cloak rooms is warmed by hot-water pipes running round three sides of the same, for the purpose of drying the children's clothes when wet. The fronts of the cloak-rooms, being fitted with wire gratings, admit of the hot air escaping and warming the staircases and landings. The system of ventilation adopted is that of simple inlet and outlet, the whole of the windows throughout being of a special design, whereby, upon the lower sash being slightly raised, an upward current of air is admitted at the sill level and also at the meeting-bar level without causing draughts. A separate and distinct extraction shaft for carrying off the vitiated air is carried up in the chimney-stack from each class-room. The latrines, which are in two blocks, to suit the entrances, at each end of the buildings, are fitted with a range of closets-pans and flushing apparatus, specially designed by the architect. The walls are of yellow stock bricks faced externally, to a height of 4 ft. all round, with blue Staffordshire bricks, and above that height with malm, relieved with red brick pilasters and terra-cotta terminals, gauged red brick arches and aprons, and moulded red brick string courses. The internal face of the walls to all class-rooms, central halls, corridors, and cap and cloak rooms, to a height of 4 ft. from the floor, and the walls and newels of the staircases throughout, are faced with brown salt-glazed bricks. The locks, fastenings, and fanlight gearing throughout have been manufactured by Messrs. Hart, Son, Peard, & Co.; the sanitary fittings by Messrs. Tylor & Co.; the hot-water heating apparatus by Messrs. Winter Smith, Gray, & Co.; the stoves by Mr. Thomas Easley; and the wood-block flooring by the Westminster Patent Wood Block Flooring Company. The school furniture has been supplied by the Bennett Furnishing Company, of Glasgow. Four covered playsheds are provided for use in wet weather. The whole of the works have been carried out by Mr. F. T. Coxhead, of Leytonstone, Mr. Morley acting as the superintending foreman. The total cost of the buildings, including furniture, boundary-walls and fencing, latrines, play-sheds, drainage and paving of playgrounds, and architect's charges will not exceed 10*l.* per head. The schools have been erected from plans prepared by Mr. C. J. Dawson, F.R.I.B.A., Architect to the Board.

WESLEYAN METHODIST CHAPEL, FELTON (NORTH-UMBRIA).—This new building has just been opened. It is built in style, built of local stone, and presents a high pitched gable towards the street. This gable is set back sufficiently to allow of two flights of steps; those on the north of the central entrance gates leading to the porch into the chapel, and those on the south side, to the path which leads to the schoolroom, which is placed across the western end of the building. The size of the chapel internally is 30 ft. in length by 24 ft. in breadth, and the schoolroom is 30 ft. by 15 ft., a part of the south end being screened off by revolving shutters to form a swing-room, in case of tea-meetings, or at other times a minister's vestry. The architect is Mr. F. R. N. Haswell, F.R.I.B.A., of North Shields.

NEW BOARD SCHOOLS, HEeley, SHEFFIELD.—On the 11th inst. the new schools erected by the Sheffield School Board in Gladstone-road, Heeley, were opened by the Ven. Archdeacon Blakeney. The schools, which have been built by Messrs. W. Ives and Co., contractors, of Shipley, are erected from the designs of Mr. C. J. Innocent, architect, Sheffield, and they are spoken of by the *Sheffield Daily Telegraph* as being the finest schools yet erected in Sheffield. In the school for boys and girls each department has a large room and five other rooms, which can be used for class teaching, with an arrangement by which a number of them can be thrown together for general purposes, and thus obtain a much larger room. There has been accommodation provided for 420 boys, 420 girls, and 360 infants. The infants occupy a separate building, and here the arrangements of the general school-rooms and class-rooms have been arranged on what the same journal says is an entirely new plan. The maximum of light has been

secured all through the schools, and the rooms are exceptionally bright, well warmed and ventilated. In each department there are two rooms set apart for the use of the teachers; and in every way the comfort of the staff and of the scholars has been studied. The cost of the site, which occupies 7,550 square yards, is 2,530*l.*; and the cost of the buildings, including the furnishing, is 11,170*l.*, making a total cost of 13,700*l.* As the accommodation is for 1,200 children, the cost per head for the site amounts to 2*l.* 2*s.*, and for the building and furnishing 9*l.* 5*s.* 2*d.*, the schools thus costing per head 11*l.* 7*s.* 2*d.* The amount of the contract, including the building of the caretaker's house, the raising of the extensive boundary walling, the playgrounds, and the sheds, was 10,200*l.* The heating apparatus has been fixed by Messrs. J. H. Pickup & Co. (Limited). Mr. Cartwright has acted as clerk of the works. The schools already opened by the Board provide school places for 29,625 children, and the opening of these additional schools will raise the total to 30,532. During the opening proceedings the architect was highly eulogised by more than one of the speakers.

SANITARY AND ENGINEERING NEWS.

NEW WATERWORKS, MARGAM, GLAMORGAN.—On the 17th ult. the new waterworks which have been provided to supply with water the Lletythiri, Pen-y-gwryd, and Gwariacha districts were opened. The most populous part of this Local Board district is supplied from a reservoir at Lletythiri, which has a storage capacity of 1,700,000 gallons, but the hamlets named above have up to the present had a very inefficient supply. The springs which accumulate on the slopes of the Lletythiri Mountain have been conducted down to the foot of the hill, where a storage reservoir of a capacity of 10,000 gallons has been constructed. From this pipes conduct the water to taps situated in convenient spots in the three villages. The contractor was Mr. John Davies, of Aberavon. The total cost was 1,000*l.*, which was defrayed by Miss Talbot.

SEWERAGE AND SEWAGE DISPOSAL SCHEMES, CHESTER-LE-STREET.—On the 18th ult. Mr. Arnold Taylor, Deputy-Chief Engineering Inspector of the Local Government Board, held a Government inquiry at the Board-room, Chester-le-Street, Durham, as to sanction to borrow the following amounts for schemes of main sewerage and sewage disposal for the following places, viz.:—Birtley, 5,000*l.*; Edmondley, 2,000*l.*; Scariston and Daisy Hill, 4,500*l.*; and Witton Gilbert, 2,300*l.* The schemes include main sewers, with ventilating and flushing arrangements, and land for sewage disposal by the process of intermittent land filtration. The plans, estimates, &c., were fully explained by the Engineer, Mr. D. Balfour, M.Inst.C.E., F.G.S., of Newcastle-on-Tyne; and after due consideration of the schemes, the Inspector expressed himself as fully satisfied with the proposed works as being the most efficient and economical in the circumstances. Provisional Orders for the compulsory purchase of the several lands had already been obtained, and the various sites visited and approved of by the Inspector.

WEST BRIDGEFORD WATERWORKS.—An industrial water syndicate has been formed at West Bridgeford, and it has been decided to put down a deep boring into the Bunter sandstone to test the quality and quantity of the water. The West Bridgeford Local Board are now supplied by the Nottingham Corporation, but a large section of the ratepayers wish to have separate works. Mr. W. H. Radford is the engineer.

ORPHAN WORKING SCHOOL, HAVERSTOCK-HILL.—These schools, which usually have over 600 children in occupation, have had to be closed, and the children removed, owing to defects in the sanitary condition of the buildings, and the Estates Committee instructed their architect, Mr. Chas. Doll, to prepare plans and specification for putting matters in order. Mr. Doll prepared two schemes, one for improving the existing sanitary arrangements in their present positions, and another for building detached separate sanitary blocks. The Committee, under the advice of Mr. Edward Tidman, C.E., have adopted the system of separate detached blocks.

ESSEX COUNTY COUNCIL.—Mr. Edward Tidman, C.E., F.S.I., of Westminster, has just been appointed by the Technical Education Committee of the Essex County Council lecturer on "Hygiene," and will shortly commence a course of lectures under their auspices.

TIME MEASUREMENT FOR PHOTOGRAPHIC PLATES.—Messrs. Marion & Co., of Soho-square, send us a description of Hurter & Driffield's actinograph, by which the "speed" of a plate, —i.e. the necessary time of exposure for the best result,—is calculated for various times of the day and (approximately) for various states of the atmosphere in regard to light. It is proposed that manufacturers should test their plates according to the actinograph, and indicate their speed of production by a number, when reference to the actinograph index will give the exposure for the plate under various conditions of light. The subject may be of interest to some of our readers who make their own photographs of architecture.

CONTRACTS, AND PUBLIC APPOINTMENTS.

CONTRACTS.

Table with 5 columns: Nature of Work or Materials, By whom Required, Architect, Surveyor or Engineer, and Tenders to be delivered. Includes entries for street improvement works, excavation work, and alterations to St. Augustine Manor.

CONTRACTS.—Continued.

Continuation of the Contracts table, listing items such as new school, granite seats, and broken granite, with corresponding architects and tender dates.

PUBLIC APPOINTMENTS.

Table with 5 columns: Nature of Appointment, By whom Advertised, Salary, and Applications to be in. Lists positions like Sanitary Inspector and Clerk of Works.

Those marked with an Asterisk (*) are advertised in this Number. Contracts, pp. iv., vi., & viii. Public Appointments, p. xx.

FOREIGN AND COLONIAL.

FRANCE.—Baron Alphonse de Rothschild has presented to the Louvre two remarkable Florentine bronzes of the sixteenth century. The museum has also received from Dr. Fouquet, of Cairo, some fine specimens of Medieval Arabian art. The Paris municipality intends to restore the fine frescoes in the Central Hall of the Palais de la Bourse, executed by Pujol. A competition is to be opened shortly for the decoration of the Salle des Mariages of the Mairie of Montreuil-sous-Bois. The decoration will include four panels, and will cost about 20,000 francs. M. Cargill, pupil of MM. Daumet and Girault, has obtained the Godeboeuf prize at the Ecole des Beaux-Arts. The subject was "Un lustre électrique." M. Dalou has been commissioned to execute, for the Conservatoire des Arts et Métiers, the statue of Boussingault, who is regarded as the founder of Agricultural Chemistry. A committee has been formed with the object of raising at Colombes (Seine) a monument to Litolff, the musician, who died recently. M. Lucien Pallez is commissioned to execute it. A fire has partially destroyed the fine Salle d'Audience at Grenoble. The fire has nearly ruined a splendid ceiling of historic interest, as well as some remarkable sculptures dating from the fourteenth and fifteenth centuries. The building was one of the ancient residences of the Dauphins of France.—The new railway line between Brienne-le-Chateau and Soresy is shortly to be opened.—The French Government has issued a new postage stamp for the colonies. The vignette is composed of two figures seated on the prow of a ship and symbolising Navigation and Commerce; they each hold the national flag with one hand.—M. Justin Rochet has been appointed architect to the general administration of "Assistance Publique" at Paris.—On the occasion of the new year M. Daumet, president of the Société Centrale des Architectes, has been promoted to be officer of the Legion of Honour. Among the architects MM. Leclerc, Mayeux, and Trélat have been created chevaliers.—The late M. Bailly has left a sum of 50,000 francs which will be converted into 3 per cent. rentes and will go to the foundation of an annual prize to the author of some work of architecture. He has left the Académie free to decide on what terms the prize should be awarded.—The bust of Jules Grévy by Carrier-Belleuse has been placed in the Palais de Justice at Paris, in the Advocate's Library.—The death is announced of the painter Charles Louis Muller, Member of the Institut, at the age of seventy-six. He was a pupil of Gros and Cogniet, obtained medals at the Exhibitions of 1835, 1849, and 1854, and a first-class medal at the Universal Exhibition in 1855. Among his numerous works may be mentioned the "Assassinat d'Arthur de Bretagne par Jean Sans Terre" (Salon of 1839); "Jésus et le Démon sur La Montagne" (1840); "Combat des Centaures et des Lapithes" (1843); "Entrée de Jésus à Jérusalem" (1844); "Primavera" (1845); "Lady Macbeth" (1849); "L'Appel des Durriers Valmies de la Terreur" (1850). This large picture, which fell a few years back to be seen at the Luxembourg, aroused great enthusiasm on its first exhibition. The works which followed it were little appreciated, and the artist was so much affected by their non-success that he retired almost altogether from society. He exhibited in 1857 a picture representing the arrival of Queen Victoria at the Palace of St. Cloud. He also decorated the "Salle des États" at the Louvre, and the cupola of the Pavillon de la Fontaine.—The fortieth

Exhibition of the Société des Amis des Arts of Bordeaux will open on March 7. SWEDEN AND NORWAY.—The students of the Upsala University have decided to accelerate the work on their new assembly-hall, according to a new programme, by which the cost of the building will be reduced to one-half, viz., 36,000. The budget of the city of Stockholm for the current year provides for 15,500 for the improvement of streets and open spaces.—We have previously referred to the competition for a new exhibition building at Bergen, in Norway, and we now learn from the Teknisk Ugeblad, the organ of Norwegian architects, that the first prize of 1,200 kr. has been awarded to Herr H. Baehor, and second prize or 800 kr. to Herr H. Bull. The journal named again expresses great indignation with the competition, on the ground (1) that a second programme was substituted one month after the issue of the first, and (2) that on the first list of the jury the names of two prominent architects were entered without their consent, and when withdrawn the names of a contractor and a local architect not standing were substituted. The architects whose time and labour have been wasted intend to claim damages.—At the last meeting of the Polytechnic Society of Christiania, Herr G. Stenber, engineer, read a paper on the construction of iron bridges by native workmen, maintaining that native work was as good as foreign, as shown in the new bridge over the river Rena, the longest in Norway. He, with several other speakers, urged that the work of constructing the great bridges for the new railways about to be built should be given to the native engineering firms.—The secretary of the Royal Hunt Club in Madrid has requested Norwegian and Swedish manufacturers of timber vials to forward designs for a club house in Norse style at the El Pardo, near Madrid.—The first export of timber vials to India from Norway has been made by a firm in Thronhjem.

MISCELLANEOUS.

MESSRS. FOY, MORGAN & CO.'S ANNUAL WOOD REPORT, 1891, says:—"For London timber merchants there can be no doubt that the results of the past year's trading must be considered satisfactory, and to have gone some way to repair the disastrous losses incurred in 1890. It will be remembered that, although the close of 1890 was weighted by a heavy stock, the level of prices was such as to promise a good demand and general improvement in the market. That these expectations were falsified must be attributed to the heavy failures which took place early in January, and to the results entailed by the consequent shrinkage of credit. For those reasons the f.o.w. sales for London were restricted, and the necessity for consignments was avoided by the abnormal demand from France, caused by the desire of the merchants to forestall the proposed import duty. The coast ports absorbed a large quantity of goods for early summer shipment, and thus, when the results eventually came into the f.o.b. market, the smallness of the available stocks precluded the possibility of over speculation. The market began to show signs of mending about May, at first, however, almost imperceptibly, and it was not until the middle of September that the rise in prices attracted general attention. The last quarter of the year has been characterised by a certain expansion of the imports, due to the expectation on the part of merchants of higher prices, but also by a lessened

demand arising from the unwillingness of consumers to pay enhanced prices. As soon as these opposing interests have been reconciled, and the market has settled down, a fair trade may be looked for. Among the Deal sizes the noteworthy features of the year have been, with respect to Redwood, the great scarcity of 11-in. widths, and the consequent widening of the difference between the values of 11-in. and 9-in. Redwood, of all qualities; it being probably many years since 11-in. Fourths have realised 20s. to 25s., and Mixed and Thirds 40s. to 60s. per standard more than 9-in. With respect to Whitewood the tendency has just been the other way, 11-in. having been seldom more plentiful than now, and 9-in. seldom scarcer. This is directly traceable to the early sales of Whitewood to the French market. In all qualities except Fir, there is practically very little difference in the present values of 9 and 11-in.; White Spruce 11-in., however, has always fetched 10s. more than 9-in. Batten sizes have generally tended to the reverse of the position occupied last autumn. Thus the glut of 2-in. battens, which occurred last fall, was found to consist mainly of the narrow widths, namely, 2 by 4, 2 by 5, and 2 by 6 in., the extreme depression in the prices of which consequently stood in marked contrast to the comparatively stable prices at which 2 by 7 and 8 in. were realised; whereas the close of this year discloses an inadequate supply of, and a rising market for, the former sizes, while 2 by 7 seems sufficient in stock, and exhibits no change in the lower qualities of 2 and 3-in. battens have been in moderate supply throughout the year, and prices have shown only a slight fluctuation, with apparently very little immediate prospect of increasing."

THE ENGLISH IRON TRADE.—The English iron trade remains practically unchanged, business, on the whole being of but limited dimensions. The exports of iron and steel for the past year show a falling-off of no less than 700,000 tons as compared with 1890. During December they suffered a decline of 40,550 tons. In all the pig-iron centres trade is quiet, and only a moderate business is doing in manufactured iron. Tin-plates are inactive. The steel trade generally exhibits fair movement. The engineering trades are moderately active; but prospects are somewhat gloomy. Shipbuilders are busy. The coal trade is tolerably brisk, the demand being chiefly for household qualities.—Iron.

WESTMINSTER SCHOOL OF ART.—We are asked to mention that provision is made for a limited number of free students at this School of Art. Candidates must be workmen resident in the City of Westminster, or the sons of such workmen, and a preference is given to residents in the parishes of St. Margaret and St. John. They should have some aptitude for drawing, and candidates between the ages of fifteen and twenty-five are preferred. Applicants are invited to call on the Curator, at the Royal Architectural Museum, 18, Tufton-street, Dean's-yard, Westminster, on Monday, Wednesday, or Friday evening, between 7 and 9.30 p.m., and to bring with them a letter of recommendation from a clergyman, or some other person on whose testimony reliance can be placed.

FURTHER ENGINEERING WORKS AT ANTWERP.—Although the dock accommodation at Antwerp is constantly being improved, it is still found insufficient, and it has therefore been decided to construct another large dock, in order to establish direct communication between the African Basin and the Scheldt. The project has been sanctioned by the Government.

ELGIN.—Accepted for the erection of a villa-residence in Roid-baven-street, Elgin. Mr. George Subbitt, architect, Elgin:—
 Mason, Wm Scott.....
 Carpenter, Geo. Mitchell.....
 Plasterer, Jas. Brodie.....
 Plumber, John Hunter.....
 Sinker, John Wilson.....
 Painter, John James.....
 [All of Elgin] Total cost, £1,000.

LONDON.—For alterations at the "Bow Bells" Bow-road, E., for Mr. J. W. Gibbs. Messrs. Fletcher & Miggott, architects, 73, Bow-road, E.:—
 Laocelles & Co. £782
 Sait, 778
 Walker Bros. 625
 Tools 625
 Courtney & Fairbairn £525
 Sheffield Bros., Stoke New-ington* 537
 * Accepted.

LONDON.—For alterations and additions to the "Dolphin" public-house, Finch-hedge-street, Euston-road, for Mr. A. Shoubert. Messrs. Karstake & Murtimer, architects:—
 Lidstone £1,365 8 11
 Hulton Bros. 1,815 0 0
 Picken 1,855 0 0
 Higgs & Hill 1,865 0 0

LONDON.—Accepted for pulling down and rebuilding Nos. 49 and 51, Lion-grove, Paddington. Messrs. Wilson & Long, architects, 15, King William-street, Strand:—
 Williams & Richards, Clapham Junction £1,648 0 0

NANTWICH.—For draining, making-up, and metalting road at the hospital, for the Union Guardians. Mr. J. A. Davenport, surveyor, Heathfield, Nantwich:—
 Henry Chesters £175 0
 George Cox 165 0
 Thomas Jones 160 0
 John Thomas Greig, Willington* £155 0
 * Accepted.

SOUTHAMPTON.—For sewage machinery, for the Corporation. Mr. W. B. G. Bennett, Borough Surveyor, Municipal Offices Southampton:—
 J. R. Hainsworth & Co. £1,190 0 0
 Hughes, Mann, & Co. 550 0 0
 Gotto 787 0 0
 Crossley Bros. 770 0 0
 Leste, Edwards, & Norman 770 0 0
 Campbell Gas Engine Co. 735 0 0
 Jewell & Son 702 0 0
 H. Frithen 680 18 4
 Fraichitt Bros. 478 0 0
 Maslove, Allott, & Co. £530 0 0
 Holey & Co. 527 0 0
 Baines, Hobson, & Co. 535 0 0
 Fielding & Platt 584 0 0
 W. Tinker & Sons 581 9 8
 Wells Bros. 552 18 0
 Noble, Roberts, & Co. 539 10 0
 Wynn Bros. 559 0 0
 British Gas Engine Co. 467 5 0
 Dink, Kerr, & Co. 439 0 0
 London (accepted).....

SOUTHAMPTON.—For laying certain sewerage pipe sewers and constructing manholes in connection therewith, and for the erection of an engine-house and pump-well and other works incidental thereto, for the Beaulieu Valley Drainage, Southampton. Mr. W. B. G. Bennett, C.E., Borough Engineer:—
 J. Crook & Son £1,248 11 1
 H. I. Sanders £721
 J. Crook & Son 888
 Roe & Co. (accepted) 475
 [All of Southampton].

UPTON PARK.—For alterations and additions to the Public Hall, Upton Park, E., for Mr. W. S. Hammetton. Mr. J. H. Carte, architect, Upton Park:—
 Watson £795 0 0
 Walls 767 15 0
 Wiles 672 0 0
 Chas. L. Cole* £260 0 0
 Hammetton 350 0 0
 * Accepted.

The Builder Cathedral Series.

The Human Habitation.

ALL who visited the Paris Exhibition of 1889 will remember the series of erections illustrating the history of the Habitation which were ranged along the Quai d'Orsay, and of which we gave at the time a description illustrated by sketches. The collection of models of dwellings, though it could hardly pass for a serious illustration of the vast subject of human habitations, was a remarkable *tour de force* in the way of archeological illustration, considering that it was got up against time, at short notice, and as a mere pendant to the main body of the Exhibition. M. Chas. Garnier, under whose direction the work was carried out, has not been content with this extemporised scenic illustration, but has since then been occupied, in conjunction with M. A. Ammann, in carrying out the illustration of the subject in a more full and deliberate manner. The result is before the world in a ponderous quarto of nearly 900 pages,* produced by a joint effort which is compared in the lively and piquant preface (in which it is not difficult to trace the hand of M. Garnier) to the old fable of the blind man and the paralytic: "One of the authors is a historian who does not see very clearly into matters of architecture; the other is an architect who hobbles very much in the pathways of history." Mutually assisting each other, they have been able to make a very long journey, "puisqu'il dure depuis plus de dix mille ans!"

The object of the book is rather to popularise the subject than to settle any disputed points in archeology; in fact, it may readily be supposed that a book on so vast a subject produced in three years' time could hardly lay claim to occupying a position of exact criticism, since from that point of view the

subject is too large for the lifetime of any one man. Contested points in regard to a subject of this kind can only be settled by those who devote themselves specially to one chapter of the history and follow it out in all its details. What the authors claim to have done, we may gather from the wording of their preface, is to have brought together and arranged in a systematic manner the best and most reliable information available from a collective treatment of their own researches and those of others who have treated special branches of architectural history.

The book is divided into five main heads, the first including the Pre-Historic period, the four others the Historic period, divided under the following sections—(1) Habitations prior to the Aryan invasions; (2) The Aryans and civilisations arising out of the Aryan invasions; (3) The great invasions and their consequences; * habitations of the Middle Ages and of modern times; (4) Habitations of people who have remained apart from the general movement of humanity. This latter heading includes the Chinese, the Japanese, the Cambodians, early American dwellings, &c., and makes (whether intentionally or not) a kind of connexion with or return to the opening subject, for it is in a considerable degree from the existing habitations of uncivilised tribes, where a kind of hereditary instinct rules, that we are able to conjecture the probable forms of pre-historic uncivilised habitations. It is in tacit recognition of this fact, we presume, that we find in connexion with the first chapter in the Pre-Historic section a view of the existing habitations of the tribe of Bongos, in the upper valley of the Nile: tent-like circular huts with thatched roofs and low walls of staves and wattles below.

The subject of pre-historic dwellings is fascinating enough in a speculative sense, and of course cannot be passed over in a general review of the history of the habitation, but it is an unsatisfactory element in a historical treatise, simply because it must for the most part be mere speculation. As in most cases, it leads the authors to those vague and general terms which we find in all such histories. Taking the habitations of the aboriginal Australian natives as known at

the present day, and conveniently assuming Australia as "peut-être le plus ancienne terre de notre globe," it is "natural to admit" that this strange continent has maintained to our day the most ancient "documents" of the history of the race, and then "d'après ces données, nous pouvons aisément figurer quelle était l'existence des hommes vivant aux époques le plus reculées que vous puissiez atteindre avec certitude." So we can in a general way; they were probably nomads, ignorant of the culture of the earth, chased by the large animals of those days, and having little to distinguish them from those animals except a certain faculty of arranging an artificial shelter from the weather where a natural one was not available, and of making some very rude cutting implements. All that can be imagined in a vague manner, with more or less realism according to the picturing power of each reader's mind. But it does not aid very much in tracing the history of the habitation. The authors, we observe, adopt the view that the formation of some kind of screen preceded the habitation in caves, and remark on it as a very important step in advance when men exchanged a temporary constructed shelter for a cave. We do not see why caves should be regarded as chronologically separate from the constructed shelter or *abri*. The use of caves for habitations would depend mainly on whether there were accessible caves in the locality; and in any case their use can hardly be considered a step in advance of the constructed shelter. Men living in natural caves have, so far, made no more progress in regard to a habitation than animals. The scooping-out of caves artificially is another matter, but the authors refer in the first instance to those "toutes préparées par la nature." A more important distinction between early classes of habitations is between those which were merely shelters from the elements, and those which were intended as defensible against human enemies. Between the shelter and the fortress is an immense step, and we should be disposed to say that it was the fear of other men, the tendency to fight and pillage, and therefore to form places of retreat and security, which was the more important factor in the development of the early habitations of mankind.

* "L'Habitation Humaine": par Chas. Garnier, membre de l'Institut, Architecte du Nouvel Opéra; et A. Ammann, Agrégé de l'Université, Professeur au lycée Louis-le-Grand. Ouvrage illustré de 335 vignettes, contenant 24 cartes. Paris: Librairie Hachette et Co.

* This appears to refer to the historic invasions from the north to the south of Europe since the Christian era.

This desire for security against attack was of course the influence which developed the elaborate system of lake dwellings, our knowledge of which is only a matter of comparatively recent acquirement, and was at first even received with scepticism by those outside the world of archaeologists. This dream of security, say the authors, had long haunted the brain of Troglodyte man, who probably first thought of some means of fortifying the entry of his cave, even as Robinson Crusoe did so elaborately in his island. Indeed, the whole description of the fortified cave in that wonderfully realistic narrative is a striking exemplification of the kind of work to which early mankind might have betaken themselves in the endeavour to get security from attack or at least from surprise; only the civilised brain of Crusoe (or Defoe) was equal to a systematic plan of fortification beyond what we may suppose the ingenuity of primitive man to have been equal to. Of such cave fortifications we have, however, no positive evidence, however probable the attempt may seem. If it was attempted, there seems to have come a time when it was recognised that it was a failure, or at all events that dwellings built out over the water were much easier to defend. For it is a primary object of all kinds of fortification to reduce as much as possible the length of barrier to be defended. Now in the case of a cave the fortification was almost necessarily a somewhat extended one, if it were to defend the approach to the cave: in a lake-built village the access to be defended could be reduced to a single narrow gangway, capable of being entirely cut off at pleasure. Our authors, as in the former chapter, give an illustration of the same kind of device from modern life. Living on trees seems an even more out-of-the-way and difficult kind of arrangement than living on lakes, yet villages in the Soudan, according to Dr. Nachtigall, are in the present day built in the boughs of trees, and the authors give, from his description, a sufficiently dramatic representation of an attack on a tree-village. The existence of such a method of building in the present day renders it probable that a similar resource occurred to peoples in the same stage of civilisation in early times: according to Henri Mürgler, indeed, it is a natural resource of distressed persons in all stages of civilisation, and a needy literary man in the "Vie de Bohême" gives his address as "Boulevard So-and-So, third tree, fifth branch." The building of lake houses, however, was a step a good deal in advance of either cave-dwelling or tree-dwelling; the fixing of the supports for the platforms in the bed of the lake was a comparatively advanced piece of engineering, and the making of the platforms and houses thereon a piece of construction requiring care and skill. On the other hand we may presume that the development of the lake dwelling preceded the development of the boat, otherwise the security sought for would have been very largely discounted. Nowadays such lake villages as exist are found, as the authors show in illustrations, along with the use of canoes or other kind of boats; but it seems more probable that the earliest form of lake village was in a pre-boating period, and consisted of a peninsula of dwellings accessible by a narrow bridge, a portion of which was removable.

If we come to think of it, water has in later ages been a very important element in the defences of dwellings or fortifications. We have the moated châteaux of France as examples—practically lake dwellings of a more elaborate description; the moat for many centuries formed an indispensable girdle to castles and strongholds in various countries. And our own country is an example, in her past history, of the strength and security given by an insular situation, which is only the same thing on a larger scale.

When we first come within the historic period we are still to a great extent in the Pre-historic position in regard to the everyday habitation. The great buildings erected at the service of either religion or war, the

temple and the tomb on the one hand and the fortress on the other, were monumental in character, and have endured so far as to leave us their main architectural elements complete, or open to intelligent study. But the everyday house was a more fragile and temporary structure, and has disappeared. Thus, in the book before us, the Egyptian habitation, the first on the list in what are called Historic times, is only decipherable from the data furnished by a few occasional conventional plans and representations, which leave us very far from arriving at a realistic conception of it. We know much more of the appearance and the social customs of the Egyptians themselves, from their pictured representations, than of the arrangement of the houses they inhabited. The authors go into a long description of the Egyptian house, but the only documents of any importance which they offer us are a "Plan of an Egyptian house" from a "peinture provenant d'un tombeau," and what they call a "maison égyptienne (d'après Champollion)," the latter a conventional kind of section with no unity of scale, and in which the figures alone convey the impression of being correct representations of fact; the house is capable of a very liberal interpretation. French writers are so fond of a complete theory that they are not easily deterred by a scarcity of data for it, and we can only regard the long description of the Egyptian house as an interesting but more or less imaginative document. It is characteristic of French archaeological work of this class that no decisive information is given, in regard to the cuts, as to the precise place from which they are taken, or the presumable date of the representations. They furnish excuse for and illustration to a theory and a good deal of picturesque writing, but leave the less imaginative English reader unconvinced.

It is probable however that the authors are quite right in their dictum that the conditions of the climate as well as the social habits of the Egyptians led them to avoid confinement within the house as much as possible. The social habits in a great measure would arise out of the nature of the climate; they can hardly be considered entirely apart from it. There is however one point in regard to social philosophy, touched upon by the authors, which is entirely independent of climate. They remark on the fact that the position of women in Egypt was obviously that of a social equality with men; hence, they observe, we find "no gynæceæ, no harem, none of those domestic prisons in which Oriental civilisations have so often enclosed the women of the establishment." That this free position of women in ancient Egypt did exist is obvious enough from the Egyptian representation of social life, in which women are seen seated at entertainments and making calls much as they do in modern European society; though we doubt if this conclusion could have been arrived at from the dressing up of rather imaginary house plans out of the data furnished by the conventional representations on which these plans are professedly founded. All that can be said is that these representations of the arrangement of the house interior, so far as they are comprehensible, offer (as one might expect) no hint at variance with the social freedom of women as evidenced in the Egyptian representations of figures of contemporary life.

The social position of woman is however an extremely important factor in determining the arrangement of the house interior, either in a negative or positive sense, among all civilised peoples. The Oriental seclusion and comparative degradation of woman is an extreme instance. But in countries and times when woman took her place on a more or less social equality with man, there is even then the consideration, operating distinctly on the plan of the house, whether men and women were to live together habitually by daytime, or whether there was to be a separation of the sexes in their daily life, a "woman's quarter" separate from the rooms usually occupied by the men. This idea obtained, as we know,

in Greece, where nevertheless women, even in the Homeric period, were in no condition analogous to that of Oriental harem life, though it could hardly be said that they enjoyed (or perhaps were fitted for) the modern position of intellectual and social equality of the sexes. The higher civilisation and culture advance, the more does this separation of the sexes disappear in family life and consequently in the family abode. In modern houses it may be said that the only survival of the old separation of the sexes in family life during waking hours is to be found in the existence of the smoking-room and the boudoir. And the provision for these, though they may be carefully arranged for a certain degree of seclusion, can hardly be said to affect the general character of the plan of the house; they can be worked into almost any type of plan. In fact, we have almost ceased to have a recognisable type of house-planning in modern Europe, unless we regard as one type that superposition of dwellings in the same block which is called "houses in flats." That is perhaps the most distinctively modern European type that can be named.

Viewing the subject at large, we may say that the most important influences in determining the type and arrangement of the dwelling-house have been (1) climate, (2) the social position of woman, (3) the habit of the society generally, whether hospitable and social or otherwise, (4) the degree of privacy thought necessary indoors, and (5) the state of police and government and the degree of security guaranteed to life and property. All these circumstances influence the arrangement and architectural treatment. The influence of climate is too obvious to need more than an allusion. In a hot and comparatively rainless climate the window openings diminish, and are covered with blinds or screens which may form an important decorative feature; cornices project for shade; open loggias or verandahs abound for the same reason; the roof is flat, partly because there is no need to make it otherwise, partly because it is a place for coolness when the sun is down. In the cold and rainy climate the loggia is rare, the windows expand and are constructed to take in all the light they can; the roof rises into a slope. The social position of woman indicates whether the house shall be divided into two distinct portions or be planned as a united whole. The habit of the society as to hospitality and frequent intercourse will stamp itself to a certain extent on the dwelling, which will have its wide and ornate entrance-door to invite access, or its narrow wicket jealously guarded, according as its owner does or does not wish to entertain strangers; will present an external attractiveness and cheerfulness, or an exterior blank wall with all the amenities of the architecture turned within. The degree of privacy rendered requisite by the manner of the day of course affects the type of the house most decidedly. In the simplicity of early Medieval days, when a man lived in the same room by day and all, or nearly all, slept in the same room by night, house-planning was a very simple problem, as more refined manners demand greater privacy the house divides itself up into separate rooms, and is even planned with corridors and staircases for a separation of traffic. An intermediate stage between the two conditions is that in which one central living room or hall suffices for all purposes, and sleeping rooms and other smaller rooms are divided off around it. We have a survival of this in the central hall which is so common a feature in large mansions of the modern era. The introduction of this feature in small houses is an idea of the present day which has been carried out occasionally, and which will probably receive more development, though the liking for it may be said to depend more on architectural than on social motives. There is no better means of giving dignity to a comparatively small house than to give it a large central apartment fit for partially living in; there is all the difference in the world between such a house

in point of effect and spaciousness of appearance, and one with the mere "entrance hall and staircase" of the average dwelling-house: but of course it is not economical. The fifth influence named, that of the state of government and of security to property, affects the house to some extent on the same lines as the third; an owner may be glad enough to see his friends, but if he has to provide against the forcible entrance of his enemies, or any who may choose for the moment to fancy themselves such, his house will have to be constructed accordingly: it must, if it be not principally a fortress, partake more or less of the character of one.

Large palaces, which are exceptional buildings, are not so interesting or instructive in connexion with the subject as ordinary dwelling-houses; and hence the plan of the Palace of Sargon, introduced as an illustration of the Assyrian house, seems rather beside the mark, and the illustration of the "Maison Assyrienne de l'Exposition de 1889" is beside the mark in the opposite direction; it all runs to height, a tall building on a small base, and seems rather like a piece cut out of a building than the whole building. This was a natural result of the necessity for keeping these model representations of houses within bounds as to size and cost, and it would have been better and more to the purpose if the authors had abstained from reproducing the imitation buildings of the Exhibition, confessedly imperfect and got up in a hurry, and had directed their efforts to making new drawings representing what we might really conceive the original buildings to have been. None of the models of the Quai d'Orsay, with the exception of some of the primitive dwellings and huts of savages, produced this impression; they showed characteristic details, but not complete buildings, and it would have been better to have forgotten them now, as temporary structures which had served their purpose, but which were not quite suitable for introduction into an important publication intended to be of permanent interest. We certainly cannot think that the "Maison Phénicienne," which is admitted by the authors to be "in part hypothetical," reproduces with any probability the civil architecture of the Phœnicians, or "may be considered as the type of one of their constructions." On the contrary, it strikes us as a remarkably Parisian piece of archaeology. Nor is it by any means safe, as in the chapter on the habitations of the Etruscans, to take urns in the form of houses as models of the habitations themselves, which seems to have been the case with the Etruscan house of the Quai d'Orsay. In all ages such representations, like the representations of buildings on coins, have been mere reminiscences rather than copies of the actual building. They give hints as to some general features, but not more. There are coins representing the temple of Diana at Ephesus, which in certain respects confirm the descriptions and agree with the discovered remains of the building, yet how utterly unlike they are to what we now know the building must have been. Had we taken those as guides to a restoration of it, before Mr. Wood's discoveries, what a grotesque idea of it we should have evolved. Yet this seems to be very much what the authors of the work before us have been doing with some of their models.

We cannot help feeling a certain scepticism, also, about such illustrations as those of the peasants' houses on the borders of the Red Sea (page 362) which are intended to show the *origines* of the Greek columnar style. They seem too good to be true; they do not impress one as sketches taken on the spot so much as illustrations worked up to take their place satisfactorily as links in a chain of evidence which it is desired to establish. We are not told by whom, when, or where they were taken; a frequent defect, we may notice, in French works of this description. Such documents cannot be too precisely authenticated; but we get no authentication.

All that we mean to imply is that this is hardly a book to be taken *au pied de lettre* as

a historical treatise. It is a remarkable work in its extent, its admirable and fascinating literary quality, its profusion of illustrations, and the immense amount of ground it covers; it is full of brilliant suggestion, and is a volume of such extent and elaboration that it is impossible to do justice to it, or even to give an adequate idea of its contents, within the limits to which such an article as this must be confined. But the very extent of the subject-matter is such as no one without superhuman faculties could have adequately dealt with in less than a lifetime, if indeed it is not more than enough for any one lifetime. It must be regarded rather as a remarkable and brilliant effort to convey in one volume a comprehensive sketch of a subject which is almost endless in its ramifications. As such it is well adapted to increase the interest of cultivated readers generally in the subject of architecture and architectural history. It can hardly take its place as a book to be relied on as an unimpeachable authority. But it must be read with interest, even with enthusiasm, by all who are interested in architecture.

NOTES.

THE exhibition of students' drawings at the Institute held during the past week in connexion with the annual awards of prizes and studentships cannot be considered a strong one. Although much solid and good work has been done amongst the old buildings, the designs are distinctly below the average. It is an exhibition, in short, rather of draughtsmanship than of design. Nine competed for the Soane Medallion—the subject being a chapter-house with an approach from a cloister—Mr. Rimmer being the successful one. His design consisted of an octagonal chapter-house of somewhat florid detail surrounded by an ambulatory, this latter taking the form of shallow semi-octagonal chapels between the angles. The perspective, showing the building perched on the edge of a cliff, though perhaps hardly the most likely position to be chosen, undoubtedly added some dignity to a design which was not in itself remarkable for originality or power. Mr. Begg's design, placed second, seemed to us distinctly more dignified, the plain wall space over the window-heads giving it repose; the window-jamb appear weak, however, and either a thickening of the hutchesses or the carrying down of another order from the window-head would have given it more apparent strength. The others were not remarkable for their design; one or two were, however, for their draughtsmanship. The Tite prize, won by Mr. T. R. Kiteell, was for a church-steeple, and there were four competitors. Three competed for the Grissell medal—a stone railway-bridge—and two for the Masonry prize. At the further end of the room were exhibited Mr. Greenslade's sketches made during his Pugin tour last year—carefully pencilled drawings of Lincoln, Ely, and Norwich. One of the best was a measured drawing of a bay of the presbytery aisle at Lincoln. Mr. D. J. Blow has been elected Pugin student for the present year, and although we have seen the drawings submitted before, they promise well for the sketches and measured work to be done by him. Mr. Chas. A. Nicholson is placed second, and sends some careful pencil sketches and measured work. The absence of coloured work and measured drawings finished in ink, in competition for the Pugin, is noticeable in the majority of cases. The silver medal has been awarded to Mr. R. S. Balfour for a careful and valuable series illustrating Heriots Hospital at Edinburgh. A good set of drawings of Castor Church, Northants, was among those sent in, and there were also on the wall sets of drawings of the Salishury Chantry at Christchurch, Hants, and the very beautiful Chapel at the Hospital of St. Mary, Chichester. We give a list of the prize-winners on another page.

FROM a memorial addressed by the Governors of the Manchester Royal Institution to the Mayor of Manchester, a

copy of which has been forwarded to us, it appears that the Royal Institution Gallery, in which the autumn picture exhibitions at Manchester have been held hitherto, is now so far occupied by pictures bought for the permanent collection that it no longer affords adequate space for the annual exhibition, unless by the process of taking down and temporarily storing away all the pictures of the permanent collection to make room for the annual exhibition, which we agree with the memorialists is a most undesirable process, both in regard to the pictures and the public. The memorial therefore prays that the Corporation of Manchester would turn their attention to the provision of a new gallery for Manchester, suitable for the Autumn Art Exhibitions, and which might be useful for other purposes of exhibition at other times of the year. The memorial concludes,—

"We feel very strongly that Manchester, so rich in its private collections, ought to maintain its position in relation to its public collections, and as an art centre generally, it should not be allowed to fall behind Liverpool, Birmingham, Edinburgh, or Glasgow. The latter city is, at this moment, maturing plans for a new art gallery, on a very large scale, and, as they have given great consideration and attention to the requirements of such galleries, we think it would be well to make inquiry as to the exact nature of the project."

We will add one recommendation. If a new Exhibition Gallery is built for Manchester, let it be planned from the first to provide rooms not only for painting and sculpture, but for architectural drawings and models and for decorative design, and thus set an example of breaking through the superstition that "art" means only pictures and sculpture.

ON last Tuesday evening, in the Elgin Room, British Museum, Miss Eugénie Sellers gave the first of what promises to be a highly successful course of lectures upon Greek Art and Life, as promoted by the London Society for the Extension of University Teaching.* Miss Sellers's address has for their subject Greek Sculpture in the fifth century B.C., as illustrated by the Parthenon and its marbles. She invoked her audience to clear their minds of all pseudo-sentiment and unreasoning rapture, reminding them that the Athenians were as human as ourselves, and that their art, albeit beautiful and matchless, is in some points not absolutely perfect. This she illustrated for the moment by pointing out how even Pheidias in his Ionic frieze of the cella, or *naos*, failed at the junction of the two ends of the rihhon, as it may be termed, which represents the Panathenaic procession. Miss Sellers glanced further at shortcomings in the direction of decorative arts as applied to their buildings, as contrasted with the Renaissance. She briefly compared the sculptures of the frieze of the Parthenon and of the Phigaleian temple to Apollo Epicurus, or the Deliverer, near to Basse, in Arcadia,—though of the same date. She referred to the labours of Wood and of Professor Cockerell in preserving sculptured remains of the Artemision at Ephesus, and Apollo's temple in Phigaleia; and gave an able description of the frigid reception that was accorded to the Elgin Marbles upon their arrival in England, when Haydon, the painter, stood almost alone in combating the supineness,—and, indeed, the hostility,—of the Committee who deliberated upon their purchase for the nation. The class was then taken into the Harpy-tomb, the Phigaleia, and Halicarnassus rooms, where some of the objects are being re-arranged so as to form, in a measure, a chronological exposition of Grecian sculpture.

FROM an advertisement in our columns it appears that engineers are liable to have the same liberal conditions extended to them in competitions which are frequently offered to architects. The Corporation of

* The latter five lectures upon the daily life and thought of the Greeks will be undertaken by Miss Millington-Lathbury.

Beaumaris offer a premium of ten guineas for the best design for a Promenade pier, to cost 3,000*l.*: a contemptible sum even as a premium. But they proceed to say that their decision as to the merits of the designs will be final, that the design for which they give the munificent sum of ten guineas is to remain their property, and that they do not bind themselves to carry out any design submitted. What class of engineers (or architects) do they suppose will respond to such an advertisement?

WE have received a circular from the "Artistic and Literary Association, Limited," which, we are told, is the designation of a new publishing company whose chief object is "to afford to those of its members who are artists or authors the unique advantage of sharing as publishers as well as originators in the profits accruing from their own works." We fear we fail to understand the exact meaning or object of the institution. We have always been under the impression that authors did participate in the profits of the sale of their works—at all events that they can make arrangements to do so unless they prefer to sell outright; and artists are not in the same position, inasmuch as a work of art is a single production, and not a thing to be multiplied in subsequent editions like a book.

THE exhibition of pictures by Mr. H. W. B. Davis at the Gallery of the Fine Art Society in Bond-street is one of the most satisfactory of these personal exhibitions which we have lately seen. Mr. Davis's "landscapes with cattle," as they may mostly be termed in the old crusted catalogue phrase, have the peculiar charm of combining realism and finish with poetic sentiment. There is no slurring over of detail, but the broad effects and the sentiment of nature are always present; and the animals introduced in the pictures, though finished and learned enough to hold their place as animal paintings alone, never seem to obtrude on the landscape; they take their part with it as a portion of the materials of the picture in a perfectly natural manner. Perhaps this result is partly due to Mr. Davis's method (as described in the prefatory notice to the catalogue by Mr. M. Phipps Jackson), of making a complete picture of the landscape first, and then introducing the groups of cattle. But Mr. Davis's landscapes do not depend on the cattle element for their interest; many of them are landscapes pure and simple, and very beautiful examples of landscape painting. Among those in this collection may be specially named "Now came still evening on" (7); "Sunny evening in April, Picardy" (20); No. 27, a study for No. 7, and in some respects finer in effect than the larger picture; "A break in a rainy sky" (32); "Conyhurst Hill, Surrey" (42). Some of the most powerful things are among the smaller studies, "Cloud and Sunshine" for instance (12), a grand little study of sky; and one cannot but remark on Mr. Davis's peculiar power of giving an effect of real light and radiance to the moon in his evening scenes; a point in which his works of this kind remind one much of Daubigny. One of the most remarkable things in the room is a sketch of moonlight effect (49) in a night sky covered with broken clouds whitened by the moonlight; the effect is remarkably true, the more so as Mr. Davis avoids the mistake of many painters of moonlight, that of showing too much detail. We should much have liked to have seen in this Exhibition a painting of Mr. Davis's earlier period, which was known to many in the collection of the late Mr. Pfeiffer of Putney; a painting of a down with sheep, showing one of the most remarkable studies of foreground vegetation we have ever seen. It is very different from the manner in which the artist paints now, but not the less excellent of its type. We know not what has become of the picture. The late owner wished it presented to the National Gallery; it was declined on the ground that it was the

work of a living artist, though there are works by living artists (not the equals of Mr. Davis) already in the gallery.

A COLLECTION of Mr. Walter Severn's pictures and sketches in water colour is on view at the rooms of the Dudley Gallery Art Society, of which Mr. Severn is president. The result is not altogether satisfactory. Seen apart, many of these works would give the impression of considerable power over bright sunlight effect, and careful finish. Seen together, they give the impression of mannerism and repetition of rather superficial effects, especially in the treatment of water. Among those we like best are "Loch Gougha" (13), "Balloch Pier" (18), "Conway Castle" (22), "Netley Abbey" (30), "The South Stack, Anglesey" (31), and "Evening, Loch Lomond" (44). Mr. Severn paints architecture well and carefully, and we should have been glad therefore to have seen more architectural subjects in the collection: the view of Netley Abbey ruins is admirably like the place. But the landscapes hardly gain by being shown collectively.

IN reference to our "Note" last week as to an advertising architect who called himself "An Associate of the Institute of Architects," we are informed that the person in question is not a member of the Institute. He "ceased to be a member" some time since by a resolution of the Council in accordance with the provisions of one of the Bye-laws. The case is occupying the attention of the Institute authorities.

NOTES ON CHALICES AND PATENS.

THESE have been made of various materials in different ages of the Christian Church,—gold, silver, brass, tin, pewter, wood, stone, horn, glass, and in many Canons and Councils one sort would be ordered and another prescribed.

Becon says: "The cup wherein the Sacrament of Christ's blood was ministered, which we now commonly call the chalice, was in the time of the Apostles and of the Primitive Church made of wood. But Pope Zephyrinus commanded chalices of glass to be used in the year of our Lord 202. And afterwards Pope Urbanus ordained that the chalice should be made either of silver or of gold in the year 227." (Works 3, 262.)

This assertion probably only applies to certain countries, as six centuries later orders had to be made with regard to the material employed. St. Chrysostom, however, speaks of a "gold or jewelled chalice," Hom. 50 on St. Matt. St. Ambrose says, "Sacraments need not gold;" and sold his church plate to relieve captives. The Legatine Council of Cealcythe, A.D. 785, c. 10, forbids the chalice or paten to be made of horn; Efrisi's Canons, A.D. 975 requires the sacred vessels to be made of wood; Edgar's Canons, a few years before, 960, require metal, and forbid wood. The Canons of Winchester, 1071, c. 11, forbid wax or wood. Richard's Canons, 1175, require gold or silver; the Council of Rheims, 630, allows tin, but not brass. Habert Walter, 1195, c. 9, requires silver.

One ancient reason for discarding wooden chalices is because the wine soaked into the wood, as is shown in the following quaint passage in the Black Letter volume, "The Pageant of the Popes," date 1555:—

"Zephyrinus was a Romaine borne, a man, as writers do testify, more addicted with all endeavour to the service of God than to the cure of any worldly affairs. Whereas before his time the wine in the celebrating the *communi* was ministered in a cup of woods, he first did alter that, and in steade thereof brought in cappes or chalices of glassa. And yet he did not this upon any superstition, as thinking woods to be unlawfull, or glassa to be more holy for that use, but because the one is more comly and seemly, as by experience it appeareth, than the other. And yet some wooden doutles do dreame that the wooden cuppen were chaunged by him because that part of the wine, or as they thought the royall blood of Christe did soake into the woode, and so it cannot be in glassa. Surely soner may wine soake into any woode than any witte into those wine heads that thus both deceive themselves, and slander this godly marty

who, in the year of our Lorde, 220, suffered martyrdom under Aurelius."

Gold and silver chalices were probably in use from the earliest Christian times, and wood and stone were most likely used in the poorer churches. The Council of Tribur, in 895, did not ordain that chalices must be of the precious metals, but only forbade their being of glass or wood.

In the ancient Irish churches stone chalices were very usual.

Pre-Reformation chalices in England are very scarce; indeed, Mr. Cripps says he can find but half-a-dozen. The finest of these are at Wive-liscombe, in Somerset; Bishop Fox's chalice at Corpus Christi College, Oxford; and Sir Thomas Pope's chalice at Trinity College, Oxford. Of the communion cup with its cover (temp. Ed. VI.), there are still fewer examples than of the earlier ones. There is one of 1548-9 at St. Lawrence, Jewry, two at St. Margaret's, Westminster, of 1551-2; and others of the same date at Hunstanton, Norfolk, and Totnes (Devon).

A beautiful specimen of an ancient paten is at Wyke, near Winchester. It is of silver, formerly gilt, of which traces are very faintly to be seen. The design consists of an Agnus Dei, in a sunk central circle, round which eight ornamented follis are described, while round the whole, on the rim, is the following inscription:—

✠ CUNTA (cuncta!) CREO: VIRTUTE REBO: PIETATE: REFORMO."

In the Christy collection are two patens, which were found on St. Louis Hill, Carthage, with chalices, liturgical spoons, and seals. They are inscribed respectively, "Feliciter loquere," and "✠ DD. TORRESCONI CLABERT."

About 1854, a Cork jeweller bought a chalice from an Irish peasant, who had found it in a bog near Berehaven, in West Cork. It was a silver one, richly adorned with a foliage design enclosing a cross over a skull. Near the rim, in a small compartment, was a cock. The bulb beneath the cup, was chased in Norman style, similar to the type on some silver pennies of the Conqueror; over on some silver pennies of the Conqueror, it weighed 12 oz., and was richly gilded. On the rim was the inscription, "Cornelius O. Sullivan Sacerdos Me Fieri Fecit 1590 Dulcis Jesus Gloria Soli Deo Sa Ma O. P. N." The same jeweller had another chalice, an octagon one, with scroll-work, and the following symbol: the Cross, on the left a ladder, and on the right a spear; a heart transfixed with two arrows in saltier, and the letter H surrounded with a Cross pattee *fléchée*. The inscription ran thus,—"ORATE PRO ANIMA I DANIELIS SUIVNYE SACERDOTIS LIMORENSES DIGRESSIS QUI ME FIERI FECIT A° 1640." It weighed about 16 oz.

Another Irish chalice was inscribed,—"MAURICIUS COSTUN SACERDOS HANC CALICEM DD. ALTARI CAPELLE BEATE MARIE CLOYD 1607."

The next two inscriptions are on chalices in two churches (R.C.) in Cork:—

"DEO OPT MAXIMO ANO DNI 1598
DEDICABAT ALSONA MIAGHAE HUNC
CALICEM UT PRO ANIME SUE
SALUTE JUGITER AD DEUM OBETUR."

And
✠ Fr. Gulielmus iris Pro Conv^o 8^o Fran.
Cork Me Fecit Fieri 1611."

Both these run round the rim of the base. I Rheims Cathedral is a most splendid chalice of the eleventh century, gold, most beautifully set with diamonds, pearls, and rubies of priceless value. It belonged in old times to the church of St. Remy, and is known as the chalice of St. Remy. On the band is deeply cut—

✠ Quicumque hunc Calicem invadaverit verab Hic (hanc?) Ecclesia (Ecclesiam?) Remensis Aliquo Modo Allianaverit (Alien averit?) Anathema sit Fiat Amen. ✠"

Inventories of the vessels existing in various English churches before the Reformation, and those taken at the time of the Reformation, show that the churches had gradually acquired gold and silver and precious stones, in the form of shrines, images, reliquaries, vestments, sacramental vessels, &c., to a great value. The Commissioners of Henry VIII. and Edward VI. visited all the monastic and collegiate churches to despoil them of all that was most valuable which was confiscated to the King's use. The seizure of the parish plate was not decided upon till the last year of Edward VI., and probably then only partially carried out. Later on the accession of Elizabeth, inquiries were

made about the Church plate, and then it was found a great deal had disappeared, sold by churchwardens to save Church rates in some cases, or stolen by them, or their superiors.

Later, even in the present century, through ignorance, old Church plate has been exchanged for more admired and much less valuable modern plate, or some may have been simply stolen and sold to pawnbrokers and silversmiths. Other plate has been burnt with its church, or perhaps when boused in the vicarage. At Tawstock, in Devon, was a cup, dated 1576, which, with other very good Church plate, was stolen in 1841, and the thieves were never traced.

Hasted says of a Kentish church in his history: "When dressed up for the Sacrament, and covered with its costly and splendid service of rich plate, it has an appearance of grandeur and magnificence that blots from the mind as far as possible a regret for its having been bereaved of its former ornaments. All the plate (except the two great candlesticks) was new gilt, which altogether make a very handsome and splendid appearance."

Early in this century a silver chalice, dated 1337, was mentioned as being in Pakefield, near Lowestoft, but has long disappeared.

The inventories of Church plate taken in Edward VI.'s time are not all extant, but the following is taken from the MS. of the Cumberland inventory of 105 churches. "Of these churches eighty-seven had each but one silver chalice, fourteen had each two silver chalices, and four had each three. Eight had tin chalices, and two had none at all. Nothing else of silver was in any of the churches, except one broken cross and one pyx. There were but three other pyxes, one of which was of copper gilt, and another of latten; the description of the third is torn off. Only one church had cruet, and those of tin for the wine and water at the altar. Twenty churches had candlesticks of brass or latten. No paten or cover is mentioned. Nor is the weight of anything specified." This is a poor record of Church plate compared with that of many counties, but, however, all was fish that came to the king's net! Bishop Boniface has a quaint saying of wooden chalices: "When priests were gold, the chalice was of wood; now when the vessel is of gold, priests are wooden." He and St. Ambrose would have agreed in thinking against many contrary opinions of their times that Church plate can sometimes serve humanity better than by being kept sacred in the churches.

Two chalices, each with three bells hung around them, dated 1490 and 1530, were exhibited at Lishon by the Royal College there. Possibly, they may have been chiborium or pyxes; and, if so, the bells rung as they were carried along, and so would serve to give notice of the approach of the priest carrying the Blessed Sacrament.

Among the parochial payments of S. Andrew, Holborn, in 1578, is noted "Paide for the exchange of two chalices with the covers, weighing xxxiij oz. halfe, for a communion cup weighing xxx oz. and halfe, the exchange with the odd oz. at xliiij. viijd."

Of old it was the custom to place a chalice and paten, symbolical of his office, upon the breast of a priest in his coffin. William of Bleyes, 1229 A.D., ordered that a parish should, in addition to the usual sacred vessels, always keep an unconsecrated chalice, which might be of tin, for burial with the priest (see Wilkins, i. 623). Several examples of these mortuary chalices so buried have been found and preserved,—at Cheam, Surrey; Nettlecombe; and at Corpus Christi College, Oxford. The two latter have patens, silver, with a broad rim, the centre sunk in a sexfoil pattern, with an engraved head of our Lord in the middle.

The following notes from the List of Church Goods in Cornwall, Augmentation Office, 6th Edward VI., are interesting:—

"The pish of Delyn (St. Endellion), the sayde pishners have ij chalices p'cell gilt. The Parische of Eglshayle the sayde parishes hath ij chalices of sylver."

In the Bodmin Corporation records, among the assignment of goods to the Church, in 1596, is "for ye comynon tabell ij polys, one of brasse, and a nother of yron. One comynon cup of sylver and one other gilt, w^{ch} hery cook ved at weddynges." There may be others, but the document is so faded and worn as to be in many parts quite undecipherable.

At Bilsland is an old chalice, still in use, but the cover is lost. It is thus noted in the Parish

Register:—"Anno Dmi, 1601. At the Easter Anno pd. George Marrett did freely give and deliver one fayre silver cup wth a cover therevnto double gilted to remaine for a comynon cup for the parische of Bilsland, wth out any clayme." At Minster (also in Cornwall) are two "fayre sylver chalices" with covers, one very ancient. C. F. Y.

ROYAL INSTITUTE OF BRITISH ARCHITECTS:

AWARD OF MEDALS AND PRIZES.

At the business general meeting of the Royal Institute of British Architects, held on Monday evening last, the following report of the Council on the award of medals and prizes for the year 1891-92 was received and adopted:—

"Gentlemen,—In accordance with the provisions of By-law 66, the Council have the honour to report that they have examined the several essays and drawings submitted for the Silver Medals of the Royal Institute, the Soane Medallion, the Pugin Studentship, the Godwin Bursary, the Tite Prize, the Grissell Medal, and the Scientific Masonry Prizes.

The Essay Medal and Twenty-five Guineas.

Five Essays were submitted for the Silver Medal of the Royal Institute, the subject being 'The architectural treatment of the Fireplace and its accessories,' under the following mottoes:—i. Ignigenus. ii. Lincoln Green. iii. Proaris et focus. iv. Terra del fuego. v. Veritas filia temporis.

The Council have awarded the Silver Medal and twenty-five guineas to the author of the essay bearing the motto (v) 'Veritas filia temporis,' as showing the best literary treatment of the subject, and as being adequately illustrated; and they desire to honourably mention the essay bearing the motto of (i) 'Ignigenus,' as possessing merit, principally in the illustrations.

The Measured Drawings Medal and Ten Guineas.

Three sets of measured drawings were received for the Silver Medal of the Royal Institute, under the following mottoes:—i. Black spot,—Salisbury Chantry, Christchurch. ii. Nitor,—Heriot's Hospital, Edinburgh. iii. Polux,—Castor Church, Peterborough.

The Council have awarded the Silver Medal and ten guineas to (ii) Nitor, for measured drawings of Heriot's Hospital, Edinburgh; and a Medal of Merit to (i) Black Spot, for measured drawings of the Salisbury Chantry at Christchurch, Hants.

The Soane Medallion.

For the Soane Medallion and, subject to the conditions laid down, £100 for foreign travel, nine designs for a Chapter-house were submitted, under the following mottoes:—i. Abbotshury; ii. Anno 1891; iii. Byzantium; iv. Ex cathedra; v. Griffin; vi. Red Cherub; vii. Sun; viii. Plume; ix. Volunteer.

The Council have awarded the Medallion, with the sum of 100*l.* for foreign travel as laid down in the conditions to the design bearing the motto (i) 'Abbotshury;' and a medal of merit to the design bearing the device of a (vi) 'Red Cherub.'

Pugin Studentship.

For the Pugin Travelling Studentship applications, each with a select number of drawings and sketches, were received from the following gentlemen:—i. Mr. Detmar J. Blow; ii. Mr. Erskine S. Cumming; iii. Mr. Charles R. McIntosh; iv. Mr. Charles A. Nicholson; v. Mr. Percy D. Smith.

The Council have awarded the Studentship to (i) Mr. Detmar J. Blow, born in November, 1867, whose measured drawings of Beauvais Cathedral and of Barfreston Church have afforded him admirable training; and they desire to record that Mr. Blow received a medal of merit for drawings submitted for last year's studentship, and that he was honourably mentioned in 1890. The Council have also awarded a Medal of Merit to (iv) Mr. Charles A. Nicholson, born in April, 1867, for a fine set of drawings.

Godwin Bursary.

For the Godwin Bursary applications were received from the following gentlemen:—i. Mr. Owen Fleming, Associate. ii. Mr. Banister F. Fletcher, Associate. iii. Mr. Edwin O. Sachs. iv. Mr. T. Locke Worthington, Associate.

The Council have awarded the Bursary to Mr. T. Locke Worthington, Associate, who pro-

poses to visit France, principally for the purpose of studying tenement buildings.

The Tite Prize.

For the Tite Prize—being a Certificate, and, under conditions, 30*l.* for travel in Italy—four designs for a Church Steeple were submitted, under the following mottoes:—i. Ashlar; ii. Quis; iii. Red Lion; iv. Design in a Circle.

The Council have awarded the Certificate and, subject to the conditions laid down, 40*l.* for travel in Italy, to the design (iii.) bearing the device of a Red Lion.

The Grissell Medal and Ten Guineas.

For the Grissell Gold Medal, for design and construction, three designs for a stone railway bridge were submitted, under the following mottoes:—i. Equilibrium. ii. Fundamentum forte opus snstinet. iii. Jacta est alea. The Council have awarded the Grissell Gold Medal and ten guineas to the design bearing the motto of (iii) 'Jacta est alea.'

The Scientific Masonry Prizes.

For the Scientific Masonry Prizes of six guineas and four guineas two designs have been submitted of the vaulting of an octagonal turret, under the following mottoes:—i. Saxum (with a model). ii. Voussoir.

The Council have awarded the prize of six guineas to the design bearing the motto (i.) 'Saxum'; and the second prize of four guineas to the design bearing the motto (ii.) 'Voussoir.'

It was subsequently announced that the authors of the premiated or commended essays, designs, and drawings before referred to were as follow:—

- "Veritas filia temporis," Mr. Charles E. Sayer, A.R.I.B.A.
- "Ignigenus," Mr. Richard Glazier, A.R.I.B.A.
- "Nitor," Mr. R. Shekleton Balfour.
- "Black Spot," Mr. Percy D. Smith.
- "Abbotshury," Mr. Heber Rimmer.
- "Red Cherub," Mr. John Begg, A.R.I.B.A.
- "Red Lion," Mr. T. Rogers Kitsell, A.R.I.B.A.
- "Jacta Est Alea," Mr. Harold Harlock.
- "Saxum," Mr. Herbert S. Wood, A.R.I.B.A.
- "Voussoir," Mr. Erskine S. Cummings.

ARCHITECTURAL SOCIETIES.

LEEDS AND YORKSHIRE ARCHITECTURAL SOCIETY (INCORPORATED).—A general meeting of this Society was held at the Rooms, Albion-place, Leeds, on Monday last, the President, Mr. W. H. Thorp, F.R.I.B.A., in the chair. Mr. J. M. Brydon, F.R.I.B.A., read a paper entitled "The English Renaissance." After briefly sketching the rise and development of Italian Renaissance, and showing the influence it had upon the English type, Mr. Brydon, taking such well-known typical examples of the English school as the contemplated palace at Whitehall, Ashburnham House, St. Paul's Cathedral, Elenheim, Somerset House, &c., dwelt upon the genius of their great designers, and the other masters of the craft of that period and later periods. Inigo Jones, who set on foot the English style, which in many respects possessed worthier features than its prototype, and which has left us in these days a precious heritage to study and maintain; Sir Christopher Wren, whose *magnum opus*, St. Paul's Cathedral, although marred by the architect having to follow the Cathedral form, and adapt the new style to the old Medieval type of plan, instead of following his own bent, is, in Mr. Brydon's opinion, one of the greatest ecclesiastical structures of this style in the world. Mr. Brydon commented on the various distinctive features and characteristics, and drew from the examples lessons for the guidance of students of architecture of the present time.

LIVERPOOL ARCHITECTURAL SOCIETY.—This society has established a series of students' classes for the study of various subjects connected with architecture, building construction, and sanitation. Lectures are to be given by architects and engineers on the various subjects specified. Students' meetings are to be held weekly during the session.

MANCHESTER SOCIETY OF ARCHITECTS.—In a circular issued by the Education (in Architecture) Committee of this Society, it is stated that one of the leading objects of the reconstruction of the Society was to afford facilities for the study of architecture, other than such as are found in ordinary office routine. This has now been to some extent accomplished by the formation of two classes for instruction in

Bermondsey Public Library. Mr. J. Johnson, F.R.I.B.A., Architect.

(1) History and Development of Architecture, and (2) Materials and Construction, which will be open to students, whether members of the Society or not. Mr. H. E. Stelfox, A.R.I.B.A. (Ashpitel Prizeman, 1888), has been appointed Lecturer, and the classes will be held weekly, at the Society's Rooms (Literary and Philosophical Society, 36, George-street), commencing from Monday, the 18th inst. Any further information may be obtained from the Hon. Sec. of the Education Committee, Mr. Ph. E. Barker, 24, Brazennose-street, Manchester.

DUNDEE INSTITUTE OF ARCHITECTURE.—On the 14th inst. Mr. R. C. Ritchie, of the Electric Construction Corporation, Limited, London, delivered a lecture to the members of the Dundee Institute of Architecture, Science, and Arts, on "Electric Light Supply." Mr. William Mackison, C.E., presided, and there was a good attendance. The chairman, in introducing the lecturer, made a few sympathetic remarks regarding the death of the Duke of Clarence. At the conclusion of the lecture several questions were put to Mr. Ritchie, who, in reply, said that electric light cost about 50 per cent. more than gas in London, and he predicted that in a short time they would be able to produce it at as cheap a rate. Regarding the propelling of tramway cars by electricity, he said that it was all a matter of traffic. If there was little traffic horses would be the cheapest, but where there was a large service, electricity would be preferable. On the motion of the chairman, Mr. Ritchie was accorded a vote of thanks for his lecture.

PUBLIC LIBRARY, BERMONDSEY.

This building was opened last Monday by Sir John Lubbock. It has been built from the designs and under the superintendence of Mr. J. Johnson, to whom we are indebted for the accompanying sketch of the building.

The principal entrance in the centre of the building, emphasised by an Ionic portico, leads to a hall and staircase, 15 ft. wide; on the right is the newspaper reading-room, 41 ft. by 33 ft. Immediately opposite the entrance is the lending library, 41 ft. square, fitted with cases for 20,000 volumes. "Cotgreave's" Indicators are used for ready reference. The librarian's room and residence, with private access to lending department, adjoins the main entrance, thus giving complete control of the building. The stone stairs, with central and return flights, terminate in the large first-floor landing, paved with marble mosaic; the landing is arched at the sides, and has a large cove with lantern-light in the centre. The reference library is 41 ft. square, with a domical roof in the centre, supported by four Corinthian columns. It is lighted by the clearstory at the base of the dome, also by the windows in the side walls; the reading-tables are in the centre, the bookcases are arranged on the alcove plan around the sides. Next the landing is the magazine reading-room, 41 ft. by 24 ft.; adjoining is the ladies' reading-room, 20 ft. by 16 ft., with lavatory accommodation. On this floor is the commissioners' committee-room, with separate

access from the exterior. The whole of this second floor is occupied by the librarian's apartments, forming a complete residence, with bath, warders, stores, coal-lift, and every residential convenience. In the basement are provided lavatories, &c., for the general readers; also a large space for additional book-store when required, a bookbinding-room, a general store-room, coal-cellar, and heating chamber. There is a side entrance for the attendants, with a hook-lift, so that every portion of the building can be conveniently reached without entering the principal staircase. Mr. Johnson's design was selected out of fifty-seven submitted in public competition. The builders are Messrs. F. & H. F. Higgs, of Loughborough Junction. The iron construction was executed by Mr. Dawney; the warming (by radiators which keep a satisfactory temperature) was executed by Mr. J. Todd, of Wandsworth, who also provided bells and speaking-tubes; the marble mosaic by Messrs. Diespecker & Co.

The exterior is of Renaissance character, freely treated, executed in red Elham bricks, with dressings of Monks Park Bath stone; the carving has been executed by Mr. Baird, of Herne Hill, from the architect's designs; the central figures of "Literature" and "Science" are by Mr. Lawlor. The central turret was introduced to give height and dignity to the front, on account of the massive character of the adjoining Town-hall.

**THE ARCHITECTURAL ASSOCIATION:
THE DESIGN OF TECHNICAL COLLEGES AND
SCHOOLS.**

The first meeting of this Association since the Christmas vacation was held on Friday, the 15th inst.

Mr. Leonard Stokes, past President, was voted to the chair, in the unavoidable absence of the President, Mr. F. T. Bagge (who was out of town) and of the two Vice-Presidents, Messrs. F. K. Farrow and E. W. Mountford, both of whom, it was stated, were, in common with Mr. E. S. Gale, senior honorary secretary, and many other members of the Association, suffering with the prevailing epidemic of influenza.

Messrs. J. Aldridge and J. E. van Ahholt were elected members of the Association.

Mr. F. T. W. Goldsmith, honorary secretary, announced that Mr. T. M. Rickman had promised a donation of five guineas per annum to the Association's general fund, and that the Royal Institute of British Architects had promised to subscribe £100 per annum for three years. These announcements were received with much applause, and on the motion of the Chairman the secretaries were instructed to convey the hearty thanks of the Association to the donors.

The Chairman, in feeling terms, alluded to the lamented death of H.R.H. the Duke of Clarence, and proposed that a vote of condolence with the Prince and Princess of Wales be sent by the secretaries in the name of the Association. This was assented to in silence, all the members standing.

Professor Garnett then read the following paper on "The Design of Technical Schools and Colleges:—

Presuming the governing body of the school or college does not consist of educational specialists, it seems that the first step to be taken is to learn from some qualified person or persons what subjects should be taught in the institution, how they should be taught, and what accommodation and appliances will be required for teaching them. I have the honor of knowing some architects who are themselves educational experts, and if the governing body enjoys the advantage of having secured the services of one of these gentlemen it may proceed with safety without further preliminary; but men who can act in the double capacity of architect and educational expert are exceptional, and properly so, for although we may sometimes with advantage ask the advice of our solicitor not only on the form in which our bequests should be drawn up, but also on the manner in which we shall dispose of our belongings in our wills, it does not appear to me to be reasonable to expect the architect to tell us both what we want and how to secure it.

Hence it is generally desirable that the chief technical teacher, and sometimes two or three other members of the staff, should be appointed at the same time as the architect, though it will not generally be necessary to secure more than a very small portion of the services of the teachers until considerable progress has been made with the building. It should be the duty of the teacher, as soon as he is appointed, to advise the governing body with respect to the accommodation required in the several departments, the relations of these departments to one another, and the special appliances required in each, particularly those for which provision must be made in the building. Attention should be specially directed to the relative positions of the rooms devoted to the several departments, so that while each department forms by itself a compact whole, it should be contiguous to other departments to which it is, in the character of its work, most nearly akin, that the appliances of each department may, as far as possible, be available to those students and teachers in other departments who are most likely to require their use. For example, a photographic laboratory should be situated as near as possible to the chemical laboratory on one side and the art studios on the other. By associating the department of photography with that of chemistry it becomes unnecessary to replicate balances and other appliances for quantitative chemical analysis, while by making the art studios readily accessible to the students of photography the best possible facilities are afforded for camera practice and the study of grouping and light and shade. For similar reasons the metallurgical laboratory should, if

possible, be placed between the departments of chemistry and of mechanical engineering, so that all facilities for chemical analysis may be readily accessible on the one side, and testing machines for the systematic examination of the mechanical properties of the metals and alloys may be equally available on the other. On the same principle, the department of electrical engineering should adjoin the engineering laboratory and workshops, for the double reason that steam-power may be available, and because every electrical engineer must be at the same time a mechanical engineer. Students of electrical engineering must also have ready access to the physical laboratory; but it is not desirable that the engine and dynamo-room should be geographically near to the physical laboratory, on account of the disturbance to all magnetic measurements which would be caused by the proximity of heavy moving machinery, of powerful electro magnets, and of strong electric currents.

But while it is desirable that the relative positions of the several departments should be carefully chosen, it is of paramount importance that each department should be compact in itself, so that its work may be conducted by the smallest number of superintendents. If the Professor of Chemistry has his students' laboratory at one end of the building, his lecture-room at the opposite end, his preparation-room somewhere near the middle, and his private room in some remote corner, the amount of assistance he will require will probably be doubled. His private room should be as near as possible to his students' laboratory; if it communicates directly therewith a further advantage will be gained; and his preparation-room should adjoin the laboratory on one side, and his lecture theatre on the other.

It very frequently happens that it is not possible to erect at first the whole of the buildings which it is intended ultimately to provide, and the question then arises whether a school or college complete in all its departments should be erected on a small scale, or whether plans should be made for the whole building, as though it were intended to erect the whole at once, and a selected position, representing certain departments only, should be built at first. There is, of course, some inconvenience attending the latter course pending the erection of the remaining portions of the building, but this inconvenience may be made comparatively small by a careful selection of the departments for which provision is at first to be made. If the former method is adopted, the institution will be complete in itself during the early years of its existence; but when the enlargement is carried out, several departments will be partly located in the old and partly in the new buildings, and the conduct of the work of each department will be rendered difficult and expensive. In selecting the departments for which provision should be made at first, it should be borne in mind that work which requires specially-constructed buildings cannot be satisfactorily conducted in ordinary lecture-rooms or class-rooms, while a class on mathematics or modern languages is not greatly inconvenienced if it is required to meet in a room provided with draught closets, or special supports for tables, or lighted as an art studio, or in some other way adapted for a purpose other than that for which the class is assembled; provided only that sufficient space is available for seats and desks, and the room is not one in which it is impossible for a lecture to be heard. Hence it is best to commence with the departments of chemistry, physics, applied mechanics, engineering, and fine art, erecting these departments as completely as the character of the plan for the whole building necessitates. Any rooms in these departments which are not at first fully occupied by the work of the department will be available for classes on mathematics, languages, and commercial subjects, while, at a push, a chemical laboratory will serve very well for biological work.

As regards the position of the several departments, it is desirable that in any institution in which popular lectures, university extension lectures, or any large evening classes form an important feature, there should be a large lecture theatre, as near as possible to the public entrance, and that it should be on the ground floor. This lecture-theatre may be common to several departments, but should be readily accessible from the physical department, as physical apparatus is likely to be very largely used in the theatre, and such apparatus is often very ponderous or very delicate. In this

theatre as much length as possible should be given to the lecture-table. For a theatre capable of holding two or three hundred persons a lecture-table 30 ft. by 3 ft. is not too large, and 3 ft. is a convenient height. The table should be carried on its own foundations, the supports being entirely distinct from those which carry the floor, so that any movement of the audience may not disturb the most delicate apparatus on the table. It is generally best to carry brickwork for the support of the table up to within two or three inches of the floor level. The space beneath the table and within the brick wall should be accessible from the lecturer's side, as it may be usefully employed to accommodate resistance-coils and other accessories of the lecture-table. The floor should be carried on walls built a foot or more away from the wall which carries the lecture-table. In the Cavendish Laboratory at Cambridge the lecture-theatre is on the first floor, and the lecture-table is an oak slab carried on an 18-in. wall, which forms one wall of the gateway, the floor being carried on brick piers erected for the purpose, a few inches away from this wall, and this arrangement may be desirable when it is impossible to find accommodation for the lecture-theatre on the ground floor. As much space as possible should be left behind the lecture-table for such apparatus as cannot conveniently be placed upon the lecture-table itself, as well as to give a reasonable length for a beam of light reflected from the mirror of a galvanometer or other instrument on the lecture-table, and observed by the audience as it traverses a graduated scale on the wall behind the lecturer. Eight feet is not too much space to leave between the lecture-table and the wall. The gas or other lights in the room should be controlled by a valve or switch fixed underneath the lecturer's table, and readily accessible to the lecturer.

Another important adjunct to a lecture-theatre is a platform for the magic-lantern, which, like the lecture-table, is entirely independent of the floor of the room or of the gallery supports. For the exhibition of ordinary slides such an arrangement is, of course, unnecessary; but when it is desired to exhibit on the screen the motion of a magnet suspended by a silk fibre, or any other delicately-suspended body, the unconscious movements of the most attentive audience will be sufficient to completely spoil the experiment unless a special support for the lantern is provided. A hollow brick pier standing on its own foundation, and carried up through the gallery without coming in contact with the seats or floor, forms a very convenient support for the lantern. Gas, bottles, and other appliances may conveniently be stored within the pier, and, if an electric lantern be used, the conductors may be brought up from the basement and through the pier, and regulating resistance fixed within the space enclosed by the brick walls, which form an almost fire-proof structure. The windows should be arranged in order to throw the greatest possible amount of light upon the lecture-table, but the room should be capable of being darkened completely. If possible, openings should be made in the ceiling directly over the lecture-table, through which apparatus may be suspended at any height above the table from the floor above. A water-supply and sink should be within easy reach of the lecturer, and a large fume-closet with glass front should be fixed in a position in which the audience can readily see its interior. A chamber heated by a steam jacket, and provided with a glass front, is a very valuable accessory to a lecture-theatre, as it enables electrical and other apparatus to be kept warm and dry and in working order, whatever may be the state of the weather or the hygroscopic condition of the overcoats of the audience.

In the Physical Lecture-Theatre at Newcastle the seats have been so arranged that any person can see the front edge, and therefore the whole top, of the lecture-table over the head of a person who, when sitting down, is 2½ inches taller than himself. This condition gives a slightly concave profile to the seats, but the steepness of the gallery is rapidly reduced if the distance between the lecture-table and the first row of seats is increased. It is only when the length available for the theatre is small and the seats have to be brought very near to the lecture-table that the gallery becomes inconveniently steep.

[Continued on page 62.]

Illustrations.

DESIGN FOR A LARGE TOWN MANSION.

THE illustrations show the perspective view, section, and principal floor plan of the design to which the Royal Academy Gold Medal and Travelling Studentship of 2001, have been awarded this year. The author of the design is Mr. A. H. Hart, Associate of the Institute of Architects, who has given us the following brief notes as to the objects put before the competitors and the manner in which he has treated the problem:—"The building required was a large town house, planned with a view to the proper placing and lighting of pictures, sculpture, and other works of art. The site was 150 ft. deep, with a frontage of 70 ft.

The problem, therefore, was to secure a symmetrical plan, such as a town mansion required, without in any way sacrificing convenience, and to provide proper accommodation for the display of pictures and sculpture, with efficient light both for the works of art and the house generally. To secure all these properties upon a deep site with no light obtainable on either side made the problem a difficult one.

The house is planned without a picture-gallery, the object being to display the pictures and sculpture in the rooms themselves, so that the inmates may enjoy them upon all occasions. An endeavour has been made to let the works of art form part of the architecture and contribute towards a harmonious whole, rather than to appear independent, as they generally do in a museum.

The first floor is devoted to the state apartments, in which stateliness and freedom of circulation have been aimed at, whereas the ground-floor contains the family living rooms, &c., where comfort is the first consideration.

The house is designed in the François I. style, and an attempt has been made to combine richness with dignity."

"MUNSTEAD CORNER," GODALMING.

This house, now approaching completion, is situated about one mile from Godalming. The walling generally is of Bargate stone, the upper story half timbered. The roofs are covered with red local tiles. The chimneys are of red brick.

Messrs. Mitchell Bros., of Shalford, are the contractors, and Mr. Edwin L. Lutyens is the architect.

The drawing of the house was exhibited at the Royal Academy last year.

DESIGN FOR A PROPOSED CHURCH.

This church has been designed for a large manufacturing town in the Midlands.

In plan it consists of nave and aisles, with transepts; the vestries are on the north side of the chancel, and the organ-chamber is above them, with openings into the chancel and north transept. The chapel is at the east end of the south transept, and will be vaulted. The chancel, also to be vaulted, has an ambulatory around it. The nave is 30 ft. wide, and has a lofty arcade and a flat-pitched roof of clearly character.

The church will accommodate 800 persons, and will cost about 10,000*l.* without the tower.

The drawing of the church was exhibited at the Royal Academy last year.

JOHN E. NEWBERRY.

WAYSIDE NOTES IN EAST ANGLIA.

DOORWAY, ST. ANDREW'S HILL, NORWICH.

This doorway leads from St. Andrew's-hill to a passage in the rear of an old flint building known as the Old Bridewell.

It is fifteenth-century workmanship, and is constructed of English oak. The massive frame is moulded, and the four-centred head has carved spandrels, the door being hung on book-binges to the frame, and being square headed. Above the arched head is a traceried transom light of open pierced work, but not glazed. Above the traceried panel is a cornice of battlemented moulding. It is a curiously unusual form, and very quaint.

OLD DOORWAY, GUILDHALL, NORWICH.

Though now forming part of the Guildhall, this doorway was not originally built in its present position. It was taken down from an old house formerly standing in London-street, Norwich, and was known as the Bassingham Gate. A drawing exists, published early in the nineteenth century, showing it *in situ* in 1815.

The arch is elaborately moulded, the projecting moulds dying upon the caps of columns worked in the jambs on either side. The centre columns are interrupted, and canopied niches are placed in the jambs, the pedestal of the niche being supported by the column, which runs on to the base. The hood mould is crocketed, and, in place of the final at top, a shield bearing the Royal Arms of England, with supporters, is carved.

In the left spandrel, looking at the doorway, is a filling-in of vine-leaf ornamentations, in the centre of which is a shield bearing the Norwich city arms; the corresponding right-hand spandrel is filled in with roses, and the shield with armorial bearings,—probably the quarterings of the original possessor.

NORTH WALSHAM CARVINGS.

In the pages of the *Builder*, August 24, 1889, there is a short description of North Walsham Church, and allusion is made to the elaborate woodwork and carving, and to the old screen, portions of which are still retained in the church.

I give a sketch of a piece of the screen now worked into the front of a bench, and also a fine poppy-head from one of the bench-ends. It may be mentioned that the church has no special obancel, and the western portion of the tower has collapsed, owing, it is said, to the imperfection of the round lint-bonding.

A careful drawing of the Paston monument in the church appeared in the *Builder* of August 31, 1889.

STRANGERS' HALL, NORWICH.

The newel and baluster are from a building in St. Gregory's parish, now known as Strangers' Hall, though believed to be by most archaeologists an old fourteenth-century city mansion. It was used at one time as a Guild Hall for the ancient guild of St. George, patron saint of England, and probably received the cognomen of Strangers' Hall from the fact of its having been lent to foreign refugees during the persecutions of the Huguenots. It has a beautifully-carved doorway to the street, and many points of interest inside.

COSTESSEY.

This picturesque locality lies about five miles out of Norwich, and is chiefly famous for its fine old Hall, one of the seats of the Staffords, though not at present occupied by the family. It was built by the Jenningsbams in Queen Elizabeth's reign, and consists of a huge quadrangular building, principally in red brick, the details of which are highly ornate. The church does not exhibit any special features beyond a well-proportioned porch, and a picturesque little brick-capped tower, with spirelet of wood.

JOHN S. CORDER.

THE DESIGN OF TECHNICAL COLLEGES AND SCHOOLS.

(Continued from page 61.)

It is imperative that the principal laboratories in the physical department should be upon the ground floor, and that there should be no basement story below them. At least one room should be set apart for exact measurements in electricity and magnetism. The chief tables in this room should be of slate, carried on brick piers, which are built from their own foundations independently of the floor. Professor Ayrton has found it convenient to place slag wool between the brick piers, and slate slabs, instead of fixing the slate to the piers by cement, but the risk of vibration being communicated to the instruments depends greatly on the nature of the soil in which the foundations are placed and on the character of the traffic in the neighbourhood. Other things being equal, that side of the site which is most remote from the public thoroughfares, or traffic of any description, should be selected for the physical laboratory. Professor Herschel's laboratory at Newcastle was within a few feet of the North-Eastern Railway, and the approach of an engine was heralded by the disturbance of his magnets. The side tables throughout the physical department may be conveniently suspended from the walls. A plate of pine 6 ft. or 7 ft. in height, 6 in. wide, and 2 in. thick, is fastened to the walls by ordinary engineers' bolts, made of Muntz metal, which screw into sockets made of brass or Muntz metal, and built into the walls. Except in the neighbourhood of the electrical-room, iron screws may be employed instead of brass, provided they are carefully protected from rust

during the erection of the building by tar, or whitelead and tallow. The plates of pine terminate a little above the floor, and to them are mortised brackets suitable for carrying the slab of teak or ash which is to form the table. By this means we not only secure a table with supports independent of the floor, but for a height of 3 or 4 ft. above the table, but for a wooden plates, to which shelves or instruments can be attached without interfering with the walls, which in a physical laboratory may with advantage be of bare brick, provided its surface is smooth and hard. With the supports described, and with socket screws built into the walls in positions suitably chosen, it will generally be found unnecessary to make any other attachments to the walls whatever.

In the general physical laboratory gas and water should be provided, and, if possible, a fume-closet. If the building is heated by steam, a few T-pieces, which flexible tubing can be connected to the heating pipes, will enable steam at a pressure of 3 lbs. or 4 lbs. per square inch to be available for experiments in calorimetry and other branches of physics.

When the physical laboratory is on the ground-floor, ordinary wooden tables may be conveniently carried on brick piers, 9 in. or 14 in. square, carrying stone caps only 6 in. square, which project through the floor without touching it, and form supports for the table legs. The brick piers carrying the tables should stand on foundations independent of those of the dwarf walls which carry the floor joists.

When the physical laboratory is on one of the upper floors, the table may be rendered to a certain extent independent of the floors by the contrivance adopted at the Cavendish Laboratory. Here corbels are fixed in the walls 1 ft. below the ceiling, and on these rest beams, upon which are fastened blocks, which project through the ceiling and floor to the floor-level of the room above. These blocks support the table-legs, which are thus carried from the walls of the building, but as the floors are carried from the same walls, it is obvious that the tables will not be free from vibrations which can be transmitted through a short length of wall. Tables mounted in this way are, however, immeasurably superior to tables simply resting on a wooden floor, and are sufficiently good for nearly all purposes, provided that the blocks on which the table-legs stand remain clear of the floor; but there is a great tendency for these blocks to twist and come in contact with the floor on one side, in which case the whole arrangement becomes practically worthless.

In the physical laboratory there should be at least one stone slab about 3 ft. square placed at the floor-level, but resting on another instrument of its own, so that a kathetometer or other instrument may be placed upon it and may be unaffected even by the movements of the observer himself. If it is possible to arrange trap-doors in the floors above the physical laboratory, so that wires or threads may be suspended freely from the roof of the building, such contrivances will frequently be found useful; but where this is not possible, supports should be arranged in accessible positions as high above the floor as may be, either by means of cantilevers fixed to the walls by socket-screws or otherwise, or else by beams carried across from wall to wall.

It is generally best to place the chemical laboratory on the uppermost floor, constructing it with an open roof, so as to give as much air space as possible. It is unnecessary here to enter into the details of the benches in the chemical laboratory, as full descriptions of many forms of benches have been published, notably by Mr. Robins, in his work on "Technical Schools and Colleges," which is, so far as I know, unique, and is certainly invaluable. There are, however, a few points in connexion with the fittings of the chemical laboratory to which attention may be directed, and in the first place it is desirable that the use of lead should be avoided as far as possible in the drainage of the benches. The benches themselves are best constructed about 5 ft. wide, and of length determined by the dimensions of the laboratory, but so arranged as to give not less than 3 ft. 6 in. to a junior student, and not more than 4 ft. 6 in. to a senior student. The depth of the cupboards and drawers from back to front is such as to leave a space in the centre of the bench running throughout its whole length of sufficient width for a man to pass through. This space serves to carry the gas and water pipes and the drainage trough. The

DESIGN FOR A PROPOSED CHURCH EAST ELEVATION -By Mr J E NEWBERRY, A.R.I.B.A.

latter may be made of 1 in. or 1½ in. red deal boards, jointed so as to form a V trough about 6 in. in depth. The trough is thoroughly caulked with a mixture of pitch and tar, put on hot, and this trough serves to collect the drainage from the sinks and deliver it into a sludge-box or small settling-tank, through an overflow on one side. The overflow from the sludge-box is delivered into a similar trough laid in a chase in the floor, which conveys it to the down-corer outside the wall. In place of V troughs, semi-circular troughs cut from the solid in red deal may be employed. These semi-circular troughs are largely used in chemical works, and avoid the joint of the V trough. For the down-corer best stoneware pipes, salt glazed, may be employed, but cast-iron pipes coated with preservative compound will last a very long time, and some experiments will probably be made shortly upon the suitability of enamelled cast-iron pipes for this purpose. Rectangular troughs have no advantage over V troughs, and only offer a much larger surface for the acid liquids to act upon. The chases in the floor, which may carry gas-pipes, water-pipes, pipes for distilled water, compressed air for the blowpipe, and vacuum for filtration purposes, in addition to the drainage troughs, should admit of being opened throughout their whole length for the purpose of inspection.

Fume-closets are generally more conveniently placed upon the walls than upon the working benches, and this arrangement simplifies the removal of the fumes without incommoding the laboratory with exhaust-pipes to the ventilating shafts. Special fume-closets should be provided in the walls for the conduct of evaporations which occupy much time, and in these closets both gas and steam should be available for heating purposes. The water-supply to the benches should be at a low pressure. Ten pounds on the square inch is more than sufficient, and ½ in. taps are quite large enough.

In many laboratories it is necessary that the same bench should be used by two different students at different times. In such cases the bottle-racks should be sufficiently large to accommodate two sets of re-agents, and each set should be provided with a locking-har or frame, so as to be available to only one student, who will then be solely responsible for their purity. When three or more students are obliged to use the same bench, personal responsibility for the purity of the re-agents must be sacrificed.

The balance-room is an essential appendage to the chemical laboratory, and, while readily accessible therefrom, care should be taken that it does not communicate directly therewith. The chemical laboratory and the balance-room will generally be on the first or second floor, and in that case the balances should be carried on the walls by brackets. If a separate sulphuretted hydrogen chamber is provided, it should be as far as possible from the balance-room.

A separate room should, if practicable, be set apart for gas analysis and for other operations which require the use of considerable quantities of mercury. The floor of this room should be of asphalt, in which a shallow channel of circular or other convenient form is made for the purpose of collecting any mercury which may be spilled and conveying it to an iron receptacle, whence it is collected and redistilled for future use. When mercury is spilled on a wooden floor, unless the joints are exceptionally close, a very large portion is lost and accumulates between floors and ceilings.

It will generally happen that the same lecture-room will have to be used by several departments, but it is very desirable that separate lecture-rooms should be provided for the departments of physics and chemistry, though each of these rooms may be used for lectures on any other subjects. For lectures on chemistry and physics a large amount of apparatus is frequently required, and sometimes it is desirable that the same apparatus should remain properly adjusted on the lecture table for several lectures in succession. This is notably the case with galvanometers and electrometers, some of which require much time for their adjustment. Such apparatus would not have to be distributed in order to make provision for a lecture on a purely literary subject or one which required only the magic-lantern or diagrams for its illustration or only a comparatively small amount of lecture-table apparatus. But if the same lecture-room has to be used both for chemistry and physics a great and wasteful expenditure of labour will

be incurred in removing the apparatus after each lecture.

The engineering laboratory and the principal workshops must be on the ground, and, when land is available, they are best placed in a one-story building, with a "ridge and furrow" roof, separate from the main building, but communicating directly with it. When it is necessary to place the engineering laboratory and workshops on the ground floor of the principal building, the floor above should be of concrete, and the principal shafting should be carried on A frames, or other supports independent of the structure of the building.

The engineers' drawing office should be readily accessible from the workshops, so that the superintendent of the department may be easily able to supervise both, as it will not generally be possible, or even desirable, to employ separate staffs of teachers for the drawing office and workshops, though in commercial works the drawing office staff is clearly differentiated from the shop foremen and managers.

The biological department may with advantage be located on the highest floor, so as to command the best possible light and ventilation. A good range of windows on the north side coming within 3 ft. of the ground is, perhaps, the chief desideratum in a biological laboratory. Sinks, a good water-supply, and tables which are strong enough not to yield to the pressure of the hand, because perfect steadiness is required for microscope work, with gas connexions for table-lamps on every table, are also important desiderata.

The uppermost story is also specially fitted to meet the requirements of the department of fine art, but of these requirements it is unnecessary for me to speak, inasmuch as every architect is necessarily thoroughly conversant with them. I will only point out that an open Mansard roof constructed with steel principals, which are stiffened by gusset stays so as to avoid the necessity for tie-bars, which might throw a shadow on a cart, seem most suitable for roof construction in this department.

Lastly, with regard to the general arrangements of the building:—

A corridor of ample width should be carried on the ground floor throughout the whole length of the building, but in many cases through corridors will not be necessary on all the floors, provided that there are sufficient staircases to allow ready access to each department. It is difficult to carry corridors through a building on every floor without interfering with the access of light to the rooms, and in order to permit of the lighting of the rooms from both sides it is sometimes worth while to dispense with the through communication. In the College at Newcastle the first and second floor corridors extend for only one-quarter of the length of the building, so that the chemical laboratory and adjoining rooms, the physical lecture theatre, the apparatus rooms, the first-floor physical laboratory, and the optical laboratory occupy the whole width of the building, while the through corridor on the ground floor is built like the side aisle of a church as an annex to the main building, but the roof being a lead flat and the corridor only 3 ft. high, while the ground-floor rooms are 16 ft. 6 in. high, it has been possible to construct windows above the roof of the corridor to afford a cross light to the ground-floor rooms.

Where steam power is required in the workshops or laboratories, it is most economical to employ low-pressure steam for the heating of the building, and to adopt engines which admit of efficient working with a back pressure of four or five pounds per square inch on the exhaust, so as to enable the heating-pipes of the building to be employed as a surface condenser. If the building is lighted by electricity, the utilisation of the exhaust steam becomes an important consideration, as when the whole of the building is lighted, the exhaust steam from the electric light engines is about sufficient for the heating on a very cold day. For example, a room of a floor area of 1,200 square ft., and 16 ft. in height, may be very brilliantly lighted with high efficiency lamps, by the expenditure of two electrical horse-power. To develop this amount of power by non-condensing engines of twenty or thirty horse-power, and of moderate efficiency, will require about 75 lbs. of steam per hour. A much greater efficiency may, of course, be obtained with larger engines, or with high-speed engines coupled directly to the dynamo, and specially constructed for electric lighting. Now, 75 lbs. of exhaust steam in

condensing and cooling in the pipes will give about 40,000 pound-centigrade units of heat, and this will raise about 10,000 lbs. of air through 16 deg. C. This quantity of air is equivalent to 130,000 cubic feet, and the capacity of the room being only 19,200 cubic feet, the air might be changed about seven times in an hour, which is more than twice the frequency required for class purposes. The ordinary allowance of electric light is one 60-watt lamp for 64 square feet of floor, reducing the quantity of steam for the room mentioned to rather less than 60 lbs. per hour. As the corridors and some other parts of the building do not require to be illuminated as brilliantly as the class-rooms, and as the ventilation will be contained in many of the rooms when the lights are not burning, it will be found that if boilers are laid down for the supply of the electric lighting engines they will suffice and not be much too large for the heating of the building in cold weather. When the engines are not running, the heating coils will, of course, be supplied directly from the boilers through a reducing valve.

If it is necessary that any section of the building should be heated by a low pressure hot water system, and if steam boilers are provided for the electric lighting and steam heating of the remainder of the building, it seems undesirable that a special boiler fire should be kept up for the one section, especially if that section of the building to be heated by hot water is remote from the boiler-room. In this case the hot water circulation may be maintained by a coil of steam-pipe carried through a tank in which the hot water circulating pipes are connected, the tank being placed, like a circulating boiler, at the lowest level available, and the steam supplied from the main boilers and drained back to the hot well.

For the conduct of steam-pipes, return hot-water pipes, gas-pipes, cold-water pipes, electrical conductors, and, with some systems of ventilation, of the exhaust air-shaft, it is desirable that a subway or basement corridor, should be constructed throughout the length of the building. From this corridor access may be obtained to the space beneath the floors of all ground-floor rooms whose floors are boarded in the ordinary way.

The question of ventilation has already been alluded to in relation to the heating, as the two subjects are inseparably connected. It has been pointed out by Professor O. J. Lodge, and it is a matter of common experience, that when the air is warmer than the walls or other objects in the room there is a tendency for the dust in the air to be deposited on the colder surfaces, and this is generally associated with an unpleasant feeling of "stiffness." Hence heating by heated air is a dirty method unless steps are taken to cleanse the air before it enters the rooms. This may be done to some extent by causing it to pass through a sheet of water produced by a "sprayer," but the method is somewhat expensive. Any attempt at filtering the air through wool or other material introduces an amount of resistance to the current which is practically fatal. On the other hand, if the incoming air is cold, and the room heated only by radiation from the steam-pipes, it is very difficult to avoid currents of cold air, with the practical certainty that the inlets will be closed by the persons occupying the rooms.

A compromise between the two methods leads in some cases to satisfactory results. By boxing-in one-half of the steam-pipes with wooden casing, and allowing air to enter through the walls beneath the windows, and to pass over the hot pipes, and thence diffuse through the room, the whole of the entering air may be suitably warmed, while one-half of the steam-pipes remains for the heating of the walls and furniture by radiation.

If radiators, instead of steam-pipes, are used in the best rooms, care should be taken in selecting the type of radiator to see that the castings, if such be employed, are so designed that it is impossible for unequal heating to cause strains of such a nature as to produce fracture of the casting. If two terminals are connected by three or more tubes forming one casting, it is possible to arrange such a distribution of temperature as to necessitate the fracture of at least one of the tubes. If the castings are held together by light wrought-iron ties which are external to the steam-tubes, so that their temperature is raised very slowly, the ties are liable to be strained beyond their elastic limits during the rapid heating of the castings, and to require frequent screwing-up in

order to keep the radiators steam-tight. There are types of radiators in the market which avoid all these difficulties.

With regard to the removal of the exhaust-air, there is little doubt that mechanical ventilation is most effective, and air-propellers of the Blackman type, driven by a gas-engine or electric motor, have proved very successful, even when the air has had to be drawn through a couple of hundred feet of tubes. The propeller may be inserted in a wall at the top of the principal staircase, or in some other convenient position, and the corridors may be used as air-ways, the air entering the rooms as above described, and passing through the opposite walls into the corridor. The system, perhaps, offers the least resistance to the air-currents, and a large propeller driven at a comparatively slow speed will do its work without noise or vibration. An electric motor may be directly coupled with the fan, whatever its position, or the fan may, itself, be wound as a motor, but if a gas-engine is employed, the power should be transmitted by a belt outside the building. It is clear, however, that the chemical laboratory, or any other rooms in which noxious fumes are produced, must be cut off from this general system of ventilation, and be treated specially. If it can be arranged to erect the boiler-chimney-shaft within a few feet of the chemical laboratory, the exhaust from the fume-closets, as well as the general ventilation of the laboratory, may be carried into the shaft, at the cost of somewhat reducing the steaming power of the boilers. It is very undesirable that any attempt should be made to carry the whole exhaust from the building into the boiler-shaft. If the chimney-shaft is not available for the chemical laboratory, it is best to provide a special fan for the exhaust of the fume closets and the laboratory generally, conducting the air to the fan along a system of carefully-constructed tubes. In small laboratories the general ventilation may be effected by ventilators in the roof, and the exhaust of the fume closets may be carried out by ordinary chimney-flues, in which an upward current is maintained by a gas-burner; but when it can be employed the fan gives by much the best results.

It should always be borne in mind that any system of air conduits will serve also as tubes for the transmission of sound, so that rooms, like workshops, in which noisy operations are carried on, should be provided with separate ventilation. It must also be noticed that when a fan is driven at sufficient speed to exhaust through a great length of narrow tubes, it will necessarily be noisy, and the sound will be carried to every room which communicates with the ventilating system.

Where rooms of different capacity communicate through independent tubes of different lengths, with the same exhaust chamber, the diameter of the tubes should be proportional to the fifth root of the square of the quantity of air to be removed per hour, and to the fifth root of the length of the tube.

The great expense incident to efficient ventilation lies in the heat required to raise the temperature of the entering air in very cold weather. For example, suppose a building to contain 1,000,000 cubic feet of air, and this is to be renewed only once an hour on the average of the whole building, and that the entering air must be heated through 27 deg. F., or 15 deg. C. The weight of 1,000,000 cubic feet of air will be about 77,000 lbs., and its specific heat being .24, the number of heat units required to raise this quantity of air through 15 deg. C. is 27,200 lbs.—centigrade units. This will involve the condensation of 504 lbs. of dry steam, and the combustion of about 60 lbs. of coal; but this allows nothing for the cooling of the air within the building, which in a brick or stone building takes place mainly through the windows.

If we adopt the usually-accepted principle that the amount of carbon dioxide in the air should not be allowed to exceed .06 per cent., and that the supply of fresh air should, therefore, be at the rate of about 3,000 cubic feet per hour for each individual, and three times that amount for each ordinary gas-burner (but nothing for electric lights), we find that for 1,000 persons in a building lighted by 333 gas-burners 6,000,000 cubic feet of air per hour will be required, necessitating the combustion on a very cold day of 360 lbs. of coal per hour. If electric light were substituted, current for 333 sixteen-candle lamps would require only 120 lbs. of coal per hour for its production, but

if the gas-burners are so arranged that the products of combustion escape immediately, there can be no need for the double supply of air, and if the products of combustion mix with the air they will supply more than half the heat required to warm it.

In the above sketch, arrangements have been suggested suitable for a building of considerable size, possessing, for instance, a capacity of 1,000,000 cubic feet. In the case of small schools, the same guiding principles may be adopted, though it will be impossible to attain the same degree of specialisation in the appropriation of the rooms. At the Royal Grammar School, Newcastle-upon-Tyne (Mr. R. J. Leeson, of Newcastle, architect), a stone building which had formerly been used as an elementary school became available for the departments of chemistry and physics. The principal school-room measured internally 56 ft. by 30 ft., and the infants' school-room 30 ft. by 20 ft. In addition to these rooms there was a small master's room. When a matchboard ceiling was removed there was an open roof with the ridge about 30 ft. from the floor, and a large lantern with louvres for ventilation. Skylights were inserted on the north side of the roof, and plate glass windows were substituted for the wooden frames, and small diamond panes which had previously done their best, by accumulating dust, to obstruct the light. The floor was about 2 ft. above the level of the ground outside, and there was a clear space beneath the floor about 4 ft. in height. In the large room there were two fireplaces with open chimneys, and one in the small room. The open fires were replaced by "tortoise" stoves, and the open chimney-breasts closed by sheet iron. The chimneys then served both for the stoves and for the fume-closets.

The infants' room was made to serve the double purpose of balance room and physical laboratory. Around three sides of the room an ash table was suspended from the walls on brackets similar to those previously described, while a large and heavy table, measuring 10 ft. by 5 ft., was placed in the centre of the room, and carried on brick piers, whose stone caps were finished off level with the floor. The large room was divided into two by a pitch-pine partition. The smaller portion, measuring 30 ft. by 22 ft., was fitted up as a lecture room, capable of accommodating sixty boys; the larger, measuring 34 ft. by 30 ft., was fitted as a chemical laboratory. Two benches, each 25 ft. in length, occupied the centre portion of the laboratory, and afforded accommodation for thirty-two boys working at one time, while tables were provided along the side walls to supplement the accommodation afforded by the benches. The sinks drained directly into a V trough, coated with pitch, and suspended by iron ties from the joists beneath each bench. One of the two troughs was continued under the floor of the lecture room to take the drainage from the lecture table. The two troughs discharged into a third trough, which crossed their ends at right-angles, and carried the drainage through a hole in the front wall and discharged it over an open gulch of glazed stoneware. A number of Tohin's pipes, 1 ft. square and 8 ft. in height, served for the access of fresh air.

Where the students are mostly adults, 3 ft. is a convenient height for laboratory benches and tables, and 2 ft. 9 in. or 2 ft. 10 in. in the case of school laboratories.

It is impossible in a paper of this description to enter into the arrangements which must be made in order to provide for the teaching of special local industries. Where such teaching is necessary, the first thing to be done is to acquaint oneself with the machinery and methods employed in the factories or workshops where the particular trade is practised, and then to learn precisely the extent to which these appliances should be introduced into the technical school. When spinning and weaving are taught, the technical school is to a very great extent simply a model factory or weaving-shed; but in most cases, it is the function of the technical school to provide those facilities for instruction and experimental investigation which are not to be found in the workshop; and it is comparatively seldom that the equipment of the factory requires to be reduplicated in the technical school.

In teaching purely technological subjects, the classes for which consist wholly of members of one particular trade, it is most important that the instruction should be under the general direction of a committee consisting wholly of

members of that trade—masters, foremen, and operatives being all duly represented. Such a committee will do more to inspire confidence among apprentices and workmen in the practical character of the teaching than the most distinguished governing body; and there is no danger that under such direction the teaching will sink to pure empiricism if the teachers or the permanent staff of the institution are men of the right stamp.

The paper was illustrated by working drawings and tracings of the existing and some of the proposed buildings of the Durham College of Science, prepared by Mr. R. J. Johnson and Mr. F. W. Rich, the architects, to whom the author tendered his acknowledgments.

A brief discussion ensued as to various matters of detail, the members taking part in the discussion being Mr. Paul Waterhouse, Mr. C. H. Brodie, Mr. W. J. H. Leverton, Mr. W. H. White, and Mr. E. Sim. Professor Garnett having replied to several questions which were asked, the proceedings terminated.

THE LONDON COUNTY COUNCIL.

The first meeting of this Council since the Christmas vacation was held on Tuesday afternoon last, the Chairman, Sir John Lubbock, presiding, but, for the reason hereafter mentioned, its sitting was a short one.

Vote of Condolence with the Royal Family.—On the motion of the Chairman, a vote of condolence with the Royal Family on the death of the Duke of Clarence was agreed to unanimously, and it was further resolved to take only non-contentious business, and to adjourn early.

The London Water Question.—The Chairman announced that he had received the following important letter from the President of the Local Government Board:—

"Local Government Board, Whitehall, S.W.,
Jan. 13.

SIR,—Referring to the correspondence which has taken place between the London County Council and her Majesty's Government, I have to intimate to you for the information of the Council that her Majesty's Government have resolved to advise the appointment of a Royal Commission to inquire—
"Whether, taking into consideration the growth in the population of the metropolis, and the districts within the limits of the metropolitan water companies, and also the needs of the localities not supplied by any metropolitan company, but within the watersheds of the Thames and the Lea, the present sources of supply of these companies are adequate in quantity and quality, and, if inadequate, whether such supply as may be required can be obtained within the watersheds referred to, having due regard to the claims of the districts outside the metropolis, but within these watersheds, or will have to be obtained outside the watersheds of the Thames and the Lea."

I remain, Sir, your obedient servant,

CHARLES T. RITCHIE.

To the Right Hon. Sir John Lubbock, Bart., M.P.,
Chairman, London County Council."

The proposal contained in the letter, said Sir John Lubbock, was substantially in accordance with the suggestion made to the Government by the Council, and he was sure that the decision of the Government must be satisfactory to them all.

The letter was ordered to be recorded on the minutes, and was referred to the Special Committee on Water Supply.

Date of the First Meeting of the New Council.—The General Purposes Committee reported as follows:—

"In our report to the Council of the 1st of December we pointed out that by the County Council Elections Act, 1891, the Council may fix the day and hour for the statutory meeting at which the Chairman and Aldermen of the new Council are to be elected.* Having considered the matter, we have come to the conclusion that Tuesday, the 15th day of March, will be the earliest convenient day for the meeting. We recommend:—

"That Tuesday, the 15th day of March next, at 3 o'clock, be fixed as the day and hour for the statutory meeting at which the Chairman and Aldermen of the new Council are to be elected."

This was unanimously agreed to.

Tenders: Return of Deposits of Money.—The General Purposes Committee's Report also con-

* As we have already announced, the date of the election of the new Council itself has been fixed to take place on Saturday, March 5.

tained the following paragraph and recommendation, which were agreed to:—

"The Main Drainage Committee has represented to me that it would be desirable that some general order should be made with reference to the return of the deposits of money made by persons applying for specifications and drawings of an advertised work. In many cases the money deposited is returned to persons who subsequently send in *bona-fide* tenders, but in some case of large works, in connection with which great expense has been incurred in the preparation of drawings, it has been the practice to retain the amounts deposited. We think that this variation in money so deposited continues, and that in all cases money so deposited should be returned to persons who send in *bona-fide* tenders. We accordingly recommend—

"That the following be a standing order of the Council.—The money deposited with the Council by persons who apply for specifications and drawings of an advertised work shall afterwards be returned to those who shall have sent in *bona-fide* tenders."

Emmanuel Hospital, Westminster.—The Corporate Property, Charities, and Endowments Committee presented the following report on the proposed removal of this building:—

"This foundation has recently been the subject of a special inquiry held by Mr. Clahon, on behalf of the Attorney-General, with a view to ascertain the wishes of the inhabitants on the question which has been raised whether the site of the hospital should or should not be sold; and, at our request, a gentleman from the Solicitor's department attended the inquiry to watch the proceedings on behalf of the ratepayers.

The charity was founded in the time of Queen Elizabeth, and the hospital buildings erected shortly after its foundation are still standing, and are still used as almshouses. It appears, however, that the income of the endowment has largely fallen off, and is not likely to recover itself. The present annual income of £207, is all that is applicable to the hospital (as distinguished from the schools, with which we do not now concern ourselves), and this is found insufficient to carry on the work of the charity; several of the rooms are in consequence unoccupied, and the property is in a state of dilapidation. The site, however, is situate in close proximity to Victoria-street, and is now a very valuable one, and if it were sold a large sum might be expected to be applicable, either for the establishment of the hospital elsewhere, or for some alternative scheme.

We are of opinion that the site of the hospital should be sold, and that the proceeds should be devoted to out-pensions for the aged instead of the hospital being erected elsewhere. We think that the views of the Council should be submitted to Mr. Clahon, with a view to his transmitting them with his report to the Attorney-General, and he has indicated his willingness to do this.

We therefore recommend:—

"That the Council do approve of the proposal to sell the site of the hospital, and that the Clerk be instructed to inform the Attorney-General (through Mr. Clahon) and the Charity Commissioners to that effect, and also to intimate that in the opinion of the Council the proceeds of the sale should be devoted to out-pensions for the aged instead of re-erecting the hospital elsewhere."

On the motion that this recommendation be agreed to, Mr. Acworth said he should oppose the proposal strongly, as its adoption would have the effect, without doubt, of covering what was now a great part virtually an open-space, surrounded by low buildings, with lofty blocks of flats or other buildings.

As the recommendation was thus opposed, its consideration stood adjourned.

After transacting some other business, the Council adjourned at 10 minutes to 4 o'clock.

DECORATIVE WORK.—In the little R.C. Church of St. Joseph, at Christchurch, in Hampshire, two designs, executed in the "Corvo Arras" method, were unveiled for the first time on Christmas Day. The panels (each 100 in. by 34 in.) are adapted to their position on either side of the chancel arch, with lines that harmonise with the building. The subject is the Annunciation. A ray of light crosses from the upper left-hand corner of one to the lower right-hand corner of the other. In this ray, on the left panel, the Archangel Gabriel is kneeling, in a habit of primrose blue with apparels and drapery of blue embroidered on silver. He hears a heavenly voice, and with sapphires. On the other panel, the Virgin sits on a throne. On the foot-stool beneath her feet is brocaded the dragon crushed and dead. Behind her, bearing aloft a crown of fleur de lys above her head, the Archangels Michael and Raphael float in the air. The whole design is encrusted with gems, and silver, and gold, like the initials of an antique missal.

LIVERPOOL ENGINEERING SOCIETY.—The sixth ordinary meeting of the present session was held at the Royal Institution, on Wednesday evening, January 13, Mr. F. Huddleston, Assoc. M. Inst. C. E., occupying the chair. Mr. A. J. Maginnis, M. Inst. N. A., read a paper entitled "Transatlantic Lines and Steamships, No. 2."

Correspondence.

To the Editor of THE BUILDER.

THE NEW BUILDING-BY-LAWS FOR LONDON.

SIR,—It would be well that the new By-laws should be carefully read by everyone who has to do with building works in the county of London. It sometimes seems as if some people do not read their *Builder*, as they should properly, from first page to last every week, and people of that sort may remain ignorant of the new things in the By-laws for a long time, and give to themselves and to others very much trouble in consequence.

I would suggest that the London County Council should make a special effort to bring the By-laws well under people's attention. A letter might be sent, pointing out the novelties, copies of the By-laws being enclosed with the letter. If every architect, surveyor, house agent, master bricklayer, carpenter, and plasterer in London was reached in that way, a good beginning would be made. The expenditure would be very small, and the saving to the community, probably, a thousandfold at least.

Contractors should supply foremen, subcontractors, &c., with copies of the By-laws. The R.I.B.A. might lay in a small store, and supply copies to members at, say, a shilling for twelve, for distribution to clerks of works, hanging-up in offices, &c.

A DISTRICT SURVEYOR.

FLOORING-BOARDS ON CONCRETE.

SIR,—In some workmen's dwellings, I am anxious to lay ordinary deal flooring tongued, directly on concrete, composed of coke breeze and Portland cement, to which the flooring would be nailed.

Will any of your readers kindly state their experience of floors so laid? Are the boards liable to "cockle" or to decay more rapidly than if laid on joists? If they are, what is the best means of getting over these objections? Block flooring would be too expensive. SURVEYOR.

11, Leinster-street, Dublin.

BOLSOVER COLLIERY COMPETITION.

SIR,—I wrote for the particulars of the above competition, and duly received a copy of the same from a Mr. Houlton.

It may interest your readers to know that, on perusing the requirements, I found that a sum of 40L was offered for the best set of plans for seven private houses, schools for 600 children, a workmen's club, a hospital, and a co-operative store. I need hardly say that I returned Mr. Houlton his particulars, and at the same time expressed a hope that no one in the profession would find it worth while to undertake this exceptional amount and charming variety of work, for the ridiculous sum offered as first prize by the Bolsover Colliery Company. H. G.

The Student's Column.

WARMING BUILDINGS BY HOT WATER. IV.

DISPOSITION OF PIPES IN AND NEAR BOILER.

It will be found that in describing different phenomena, reference may be made more often to horticultural than to building works. The reason for this is that minor points and features of no great moment do not need the consideration in the latter that they do in the former undertakings, with the low power of circulation that is the prominent feature; consequently, unless the question touched upon is of some importance, it may probably be spoken of as applying to horticultural works only. Of course, all methods and works will be treated as fully as possible; but the two descriptions of works now being spoken of cannot well be treated together, on account of the vast difference the speed of circulation in each makes. In speaking of air displacement, and some appliances, &c., the two subjects need no separation, but otherwise than this, they will be dealt with distinctly, and horticultural works had better be taken first.

The preceding papers have shown the necessity of terminating the two different services, that is, the flow and the return,—at different levels in the boiler: the flow the highest, and acting as an outlet for the heated water; the return at the lowest point, being an inlet for the cold or cooler water. The most desirable

point for the flow-pipe to be connected is at the crown of the boiler, the very highest point on the top, this being conducive to the free and unimpeded escape of the outgoing water, and also permitting of the free exit of air. Fig. 7 shows in front elevation the flow-pipe situated upon the apex of a saddle-boiler,—its correct position.

FIG. 7. FIG. 8.

If we carried the flow-pipe from the side of a boiler, the fact of its starting in a horizontal direction would not suffice to destroy the circulation (provided the return-pipe entered at a still lower point, and other features were correct), but it would leave no means for the air to escape from the upper part of the boiler, as fig. 8. This would cause not only inefficient results, but the destruction of the boiler by the action of the fire on the unprotected boiler-plate. The inflow of water when the apparatus was charged would not expel the air, as might possibly be supposed; and even if it did, there is the perpetual absorption and expansion of air by water, in the cooling and heating processes, so be guarded against. When the flow-pipe starts from the side of a boiler, as is most usually the case with small boilers, and also with the Longborough pattern boiler, it has of necessity to be taken from the extreme highest point to avoid this trouble. A collection of air at any point in an apparatus will nearly always ruin its efficiency.

If there were two or more flow-pipes proceeding from a boiler, as is usually the case with the larger sizes, it would not matter if any were connected at lower points, provided one started from the top. One pipe would quite overcome the air-collection difficulty, but it is better for general purposes to take all flow-pipes from the top if anyway possible, more especially in large works. However favorable general conditions may be to an effective circulation, it is not well to do anything opposed to efficiency if it can be avoided.

In ordering boilers, the desired number, sizes, and positions of the pipe connexions are usually indicated, and so furnished and fitted by the maker. In this case no fear need be experienced of the connexions being wrongly made; and, as a rule, the fittings for connecting cast-iron pipes to boilers cannot very well be wrongly attached. If, however, it is proposed to use wrought-iron pipes, as is nearly always the case in building works, the most the maker generally does, unless otherwise instructed, is to drill and tap (screw) holes in the boiler of a suitable size for the pipe in question. If this be so, there is the possibility of the fitter screwing his flow-pipes right through the substance of the boiler, so that it projects inside.

If this projection occurs, it becomes impossible to fill the boiler quite full, as the water cannot rise above the end of this pipe, as fig. 9. This would be rather evidence of bad work than otherwise, and if there be the least likelihood of its occurring, it is better to have a flange affixed for the flow-pipe to be connected into. With a flange we may screw the pipe in about 1/2 in. without causing the trouble referred to.

FIG. 9. FIG. 10.

With the return-pipe we have practically none of the details to consider that are so important with the flow. The chief point is to give it the lowest possible position, and when convenient, as far removed from the flow as possible. The return can rarely ever be brought vertically into the boiler, as the pre-

sent forms of boilers, almost without exception, necessitate its entering at the side. With the saddle-boiler it would enter as fig. 10, but where circumstances and the size of the apparatus are favourable, it is a good plan to have a return entering on each side (there are commonly two returns and one flow connected to the boiler, as will be seen later). When the boiler has but one return, as illustrated, it causes, by the action of the water, the greatest deposit to accumulate in the bottom of the boiler on the opposite side, instead of being more equally distributed. This leads to an early fracture of the boiler at this point, unless it is cleaned out with regularity. If there be two returns, one on each side, the deposit does not so readily collect at one point, and this tends to lengthen the life of the boiler.

There is no question of air dispersion, or of freedom in the action of convection currents, to be considered in the connexion of the return pipe to the boiler. It is sufficient that it should be properly connected, and cause no obstruction to the regular passage of water through it.

It is usual when carrying out these works to arrange for the flow-pipe or pipes to be carried above the returns; that is, the two pipes are run one above the other, the flow uppermost, and the return beneath. This applies whether there be but two pipes or a number, and it also applies whether the pipes be mains or branch services. The regularity of this practice induces many people to think that the arrangement is necessary to effect the proper circulation of the water. This, however, is not the case,—it is merely a practice, and nothing more, but, of course, it is based upon getting the best results, and being a method that prevents doubt and confusion when erecting new or re-arranging old works.

If it would prove a convenience there is not the slightest objection to carrying the flow and return side by side, and this is usually done when two pipes are run in a channel (with grating over), this arrangement permitting of the channel being shallow, and both pipes are effective in distributing heat. They would not be so effective if one pipe was below the other in a trench, as the lower would be interfered with by the confinement. If, also, it ever became necessary to reverse the usual position of the pipes, and carry the flow beneath the return, it would not destroy efficiency, provided the connexions at the boiler were correct; as fig. 11 for instance. The customary arrangement is as fig. 12.

Fig. 11.

Fig. 12.

The object in showing this is to do away with the general idea that the least departure from the ordinary state of things will ruin the undertaking. In conducting experiments with the little glass apparatus already referred to, there will be found a real difficulty in preventing the water circulating, however oddly the pipes may be carried, provided there is free escape for the air. It will be found that an accumulation of air at some point is the commonest difficulty to overcome, and, if this can be avoided, then a circulatory motion is sure to set up in the water. In experimenting with unusual arrangements of the pipes, the chief difficulties, after the air question is settled, will be the liability of a reversed circulation, or perhaps a circulation in the right direction, but too sluggish to be of service if the works be extensive. As a rule, however, for ordinary requirements, it can be arranged for the pipes to be carried according to the usual method,

OBITUARY.

MR. ALFRED PORTER, F.R.I.B.A.—We regret to hear of the death, on the 14th inst., of Mr. Alfred Porter, F.R.I.B.A., aged fifty-five. He became an Associate of the Institute in 1856, and a Fellow in 1860.

MR. THOMAS MORGAN, F.S.A., died on the 13th inst. at his residence, Hillside-house, Streatham, Surrey, at the age of seventy-two. For a considerable time he was a Vice-president of the British Archaeological Association, and for fifteen years was their honorary treasurer. During his connexion with the Association he contributed, as the *Times* says, "many scholarly and learned papers, chiefly relating to his favourite subject, Roman archaeology. In 1855 he published his 'Roman-British Mosaic Pavements,' which contained a history of their discovery and a record and interpretation of their designs, and which is now a standard work on the subject. Up to a few days before his death he was busily engaged completing another work on a kindred subject." All who knew him and had accompanied him on archaeological excursions will remember his amiability and the ardour with which he entered into his favourite pursuit.

GENERAL BUILDING NEWS.

NORWICH CATHEDRAL.—The Dean of Norwich, preaching in the cathedral on Sunday morning, the 19th inst., gave notice that on and after Monday, the 11th, all the services would be held in the nave, the reason being the restoration of the three great columns which, with the fourth, recently repaired, support the tower. The three columns, now at last to be dealt with, have been in a state of dilapidation for some fifty years, if not more. From inquiries which have been made (says the *Norfolk Chronicle*), it is encouraging to learn that the stone to be used in the work is already cut. A large staff of masons have been busily engaged under the direction of the cathedral architect, and this portion of the cathedral restoration will proceed as rapidly as is consistent with security, and with due regard to the preservation of that regularity which so strongly characterises Norman work. The Ethelbert gate is now complete. This structure has been restored under the direction of Mr. Ewan Christian. The restoration of the cathedral is to be reported upon by Mr. Pearson.

NEW CHURCH AT SHALDON, TEIGNMOUTH.—The river Teign divides Teignmouth and the pretty villages of Shaldon and Ringmore, the latter place having one of the most interesting and complete little thirteenth-century churches that the large county of Devon can boast of, with an east window that commands the admiration of all who see it. It has been found necessary to build a separate church for the larger place, Shaldon, for which Mr. Edmund Sedding, of Plymouth, has been asked to prepare plans.

YORK CITY AND COUNTY BANK, LEEDS.—New premises for the York City and County Bank are now being erected at the junction of Park-row and Bond-street, Leeds. The exterior of the building is being carried out in Bradford stone. The ground-floor is treated externally with rusticated quoined courses, the windows being circular-headed, and the entrance to the bank is placed at the angle of the building, the frieze and pediment being carried by polished red granite columns. Extending upwards over the height of the first and second floors are eight pairs of coupled Corinthian columns, and the whole is crowned by an elaborate frieze and cornice. The interior arrangements will, according to the *Leeds Mercury*, both in design and finish and completeness of equipment, be carried out in a style consistent with the external appearance of the building. The basement contains porter's house, strong-rooms, heating and dynamo rooms. On the ground-floor, and facing Park-row, is the bank room, lighted at the back by a lantern light, and opening out of the public room are the manager's and waiting rooms, strong-room, &c. The walls of the bank will be lined internally with Burmantofts faience. All the counters, desks, &c., will be in half-polished oak, having brass fittings of special design. There will be a fine suite of offices on the ground floor, with separate entrance from Park-row. The first and second floors, which will be entered from Bond-street, will also be fitted up as offices, having strong-rooms on each floor. The works are being carried out by Messrs. W. Nicholson & Son, of Hunslet, from the designs and under the superintendence of Messrs. Smith & Tweedale, architects, Leeds. Mr. Appleyard, of Leeds, has been entrusted with the execution of the carved work.

HOSPITAL FOR INFECTIOUS DISEASES, BRENTFORD.—The new hospital erected by the Brentford Local Board for the reception and treatment of cases of infectious diseases was opened on the 14th inst. The building has been constructed by Messrs. Allen Sons, of Kilburn, from plans by Mr. J. H. Strachan, the Surveyor to the Board. It has aspects to the west and east, and is built on a piece of land contiguous to the Board's sewage works in the Ealing-road. It has a main approach from Claypotts lane, in addition to one from the Brentford sewage works. In shape it is oblong, with a wing at either end, and it consists of one story

throughout, raised 8 ft. on concrete to the level of the road. It is built of stock bricks, with facings of Lawrence's red bricks. Its extreme length is 125 ft., and the widest part, exclusive of the wards, is 20 ft. across. The basement will be used only as collage. Forty-eight feet away from the main building, and adjoining the main entrance in Claypotts-lane, is situated the administrative cottage, containing a sitting room, kitchen, surgery, four bedrooms for the use of the nurses, and a bathroom, all spacious and conveniently adapted for the purposes for which they are required. In another direction, 40 ft. away from the main building and 40 ft. from the nearest fence, is the mortuary, laundry, and disinfecting house, each of which is fitted with its necessary furniture. The hospital itself is 80 ft. from Claypotts-lane, and 55 ft. from the boundary fence of the sewage works. The wings are occupied solely as wards, and their dimensions are 30 ft., 18 ft., and 13 ft. high, the latter figure representing the height of all the rooms in the building. The smaller wards measure 24 ft. by 18 ft. by 13 ft. high; and the two nurses' duty rooms, which adjoin the wards, are 16 ft. by 14 ft. by 13 ft. high. The whole of the interior walls have been finished in Parian cement, painted and varnished to a high gloss. All the interior and exterior angles in the wards and nurses' duty rooms have been rounded, and the skirting and cornices have been designed with a view of preventing the harbouring of germs, &c. Attached to each ward are verandahs fitted with necessary conveniences for the use of the patients who become convalescent. The building is constructed for the accommodation of ten cases of an infectious nature only at a time, and it is designed so as to permit of the admission of two kinds of diseases, and further, the wards are so arranged that a person cannot get from one block to another without having to walk a distance in the open air of 56 yds. The sanitary arrangements are of the ordinary kind, and lighting is by means of gas brackets. The heating is by fireplaces, which also act as ventilators, and the lights are ventilators being inserted in the skirting and the windows having faillights opening in the wards near the ceiling, so arranged that a through current of air is ensured in each ward. The contract price for the erection of the building was £3,630L, and it was stated by Mr. Strachan during the proceedings that the building had been erected absolutely without "extras."

NEW BUILDING IN BIRMINGHAM.—Mr. F. W. Lloyd, the City Buildings Surveyor of Birmingham, has supplied us with a return of new buildings, &c., for which plans were approved during the year 1891, together with a summary of the three previous years. The total for 1891 was 1,541, as compared with 1,708 in 1890, 1,530 in 1889, and 2,557 in 1888. About 1,000 houses are erected each year in the city. During the year 815 notices were forwarded to property owners and others as to dangerous buildings, projecting signs, emblems, &c., and a quantity of land, amounting to 176½ yds. super, has been conceded to the Corporation by owners of property setting back projecting windows, steps, &c.

NEW SWEDENBORGHIAN CHURCH, SALFORD.—A new Swedenborgian church was formally dedicated on the 15th inst. It is situated at the corner of Walmsley and Lower Broughton-road. The new structure is of Gothic design, and has been erected by Mr. J. Ramsbottom from designs by Mr. Thomas Browne, architect, Manchester, at a cost of £3,000. The church consists of chancel, minister's and choir vestries, and a ladies' retiring-room. There is also a school-room under the church, giving accommodation for 350 scholars. The church will seat about 300 worshippers. It has been built to replace the church known as "The Temple," the site of which was recently acquired by the Lancashire and Yorkshire Railway Company.

NEW BANKING PREMISES AT ABLINGTON, LANCASTERSHIRE.—On Monday last new premises for Messrs. Williams, Deacon & Co. and the Manchester and Salford Bank were opened for business. The new building, which occupies a prominent corner site in Church-street, have been erected from the designs of Messrs. Jolly & Buckley, architects, Chorley. It is constructed of Yorkshire stone parapets, with polished stone dressings. The style is Classic. The contractors were: Excavator and mason work, Mr. W. Fairclough; carpenter and joiner's work, Mr. Robert Brownley; slater, plasterer, and glazier, Mr. W. Hampson; plumber, glazier, and painter, Mr. T. Sharples. The work has been carried out at a cost of about £500.

LOCAL BOARD OFFICES, FELINSTOWE.—The foundation-stone of the new offices for the Felinstowe Local Board was laid on the 14th inst. The site was given to the Board by Captain E. G. Prateman. The new offices will front Undercliff-road at a point just beyond the road leading up to the cliff near the Convalescent Home. The new building, which is to be "Early English" in character (according to the *Singful Chronicle*), will occupy a frontage of some 62 ft. to Undercliff-road, its extreme depth being 32 ft., and its mean depth about 26 ft. There will still leave room for the erection of a further building 40 ft. by 25 ft., should it be thought desirable to add to the offices at some future time a reading-room and library, or, as the population increases, a building to which the name of Town Hall might be given. The front elevation

will be of plain red brick on a plinth of blue bricks, with tiled roof, relieved by a gable at the east end. The architect is Mr. G. S. Horton, the Board's Surveyor, and the contract, for 1,670*l.* has been entered into by Mr. H. Runnacles, Halsstead.

NEW CHURCH AT STAINES.—The Solicitor-General and Lady Clarke have generously undertaken the cost of a new church at Staines, at a cost of not less than 5,000*l.* A site has been secured facing the river, and the building is to be designed by Mr. G. H. Fellowes Payne, whose fine church at West Dulwich, which we illustrated in the *Builder* October 18, 1890, has attracted so much admiration.

SANITARY AND ENGINEERING NEWS.

SEWERAGE WORKS, &c., AT ACCRINGTON.—On the 14th inst. a Local Government inquiry was held at Accrington, by Colonel W. M. Ducal, R.E., into an application made by the Council for the borrowing of 12,740*l.* for works of sewerage, street improvement, public lighting, and the erection of stables. The Town Clerk said the first item on the application was for the improvement of Willows-lane, for which they asked 1,700*l.*, and for sewerage to same 1,000*l.* The period for which they asked the loan, as under the Public Health Act, was for a term not exceeding sixty years. In regard to the Dyke Nook sewerage scheme, the Town Clerk said this was to prevent the pollution of the Altham stream, which ran through the borough from the adjoining township of Altham, within the Rural Sanitary District of the Burnley Union, and from that authority they had received now, for a period extending over four or five years, written intimations that unless they took their sewerage out of the stream they would take proceedings against them. The amount asked for under that head was 4,930*l.* For the sewerage of Burnley-road the Council asked 1,494*l.* For part of this district there was practically no system of sewerage. The cost of similar works in Wakefield and adjacent streets was included under the head of the Dyke Nook scheme. For the Corporation stables they asked for the "extras," which, on an estimate of 15,000*l.*, only amounted to 150*l.* The last item of the application was for 2,022*l.* for street lamps and their erection. The town was rapidly increasing, and that sum would provide them with lamps for eight or ten years. The Inspector subsequently visited the various places referred to in the application.

CASTLE DONINGTON SEWERAGE.—The Shardlow Rural Sanitary Authority have applied to the Local Government Board for a loan of 4,000*l.* for the sewerage and sewage disposal of Castle Donington. The sewage will be purified by irrigation on land. Mr. V. H. Radford is the engineer.

SEWAGE PURIFICATION AT BIRKDALE.—Major-General C. Phipps Carey, R.E., of the Local Government Board, recently held a public inquiry at the Town-hall, Birkdale, about the disposal of the Birkdale sewage. The lime treatment of the sewage having produced bad results, the Southport Corporation obtained an injunction against the Birkdale Local Board for polluting a brook. To revoke this injunction, the Birkdale Board proposed to continue treating their sewage with lime, but carrying their effluent therefrom through a pipe-sewer into the sea. This was opposed by the Corporation of Southport and by neighbouring landowners. Dr. E. Frankland, F.R.S., of the Rivers Pollution Commission, and Mr. Mansergh, M.Inst.C.E., gave evidence for the Southport Corporation against lime treatment of the sewage. These eminent authorities recommended the Ferrozone and Polarite process of the International Company, as in their opinion it would produce the most satisfactory results, and would be less costly than the method proposed. After hearing this evidence, the representatives of the Birkdale Local Board withdrew, and, after a short deliberation, announced their willingness to give an undertaking to adopt the international process, whereupon the opposition of the Southport Corporation and the other opponents was withdrawn. The Birkdale Board have accordingly instructed Mr. Charles H. Boleo, M.Inst.C.E., of Liverpool, the Consulting Engineer to the International Water and Sewage Purification Company, Westminster, to prepare the scheme in conjunction with Mr. J. H. Fairbairn, the Surveyor to the Board.

UNIVERSITY EXTENSION LECTURES.—The following are the remaining lectures of the course which are being delivered by Mr. T. Locke Worthington at Hampton Court, before alluded to in our columns:—January 15, "Basilican Romanesque," "Diocletian Romanesque," "Primitive Romanesque" (so-called), "Norman Romanesque" (so-called); January 16, "The Primitive and Mature Romanesque of England"; January 29, "The Periods of Pointed Gothic in England"; February 5, "The Later Periods of Pure Gothic in England"; February 12, "The Movement and Styles of the Renaissance"; February 19, "Modern Architecture in London." New Style of Architecture and Modern Developments. The above course, reduced to two lectures, will be repeated at Finchley and at Sutton (Surrey).

FOREIGN AND COLONIAL.

FRANCE.—M. Bonnat has been elected President of the Société des Artistes Français, in place of M. Bailly, and M. Dutert has succeeded M. Bailly as member of the Conseil Supérieur of the Ecole des Beaux-Arts. The Champ-de-Mars Salon is to open on May 7. M. Edouard Carlier has been appointed Conservator of the ceramic museum at Sevres, in place of M. Baumgart. The architectural department under the Municipality of Paris has prepared plans for the restoration of the tower of the Ducs de Bourgogne, known as the "Tour Jean Sans Peur." The Municipal Council has under consideration a proposal to erect statues of Racine and Corneille in the Place du Théâtre Français. The impressionist painters have made a curious attempt at practical architecture; a house is being built in the Quartier des Invalides, from the designs of M. Besnard, the painter. The decorative paintings are being executed by M. Luce, and the sculpture by MM. Barthet and Léon Gausson. M. François Lafon is to execute, for the foyer of the Théâtre du Châtelet, two decorative panels symbolising "Dancing" and "Music"; these are to replace the portraits of Napoleon III. and the Empress Eugénie which formerly decorated the two fireplaces of the foyer.—There is to be an art exhibition at Amiens from June 5 to July 14.—At Châtillon-sur-Loire there have just been discovered the remains of three aqueducts, in the course of the works for the formation of a canal. The largest of these is not less than 1,500 metres in length. Knives, pottery, and ancient arms have been found during the excavations. As a statue of Venus and some Gallo-Roman coins were found in the same place some years ago, it is supposed that there was an important Roman station here.—A statue to Montesquieu is to be erected at Brede, near Bordeaux.—A statue to the painter Ribot is to be erected at Breteuil.—The "Union Artistique du Nord" is to open shortly at Lille, an exhibition of art industries applied to the habitation.—Parliament has passed an additional vote of a million francs towards the construction of the Ecole des Arts et Métiers at Lille, which will be shortly completed.—The monument to be erected at Mée (Seine-et-Marne) to the memory of Champi is to be carried out under the direction of MM. Daumet and Vautromer. The sculptural portion is to be entrusted to M. Antonin Mercier. The monument will be composed of three steles in marble; the centre one will be surmounted by a reproduction of Chapu's fine figure of Immortality, from the tomb of Jean Reynaud. The two other steles will be adorned with medallions of the sculptor's father and mother.—In the course of road works at Ghoggia, in Tunisia, the Government contractor has discovered two fine and well-preserved Roman statues, which have been placed in the Museum at Baric.—The Louvre is to receive shortly several archaeological curiosities discovered last year at Lambessa (Algeria), especially a fine sarcophagus of early Christian date.—The death at Paris is announced of M. Pierre Chabat, architect, at the age of sixty-five. He was a pupil of Garroz, and had filled the position of a Professor at the Conservatoire des Arts et Métiers and at the Ecole Spéciale d'Architecture. He carried out the abattoirs at Pontoise, Biarritz, and Monterau. He was well known by numerous publications, among others his Dictionary of "Termes de la Construction," a very useful and complete work.—M. Conil-Lacoste, "architecte-réviseur" of the City of Paris, has died at the age of seventy-four. His son, also an architect, took part in the work of construction for the 1890 Exhibition.—We have to record also the death of M. Riffaud, contractor, who has had a share in many of the larger works in Paris and its environs, especially the new Louvre, the Comptoir d'Escompte, the Crédit Lyonnais, the Château de Chantilly, the Hôtel de Ville, the Pavillon Marsan, and the Church of the Sacré Cœur; he also carried out the new portions of the Faubourg St. Honoré, and the alterations in the neighborhood of the Ar. de Triomphe. He began life as a simple stonemason.

MISCELLANEOUS.

FREE LECTURES AT CARPENTERS' HALL ON MATTERS CONNECTED WITH BUILDING.—Under the auspices of the Worshipful Company of Carpenters, in conjunction with the Sanitary Institute, the usual course of free lectures to artisans and others on matters connected with building has just commenced. The first lecture of the series was announced to be given on Wednesday evening last, by Sir Douglas Galton, on "Ventilation, Warming, and Lighting." The remaining lectures of the course are as follow:—January 27, Mr. P. Gordon Smith on "Building Acts and By-laws adapted to various Localities." February 3, Professor H. Robinson on "Drainage of Buildings and Building of Sewers." February 10, Professor W. H. Corfield on "Water Supply and the Pollution of Water." February 17, Professor Banister Fletcher on "Sanitary Building Construction." February 24, Professor A. Wynter Blyth on "Sanitary Appliances." March 2, Professor T. Roger Smith on "Sanitary Construction of Public Buildings."

PROGRESS AT WEST HARTLEPOOL.—This town, judging from recent proceedings of the Council, appears to be fully alive to the duties devolving upon it in view of the very rapid increase in its population. A large outfall sewer for the Northern District has recently been completed. A new cemetery, twenty acres in extent, with boundary wall and specially-designed drainage, is now in progress, and is expected to be completed shortly. New abattoirs are to be erected as soon as a suitable site can be obtained. A large central depot and stable yard has been completed, with stabling for all the Corporation horses, cart-sheds for forty carts, steam-roller house, and special machinery for cutting chaff and grinding corn for horses. Besides the new station for the fire brigade, with special drying tower for the hose pipes, a new façade to the Public Market, composed of six large three-story shops and offices, is to be built at once; the designs and plans were approved at the last Council meeting. Two new intercepting sewers of large dimensions are to be proceeded with at an early date, one along the Burn Valley, as an outlet for the Park district (which is rapidly developing), and the other as an outlet for the entire western section of the borough. New streets at an estimated cost of many thousands of pounds are also in hand. A large scale-plan of the borough has been made, and a survey of the whole of the sewers in the borough is in progress, which will give the position, direction of flow, size, kind, depth, and condition, together with the manholes, ventilators, and gullies. Mr. J. W. Brown, A.M.Inst.C.E., F.G.S., the Borough Engineer, who has designed and carried out or is carrying out the whole of the above works, would appear to have plenty of work on hand at present.

THE COPPER TRADE IN 1891.—Messrs. Steidman, Crowther, & Co.'s "Metal Report for 1891" says that the copper trade was very active during the year for both consumption and speculation. Supplies from the United States increased 13,000 tons; those from Chili were 5,000 tons less than in 1890, a result arising in large measure from the civil war in that country. The imports from other sources altered but little, but deliveries so far exceeded supplies that the stock was reduced 8,000 tons during the twelvemonth, and to a smaller figure than it had touched for four years. The exports of manufactured copper showed considerable increases over those of 1890, especially to Brazil, the Levant, and the East India shipments to India, however, were yet a long way below those of the years 1884 to 1887, periods of low values. In the Warrant market G.M.B. copper fell during the first three months from 53*l.* to 51*l.*, notwithstanding decreases in stock and irregular supplies from Chili. In March an upward movement began which was helped by the news of the closing of the Anaconda Mine in America. The rise continued till June, when G.M.B. touched 58*l.* 10*s.*, the highest point during the year. In July, large forward sales caused a relapse to 51*l.* 10*s.*, followed by a recovery to 53*l.* The promptness of this copper, when they fell due in October, were met by a supply of warrants that had been held off the market for some considerable time, and the oversupply of cash copper brought about a decline of 5*l.* per ton. In November the market was further depressed, partly by the re-opening of the Anaconda Mine and partly by the fear that part of the large stock of copper held by the Société des Métaux in France would be thrown on the market when the works were put up to auction by the liquidator of the company. This sale was successfully concluded on December 2, when there followed a strong reaction, and G.M.B. advanced from 44*l.* 10*s.* to 47*l.* 5*s.* The rise held but a short time, as a desire to realise, and lower quotations from America, brought back the market to 44*l.* 10*s.* Good buying the last week of the year sent the price up again to 46*l.* 12*s.* 6*d.* cash.

LECTURES AT YORKSHIRE COLLEGE.—Mr. W. Spiels, Lecturer in the Sanitary Engineering Department of Yorkshire College, Leeds, is delivering a series of Thursday afternoon lectures at the College on Sanitary Science as applied to Towns; The Public Health Acts, 1875 and 1890; The Rivers Pollution Prevention Act, 1876; and The Sewering of Towns. The latter subject includes the selection of lines and routes; sewage and rainfall; sizes, inclinations, flow, and discharges of sewers; construction and materials; ventilation and cleansing; and sewage disposal works.

INSTITUTION OF MECHANICAL ENGINEERS.—The annual general meeting of this Institution will be held on February 4 and 5, in the hall of the Institution of Civil Engineers, Great George-street. The papers to be read and discussed (after the adoption of the annual report, the election of officers, &c.) will be (1) "Notes on Mechanical Features of the Liverpool Waterworks, and on the Supply of Power by pressure from the public mains, and by other means," by Mr. Joseph Parry, Water Engineer, Liverpool; and (2) "On the Disposal and Utilisation of Blast Furnace Slag," by Mr. William Hawdon, of Middlesbrough.

BOROUGH SURVEYORSHIP, LUTON.—Mr. T. Ridyard Roscoe, C.E., Assistant Surveyor, Islington Vostry, N., has been appointed Borough Engineer and Surveyor of Luton, in succession to Mr. E. J. Lovegrove, A.M.Inst.C.E., who was recently appointed Borough Surveyor of Richmond.

COMPETITIONS, CONTRACTS, AND PUBLIC APPOINTMENTS.

COMPETITIONS.

Table with 4 columns: Nature of Work, By whom Advertised, Premium, Design to be delivered. Includes Wesleyan Chapel & Schools, Blain, Mon.

CONTRACTS.—Continued.

Table with 4 columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, Tenders to be invited. Includes Fete Shops and Homes, Trafalgar Street.

CONTRACTS.

Table with 4 columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, Tenders to be delivered. Includes Drainage Works, Richmond (Surrey).

Table with 4 columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, Tenders to be delivered. Includes Metro Asylums, A. & C. Harton.

PUBLIC APPOINTMENTS.

Table with 4 columns: Nature of Appointment, By whom Advertised, Salary, Applications to be in. Includes Sanitary Inspector, Islington Vestry.

Those marked with an Asterisk (*) are advertised in this Number. Competitions, p. iv. Contracts, pp. iv, vi, viii, & ix. Public Appointments, p. xx, & xxi.

THE SLADE PROFESSORSHIP OF FINE ARTS AT CAMBRIDGE.—The Vice-Chancellor gives notice that the Professorship of Fine Art in the University of Cambridge, on the Foundation of Felix Slade, Esq., will become vacant on February 22, and that the election of a new Professor will take place on Tuesday, February 23. The Professor will receive by way of stipend the dividends of a sum of £1,186, 12s. 7d. New Two and Three-quarters per Cent. Consolidated Annuities. He is not required to reside at the University. Candidates are requested to send their names to the Vice-Chancellor on or before Tuesday, February 16.—Cambridge Chronicle.

THE ENGLISH IRON TRADE.—The English iron market continues very quiet, and there are no indications of an immediate revival. Very little change is exhibited in any of the branches of the trade, and prices remain practically unaltered. Pig-iron is still dull at most of the centres; but a slightly better tone has been manifested in the Cleveland market. Manufactured iron is coming in moderate request, and in the steel trade business generally is not too brisk, except in shipbuilding material, which, however, in the North-west is in lessened demand. The triplate trade is still quiet, but better times are anticipated. Shipbuilders and engineers are, on the whole, moderately busy. The coal trade exhibits fair activity.—Iron.

THE SANITARY INSPECTORS' ASSOCIATION.—In consequence of the death of the Duke of Clarence, the annual dinner of this Association has been postponed from February 6 to March 12.

SETTING CIRCULAR SAWS.—Messrs. A. Ransome & Co. send us the description and illustration of an apparatus for setting the teeth of circular saws with rapidity and a certainty of the right set. The saw is mounted horizontally on a travelling pivot, to suit any circumference of saw; the periphery of the saw rests on an anvil with a bevel on the edge. The saw is turned round and a blow of a hammer on each alternate tooth gives it the angle of the bevel, all the teeth being necessarily set at the same angle. The saw is then reversed and the remaining alternate teeth set in the same way. The bevel is eccentric, and the anvil can be turned on its axis so as to give any required angle of setting.

THE NORTHERN OF SWEDEN TRUNK RAILWAY.—Work on the Northern of Sweden Trunk Railway, a line running right through the whole of Northern Sweden, and which is to be continued to the Russian frontier, is actively progressing. The other day a further section, 30 kilometres in length, was opened, making its total length from Stockholm 555 kilometres, and by 1894 it is expected that the distance to Boden will have been covered, 300 kilometres. Thereby this railway and those of the rest of Sweden will have joined the Lulea-Gällivara Railway. The distance hence to the Finnish frontier is estimated at some 500 kilometres. On the other hand, the Northern of Finland Railway now terminates at Uleaborg, about 150 kilometres from the same.

UNREASONABLE STREET SCAVENGING.—Travellers in Holland know that there is in general use there

a method of street scavenging which consists in thoroughly washing the surface with water from a hose, followed by a good brushing. Dwellers in London will have noticed that in certain parishes an attempt has been made to adapt this cleanly Dutch custom to English ways, and that the once Dutch, for, whereas in Holland the washing is done at cock-crow, and the man with the hose is closely followed up by an army of sweepers, the time chosen in London appears to be from nine to noon, and the street,—and often the pavement also,—is allowed to remain for long covered by a mixture of mud and water, with which the two or three languid sweepers are unable to cope. The consequence is that thousands who have trust in the absence of rain to take them to shops or offices dry shod, find themselves quickly suffering from the miseries and dangers of wet feet. Probably in no other city in the world would such a piece of humiliating blunder be allowed to continue for a week.—British Medical Journal.

TRADES HALL FOR EDINBURGH.—It was briefly announced at the meeting of the Edinburgh Trades Council on the 5th inst. that a gentleman in Edinburgh had made the offer of a sum of money for the purchase of premises to be used as a centre for trade organisation in the city. The sum which he has offered amounts, it is said, to 4,000*l.*, and he is willing to increase the amount if necessary. The offer has been made through the officials of the Trades Council, and already the project has been so far advanced that the building known as the Trades Hall in the High-street has been purchased. The Trades Hall, originally a bank, afterwards used as a Free Church, then purchased by the Good Templar organisation, is a commodious building, having a large upper and smaller lower hall, a number of committee rooms, a range of vaults, keeper's house, and other accessories, and is at present largely used by the trades as a meeting-place. It will require an extensive overhaul, but as the purchase price of the building is understood to be 2,700*l.*, that leaves a balance of 1,300*l.* for renovation. The premises will be under the management of a Trades Committee, and will be used as a centre of labour propaganda, which will be pushed by means of lectures, by the formation of a library, and in other ways. It is probable that such terms will be offered to trade unions as will induce them to make the hall their meeting-place, instead of meeting, as at present, in different places in the town.—Scotsman.

LEGAL.

CASE UNDER THE METROPOLIS LOCAL MANAGEMENT ACT:

WANDSWORTH DISTRICT BOARD OF WORKS v. LOWER. THIS case came before Mr. Denman, at the Wandsworth Police-court, on the 19th inst. The defendant, a local builder, was summoned under section 76, Metropolis Local Management Act, for a breach of the Regulations for the Construction of New House-drains, adopted some time since by

the Wandsworth District Board of Works, in respect of two new houses, Rectory Grove, Clapham. Mr. W. W. Young, Solicitor to the Board, supported the summons.

Mr. S. Fairchild, Sanitary Inspector for the Parish of Clapham, stated that the stone-ware traps of the water-closets were not in conformity with the regulations, but that the joints, as required by the Regulations, but that the joints were made by simply inserting the outgo of the traps into the branch piece of the soil-pipes and stopping it round with red-lead. And also, that the waste-pipes from the sinks were fixed without syphon-traps intervening between the sinks and the discharging ends, the Regulations requiring that waste-pipes from lavatories, bathtubs, and sinks shall be trapped at the outgo of the receptacles and made to discharge outside over the seat of syphon gully trap. Inspector Fairchild produced models and drawings, and explained how the work should be executed so as to ensure the sanitary condition of new houses.

The defendant took several exceptions to the regulations, and finally contended that the Board of Works had not the power to make drainage regulations under the Metropolis Local Management Acts.

Mr. Denman, the magistrate, in giving his decision, said that the Board had the power under section 70 to make regulations, and he must decide against Mr. Lower.

Mr. Young did not press for a penalty, this being the first case in respect to these regulations, and he would be satisfied if the defendant undertook to make the necessary alterations within a month.

The learned magistrate advised Mr. Lower to adopt this course, and he consented to do so.

EMPLOYERS' LIABILITY:

PATMORE v. KENERLEY.

In the City of London Court last week, before Mr. Julian Robins (Deputy Judge), the case of Patmore v. Kenerley & Shiefer was heard, in which the plaintiff, John Patmore, bricklayer, sought to recover 50*l.* damages for personal injuries sustained in an accident caused by the alleged negligence of the men in the employment of the defendants, Messrs. Kenerley & Shiefer, builders, 31, Lombard-street, E.C.

Mr. Walters, counsel for the plaintiff, said the accident happened on October 2 last, at the New English Homes, Holloway-road, which were being built by the defendants, the plaintiff at the time being a bricklayer in the service of the defendants. The building was being erected without any scaffolding at all. As the building progressed, the beams of each floor were put in, and a structure called a Yankee jib was put at the top, which was used for the purpose of raising materials.

The Deputy Judge: It is a sort of crane?

Mr. Lynch (for the defendant): It is a derrick. Mr. Walters, continuing, said as each floor was raised, the defendants built up the next floor upon trusses, the beams were then put in on the floor

above, and the jib was raised to the next floor, and so on. The sole access to the top of the building was by means of a ladder which was placed in such a position that when the crane was being worked it caused it to become very dangerous. Bricks and mortar were constantly dropping on to the heads of those who had to use the ladder, and the plaintiff had on several occasions complained to the defendants' foreman about the unsafety of the place. He was only laughed at. While the plaintiff was descending from the ladder when about half way down a quantity of bricks and masonry work fell from the top, and this would have struck the plaintiff on the head, the consequences being very serious. Seeing the great danger the plaintiff was in, several people shouted to him to jump to the ground. Knowing the chances he ran if he stayed on the ladder, the plaintiff jumped to the ground, a distance of 25 ft. He was seriously injured as it was; but had the plaintiff not jumped, the bricks would have fallen on his head. He was immediately removed to the Great Northern Hospital, where he was detained for eight days, and afterwards attended the hospital for two weeks as an out-patient. This claim for damages was now raised under the provisions of the Employers' Liability Act, because of the defect in the non-protection of the space above the ladder—the only means of access.

For the defence, Mr. Jubal Kennerley, one of the defendants, stated that he was present when the unfortunate accident happened to the plaintiff. The plaintiff should have used a different ladder to the one he came down by on the day in question. Witness never knew that the ladder the plaintiff did use was dangerous. He had gone up and down it himself. The accident was brought about by the man in charge of the derrick pulling it in too early, when several bricks fell out. There was no need for the plaintiff to have jumped as he did. The truth was, the plaintiff became frightened, and hearing men calling out, being a nervous man, he jumped to the ground. In cross-examination, he said the structure used for raising the building was much in vogue in America. No security was provided by boarding in the place, because it was not necessary.

The defendant's foreman denied that any complaint was ever made to him about the defective condition of the works.

The Deputy Judge, having regard to the importance of the case, said he would take time to consider his judgment. Two days later he delivered judgment at great length, finding for the plaintiff for 45*l.* and costs.

MEETINGS.

FRIDAY, JANUARY 22.

Royal Institution.—Professor J. A. Fleming on "The Induction Coil and Alternate-Current Transformer." 7.30 p.m.

MONDAY, JANUARY 25.

Royal Institution of British Architects.—Address to Students by the President, Mr. J. Macvicar Anderson, who will present the Prizes and Studentships for the year 1891-2.

Royal Academy of Arts.—Professor Alchison, A.R.A., on "Saracenic and Turkish Architecture." 11. 8 p.m.

Society of Arts (Anti-Corrupt Lectures).—Professor George Forster on "Development of Electrical Distribution." 11. 8 p.m.

Liverpool Architectural Society.—The Rev. F. F. Green on "The Rise of Civilisation in Babylonia." 7 p.m.

TUESDAY, JANUARY 26.

Society of Arts (Applied Art Section).—Mr. William Morris on "The Woodcuts of Gothic Books." (Illustrated by Lantern Slides). 8 p.m.

Institution of Civil Engineers.—(1) Further Discussion on Mr. Wilfrid Airey's Paper on "Weighing-machines." 8 p.m. (2) Reception by the President and Council in the Library. 9 p.m.

Glasgow Architectural Association.—Mr. James Lindsay, A.R.I.B.A., on "Approximate Estimating." 8 p.m.

Liverpool Engineering Society.—Adjourned Discussion on Mr. A. J. Maginnis's paper on "Transatlantic Lines and Steamships." 8 p.m.

WEDNESDAY, JANUARY 27.

Carpenters' Hall, London Wall.—Mr. P. Gordon Smith, F.R.I.B.A., on "Building Acts and By-Laws for Controlling the Construction of Buildings, adapted to various localities." 8 p.m. (Admission Free).

Royal Meteorological Society.—Annual General Meeting. Address by the President (Mr. Baldwin Latham, M.A., C.E.) on "Evaporation and Condensation." 7.15 p.m. (Postponed from the 20th inst. in consequence of the death of the Duke of Clarence.)

Society of Arts.—Mr. F. W. Edridge-Green on "The Scientific Value of Loveland's Findings." 8 p.m.

St. Paul's Ecological Society.—Mr. T. A. Martin on "Some Religious Subjects on Miscricones." 7.30 p.m.

THURSDAY, JANUARY 28.

Royal Academy of Arts.—Professor Alchison, A.R.A., on "Saracenic and Turkish Architecture." 11. 8 p.m.

Royal Institution.—Dr. A. S. Murray, on "Some Ancient Vases of Loveland's Findings." 8 p.m.

British Museum.—Miss Millington-Lathbury on "Greek Temples, and leading motives of Greek Religion," as illustrated by the monuments in the Museum. 8.45 p.m.

Institution of Electrical Engineers.—Inaugural Address by the President, Professor W. E. Ayrton,

F.R.S. 8 p.m. (Adjourned from the 14th inst. in consequence of the death of the Duke of Clarence.) Society of Architects.—Edinburgh Architectural Association.—8 p.m.

FRIDAY, JANUARY 22.

Architectural Association.—Mr. N. H. J. Westlake on "Fashion in Architecture and its kindred Arts." 7.30 p.m.

Institution of Civil Engineers.—Students' meeting. 7.30 p.m.

Liverpool Engineering Society.—Annual Dinner.

SATURDAY, JANUARY 30.

Royal Institution.—Professor J. A. Fleming on "The Induction Coil and Alternate-Current Transformer," 11. 3 p.m.

RECENT PATENTS:

ABSTRACTS OF SPECIFICATIONS.

20,215.—WINDOWS: W. Hooker.—This patent relates to an improved system of hanging sliding windows to be opened from the inside, for cleaning, &c., by detachable hinges, the wings of which are attached to plates on sash-frames and sashes, the plates being slotted and dovetailed to receive the lower wings of hinges which are connected to the plate on the frame and the upper wing in a similar manner to the style of sash.

2,231.—SCAFFOLDING: W. Parscy.—Instead of the usual mode of timber scaffolding, scaffolds of iron or steel frame are constructed of suitable shapes, such as angles, tees, &c., all the parts of which are interchangeable in their relative positions, and have holes drilled or punched in them at some uniform pitch throughout, or are provided or formed with equivalent sockets, so that they can be put together by bolts and nuts, cotter, or drift, or the like to form pillars, girders, or other forms, with the distance and diagonal bracing bars to form perfectly high structures of various dimensions. The scaffolding may be taken down and used over and over again.

3,055.—METALLIC CHIMNEYS: T. P. Lonnes.—This specification relates to improvements in the manufacture of metallic chimneys and flues. Sheet-metal, copper, tin, or other metallic plates are cut approximately to the required sizes. These plates are sheared, stamped, pressed, corrugated, buckled, and hanged to form a form of corrugated sheet-metal. In some cases the whole of the plate is corrugated and buckled except the flanged edges, the plate being made in portions of cylinders or of a frustrum of a cone. In other cases the plates are stamped out plain and rectangular with flanges all round, and sometimes tapered at one end, and when riveted, grooved, or soldered together they form polygonal structures for various purposes.

11,312.—DOORS AND GATES: R. H. Davis.—This patent relates to an apparatus for fastening and securing doors and gates, and facilitating opening and closing of same. This is effected by means of a stay with a knuckle-joint or hinge in or near the middle, each end of the stay being provided with a plate, bracket, or staple attached to the one end to the door, and the other to a post, wall, or other suitable place.

17,389.—CHIANDRIERS, &c.: R. Roderick.—This relates to a method of supporting and retaining in position gasaliers, chandeliers, and the like, by using a circular, oblong, or other shaped collar of metal, which forms the balance weight, instead of the separate weights now used. To the metal collar, which extends round the middle of the gasalier, &c., the ceiling chains are connected, and the gasalier can be raised or lowered in the usual way.

19,131.—SASH CORDS: E. J. Jeyes & C. J. E. Kinson.—By this invention it is proposed to remedy the defects in the usual method of attaching sash-cords to window-sashes. These defects are stated to be the liability of the cords to be broken away from the sash, and the expense of fitting. The improvement is effected by means of a metal ring or ring with a cut away part, perforations, and bevelled or sharpened lower edges, the whole being sunk into the window-sash. The end of the cord is passed through the cut away part and knotted.

NEW APPLICATIONS FOR LETTERS PATENT.

January 4.—155, H. Schmidt, Iron Retaining Wall. January 5.—165, I. Hunt, Glazing Earthenware Pipes, Tiles, &c.—166, A. Cannon, Chimney-pots.—174, E. Deau-n, Glazing Leds, &c.—187, G. Skimmer & J. Hill, Attaching Door-knobs or Handles to their Spindles.—190, S. Dix, Water-closets.—215, A. Boulé, Fire-grates. January 6.—251, H. Crith, Preparing, Fitting, and Laying Blocks for Floors, &c.—253, J. Cassick, Chimney-pots for preventing downward draught.—285, R. Barker, Sewer-pipe and Drain-tile Machines.—288, R. Barker, Sewer-pipe and Drain-tile Machines.—308, W. Sykes, Joining Earthenware Pipes, &c. January 11.—323, A. Whitmore, Wood-block Floors.—327, T. Helliwell, Glazing Buildings.—304, H. Couilly, Water-closets.

January 8.—F. C. Parkinson, Guarding Circular or other Saws.—432, A. Ford, Exits for Doors, Windows, &c.—446, A. Haworth, Pipes for Sinks.

January 9.—488, T. Wilkinson, Joints for Sewer and other Pipes.—489, H. W. Winton, Chains or Orbits for Bricks, &c.—497, R. Lorch and others, Construction of Hinge-joints.—507, G. Martin, Screw-drivers.

PROVISIONAL SPECIFICATIONS ACCEPTED.

17,854, J. Green and G. Meade, Window Sash-fashers.—20,323, A. Fiddes and others, Hot-water Apparatus for Heating Horizontal Buildings, &c.—29,549, S. Kirk and W. M. Corbett, Lock and Hanging Sawing-frame and Sash.—20,643, R. Rankin, Marking the Staves and Rails of Doors and Sashes and other Joiners' Work for Mortising while on Side of Tenoning-machine or otherwise.—20,838, E. Heyleureich, Tool-holder.—21,142, W. Adams, Ceiling Groove for Electrical Fittings.—21,145, J. M. Hardy and W. Garland, Hand-cranked Sawing-machine.—21,520, T. Harries, Artificial Stone.—21,763, J. Saunders, Opening and Closing Fanlights, Casements,

&c.—22,202, C. Henshaw, Shop Door and Casement-fashers.—22,272, E. Wilson, Machine for Curving or Shaping Wood.—22,552, W. Horn, Brick Kiln.

COMPLETE SPECIFICATIONS ACCEPTED.

(Open to Opposition for Two Months.)

3,877, C. Green, Window Ventilating of Dwellings-houses and other Buildings.—16,818, W. Thompson, Blocks or Stones for Use in the Sinking of Wells or Shafts and in the process of placing the same in position.—20,220, B. McMillen, Window-sash Balance.—21,423, P. Jensen, Heating Buildings by means of Steam or Hot-Water.

Examples of Mosaic Paving.

the large thin folio volume brought out under this title,* Mr. Bolton has undoubtedly initiated a new and valuable method in the illustration of ancient examples of mosaic paving.

Published illustrations of such examples have hitherto consisted in general of small drawings in which the pattern or design was delineated with as much truth as could be achieved on a small scale, and the ground of the drawings covered with lines to represent the jointings of the mosaic cubes and convey a general idea of mosaic surface, with little attempt at any precise reproduction of the actual facts of the work in detail. As, however, in ancient buildings much of the character depends on the arrangement of the masonry, so in ancient mosaic much of the character depends on the size, shape, and arrangement of the small cubes which form the design. In measuring old buildings enthusiasts have not infrequently measured and plotted all the jointings of the masonry. A similar process is practically impossible with mosaic, but the jointings of a fair-sized portion can be reproduced the actual size by rubbing, and photographed down to a convenient scale for publication. In this instance the examples are reduced to only one-half the original size, which for purposes of study and comparison is nearly as good as the full-size.

The author is undoubtedly quite right in his remark that "the secret of the art of mosaic paving consists in the due recognition of its cube formation." It is this which gives to the surface that peculiar rich and varied texture which is the special attribute of mosaic. An attempt to carry out the work so carefully and with so much finish as to hide the joints is only taking a great deal of trouble to do what could be done much more completely and with less trouble and

* "Examples of Mosaic Pavings; from Remains of Floors at Pompeii and Venice, with Additional Patterns from Palermo and Rome." By Arthur Bolton, R.I.B.A. London: B. T. Batsford, 1891.

cost by intarsia work with large pieces of material cut to the required shapes. Wall decorations in mosaic, especially where the subjects approach a pictorial character (which must always, however, be in subordination to a severe conventionalism), may be carried further in refinement of finish than pavements, but even here the toothed surface must not be refined away; part of the effect of the decoration depends on it. In the case of pavements this rule holds good in a more decisive manner. For mosaic in such a situation is really a form of pebble paving; it has actually been carried out in one or two known instances with natural pebbles, and the roughly-squared cubes of ancient pavements in *opus tessellatum* still preserve something of this character. The surface formed has the practical advantage of being a remarkably good one for foothold; the artistic interest consists in the arrangement of the pebbles so as to form a design. To lose this pebbly character is to lose the whole characteristic of this method of forming a floor. Hence, however the finer methods of *opus vermiculatum* may be applicable to wall and ceiling decoration, it is unsuitable to transfer this method to floors.

It must be admitted, however, that the recognition of this pebble character as suitable to mosaic pavement carries with it a great deal of restriction as to the class of subject and the style of ornament which can properly be treated in a mosaic floor of this type. And in this respect it appears to us that Mr. Bolton's natural enthusiasm for the style of work which he has so well and carefully illustrated has rather misled him. We can see nothing for admiration in the clumsily-designed figures executed in large irregular tesserae, of which he has given one example full size in Plate iii., a figure representing (so he says) a man swimming. We doubt the interpretation even; the position of the arms might represent the action of "hand-over-hand" swimming, but there is no corresponding action of the legs, and the delineation of the hands and feet is ludicrous in its coarseness. The size of the tesserae in comparison with the scale of the figure renders it in fact quite impossible to give any satisfactory representation of the figure, and we should be disposed to apply to it the same

criticism which Professor Middleton applies to the larger mosaics of Caracalla's Baths: "The floors were mostly of mosaic, with coarse figures of athletes, gladiators fighting with beasts, or tritons and dolphins, all rudely executed with large tesserae, and usually drawn in the most clumsy and inartistic way possible." Generally speaking, in fact, Roman pavement mosaics, however they may claim the merit of frank recognition of the character of the material, are in an artistic sense bad and coarse in execution and mistaken in taste; they represent subjects which cannot adequately be represented in mosaic of this class, and are far too naturalistic in their aim and conception. A fine exception is the notable pavement from Cirencester (not given in this book) of Orpheus taming the beasts, where Orpheus is in the centre of a circle formed by a conventional wreath or garland, while the beasts and birds, treated in profile, walk round the circle in a regular and symmetrical order; an example of true conventional treatment of a legend, suitable to the material and the situation. But anything nearly approaching naturalistic treatment on a mosaic floor is entirely out of place, both in regard to the method of execution and the position in which the work is placed. Naturally-treated figures are out of place even in a mural mosaic, with small tesserae; they are doubly out of place on a floor, which is a thing to walk over, and more so than ever when made with large tesserae, with which anything like correct representation even of silhouette figures is an impossibility. The famous Pompeian hour, given in Plate vi., is equally out of place as far as design is concerned, but it is a very remarkable example of spirited and to a great extent truthful representation or rather indication in work of this kind; the manner in which the cloven hoofs are indicated is especially masterly; but this is work executed in much smaller tesserae. This figure furnishes Mr. Bolton with matter, however, for a very true bit of criticism, as to the importance of preserving the relation between the ground and the design; and he points out quite rightly the artistic importance of the indication of the ribs of the animal, light against the mass of the rest of the body, thus bringing a portion of the tone of the ground

into the figure. Without these the boar would be a dark mass, distinguishable by outline merely. But this boar is obviously, in every respect, the work of a very clever artist, and deserves all the author claims for it, which certainly cannot be said of the "awimning" man before referred to.

It may be questioned whether the best application of mosaic is not found in geometric patterns rather than in designs from life. At all events, where the latter are introduced, they should be of a very conventional type, and treated rather as centre points in a scheme of geometric design than as the main factors of the design. The kind of things that are frequently found in Roman mosaic are really not design at all; merely attempts at realistic representation introduced at random. In geometric patterns for mosaic the Romans were often exceedingly successful, and have indeed produced some of the best pattern designs that have ever been seen; designs which have passed into what may be called "proverbial" use, forming common elements of mosaic design just as proverbs come to form part of common conversation. It was by the use of intercepted circles or segments that some of the best of these diaper designs were produced; one or two examples of this class are given in Mr. Bolton's book, though not among the very best of them. A remarkable piece of pattern-work is given on Plate viii., the pavement of the "House of Sallust;" this is an exceedingly ingenious piece of design as far as its lines are concerned, but one requires something more than line in a mosaic diaper, it should be rather an arrangement of contrasted surfaces than of mere lines. It would be quite possible to work out such a design on the lines of the "House of Sallust" pattern. The employment of a design formed mainly in lines is suitable for scrolls and conventional foliage; but a diaper pattern in lines only has a thin and hard effect. One absolute rule may be laid down, viz.; that nothing in mosaic pavement should be designed so as to give the effect of relief of surface. The Romans were well-known sinners in this respect, and seemed to enjoy the use of shading so as to produce the effect of solid cubes with sinkings between them. It would be impossible to misuse the material or the art of design (so-called) more utterly, and it does not appear that Mr. Bolton has quite the holy horror of this kind of work which we should have expected him to express.

One or two chromo-lithographs are given, showing examples of colour in mosaic. One of these, Plate x., from the house of Holconius at Pompeii, is about as poor a piece of work of the kind as could well be seen, and, both in colour and design, looks like a very commonplace piece of worsted-work for a cheap cushion or footstool. The peacock from the pavement of the Church of San Donato, Murano, is a fine piece of conventionalism in its way; the treatment of the bird, within the limits of mosaic, is excellent, and the colour effect rich and harmonious, but the large irregular pieces of coloured enamel in the tail of the bird, put in in one piece, have not the best effect, and the introduction of large single pieces in this manner, among the smaller cubes of the rest of the work, is quite out of keeping with the proper principle of mosaic, as the author indeed points out in the course of his introductory remarks, though he seems to have passed it over here.

As an illustration of ancient mosaic this book is a new departure which the author might very well follow up on a larger scale in future. He tells us that the book was not planned till after his return from Italy, or some examples would have been included which have now been unavoidably omitted. The method of production enables one to study the character of the ancient mosaic work depicted, almost as well as from the originals; and the plates serve to remind one of what is often forgotten in modern mosaic, that too great symmetry and rigidity in laying the tessere is not to be desired, and in fact detracts from the proper character

of the work, giving it a hard mechanical appearance. Mosaic pavement is a pavement of blocks on a small scale, and should preserve this character whatever design it is worked into; care being taken however that there should be some fit relation of scale between the size of the blocks and the scale of the design. The Roman tendency was to introduce designs too small to be properly defined by the tessere, or to use tessere too large for the design, whichever way we take it. For a pavement this is a better mistake than using the tessere too small; but it is still a mistake, and some of the plates in this book illustrate the fact, though in general they serve to exemplify the true and proper use of mosaic in pavements.

ANCIENT SCULPTURES FROM CENTRAL AMERICA IN THE SOUTH KENSINGTON MUSEUM.

WITHIN the past four years some interesting additions have from time to time been made to the exhibits in the Architectural Court of the South Kensington Museum, in the shape of casts of obelisks, altars, and, in some cases, originals of pieces of sculptured stones from certain of the ruined "cities" or pueblos of Central America. The originals, or the moulds, as the case may be, were brought to this country by Mr. A. P. Maudslay, who has devoted so much time to the research and systematic exploration of the sites of these ancient Indian towns. Most of the objects represented were found at Copan, in Honduras, and there is a large model of the mounds and ruined terraces of that place, clearly showing the enormous extent of the excavations and surveys made and indicating the sites whereon the obelisks, &c., were discovered. Excellent descriptions of the works at Copan have been published by Mr. Maudslay, notably in the "Proceedings of the Royal Geographical Society," Vol. viii., n. s. 1886, pp. 568 *et seq.*, and "Biologia Centrali Americana" *Archæology*, pt. 1, 1889. The former also contains descriptions of the remains at Quirigua, whilst the text of the latter work, illustrated by photogravures, is accompanied by a large atlas, with photographs reproduced by the autotype process, and the manner in which the whole has been "got up" is certainly worthy of the important discoveries to which they refer.

Other travellers, and especially Messrs. Stephens & Catherwood, have also written of the Copan ruins, and all agree that the most interesting are the sculptured obelisks or monoliths, of which five are represented by plaster casts in the Museum. Three of these are elaborately carved, and each bears on its front a long-robed human figure, standing full-faced in a stiff and conventional attitude, with profuse head-gear; the sides and back of the monuments being covered with tables of hieroglyphics. The fourth has a human figure both back and front, with heads represented on its sides, whilst the fifth is covered with hieroglyphics on all sides. The human figures alluded to have been described as priests in pontifical robes; but evidence is not wanting to show that they represent gods; some which were found certainly look like idols. Nobody has yet succeeded in unravelling the meaning of the hieroglyphics, which are found not only on the monoliths, but on the altars and some of the tablets. Mr. Maudslay says* that the "tables of hieroglyphs should be read in double columns from left to right and from top to bottom."

One of the most interesting points which I have noticed is that all the inscriptions which I have reason to believe are complete from the commencement are headed by what I shall call an initial scroll (the type of which is permanent throughout many variations), and begin with the same formula, usually extending through six squares of hieroglyphic writing, the sixth square, or sometimes the latter half of the sixth square,

being a human face, usually in profile, enclosed in a frame or cartouche."

Four blocks from Copan, which are believed to be altars, are exhibited in the Museum. The carvings on the sides of one of these represent men in an Eastern-looking head-dress, the majority of whom are sitting cross-legged on small tablets of hieroglyphs, a position which, to judge from similar carvings in the other stonework, seems to have a peculiar significance. In this connexion we may call attention to the face of a step found in a temple, the original of which is also seen in the Museum. It may be noted that none of the seated figures are exactly in the same posture, some have one foot on the ground holding a scroll or other object in one hand, and having the arm raised in the air or resting by the side, and each figure possesses different details on the head-gear so that the monotony of the whole is somewhat relieved.

The plaster cast of a seat, the original sculptures of several heads, the body of a "singing girl," and a foot showing thought passing between two of the toes and fastened round the ankle by a buckle, all of which were found amongst the ruins, are also exhibited.

Before the survey of Copan was commenced, the whole site was covered with forest trees or an almost impenetrable scrub, and it was found necessary to clear a great part of this growth away before any idea of the place could be obtained. The monuments had also to be cleaned down, the superfluous moss and vegetation having to be removed before casts could be taken. Without going much into details, it may be mentioned that the structures met with during the course of the excavations were composed of a rubble of stone and earth, faced with well-laid masonry. It was shown that the pyramidal structures were almost in every case the raised foundations which supported roofed buildings,—probably temples,—which were approached by steep flights of steps; the buildings were most profusely ornamented with sculpture. To give some idea of the character of this work, Mr. Maudslay illustrates an elaborate doorway leading to an inner chamber of a temple, and also sundry fragments and figures from other positions which are highly instructive. Speaking of the doorway he says that there are in the design good examples of two marked characteristics of all American sculpture, namely, the inability of the artist to leave plain surfaces alone, and the love of introducing grotesque faces or scroll-work derived from the into the ornamentation of details.

The smaller mounds shown on the model referred to in the Museum are the remains of what were probably dwelling-houses. A were stone-roofed, and the "system of roofing here used (as in almost all ancient American buildings) was what may be called the horizontal arch." The age of these buildings is extremely doubtful. Certain authors are of opinion that they were erected and used by the Indians at the time of the Spanish discovery and conquest of the country, but seems that there is very little to support this view. The doings of the Spanish conquerors are fairly well known through the writings of Cortez, Bernal Diaz, and others, who either mentioned or described important places. No mention is made of an important city at or near Copan, and the Indians in the vicinity were not advanced enough in the arts of civilisation to have executed such works. We think there can be no doubt that the civilisations which produced the buildings and sculptures at Copan and in all similar ancient pueblos in Guatemala, Honduras, and Yucatan, had passed away long prior to the Spanish conquest. They were in a flourishing condition in the time of Cortez, he would certainly have mentioned them, as he gives such good account of his different journeys.

The largest obelisk represented in the collection at the South Kensington Museum comes from Quirigua, and does not materially differ from those described from Copan.

* "Proc. Roy. Geog. Soc.," *op. cit.* p. 593.

ving the conventional erect human figures, ne on both back and front, the sides of the monument being covered with hieroglyphs. A large, rudely-carved tablet, showing a seated human figure holding a bowl with an animal's head in it, comes from the same age.

There are also some tablets, carved in relief, in excellent condition, from ruins on the bank of the Usumacinta river, Mexico, which forms the boundary of the province of Yucatan and the Republic of Guatemala. Some of these represent a serpent with a human head rising out of a bowl and leaning over a man crouched or sitting on his haunches. The serpent plays a conspicuous part in many of these ancient Central American works, and by means of such symbols, given with the numerous picture writings and strings and tables of more or less grotesque hieroglyphs, we may some day be able to learn more concerning the remarkable people who made them. The indefatigable manner in which Mr. Maudslay has photographed and had plaster casts made of all the best-preserved or striking hieroglyphs on the spot, in spite of the many dangers he has encountered, is deserving of the highest praise. We may mention that he has also represented a series of the plaster casts to the Archaeological Museum at Cambridge.

NOTES.

THE Royal Academy, we are glad to see, has recognised Architecture in its last election of Associates, and added an able and cultivated gentleman to its numbers in the election of Mr. T. G. Jackson. That Mr. Jackson should be the next choice whenever a new Architect associate was elected must have been considered for some time past a foregone conclusion, and we have only wondered that the honour should not have been offered earlier to an architect whose claims to it were so indisputable. The other Associates elected were Mr. Stanhope Forbes and Mr. Harry Bates, and both of these elections will also be thought to meet with general approval. Mr. Stanhope Forbes may be considered to be a *princeps* among the younger school of painters of the day, to use a hackneyed term which seems, however, hardly adequate to designate a class of paintings which combine so much admirable delineation of character with so much of moral feeling and purpose. Mr. Harry Bates, on the other hand, is an artist simple and direct, who uses sculpture as a form of poetic expression, sometimes in telling again an antique legend, sometimes in the mere expression of energy and grandeur of line and modelling, as in his powerful group of Hounds in leash. There can be no question of his claim to the honour; but we regret that in doing justice to some of the younger sculptors of the day the Academy is so persistently passed over an older and more eminent, Mr. G. A. Lawson, whose works have exhibited qualities both of design and conception which have not received the recognition they merit.

THIS article in the current number of the *Quarterly Review*, on "The Water Supply of London," is obviously written in the interests of the Water Companies. The object is to show that the Thames can be relied on for everything; that the objection to the use of the Thames on the ground of pollution of the water is without foundation, and that the water supply of London can be better provided by private enterprise than by public supply. That the complaints sometimes made as to the character of the water at present supplied to London have often been grossly exaggerated is perfectly true, and it is really true that the Companies have improved the supply very much in the course of their existence, and have in fact done their best for the public in regard to the quality of the supply, whatever may be thought as to their

tactics in regard to their commercial dealings with their customers. To maintain, however, the advisability of trusting to open rivers for water-supply is to ignore the increasingly pronounced opinion of the medical profession generally; while in considering the capacity of the Thames to maintain an adequate supply for London the *Quarterly Review* quietly ignores altogether the fact that the river, *quod* river, is in process of being ruined by even the present amount of abstraction from its stream; let alone what further raids may be made upon it by a constantly-increasing demand. The *Quarterly Review* refers complacently to the testimony of the late Mr. John Harrison in regard to "other additions that might be obtained, if necessary, within the locality." If the writer of the article had been present at the meetings of the Institution of Civil Engineers a few months ago, when Mr. Harrison's propositions were discussed, he would perhaps scarcely have had the hardihood to cite an authority whose proposals and arguments were so completely and almost contemptuously disposed of as were Mr. Harrison's on that occasion. The scheme for storage reservoirs in connexion with the upper portions of the Thames is advanced again as a solution of the difficulty, with a convenient forgetfulness of the fact that reservoirs in such a position (the only possible position if they are to supply by gravitation) must allow the great bulk of flood water to escape, while they must utterly ruin the upper portion of the Thames as a river. The bias of the whole article, in supporting the water companies through thick and thin, and ignoring every scheme that might be supposed to be in opposition to their interests, is so obvious as to be almost ludicrous; but such an article may do a great deal of harm in influencing the large majority of readers who know nothing of the subject, and who fondly imagine that a paper of this kind in a review of long standing is to be taken as an impartial discussion of the subject. Probably the editor of the *Quarterly Review* is no better informed on the subject than the bulk of his readers; but the appearance of an article in this style of manifest advocacy, on a subject which especially demands, in the public interest, a purely impartial and scientific treatment, is not creditable to a review of the standing and position of the *Quarterly*.

THE present epidemic of influenza draws attention to the great desirability of every house in the country, and every large house in town, having a large room or rooms isolated as far as possible, and capable of being used as a sanatorium. In every large family there is always liability to infectious diseases, and if there is a part of the building which can be used with success as a sanatorium, it is, undoubtedly, a safeguard against the spread of disease, and a great convenience to all concerned. In small houses this kind of isolation is practically impossible; but this fact again compels attention to the want in London of hospitals for the use of those who can pay for them,—not in cases of accident, but in cases of disease, especially of an infectious character. There is an idea that a hospital of such a kind is a danger to the community; on the contrary, by concentrating sick persons in a proper building, and removing them from private houses, much of the risk of the spread of disease is removed. We are thus brought face to face with another consideration, viz., whether such hospitals should be erected and managed by the governing bodies of localities? Some day they will certainly form one of the types of buildings necessary in any well-organised social community.

IT is curious how long a monument of first-rate importance may lie *perdu* in an archaeological collection of long standing, apparently just because the collection itself is so well known that the novelty hunter passes it lightly by. A terra-cotta relief, just

published in the last issue of the Roman section of the *Mittheilungen* of the German Archaeological Institute (vi. 3), well illustrates this point. Dr. Studniczka has discovered in the well-known Santangelo collection of the Naples Museum, hidden in a mass of terra-cotta lamps of Greco-Roman date, an archaic relief, curious and important, both for subject and treatment. The relief, of which about a fourth at either end is unfortunately broken off, represents a female *Xoanon* of the most archaic type. The figure is standing erect, with hands stiffly dependent at each side. The right hand held some uncertain attribute; but the remarkable point about the figure is the elaborate decoration of the formal, foldless robe. It is divided into three parallel friezes. In the topmost of these is depicted, in the well-known type, Ajax carrying the body of Achilles. In the second frieze a *choros* of women are dancing hand-in-hand; in the third a similar *choros* of men. Clearly we have here the copy of a cultus image wearing a ceremonial robe, just such a robe as was worn for the Panathenaic at Athens. Dr. Studniczka's paper should be read by all those interested in archaic art. In the same number of the *Mittheilungen* is published a charming little bronze, which its owner, a dealer in Rome, lent to Dr. Petersen for the purpose. The bronze represents a boy, stooping, with a hand firmly planted on each knee and his feet somewhat widely apart. The meaning is made clear by a vase in the British Museum (recently published by Mr. A. H. Smith, in the "Journal of Hellenic Studies," 1890, plate xii, p. 279). Here a family of Satyrs are playing a sort of modified form of leap-frog—the leaper, instead of clearing the Satyr who is "giving him a back," descends on his shoulders, and there remains. Examined by the light of this vase, the outline of the bronze becomes clear, and to make things yet more satisfactory, traces of a figure now broken off are observable on the boy's shoulders. It is an interesting instance of the light thrown by vase-paintings on sculptural art, as well as a pleasant glimpse into the boy-life of antiquity. The boy who carried the other was called, we learn from Pollux, the "donkey," and he was sometimes made to fill the post by way of "forfeit."

ADVERTISING to two of our "Notes" of the 16th and 23rd instant, we are sorry to find that an attack of influenza incapacitates Miss Sellers from continuing, for the present, her class at the British Museum. Last Tuesday Miss Millington-Lathbury, upon very short notice, took her colleague's place, and gave her opening lecture upon the daily life and thought of the Greeks, dealing from an archaeological standpoint chiefly, with their temples, ritual, and religious cult. Showing, firstly, how the king-priest, as priest-king, had his counterpart in the head of even the smallest or meanest household, the lecturer dwelt upon the political solidity which grew out of the religious ceremonies of the Greeks, and explained how these,—which, however simple or complex, they always exactly observed,—expressed conceptions of a deity whom they at first saw in every natural thing, and went on to set up as a god, humanwise, of something—a god to be propitiated and dreaded, and on occasion, as we know, to be cajoled. Thus they passed from animism to an at once elevated and debased anthropomorphism. The temple of such a deity was not, Eleusis excepted, a resort for worshippers or suppliants: it was his secluded dwelling-place and treasury; the altar, whether there or at their own homes, formed the point around which the cult concentrated, and on the altar they made sacrifices of expiation or appeasement, with an underlying idea that the deity should partake of their cheer, hospitably offered. Then, with the aid of plans, Miss Millington-Lathbury traced the temple's growth. The pristine wooden hut yielded to one of brick or clay, and that to the stone-built cella, though it seems that wood was never quite discarded; yet with its successive accre-

* Illustrated in the *Builder* for June 6, 1891.

tions of portico, πρόναος and δισπηδόμας, until they attained to the dipteral Olympeum itself, the whole τέρρον was but a fort or stronghold for the cella (ναός, or σκεύος), wherein the god abode. And here it occurred to us that the difference between the old religion and the new might be briefly illustrated by contrasting the templum, or τέρρον, or hedged-in enclosure, wherefrom, save in a few instances, the dead, and many of the living, were excluded, with our church, or τὸ κληρικόν, the Lord's house, in which all alike gather for praise and prayer. We may add that in regard to the lighting of Grecian temples the lecturer expressed accord with Dr. Dorpfeld's opinion, on which we recently commented.

THE restoration,—or, rather, re-erection,—of the monument of Queen Eleanor in Lincoln Minster, unveiled recently, is noteworthy as being the munificent gift of a leading Nonconformist to the cathedral of the city of his adoption. The monument takes the place of that erected by Edward I. over the portions of his consort's body removed in the process of embalming, which, though on a somewhat smaller scale, was in all essential features a replica of that placed over her grave in Westminster Abbey. The priceless "Hatton MS." belonging to Lord Winchelsea, and deposited temporarily by him at the rooms of the Society of Antiquaries for inspection, among the many drawings of sepulchral memorials in our cathedrals and great churches, taken under the direction of Sir W. Dugdale before the outbreak of the Great Rebellion, contains a careful representation of this monument, which, aided by the Westminster tomb, has served as a guide to Mr. Pearson and Mr. Nicholls in their restoration of the tomb and effigy. The effigy of the Queen, which was cast by Mr. Singer, of Frome, is executed in gilt bronze; the altar tomb, on which the effigy reposes, of dove-coloured Hopton-Wood stone, contrasts well with the subdued brilliancy of the effigy. The sides of the tomb are decorated, as at Westminster, with shallow canopied recesses containing shields with the armorial bearings of England, Castile and Leon, and Pontieu, dependent from bunches of natural foliage,—oak, vine, and maple. The carving of these, as well as of the crockets of the canopies and the other decorative work, is admirable. Mr. Pearson may be congratulated on the success, from one point of view, of a somewhat difficult undertaking. Whether this re-making of approximate copies of lost monuments is a process altogether worth the pains and cost expended on it, may however be a question.

A COMMITTEE of those interested in architecture and the various artistic crafts, such as decorative painting, wood and stone carving, metal working, &c., has been formed in Edinburgh. Dr. Rowand Anderson, President of the Committee, in an address to the Edinburgh Trades' Council on the subject last week, said:—The kind of technical education they proposed was the teaching of the eye and the hand to work in harmony and sympathy with one another, and of the judgment and imagination to invest all handicraft work with intelligence, purpose, and grace. For this purpose they would require 2,000*l.*, and 1,567*l.* had already been received or promised. Funds would also be required for travelling and other scholarships. The sanction of the Secretary for Scotland had been obtained for the use of the rooms in the Royal Institution formerly occupied as an antiquarian museum. It was intended that the classes should be managed by a representative Committee and a Committee of the Board of Manufactures, and that they should be conducted by men of eminence. At present, work requiring an artist had too often to be left out of consideration, or when art was required, workmen had too often to be brought from elsewhere, or the work sent out of the country. There was, he argued, no reason why Edinburgh should not be a centre of art.

THE Official Examiners have passed the Bill for enabling the trustees to borrow 100,000*l.* for an enlargement, with improvements, of the Borough Market, one of the oldest in London. In 1290 a number of stalls were cleared away from London Bridge; and for a long period, as we gather from Dr. Rendle's communication to *Notes and Queries* of December 17, 1887, the market was carried on within the precincts of (old) St. Thomas's Hospital, or at St. Margaret's Church-gate, and then in Long Southwark, as they called the main street between the church (its site being that of Town Hall-chambers), near the Tabard Inn, and the bridge-foot. In its midst stood a cage and pillory, with whipping-posts near at hand. Booths and stalls, too, seem to have been placed in the churchyard. In Stow's time they sold leather on St. Margaret's-hill, and the church, "being put down," served for a comptor, or jail, as well as for courts of assize and the Admiralty. Under an Act of 1756 the Local Authorities suppressed the traffic; a subsequent enactment set up the market again, in the Triangle at the back of Three Crown-court, and near to Foul-lane and Rochester-yard: a site anciently known as Grimes Croft, which William, second Earl Warren, had granted to the monks of Rochester. There stood Rochester House, an "inn" of the Bishops of that See, and pulled down in 1604. Fifty years ago they extended the market area by demolishing St. Saviour's Grammar School, which Thomas Cure, Queen's saddler, and a great benefactor to the parish, had, with others, founded in 1562, and to which Queen Elizabeth gave a charter of incorporation. The old school buildings, on the site of the prior's house, south of St. Mary Overie's, were rebuilt after the great fire, which devastated this part of Southwark in May, 1676; the new buildings were erected, 1838, after the designs of Mr. Christopher Edmonds, architect, on land given by Dr. Sumner, Bishop of Winchester, in the street bearing his name. In 1885 Mr. McIntyre North, architect, prepared plans for a proposed increase of this market, by taking in more ground between Borough High-street and Messrs. Barclay & Perkins' brewery, Park-street, at an estimated cost of about 65,000*l.* The annual profit, arising from the sale of mostly fruit and vegetables, was then assessed at nearly 7,000*l.* Rebuilt in 1686, the Town Hall was pulled down in 1793, and its statue of King Charles II. re-erected in Three Crown-court, where—as at King's Cross—the pedestal served for a watch-house and lock-up.

THE great height of buildings in America is beginning to make the fire insurance companies uneasy. It appears that the Chicago Fire Underwriters' Association, which includes all American and foreign companies doing insurance business in America, with one exception, has decided that all office buildings of non-combustible description should be limited in height to not more than one and a-half times the width of the street. It further appears that this important association regards many of the so-called non-combustible buildings as practically unsafe from their great height. There is no doubt that high buildings are one of the dangers of modern city life,—a danger which will probably increase rather than decrease. The United States would have to pass a general Act of Congress on this point if they wish to have uniformity and safety; but the subject is one of those which by the constitution is essentially one which must be dealt with by each State according to its own views.

IN a letter in the *Times* of the 26th, in regard to the ventilation of the House of Commons, Sir Douglas Galton gives a description of the "wet screen" in use at the Victoria Infirmary at Glasgow for the removal of dirt and fog from the air previously

to its entering a building. He gives the following description of the process:—

"In this infirmary the air is renewed six times an hour. This volume of air before it enters the wards is filtered and washed by being passed through an air-washing screen of cords, formed of horse-hair and hemp, closely wound over a top rail of wood and under the bottom rail, forming a close screen 16 ft. long by 12 ft. high, affording nearly 200 square feet of surface. There is a constant trickling of water down this screen, by which it is kept wet, and the air, in filtering through it, has the dust and soot particles removed, and when once these have adhered to the wetted surfaces a current of air of considerable velocity will not carry them through the screen, but the falling water floats them down into the drain. An automatic flushing-tank is fixed in a position whereby twenty gallons of water is instantaneously discharged over the surface of the screen every hour, to flush and remove any accumulation of wetted dust, soot, or germs which may be removed from the screen by the trickling water over its surface."

Sir Douglas Galton recommends this method as one which, among other advantages, will keep fog from entering into the ventilating chambers and hence into the building, and states that on very foggy days the air within the Infirmary was perfectly clear and pure.

THE recent litigation in regard to certain patents, in which Messrs. Nettelford Limited, were plaintiffs, in which the hearing of the case lasted for a number of days before Mr. Justice Romer, has drawn public attention to the trial of patent actions. We have more than once pointed out that the Judge on such occasions should be assisted by skilled assessors. It is impossible for a lawyer, however able, to be capable of grasping a number of technical details in a moment. The result is that a great deal of groping in the dark goes on. Counsel become prolix, and scientific witnesses enter too much into minutiae. The Judge had scientific men sitting with him, but he would feel strong in their assistance, and the cause could be tried with much greater quickness. It is sometimes said that these patent cases, and building and engineering cases, should be tried by a special Judge. We can see no reason for this if the Court is assisted by skilled assessors. At the same time, if one Judge had the entire management of patent litigation, and was also assisted by assessors, there is no doubt that this would be an important legal reform. But a minor and useful one would be for any Judge to be able to summon assessors in special cases which require scientific knowledge.

IN certain districts of North Germany some of the water-supply contains as much iron as to render it quite unfit for transmission through pipes for domestic purposes. The iron usually takes the form of a ferrous carbonate, which is held in solution by free carbonic acid, although a small proportion may exist as ferro-phosphate. Ammonia is almost invariably present, and there is often a considerable amount of chlorine. Mr. I. Proskauer, in *Zeitschrift fuer Hygiene*, has given the results of investigations into this subject, the above facts being taken from his analyses of the deep-well water of the Berlin district. In the well water of the North German plains a notable feature is the considerable quantity of sulphuretted hydrogen, which, however, is given off on exposure to the atmosphere. Ammonia, sulphuretted hydrogen, and chlorine characterise the waters of thinly-inhabited districts, as well as those thickly populated, from which it is concluded that the contamination does not owe its origin to sewage. In order to overcome these defects, a course of treatment by exposure to the atmosphere has been followed. This leads to the iron becoming separated from the water and deposited,—a fact which is attributed to combination with oxygen, and the consequent formation of insoluble compounds. Several ways have been tried by which the aëration of the water might be effected, but this does not appear to be so easy as would at first be thought. For this reason the Potsdam supply proved a failure, not through the unwhole-

* See the woodcut in the *Mirror*, April 13, 1890. Here Dr. Heberden, and John Harvard, founder of Harvard, U.S.A., are believed to have been educated.

ness of the water, but through the coking of the pipes. Large volumes of air are pumped in, and the water was also mixed with purer water from Lake Tegely. The light of further experiment, it was concluded that by throwing the water in a series of cascades, and afterwards filtering, the difficulty could be got over. In the Berlin waterworks, Mr. Oesten, the Engineer, is devised an apparatus by which the water made to pass in fine streams through a stance of about 6 ft., and it is then passed through a filter. It is said that with this process of aeration, filtration can safely be performed at three times the speed of ordinary filter-beds used for purifying surface-water.

In a paper read before the Dresden Society of Engineers and Architects, some particulars have been given of the regulations in force with regard to the hygienic conditions of railway carriages on the Prussian State railways. The amount of air-space in the compartments required per passenger is 68, 80, and 30 cubic feet for first-class, second-class, and third-class carriages respectively. The average percentage of passengers being 24.6 per cent. of the available seats, the amount of air-space actually provided is approximately four times as great as that above stated. The amount of ventilation required, in order to limit the percentage of carbonic acid in the air of a railway compartment to one-tenth per cent., varies between 60 and 1,360 cubic feet per hour per passenger. Herr Pfuelzner, the author of the paper referred to, considers it hardly possible to obtain so vigorous a ventilation without producing draughts. In England it would seem as if we had solved the paradox of producing draught without any ventilation at all, so draught to the legs and feet, and so stuffy may be the upper part of a carriage; though in rolling-stock fitted with "torpedoes" there is a great improvement in this respect. The author of the paper objects to stoves for heating as being dangerous, preferring steam-pipes under the seats, but below the level of the floor. Carriages with iron or steel under-frames, he states, are more noisy than those with under-frames of wood. On the other hand, spoke-wheels are less noisy than solid disc wheels, but the former produce more dust.

THE Electrical Exhibition at the Crystal Palace is still far from complete, though it has now been opened for nearly three weeks. In the South Gallery most of the halls are still empty, and some elaborately-furnished rooms are lighted by a line of gas-lights a few feet from the floor. The catalogue as reached a second edition, though still stated to be "under revision." The plans of the Exhibition in this edition are on a larger scale, but the general arrangement of the work is unaltered, and it still tells us that the Board of Trade unit is 1,000 watts per hour, or watt-hours, as though the expressives were equivalent. The machine-room is open, and the exhibits in it fairly complete, as also are most of those in the nave. Amongst these latter, some of the most generally interesting are the portable lamps and the apparatus for heating and cooking by electricity. In the Gallery, Mr. Harness collects a crowd to receive shocks from a person on an insulated stand, who is charged by means of a large influence machine—a well-worn experiment that seems never to lose its charm.

THE Committee of the Whitworth Institute have taken a very unusual course in relation to the competition for designs for the proposed building (the result of which is briefly noticed in our "Competitions" column), in admitting competitors only to the exhibition of the drawings, and refusing to admit a representative of an architectural journal, or (we presume) of any paper, to inspect and criticise the designs. The matter is of no consequence to us, but we do not think the arrangement will be satisfactory to competi-

tors, who wish an award in an important competition to be open to public criticism; and the reasons given for it appear to indicate that the committee are under a misapprehension as to the nature of the interest which architectural journals and their readers take in a matter of this kind. The committee are apparently committed to some change of policy in the matter, and do not wish any public clue to be given as to what they have intended or now intend. We care nothing whatever about their policy; the matter to our readers is simply a consideration of the manner in which a given architectural problem has been treated in regard to plan and design, with the further interest to competitors that they may wish to have the award independently criticised, if there should be anything open to criticism in connexion with it. We may point out also to the Committee that it would of course be perfectly easy, for any journal which chose to adopt such a method, to get a competitor to write an account of the designs. We expect to find that this has been done, and in that case all the committee will have got by their scrupulous adherence to official privacy will be the publication of descriptions written by interested persons, instead of by perfectly independent critics who have no interest of their own to serve.

SARACENIC ARCHITECTURE.*

BY PROFESSOR AITCHISON, A.R.A.

If the saying of Sir Joshua Reynolds be true "that it is by being conversant with the inventions of others that we learn to invent." I want no further excuse for speaking of Saracenic architecture.

The vulgar reproach addressed to architects is that they do not invent a new style, while the Saracens certainly did, which, in its developed form, no one can mistake. Those who reproach architects with not inventing a new style forget that hundreds of years are required to evolve one, and that one of the conditions of its evolution is that the peoples should appreciate and admire the new grafts on the old stock.

The architects of the early Saracenic monuments were probably Byzantine, or if not they were natives of the countries the Saracens conquered. When the Saracens began to have a style it would be interesting to know on what former style it was founded, and of what nationality the architects were who made the first steps forward. It would, however, be a hopeless task to trace their genealogy, as polygamy then prevailed, even if we knew their names, and few of their names are known, so we must be content to call that architecture Saracenic that flourished in countries under the rule of the Caliphs, unless we know to the contrary.

I was curious to learn what architectural art the Saracens brought with them from their native land, but if they had any, it seems impossible to ascertain what it was. Mecca is said to have been built with stone cut from the granite mountains that surround it, but I had never seen even a photograph of it, until Mr. Carpenter lent me these a few days ago. The Kaaba, or great Temple of the Arabs, supposed to have been built by Abraham, existed in Mohammed's time, and was rebuilt when he was a man of thirty-five, after being ruined by a flood. We know that its walls were then taken down to the footings, and rebuilt to a height of 4 ft. or 5 ft. with pieces of grey granite from the adjoining mountains, and that at this point the black stone was carried to it in Mohammed's Cloak by a man holding each corner, and that each of the men belonged to one of the four divisions or tribes of Mecca. It was fixed in the south-east angle by Mohammed himself. What the upper part of the Kaaba was made of we do not know. A Greek or a Byzantine ship had been wrecked at the time of the rebuilding, on the neighbouring shore of the Red Sea. The Koreish bought the timber of the vessel, and employed the captain, named Bacim, who was skilled in architecture, to assist in the rebuilding of the Kaaba, and it was roofed with sixteen rafters or joists, resting on six central pillars.

* Being the first Royal Academy Lecture on Architecture this session. Delivered on Monday evening, January 25.

The Kaaba was originally covered with cloth that hung like a curtain on all sides, and was its only roof, i.e., it was an hypaethral temple, until this wooden roof was made by Bacim; it was subsequently enlarged by the Caliphs Omar, Othman, Ibn-Zobeir, and Abd-al-Melik, afterwards by the Sultans of Egypt, and its present form dates from the work of the Sultan of Turkey, Amurath III., in 1576, in our Queen Elizabeth's reign. On the east side, about 6 ft. from the corner of the black stone, was a door 6 ft. or 7 ft. from the ground, and entrance could only be got by a set of steps on wheels being rolled up to it.

It is not quite clear whether the idol Hobal, of red agate, was inside the Kaaba or outside. The Kaaba must, I fancy, have been mainly of wood, as it is said to have been burnt down in Yezid I. and Abd-al-Melik's time, but it may have been that the curtains caught fire and burnt the roof, the curtains or coverings in Omar's time were of linen, and afterwards of silk and cotton brocade, attached to the walls, and till the time of the Abbassides the new coverings were put over the old ones. There was a celebrated temple in Arabia, mentioned by Diodorus Siculus about 8 B.C. (Lib. 3, cap. 3).—"The people that inhabit these parts are called Bizomenians, and live upon wild beasts taken in hunting. Here's a sacred temple in high veneration among all the Arabians;" but whether it was the Kaaba or not I am unable to say, though it is believed to have been, as there was no other celebrated temple in Arabia. The Kaaba is now said to be an irregular oblong in plan, about 50 ft. by 40 ft.

It is stated that in Mohammed's time, an aqueduct was tried to be built from Mount Arafat, but without success, so the Saracens of his day were evidently not great builders; although there were Christians, Jews, Abyssinians, and Persians among them. Mohammed, it is true, had a mosque built at Medina when he settled there, but it is believed to have been mainly of wood, with wooden columns; his wives' houses, that formed the east side of the enclosure of the mosque, were of unburnt bricks, with partitions of wattle and daub. Mohammed had no house of his own, but lived with his wives in turn; he, however, speaks of columns and arched vaults in the Koran (cap. 104); and a splendid tomb, with a cupola, is said to have been built over his grave, but of what material we know not. His tomb was built in Ayesha's house, at the spot where he died, and the tombs of the two succeeding Caliphs were also erected there.

The Saracens were of three sorts.—(1) Wandering tribes of herdsmen or nomads, who, as Aristotle says ("Politics," Lib. I., cap. 8), combined brigandage with it for convenience; (2) those who lived in towns and tilled the land, as the people of Medina; but husbandmen were looked down on by the wandering and by the trading people; and (3) those who were carriers and merchants, like the people of Mecca, all of them seem to have found it convenient to add brigandage to their other occupations; one of the principal quarrels between the people of Mecca and Medina, after Mohammed settled there, was the marauding expeditions to be ordered against their caravans.

The Meccans looked upon themselves as the people of most capitals do, and the tribe whose head men had the care of the Kaaba, and the well of Zem-Zem, the Koreish, considered themselves as by far the most important tribe, looked down on the rest, and held the wandering Arabs in contempt; but, unfortunately for the continuance of Saracenic sway, the wandering Arabs equally despised husbandmen and merchants. After their first foreign conquests, the leading families of this tribe of Mecca were called the Princes of the Koreish, and Mohammed was of this tribe. The east coast of Arabia was a convenient landing-place for the products of Persia, India, and the far East, as well as for those of the east and south coasts of Africa; while the ports on the Red Sea were possibly used for the exchange of the products of the East with those of Europe, Asia Minor, Syria, and the North Coast of Africa; though in old times all the main trade routes were land routes, and the whole Saracenic Nation was at one time engaged in carrying. This business was greatly interfered with by the Romans discovering the passage to the East by the Red Sea, through the Straits of Bab-el-Mandeb, "The Gate of Tears," and was the probable cause of the large migration of Arabs to the

North of Syria, but caravans still went to Palestine and Syria, as Mohammed accompanied his uncle Abn Talib there, and it is said that the one caravan in Mohammed's time went to the Court of Cosroes, the King of Persia. Even as late as the first three Caliphs, there was great reluctance shown by them to let their people trust to the dangers of the sea. Arabia itself is said to produce frankincense and other gums,—gum-arabic, for instance,—manna, and odoriferous herbs, we have all heard of "the perfumes of Arabia." It also contained precious stones, the onyx, the ruby, and the Mocha stone, and pearls were found in the Persian Gulf. Coffee was not then discovered, and it is doubtful if the lead mines were worked; silver and gold were said to be found there, but as Arabia was an emporium, it is only from modern travellers that we can judge of what it produces, as the old writers spoke of all the things that came from Arabia as native products, hence its ancient reputation for wealth.

Although architecture has perhaps no direct connexion with any form of belief, still temples have mostly been the greatest works that architects have created, and each particular belief has greatly influenced the adornments bound up with the architecture; so I think it necessary to say something of the new religion of the Saracens, for it welded for a time a set of hostile tribes into a nation, and sent them forth to conquer all the countries of the ancient world; it thus caused the creation of mosques, and probably the modification of the plans of other buildings, and of ornament, the latter through the exclusion of animal life.

Before Mohammed published the Korán, and declared himself the last prophet of God, the Arabs were mostly idolaters, though some had embraced Judaism or Christianity; the idolaters mostly worshipped the host of Heaven, or some particular gods or goddesses, and did not believe in another life; this time of idolatry was afterwards called by them,—“the days of ignorance.”

The Kaaba at Mecca was the great temple of Arabia, to which all the tribes came once, and sometimes twice, a-year to worship and to sacrifice, and these were called the greater and less pilgrimages. The four months kept sacred from war were devoted to the time occupied in making the pilgrimages, the sacrifices, and the religious exercises.

In the enclosures round the Kaaba were 360 idols, including the black stone, probably a meteorite, said by modern travellers to be roughly hemispherical, about 6 in. high and 8 in. in diameter, and of a reddish-black colour.

During the time of the pilgrimage a fair was held at Mecca; Mecca itself was in a barren valley that produced nothing, so that two caravans a year had to bring the Meccans the staple articles of food, besides what they got from the environs. The pilgrimage of people from all parts of Arabia to the Kaaba, and this fair greatly enriched the inhabitants.

The condition and habits of the Arabs in the days of ignorance were thus described by a new convert to Islam:—“The men who had clothes had generally a garment of camel's hair, besides the turban; fed on fruits, parched grain, hroiled snakes and lizards, and drank brackish water, killed anyone they could who was worth robbing, and buried alive all their superfluous female children. Their courage, ferocity, and bloodthirstiness were probably unparalleled, until the turn of the Tartars came; they were probably not more inhuman and perfidious than other savages, and, as Cetywayo said of the negroes, could only be governed by killing large numbers of them. Hajjaj, the governor of Cuifa and the East, is said to have put 120,000 persons to death, besides those slain in battle, by the time of his death, 95 A.H., 713 A.D. The Saracens were insubordinate, quarrelsome, vindictive, and revengeful to the last degree, and so fond of fighting that Khalid, their great general, called by Mohammed ‘the Sword of God,’ told the Persians that ‘his men were as fond of death as they were of life,’ and afterwards the Caliph Omar said:—‘My people are as fond of fighting as the Christians are of eating swine's flesh and drinking wine.’”

The Arabs valued themselves on their eloquence and poetry, on their skill in horsemanship, and the use of arms; on their hospitality, and the number of their sons. Like all conquering nations, they were probably the strongest, most vigorous, and best-educated people then in the world, though few of them could read or write; they were frugal, mainly

no doubt from necessity, hardly from constant exercise, and exposure, accustomed to endure the extremities of cold and heat, of hunger and thirst, and the terrors of solitude in a country infested with beasts of prey, keenly observant of the stars, and of every slight natural indication that would enable them to find their way over trackless deserts and pathless mountains, or to discover underground springs and they had to practise every art and every device to preserve their lives amid hostile tribes, beasts of prey, and sand-storms. They were adepts in every race of savage warfare and were a constant terror to their neighbours from their incursions and robberies, but the reason they were not a menace to the adjoining potentates was that they had no cohesion, and were always quarrelling and fighting with one another, consequently, outside their own country, they never made any permanent head against the armies of the Kings of Persia, or the Byzantine Emperors, until after their conversion to Islam.

It would be interesting to know what industrial arts they possessed in Mohammed's time: he said, there were five iron things that came down from heaven, the anvil, the tongs, the great and little hammer, and the needle. We know he cobbled his own shoes, that one of his wives tanned leather, that there were sword cutlers, that there was striped stuff called the cloth of Yemen, that they arched his grave over with unburnt bricks, and that the men possessed the art of dying their hair red.

Mohammed was the illiterate prophet who could neither read nor write, and propagated his faith without the aid of miracles. He believed that the Angel Gabriel repeated to him certain passages from an inscription by the throne of the Almighty, which, when completed, formed the Korán, but it must be observed that both at home and in his travels he had heard much of religions from Jews, Romish, and Orthodox monks, the Christians of Arabia and Abyssinia, from the Magians of Persia and possibly from the Buddhists, and he admittedly borrowed many of the stories in the Korán from the Old Testament, the Talmud, and the Apocryphal Gospels; he had been much struck by the preaching of Coss, Bishop

of Najrán, had visited synagogues, Christian churches and shrines, and had observed the sacred pictures in the churches and abhorred them, so that he afterwards had the pictures in the Kaaba erased. I presume idolatry was so ingrained in the people that it was difficult to eradicate, for though he allowed chess playing, he looked with an evil eye on chessmen carved into figures.

The inspirations furnished him with a pure monotheistic creed, with a resurrection, a day of judgment, and an eternity of pleasure or pain, forbade idolatry and infanticide, and contained a few stories, a few moral, administrative, and ritual observances, and incited an ascetic life of prayer, fasting, and almsgiving. The inspirations also informed him that all martyrs went straight to paradise, and that those killed in battle against unbelievers were martyrs, and declared that he was the last prophet.—Adam, Noah, Abraham, Moses, and Jesus Christ being his precursors,—that their doctrines were superseded by his, and that there should be no priests or monks. The short creed of Islam is,—“There is no God but God, and Mohammed is his apostle.” The Moslems call a prophet who is the author of a book an apostle. At first his inspirations were rather Christian in spirit, and his Kibla, or the line of prayer, was to the Temple of Jerusalem. After his first revelations he converted his elderly wife and his slaves; afterwards a few relations and others, but, as he insisted on publicly preaching against idolatry, on the unity of the Creator, and that he was the prophet, he incurred the enmity of the people; he and his converts were persecuted, and, after escaping assassination on several occasions, his converts eventually fled to Medina, and were followed there by him and Abu Becker, the father of his wife, Ayesha; this was called the Hegira, or flight, and became, in the days of Omar, the Moslem era. It happened on June 20 or July 15 or 16, 622 A.D., and those who fled were called Mohajirin, or the flyers, and those who received him at Medina, the Ansars, or helpers. Some of his first inspirations were altered, and some were reversed at Medina, his Kibla was there changed to the Kaaba at Mecca.

and the idolators, including his enemies, were not merely left for punishment in the next world, but were to profess Islam or be exterminated in this; Jews and Christians, however, were to be tolerated on the payment of a tribute. One-fifth of all plunder taken by the believers was to go to the prophet for the support of the faith and for alms to the faithful, and there was also a tithe on all Moslems for the same purpose. I should say that, besides prohibiting infanticide, the Koran greatly improved the condition of women and orphans as regards their property and their treatment, though some say that the restriction of the freedom women enjoyed in the days of ignorance was not counterbalanced by the advantages they gained under the Koran.

The peculiar veneration that Mohammed's converts had for him went so far that they saved the water he washed in as something holy, and cherished as relics and talismans the hairs that fell from him. Sidi-Sahah, one of the companions, was presented by Mohammed with three hairs from his beard when he was being shaved. These Sidi cherished, and after the "Apostle's" death he accompanied Ocha to Kairouan, where he died, and his instructions were that one of these hairs should be placed on his tongue, and one on each eye when he was buried, which was done. Mohammed's followers were also delighted by his consecrating the wells of drinking water by spitting into them. The alterations in the faith and ritual, the command to bring in the whole world to Islam by the sword, together with his successful marauding expeditions, brought in many converts. A few battles with his enemies the Meccans, the destruction of the neighbouring Jews, and the apportioning their land among the refugees, brought in more, so that after a few

years he summoned the Byzantine Emperor, the King of Abyssinia, the King of Persia, and the Jewish, Christian, and idolatrous tribes out of Arabia to be converted to Islam. On account of the murder of one of his messengers by Sharahlil, the chief of an independent tribe, he despatched an army against him, but the Saracens were nearly cut to pieces at Muta by a Byzantine army, led by the brother of the Byzantine Emperor Heraclius, aided by the forces of Sharahlil. The same year of the Hegira, in spite of this defeat, he was enabled to take Mecca, practically without resistance, though there was some slaughter in one quarter of the city, and to make the whole of the idolatrous inhabitants embrace Islam, by that most cogent of all reasonings,—the sword; he then had all the idols in the Kaaba and its courts destroyed. It was then necessary to convert the rest of his idolatrous countrymen, and make them pay the tithe for the support of the faith, those that objected were butchered to the last man, and all the women and children sold for slaves.

In spite of Mohammed having become the prophet and absolute prince of the most warlike people in the world, he still kept to his frugal fare, his poor dress, and lived with his wives in their mean houses at Medina; he claimed nothing of his people beyond his share of the plunder, the tithe, and tribute, but absolute obedience, and an extra allowance of wives; the army being paid by the plunder they took.

On Mohammed's death at Medina in 11 A.H., 632 A.D., the converts outside Mecca and Medina mostly relapsed into idolatry, partly from habit and partly from their objecting to political subjection and to paying the tithe, but all the hacksliders and recusants were either converted to Islam or hatched in the reign of

his successor, the Caliph Abu-Beker. When the whole of the natives were nominal believers, the Saracens were launched on Chaldaea and Syria, and in little more than a century they had not only conquered Persia, Khorasan, Afghanistan, Bokhara, Scind, and the Punjab, from the Indus to the feet of the Himalayas, and had penetrated to Samarcand and Kasgar, but they had also subjugated Mesopotamia, Syria, and Palestine, Egypt, and the north coast of Africa to the Atlantic, the greater part of Spain, the south-east of France, and had ravaged Asia Minor and the main islands of the Mediterranean, and besieged Constantinople.

Mohammed's immediate successors, the Caliphs Abu-Beker and Omar, imitated his frugality, simplicity of dress and living; but, as in Omar's day, the fifth of the plunder, the tithe and the tribute became enormous, he paid large stipends out of it to the early believers, thus creating a sort of superior nobility above those of the Koreish, which afterwards brought trouble, though he kept nothing for himself, but distributed daily the Caliph's share. At his death only one piece of gold was found in the treasury, which had been overlooked in a dark corner. The third Caliph, Othman of the Omeyya family, had other views, became enormously rich, built himself a palace at Medina, with marble columns, and walls covered with costly stucco, and gave all the principal employments to his relations. All the nobles of the Koreish, and the governors of cities or countries, built themselves palaces in many places; some of them had revenues of a thousand gold pieces a day. This caused a great scandal to the ascetic Moslems, just as splendid private buildings had scandalised the Romans of the Republic, and, of course, the poor were furious with envy; from this time forward there were constant riots, rebellions, and revolutions; and the old tribal feuds broke out again. After the first three Caliphs, the Caliphate became a vulgar despotism of the ordinary type, only with religious despotism superadded.

Even in the first few years of the second Caliphate, these half-starved barbarians, the Saracens, had obtained the main treasures of the Persian Empire, and the rich plunder of Syria; private troopers had got 500L or 600L a-piece as their share in one expedition, equal to at least ten times that amount now; the imperial carpets of Persia, embroidered with gold and precious stones, were cut up and sold by auction at Medina. The army took to drinking wine, and exchanged their camel's-hair garments for silk robes, while their generals hatched in wine, for which they were all hastinadged by Omar's orders. Great Arah settlements, Kufa and Mosul, were at once made on the Euphrates and Tigris, and these as well as all the other settlements must have had mosques built. In some places, as at Damascus, the cathedral was shared between the Moslems and Christians. We know of the Mosque of Amru being built at Cairo, and Omar's mosque at Jerusalem, but whether this was the dome of the rock or the Mosque El Akshab, I must leave the learned to decide, the best authorities believe it to have been a little wooden mosque; these monuments, when not of wood, were doubtless constructed with materials plundered from ancient edifices, and were designed by Byzantine, Syrian, Persian, or Koptic architects.

If Byzantine architecture is chaotic as regards dates, what can he said of Saracenic architecture, of whose early work we know nothing, nor of the Indian, or Koptic architecture, from which or from the Byzantine all their new architecture must have been taken, and we know very little of Persian architecture. Even before a conquered world lay at the feet of the Saracens, fierce conflicts were waged between the rival Caliphs and claimants of the Caliphate; religious seditions were rife and tribal feuds, so that between them everything was destroyed; the holy Medina, the scene of much of the prophet's life, inspirations, and preaching, and the site of his tomb, was given up to pillage by Yezid I.; horses were stabled in Mohammed's mosque, and the very Kaaba of Mecca was hurt down; and besides all the plundering, burning, and destruction in the days of the Omiades, in the first days of the Ahmassides, 132 A.H., the empire began to break up. Spain never acknowledged their sway, and all North Africa, except Egypt, had to be re-conquered, and still greater destruction took place at the end of the Ahmasside dynasty, when the private disputes of Turks and Tartars were added to those about the religion, the predominance of tribes, and rival dynasties

claims. After the Araoian Caliphate was at an end, and the rulers were mainly Turks, the part under their sway was like the East after Alexander the Great's death, the kingdoms were constantly being overrun and re-conquered, and then there was the destruction by the Crusaders. Subsequently a fresh tide of destruction overwhelmed the greater part of Asia when Tamerlane and his savage hordes swept over it.

I think it most probable that while the Conquests were being made, the Saracens, who were little better than banditti, loosely held together by a common faith, and the love of bloodshed and plunder, were not very likely to settle down to study the fine arts, even if pure Arabs ever did, and this is, to some extent, borne out by the fact that Velid I., 85 to 96 A.H. (703 to 715 A.D.), although he built much, and encouraged manufacture and design, accepted 60,000*l.* in gold, camel-loads of mosaic, and one hundred Byzantine mosaics from Justinian II., Philip Bardanes, or Anastasius II., for the construction of new mosques and the repair of old ones; it is also said that, in a treaty between him and the Byzantine Emperor, the latter was to furnish the mosaic for his new mosque at Damascus.

As late as Abd-al-Rahman I., the last of the Omiaids, who became Caliph of Spain, and reigned from 138 A.H. (754-787 A.D.), architects and skilled workmen are said to have been sent him by the Byzantine Emperors to build the mosque at Cordova, and all the monarchs of Europe sent him columns plundered from ancient edifices for the same purpose. Ab-al-Rahman I. is said to have founded universities in Spain.

We do not read of much study of philosophy and the arts till the days of Harun-el-Rashid and his son Mamun, 169-183 A.H. (785-813 A.D.).

Harun was the son of the Calif Mehdy, and Kheizran, the daughter of the Governor of Herat. His famous Vizier, Jafar, the haremide, so well known to us from the "Arabian Nights," a patron of learning and the arts, was descended from a great family of Bikh. He is said to have been the greatest instance of the vicissitudes of fortune, for in Harun's "Book of Accounts" 400,000 pieces of gold are entered as the price of a dress of honour for him, and a few days afterwards ten karats (5*l.*) for reeds and naphtha to burn Jafar's body. Mamun was also the son of a Persian Princess, and for some time held his Court at Marve. I merely mention this to account for the encouragement given by them to Turks, Persians, and Indians. Mamun is said to have founded colleges and libraries, and to have commanded Mohammed Ben Musa to publish a book on quadratic equations, called "Al Jebra al Moka-bala" (restoration and reduction), from which comes our word Algebra. The substance of the work appears to have been derived from Hindoo sources. Subsequently, the works of the Greek physicians, philosophers, arithmeticians, and geometers were translated, and physic and mathematics became favourite studies of the Saracens. The Abbassides had great influence in Persia, Khorasan, Afghanistan, and Bokara. They were descended from El Abbas, the time-erving uncle of the prophet, and, not like the Omiaids, descended from his enemies. They seem, however, to have been less noble and less liberal, and even more bloodthirsty and perfidious than the Omiaids, yet their reigns are held to be the golden age of the Caliphate: they introduced Turks for their fighting men, and Greeks and Persians for posts where intellect was wanted, commonly called officers of the sword and of the pen. After their extinction, Turks mostly filled their places; the Arab race having lost its religious enthusiasm, fell gradually into a lower grade.

In some respects the Moslem world,—as far as architecture was concerned,—was in much the same position as Europe is now; it had become enormously wealthy, new buildings were made on an unprecedented scale, and the main architecture of the world lay before it for study, but there was no Saracenic style; the buildings were in the style of the country or town in which they were erected, or in the style used by architects who designed them. I say this, however, with some diffidence, for the mosque at Cordova, San Cristo dela Luz, at Toledo, and Sta. Maria dela Blanca, are unlike anything else I know. The attractions of living styles are greater than we could imagine, if we had no such frequent examples before our eyes.

English architects of all degrees of excel-

lence and talent go to our dependency, India, and whether they affect Classic, Gothic, or Renaissance architecture here, they at once take up with the native style of that part of the country they inhabit, or paraphrase the Moslem buildings they find there; and it is the same in Egypt. The last hotel built by an English architect, close to the Pyramids, has its architecture borrowed from the mosques, even to the niche. It is admitted that the Saracens brought no style with them from Arabia, but adopted features that pleased them from the countries they conquered, the most characteristic feature being the minaret, and this is said to have been Persian; the dome was taken from the Byzantines or Persians, the niche (mehrab) from the apex of Christian churches, floral ornament that was not Byzantine probably from Afghanistan or India. Fergusson remarks on the similarity of the ornaments on the tomb of Mahmud of Ghuzni to those used in the mosque of Ahmed-Ibn-Tulun at Cairo, only this would suppose that it was not indigenous, unless indeed it was not done till Lagin's time, for Ahmed-Ibn-Tulun died in 883 A.D., and Mahmud of Ghuzni was not born till 967 A.D. Architects in the Arabian Nights are mostly called mathematicians or geometers, and when they were thoroughly imbued with geometry, they made great advances on the geometrical patterns of the Byzantines, on which it was based, so as to completely transform them. One of the most striking peculiarities of Saracen art is the stalactites. There is an ingenious and plausible theory that may turn out to be the true one, that the stalactites or honeycomb work sprang from the brick niches in the domes or steeples of the tombs of Ezekiel and of Zobeida, Er-Rashid's head wife, both near Baghdad. These spires strongly remind us of jelly-moulds. If it came from these niches the Moslems developed them to a degree that bears no resemblance to the originals, for who would trace from this the stalactite domes of the Alhambra? These are certainly some of the most wonderful achievements of man, in fact, they suggest the work of enchanter, or of being sent down from another world. At first sight their maddening complexity and their apparent want of support makes it impossible for us to conceive that mere human beings could ever have invented or produced them; one would be led to believe that the Spanish ones were suggested to some genius by his seeing some pieces of wood of unequal length, whose ends had been shaped, put together for mosaic, like Tunbridge ware, for every wood corbel or capital I examined in Spain was made up of separate squares, oblongs, and triangles. The Saracens also invented a system of ornament, in which one pattern was laid over another in low relief, and perfected by colour and gilding; this is magical in effect, for each change of position brings out a new pattern and a new predominating colour. To them, too, we owe the perfection of mnemonic ornament, formed by overlaying a floral ground with Kufic or other writing, which is as distinctly Moslem as their maddening geometrical ornament on stalactite work. The ancient Egyptians, Persians, Greeks, Romans, and Byzantines produced works infinitely grander and more dignified; and the Greeks works infinitely more beautiful, and of a higher style of beauty, but no people have ever produced anything so magical or so sumptuous in colour. The human figure and the representation of any living thing was forbidden by their religion, though Mesopotamians and Persians did even try their hand at this form of art. By the Moslems every handicraft was carried to a perfection before unknown in the world; from the temper of a sword-blade to the weaving of a robe or a carpet; even now their enamelled glass and pottery, their damascened work, their wooden lattices, cabinet-work, carpets, and illuminations, are, in some respects, unsurpassed, and fine specimens fetch their weight in gold. And so superior were their works to those of European manufacture, that when the Christians began to imitate their costly stuffs, chased brass, or damascened work, it was a common practice to put Arabic letters on them, to enable a market, in the form of texts from the Koran, but meaning nothing. As late as the Porta della Carta of the Ducal Palace at Venice, Arabic letters in imitation of an inscription were put on the dress of one of the figures, the solution of which was long an enigma to scholars.

It is quite possible that the real Saracens had no capacity of invention nor for the fine arts. At any rate, scarcely any buildings of great

artistic merit have survived them, for, with the exception of the Mosque at Cordova, real Saracenic buildings are of the eleventh and twelfth centuries. But, supposing they had neither taste nor invention, they would none the less claim our admiration and gratitude. They expunged the worn-out civilisations of the world, and imparted to the survivors their own resistless energy, their simple faith, and a lavish generosity, so that their successors, perhaps blessed with higher capacities, overspread the world with elegant and sumptuous monuments from Spain to the Indus, and from the Red Sea to the Atlantic. Every country beneath their sway flourished like a garden. Stock was increased, and the breed of horses greatly improved. Every town was a hive of industry, from which issued the most splendid arms and armour, glass, metal, and woodwork, enamelled earthenware, velvet, satin, silk, and cloth of gold, of splendid patterns and gorgeous colours; from them lawns, crapes, and delicate muslins were spread over the earth, arts and literature, science and speculative philosophy found their homes amongst them, and spread light among the surrounding darkness; the inventions of the East were communicated to the West, not the least of which were the Arab arithmetic, algebra, and the mariner's compass, until they may be said to have been smothered by the wealth and plenty their industry had created. The splendid mosques, tombs, towers of victory, hospitals, khans, and palaces with which the Moslem conquerors enriched India alone probably exceed in number and magnificence all the monuments of Europe since the Renaissance; not to speak of bridges, aqueducts, and tanks, new phases of architecture, and new systems of illumination and ornament were invented, and in the later Crusades the manners and morals of the Moslems were held up as patterns to the Christians by their priests.

It seems a pity that most of their monuments are perishing by decay, or by more wanton destruction, and when they are gone we shall have but indifferent records of their glory.

We are now in Egypt and in India: in both these countries we have done much for the natives, and nothing for ourselves. It is humiliating to remember that the great Napoleon, though he only held Egypt for a short time, began that work on Egypt that the succeeding French Governments continued and completed in thirty-seven volumes of "Atlas" folio. There is very much admirable Saracenic work to be deciphered and delineated, and we also hold Scind and the Punjab, that were the extreme confines of Saracen sway, not to speak of the Mohammedan art of India that was created under the Mogul rulers.

From our friendship with the monarchs of Afghanistan and Persia, their monuments might be drawn and published, which would probably give us the clue to the development of Saracenic art. Unhappily our Government is not only quite unmindful of such duties, but does its best to prevent private enterprise. In France an expensive work of the sort would be patronised by the Government, and even if it did not contribute directly to it, many copies of the work would be purchased and distributed in libraries and art schools; but here, on the contrary, the unfortunate author would be plundered by the Government; and yet we wonder that so few magnificent architectural works are published in England.

ROYAL INSTITUTE OF BRITISH ARCHITECTS:

THE PRESIDENT'S ADDRESS TO STUDENTS.

The sixth ordinary meeting of this Institute for the present session was held on Monday evening last, at 9, Conduit-street, Mr. J. Mævicr Anderson, President, in the chair.

Mr. W. H. White, Secretary, said he announced with regret the decease of Mr. Alfred Porter (Fellow) and Mr. H. C. Elworthy (Associate).

Mr. Aston Webb, Hon. Secretary, read a copy of a letter from the Council of the Institute to the Architectural Association, notifying to the latter body the determination of the Institute to grant 300*l.* in support of the Association's educational scheme, such sum to be paid in three annual instalments. A letter from the Secretary of the Architectural Association, conveying a special vote of thanks to the Royal Institute for its promised donation, was also read by Mr. Webb.

The President then delivered the following address to students:—

If it be true that one of the chief difficulties that attend the study of architecture is to be found in the number and variety of subjects with which it is essential to be more or less familiar, it is no less true that the comprehensive nature of the pursuit constitutes one of its greatest attractions, for it opens up a field of inquiry over which the mind may roam with ever-increasing vigour and interest. Absorption in one particular subject of study may produce lassitude, but no amount of devotion to a study so varied as that of architecture should ever conduce to such a result, for mental refreshment is to be found—not in cessation—but in variety of thought, and the student of architecture need never experience difficulty in finding mental repose by turning from one to another of the many fields of research that lie before him. For example, in History he will find the phases depicted through which the art has passed in by-gone ages; in Literature he will become familiar with the opinions of great masters which imparted individuality to the art of different epochs; in Nature he will gather, from the development of the mineral and vegetable creations, the properties of the materials in which his designs will have to find expression; in Science he will learn what is the strength and formation of such materials, and how to adapt them to his requirements without doing violence to their material characteristics; in observation of the executed works of others, whether ancient or modern, he will, from sketching and measurement, discern how successful results have been attained, or artistic effects produced; while in Design he will apply the varied knowledge he has thus acquired from History, Literature, Nature, Science, and observation, and, by the artistic and scientific treatment of the materials at his command, he will impress his ideas and personality on the architecture of his day.

For the successful pursuit of a study so varied and so fascinating many qualifications are desirable, but three are essential: Natural aptitude, Application, Imagination. Without the first, the student will do well to abandon the career, even though he may have spent time in discovering his want of affinity with it. Many illustrations from real life might be quoted of men who had devoted years to the preliminary study of a profession only to find that they had no aptitude for it, and have with good sense left it for a more congenial career, in which they have earned reputation and renown. If the heart, as well as the intellect, is not engaged in the work of life, you may possibly, in favouring circumstances, attain to respectable mediocrity, but you will never achieve real success. Be sure, therefore, at the outset, that you possess that earnestness of purpose and heart-love for your work which spring from natural affinity, and cannot exist without it. It is needless to insist on the importance of Application. Original genius or natural endowments cannot be acquired or imparted, but it is marvellous to what an extent application compensates for the lack of such gifts. Was it genius that led George Stephenson to perfect the invention of the locomotive steam-engine,—probably the greatest promoter of civilisation that the world has ever seen,—or was it simple indefatigable application? Read his life, if you have not done so, full of lessons for all, and judge for yourselves. Or, again, look at a life but recently terminated; admittedly endowments with genius, but possessed of good sense, honesty of purpose, and earnest application, how startling the success, how remarkable the position, which was achieved by the late First Lord of the Treasury! If you have application, you possess one of the most powerful levers with which to remove and triumph over difficulties. But it is obvious that natural aptitude and application, invaluable as they are, are not sufficient to qualify you for the career on which you are entering. Far away the most important work of your lives as architects will be that of design, and if you are devoid of the mental endowment of imagination,—by means of which alone can there be design,—you will be like a ship without compass or rudder, your lives will be aimless, and you will miss the prize of your calling. Possessed of all knowledge, your works, without imagination, will be but imitations and reproductions, not designs. Equipped with learning, but devoid of creative power, you would not be artists, and, therefore, could not be architects.

have glanced at the varied nature of your

engagements as students of architecture; it would be manifestly impossible within the brief compass of this Address to discourse on all, or even a few, of these with any prospect of a beneficial result. I propose, therefore, to confine my remarks to one branch of them only, and to ask your attention to a few suggestions respecting it. The subject which I have selected is what I do not hesitate to refer to as "The Art of Planning." No doubt there are those who will regard such a designation as a contradiction in terms, for it is to be feared that there are not a few who consider planning as at the best, a very prosaic part of an architect's work, and to whose poetic fancies the idea of elevating it to the dignity of an art may appear to be sort of architectural blasphemy. There are others who, without going so far as this, do not hesitate to relegate planning to an inferior and subordinate place, not worthy of the exercise of the higher and artistic faculties of the designer,—a constructive skeleton, as it were, admirable it may be in its mechanism, but which the architect must clothe with grace before it can be admitted to the sacred courts of art. Now I do not hesitate to declare that such views of planning are thoroughly fallacious and injurious to the best interests of architecture, because derogating to a commonplace utilitarianism what is really an integral and inseparable part of the art, the root from which grow the loftiest conceptions, the suggestive source from which springs all that follows.

Thus viewed, you will see at once that it is impossible to exaggerate or over-estimate the importance of the study of planning. It may indeed be safely asserted that there is no study in which the human mind can engage, on the results of which the comfort, convenience, and happiness of society so much depend. This, I admit, is claiming a good deal, but no more than the study properly demands. It is not my purpose at present to emphasise utilitarianism, but do not forget that every building is designed for use; to say so is not to derogate from art, because the highest art is displayed when a building is so designed as most successfully to fulfil its purpose by combining fitness with beauty. Thus the primary field for the exhibition of the architect's art is planning. This does not appear to admit of doubt. Let me demonstrate it. What is architecture? Is it the mere clothing of the structure? or is it the artistic design of the structure itself? Unquestionably the latter, and if so, how can the study of planning be other than artistic work, the primary stirring of the dry bones out of chaos, and the life inspiration which creates out of them the useful and the beautiful? For planning is not the mere casual throwing together of so many forms; it is the chance disposition of so many lines representing walls, enclosing so many haphazard spaces representing rooms; it involves the exercise of imagination. The design of the plan is the medium for educating this quality, just as much as the design of the elevation; it is customary, no doubt, to hear the word design applied to the latter much more than to the former, but the one is really just as much design as the other; consequently the plan affords the opportunity for the display of artistic power just as much as the elevation. Not only so, but a true artist, while studying and elaborating his plan, has a mental drawing-board by his side, on which he rears in his mind's eye forms and proportions suggested by it and emanating from it; he disposes the arrangement so as not only to meet the requirements but also so as to produce a happy result in point of effect; in short, the two things go together, they are mentally indivisible, and must be elaborated, not without reference to one another, but in unity. Hence experience demonstrates that a good plan will generally be found to produce a good elevation; they are integral parts of a whole; the one having been artistically studied with a view to the other, the result will be harmonious; if the tree is good, so will the fruit be.

Did time permit, it might be interesting to divide the subject, and classify it under separate heads, treating each in turn, as for example:—The plan ecclesiastical, the plan collegiate, the plan palatial, the plan municipal, the plan judicial, the plan official, and the plan domestic; and a moment's reflection will show you how easily we could find in the elaboration of the characteristics and requirements of each, much that might profitably engage our attention. I must, however, content myself with a more general treatment, touching briefly what may be called principles, leaving the application of them to your own imagination.

None but those who have made a real study of planning, have any conception of the infinite breadth and variety of the field of design which it creates; they only know experimentally the charm of puzzling over difficulties; of revising, re-arranging, and re-disposing, in order to overcome them; they probably create other difficulties, which in their turn have to be surmounted by a further similar process, and so on, until, after many disappointments, many failures, and many inventions, a satisfactory result is at length reached. It is now many years since I resolved never to let a plan leave my hands until I felt satisfied that it was right; and in battling with the difficulties thereby created until they have been successfully overated, I have found some of the most engaging studies of professional life. The question with you should never be, whether a plan is good enough,—that is an unworthy standard,—but rather, is it the best that I can design? the former, the "it-will-do-well-enough" standard prevails far too commonly, the latter is the only standard really worth working for, because the only one which will lead to attainments beyond mediocrity. Never, then, rest content with a plan until you are satisfied that it meets and fulfils all the requirements of the case, in the best and most complete manner that you can think of; the plan is the foundation of the whole design, and I need not say to architectural students that if the foundation is faulty, there is not much hope for the superstructure.

It may seem like insisting on an elementary truism to say that the plan of a building must necessarily be adapted to, and governed by, the exigencies of the site, but the not infrequent violation, or rather neglect, of so obvious a principle, justifies me in emphasising its importance. The peculiarities of a site in respect to levels and aspect frequently constitute difficulties that at first sight appear insurmountable, but out of which emanate in skillful hands the happiest results, which otherwise might not have been thought of, or attained. Herein is displayed the skill of the artist, to lay hold on all such adventitious circumstances and hindrances, and conform them to his will, translating obstacles into mediums for achieving success. The neglect of such opportunities is unpardonable, and betrays the bungler.

Prospect, again, constitutes an important factor in planning. When the right aspect presents the best views, the case is simple, but this is often not the case, and few conditions call for more ingenuity than when the proper aspect is at variance with the prospect that it is desirable to secure. In towns, indeed, aspect and prospect must necessarily, and to a great extent, be subordinated to immovable conditions, but in the country it is different. While, therefore, striving for comfort, convenience, and grace within, never neglect an opportunity of securing the inestimable attraction of a higher than any art loveliness, the prospect of nature and creation. In connexion with prospect let me in passing condemn a practice too much in vogue, the glazing of the upper portions of windows with tinted stained or painted glass, sometimes uglier than anything it is intended to obscure from view. Situated as we are in London, the expedient is, no doubt, attended with advantages, shutting out hideous objects which one's neighbours are so fond of obtruding, or excluding the impertinent gaze of the too curious; but in the country, where it is frequently adopted, what possible justification can be urged? Is it possible that anything can compensate for the light of the sun, the beauties of nature, or the marvels of the heavens? Never, then, attempt to obscure the contemplation of God's universe by the commonplaces of humanity.

I would say, further, that a plan to be good must be simple. No doubt the arrangement of some buildings is necessarily more elaborate than that of others; but you may take it as an unerring guide, that when you find a plan becoming complicated and confused, you are on the wrong tack. I have seen an artist, after hours of work, wipe from his canvas all he had painted, and then make a fresh start with manifest advantage and no real loss of time; so when your planning results in complication, your best course is ruthlessly to obliterate what you have done, and begin *de novo*. Nothing will compensate for the absence of simplicity in a plan. This is a golden test which I have never hesitated to apply, and I speak from no inconsiderable experience.

Illustrations.

OLD HOUSE, IPSWICH.

THIS house, which is known in the town as "the Ancient House," is one of those buildings which has passed through many hands, and has received great care from its various owners, who were all presumably wealthy men. Erected in Tudor times, it was added to and beautified in Elizabeth's reign, still further decorated in the Jacobean era, and shortly after the accession of Charles II. the magnificent pargetted front was added, and, finally, in Queen Anne's reign the front rooms on the ground floor were all redecored in the prevailing style of the time.

The principal front is towards the Butter Market, but it has also a return elevation to St. Stephen's-lane. The first floor consists of four large oriel windows to the Butter Market, and one on the return elevation to St. Stephen's-lane. These oriels sustain a wide projecting cornice, and between them are massive pilasters, all in plasterwork. Above the oriels, set back to wall line, are four dormer windows breaking out of the main roof.

Many years ago in one of the attics there was a portion of the roof space that had not been carefully investigated for a long space of time. It chanced, in 1801, that this was broken into, and the result was that a beautiful little single hammer-beam roof was revealed with carved arches and angels on the ends of the hammer-beams. On examination this proved to be the roof of a chapel or hall ceiled and floored over at the plate level, the main body being absorbed in the room below. The space covered by this roof was 23 ft. long by 15 ft. 7 in. wide, and the principals were three in number. This ancient relic gives us a clue to the probable age of the original structure, which was probably the residence of a wealthy man in the fifteenth century. The next addition seems to have been made in 1567, as in that year a certain George Copping and Elizabeth, his wife, caused a room on the ground-floor to be panelled out and inserted the date and their monograms in the mantel-piece. An open corridor with rooms over it, forming the wing before alluded to, in St. Stephen's-lane, was also added about this time.

In 1603 a room on the ground floor, away from the street, was panelled in oak whole height of the room, the beams were encased in panelling, and a gorgeous mantel-piece was put up, covering the end of the room entirely with the exception of two small doorways. This, presumably, the work of a man called John Sparrow, who owned the house at this time, and from whose family it derives the name of "Sparrow's House." The initials J. W. S. and the Sparrow arms, together with the date 1603, all appear on the mantel, and a representation of the arms is also repeated in the glass in the window, though this is evidently not in its original setting.

The treatment of the design is as follows:—On a brick base, some 4 ft. high, is placed an oak sill, into which are framed elaborately carved pilasters, 7 ft. 4 in. high, with Ionic caps, from which spring highly ornamental carved brackets carrying the overhang, the corner-post being similar in design to the pilasters, but on a larger scale, and placed anglewise. The overhang, which is very great, is still further emphasised by the projection of four oriel windows to the Butter Market and one to St. Stephen's-lane. Above the oriels runs a bold Classic cornice in wood, and over each oriel to the front is a dormer window lighting the attics, also enriched with pargetting. On the front faces of the oriels to Butter Market the four quarters of the globe are represented in high relief in parget, and the return oriel to the lane has Atlas supporting the world on its similar face. The curved sides of the oriels are decorated in scroll work and other devices. Under the upper cornice are swags composed severally of flowers, fruit, birds, fishes, and musical instruments. Between the two centre oriels is a panel containing the Royal Arms, with supporters and crest, and the letters C. H. R. (Charles II. Rex.). In the gables above are various Classic scenes and characters, and on the end gable St. George slaying the dragon, and Pheidias and Corydon below. The modelling is coarse, but the general effect is bold and striking. In the centre of the house is a courtyard, with some rich parget work depicting a triumphal procession on a gable face. Inside are several panelled

rooms and some highly ornate ceilings. The building is minutely described in Glyde's "Old Ipswich." JOHN S. CORDER.

ST. CUTHBERT'S COLLEGE, WORKSOP.

THE drawings show the southern front of the quadrangle and the southern side of the dining-hall of the buildings now in course of erection for a lower middle-class school in connection with Lancing and Denstone Colleges, corresponding with the schools at Ardingly and Ellesmere.

The college is founded by the Provost and Fellows of Denstone College as a public school for 500 boys, to be boarded and educated at a cost of less than twenty guineas a-year, and the buildings are being erected under the College Architects, Mr. R. Herbert Carpenter and Mr. B. Ingelow, of London. The site, of ninety-three acres, given by the Duke of Newcastle, commands the Clumber Woods on the south, and the Priory Church and town of Worksop to the north-west, with the Yorkshire hills beyond. In addition to his gift, the Duke has formed and planted the roads and grounds.

Excepting the chapel and dining-hall with its offices, the buildings are arranged round a quadrangle, 170 ft. square, of which the school-room and class-rooms occupy the north side; and dormitories, day-rooms, masters' rooms, &c., for 200 boys on each of the side wings, with dormitories, associates' rooms, &c., in the southern front building, the headmaster's house being at the south-west angle. The chapel is to the north-east, and the dining-hall (and offices, laundry, &c.) to the north-west of the great quadrangle. The chapel, exclusive of the ante-chapel, will be 140 ft. long by 40 ft. wide; the hall, 120 ft. by 36 ft.; the school-room, 100 ft. by 36 ft.

The buildings are faced with Nottingham bricks, which are also used for mouldings. The dressings are of Kiveton Park (Anstone) stone. The principal rooms and the cloister, which is on the inner side of the quadrangle, are faced with similar bricks, while Lincoln bricks are used for the inner walls.

The contract for a great part of the superstructure is taken (in divisions) by Mr. Vickers, of Nottingham, the foundations having been put in by Mr. Dentley, of Waltham Abbey. The architects' clerk of the works is Mr. F. E. Smith.

The elevations are from drawings exhibited at the Royal Academy of 1891.

MISSION CHURCH AND HALL, CANTERBURY-ROAD, S.E.

THIS building, the drawing of which was in last year's Academy, has been erected for the Mission at Camberwell in connexion with Corpus Christi College, Cambridge. It is a building of two floors, baving on the ground floor a large hall with glazed brick dado, 5 ft. high all round, and a platform at one end, kitchen, heating-chamber, &c., and a distinct entrance to the hall from the street. On the first floor, approached by two wide stone staircases, with separate entrances to the church, capable of seating about 400 people, with chancel, organ-chamber, and vestries. The exterior is faced with red brick, and has stone dressings with traceried windows to the chancel of the church. All floors are fireproof, and the heating has been carried out on Grundy's Hot-air System. The cost of the buildings was nearly 5,000. The architect is Mr. Richard J. Lovell, of London, who was also the architect of Holy Trinity Church and buildings, Old Nichol-street, Shore-ditch, completed some little time ago, and originally built in connexion with Magdalene College, Oxford Mission, but now used and consecrated for a parish church.

NEW MINERAL-WATER WORKS AT COLWALL, NEAR MALVERN, FOR J. SCHWEPPE & CO., LIMITED.

THIS building, which is now nearing completion, is being erected for the Directors of J. Schweppe & Co., Limited, for the manufacture of their mineral waters.

It is placed at the foot of the Malvern hills, close to the Great Western line, and adjoins Colwall station, in the midst of some of the most beautiful scenery of the west of England, and considerable trouble has been taken to make the building harmonise with its beautiful setting, the usually more or less hideous "factory" features having been so toned down

and metamorphosed as to be quite unobjectionable.

The building, which forms the nucleus merely of a much larger establishment proposed in the future, consists of a manufactory, with packing, unpacking rooms, store-rooms, carpenters' shop, engine-room, boiler-house, &c., and is of red local bricks, with Bath stone dressings, roofed with Broseley tiles; the internal paving is being carried out by Stuart's Granolithic Company; the ornamental ironwork by Messrs. Braun, of Birmingham; the cranes and hoists by Mr. Stannah; and the boilers, engine, &c., by the Riley Manufacturing Company, of Lambeth. The contractors for the whole are Messrs. Josh. Wood & Son, of Worcester. The architects are Messrs. Truefitt & Truefitt, of London.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

(Continued from page 73.)

Again, a plan is only good when it is the embodiment of thrift. Much has been said, and more has been written, on the moral aspect of thrift, and it would be easy to enlarge on the advantages of its application, not merely to the life, but also to the artistic work of the student of architecture. I must, however, be content for the present to deal with it in its relation to my subject, and to show that without thrift, both of space and material, a plan cannot properly fulfil its purpose. Thrift is not parsimony, any more than liberality is waste. Each space in a plan, be it room, hall, stair, or passage, should be just the size that is necessary for its purpose; if it be less, there is parsimony, for what is inadequate will have to be enlarged hereafter at much more than what would have been the original cost; if it be more, there is waste, for it has involved the expenditure of more capital than was required, and will incur needless labour and consequent cost in maintenance. Take, as an illustration, a room which has been designed on a scale beyond the necessities of its occupants; it is obvious that it has cost more to build and furnish than it should have done, and involves a perpetual cost for maintenance and service, which should have been avoided; hence the happy medium is to be found in thrift. So in respect to materials; walls should be of sufficient thickness, floors and roofs of sufficient strength for their respective functions, not much more, and not much less; else there will ensue, either waste in the first instance, or parsimony, which will involve waste in the long-run. There are, however, cases in which materials should not be too sparingly employed; in a mansion, for example, intended to be a family home, and to pass from generation to generation, it would be unwise, and out of keeping with its purpose, to apply too literally such a condition as this; for nothing imparts more dignity and a greater idea of the enduring purpose for which such an edifice is designed than massive walls, thicker no doubt than may be actually required for sound construction, but not more than is called for in order to be in harmony with the traditions and associations that the structure will represent. This, however, is but one of those exceptions that prove the rule of thrift which I have enforced. I am, of course, not unprepared for the inevitable protest of the art-student, who in a burst of aesthetic enthusiasm will denounce the suggestion that so prosaic a quality as thrift should dare to enter the hallowed sanctuary of the art studio; but while entertaining much sympathy with the enthusiasm of youth, and by no means desiring to curb it, and while respecting opinions which I doubt not are perfectly genuine, I venture to think that it would be easy to demonstrate that it would be in the true interest of art, were her portals more frequently and more hospitably thrown open for the admission and entertainment of the prosaic maiden I have introduced to your notice. How often, for instance, might she, with manifest advantage, restrain the artist hand in scattering with inartistic profusion ornament which is misplaced and therefore ineffective? But to enter on such matters would be to deal with other branches of the architect's studies, and be foreign to my present purpose.

I need not detain you by enumerating conditions, more or less obvious, each one of which contributes in its place to the merit of a plan. Apart from considerations of aspect, prospect, and dimensions, each place should be—not only

convenient in itself—but should he in its proper position in relation to other places; the work of an establishment, as well as the cost, may be materially diminished or increased, according as this condition is observed or neglected. Doors, windows, fireplaces, should be arranged so as at once to promote comfort and convenience without needlessly destroying wall-space, or incurring draughts; the amount of window-space should be regulated according to the aspect; and many other considerations of a similar nature should be duly thought of; in short, the perfect plan is, and can only be, the result of the thoughtful study of each principle and every detail: none are too minute to be overlooked: as little things sweeten life, so attention to little details makes a plan complete.

I have written to little purpose if I have not convinced you that planning is one of the most important, difficult, and artistic studies of the architect.

Now let me inquire why it is that plans are so frequently had. I am aware that there are men in the profession who are adepts in planning, and whose productions in this respect we admire. But are they the majority? Rather, I fear, will they be found to be the small minority. Rarely do I examine published plans without detecting faults which are obviously not the necessary outcome of the circumstances. Why is this? In the majority of cases it does not, I believe, arise from lack of ability on the part of the author, but from the neglect to apply the ability he possesses to the working out of a good plan. Where plans are had, they are so from two causes. 1. It is impossible to produce a satisfactory result without practical knowledge of the requirements; in the case of a gentleman's house, for example, how can we expect to succeed without being familiar with the nature and working of the establishment? 2. Plans are had because they are not studied as they should be; I am satisfied that there are many practising architects who have never realised the true nobility of planning, who have never experienced the fascination of the almost exhaustless field it presents for the display of imaginative artistic skill, and who consequently have concentrated their artistic powers in the design of the elevation. Need I guard myself from possible misconception by adding that not one word I have written is intended to militate against the importance of artistic design as applied to the elevation? My subject is Planning, and my remarks naturally apply specially to it. Moreover, architects are not likely to regard the design of the elevation as the least artistic portion of their work, and it is because I entertain the conviction, judging from results, that they do far too much regard the design of the plan in that light, that I have emphasised its artistic character.

The architecture of the future will derive its character, and find its development, from the students of to-day; hence I have been tempted to embrace this opportunity to bring specially before you the subject of planning, believing that those who undervalue it do so because they have not studied it and tasted its fascination, and in the conviction that there is no more useful as well as artistic study in which you can engage. Remember that the subject vitally affects you who are devoting your lives to the study of architecture, and that your treatment of it will still more vitally affect those for whom, by and by, you will be called on to design; nothing will so certainly secure for you their grateful blessing as to promote the comfort, convenience, and beauty of their homes, for on nothing does the daily happiness of civilised society so greatly depend. If I have succeeded in elevating the study and lifting it out of the prosaic level from which it is too generally regarded; if I have inspired in any of you, whom it is my privilege to address, the determination to throw yourselves into it with an enthusiasm which you may not hitherto have displayed; if I have thus, through influencing you, sowed seed which will fructify for the benefit of succeeding generations; if I have demonstrated that in this study is to be found one of the most interesting, fascinating, and artistic pursuits, the time will not have been mispent which we have this evening devoted to the consideration of the Art of Planning.

On the conclusion of his address, the President stated that he had originally intended to embody in it some critical observations of the prize drawings; but in consequence of illness

he had been unable to do so. Mr. Aston Webb, however, had been kind enough to prepare some critical remarks with regard to the drawings, which he would now call upon him to read.

A REVIEW OF THE STUDENTS' WORK.

Mr. Aston Webb, before reading his criticism of the various drawings which had been submitted, said that he was sure they must all feel delighted to have their President back in his accustomed place that evening. He was sorry that, under the circumstances, it had fallen to him (the speaker) to read the notes instead of the President. He continued as follows:—It has been usual year by year for the Institute to publish in its *Proceedings* a more or less critical notice of the designs submitted for the various medals and prizes annually offered in competition by this Institute, and it has been thought that it might interest our students if I were to put down, as your Honorary Secretary, a few notes on the designs and drawings submitted this year. In doing so, I shall address myself to the students, and especially to those who are intending to compete in future years, and if what I say has been often said before, this is my excuse for it. The prizes which are offered by the Institute are for,—1. Original architectural designs. 2. Designs in which construction is the principal problem. 3. Drawings of old work on given subjects and written essays.

Pugin Studentship and Institute Silver Medal.—I will take the drawings of old work first, for which are offered the Pugin Studentship and Institute Silver Medal, and before noticing the drawings sent I should like to say a word on the sketching of old work generally. This sketching may be of the greatest use to you hereafter, or it may be absolutely useless; you must sketch with your head as well as your hand, as Mr. Waterhouse said in one of his addresses; do not lay by too many pretty sketches to be shown to admiring relations and friends, for if they are of such general interest you may be pretty sure they are of no practical value. I believe you learn far more by measuring thoroughly a well-designed, moderate-sized church, a single bay of a cathedral, or a complete portion of any other good building plan, elevation, section, and details, and by trying to understand what were the difficulties of the designer and how they were met, than by any number of sketches of pretty bits. Not that I mean for a moment to underrate the importance of detail,—it is, of course, the essence of design; but many of the sketches one sees are valueless without some figured data of the position in which they occur. When you sketch an arcade, make a plan, however rough, with figured dimensions of the width of nave and aisle, and heights of both; if you sketch carving, note the height from ground and the scale of the work around; above all things, learn to appreciate scale and dimensions,—a difficult thing to do, no doubt. In sketching a roof, make a note of the main scantlings and a window, the size of mullions, widths of lights, thickness of wall, height from ground of the sill, and so on; this seems a mere truism, yet it is often absent, even in the drawings here. It is not necessary that all your drawings should be geometrical ones, but do not be afraid of disfiguring your sketches with a few main dimensions: it will add to their value. The late Mr. Street's sketches were models in this respect, as in so many others. Try and realise the scale and dimensions of things, how they were designed for their respective positions; and so, when the time comes to turn your own ideas into stone, you may be able to realise your own ideas, and know beforehand what will be the result of the work you will produce so sanguinely at your drawing-board. If you do not do this, disappointment and discouragement only await you. Remember most can appreciate the effect of work when executed; it is for an architect to appreciate its effect in an earlier stage when it is on paper only. But to turn to the drawings.

For the "Pugin" this year five sets of drawings have been submitted, the Studentship being awarded to Detmar J. Blow, his principal contribution being plans, sections to $\frac{1}{2}$ -in. scale, and full-size details of the choir aisle of Beauvais Cathedral, a case in point of what I have just said, for I am sure Mr. Blow would tell you how much benefit he has gained by this sound and solid work. Perhaps more time than necessary has been spent in shading and tinting these geometrical drawings, though one is unwilling even to suggest an objection to the

means employed in obtaining so excellent a result.

The portions of Barfreston Church are also most thorough and careful; while the coloured sketches show much appreciation of tone and colour, and make us look forward with interest to the result of Mr. Blow's tour next summer.

Another beautiful set of drawings for the same prize are those by Charles A. Nicholson. He sends a particularly able set of interiors, drawn firmly in pencil and well selected; particularly one may mention the Lady-chapel of Long Melford, a perfect little building, and the church at Tilney All Saints; but how much a rough figured section would add to the value of these. The stalls of the choir of Lincoln is another interesting sketch, and the two roofs of St. Stephen's, Norwich, and Wymondham Church, are as well sketched as could be. From these sketches there can be no doubt we shall hear of Mr. Nicholson again.

In quite a different manner are the drawings submitted by Mr. C. R. McIntosh; particularly admirable being his pencil-drawings of Italian Renaissance work,—holy water stoups, torch-holders, &c. The coloured sketches of the Certosa of Pavia are also very delicate and full of feeling, though their effect, I venture to think, is rather interfered with by the exaggerated blue of the shadows. I am also a little doubtful whether the manner of mounting has been the best for drawings of such delicacy.

E. S. Cummings sends another good set. The drawings are wonderfully neat and clean specimens of pencil-work, though I would suggest to Mr. Cummings not to carry the dot-and-spot manner too far; it is very effective as shown in his drawings, and it is pleasant enough to play with, I know, but it is dangerous, and I am afraid leads nowhere. Mr. Cummings, I think, has carried it as far as it ought to go, if not a little farther. The shaded details of carving in the Lady-chapel at Ely are charming, and in quite another manner, though perhaps a trifle overworked.

Percy D. Smith sends some interesting bits, but largely taken from work somewhat later in character than is intended for the study by competitors for the "Pugin," which they should do well to remember was founded for the study of that Gothic architecture which was so much admired and understood by the man in whose memory this studentship was founded.

After the "Pugin" drawings we come to those submitted as the result of his Pugin tour by S. K. Greenslade, the Pugin Student of last year. These are all good, and should be very satisfactory to those who took part in founding this studentship, many of whom are still amongst us. Here is a carefully-measured bay of the Presbytery of Lincoln, plan, section, internal and external elevation. Mr. Greenslade not only knows how to draw, but knows how to select the subjects to be drawn. There is a capital sketch of St. Peter Mancroft, east front, which I missed when I was there. There is a view across the nave at Lincoln showing the Lady Chapel, in which, however, one misses a plan, and many others equally good. Mr. Greenslade appears a giant for work, and has attacked no less than four cathedrals,—Ely, Lincoln, Norwich, and Exeter,—in this single tour, to say nothing of smaller churches such as St. Peter Mancroft and others; dimensions are abundantly sprinkled over these drawings, and add greatly to the value of them.

The other competition for drawings of old work is the Institute Silver Medal, which has been obtained by R. S. Balfour for a very complete set of drawings of Heriot's Hospital, Edinburgh, shown by plans, elevations, sections, perspective internal details, and mouldings to a large scale.

Percy D. Smith obtains a Medal of Merit for a careful, if rather hard, set of drawings of the magnificent Salisbury Chantry at Christchurch, erected at that interesting period when a Gothic architect was yielding to the handshakes of the Italian Renaissance. A chapel of St. Mary, Chichester, appears a most interesting building, though, again, one misses a plan; a sketch of the slightest character would have been welcome.

"Pollux" sends a thoroughly careful and complete set of drawings of Castor Church, Peterborough.

The next set of prizes are those offered for original design, and while in the previous sets of drawings we find the power of draughtsmanship fully developed, the power of design is of slower growth and not developed to the same extent. Remember in these competitions it

becomes a matter of far more importance than you show than bow you show it, and though draughtsmanship may greatly help a design, it cannot convert a bad into a good one. A carefully thought-out design will stand a better chance of success than one less considered, however elaborately worked up, and it may be useful to remind intending competitors of the clause in the conditions, "the geometrical drawings must be in outline, with the openings and sectional parts alone tinted in monochrome or hatched." This is intended to exclude shading or etching, but not of course stone-jointing.

The Essay Medal.—Five essays were received, the prize being awarded to "Veritas filia temporis" (Chas. E. Sayer). I have not read these myself, but the judges have done so most carefully, and I believe had no difficulty in coming to the decision they did.

The Essay Ignigenus (Richard Glazier) is very beautifully illustrated, but I understand the judges consider these essays show a tendency to become too much a mere catalogue of the illustrations, whereas literary power and merit is what is primarily intended to be rewarded in this prize.

The Soane Medallion.—This prize is now the most valuable one offered by the Institute, and open to all British subjects under thirty years of age. The amount has this year been increased from 50% to 100%, and the subject given was a severe one. A chapter-house to a cathedral, plans, section, and elevation to quarter scale, with full-size details, and an exterior perspective. The labour thus entailed was considerable, and I have known of more than one who relinquished the task. Eight, however, have sent in designs which show a great deal of honest hard study and work. Two were so equal that the judges had considerable difficulty in placing one first, but, as you are aware, they finally placed "Abbotsbury" (Heber Rimmer) first, and "Red Cherub" (John Begg) second.

In considering the designs for a chapter-house one naturally turns to those in our own cathedral establishments, where we find the general form is octagonal, though by no means necessarily so. Canterbury and Ely and Norwich (before it was destroyed) had chapter-houses, parallelograms on plan, while that at Lichfield is an irregular octagon. The grouping of most is supported by a central column and as a rule they are level, or nearly so, with the cloister, though Westminster Abbey and Wells are well-known exceptions.

Of the eight designs submitted four are octagonal, three are hexagonal, and one is more or less of a parallelogram. Several provide an ambulatory round the outside between the buttresses, which appears to have no particular use beyond extending the cloisters, and adding, as it undoubtedly does, to the picturesqueness of the exterior.

The design marked "Abbotsbury," to which the Soane Medallion has been awarded, is shown in an admirably worked-out set designed in a Late Decorated style. An octagonal building is raised some 8 ft. above the cloister level, is surrounded by an ambulatory at the cloister level, out of which open recesses which in any other position would have been chapels. The appearance of the exterior as seen in elevation is almost that of the apse of a great church. It is placed on the summit of a rocky eminence, which makes me regret that it does not grow out of its foundation more as the buildings do at Mont St. Michel; for instance, the perspective as shown could only have been taken from a similar rocky eminence adjoining, and the building hardly has the appearance of being designed for an unusual site such as this. The interior is vaulted without the aid of a central column, but a pendentive common in fan-vaulting is suspended from the centre, which I venture to think would have been better omitted, as it seems to suggest a central column which was afterwards thought better of.

Though the chapter-house is raised, no crypt is shown under, and which crypt, owing to the ambulatory, would have been in perfect darkness. The entrance to the chapter-house is very dignified and noble, and the whole design shows a good knowledge of the capabilities and treatment of Gothic work, and is most conscientiously worked out, though the detail hardly comes up to the small-scale drawings.

The design marked "Red Cherub" (John Begg), to whom a Medal of Merit has been awarded, is hexagonal on plan, with a central shaft, the style being a Late Perpendicular. A narrow pas-

sage here runs round outside the chapter-house, which appears to me needless, though it makes a very picturesque feature in the view, with its square little windows between the buttresses. The perspective is very well drawn, and cleanly washed in in monotone. A feature in the exterior has been made of the disposal of the water from the roof through and down the face of the buttresses, finally being discharged into the open by gargoyles,—a method which, if I am right in understanding it, would not be very dignified, nor, I think, an advisable way of disposing of the water from the roof. I am aware flying buttresses over aisle roofs were used in this way, but this is hardly a case in point. The great vault of the chapter-house is elliptical, and does not reach within 8 ft. of the tie-beams of the roof over; this space is, therefore, wasted, and would have better been thrown into the chapter-house. An elaborate timber roof is shown over, which might well have derived some support from the cloister. The sections of the entrance from the cloister are admirably drawn, and show much knowledge of Gothic,—as, indeed, does the whole design. As I am criticising, I should doubt the good effect of the hexagonal form, and wish the tracery and mullions were thicker and the horizontal division of the lights different; in the perspective the lights in the windows nearest the buttress in high light are in each case darkened, apparently for the purpose of throwing up the buttress, but the effect cannot, I take it, be natural, or therefore proper.

Another very interesting design is submitted under the motto "Sun"; this, again, is hexagonal on plan and treated in a later manner. The centre space is covered with a cupola, the centres of support to which are shifted from the angles of the hexagon to the centres of the sides, the small spandrel spaces thus formed outside the cupola being stone-vaulted in the usual manner, the cupola itself being left perfectly plain, no doubt for decoration. This is an ingenious arrangement, and would, I think, look well, the objection being that the weight of the cupola is thrown off the angle buttresses, which would probably be strong enough, to the intermediate ones, which would not. This cupola forms the actual roof of the building, with no other external covering. Had the author heard Mr. Somers Clarke's paper on Seville Cathedral, which was treated somewhat in this way, he would probably have thought better of this. In this country a further difficulty would arise, inasmuch that when the building was heated the condensation would make it practically uninhabitable. On the exterior the want of a roof is much missed. The arrangement of entrance and steps is charming, though it hardly grows out of the requirements; but the whole design shows great originality and power of treatment, and we shall look forward to further work from the same hand with interest and expectation.

"Volunteer" sends a Renaissance design octagonal on plan, surrounded by buildings some 20 ft. wide, used partly as a library, and which would cut off far more of the chapter-house than shown on the perspective; the lighting is deficient, the central eye with a cupola over it being of little use for this purpose. I think also if the author had considerably increased the height of this chapter-house he would have added much to its effect in the interior and exterior.

"Byzantium" sends a clever design, but from the colour of the sky in the perspective it is presumably not to be erected in England. The author could, I think, hardly have expected to carry off the prize with this design; it undoubtedly has good points in its particular style, and the perspective is well and powerfully coloured, but the immense labour spent in etching up the sections and plan, which is contrary to the rules as I read them, might certainly have been better employed.

"Blue Griffin in Circle." A clever Renaissance design, octagonal on plan, covered internally with a plain vault, with suggested decoration most admirably shown. A very well-tinted perspective shows the exterior, but the parapet and niches externally are, perhaps, rather restless, and the detail hardly comes up to the rest of the work.

"Ex Cathedral" has not been afraid of plenty of wall-space—a good feature—but the decorative portions might have been more studied. A very good internal feature, as it seemed to me, is a gallery running round, which would be very effective, and might be useful on occasions.

"Plume," another hexagonal plan, has a cleverly-treated exterior, shown in a powerfully-drawn perspective. The triangular buttresses, with their arch moulds dying upon them, might be made a very effective feature, and the parapet without a cornice below it is a novelty. The detail shows profiles only.

"Anno 1891." A very good design, admirably worked out; and, with some of the labour spent on the design which has been spent on the perspective, it might have become one of the best in the room. I don't feel equal to say anything about the perspective. It is clever, no doubt, but that sort of thing has been done before. If the author contemplates another such, and would take my advice, I should certainly say "Don't." The motto of "Anno 1891" on such a drawing is out of place; it is at least 500 years before that.

The Title Prize.—A design "For a Church Steeple," according to the principles of Bramante, Palladio, or Sir William Chambers. Four designs were sent in for this, and the prize has been awarded to "Red Lion" (T. R. Kiteell) for a very good design after the manner of Wren or Chambers, Bow Church in Cheap-side, apparently, being the model. The perspective hardly does justice to this design. The detail is strongly drawn, and with great feeling. The section is careful and interesting, but hardly satisfactory constructionally. There are no less than four complete stone cupolas to carry the various stages, and these in many cases are heavily weighted, while I do not see any ties to take the thrust. I took the opportunity, through the kindness of the architect, Mr. Innes, to go up the Bow Tower the other day, and I should strongly recommend Mr. Kiteell and all students to take the opportunity of an Association visit to inspect it. This spire, as all know, is constructed on a single elongated cone most securely tied to the springing. The whole is a splendid piece of work, composed entirely of Wren's favourite materials, Portland stone and English oak, easy of access throughout, and perfectly sound.

"Ashlar" is another Wren or Chambers design. The circular spire is very small, increasing the difficulty of construction, and requiring stronger terminals than are shown at the angles.

"Quis" is a carefully-drawn design, but the subject is rather beyond the candidate's power. He requires a greater knowledge of detail, and will no doubt do better another time.

"Design in a Circle" is a capital Renaissance design, reminding one somewhat of St. Mark's, Venice, presumably after Bramante, and shown in a well and firmly-drawn perspective. The figure drawing is first-rate throughout. The detail is disappointing, probably through want of time. For the safety of the structure I should say the bells are hung too high.

The Grissell Gold Medal.—Three sets of drawings were submitted for a "Stone Railway Bridge," the prize being gained by "Jacta est alea" (Harold Harlock) for a design admirable in its simplicity, as such a structure should be. The calculations are carefully gone into, and the judges had no difficulty in awarding the prize.

"Equilibrium" is another simple and very good design; but in order to maintain its motto, the foundations even if on rock should surely go down below the river bed.

"Fundamentum forte opus sustinet" is a good design spoilt by unnecessary abutments at the springings of the arch, which could be no use, and interfere with the continuous intrados of the arch, which should be naturally the most-effective feature of the design.

The Masonry Prize.—The judge here had no hesitation in awarding the prize to "Saxum" for his drawing and model, which he states are admirable, and show a perfect knowledge of the subject; "Voussoir" is also very carefully worked out.

The Godwin Bursary.—Four applications for this were received, Mr. T. Locke Worthington being successful. I may give students a hint that, in applying for this, which they would do beforehand to consider carefully the subject they propose to take up if successful, and then to show that they have prepared themselves by preliminary study to take advantage of what they may see abroad in connexion with the subject; foreign travel without preliminary study is of little worth.

I have now been through (very imperfectly, I am afraid) all the work submitted this year. I think the Institute may be proud of it, and probably those who have not got prizes would

be the first to admit they have got much benefit by the work. It would have been a more congenial task to me to have pointed out only the merits of these drawings, but I suppose a critic's duty is to criticise. I have spent a good deal of time among these drawings, and am much impressed with the ability shown in practically all of them.

In a short time the competitors will be competing in a still more important sphere, and either encumbering or beautifying the face of this fair world of ours with their buildings. If the promise of their draughtsmanship of to-day is fulfilled in their buildings of to-morrow, we may be very hopeful of the architecture which is yet to come.

The President said they would all agree with him in thanking Mr. Webb for the admirably exhaustive and critical notes which he had made upon the competition drawings. Those criticisms would be particularly useful because they referred not only to the drawings submitted by prize winners, but to the other drawings submitted. He had listened with great interest to the remarks made by Mr. Webb, and he would recommend the students to take them to heart. Friendly criticism was always valuable, especially when coming from one so competent to offer it.

Mr. John Slater, in proposing a vote of thanks to the President for his address, said that while they must all agree with the remarks made by the President concerning Mr. Webb's criticisms of the drawings, they must also acknowledge the merit of the President's own address. He was sure that they must all have been impressed by what the President had said as to the art of planning, and if those who were present that evening were to take to heart what he had said, it would be to their advantage in the future.

Mr. Charles Barry, in seconding the vote of thanks, said that the President's address was made to students, but he thought it contained some excellent advice which would appeal to those who, perhaps, like himself, no longer thought they were students, although, in point of fact, there was no time in the life and practice of an architect at which a man was not a student. In that sense the address would be of value to them all. He had been interested in hearing the catalogue of subjects which the President had given them, the study of which was to give them relief in their occupations; but the President had omitted one subject which was of great interest, viz., the study of the characters of clients, both single and corporate. He would strongly recommend them not to neglect that form of diversion. Diversion of that kind was frequently very necessary. The President had, he was sure, every reason to believe that planning was an art, for it was well known to most of them that the plans which had emanated from his hand, as well as from the hand of his old master Mr. Barr, were models of the most careful study of adaptability to the purposes concerned. He thought they must all feel the force of the President's observation that no man could make a good plan without picturing in his mind what the elevation would be and what the character would be, and without regarding its adaptability to the purpose for which it is intended.

Mr. Slater then put the vote of thanks, which was unanimously agreed to.

The President, in acknowledging the vote, said, in reference to Mr. Barry's remark about the study of character, important and interesting as that study was, and although some part of an architect's success depended upon the tact which was displayed in dealing with clients, still it was hardly a matter which formed part of the subject of planning. If he had lifted the idea of planning out of the too prosaic level in which it was too generally placed, and if he had led any of them to regard it as an artistic study, he was much more than rewarded for the time which he had devoted to his address.

The President then proceeded to present the prizes for 1892, a list of which appeared in the *Builder* last week, page 59.

The meeting then terminated.

LIFT AT THE METROPOLITAN TABERNACLE.—A hydraulic lift is to be fitted up at the Metropolitan Tabernacle to take Mr. Spurgeon from the yard up to his Vestry or down into the Lecture Hall. Messrs. Easton & Anderson, Ltd., are constructing the lift, which, it is stated, will be the first lift ever erected in a place of worship, at any rate in this country.

ARCHITECTURAL SOCIETIES.

BIRMINGHAM ARCHITECTURAL ASSOCIATION. On the 19th inst., a paper entitled "Four Suffolk Churches" was read before this Association by Mr. Paul Waterhouse, A.R.I.B.A. The churches dealt with by the lecturer were those of Southwold, Blythburgh, Covehithe, and Walberswick, of which the two latter are for the greater part in ruins. Mr. Waterhouse detailed something of the history, characteristics, and present state of these churches, and dwelt on the marked peculiarities which emphasise the church work of the particular period and locality represented by them. The lecture was illustrated by photographs, and by sketches, mostly the work of the author, though some were by Mrs. Paul Waterhouse. In explanation of the building methods of the early fifteenth-century, quotations were made from Gardner's "Danwich" (published in 1735), which preserved, among other miscellaneous information on the buildings of the neighbourhood, a *verbatim* copy of the contract for building Walberswick Church, bearing date "the fourth yeere of King Henry the Sixte." The lecturer pointed out as two prominent features of the procedure of the time, the absence of an architect and the explicit directions that the various details of the design were to be imitated from such points as were most admired in the then existing churches of the neighbourhood. Mr. Waterhouse dwelt on the terrible architectural results of the Cromwellian iconoclastic fury, which was particularly savage in the Eastern Counties, and concluded his paper with an imaginary picture of the glories which must have existed before the destruction of those days. In proposing a vote of thanks to Mr. Waterhouse for his able paper, Mr. W. H. Bidlake said that the county in which the churches described lay was one which, from its historical associations and from the fact that it was a county which had, from being the seat of a wealthy commerce, become the scene of agricultural pursuits, appealed strongly to the imagination. The severe outlines of the churches of the Eastern Counties appeared to him particularly impressive, standing, as they did, in the wide, flat lands of the district, and the churches had great apparent stability, notwithstanding the weakness caused in appearance by the almost continuous clearstory windows. The vote of thanks was seconded by Mr. Donleedy, and supported by Mr. F. Barry Peacock (Vice-president), Mr. W. Hawley Lloyd, and others, and was unanimously passed.

CARLISE ASSOCIATION OF ARCHITECTS, ENGINEERS, AND SURVEYORS.—The usual fortnightly meeting of this Association was held on January 12, when Mr. J. Rush Dixon, C.E., of the City Surveyor's Department, read a paper on "Road and Street Formation." The laying out and various modes of formation of streets, with their footways, kerbs, channels, and carriageways were fully described. The lecturer also gave a specification of the materials and formation of footways of gravel, tar, asphalt, cement, brick, and flagging, and of carriageways by macadam, tar-paving, asphalt, concrete, and stone-pitched pavements. The advantages, durability, cost, and disadvantage in each system were given, and the various thickness of material illustrated by drawings.

GLASGOW ARCHITECTURAL ASSOCIATION.—The usual monthly meeting of this Society was held on the 19th inst., when a paper on "Electric Lighting" was read by Mr. Alexander, electrical engineer. After an introductory notice of the extraordinary development within the last few years of the practical application of electricity to lighting, a short history of the first discoveries by Davis and Faraday was given. From laboratory to workshop he passed, and described the varieties of dynamos. The measurement of the force transmitted from producer to consumer was of the greatest commercial importance; this was described, and also the safeguard against fire or dangerous shock afforded by means of fuses that readily melt and at once cut off connexion upon any dangerous increase of electrical power. The three-wire system, by which the public will be supplied from the Corporation central stations, was described. Finally, a specification was given of the requirements in appliances of a private house having 100 lights, with the approximate cost. Throughout the lecture experiments were made, apparatus and specially-prepared diagrams being shown; and at its close a hearty vote of thanks was awarded to Mr. Alexander.

—The following resolution ament the proposed Buildings Regulation Bill was then submitted as the outcome of a special meeting held last month, and revised by committee:—"The Glasgow Architectural Association, having considered the draft of the Glasgow Buildings Bill, while approving of its general purpose, believe that many of its provisions are inimical to the interests of architecture in Glasgow, and consider that a number of the by-laws in the schedule annexed to the Bill are most unpractical and unscientific in their relation to building construction; also, that it is very undesirable to promote any new Building Act which maintains the unskilled character and empirical procedure of the Dean of Guild Court, and does not provide for some form of control by qualified District Surveyors or otherwise, and for appeal in certain matters to a skilled and competent tribunal." The resolution, having been duly moved and seconded, was unanimously carried.

LIVERPOOL ARCHITECTURAL SOCIETY.—On the 25th inst., at the meeting of the Liverpool Architectural Society, in the Royal Institution, the Rev. F. F. Grensted delivered the third lecture of his series on "Egypt, the Home of the Early Arts," and dealt with the rise of civilisation in Babylonia, showing by some interesting photographs of sculptural remains that the great characteristics of the people were pride, war, and field sports.

NORTHERN ARCHITECTURAL ASSOCIATION STUDENTS' SKETCHING CLUB.—The second annual social gathering and exhibition of sketches of this club, was held on Monday evening last, when eighty or ninety members and friends were present. The exhibition included the work done by members at the fortnightly excursions, and Mr. C. Spooner kindly lent his Royal Academy Studentship drawings, which were greatly admired by those present. The President, Mr. W. S. Hicks, in opening the proceedings, congratulated the members on their work during the past year and his compliments were endorsed by Mr. Archibald Dunn. A programme of vocal and instrumental music was given by the members and their friends.

THE ARCHITECTURAL ASSOCIATION (DISCUSSION SECTION).—The last meeting of this section was held on the 20th inst., when Mr. A. H. Clark read a paper on "English Spires," dealing principally with their various forms and æsthetic qualities. The special visitor for the evening was Mr. Philip J. Marvin, who, having had unusual facilities for studying the actual erection of spires, was able to give some most useful information. The paper was well illustrated by Mr. Clark's own sketches, principally from that county of spires—Northamptonshire.

THE LONDON COUNTY COUNCIL.

The usual weekly meeting of this Council was held on Tuesday afternoon last, the Chairman, Sir John Lubbock, presiding.

Mode of Repayment for Local Loans.—The greater part of the meeting was occupied in the discussion of the following report of the General Purposes Committee as to the mode of repayment for local loans:—

"We have had under consideration the question as to the mode in which loans advanced by the Council to local bodies should be repaid. The Council is aware that as a rule the loans advanced by the late Board and the Council to Vestries and District Boards are repayable by equal annual instalments of principal, and the interest quarterly on the amount outstanding. The loans vary in period of repayment from 5 to 15 years for paving, 20 to 30 for works and buildings, and 60 years, or approaching thereto, for land and improvements to streets and bridges. This mode of repayment provides that in cases where there is the least outlay for repair and maintenance (*i.e.*, at the commencement of the loan), the work having but just been completed, there shall be the largest payment of principal and interest together, and the smallest at the end of the term, when the cost for repair and maintenance is necessarily increased, the two thus fairly balancing each other. In addition however to this, the payment of the interest quarterly provides the means to meet the quarterly payment of dividends on the Council's stock, which, when not thus provided, have to be obtained temporarily from other sources.

As regards loans to Guardians, whose power to borrow does not extend beyond 30 years, the case is different. The Metropolitan Board was first authorised to advance these loans by the Loans Act of 1875, and in 1876 the Local Government Board was requested by the Guardians of St. Marylebone to obtain the sanction of Parliament

to an extension of the period for loans to Guardians. The Local Government Board did not deem this course expedient, but desired the late Board to meet the case by allowing Guardians borrowing them to repay their loans by way of annuity. To this the Board assented, and the loans for new workhouses or new additions have been made repayable by the annuity system, when sanctioned by the Local Government Board, ever since.

Having regard to the near dissolution of the Council, we do not think it desirable that the course hitherto followed should be altered, nor that it should be the rule to make loans, for whatever period of currency, repayable on the annuity principle; but that they should be repaid on the lines previously stated. We think also that it would be well to settle the question, and we therefore recommend the Council to pass the following resolution—

"That the terms as to repayment on which loans were made prior to December 15 shall remain unchanged during the remainder of the Council's term of office."

Mr. Campbell moved, as an amendment, "That the Council, under the circumstances, holds it inadvisable to pass any general resolution on the subject, and is of opinion that each application for a loan should be considered and decided on its own merits."

After a long discussion, the amendment was rejected by 44 votes against to 39 for it,—a majority of 5 votes against.

Mr. J. Williams Benn moved, as a further amendment,

"That the consideration of the subject be adjourned until after March 5."

This amendment was seconded by Mr. Dickinson, and carried by the narrow majority of 1,—43 for to 42 against.

Site for the Proposed New Offices for the Council.—The Offices Committee presented the following report—

"The Council, on January 23, 1890, passed the following resolution:—

"That it be an instruction to the Council Chamber and Offices Committee to consider and report as to acquiring a suitable site for a Council Chamber and offices, having also regard to any site which already has erected upon it buildings of a character likely to be available for the purpose."

We have from time to time given careful attention to the matter, and we now report for the information of the Council that we have under consideration three sites, either of which, subject to price, would be suitable for the erection thereon of new offices for the Council. We are, however, unable to proceed further until the Council gives us authority to enter into negotiations. We accordingly recommend—

"That we be authorised to enter in negotiations with regard to the sites referred to, and to report the result to the Council."

The recommendation was agreed to without discussion, and after transacting other business the Council adjourned.

COMPETITIONS.

WHITWORTH INSTITUTE, MANCHESTER.—In the first competition for the Whitworth Institute at Manchester, the assessor, Mr. A. Waterhouse, R.A., has recommended the following three designs for premiums, in the order named: "Terra-cotta (No. 2)," by Messrs. T.W. and R. F. Beaumont; "Floreat Mancunium," by Mr. Archibald Neill; and "Three Sisters," by Mr. Geo. Freeth Roper. From what we hear, it seems doubtful whether anything further will be done on the lines of this competition, as circumstances have occurred to alter the views of the promoters, and the scheme, if carried out, will probably be much modified.

NOTTINGHAM MASTER BUILDERS' ASSOCIATION.

The annual meeting of the Nottingham Master Builders' Association was held on the 22nd inst. at the Mechanics' Institute, Mr. J. W. Woodcock presiding over a large attendance, in the absence of Councillor Wright (President). The following are the objects of the Association:—The consideration and discussion of all questions affecting the building trades; the promotion of excellence in the construction of buildings, and just and honourable practices in the conduct of business; the adoption of equitable forms of contract and encouragement of settling disputes by arbitration; the providing of facilities for social intercourse between the members of the Association and their friends, &c.

After the general business had been disposed

* That is to say, until after the election of the new Council, which is fixed for that date.

of, and the officers elected for the ensuing year, notices from the Bricklayers' and Laborers' Societies asking for an advance of wages and code of working rules were read and discussed.

It was the unanimous opinion of the members that the present state of the building trade in Nottingham did not justify any advance on the present rate of wages.

Books.

Principles and Practice of Plumbing. By S. STEVENS HELLYER. London: Geo. Bell & Sons. 1891.

MR. HELLYER is so well known as a writer on matters connected with the plumber's craft that it is not surprising to find that he is the author of the volume on that subject in the series of technological handbooks edited by Sir H. Trauman Wood, and the choice is sufficiently justified by the extensive and thorough knowledge which Mr. Hellyer possesses of all kinds of plumbing work.

We regret, however, to find in this, as in other books written by Mr. Hellyer, that he is too much addicted to attempts at humour, which savour somewhat of vulgarity without being amusing. We can excuse Mr. Hellyer for his very natural expression of his opinion that his own manufactures are superior to those of his competitors in trade, but we should very much more enjoy the useful information which he gives us if he would not try to be funny.

Mr. Hellyer commences with a description, or rather illustrations, of the tools employed by the plumber, and then proceeds to tell us something of the history and manufacture of lead. In connexion with this he gives a very useful table, for which we have searched in vain in many other works on plumbing, of the weight of different lead pipes according to their substance. Some particulars about tin and its connexion with plumbing are also interesting and useful, as is also the description of soldering and lead-burning apparatus. The author then proceeds with a very excellent account of the execution of the various parts of the plumber's work applied to roofs, which will be of very great service as an addition to the practical experience of young plumbers, and also furnish for their employers many useful hints amongst which is a table of the different thicknesses of lead to be employed on the different parts of a roof. The description of bossing is very well treated, and the chapter on roof cess-pools is particularly minute and careful. We are specially glad to note the emphasis the writer lays on the importance of avoiding solder as much as possible in roof work, and also his advocacy of over-pipes from cess-pools. In the description of hips and ridges there is an omission which might be well supplied in any future edition. The author assumes that lead hips and ridges are universally formed over wood rolls, and omits to make any mention of the devices so frequently employed in our days for constructing hips with the lead work covered by close-set slates. In speaking of rolls we notice that Mr. Hellyer advocates the keying of lead into the acute angles by the diminished roll rather than the right-angle junction employed by some practical men.

Very helpful to those readers, whose minds are not of a high mathematical order, will be the explanation of the manner of calculating the number of soakers for any particular piece of roofing. Another example of careful attention to minute detail is the description of a good method of constructing a torus moulding to a lead flat, a matter which is often not so skilfully arranged as it should be.

Leaving the subject of external plumbing, the author then proceeds to internal work, commencing with a full account of the various joints and the methods of making them. Mr. Hellyer defends the use of copper-bit and blow-pipe joints, though he is rightly careful to limit their application to special circumstances only; we should like to see also considerable emphasis laid upon the necessity for the workmanship of these joints being very accurate and careful, even in the limited number of cases where they may be used. Following the subject of joints comes that of hends, and we are glad to see that the author rightly condemns the use of mitre joints instead of hends. Any plumber who values his reputation as a craftsman should never make a joint where a hend serves the purpose. Apart from the question of skill, it will be within the experience of some of our

readers that plumbers occasionally make joints for the mere purpose of charging for them, even, as we have sometimes known, if they have to cut a pipe in a half to do it.

Mr. Hellyer then once more gives us his views on the subject of traps, many of which, as he frankly says, have already appeared in other of his writings.

The chapter on lining cisterns and sinks with lead is well and carefully treated; and Mr. Hellyer then proceeds to treat in detail the plumbing work connected with soil-pipes, water-closets, sinks, baths, and lavatories, his views and practice as to which are well known to most of our readers.

The work finally concludes with some chapters on house drains, which do not, of course, profess to treat the subject so fully as Mr. Hellyer has done in other of his works.

Architectural Perspective. By F. O. FERGUSON. London: Crosby Lockwood & Son. 1891.

It is a great advantage for young architectural draughtsmen to have placed before them a clear and straightforward description of the way in which they may prepare architectural perspectives without going through the large amount of needless drudgery usually entailed by attending any school of art class on perspective after the South Kensington fashion.

Decidedly the best way for a young architect to learn so much of perspective as is necessary for him, is to get an expert draughtsman to give him two or three hours personal instruction; then, if he has a clear head of his own and a reasonable amount of artistic ability, he will be quite free of books and teachers for the remainder of his days.

For those who are unable to get this personal instruction, Mr. Ferguson's book will do something and enable them to make a fairly decent perspective without an undue amount of labour, but there are some points upon which the author would do well to obtain a few more wrinkles before he issues a new edition.

The best positions for the point of sight, picture plane, and consequently the measuring line, are not sufficiently explained. Mr. Ferguson's method of making the measuring line on the nearest angle of the building with his picture plane touching the same angle is not calculated to produce the best grouping. Further, the rule which the author gives, that the point of sight should be distant about three times the height of the building, is only one of the points that an expert takes into consideration, as will be seen from the large extent of the angle of vision which the author uses.

The most serious blemish in the book, however, is fig. 24 in Part I., where we have what is evidently intended to be an example of isometrical projection, but clearly showing that the author does not understand correctly what isometrical projection is, nor its advantages when properly used. We quite agree with the author's opinion that the diagram he shows "is extremely ugly"; this ugliness would vanish to a very considerable extent if the diagram were correct.

The plate which Mr. Ferguson shows of his finished drawing will hardly commend itself to embryo draughtsmen, who have the advantage of frequently seeing much better specimens of pen-and-ink drawing. Mr. Ferguson would do well to obtain the collaboration of some of our well-known experts in draughtsmanship to give an illustration of what is understood in our days as the artistic treatment of light and shade in architectural drawing.

Notes on Building Construction. Part I. New edition. London: Longmans, Green, & Co. 1891.

In our review of the new edition of Part II. of this well-known students' manual, we called attention to the omission of certain chapters which had appeared in the first edition of Part II. We are glad to find that in the new edition of Part I., which has now reached us, these matters have been included, so that the important subjects of riveting, centring, and the building up of timber beams, are no longer omitted, as would appear from an examination of the new edition of Part II. only. The chapters on these subjects are practically the same as before with some few modifications, and additions which have been judiciously made, and increase the value of the work.

The chapter on iron roofs has been practically re-written, and although the volume is intended for elementary students only, it virtually con-

tains information, well and clearly expressed, sufficient for the practice of certainly the majority of architects.

The inclusion of a so clear and thorough description of the construction of iron roofs in what is now the standard handbook for architectural students, cannot fail to render the use of iron for this purpose more general amongst the rising generation, who will no longer be led to look upon ironwork as something which is beyond their capabilities, and only to be employed with the extraneous assistance of a civil engineer.

The remainder of the work is almost the same as before. Some few additions, chiefly an increase in the number of illustrations, have been made, and will enable the "Notes on Building Construction" to maintain the high position it has reached as a manual for architectural students.

The Essex Review. Vol. I, No. 1, January, 1892. London: T. Fisher Unwin; Chelmsford: Edmund Durrant & Co.

This is the first number of a quarterly publication, the object of which is "to gather up into one publication all matters of permanent interest relating to the prosperity, history, and literature of the county." The idea is an excellent one, and the first number promises well for the future. It contains "Notes of the Quarter" in regard to a variety of subjects, including new churches and church restoration. The Rev. Thomas Rogers, Mns.Doc., furnishes well-written notes on what has been done in music in the county during the past quarter, and Mr. F. Chancellor contributes the first of a series of articles on "Essex Churches," a description (with an illustration) of St. Augustine's, Birdbrook. The housing of the agricultural labourer in Essex is the subject of another article, and various notes and queries, and notices of new books, are added. *The Essex Review* ought to be a publication of much interest to the inhabitants of the county, and certainly, if it goes on as it has begun, deserves their support.

"The Advertiser's A.B.C. and Press Directory" (London: T. B. Browne, 163, Queen Victoria-street), is a well-arranged and admirably printed directory of English, Colonial, and Foreign newspapers, which are well indexed. In some respects, however, the lists of foreign papers need revision. For example, there is more than one newspaper published at Dunkerque, and the one mentioned in the book, the *Phare de Dunkerque*, is a daily and not a weekly journal. The ordinary directory matter is prefaced by some interesting articles concerning the production and distribution of newspapers. Particularly interesting are the articles on "Special Newspaper Trains," "The Old Journalism and the New," "Lobby Men and Lobby Managers," and "The Gallery of the House of Commons."

Our trade contemporary *Timber* issued last week an interesting illustrated number entitled "Timber and Woodworking Machinery." It contains a great deal of information about timber, its production, conversion, and conveyance, and is very fully illustrated.

The Manufacturers' Engineering and Export Journal is the title of a new monthly journal the first number of which has been sent to us. It is published at 22, Paternoster-row.

We have received Messrs. Line & Sons' illustrated catalogue of wall-papers, glazing, &c. The illustrations of wall-papers show some good designs by Mr. Brophy, Mr. A. Silver, and others. There is also mention of an embossed wall-covering consisting of wood fibre embossed in hollow relief, "as lasting as the wall itself," and which may have an excellent effect in suitable regions; we do not approve of these relief papers for London houses: they collect and hold dirt. The particular design illustrated of this material is rather like "Japanese run mad," but no doubt it would have its admirers. The examples of combed wall surfaces in "Alahastine" suggest a good many possibilities of diaper surface decoration of a simple kind.

THE FIRST SUSPENSION BRIDGE IN ICELAND.—After twenty years of agitation, the first suspension bridge in Iceland has been finished. It spans the Olves river, is made of iron and steel wires, and is 380 ft. long and 6 ft. wide, the height above the river being 60 ft. The cost of the bridge is 3,500*l.* It has been made in England by Messrs. Vaughan & Dymond, Newcastle, and placed in position by English engineers.

Correspondence.

To the Editor of THE BUILDER.

ADJOINING BUILDINGS.

SIR,—One cannot pass along any thoroughfare in London without being struck by the careless way in which architects, in designing their own buildings, treat adjoining ones. No attention is paid to the horizontal lines of floors, openings, or cornices on either side. The elevation is worked out in the office, without any reference to their neighbour's design, with the result that strings and cornices are either ruthlessly cut off and left unreturned, or jumbled into their own elevation, and thus spoil both buildings. The County Council, District, and parish Surveyors should all insist upon some definite rule to govern such cases, and then see it properly enforced. I cannot conceive anything easier for an architect to carry into execution.

A somewhat similar matter is the treatment of adjoining chimneys. Mr. Edin's successful building for the Junior Constitutional Club in Piccadilly is a case in point. Here the chimneys of houses on east and west sides are carried up, no doubt at the expense of the owners of the Club, in different material and design to the club, and effectually destroy the otherwise satisfactory appearance of the gables and chimneys of the club. Truly in this case to have so treated the adjoining chimneys both in design and material to accord with the club, would neither have been a difficult or an expensive work, and could not have been objected to by adjoining owners. R. J. W.

* * * The problem is not quite such an easy one as our correspondent seems to think, though no doubt more attention might be paid to it in many cases.

FLOORING-BOARDS ON CONCRETE.

SIR,—If "Surveyor" lays a tongued floor directly on concrete, I think he will have trouble from dry rot. I have heard of ordinary floors, not tongued, being so laid, but how they have behaved I know not.

Let me caution "Surveyor" against carrying his coke-breeze concrete into the fireplaces. It is a very perfect conductor of heat. The heat will accumulate in it sufficiently to char any wooden skirtings or other combustible work, at quite a respectable distance from the fireplace. This I know from ocular demonstration.

I am not sure that coke breeze is a safe material to place even near flues. The mere admixture of cement with it does not entirely deprive the coke of its very combustible properties.

Another bint as to coke-breeze concrete. It is apt to scale off from below the flanges of any iron joists which may be embedded in it. I should, therefore, hesitate about plastering directly on to the concrete. Of course, the soffit can be battored and lathed. Possibly the same scaling-off may sometimes occur with other concretes. Possibly, too, a liberal use of cement may get over this difficulty.

The concrete, whatever the "aggregate" used, must have plenty of time to dry,—not always an easy matter when a building has to be rushed. The floor-boards may be cut and laid in place, and nailed later on.

Coke-breeze concrete has, of course, the advantage of being light, and of taking nails kindly. The disadvantages are, I think, those which I have cited, and also that, like all concretes made with porous material, it lets water through too freely; so the extinction of even a small fire may do a good deal of mischief. ANOTHER SURVEYOR.

January 25, 1892.

BOLSOVER COLLIERY COMPETITION.

SIR,—I am glad to see that your correspondent "H. G." has brought to light the conditions of the above-named competition; but he has, I think, missed one of the most beautiful points, for the whole seven houses, schools for 600, workmen's club, hospital, and co-operative stores are to be carried out for 3,000*l.* I did not return my particulars, but have kept them as a sad memento of what our profession has fallen to, and whenever I feel unduly elated by success I shall get them out and read them through. J. H. H.

THE ENGLISH IRON TRADE.—The most important feature in the English iron market has been the drop of 4s. in the price of Scotch warrants. The result has been the disorganisation of the small amount of legitimate business being transacted, buyers holding back until the market becomes again settled. Heavy sales of Cleveland and hematite warrants took place on Monday, on the reduction in the price of Scotch warrants being published. There is less doing in manufactured iron and common bars, and black sheets are 2*s.* 6*d.* and 5*s.* lower respectively. Tinplates are quiet, but the improved tone continues. There is very little change in the steel trade. Shipbuilders are still busy, and engineers maintain fair activity. The coal trade is somewhat quieter.—Iron.

The Student's Column.

WARMING BUILDINGS BY HOT WATER.

V.
ARRANGEMENT OF PIPES. AIR IN PIPES.
(HORTICULTURAL WORK.)

IT is sometimes questioned as to where the vertical portion of the return-pipe should be situated, and likewise, upon the same grounds, where the vertical portion of the flow should be. As a rule, both are near to, or directly in, the boiler, this being convenient, and it is also the correct position, although the majority of workmen would be quite at a loss to explain why.

It has been shown that the circulation is wholly dependent upon the difference of gravity or weight between the water in the flow-pipe and that in the return (the vertical portions of the pipe, not the horizontal, which have no assisting effect), and the greater this difference the more effective or strong the circulatory movement will be. There are two ways of increasing this difference in weight in the two vertical columns, viz., by increasing their height, as will be understood (a means not available in the low-lying horticultural works), and by increasing the difference in temperature of the two columns of water, for we have shown that a variation in temperature is a certain variation in gravity or weight. The former method applies to buildings, in which the pipes commonly extend up great heights, and at all times higher than in greenhouse work. The latter method will explain why the vertical portions of the pipes in a horticultural apparatus should be near the boiler in the following way.

If an apparatus is erected as fig. 13, which is the approved way (the extent of pipes and

Fig. 13.

branches do not affect this explanation), we shall get the hottest water as it leaves the boiler, in the vertical portion of the flow pipe, *a*. As this water travels on and along the horizontal pipe, it loses heat (as it is intended to do), and becomes of an increased weight, until, as it is upon the point of entering the boiler again by the pipe *b*, it is of its greatest density, and differs the most from the water in the pipe *a* in temperature, and consequently weight. Therefore, if it is the difference in weight of the water, and this is only effective in vertical pipes, then near the boiler is the most effective position for them, for here, both in the flow and the return, we get the two extremes of temperature.

Sometimes it is argued that the vertical portion of the return should be at the opposite end to the boiler, as fig. 14, the supposed favourable

FIG. 14.

feature being that the fall, *i.e.*, the descent of the heavier water, occurs before it has to pass along the lower horizontal pipe; and, as a horizontal pipe is opposed to the circulation, by offering a certain resistance by friction, the descent occurring first aids in getting the water towards the boiler. But the least investigation shows that a loss is experienced in the fact that when the water falls at the further extremity of the apparatus, as fig. 14, it cannot be so cool as it would be near the boiler, as fig. 13. As (it will bear repetition) the circulation is dependent upon the water in this return pipe being heavier than the water in the flow-pipe

from the top of the boiler, it must be better to let its effective vertical part be where the water will be coolest and heaviest, that is, near the boiler, than for it to be away where the water has not lost so much heat.

In brief, the water is hottest in the pipe which leaves the top of the boiler and coolest in the pipe that enters the bottom of the boiler. By keeping the vertical (*i.e.*, the effective) parts of the pipes near these two points, we get the greatest possible difference in temperature, consequently weight and motive power.

Another argument to be heard occasionally, and worth mentioning, is that, by carrying the flow-pipe in the ordinary manner, but sloping the return all the way to the boiler, as fig. 15,

FIG. 15.

advantageous results are obtained by reason of the fall of water being free through the whole length of the return and no part horizontal. (It must be noticed by the way that this arrangement would be useless in a large apparatus, as it would not admit of branch services being connected very easily.)

This suggestion sounds very feasible, but it is nearly as valueless as the last. The fact of the return pipe being given this descent its whole length does not increase the aggregate distance it falls; that is, if the distance between flow and return pipes at the boiler be as in figs. 13 and 15, the actual fall given to the return pipes cannot exceed that distance in either case. Sloping the return all the way, as fig. 15, is a disadvantage from the fact that the descending force of water commences a long way from the boiler where the water has only lost a part of the heat it will lose before it re-enters the boiler. In other words, the actual result is as near as possible like giving an abrupt descent to the return, half way between boiler and extremity of apparatus, as fig. 16.

Another arrangement sometimes suggested is to make the pipes wholly returns, as fig. 17.

FIG. 16.

FIG. 17.

FIG. 18.

From the information given, it will be seen that this is a worse arrangement than ever. In this case it is giving the water the fall or descent immediately it leaves the boiler when it is hottest, and it would give a worse circulation than any example yet given. It would practically amount to arranging the pipes as fig. 18.

These different suggestions, although some of them are next to impracticable, are given so that the reader may know what lines of argument are occasionally taken when discussing these works, and become familiar with the different phenomena that go to aid efficiency or otherwise. It will now be understood that the correct practice is to put all vertical pipe of the flow immediately on the top of the boiler, and all the vertical pipe of the return as near the boiler as it can be got. This arrangement is subject to conditions being favourable, and in any case allowance must be made for all pipes run in a horizontal direction having a regular rise from beginning to end.

AIR IN PIPES.

This, as before referred to, is a subject needing every consideration, for it frequently introduces real difficulties. Following the suggestion offered, we shall only now deal with the question as regards horizontal work. Its application to buildings will be treated in its place later. There is but little resemblance between the two, even as regards this subject, air tubes being used in one case,

and air cocks in the other; and there are other differences.

In the first place, let it be understood that under any circumstances an air pipe must exist at the highest extremity, which is the furthest point from the boiler, marked * on fig. 13. This would suffice for a simple little apparatus like that one. If the works be such that branch services exist, which are carried in various directions, then each furthest extremity requires an air outlet; these extremities, it is understood, being the highest points in these different directions. It is hardly necessary to explain that air, being so much lighter than water, always seeks the highest position it can occupy, and there it will persistently stay. If, however, an air pipe be at that point, then there is no question of the air remaining, for it will instantly make its exit as the water fills the apparatus.

As an example, let us suppose a simple apparatus of two straight pipes which have the customary rise from the boiler, but in which the air-pipe has incorrectly been placed near the boiler, as shown in fig. 19. The proper

FIG. 19.

position for it would be where marked *. In this case, when first filling the apparatus, the water passing in from the small cistern shown, the pipes would gradually fill up until the lower aperture of the air-tube was covered, and then it would cease. This would leave the flow-pipe from the air-tube to * more or less charged with air, and it would require some rather strenuous efforts before it could be dislodged. Assuming it could be dislodged, the trouble would only be temporarily obviated, for water varying in temperature absorbs and expels air, and an accumulation would soon be formed again. If the air-pipe be shifted to *, the remedy would be complete; but until then the apparatus would be a failure. No circulation could be effected while this air was imprisoned.

If the accumulation of air was less, and did not wholly fill the extremity of the pipe, then the water would circulate, and if the apparatus was small, probably no particular ill results would be noticeable, but if the apparatus be extensive, this fault would prove a check to the circulation until discovered. Air vents must be on the highest points, the points that the air seeks when the inflowing water begins to disturb it. We shall show in a later paper how this question often requires a good deal of consideration when pipes are dipped or run in irregular ways. It is quite useless imagining the air will find its way out if left alone, or that the water will manage in any way to displace the air, or occupy its place by some other means. When air is thus imprisoned (this word correctly expresses the state of things) there is no chance of matters remedying themselves without assistance.

SURVEYORSHIPS.

PARISH OF ST. PANCRAS.—The Vestry of St. Pancras, London, have appointed Mr. W. N. Blair, Assoc. M. Inst. C.E., the Borough Surveyor of Bootle, to the post of Chief Surveyor to their Vestry at a salary of 600*l.* per annum. There were originally seventy-three candidates for the position, and from these the Highways and Works Committee selected twenty-two for personal interview, after which they recommended for the consideration of the full Vestry the following six in the order of selection given: Mr. W. N. Blair, Borough Surveyor, Bootle; Mr. J. P. Norrington, Vestry Surveyor, Fulham; Mr. W. Howard-Smith, City Surveyor, Carlisle; Mr. J. P. Barber, Vestry Surveyor, Islington; Mr. G. J. C. Broome, Borough Surveyor, St. Helen's; Mr. H. Monson, Vestry Surveyor, St. James's, Westminster. These gentlemen accordingly had an interview with the full Vestry, who proceeded to select two of the number for final consideration, these two being Messrs.

Blair and Howard-Smith, and after a discussion lasting over some hours, a ballot was taken, when Mr. Blair was found to have received the greater number of votes, and was, accordingly, appointed.

OBITUARY.

DR. ALFRED CARPENTER.—We regret to hear of the death, at Ventnor, on Wednesday last, of Dr. Alfred Carpenter, the well-known sanitarian, of Cropton. According to the *Times*, he was born in 1825, and was a native of Northamptonshire. He was educated at Moulton Grammar School, Lincolnshire, and studied medicine first at Northampton, Infirmary, and afterwards at St. Thomas's Hospital, where, besides gaining the first scholarship ever given at that institution, he took the Treasurer's Gold Medal at the end of his course. Dr. Carpenter had long been known as an advocate of sanitary reform. In 1859 he became a member of the Cropton Board of Health, and he was Examiner of Public Health to the Universities of London and Cambridge. In 1881 he was appointed to serve on the Royal Commission which inquired into the condition of the London hospitals for smallpox and fever cases and into the means of preventing the spread of infection. Among his many works on sanitary subjects are "Hints on House Drainage," "The First Principles of Sanitary Works," and the "Physiological and Mechanical Aspect of Sewage Irrigation." We may add that many contributions from his pen on sanitary matters have appeared in the pages of the *Builder*.

MR. WILLIAM BASEVI SANDERS, late Assistant Keeper of the Records, died of bronchitis last week. When the Record Office decided, in 1861, to take advantage of the discovery of photo-zincography and to publish a series of facsimiles of the national manuscripts, Mr. Sanders was selected to take charge of the manuscripts, to see that the facsimiles made by the Ordnance Survey Department were correct, and to translate such documents as required translation. The facsimiles of Domesday Book; of the National manuscripts of England (4 vols.); of Scotland (3 vols.); of Ireland (3 vols.); of the Anglo-Saxon Charters (3 vols.); and of the Black Letter Prayer-book of 1636, with the translations and explanatory notes attached to them, are the result of his labours.—*Times*.

MR. W. FOGGIN.—On the 20th inst. the death took place of Mr. William Foggin, builder, of Newcastle. Deceased was sixty-nine years of age. Mr. Foggin was a native of Cambridge, but in early life he came to Newcastle. He had a large building connexion, says the *Newcastle Chronicle*. He built the Catholic Church of St. Andrew's, in Worswick-street, and also the Catholic schools at the Manors, the convent schools in Villa-place, the presbytery at St. Mary's Cathedral, the Freemasons' Hall in Maple-street, the Catholic Church dedicated to Our Lady and St. Owen at Tyne-mouth, and a number of other public buildings in Newcastle and the district.

GENERAL BUILDING NEWS.

LONDON BUILDING LEGISLATION.—At the next meeting of the Royal Institute of British Architects, to be held on Monday, February 8, Mr. Edwin T. Hall is to read a paper on "London Building Legislation." The paper will be descriptive of the Suggestions of the Practice Standing Committee, adopted by the Council of the Institute, for the proposed Codification and Amendment of the Metropolitan Building Acts. The main lines of such suggestions are—1. It is suggested that the details of construction, which are subject to variation from time to time by reason of, *inter alia*, new inventions, new materials, or modes of construction, &c., should be omitted from the body of the new Act, and be placed in schedules attached thereto, power being given by the Act to the County Council and to the Commissioners of Sewers, as the case may be (subject to provisions corresponding to those of Part II. of the Metropolitan Management and Building Acts Amendment Act, 1878), to vary these as occasion shall require, the object being to allow of changes in details of construction without the necessity of going to Parliament. 2. It is suggested that the new Act should be confined to and extend to everything within and enclosing the curtilage of a building, including any vaults under a public way; it is also suggested that it should include sanitation (*i.e.*, drainage, air spaces, ventilation, plumbing, &c.) and regulations respecting lines of frontage of buildings. 3. The construction of roads, sewers, and bridges, and of everything in the nature of public thoroughfares for use in common by the public, to be excluded. 4. Rights of light and air to be excluded, as they are in the nature of private property. 5. Restrictions on design, which are questions of taste, to be excluded. 6. Erections which are not buildings should be subject to control or supervision of district surveyors. Under this head would come glass covers to yards, partitions between houses, and the like, also telegraph poles, and telegraph posts on buildings, wall signs, fowl-houses, and similar domestic structures, metal pipes for flues, &c.

NEW CHURCH, WESTCOMBE PARK, BLACKHEATH.—On the 23rd inst. the Church of St. George, Westcombe Park, was consecrated by the Lord Bishop of Rochester. The church is in the Early French style, and when completed, with chancel, tower, and spire, will cost 10,000*l.* The interior and exterior are faced with red bricks, relieved by Bath stone dressings and strings, and the roof open timbered. The floors are fireproof, and covered with wood-block flooring. The church has been erected from the designs of Messrs. Newman & Newman, architects, Tooley-street, by Messrs. Balaam Bros., of Shenton-street, Old Kent-road. The pulpit was executed in oak from the designs of the architects by Mr. A. Robinson, of Broad-street, Bloomsbury. The gasfittings are by Messrs. Gardener, of Bristol; and the heating arrangements by Mr. John Grundy, of City-road. The church is built upon the slope of a hill facing the river, and, when completed, will form a prominent feature in the neighbourhood.

SUNDAY-SCHOOL BUILDINGS, SKIPTON.—On the 12th inst. the new Congregational Sunday-schools erected in Odeley-street, Skipton, were opened by Alderman J. Hopkinson, of Manchester. The foundation-stones were laid in August, 1890, and the premises have been built upon modern lines. The assembly-room, on the ground floor, contains a platform, and on each side there are six classrooms, and there is a large room which will be used as a day-school for the infants. The assembly-room is encircled by a gallery, and on each side there are also four classrooms. The building has been erected at a cost of about 3,000*l.* Messrs. Hesley & Son, of Bradford, were the architects; Mr. B. G. Skipton, was the contractor for the stone-work; Mr. Smith, of Keighley, the joinery; and Mr. G. H. Mason, of Skipton, the plumbing and painting.

HOSPITAL EXTENSION, MIDDLESBROUGH.—On the 5th inst. a new wing, which has been added to the North Ormsby Cottage Hospital, Middlesbrough, was opened by Viscountess Falkland. On the ground floor of the new building there is a large room for out-patients with a dispensary, doctors' room, and a dressing-room. The second floor contains the nurses', day, and bed rooms, bath-room, and other conveniences. Mr. Thos. Dickinson, of Middlesbrough, has executed the work from designs of Mr. J. M. Bottomley, of that town. The cost has been 2,000*l.*

PUBLIC HALL, CWMAMAN, GLAMORGAN.—The new public hall at Cwmaman was opened by Lord Aberlone on the 25th inst. The building, which is constructed of stone, has been erected at a cost of 1,500*l.* Besides the hall, which is capable of seating 700 persons, there is a library, two reading-rooms, a room for games, and a billiard-room. The architect is Mr. T. Roderick, of Aberdare, and the builders Messrs. Powell & Mansfield, of Cardiff.

WYCLIFFE CONGREGATIONAL CHAPEL, DEVONPORT.—Wycliffe Congregational Chapel, Devonport, was re-opened on the 24th inst., after extensive alterations and repairs. The whole of the roof and a large portion of the western wall has been taken down. The roof has been lowered 10 ft., and the roofs over the aisles have also been altered so that their appearance might correspond with that of the main roof. The interior has been coloured and re-varnished. Mr. H. J. Small was the architect, and the builder was Mr. J. Williams, of Stonehouse.

CO-OPERATIVE PREMISES, BROOMHILL, NORTH-UMBERLAND.—On the 2nd inst. new business premises for the Broomhill Co-operative Society were opened by Mr. Albert Grey. The building, which has cost about 2,600*l.*, has been designed by Messrs. Oliver & Lesson, architects, Newcastle, the contractor being Mr. D. M. Spence, of Amble. On the ground floor there are shops, and on the first floor there is a hall for public meetings, committee-rooms, secretary's office, &c.

GYMNASIUM BUILDING, HULME.—On the 6th inst. the Procter Gymnasium, which has been built on land in Silver-street, off Chester-road, Manchester, the gift of the Corporation, was opened for use by Lord Egerton of Tatton. The building has frontages into Silver-street, Pryme-street, and Southam-street, Chester-road, with two main entrances from Silver-street, one for members and the other for the public. The accommodation for members consists of a room, 100 ft. long by 50 ft. in width, lighted by a lantern light in roof and side windows. There are dressing-rooms and lavatories with slipper and shower baths, &c.; also three large five courts leading out of the large room. A gallery is formed across one end of the large room and down one side to accommodate the public. Two reading-rooms, committee-room, and instructor's office are also provided, with kitchen and store-rooms in the basement. The building has been fitted with gymnastic apparatus by Mr. Kenshaw. All the work has been carried out by Messrs. Wilson & Toft, contractors, from the designs and under the superintendence of Messrs. W. & G. Higginbottom, architects, of Manchester.

CANAL PROJECT IN FINLAND.—The Finnish Government has decided upon the canalisation and regulation of the rivers between Pielaives and Jivisi at an estimated cost of 28,000*l.*, a large expenditure in that country. The depth of new waterway will be 6 ft. The work will occupy three years.

FOREIGN AND COLONIAL.

FRANCE.—The posthumous exhibition of the works of Ribot will be opened at the Ecole des Beaux-Arts in May. The monument to the painter, to be erected at Paris, has been entrusted to M. Rodin, sculptor.—In consequence of the extension to the Luxemburg on the Sceaux railway, the statue of Marshal Ney on the Boulevard St. Michel will have to be moved. This, which was the work of Rude, stands on the place where Ney was shot. It will be re-erected at the angle of Rue Notre Dame des Champs and Boulevard Montmartre.—M. Gustave Moreau, painter, has been appointed to the post of "Professeur Chef d'Atelier," formerly held by Delaunay.—A bust of the sculptor Aimé Millet has been erected at Pèra la Chaise. It was modelled by one of his pupils, M. Emile Guillaume.

A statue of Chevreul, the celebrated chemist, is to be placed in the galleries of the Conservatoire des Arts et Métiers at Paris; it will be executed by M. Faval.—M. Marius Vachon has been appointed Director of the exhibition of "Arts de la Femme" which is to be organised in August at the Palais d'Industrie, under the direction of the Union Centrale des Arts Décoratifs. Mme. Rosa Bonheur will preside over the Fine-Art Section.—It is stated positively that the Minister of Public Works is at last about to submit to Parliament the long-delayed Metropolitan Railway scheme. The project will include, it is said, the completion of the Rue Réaumur, which is to connect the Rue du Temple with the Place de l'Opéra.—There is talk of the purchase by the Government of the site of the old Théâtre Italien (Place Ventadour) to instal there the Opéra-Comique. The building is at present occupied by a large financial establishment.

The Committee for the decoration of the Hôtel de Ville have commissioned M. Puvion de Chavannes to execute the decoration of the ceiling of the grand staircase, formerly given to Delaunay.—The death is announced of M. Gaivogne, of Lyons, who was specially charged with the services of the Beaux-Arts and Architecture of that town.—At Biarritz a competition has been opened for a sea-bathing establishment on the beach, to cost about 600,000 francs.—In a field near Degoin (Saône-et-Loire) there has been discovered an interesting Roman burying place, in which M. Veillerot, the antiquary, has found Gallo-Roman pottery, bronze bracelets, arms, and coins with the heads of Augustus, Nero, Vespasian, and Antoninus.—By a decree of the Council of Etat, the town of Montpellier is commended to the architect of the Municipal Theatre, M. Cassier Bernard, the amount of his fees calculated at four per cent., with interest at five per cent. from May, 1888.—It is announced from Cairo that M. Grébaud, Director of Excavations at Tel-el-Amarna, has discovered a royal tomb of the eighteenth dynasty of Egypt. This tomb includes a gallery 50 metres long terminating in a large rectangular apartment in which are found traces of painting of which the colour has faded.—M. Ernest Christophe, sculptor, has died at Paris, at the age of sixty-five. His principal works were "La Douleur," a marble statue now in the Tuilleries Gardens; "La Fortune," in the Luxemburg Museum; and a sketch for a monument to his master, Rude, now in the Museum of Dijon.—The death is also announced, at the age of eighty-one, of Comte Emile de Nieuwerkerke, formerly Superintendent des Beaux-Arts" under the Second Empire. He was a sculptor of merit, and had acquired a great many friendships by his amiability as well as his enlightened taste in matters of art.—One of the masters of French engraving, Louis Pierre Henricque Dupont, has just died at Paris, at the age of 94. We will refer more at length in our next "Letter from Paris" to the career of this eminent artist, only remarking now that he was, since 1849, a member of the Académie des Beaux-Arts, and commander of the Legion of Honour since 1878. He was, since 1863, Professor of Engraving at the Ecole Nationale des Beaux-Arts.

SYDNEY.—The tender for the erection of the Newcastle Cathedral, from the foundation already completed to the roof (which will be a separate contract), has been accepted. The architect is Mr. T. Horbury Hunt.

MISCELLANEOUS.

ELECTION OF THREE ASSOCIATES OF THE ROYAL ACADEMY.—At a general assembly of Royal Academicians and Associates, held on Wednesday evening last, Mr. Stanhope A. Forbes, printer, Mr. Harry Bates, sculptor, and Mr. T. G. Jackson, architect, were elected Associates.

RAWLINGS' EMERGENCY STAIRCASE.—This is a form of folding staircase intended especially to provide a means of exit from the upper floors of factories or other such buildings. A light folding staircase is connected with a trap-door in such a manner that when the trap-door is raised the stair is by the same action let down to the floor below. A handrail folds with it, extending sufficiently far down the stair or ladder to afford safety for children in descending. It is proposed that the trap-doors should be formed one over the other in each floor, at the farthest point from the permanent staircase, so as to afford an uninterrupted way down. Of course in a case where one floor or story

was filled with flames and smoke it would not be of much use, as it would not pass the point of danger: an outside exit is the thing really wanted. In many cases, however, it would afford an available exit, and its comparative cheapness and the readiness with which it could be fitted to existing buildings recommend it to attention.

THE SANITARY INSTITUTE.—A list of lectures has been arranged by the Sanitary Institute for the special instruction of those desirous of obtaining knowledge of the duties of Sanitary Officers. The various subjects will be dealt with in the course of fourteen lectures, given by well-known authorities, and will be illustrated with diagrams, drawings, and models. These lectures are a continuation of the courses previously held by the Parkes Museum, and it is proposed to repeat the course in London twice each year, to suit the requirements of persons preparing for the examinations of the Institute. The lectures will comprise the subjects scheduled for these examinations, and will be given on Tuesdays and Fridays, commencing Friday, January 23. Students and others desirous of attending the lectures are requested to send in their names at once to the Secretary of the Institute, 74A, Margaret-street, W.

THE SORBONNE, PARIS.—An illustrated history of this famous College is in preparation by Mr. John A. Randolph, to be published by subscription. It will be completed in six monthly parts.

DESIGNS FOR FLOORCLOTH.—Messrs. M. Nairn & Co., of Kirkcaldy, are offering a number of prizes for the best designs for floorcloth and linoleum. The judges are to be Mr. M. B. Nairn and Mr. John Nairn, assisted by one of the examiners of the South Kensington School of Art. Designers on the staff of the firm are excluded from the competition.

SOCIETY OF ARTS.—In consequence of the illness of Prof. W. C. Unwin, F.R.S., the Howard Lectures on "The Development and Transmission of Power from Central Stations," which he was announced to deliver on February 5 and five following Friday evenings, have been postponed.

CHICAGO EXHIBITION.—The first meeting of the Electricity Committee was held on Tuesday afternoon, 26th inst. Present:—W. H. Freese, F.R.S., in the chair; Sir Frederick Abel, K.C.B., D.C.L., F.R.S., Colonel R. T. Armstrong, C.B., R.E., R. E. B. Crompton, Prof. James Dewar, M.A., F.R.S., Major-General E. R. Festing, F.R.S., Prof. George Forbes, M.A., F.R.S., Prof. G. Carey Foster, F.R.S., Edward Graves, Prof. D. E. Hughes, F.R.S., Gisbert Kapp, J. C. Lam, C.M.G., W. M. Morley, J. Fletcher Moulton, M.A., Q.C., F.R.S., Prof. John Perry, D.Sc., F.R.S., Alexander Siemens, Prof. Silvanus P. Thompson, D.Sc., F.R.S., with Sir Henry T. Wood, Secretary of the Royal Commission.

PRESSED-STEEL WINDOW-FRAMES.—The National Telegraph Works Company send us a description and illustration of these frames, for which they claim the advantage over cast-iron frames that they are produced at less cost, are less than one-quarter weight, and do not require careful packing to ensure them against damage in carriage by rail and sea. Of the statistics as to weight and cost we can say nothing, merely giving the patentees' statement, but they are certainly likely to be stronger than cast-iron frames, and if all that is claimed for them is realised they certainly demand attention.

THE NINETEENTH CENTURY ART SOCIETY.—Saturday, February 6, has been appointed for the private view of the Spring Exhibition (the twenty-sixth) of the Nineteenth Century Art Society, at the Conduit-street Galleries, and the exhibition will open to the public on Monday, February 8.

THE RATING OF MACHINERY.—A conference, under the auspices of the National Society for the Exemption of Machinery from Rating, was held on Tuesday, at the rooms of the Manchester Chamber of Commerce. Sir W. H. Houldsworth, M.P., presided, and gentlemen attended from all parts of the country. The Chairman said at present the law was applied differently in different localities, and the decisions of the Judges had only made confusion worse confounded. Mr. W. Mather, M.P., said he thought it would be futile to re-introduce the old Bill into Parliament, and he was rather in favour of going in for seven-eighths of what they wanted by supporting their No. 2 Bill, drafted by the Society, eliminating words such as to prevent rating of any machine which does not require any special foundation or special adaptation of the hereditament in connexion with the use of their particular machine. He moved an amendment accordingly, and Mr. H. D. Marshall (Gainsborough) seconded. Mr. Hughes (Sheffield), Mr. Ponsler (Nottingham), and Mr. Tomlinson, M.P., supported the amendment. Mr. D. Rhodes said he thought the amendment would satisfy the Lancashire Poor-Law Guardians, of whom he was one. The amendment was carried by a large majority. The Bill to be promoted in accordance with their decision provides that machinery which is not fixed, or is only fixed to the hereditament for purposes of steadying it, and which, with the foundation thereof, can be removed without permanent injury to the hereditaments or itself, shall not be rated. Machinery for producing motive power, however, is excluded, and it is not proposed to apply the Bill to Scotland or Ireland.

COMPETITIONS, CONTRACTS, AND PUBLIC APPOINTMENTS.

COMPETITIONS.

Table with 4 columns: Nature of Work, By whom Advertised, Premium, and Date to be delivered. Includes entries for Technical School Building, Floorplans and Linoleum Design, and various waterworks and sewerage projects.

CONTRACTS.—Continued.

Table with 5 columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, and Tenders to be delivered. Includes contracts for drainage works, additions to engine house, public baths, and alterations to various buildings.

PUBLIC APPOINTMENTS.

Table with 4 columns: Nature of Appointment, By whom Advertised, Salary, and Applications to be received. Lists appointments for Sanitary Inspector, Inspector of Nuisances, and Surveyor Superintendent.

Those marked with an Asterisk (*) are advertised in this Number. Competitions, p. iv. Contracts, pp. lv., vi., viii. & ix. Public Appointments, p. xx. & xxi.

ROYAL CAMBRIAN ACADEMY OF ART.—At the annual meeting of the Royal Cambrian Academy of Art, held last week, Mr. Arthur Baker, F.R.I.B.A., author of "Pias Mawr," and architect to the Academy, was elected an Associate.

DISINFECTING APPARATUS.—The State Sanitary Department of Berlin has certain regulations as to disinfection of clothing, bedding, &c., and in order to meet these Messrs. Oscar Schimmel & Co., Chemnitz, have devised a disinfecting apparatus, which is described in a German contemporary. There are two forms, one having a chamber of rectangular section, and the other one of cylindrical form. A frame to receive the things to be treated, is arranged to run in and out of the disinfecting-chamber on rails. The chamber is then closed, and the clothing is heated by steam, which is introduced by means of two copper coils. There is a separator by which all water is taken from the steam, and the chamber and its contents are heated to 70 degs. centigrade before steam is allowed to be blown in. By means of valves the air is forced out of the clothing into the chimney, and the admission of air can be regulated. The clothing is then subjected to a temperature of 105 degs. centigrade during the space of one hour, by which time the heat has penetrated to the middle of even large bundles of clothing.

ROYAL METEOROLOGICAL SOCIETY.—The annual general meeting of this Society was held on Wednesday evening, the 27th inst., at the Institution of Civil Engineers, 25, Great George-street, S.W.; Dr. W. Marcet, F.R.S., Vice-President, in the chair. The report of the Council for the past year showed the Society to be in a very satisfactory position. In May the library and offices were removed to more commodious premises at 22, Great George-street. After defraying the cost of fitting up the new offices and the increased rental, there still remained a balance in hand of 224*l*. Thirty-four new Fellows were elected during the year, the total number on the roll of the Society now being 522. Owing to the absence of the President, Mr. Baldwin Latham, M.Inst.C.E., through an attack of influenza, his address on "Evaporation and Condensation" was read by the Secretary. The question of evaporation, the author said, is as of great importance as the study of the precipitation of water on the face of the earth, as the available water supplies of the country entirely depend upon the difference between these two acts of observation. The earth receives moisture by means of rain, dew, hoar frost, and by direct condensation. It loses its moisture very rapidly by evaporation. Although evaporation mainly depends upon the difference between the tensional force of vapour due to the temperature of the evaporating surface, and the tensional force of the vapour already in the atmosphere, yet it is largely influenced by the movement of the air, and by its dryness, or the difference between the dew point and the actual air temperature. Evaporation goes on at night so long as the water surface is warmer than the dew point. With seawater the evaporation is about 4 1/2 per cent. less than with rain-water, while with water saturated with common salt the evaporation is 15 per cent. less than with rain-water. Mr. Latham next described some percolation ex-

periments which were carried out by Mr. C. Greaves at Old Ford, by Messrs. Dickinson & Evans at Hemel Hempstead, and by Sir J. B. Lawes and Dr. Gilbert at Rothamsted. He then detailed the results of his own experiments, and also the gaugings of the underground waters in the drainage areas of the rivers Wandle and Graveney. He further stated that in the course of his observations on the flow of underground water he had observed that at certain particular seasons of the year it was possible to indicate the direction and volume of the flow of underground streams, even when they were at a considerable depth, owing to the formation of peculiar lines of fog. Dr. C. Theodore Williams was elected President for the ensuing year.

THE PROPOSED NEW STREET FROM HOLBORN TO THE STRAND.—A meeting was held on Tuesday night at the Holborn Town-hall in order "to urge the London County Council to facilitate a necessary and direct route from north to south of London through the very centre of the metropolis." Mr. T. W. Maule, L.C.C., president, and said the London County Council had favoured a scheme through Little Queen-street and Drury-lane, but all the proposals for improvements had been interrupted by the betterment question. In connexion with the proposed new street, however, two committees were sitting, and there were proposals to utilize Lincoln's Inn-fields. The latter proposition, he maintained, would mean a saving of half a million of money, and would result in the formation of a very beautiful street. Such a route would open up King's College Hospital to the public view, and would mean a very near cut from Holborn to the Law Courts. The route he advocated was via Vernon-place, Bloomsbury, Kingsgate-street, Holborn, Lincoln's Inn-fields, and Carey Market. Dr. Maury supported the route detailed by the Chairman, and contended that it was the cheapest and the best in every way. Mr. A. H. Hoare, L.C.C., said that the Improvement Committee of the County Council decided in favour of the Drury-lane scheme. Mr. J. C. Dear estimated that the new street would cost 600,000*l*, while the Drury-lane route would cost 933,000*l*. He moved a resolution cordially supporting the efforts of the Holborn Extension Committee to obtain a new street from Holborn to the Strand through Lincoln's Inn-fields, and expressing the hope that the London County Council would take early steps to carry out such a much-needed improvement. The motion having been seconded by Mr. Theobald, Mr. P. Goswami moved a resolution in favour of the alternative route approved by the London County Council, and this was seconded and adopted by a large majority.

LEGAL.

CASE UNDER THE METROPOLIS MANAGEMENT AMENDMENT ACT, 1890: WANDSWORTH DISTRICT BOARD v. BIRD. In the Queen's Bench Division on Wednesday last, judgment was given in this case, which was heard on the 14th inst., and in which the Court had taken time for consideration. The case raised the question whether under the Metropolis Manage-

ment Amendment Act of 1890 the District Board can absolutely refuse to the owner of land laid out or intended to be laid out in a street permission to excavate and remove sand, gravel, or subsoil under such land, or can only impose conditions on such removal. The statute (53 and 54 Vict., c. 65, s. 6) provides that it shall not be lawful to form or lay out any street from which the gravel, &c., has been excavated, until the subsoil has been made good and levelled, &c., and that it shall not be lawful to remove or take away sand, gravel, &c., from any land on which any street or road is laid out or intended to be laid out except on such conditions as to the making good the same as the Board may think fit. And if the Board shall refuse to give their assent or impose any conditions, &c., the owner, if dissatisfied, may appeal to the London County Council. In the present case the owner of a piece of land near the Wandsworth station of the Brighton Railway had proposed and intended to lay out a street or road, to be called Braybrooke-avenue, and had applied to the Board for power to make sewers, &c., and had proposed to excavate along the whole length for gravel, sand, &c., to be removed. He had on April 18 last applied to them to know what conditions as to levelling or making good, &c., the Board might desire to impose. On May 3 the Board Clerk wrote a letter in reply, that the Board had resolved to refuse their consent to the excavation of any part of the land for the purpose of removal of any subsoil, sand, or gravel. The owner, nevertheless, proceeded to excavate and remove a large quantity of gravel from the land. The Board took out a summons against him for excavating and removing subsoil without their consent in writing, but the magistrate (Mr. Haden Corser) refused to convict, and stated a case which raised the question.

The case was argued by Mr. Channell, Q.C., and Mr. Earl for the Board; and by Mr. R. Bray for the owner.

The Court had taken time to consider their judgment, which was now delivered in favour of the owner and upholding the view taken by the magistrate. Mr. Justice Hawkins delivered judgment at some length to that effect. The Board, he said, had complained that the owner had removed subsoil in disregard of their refusal to allow it, and he contended that their consent was not required, and that they had no power to refuse to allow it. The real question is whether their consent was required and they had power absolutely to refuse it, or whether they could only impose conditions as to making good or levelling the soil. And, on the best consideration they could give to the Act, it appeared to them that the contention of the respondent, the owner, was good, and that no power was given to the Board absolutely to refuse to allow any subsoil to be excavated and removed, but only to impose conditions as to levelling and making good the soil. The learned Judge went fully into the provisions of the Act to support this view as to its construction, and arrived at the conclusion that the magistrate was right in not convicting, and the appeal must be dismissed.

Mr. Justice Wills concurred. Appeal accordingly dismissed.—Times.

MEETINGS.

SATURDAY, JANUARY 30.

Royal Institution.—Professor J. A. Fleming on "The Induction Coil and Alternate-Current Transformer." II. 8 p.m.
St. Paul's Ecological Society.—Annual Meeting. 2.30 p.m.

MONDAY, FEBRUARY 1.

Royal Academy of Arts.—Professor Atchison, A.R.A., on "Saracenic and Turkish Architecture." III. 8 p.m.
Surveyors Institution.—Adjourned Discussion on Mr. L. Morris's paper on "The Four-Course System." 8 p.m.
Society of Arts (Cantor Lectures).—Professor George Forbes on "Developments of Electrical Distribution." II. 8 p.m.
Inaugural Address by the President, Mr. J. W. Wilson, Jun. 7.30 p.m.
Royal Institution.—General Monthly Meeting. 8 p.m.
Victoria Institute.—8 p.m.
Leeds and Yorkshire Architectural Society.—Mr. F. W. Bedford on "Spanish Architecture." 7.30 p.m.

TUESDAY, FEBRUARY 2.

Institution of Civil Engineers.—Mr. Alfred Harper Curtis on "Gold Quartz Reduction." 8 p.m.
Sanitary Institute (Lectures for Sanitary Officers).—Mr. H. Law on "Principles of Calculating Areas, Cubic Contents, &c.," interpretation of Plans and Sections to Scale. 8 p.m.
Glasgow Architectural Association.—Demonstration on "The Architecture of the Human Figure, and its Application," by Mr. F. H. Newbery. 8 p.m.

WEDNESDAY, FEBRUARY 3.

Royal Archaeological Institute.—(1) The Rev. Professor Venables on "The Roman Colonnade Discovered at Lincoln last Spring." (2) Mr. J. Park Harrison on "A Pre-Norman Church at Newbury." (3) Mr. W. G. Wood on "The Cathedral." 4 p.m.
British Archaeological Association.—(1) Mr. Thomas Blashill on "Sutton-in-Holderness and the Abbey of Marnes." (2) Mr. Andrew C. Cookson on "Dorothy Manors (at Vernon of Haddon Hall)." 8 p.m.
Carpenters' Hall, London Hall.—Professor H. Robinson on "Drainage of Buildings and Construction of Sewers." 8 p.m.
Civil and Mechanical Engineers' Society.—Mr. J. F. Reade on "Main Drainage Extension in Towns." 7 p.m.
Institution of Electrical Engineers (at the Royal Institution).—Experiments with Alternating Currents of High Potential and High Frequency, by Mr. Nikola Tesla. 8 p.m.
Society of Arts.—Mr. T. Pridgen Teale, M.A., on "Dust, and How to Shut it Out." 8 p.m.

THURSDAY, FEBRUARY 4.

Royal Academy of Arts.—Professor Atchison, A.R.A., on "Saracenic and Turkish Architecture." IV. 8 p.m.
Royal Institution.—Dr. A. S. Murray, on "Some Aspects of Greek Sculpture in Relief." III. 8 p.m.
British Museum.—His Majesty's Illustrated on "Greek Sacrifices and Festivals," as illustrated by the monuments in the Museum. 2.45 p.m.
Institution of Mechanical Engineers.—Annual General Meeting, when two papers will be read: (1) Mr. J. Barry on "Mechanical Features of the Liverpool Water Works, and on the Supply of Power by Pressure from the Public Mains, and by other means." (2) Mr. W. Hawdon on "The Disposal and Utilisation of Blast-Furnace Slag." 7.30 p.m.
Society of Antiquaries.—8.30 p.m.

FRIDAY, FEBRUARY 5.

Sanitary Institute (Lectures for Sanitary Officers).—Mr. Louis Parkes on "Water Supply, Drinking Water, Pollution of Water." 8 p.m.
Institution of Mechanical Engineers.—Annual General Meeting (continuing). 7.30 p.m.
Royal Institution.—Professor Roberts-Austen on "Metals of High Temperatures." 9 p.m.

SATURDAY, FEBRUARY 6.

Royal Institution.—Professor J. A. Fleming on "The Induction Coil and Alternate-Current Transformer." III. 8 p.m.

RECENT PATENTS:

ABSTRACTS OF SPECIFICATIONS.

1,885.—ROOFS: H. M. Symons.—This invention refers to an improved method of repairing slated roofs by the employment of metal slaps, made smaller on underside, to partly fit the bevelled edges of the under-slates, and thereby leaving a thicker substance of metal without raising the new slate more than ordinary. At the underneath side of one end of the slip a spike projects forming a nail. Nail and slip are thus in one piece, and a saving of time is effected in fixing.
2,153.—WATER-CLOSURES: J. Smith.—This specification relates to an improvement in the inlet or distributing water orifices of water-closet basins for the better distribution of the water for flushing and cleaning the basin. The novelty claimed consists in introducing the water to the upper part of the basin by three inlet openings instead of only by one as usual.
2,536.—CHIMNEY-TOWERS: J. Roe and J. Murdoch.—To prevent back-smoke and back-draughts the chimney can, it enters the top of this patent has around its circumference, near the base, a series of openings so arranged that from whatever point the wind strikes the can, it enters through the openings, and is carried upwards towards the mouth of the can, thus causing a draught or suction in the chimney. About the middle of the can a similar series of openings is provided, causing a draught in the chimney.
2,745.—WATER TAPES: H. J. Minsherp.—In a combination fitting, constructed with a stop-cock in the centre and two outlet sockets, either draw-off, taps or plugs are inserted. The fitting is fixed to the service-pipe near the main, and is used to prevent the bursting of water-supply or service-pipes.

461.—DRAIN-TESTING: T. Kemp.—This patent refers to an improved apparatus for drain-testing, passing a chemical of strong odour into the drain without the aid of a machine. It consists of a small glass tube containing the chemical, fitted with a coil spring on the outside, and an India-rubber cap firmly held on the top of the tube by a paper tape passing over and attached to the spring which seals up the contents. On the latter being passed into a closed trap, the tape becomes wet in passing through the water, and is broken by the force of the spring, and the contents of the tube are discharged.

19,076.—WATER-CLOSURES: T. Cropper.—This refers to an improvement in the soil pipe connection of water-closets. The inventor connects the earthenware trap of a closet basin with the soil pipe by means of a pipe passing down the interior of the trap, and terminating at a point below the level of the water seal in the trap. Any escape of sewer gas is impossible.

NEW APPLICATIONS FOR LETTERS PATENT.

January 11.—630, J. Wilkinson, Preventing Down-draughts in Chimneys.—834, W. & E. Freeman, Shave-book for Plumbers' use.—536, J. Robinson, Burglar-proof Sash-lifter.
January 12.—574, A. T. Sabine, Machinery for forming the Sockets of Sanitary-pipes, Chimney-pots, &c.—587, R. Tawites, Preventing Water and Gas-pipes from Freezing.—589, J. Phillips, Method to prevent Pipes Bursting from Frost.—591, W. WILD & H. H. HARRY, Coverings for Walls, &c.—600, H. Rhodes & R. Holland, Domestic Heaters.—608, R. Spring, Preventing Waste of Water in or from Cisterns.—629, J. Shannon, Wood-graining Machines.
January 13.—651, H. Sayle, New Automatic Noiseless Flushing-valve for Water-closets and Urinals.—663, L. Dove, Automatic Disinfecting Apparatus for attaching to Flushing-cisterns.—680, F. Nour, Head-service Piping.—681, C. Gos, Preventing Waste of Water.—698, A. Boulle, Ghee.—715, G. Conzels, Gully-traps.—727, J. Rainey, Tool-holding Attachment for Grindstones.

January 14.—C. Griffiths, Stoves.—758, D. Nainby, Preventing Smoky Chimneys.—757, J. Brown, Lock and Latch Furniture.—801, W. Byers, Sliding-bolts for Securing Doors, &c.—805, E. Smythies, Sash-fasteners.
January 15.—814, J. Fauda, Masons' Tools.—827, W. Orr, Metallic Drills.—828, E. Hutchinson, Bakers' Ovens.—854, E. Cooper and E. Turrill, Door Springs and Locks.—861, A. Bonik, Carving-machines.—869, G. Dunell, Metallic Flooring or Decking for Bridges, &c.
January 16.—901, A. Wilson and C. Johnson, Joints for Metal Pipes.—905, T. Lane and A. May, Chimney-tops or Cows.—907, C. Johnson and A. Wilson, Joints for Pipes connected of Stowage, &c.

PROVISIONAL SPECIFICATIONS ACCEPTED.

15,471, J. Barlow, Window and other Frames.—17,719, W. Kenney, Bolt Joints or Hinges.—20,795, J. Hughes and E. Jones, Screws and Screw-drivers.—20,805, J. Dew, Lath, Distaffing Water-closets, Drains, &c.—21,237, F. Webster and A. Thorman, Fire Stoves, &c.—22,036, W. Tucker, Anti-rip Sash-bar.—22,171, T. Smith, Compounds or Cements.—22,243, T. Buckerton, Faving Gaskets, &c.—22,428, J. Jackson, Decorative Materials for Walls, Ceilings, &c.—22,516, J. Pearson, Draught and Weather Excluders for Doors.—22,577, J. Martin, Saws.—174, G. Deacon, Glazing Root, &c.

COMPLETE SPECIFICATIONS ACCEPTED.

(Open to Opposition for Two Months.)

3,070, G. Lawford, Water Waste-preventing Cistern.—3,555, W. Thompson, Concrete-mixing Machines.—4,287, T. Panafy, Supplying Disinfectants to the Flushing Pipes of Urinals, &c.—4,481, J. Townshend, Folding or Collapsible Seats.—17,100, W. Douglas, Mortice Locks.—17,375, W. Errington, Stone-cutting and Stone-dressing Machinery.—21,005, J. Bardsley, Door Springs and Checks.

SOME RECENT SALES OF PROPERTY: ESTATE EXCHANGE REPORT.

JANUARY 14.—By C. C. & T. Moore (on the premises): No. 40, Oxford-st., the lease and goodwill, u.t. 2c yrs, r. 240, s. 510d.
JANUARY 19.—By Dunsell & Co.: 79, Ringford-rd., Wandsworth, r. 28l. 300d.; 12, Southfield-rd., f. r. 22l. 8s. 200d.—By Slade & Butler: 7 to 16, Alma-cottages, Heston, f. r. 104l. 50d.; 17 to 21, Alma-cottages, f. r. 60l. 400d.—By Sherwin & Collins: 46, Brookly's-walk, Hammersmith, f. r. 55l. 905d.; 108 to 110 (even), Glenborne-rd., Hammersmith, u.t. 90 yrs, g.r. 25l. r. 132l. 705d.
JANUARY 20.—By Kelly & Son: an enclosure of f. land, 7a, St. 21p., Folly-lane, Walthamstow, 1,300l.; 43, Calabaria-rd., Bighbury, u.t. 90 yrs, g.r. 8l. 15s. r. 42l. 315d.
JANUARY 21.—By Baxendell & Co.: "Thames Wharf" f. area, 3,000 sq. ft., Limehouse, 1,200l. By F. Parry: 27, 40, Bedford-rd., St. Paul's, g.r. 85 yrs, g.r. 8l. 100d. r. 55l. 575d.; 101, Wilberforce-rd., Finsbury-pk., u.t. 75 yrs, g.r. 8l. r. 45l. 470d. By J. J. OF
ROYAL ACADEMY ARCHITECTURE.

1501.

SOME PRESS NOTICES.

"In numerous well-drawn and well-printed plates of plans, elevations, and sections of buildings, this comely little illustrates the latest Royal Academy Exhibition of Architectural designs, and effectively proves how much greater attention that room in Burlington House deserved than it received."—*Illustration*.

"A handsome folio volume."—*Guardian*.

"A large and extremely handsome volume."—*Newcastle Daily Chronicle*.

ESTIMATES GIVEN ON APPLICATION.

TO CORRESPONDENTS.
 M. T. A.—G. F. R.—O. & Co.—W. H. B.—J. P.
 All statements of facts, lists of tenders, &c., must be accompanied by the name and address of the sender, not necessarily for publication. We are compelled to decline printing out books and giving addresses.
 Note.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.
 We cannot undertake to return rejected communications.
 Letters or communications (beyond mere news-items) which have been published for other journals, are NOT DESIRED.
 All communications regarding Henry and Artie matter should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHERS, and not to the Editor.

THE BATH STONE FIRMS, LTD.
 BATH.
 FOR ALL THE PROVED KINDS OF
 BATH STONE.
 FLUATE, for Hardening and Preserving
 Calcareous Stones and Marbles.

DOULTING FREESTONE.
 The stone from these quarries is known as the "Wootton Basses," and it is of a very crystalline nature, and undoubtedly one of the most durable stones in England. It is of the same crystalline nature as the Cheltenham Stone, but there is texture, and more suitable for fine moulded work.
 Prices, and every information given, on application to CHARLES TRASK & SONS, Doultong, Shepton Mallet.
 London Agent—Mr. E. A. WILLIAMS, 16, Craven-street, Strand, W.C. [ADVT.]

HAM HILL STONE.
 The attention of Architects is specially invited to the durability and beautiful colour of this material. Quarries well opened. Quick despatch guaranteed. Stonework delivered and fixed complete. Samples and estimates free. Address, The Ham Hill Stone Co., Norton, Stoke under-Ham, Somerset. London Agent: Mr. E. A. Williams, 16, Craven-st., Strand, W.C. [ADVT.]

Asphalte.—The Seyssal and Metallo Lays Asphalte Company (Mr. H. Glenn), Office, 42, Poultry, E.C.—The best and cheapest materials for damp courses, railway arches, warehouse floors, flat roofs, stables, oow-sheds, and milk-rooms granaries, tun-rooms, and terraces. Asphalte Contractors to the Forth Bridge Co. [ADVT.]

The Science of Construction.

WHATEVER differences of opinion may be held as to the use or desirability of examination for architectural students, we imagine there would be practical unanimity among all classes of architects as to the importance of education, and the strongest advocate of the architect's position as an artist would be constrained to admit the necessity of a certain amount of scientific training for those who, whatever their genius may be for artistic designing, are constrained by the very nature of their calling to be constructors. The constructive problems which have to be faced and worked out even in a small building are of a far more complicated nature than is apparent at first sight, and although a few years' experience will enable a man to gain such an amount of practical acquaintance with the materials which he uses that he will avoid gross blunders, yet without scientific training he will never be able to explain even to himself the reason for preferring one form to another, nor will he understand why under certain conditions materials behave in a very different manner from that which characterises them under other conditions. The "rule of thumb," which is the watchword of the severely practical man, is generally safe, but eminently unscientific, because it is useless to meet new conditions, and when these arise the practical man adopts another rule, which he defines as "being on the safe side," the result of which is generally safety at the cost of wastefulness. The evils of theoretical knowledge alone, unchecked by practical experience, are, of course, obvious, and would be far more likely to have dangerous effects, particularly with those who have to carry out designs; but in the case of the architect, who must be the designer not only of beautiful forms and harmonious arrangements, but also of strong and stable structures, we hold that he cannot afford to neglect the theory any more

than the practice of his art. The accurate determination of the conditions upon which depend the strength and the stability of structures requires, in many cases, a knowledge of advanced mathematics which is probably never possessed by ninety-five per cent. of students of architecture; and a generation or so ago, no attempt had been made to approach the elucidation of such problems from any but the mathematical side. As a consequence, the whole of this portion of his educational equipment was practically a sealed book to the architectural student, who was compelled to take on trust a number of formulæ and tables without the slightest knowledge of the principles on which they were based. Whatever else the institution of examinations by various bodies may have done or not done, it has undoubtedly created a demand for science text-books on building construction suited to the comprehension of those who are unacquainted with advanced mathematics. Among the best of these are the "Notes on Building Construction," the first three parts of which were originally published by Messrs. Livingtons, and have been noticed by us on more than one occasion. The fourth part of this work is now before us.*

We cannot recall a case where a work of this importance has been published anonymously, and we regret to notice from the preface that the author has been compelled by ill-health to depute a considerable portion of his work to an anonymous friend. Although he modestly states that by this arrangement "he feels he has conferred a great benefit on his readers," we cannot help feeling that in parts the work shows signs of negligence, and we shall be compelled to note some instances where the want of careful revision is sadly manifest. We consider the scheme of the book altogether admirable, the object being not only to give the various formulæ for calculating the dimensions of beams, girders, &c., but to explain fully the reasons for the use of these formulæ, and to show how graphic methods

* "Notes on Building Construction." Arranged to meet the requirements of the Syllabus of the Science and Art Department of the Committee of Council on Education, South Kensington. Part IV. Calculations for Building Structures. Course for Honours. London: Longmans, Green & Co. 1891

can be used for their solution with much less chance of error than abstruse mathematical calculations. The detailed manner in which the various problems are worked out, and the number of examples given, abundantly justify the publication of this portion of the work as a separate volume, for it is quite evident that it could not have been incorporated with the volume on materials without rendering it altogether too bulky.

The first chapter explains the terms in general use, such as live and dead load, breaking load, &c., the various stresses which act upon bodies, the strains in the bodies set up by these stresses, and the modes of fracture, and such expressions as the "modulus of elasticity," which is the quotient obtained by dividing the stress per unit of area by the strain, being generally expressed in pounds per square inch; or, in other words, it is the weight that would be required to stretch a rod of one square inch sectional area to double its length, supposing it did not break. The subject of equilibrium is next treated; the diagrams explaining how the re-actions at the points of support are ascertained as soon as the position of the load is known with reference to the supports are very clear, and a student carefully reading these remarks cannot fail to gain a clear insight into the subject. The determination of the external forces acting upon a structure and their re-action is generally simple enough, and the real difficulty of understanding the theory of the resisting power of materials comes in when the equilibration of the bending moment with the moment of resistance at any section of a beam is investigated; in other words, when the internal stresses produced by the action of the external forces are considered, and the way in which the fibres of the material resist these stresses. We are inclined to the opinion that the thorough elucidation of these problems can only be attained by the use of the Calculus, but after a very careful perusal of this portion of the book we are convinced that this is the clearest and most successful attempt that has been made to fully explain them in a simple manner that can be understood by the ordinary student. The terms in use, such as "neutral axis," "modulus of rupture," "shearing stress," and others, are

explained, graphic representations being always given alongside the ordinary figures, showing the varying position and distribution of loads on a simple beam. The student will easily learn how to delineate the figures, and he will, moreover, see for himself the reason why,—to take one example only,—a distributed load over a beam exerts only half the effect on it that the same load concentrated does. The difference between *strength* and *stiffness* is clearly described, and the formulae for deflection are investigated as thoroughly as is necessary. The authors in this portion of the book have been compelled to touch the fringe of advanced mathematics, and as they are obliged to use the term, "moment of inertia," we think it would have been well to attempt some explanation of it, or the student will be hopelessly perplexed when he meets it. If a body be imagined as composed of an infinite number of minute particles, each of these particles is at a certain distance from the neutral axis of the body; if the weight of each particle be denoted by w , and its distance from the neutral axis by $d_1, d_2, d_3, &c.$, then $wd_1^2 + wd_2^2 + wd_3^2 + \dots + wd_n^2$, i.e., the sum of the products of the weight of each particle by the square of its distance from the neutral axis is the "moment of inertia" of the body about that axis. It may possibly be objected that this explanation would not be of much value to the ordinary student; but even if this be so, we cannot think it right to introduce, without any attempt at elucidation, a term which by no means carries its meaning on the face of it. The effect of fixing the ends of beams, instead of merely supporting them, is excellently shown by diagrams, in which the points of contraflexure are very clearly indicated, and a careful study of these diagrams will be of the greatest possible use to the student; in fact, we are not aware of any other attempt to explain graphically the great difference in the curve of deflection of a beam caused by preventing its ends from tilting up. The diagrams to which we particularly refer are figs. 111 to 119. The next chapter is upon wrought-iron rolled beams, and the method of finding the moment of resistance of an I beam is fully and clearly shown. Cast-iron girders are next treated, but as the use of these has almost died out, and as the author himself observes that "the material of which they are made is so treacherous and uncertain that it is always necessary to use a large factor of safety," this chapter is not of very material use or interest.

The chapter on tension and compression bars is well written, and the reason why the calculation of the resistance of a compression bar is a much less simple problem than in the case of a tension bar is clearly shown, and it is easy to understand from the considerations here laid down what an important element in the strength of columns or struts a slight inequality of load constitutes, producing as it does irregularity of pressure, so that the stress never presses absolutely through the centre line. In this connexion we think the author should have made some reference to the experiments of Weyrauch, Bauschinger, and others, on the effect of variations in load, as formulae of comparative simplicity have been deduced giving a means of obtaining from the quiescent stress what is called the vibration safe strength,—i.e., the strength of pieces when subjected to alternate tension and compression. It is true that early in the book Wohler's tests are barely alluded to, but the whole question is of so much interest and importance that it should have been treated at greater length. The element of uncertainty with regard to columns and struts has evidently sorely tried those investigators who have endeavoured to make one formula apply to all cases, for in an example worked out on page 115 from the various formulae which are given, the results vary to the extent of 500 per cent., and it is not surprising that one of the most recent experimenters, Prof. Fidler, C.E., has come to the conclusion "that the strength of columns cannot be defined by any hard-and-fast line." Rivetted and other joints,

both in wood and in iron, are explained, and we are glad to find that pin joints have received adequate attention, for the increasing use of iron roofs renders it very desirable that this form of connexion should be clearly understood; and the calculations for a large plate-girder are very fully worked out, with graphic delineations of the bending moments. Ample attention is given to framed and braced structures such as roofs, and the method of drawing the stress diagrams suggested by Professor Clerk-Maxwell is explained. We should have been glad to find here a more detailed reference to and explanation of Bow's system of notation, which is so excellently adapted to all structures, whether simple or complex, and, when once mastered, simplifies calculations immensely. This is only shortly noticed in one of the appendices. Numerous examples are worked out in a large number of diagrams, some of which are in plates at the end of the work, but these have been generally so arranged that they can be unfolded and read simultaneously with the letterpress referring to them. This is a matter of no small importance. The conditions of stability of brickwork and masonry structures are investigated, such as chimney-stacks, retaining walls and arches, the diagrams illustrating the latter being to a large scale and very clearly drawn; and the last chapter treats of the motion of fluids in pipes. We should have been glad to see a few pages devoted to the motion of gases and the calculations of the sizes of pipes required for gas supply, as these are not readily attainable.

At the end of the book are a series of useful appendices, of which No. 11 seems particularly valuable; but we are not quite sure whether the last—No. 21—is not somewhat dangerous. For ourselves, we should prefer to keep in the memory the various formulae in the forms in which they are generally used; for if one sometimes uses a formula for the strength of beams, for example, in which the length is taken in inches, and the result comes out in pounds; and at other times the same formula, altered so that the length is in feet and the result in hundredweights, the chances of error are increased. A number of most useful tables are given, which appear, as far as we have tested them, carefully drawn up; but has not the author given much too high figures for the moduli of rupture of various woods in Table I.? Certainly, if the experiments carried out by Mr. Lanza in the United States are correct, these figures should be reduced. We must also say that, practically, we should scarcely be satisfied with the dimensions given on p. 310 for the tie-beams and principals of wooden roofs, even though they carried no ceiling.

We have already stated that the author has wisely given a number of examples in which the application of the rules of formulae is illustrated by working out the calculations in detail, and there is nothing more useful to the student than studying such examples, as without their help he would be likely to flounder hopelessly. In such a work as this the greatest possible care is required to ensure accuracy, as there is nothing in the context to suggest the rectification of errors, and we regret to notice some serious inaccuracies which are evidently due to carelessness, and which will mightily perplex the conscientious student. We do not profess to have checked a tenth part of the calculations; but we feel compelled to call attention to the fact that in a future edition,—which we have little doubt will soon be called for,—the whole of these examples must be carefully revised. For example, the use of the sign of addition instead of that of multiplication occurs far too often, the position of the decimal point is wrong in some cases, and many other small errors will be found; but on page 79 there occurs an accumulation of blunders that is quite inexplicable. We refer to example 6, where 20 ft. is said to equal 120 in.; 1,100 lbs. is put down as the modulus of rupture, instead of 11,000; the safe load is calculated at "about 3 tons," whereas, if the figures

actually put down are worked out, the result is 11 tons 16 cwt., while the correct answer is 5 tons 18 cwt.!!

Again, on pages 84 and 85, the introduction of the letter n into the description of the stress area (shown graphically) of the flange only of a rolled-iron joist, makes it quite wrong, and would puzzle a student very much. On page 91, example 10, in calculating the deflection of a beam by the formula $\Delta = \frac{nWl^3}{EI}$ when W is the total load on the beam, the serious error is made of putting for W the load per inch-run. In several cases we notice that the scale of the diagrams is stated to be $\frac{1}{2}$ in. = 1 ft., when it is really $\frac{1}{4}$ full size. Seriously, these errors—and we have not exhausted the list—ought not to have occurred, and it is because the book, as a whole, is so good, that we have called attention to them, in the hope that they will soon be rectified.

NOTES.

NOTHER great labour dispute has broken out in the North, originating in the apportionment of work between two branches of the engineering trades. The number actually on strike is variously stated at from 6,000 to 8,000, but only a small proportion of the strikers are really concerned with the matter in dispute. It is understood that the same question has previously been referred to arbitration, but the struggle has recommenced in consequence of dissatisfaction with the arbitrator's decision on the part of some of those affected. There is still much friction at the shipbuilding yards with regard to the old-standing question of overtime, and, although the dispute as to distribution of work seems to have been the pretext for all the strikes which have taken place during this last week, there is every probability that the former question will also be forced into prominence before work is resumed. It would be well for the strikers to consider the arguments put forward by Earl Ravensworth at the annual meeting of the North of England Steamship Owners' Association last week. There is no doubt that the present position and outlook of our trade points to a shrinkage in wages; and the maintenance of harmonious relations between capital and labour is one of the principal safeguards against this state of things becoming still more serious. The ostensible cause of the present dispute is eminently one for arbitration, and the strike is a great mistake,—especially on the part of those who are participating without any grievance of their own. The trades unions are apparently very sensitive and imaginative, one society having passed a resolution on Saturday approving of the strike on the ground that "we believe the employers are anxious to deal a blow at the organisation which dares to do battle for our trade." The "sympathy" of affiliated industries which would be highly commendable under some circumstances is now leading them to the unreasonable length of driving work out of their own yards, without any regard to the relations existing between themselves and their employers. Ill-feeling will inevitably ensue, as the consequences are sure to be disastrous to some employers with whom there is no ground for quarrel. A reckless disregard is shown for the prosperity of the district as a whole, for the coal trade and the carrying and other industries will necessarily be seriously affected by the stoppage, and it is, indeed, difficult to say where the mischief may end. Strong condemnation of strikes and lock-outs at the present time has been expressed at mass meetings in Newcastle, the men themselves being anything but unanimous as to coming out.

THE recently-issued "Second Annual Report of the Geological Survey of Texas," 1891, contains some exhaustive particulars of the different kinds of building

stone found in the State. Granites, used for building, occur in two areas,—the Central Mineral Region, and in the extreme west, or Trans-Pecos Texas. The best-known granite in the first-mentioned area is red to dark reddish-grey, varying from fine to rather coarse grain in structure, and susceptible of a high polish; it was used in the construction of the Capitol building. The outcrop of the granite, which can be quarried to any desired dimensions, covers an area of more than 100 square miles. In the northern part of Gillespie county there is a brownish granite of very fine grain, and others varying in colour from light to dark grey, well adapted for building purposes. The granites of Trans-Pecos Texas lack the variety of colour which is found in those of the central region. They are all near good railway accommodation, however. Porphyries of almost every shade and colour abound also in the western portions of the State. Amongst the marbles, that known as Austin is the most noteworthy; it is quarried from the Cretaceous formation. The body of the stone when polished is of a light yellow colour, and the tracings of the contained fossil shells in pure calcite imparts to it a very pleasing effect. The Carboniferous limestones of the northern part of the State also produce good marbles; and those known as "Burnet," from the Silurian are pink, white, buff, blue, and grey in tint. Abundant marble, destined some day to become the basis of a great commercial industry, is found in the Carrizos and Quitman mountains; it is banded or striped and clouded, as well as pure white. "Some of them," says the State geologist, "when polished will rival the Aragonite or Mexican Onyx in delicacy of colouring." The limestones of Texas suitable for building purposes are abundant and widespread in their occurrence; the best cretaceous limestone is that from the Fredericksburg and Washita divisions, which varies from white to yellow. The area of the central coalfield produces excellent building sandstone, which is extensively utilised; and the Central Mineral district furnishes good slate for roofing purposes. As a test for durability,—of building stone it is stated that, if in the field, a bed of stone under examination is entirely hidden from observation by the material of its own destruction, it will prove to be a stone that will suffer greatly on exposure; but if it stands out in bold escarpments whilst the other part of the strata are decomposed, it shows that it has a strong power to resist atmospheric influences. This may be very well as a rough-and-ready rule, but it certainly does not always apply. The method adopted in describing the building stones in the work alluded to might very well serve as a pattern to geological surveyors on this side of the Atlantic. The majority of the Geological Surveys of the United States, recognising the fact that they have been constituted to collect geological information of commercial value, carry out their work in that spirit; let us hope that the Geological Surveys of Great Britain, now that they have given us good geological maps and philosophic descriptions of the strata, &c., will shortly turn their attention also to the practical aspect of their science. There is a wide field open before them, and the public might then get some adequate return for the large sums of money annually disbursed for the purpose, from which but little result has hitherto accrued.

THE lecture on "Dust" delivered by Dr. Priglin Teale at the Society of Arts on Wednesday evening was intended evidently as the first suggestion of a new sanitary campaign against the admission of dust into our houses. The lecture consisted mainly of a exposition of the means which have been adopted by Dr. Teale for some time past to regulate the movement and settling of dust. It pointed out in the first place that the access of dust into receptacles, such as cupboards and closets, arose from the constant changes of temperature and barometrical

pressure in the atmosphere, which caused frequent currents of the air in and out through crevices and the interstices of doorways, carrying the dust with them and depositing it as the air settled. Shortly stated, Dr. Teale's principle is to stop out the air from all access to a closet or box save through one aperture, of an area in proportion to the internal space to be protected, and filling that aperture with a dust-filter, cotton-wool being the most efficient of various materials experimented on. To carry out the method requires very good workmanship and fitting of doors, and the application of air-excluding strips of soft material at the sides of doors and windows. The application of the method to keep dust out of drawers, boxes, and closets is proposed to be further extended to keep it out of houses, by similar treatment of the windows. The sash window must be given up, as not sufficiently controllable in regard to access of air, and windows formed with the greater portion fixed, and only a tall narrow sash hinged to open as a casement, and protected in the same way as closet-doors and boxes. This, of course, presupposes a special admission of air through ventilators, which are also to be protected by dust-filters. As far as concerns the exclusion of dust from closets and drawers where papers may have to remain a long time undisturbed, the suggestions are perfectly practical, and the demonstration of the results of the method incontestable. The exclusion of dust from the whole house is another matter. Some of the dust is created within the house, by decay and other causes; Dr. Teale affirms that most of the dust in towns is connected with smoke, but we think he attributes too large a proportion to this cause; and it is obviously of no use to have elaborate methods for keeping out dust if any considerable part of it arises within. The adoption of his principle for the whole house would mean an amount of delicate and costly work which cannot generally be afforded; a degree of care and supervision which would only be given by those who had an anti-dust "fad"; and, last but not least, a practical stoppage of direct fresh air through open windows. This latter, from a sanitary point of view, would be a worse evil than the dust, and we will never listen to any suggestion which is to interfere with the free opening of windows to the outer air. For the exclusion of dust from the house, therefore, we think Dr. Teale's method can hardly be regarded as "within the region of practical politics." For the exclusion of dust from store-closets, boxes and drawers it is perfectly practicable and may be very valuable, and the thanks of the community are due to Dr. Teale, in this as in so many other cases, for his investigations as well as for his clear and lucid exposition of the results.

A REPORT on the recent outbreak of enteric fever at the Foundling Hospital, by Dr. Sykes, the Medical Officer to the St. Pancras Vestry, gives an instructive account of the search made throughout the premises for any probable cause of disease, and the unexpected cause to which it was ultimately traced. The annexed plan, copied from one of the diagrams published with the report, explains the circumstances from which the disease originated. The grease-trap shown on

the plan discharged into the inspection-chamber through a pipe with the end dipped into the grease-trap to form a seal. Excreta were found in the grease-trap,

and it was discovered that the periodical discharge of an automatic flush-tank down the infirmary drain caused a backwash into the grease-trap, the flush of water coming faster into the inspection-chamber than it could get away, and some of the contents of the drain were thus washed over into the grease-trap. The grease-trap took the discharge from the coppers in the kitchen, and on filling it with a charge of ammonia and peppermint it was found that the smell in a few minutes rose from the coppers and thence permeated a great part of the building. Dr. Sykes observes,

"This grease-trap was even a better incubation-chamber than the suspected water-cistern in the warm lumber-room. The warmth from the hot-copper water, the restricted and confined air supply, the nutritive material discharged into the trap, the access of infected fecal matter, the fermentation set up, and the rush of the warm expanded air and vapour through the copper pipes and copper into the kitchen, the offices, and the staircases, are all factors favourable to the cultivation of infective matter, and to its diffusion by vapours covered by the odour of cookery."

It may be added that the pipe from the ward sinks (see plan) which also acted as a ventilating pipe to the inspection-chamber, was connected into the drain and untrapped, and may thus have assisted in leading up effluvia through the sinks; but the main evil was the close connexion of the grease-trap with the inspection-chamber on one side and with the interior of the kitchen on the other side.

THE Borough of Nottingham has issued an excellent coloured chart illustrating the relation of the number of deaths from various causes to the principal meteorological conditions on each day of the year 1891. The chart and tables of rainfall are very well got up, and the example here set might be followed with advantage by other Corporations and County Councils. The study of the results in detail is of course rather a matter for a medical journal than for our columns.

WE opened the *Fortnightly* this month with some curiosity on finding that it contained an article by Professor William Crookes, F.R.S., on "Some Possibilities of Electricity." The learned Professor had somewhat astonished the electrical world last November, in an after-dinner speech, by saying that "it has been computed that in every single cubic foot of ether there are locked up 10,000 foot-tons of energy which has hitherto escaped notice;" and we naturally expected that we might find in his article in the *Fortnightly* some explanation of this hard saying. We were, however, disappointed. The article covers much the same ground as the speech, though, of course, addressed to a larger audience. It deals with Professors Lodge and Hertz's investigations of electrical vibrations of ether, and anticipates the time when they may be made use of to telegraph without posts or wires. It alludes to Tesla's experiments with rapidly alternating currents, and points out the great possible gain in obtaining light, with far less heat, and, therefore, with far less expenditure of energy. There is also some Utopian talk of dissipation of fogs, controlling the weather, &c., and with it the very practical remark that the electro-static machine can no longer be regarded as a toy. But the 10,000 foot-tons have disappeared with the ether whence they came. Professor Crookes supplies us instead with another riddle; he tells us that the total *vis-à-vis* of sunlight per acre amounts to 800,000 horse-power per year, of which 3,200 horse-power are used by the crops. If Professor Crookes would only condescend to use words in their ordinary sense, we might make out what he means by this; at present it is much as though he were to tell us that the rainfall is equal to the speed of an express train. The article is pleasantly and easily written, and we find in it occasional gleams of transatlantic humour. Perhaps more of it than we suppose is intended to be taken humorously, which would account for much. The Professor's interest

in psychical theories is well known, consequently we are not astonished to find thought-transference and brain-waves cropping up again, this time with the suggestion that the brain-waves are electrical.

IN a recent correspondence with the County Council, the St. Saviour's (Southwark) Board of Works have moved for a removal of the bars and gates which of late years have obstructed traffic through Montague-close. A way formerly led north of the church to Pepper stairs, High-street, and (old) London Bridge. Like the Mint, and the neighbouring Deadman's-place (now Park-street) and Clink, the close has been a sanctuary, privileged, it is said, from the circumstance that Lord Montague lived there when he received the letter that betrayed Guy Fawkes. But the facts, as set forth in the *Archæologia*, vol. xii. 200-11, by no means support the "tradition"; and confusion has arisen between the names of Montague and Montague. At the suppression the priory, with the close, the church of St. Mary Magdalen, and appurtenances, its income being valued at 62*l.* 6*s.* 6*d.*, was granted to Sir Anthony Browne, Henry VIII.'s Master of the Horse, whose son was elevated Viscount Montague. This family were staunch Catholics, and the close became to be known as "Little Rome." In the "Gentleman's Magazine," September, 1808, is a view of the house they built in the close; taken down in November, 1828. It stood close against the church's north side, for in the parish books for 1596 is an entry for making a new door in the church wall entering into my Lord Montague's house. John Carter carefully inspected the remains of the conventual buildings in 1797 and 1808. Allen, twenty years later, describes the then state of a crypt standing north and south, measuring 100 ft. by 25 ft., with two aisles, and a groined roof supported by octagonal columns. Over this extended a spacious room, which retained traces of an open timber roof. Some exterior cornels carried fragments of groin-springing, probably of the cloister.† But all above ground remains, together with the two quaint rows of Alice Overman's almshouses, gave place before the large warehouses and the Bridge House Hotel, planned and designed, 1838, by George Allen, architect. The Guildhall Library contains several good views of portions of the close, with Montague House, and the main gateway at the western end of St. Saviour's.

A CORRESPONDENT writes:—"In regard to the proposed new clock for St. Paul's, we read that 'the old clock strikes the hours on the old "Phelps" bell, but the new one will strike upon "Great Paul," which is nearly 17 tons weight, with a hammer weighing 680 lbs.' Is it wise to run the risk of damaging the best and soundest bell in the British Empire by smashing a 680 lbs. hammer upon it every hour? I should like to see in print a certificate from Mr. Taylor, of Loughborough, the designer and successful founder, that he desires 'Great Paul' to be thus rudely treated; so that, when the bell gets cracked, the blame can be apportioned in the right quarter."

FROM some correspondence which has taken place in the *Manchester Guardian* it is evident that our remarks concerning the Whitworth Institute competition and the policy of privacy in regard to it are entirely in accordance with local feeling on the subject. One correspondent comments on the fact that only twenty-three designs were sent in, although the scale and importance of the building as proposed were such that it should

* The letter, inscribed to "The Lord Mow teagle," was delivered to his footman "as he passed in the streets towards night"; the conspirators agreed to preserve Lord Montague and others, with, at Percy's request, the Earl of Northumberland and Lord Montague.

† See also Conzenan and Morgan's book, 1725; the account by Carlo in the "Gentleman's Magazine," June, 1835; and "Old Southwark and its People," by Mr. Wm. Rendle, F.R.C.S., 1878.

have been one of the great competitions of the day. In reply to this, Mr. E. Salomons, the President of the Manchester Society of Architects, writes that the conditions imposed upon competitors were such that he for one felt quite unable, consistently with professional self-respect, to send in designs, and that he presumed others had the same feeling. It appears that, now that the designs are sent in on the scheme issued to competitors, the committee have changed their ideas, and that consequently the plans now sent in are useless. In that case the competing architects have certainly very strong right to complain. Competitions under the best circumstances involve an immense amount of wasted labour on the part of the architectural profession, and those who call upon architects for competing designs should at least make up their minds first what they are going to do, otherwise they are merely amusing themselves at the expense of the architects. If this present competition is really to be entirely abandoned, after the issue of an elaborate scheme of instructions, the committee ought to feel that it is incumbent on them, in common fairness (we might almost say in common honesty) to give some pecuniary compensation to the architects who have been tempted into wasting their time and labour to no purpose.

TO the February number of *A. A. Notes* Mr. W. B. Richmond contributes an excellent little paper on "Architecture from the painter's and sculptor's points of view," in which, so far from repeating a favourite theory of the moment, that architecture is nothing without sculpture, he emphasises the idea that architecture is *building*; that the business of the building is to be effective and impressive in itself without any aid from other arts; and that these can do little to redeem it if it is not in itself noble building. It is to be hoped that some of the architects who are so anxious to be sculptors, and to look down on unadorned building as uninformed with art, will duly consider this counsel from an artist who is not an architect, but who sees more art in architecture pure and simple than some architects seem able to find in it. "Give us," he says to the architects, "works of art as builders. And when you have done that, then we sculptors and painters will try in our way to help, not mar your work, which, if it is very good indeed, will need neither sculpture nor painting to make it perfect art."

MISS EUGÉNIE SELLERS is to give six afternoon lectures on Greek sculpture at the British Museum on Wednesday, February 10, and the five succeeding Wednesdays. The lectures will deal with the development of sculpture and relief, and its technique, and Miss Sellers, we perceive from the prospectus, proposes to uphold the position that the Greeks "were masters of rhythm and symmetry but not of decoration." We certainly have been under the impression that the Parthenon frieze was the finest decorative bas-relief in existence, though it is in the wrong place in some respects. An extra lecture is to be given on March 23, on the horses and other animals of the Parthenon frieze, by Mrs. N. Cohen, who has made a special study of the subject.

THE exhibition of Mr. Wyllie's "Holiday Drawings in France and Italy," at the Fine Art Society's Gallery, is a remarkable example of the varied interest which a true artist may get out of a single scene in all its different aspects. The French sketches, sixty-one in number, are the most important part of the collection, and are all at the fishing town and watering place of Berck. They are nearly all scenes on the beach, under varying aspects of weather, and with varied sketches of fisher-folk, visitors, and boats, but there is no sense of monotony in the sketches, almost everyone of which has its special interest. Two which are espe-

cially good are 15, an evening effect, and 18, the breakers on a breezy morning. A pleasant interest is given to the catalogue by a new method of presenting the subjects; instead of a series of dry titles, there is a picturesque account of the expedition and the place, signed "Marian A. Wyllie," and the number of the drawing which illustrates each sentence or allusion is given in the margin.

A COLLECTION of small oil paintings by Mr. Wimperis, "Rustic and Riverside Pictures" is on view at Messrs. Dowdswell's Gallery. It consists principally of pictures of river and meadow scenery, and shows the breadth of treatment and the fine aerial effect which have always characterised this artist's work, but to those who have known Mr. Wimperis best by his water-colours it also suggests that he is best known so; his broad free style is essentially a water-colour style, and when transferred to oil it seems a little toneless and hard, the technique which brings out the best effects of water-colours not being equally applicable to the other vehicle. In the same gallery is a collection of "Pictures of London street life," by Mr. Chas. P. Sain-ton (the son of the late eminent violinist of that name), which, amid a good deal of *chic*, contains studies of street children which are natural and piquant, especially "A Siesta in Covent Garden" (9), "Street Arabs" (21), and "A Picnic in the heart of London" (27). In "Au revoir" (25), a study of a young lady stepping into a hansom, the artist has made a pretty little *genre* picture out of an everyday London incident.

THE case of "Morris v. Brinsmead and another" throws an interesting light, for the outside public, on the manner in which laudatory paragraphs in newspapers are managed in these days. Part of the plaintiff's claim against the defendants was for commission for getting paragraphs inserted in newspapers about their pianos. This is only one instance of what is continually going on in the Press in these days, in the way of notices of inventions, and a most discreditable thing it is to the English Press of to-day, which however is probably not worse and possibly much better in this respect than the Press of some other countries. The charge is not that papers will insert such puff paragraphs for direct payment,—few of them descend to that, though many of them will bargain for an advertisement in exchange for a "notice"; but inventors and patentees can get notices (written by themselves) into a journal by paying a man who is not officially on the staff of the paper, but who has credit with them and whose contributions are accepted without any troublesome questions being asked. They are people who are useful to the paper, in short, and are favoured accordingly. In the leading daily papers of the day there are constantly to be seen descriptions and recommendations of new inventions, which are in fact written by those who are commercially interested in them, and then appear to the confiding public as independent expressions of opinion on the part of the journal in which they are printed. "Puffs" of this kind are sent to us constantly by persons interested in building inventions: paragraphs describing the excellence and advantages of their own patents, and intended for insertion as "notices." It seems almost incredible sometimes that people should suppose that any editor would accept such barefaced puffs and give currency to them; but they are accepted in many quarters, either directly, or through being smuggled in by some one who has credit with the paper; and readers may take it for granted that not one in a hundred of the paragraphs on new inventions which "go the round of the papers" are the independent opinion of an independent person; they are the statements of persons commercially interested in the matter. The cause of this, in the case of the higher class of papers, is apparently sheer carelessness and an absence of the proper sense of responsibility. The

plain rule ought to be that no one is allowed to write anonymously in a paper upon anything in which his own interests are concerned. Until that becomes a generally accepted principle, the readers of newspapers will do well to distrust all paragraphs recommending this or that invention.

LETTER FROM PARIS.

THE two grand halls, given every winter at the Hôtel de Ville by the Municipality of Paris, have had the attraction of an artistic novelty this year, as the public can now see, by the numerous electric lights, the Salle des Fêtes with its ornamental decorations; though the ceiling paintings of Benjamin Constant, Aimé Morot, and the other artists engaged, are still wanting. At the death of Lavastre, the ornamental work was undertaken by MM. Carpezat and Guffart, who have in fact only followed the scheme sketched out by their predecessor. The effect is very sumptuous, though it will look somewhat crude until the gold has toned down a little. At present, the eye finds no repose amid the crowding of bas-reliefs, medallions, statues, many-coloured emblems and escutcheons encumbering the too massive frames of the panels. This plethora of decoration makes one regret the more the Salle des Fêtes of the old Hôtel de Ville, as it used to appear at Imperial receptions, with its elegant decoration in pure Renaissance style. The ceiling was soberly treated in coffers and garlands, and the compositions with which Henri Lehmann had decorated the vault formed an admirable frame to the paintings by Horace Vernet, Léon Cogniet, Ingres and Delacroix. Instead of these we have now the commonplace figures of M. Milliet, the uninteresting compositions of M. Aublet, and the ceiling by M. Gerver symbolising Messic, the foreground occupied by an imaginary proscenium of a theatre, where the eye rests first on the realistic black dresses, lognettes, and bald heads of the occupants of a realistic orchestra.

"Fin de Siècle" is the expression that sums up the character of this decoration; nor can one admire more unreservedly the blue and red eccentricities of M. Besnard or the contorted torsos of M. Carrière, which are supposed to combine the drawing of Michelangelo with the chiaroscuro effect of Rembrandt. In the whole assemblage of work there is nothing really decorative except the large composition by M. Puvis de Chavannes, though it is to be hoped that the artist will modify the heavy effect of the mass of trees in the middle distance which seems to crush the figures. If he does away with this one fault his work will remain the dominant one in this curious collection of decorations, which impresses one somewhat like an orchestra in which each player is performing an independent part, with no reference to the others.

It is, therefore, gratifying to find that the Municipal Council have chosen this eminent artist to succeed Elie Delanay in decorating the vault of the grand staircase; though M. Puvis de Chavannes has never before painted a ceiling, and his dislike to the task was with difficulty overcome. It will be interesting to see the result, and there is no doubt at all events that in this case the decorative painting will be subordinated to the lines of the architecture, both in design and colour.

The Paris municipality have been making a curious experiment, in giving a commission to M. Jules Cheret to design some cartoons for tapestry for the decoration of a room in the Hôtel de Ville. M. Cheret is well known for his designs of posters, with which he has covered many walls as well in Paris as in provincial towns. These very original works make quite a popular museum of art, and have almost revolutionised the art of the placard. The object of the commission is to obtain some tapestry designs with little delay, as it is useless to appeal to the majestic inertia of the Gobelin's manufactory.

The "Cercle Artistique et Littéraire" of the Rue Volney has been first this year in the usual series of small winter exhibitions, and the collection is on the whole superior to its predecessors. Among the exhibits is a fine portrait of M. Henner by M. Carols Duran, two beautiful portraits by M. Jules Lefebvre, other portraits by Rixens, Weerts, and E. Sani, landscapes by MM. Yon, Bnsson, Nozal, Félix

Boucher, and a highly-coloured representation of the Ducal Palace at Venice by M. Benjamin-Constant. There is also M. Henner with his eternal blond figures, ivory on a black background; M. A. Maignan has painted a "Cigale" shivering in the snow, and M. Olivier Merson exhibits a set of important sketches for windows intended for the Church of Saint Adresse.

The Salon of Water-colour Artists has just opened its doors, we may find space on another occasion for a few words about it. We may first notice in passing a small but charming exhibition of landscape-paintings by a young artist, M. Paul Lot, collected at the Hôtel Balmes, Avenue de l'Opéra, views in Normandy and sea-pieces. M. Pissaro, the impressionist artist, has also opened an exhibition of his works in the Durand Ruel gallery, which for some years past has rather made a specialty of artistic eccentricities.

We have mentioned already that in consequence of dissensions among the representatives of the late M. Meissonier the exhibition of his works has been given up. The quarrel is in fact about to come before a legal tribunal. On the one hand the widow of the painter wishes the paintings, sketches, and statuettes to be sold by public auction, while the children of the first marriage demand that the works of their father should be divided among the inheritors instead of being sold. Such seems to be the opinion of the magistrates, who consider that such a division was much more in accordance with the painter's wishes than a sale. The decision is, however, still pending. It is somewhat pitiful to see these wretched squabbles among the relatives of the great painter almost at the very moment when the anniversary of his death, according to Parisian custom, is being celebrated solemnly at the Madeleine.

A decree of the Minister of Instruction has regulated the mode of appointment of the architects of the Service des Monuments Historiques, who henceforth will be appointed by competition. The same decree announces that in future the Inspecteurs-Généralx in this service cannot be charged with the works carried on in a classified monument. An exception is made in favour of those who are actually carrying on such works at present on a commission dated prior to this decree. Another Ministerial decree provides for the creation, at the Ecole Nationale des Beaux-Arts, of a course of history of French architecture in the Middle Ages and the Renaissance; a decision which will fill a deficiency long felt in the scheme of architectural education. We may add that the Minister of Instruction will shortly have to appoint a successor to Henriquel Dupont, who was professor of engraving in the Ecole des Beaux-Arts.

A few particulars may be added as to the work of the Ecole. On January 21 a committee, presided over by M. Guinay, gave the award in the competition entitled "Prix de Reconnaissance des Architectes Américains." The subject of the competition was "a mansion in a considerable number of storeys, similar to those in New York, Chicago, Boston, &c." After having examined nine designs submitted, the Committee awarded the prize to M. Depertthes (pupil of MM. Depertthes and Guinay). In the "Enseignement Simultané des Trois Arts" M. Binet, pupil of M. Laloux, has obtained a third medal for decorative design. In the competition in History a third medal has been awarded to MM. Goupy and Kohn, pupils of M. Reclou.

The Government some time ago commissioned four marble statues for the principal entry of the National Library, Rue de Richelieu. One of these statues has been recently erected, and gives a good promise for the decorative effect of the whole group when completed. It is the work of M. Hagnes, and symbolises "La Gravure." The others, which are to complete the group, will represent "L'Imprimerie," "Les Médailles," and "Les Manuscrits."

The Louvre has acquired recently an interesting collection of sketches, among which is a study by Pierre Guérin, "Dido and Eneas," a splendid sketch by Ingres, and three masterly drawings by Gréoult.

We have seen recently, at the atelier of M. Rodin, the clay model for the monument to Balzac to be placed in the Palais Royal. The author of the "Comédie Humaine" is represented standing, draped in a kind of monkish robe which he was accustomed to wear in his study, the arms crossed, the head raised and with an expression at once energetic and meditative. Not far from this statue will be placed those of

Cornelle and Racine, at the right and left of the entry to the Avenue de l'Opéra. The modern generation having, among so many statues, forgotten these two glories of French literature, the Municipal Council headed a public subscription for funds to arrange a competition for the execution of these two monuments.

The death is announced, at Paris, of a Swedish artist, Mdlle. Christine Lundberg, who came every winter to pursue her studies under M. Courtois and M. Raphaël Collin. She had exhibited, in the Salons of 1888, 1889 and 1890, portraits and *genre* subjects; and a picture of hers, "La Toilette," was in the Swedish section of the 1889 great Exhibition.

In the last issue of the *Builder* allusion was made to the death of Dupont, the celebrated engraver. Louis Pierre Henriquel Dupont was born in Paris in 1797, and has died therefore at the age of ninety-four. He studied painting first under the painter Pierre Guérin, and engraving under Berville. At the age of twenty he had already obtained sufficient reputation to open an atelier which had an immediate success. He gave promise already of the qualities which have been predominant in his work; a rare correctness and a remarkable purity of style. He engraved most of the portraits painted by Ingres. He had some great successes with the works of Delacroix, and finally engraved his chef-d'œuvre, the "Hémicycle des Beaux-Arts," and subsequently "The Entombment of Christ," by the same painter. He also engraved various works by Ary Scheffer, Hersent, and Lehmann, and among his engravings from the old masters may be mentioned the "St. Catharine," after Correggio, and the "Walk to Emmans," after Veronese. Among modern works which he interpreted may be mentioned also the portrait of the Baron de Rothschild by Hippolyte Flandrin, the "Ecole Turque" after Decamp, and "Entry of Henri IV. into Paris," after Gérard.

Since 1849, Dupont was member of the Académie des Beaux-Arts, and had a multitude of medals at various exhibitions, and the cross of commander of the Legion of Honour. In 1863 he was appointed professor of engraving at the Ecole des Beaux-Arts.

It is a long engraver's career of which the first plate dates from 1815. According to his express wish no discourse was pronounced over his tomb, nor any flowers or wreaths placed on it. But he remains honoured in memory as the last representative of that remarkable group of French artists of the earlier part of the century which included such names as those of Delacroix, Ingres, and Delacroix.

SARACENIC ARCHITECTURE.*

BY PROFESSOR AITCHISON, A.R.A.

I WILL begin at the beginning with the Kaaba. We heard in the last lecture that it is now about 40 ft. by 50 ft. on plan, of trapezoidal shape, and it may have been kept to its original foundation to the last. You will also recollect that in the early part of Mohammed's life it was hypæthral, the roof being formed by the cloth curtains that shrouded it, and that it was roofed with wood when he was thirty-five. I fancy the walls must have been pretty thick.

If we take 3 ft. for the walls, we get joists 17 ft. long, and the longitudinal girders could only have had a bearing of about 6 ft. 3 in. from centre to centre if there were six columns.

One is apt to think ancient ships, with the timbers of which the Kaaba was roofed, were small. I am by no means sure that the large merchantmen were not of considerable tonnage; at any rate, the ancients could and did build very large ships. The pontoon that carried an obelisk from Egypt to Rome, was big enough to form the caisson for the foundation of one side of the dock at Ostia, that the Emperor Claudius had built; and Ptolemy Philopater (222 B.C.) built a vessel 420 ft. long, 57 ft. wide, and 72 ft. from the water to the gunwale. This, it is true, was not so great as our *Great Eastern*, but it showed that the ancients could build vessels that were not in the category of fishing-smacks, so we may suppose the timbers of Bacdus's vessel were big enough to roof the Kaaba.

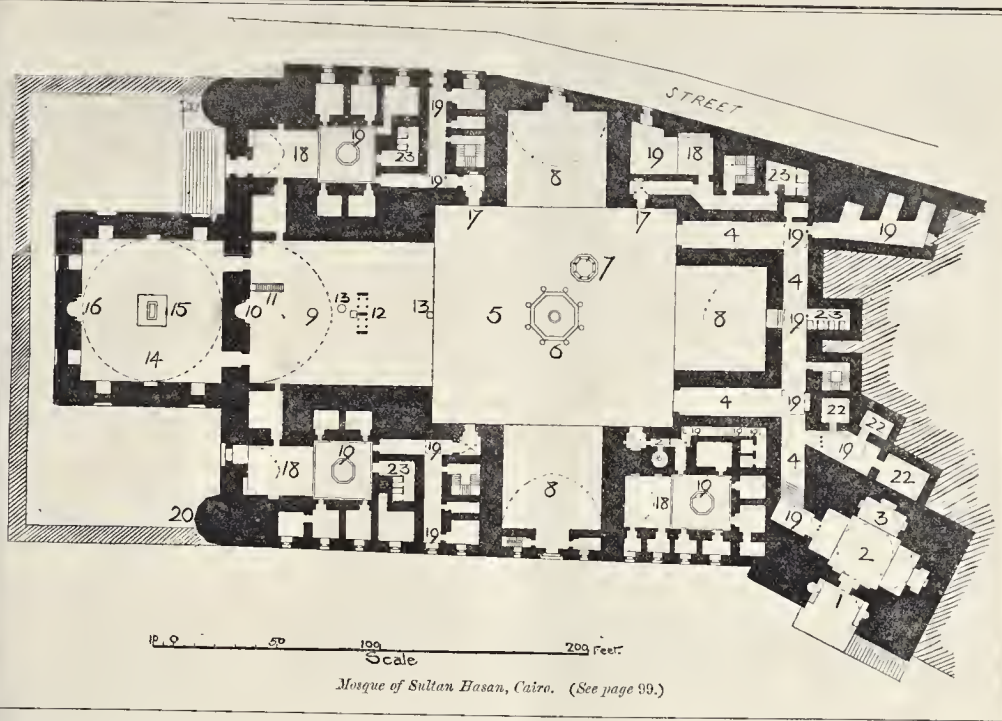

If there was any ornamental art displayed in the interior, it must have been in carving on

* Being the second Royal Academy Lecture on Architecture this season. Delivered on Thursday evening, January 23.

the beams, or in the capitals of the columns; but Bactim, the architect, was either a Greek or a Byzantine, so this art, if it existed, cannot be put down to the credit of the Saracens, and as little can the wall-paintings of Abraham and the Angels be attributed to them; these were the pictures Mohammed had erased when the idols were destroyed.

The Kaaba had a golden spout, and its doors are said to have been plated with gold; it was covered with cloth outside. It is no use speaking now of the black silk damask with which it was covered by the Abbassides, with a gold hand, and a Coptic inscription.

The next religious building we know of was Mohammed's Mosque at Medina; this, no doubt was greatly bigger than the Kaaba, as Mohammed's followers had become numerous. It is by no means certain that at the pilgrimages many were admitted into the Kaaba; at any rate, Mohammed most distinctly stated that entering the Kaaba was not necessary for the due performance of them, and regretted that he had gone into it at the taking of Mecca (8 A.H.—630 A.D.).

This mosque at Medina was probably like the Kaaba internally, only with many rows of wood pillars, probably with the girders parallel to the long side; there appear to have been buildings or porticoes for shelter on both sides of the court,—viz., one for men and one for women,—but this court seems to have been divided from the Mosque by a street. We also know that its kibia was changed from Jerusalem to Mecca,—i.e., from north to south, so the Mosque was possibly walled in; it had no mehrab, or niche, for that was only adopted in 53 A.H., and was probably copied from the apse of a Christian church, but this mosque was rebuilt, and the house of Mohammed's wives destroyed and taken into it by Welid I., between (86 and 96 A.H.) 705 and 715 A.D.

The next mosque we know of was that of Omar, at Jerusalem. Omar visited Jerusalem in 15 A.H., and it was built after he left. Some believe it was the dome of the rock.

Ferguson gives a small building about 90ft. by 80 ft. over all, in the mosque of El Aksah, as Omar's mosque, which he says is 80 ft. by 18 ft. inside, but the latest authorities believe it was a small wooden mosque since destroyed.

The next considerable one was built at Old Cairo by Amru-ibn-al-As, the conqueror of Egypt, in 20 or 21 A.H., some ten years after Mohammed's death; it was built for the use of the army, and was only about 75 ft. by 45 ft.,

and without a mehrab. It was enlarged by Moawia, and again by Abd-al-Aziz, the son of Merwan I., then governor of Egypt, who raised the roof.

In the days of Mamm (193-198 A.H.) the mosque was 435 ft. by 225 ft.; in 275 A.H. the mosque was burnt, and the green table destroyed, and was restored by Ahmed-ibn-Tulun's son, who expended about 4,080l. on it, and the architect's name was El-Adjil; a new portico was added 357 A.H., and it was restored by Saladin between 567-589 A.H. = 1172-1193 A.D., and afterwards repaired by Beybars and Kalann 658-689 A.H. It can only be hoped that from its being the first mosque built in Egypt, so soon after the prophet's death, that the peculiar sanctity, which in the eyes of devout believers still adheres to it, occasioned the restoration to be as much as possible on the original lines. All that can be safely said is that it conforms in plan to the early mosques.

The town of Kairouan was founded by Ocha, three days' journey to the south of Tunis, in 50 or 55 A.H., and the mosque was probably built shortly afterwards. Welid I.'s mosque at Damascus was probably built about 86 A.H., and the mosque and Cordova 170 A.H. = 786 A.D. The year of our era may always be got approximately by adding 622 to the year of the Hegira, but it is not exact as the Moslem year is lunar.

The original idea of a mosque for Islam was a wall at right angles to the meridian or kibia of some holy place; first, the Temple of Jerusalem, and then of the Kaaba at Mecca, with a shelter to shade the worshippers from the sun. As the prophet got old he introduced a pulpit, with three steps and a seat, so as to be heard better, and to rest when he was tired. Subsequently the exact line of the kibia was defined by the niche or mehrab, and the pulpit (minbar) became a fixture, mostly on the right side of the niche, as you face it. Nearly in face of this was the tribune (dikka), from which the Koran is recited, and the prayers intoned by the imam. A courtyard, with a tank or fountain, was wanted for the legal purifications before praying.

It is most embarrassing to know which of the early mosques should be chosen as the type, as they were all altered. I have spoken of the Kaaba, Mohammed's mosque, and the Mosque of Omar; the mosque at Kairouan, founded in 50 or 55 A.H., is said to have been wholly rebuilt by Hassan in 84 A.H., except the mehrab, and altered subsequently up to the date of

Mammn A.H. 212, so probably that at Damascus will be the best to begin with. It is about 400 ft. by 316 ft., with a small projection to the right and left, looking at the niche; the sanctuary itself is about 130 ft. deep by 400 ft. long, the rest being a courtyard, with a single portico or cloister round three sides of it; the wall with the niches is nearly due south; the sanctuary itself consists of three aisles, with the arcades parallel to the niche, or south wall, an unusual arrangement in later mosques; there are twenty-three arches, the centre one, opposite the niche, is as wide as three ordinary arcades; in the middle aisle, in front of the niche, is a dome supported on four massive piers. The sanctuary is described by an eye-witness as having pointed arches, resting on marble columns, and over them clearstory windows, the north ones are traceried and filled with beautiful stained-glass; the lower part of the walls are lined with marble, and remains of mosaic are found in the upper part of the central space fronting the niche.

The Mosque of Amru, at Old Cairo, is about 361 ft. wide by 548 ft. long, but this includes an outer court, with a khan on one side and baths on the other; the mosque proper, with its court, is about 384 ft. long by 361 ft. wide, and the sanctuary 361 ft. long by 111 ft. deep. The mosque has one single cloister to the entrance wall and a cloister on each side: looking to the niche, the right-hand cloister has three aisles, and that to the left four,—in both cases the aisles next the walls are very narrow. The mosque itself has six arches in depth, with the arcading at right angles to the niche wall, and twenty-two aisles in all,—those next the end walls are narrow, being continuations of the cloisters. The arcades have slightly-pointed horseshoe arches, supported on Classical or Byzantine columns of marble, with carved capitals; a pier of three courses rises from the cap, and then there is a slight projection formed by the heels of the horseshoe arches. The voussoirs are of two differently coloured stones alternating, and the alternate ones are painted red; the columns are tied both ways with wooden ties, after the fashion of Byzantine work. In 1866 this mosque was the Government "refuge for the destitute," and young ragamuffins were playing at huttons with the carved ivory panels they had knocked out of the pulpit.

The next is that of Kairouan, called El-Kehir. This mosque is not rectangular, nor are its sides parallel; it is about 407 ft. deep by

245 ft. wide. There is a double cloister at the north, or entrance, end, with a minaret in the middle of its length, embracing both aisles, and with similar double cloisters on each side. The sanctuary itself, which is about 156 ft. deep and 242 ft. long, has seventeen aisles at right angles to the niche wall, the middle one, in which are two domes, being as wide as two of the ordinary aisles, and with double columns, and is mainly arched the same way, though there are three lines of arcading parallel with the niche wall, which carry the domes. It has ten arches, with a wide one next the niche wall, carried on coupled columns. There is a dome in front of the Mehrah, and one over the first two arcades, both in the centre aisle. The arcades have slightly horseshoe arches, supported on marble columns with Corinthian, Composite, or Byzantine capitals. The columns are tied above the caps both ways with wooden ties. The niche is covered with inlays of lapis lazuli, mosaic, and white marble, and is flanked with two porphyry columns, said to have then been worth their weight in gold, with white marble Byzantine capitals. The pulpit is of wood, elaborately carved, and pierced, with the divisions of the balustrade vertical, — a rare occurrence in Moslem work. One point of interest attached to this mosque is its having served as the model for that of Cordova, and was doubtless endeared to Abd-Allah when he was skulking about in Nnmidia. He landed in Spain 138 A.H., 755 A.D., and was shortly after proclaimed Kaliph in Spain, in the days when the Abbasside Mansur was Kaliph at Baghdad.

The mosque at Cordova is said to have been begun in 786 A.D., the year before he died, and consisted of eleven aisles, twenty-one bays deep, and was continued by his son Hisham, and completed by him or his son El-Hakim, who added the court. El-Hakim II. (961-70 A.D.) extended these eleven aisles southwards by twelve bays, and built the niche and some chambers. El-Mansour (981-1000 A.D.) is believed to have added the eight aisles to the east, thirty-five bays deep, and probably the remainder of the court.

The total enclosure of the mosque is 580 ft. by 435 ft., and the sanctuary 435 ft. by 390 ft.; there must have been at least 650 arcade columns, besides others for enclosures. The court yards had cloisters round three sides, and were planted with orange-trees, in continuation of the columns of the open aisles.

The arcades of the mosque are at right angles to the niche wall, and consist of horseshoe arches on the capitals of antique marble columns; above these are semi-circular arches carrying the walls, which support the trusses and gutters of the roof. The vousoirs of the arches are alternately stone and cut red bricks. There was an enclosure in front of the Mehrah (the Maksura), and an enclosure or pew for the Kaliph in front of that, now called La Villa Viciosa.

The arches forming the Maksura are cusped, and each span is equal to the space between three columns, as arches below spring from each side of each column they intersect.

On corbelled projections, on each deep abacus, stand small shafts bearing horseshoe arches above the upper interpenetrating cusped arches.

In the Emir's pew, the lower cusped arches are not intersected, but have a cornice carried on colonettes; from the colonettes horseshoe arches are turned, and from the centre of each cusped arch below there is an upper cusped arch, which cuts the horseshoe arches, and fills up the spandrel. In my opinion, the architecture is more curious than beautiful.

An illustration is given of the arcading of the Villa Viciosa, and some of the ornament of the arch of the Mehrah.

Even now, with a great Christian church dropped into the middle of it, the effect of this forest of columns is wonderful, the diagonal vistas being unique. These congregational mosques of Egypt, Syria, Tunisia, and Spain are grouped together, because they seem to show the early idea of a congregational mosque; for, though some of them are not early, the early idea seems to have been kept up. The mosque at Cordova was co-eval with the first break-up of the Kaliphate, and though the next, the Mosque of Ahmed-Ibn-Tulun was not the end, still it was one more step towards the general breaking up, when each country had an independent ruler, — Saltan, if not a Kaliph, — of its own. The independent rulers and Sultans sometimes owned the spiritual supremacy of the one at Baghdad, and sometimes did not.

Saladin was the first Sultan of Egypt (567 A.H., 1172 A.D.). Selim I. the Ottoman Sultan of Constantinople took with him from Egypt Mutawakkil the last Abbasside Kaliph in 1517, who transferred the Kaliphate to Solyman the Magnificent, about 1520 A.D., so that now the Sultan of Turkey is the spiritual head of Islam. Ahmed-Ibn-Tulun was a Turk from beyond the Oxus, brought up in the Court of Mamun, and in the School of Samira, and was the cause of the murder of the Kaliph Mustain, who had promoted him to a post of honour. He was afterwards made Deputy Governor of Egypt, 254 A.H., and gradually assumed independent power, and made a good ruler; he died 270 A.H., 883 A.D. As all the title and the tribute that formerly went to the Kaliphs remained in Egypt, Tulun was enabled to spend it in improvements and buildings. He built the celebrated mosque at Cairo, which Ferguson has taken as the starting point of the Saracenic style; but I should say this was at least two centuries too early; it was finished in 265 A.H., 878 A.D.; it is said to have been designed by a Coptic architect; the Copts are the native Christians of Egypt, and are said to have been very skilful in the arts, and, until we know more about Coptic and Byzantine ornament, nothing can be safely advanced on the origin of Saracenic work. Tulun had sense enough to object to any material being used but brick, as he said it was the only thing that would resist fire and water, his architect disagreeing with him, he put him in prison, but the architect managed to bribe his gaoler to deliver a letter to Tulun,* in which he offered to build a brick mosque, and, being summoned, he drew out his design on a skin of parchment; this was approved; he was furnished with money and materials, and completed the mosque in two, — some say three, — years, and was presented with ten thousand pieces of gold by Tulun, and a pension for life. The dome in front of the niche, and the wooden stalactites beneath it, are supposed to be of the time of the Sultan Lagin (636 A.H., 1236 A.D.), who repaired the mosque and put up the pulpit, now at the South Kensington Museum: whether he put up the dome over the fountain, the court is not known, but it is said to be at least a century later than Tulun, and may be looked on as one of the first domes we know that was carried on stalactites. The mosque is surrounded by a wall and a space on three sides to keep it quiet; in the space between the outer and inner walls of the mosque, opposite the niche, there is the minaret, with a corkscrew staircase outside, and the water-wheel, and, — as I read, — the rest of the space was devoted to students, who studied theology. The outer walls are about 513 ft. square over all, inside are the walls of the mosque and its court, about 390 ft. wide by 450 ft. deep. The sanctuary is 301 ft. long by 100 ft. deep. A double cloister runs round three sides of the court, and the sanctuary itself has five aisles parallel with the niche wall, and an arcade of 13 arches; the piers are wholly formed of plastered brick, with engaged brick columns at each angle, with ornamented capitals and no bases: the piers are about 8 ft. wide, the arches form 17 bays at right angles to the niche wall, two at each end, being railed off. The arches are pointed and slightly horseshoed; over the abacus is a gulloche, which runs round the inner edge of the arch and along the bottom of the impost, and the archivolts and impost are enriched with a wide plaster ornament, both of the same pattern; this ornament consists of the "rate de cent" on a gigantic scale, each leaf is filled in with ornament, after the manner of late Roman work. I have never observed that this has been noticed, — and some of the soffits are ornamentally plastered, with a large square gulloche, the large squares and angles are filled with ornament, and the small squares with rosettes.

On the external wall, in each arcade, are arched recesses with an ornamental archivolt and impost on engaged brick columns, the shafts of which are about the height of capitals; inside the first arch is another, with a Cufic inscription round it, and the windows are filled with pierced stone lattices that much resemble the geometric patterns of the fifth century, shown in De Vogüés Central Syria, not copies, but even more ingenious. In the spandrel of each pier, a little above the impost, is a narrow opening with a stilted arch. The plaster ornament is very like Indian work. Below the

* This ruler's name was Ahmed, the son of Tulun, but the mosque is best known by the father's name.

wooden ceiling is a board with a carved Cufic inscription.

The principal mosques that still exist at Cairo are those of: —

A. H.	A. D.	Amru.
20	640	Amru.
265	878	Tulûn.
361	971	El-Azhar, repeatedly restored down to 1753 A.D.
380-403	990-1012	El-Hakim, restored down to 1225 A.D.
608	1211	Esh-Shâfi'y, a mausoleum, also restored to 1516 A.D.
647	1249	Es-Salih, a mausoleum, restored by En Nasir.
667	1268	Esh-Dhâhir (Beybars I.).
683	1284	Kalaun (Maristan, or mad house), minaret rebuilt.
687	1288	Kalaun (Kubba, tomb mosque).
698	1298	En-Nâsir.
706	1306	Beybars II., Gasbenkir.
718	1318	En Nasir, in the Citadel.
723	1323	Sengar, El-Gawaly, and Salâr, joined.
739	1338	El-Mâridâny (architect, El-Mu'allim Es-Sayûfiy).
748	1347	Aksankur, restored 1652 A.D.
756	1355	Shaykhûl.
757	1356	Suyurgbatmish.
760	1358	Sultan Hasan.
770	1368	Umm-Sha'ban.
786	1384	Barkuk (architect, Cherkis el-Haranbulû).
808-813	1405-1410	Barkûk, in the Karâfa, built by 'Abû'l-'Aziz and Farag, sons of Barkûk; architect, Lagû Tarabûlû).
823	1420	El-Muayyad; in process of restoration.
827	1423	El-Ashraf Bars Bey; also mausoleum in the Karâfa.
860	1456	El-Asraf Inal, in the Karâfa.
877	1472	Kâzî Bey, in the Karâfa; also mosque within Cairo.
886	1481	Kigmas, Amir Akhor.
905	1499	Ezbek.
909	1503	El-Ghory (two); restored 1888.

El-Azhar, the brilliant mosque, founded in 361 A.H., 971 A.D., is a congregational mosque (Djami), with oratories, and is used as a university for the study of theology and jurisprudence by students from all parts of the Mohammedan world. The mosque is, roughly, an oblong, 280 ft. deep by 295 ft. long; outside this are three mosques, a court, and some chambers, and a fountain. The sanctuary is 282 ft. long by 126 ft. deep, and has in addition an open portico beyond it. One noticeable peculiarity is that the gate of Upper Egypt, which goes into the sanctuary, is composed of two doorways that have all the appearance of Early Gothic doorways, with trefoil cusps under the semi-circular arches that stand on the capitals of three slender shafts, undoubtedly done by some European architect in the Gothic school.

As regards the plan, it has a single cloister on the four sides of the court; on the right and left are aisles of three bays, with two columns on either side of the central aisle, all used for class-rooms. The sanctuary itself has nineteen bays at right angles to the niche wall, and at its deepest is nine aisles deep. The arcades being parallel to the niche wall. The centre bay opposite the main niche has three columns on each side, which support a high pavilion.

It is useless to speak of its decoration which may date from the middle of the eighteenth century. If it was not burnt down, the 350 marble columns it is said to contain, are probably Classic and Byzantine, plundered from the temples and churches of Upper Egypt. The Mosque of Beybars I., called Esh-Dhâhir (667 A.H., 1268 A.D.) looks like a congregational mosque. It is 351 ft. deep by 345 ft. wide, with flat projecting towers at the angles, and projecting gateways on three sides. The sanctuary is 345 ft. long by 125 ft. deep. The court is surrounded by an arcade on piers, these enclose two aisles each, in the middle the supports are columns. The sanctuary is divided longitudinally in the centre by a line of arcades, parallel to the niche wall, supported on small piers. There are six aisles in depth, with the arcades of the rest supported on columns, the three centre bays next the niche are formed by arcades on piers, the square so formed in front of the niche is covered by a dome, about 39 ft. in diameter, whose angles are supported by stalactites. There are nineteen bays in the sanctuary.

The oratories or mosques of Kalaun are attached to a mad-house (Maristan), and to the

* Extracted from "The Art of the Saracens in Egypt," by S. Lane-Poole. 8vo. London; 1886.

right of the entrance is the tomb oratory or mosque (Kubba) 634-7 A.H., 1241-8 A.D.

As land got more scarce in Cairo, the old form of mosque, with its forest of columns, was given up, and a form much like the domed palaces of Persia was adopted. The mosque of Sultan Hasan is a brilliant example of this sort of mosque without piers or columns; it was built in 760 A.H., 1358 A.D. It is built on an irregular-shaped piece of ground, and though his tomb and the minarets face an open space, the main entrance is in a narrow street. At the end of the vestibule here, Sultan Hasan used to sit to administer justice. Some narrow tortuous passages from this entrance lead into an open oblong court about 115 ft. by 104 ft., with a fountain in the middle, shaded by an open octagon shelter, with a dome over it,—the dome has a band round it with the signs of the Zodiac; on each of the four sides are the arms of a Latin cross,—three are about 46 ft. wide, and the same depth, and one, forming the sanctuary of the mosque, 67 ft. wide, and 89 ft. deep, behind which is the domed tomb, also 67 ft. square. Each arm of the cross is vaulted, with a pointed vault, having an arch on each face about 92 ft. high to the crown from the pavement of the court; nothing grander can be conceived, as each of the arcways open on to the court without any screen. The vault, besides the soft of the arch, has four flush ribs with red and white voussoirs. At the niche end the sanctuary is panelled with marble up to the frieze from which the vault springs; at the end there are two doors into the tomb and the pulpit; above these doorways are two light pointed windows, with a bull's-eye over the centre. The frieze which runs round it is ornamented with a Coptic inscription on a floral ground, with a cresting above, the whole carved in low relief. The frieze is of the exact proportion required, and is in such flat relief that the ornament in no wise interferes with the general effect; the sublimity of this vast plain vault suggests Greek art.

There is a charming little mosque and tomb of Kait Bey 877 A.H., 1472 A.D., this is also without columns, and instead of an open court has a covered one, with a latticed lantern.

In the earlier mosques, the exterior has no architectural display, as they are mostly merely walls with battlements pierced in fantastic shapes, or with the regular stepped battlements called "hearded," and it is not until domes and minarets make their appearance that there are any very striking external features.

I omit the mosque of El-Azhar, as the date is quite uncertain.

It seems most probable that the wooden stalactites in the dome in front of the niche at the Mosque of Tulun were put up by Lagin 696-8 A.H., 1296-9 A.D., and that, therefore, at that time they were fashionable, though unknown in the time of Tulun 270 A.H., 883 A.D.; we may be pretty sure there was not much building in Egypt and Syria between 1099 and 1249 A.D., considering the Crusades and the disputes between the Fatemite Caliphs, the Kurd Dynasty, and the Turks or Mamluk Sultans.

One of the most striking peculiarities of the religious architecture of Cairo is this, that many of the mosques were built with courses of red and white stone, or occasionally with white and black, or they were coloured to imitate them. The black and white courses, though not so common as the red and white, are in this respect like the Cathedral at Genoa and the churches at Florence and elsewhere in Italy. The external appearance of a mosque is that of a two-storied building, the lower windows being mostly square-headed; the lintels and the arches over them mostly had the junctions of the voussoirs of the most fantastic outline, and of two differently-coloured stones or marbles; if these outlines were worked through the stones it implied incredible labour and superhuman accuracy. The upper windows are mostly plain pointed, or doublet with a bull's-eye over the centre spandrel, surrounded by a trifoliate frame. Here and there wide flat piers were brought out with stalactites between them at the top to make the cornice and battlement in one line. Sometimes there was a cornice above, consisting of tiers of stalactites, and sometimes no cornice beyond a moulding, but as a rule battlements crowned the whole. A most original feature occurs in many of the later mosques; a flat recess was made where a door occurs, which was carried up the whole height of the

two stories, and finished at the top with a trifoliate arch, mostly filled in with stalactites, while between the head of the door and the bottom of the stalactites are windows or ornamental panels. As far as we can now see, there was no general system, but each architect had genius enough to make a picturesque whole, in spite of the openings being arranged only for the plan. The architects as often as not drew away attention from the want of symmetry in the main building by curious and elaborate ornament and the sharp shadows of the stalactites, while minarets and domes broke up the outline. The front of the tomb of Sultan Hasan is symmetrical, the centre is crowned by the dome, and the whole front is flanked by two minarets. The domes mostly have a drum, and this is generally pierced; only the domes that are plain externally are usually four-centred; the later ones are three-centred, and are covered with flutes, reeds, or chevrons; while some have elaborate geometrical ornaments carved on them, and some have counterchanging ornamental patterns; some are covered with an elaborate floral ornament, and then diapered over. Domes are usually constructed over square chambers, especially if they are sepulchral. The domes have no pendentives, but are supported by corbelling at the angles, the corbelling being cut into stalactites. The edges of these mark out the external truncated gables. The angles of the square base of the dome were mostly chamfered off, and ornamented with triangular steps, or deeply moulded, while the truncated gable is most commonly filled with a triplet window, with three circles or ball's-eyes over it, enclosed in a cinquefoil border; the centre part of the gable is sometimes formed into a square, with two triangles on each side; these are commonly filled with circular ornamental panels. The pointed tops of the domes are mostly finished with a finial of bronze crowned by a crescent.

It was a favourite plan to make the bottom of the tall minarets solid up to the roof of the mosque, but it is by no means always the case; it is the case, however, at the mosque of Sultan Hasan, where the large minaret, to the top of the masonry finial, is about 330 ft. high; a great many of the smaller minarets are from 150 to 160 ft. high from the ground; they form the most striking architectural feature in Saracen mosques, and are often most elegant in shape and proportion. Sometimes they spring from above the cresting or battlements of the mosque, and sometimes their bases form projections from the main wall. As they are used instead of bellfries, the cryer calling the hour of prayer five times a day from them, they are mostly formed in stages, the balconies or the stages being carried by a deep stalactite cornice, the balustrades being of pierced stonework, or more commonly of wooden rails. The minarets are mostly crowned by a stone pear-shaped finial like an Indian cup and ball; the finials frequently look as if pierced with arrows, these are, however, slight wooden gallews, for holding lamps. The minaret of Sultan Hasan's mosque being the highest, a slight description of it may be given. Its solid base is polygonal, and gathers into a circle beneath the deep stalactite cornice of the mosque, which once had a flower-de-luce battlement; the minaret above the cornice is about 26 ft. square, and runs up vertical to a height of little more than its width, in alternate courses of red and white, it is then chamfered off into an octagon, just above that the stage is marked by a stalactite balcony, on each of the four square faces, the chamfered ones are ornamented in the flat with a square set anglewise in a square frame in each of the eight faces above it one long window-shaped recess with red and white colonettes, the tilted circular stand on slender engaged colonettes, the circular heads have half-domes in them, a deep stalactite cornice forms the next stage, with a pierced stone balustrade, and a slightly smaller octagon goes up to the next story, and here the stalactites are grouped at the angles, this also has a pierced stone balustrade, above is a circular open lantern with cusped arches on columns, this has a stalactite cornice and a stone balustrade, out of this springs the cup and ball in masonry, and above this there is a finial with a crescent, and round the pear-shaped finial are a cluster of little gallews, for supporting the lamps; in its ruined state the first stage is not marked enough by the corbelled balconies. That of the mosque of Kait Bey is one of the most elegant, but like that of Sultan

Hasan, since the battlements have gone, is a trifle thin at the base above the mosque. The treatment is very similar to that of Sultan Hasan's, but better proportioned, and the third division is circular, and covered with a geometrical pattern, with a central star on each face. Most of the mosques are roofed internally with wood, with the exception of those of Sultan Hasan and Barkuk. The latter has piers instead of columns, and the aisles of the sanctuary are domed with domes, whose pendentives are of the same radius as the flat domes, and not marked by a different curvature. Some of the wooden-ceiled mosques are panelled, but the most striking ones are those with circular timbers, bracketted into a square next the walls, the junction between the square and the circle being effected by means of stalactites. When the whole of the beams and the ceiling are painted and gilt the effect is very gorgeous, and unlike anything else one has seen elsewhere, for almost all the Venetian ceilings so treated have rectangular beams. The lattice work, inlaid wood and marble work, chased and damascened brass work, some of the mosaic where mother-of-pearl is used for white, and the stained-glass windows, are models of elaborate and excellent work, and the stained-glass windows are lovely. What the effect must have been in the palmy days, when everything was in perfection, and all the accessories were to match, we can scarcely picture to ourselves. The descriptions in the "Arabian Nights" of all this work, which in our youth we fancied were wholly imaginative, are merely descriptions of what met the writer's eyes every day. The "Arabian Nights" are believed to have been put into the form in which we read them, just after the Ottoman conquest of Egypt, and represent the palmy days of Saracen art, at the time of the later Mamluk Sultans, though the stories and adventures are said to have occurred in the days of Harun al Rashid or earlier.

FASHIONS IN ARCHITECTURE AND ITS KINDRED ARTS:

THE ARCHITECTURAL ASSOCIATION.

The ordinary fortnightly meeting of this Association was held on Friday, the 29th ult., Mr. F. T. Beggally, President, in the chair.

The following gentlemen were elected members of the Association:—Messrs. C. H. Thewlis, W. Hearn, G. B. Gosling, F. G. Hunt, R. V. Hunt, and W. J. Lengley.

Mr. F. T. W. Goldsmith, Honorary Secretary, announced that Mr. Arthur Bolton had presented to the Library his book on "Examples of Mosaic Paving," and that the Editor of the *Builder* had presented "The *Builder* Album of Royal Academy Architecture, 1891." Thanks were voted to the donors.

Mr. Goldsmith also announced that a visit would be made on February 6 to Mr. Aston Webb's new assurance office building in Moorgate-street, and also to the tower and spire of Bow Church, by kind permission of Mr. Innes. And on February 20 a visit would be made to the Imperial Institute, by permission of the architect, Mr. T. E. Collcutt.

The President said that he regretted to say that Mr. N. J. W. Westlake, who was to read the paper of the evening on "Fashions in Architecture and its Kindred Arts," was unable to be present, but Mr. Goldsmith had very kindly consented to read the paper for him.

Mr. Westlake's paper was as follows:—

I have selected as the subject of my paper "Fashions in Architecture and its Kindred Arts," and, for the purpose of illustrating this, have made a short *résumé* of some of the various changes that have taken place during the present century.

It will be at once evident that any observations on the ancient and recognised styles can only, in this slight essay, be dealt with in a summary way.

In commencing, it is my intention to epitomise some of the differences of style that fashion, from time to time, has adopted during the present century. I shall then put certain propositions before you as the cause or cause of the rapidity of these changes in recent years, and conclude by attempting to show how all this may be worked to a good purpose.

We are all of us continually told by those who claim to be men of "light and leading,"

* Illustrated in the *Builder* for May 17, 1890.

what is the thing, especially in the way of style. Notwithstanding this, we have seen sometimes the same leader change, from a dogmatic adherence in preaching the imitation of some ancient style,—because of some supposed or real subjective value that its characteristics enshrine,—and, altering his opinion, use the same arguments in favour of another, and, finally, perhaps holdily relinquishing his line of argument, opinions and all, in favour of this, advocate something entirely different. The cause of this is difficult to explain. Often it is because some architect or artist having made a success and a reputation in another style to that formerly in vogue, has attracted many followers, thus forcing a change of fashion, and your man of "light and leading" is fashionable in his opinions, or nothing.

We can all of us, however, if we will, observe motives and note their spring, and giving them as much value as we think they deserve, arrive at our own conclusions and practices accordingly, not placing any value on the mere customs or tastes of a day. We are, however, forced to ask ourselves this question: Why, during the last century the changes in architecture and the kindred arts have become rather those of fashion than of style, and why we now have no distinctive style proper to this great period—no style which embodies a real religious or national character, and why for a certain short period we design in any adaptation of either of the old styles and then discard it for another?

For me to attempt to answer this, here, would be going a little too much in advance of my introduction, and I must first give you, as far as I can recollect the succession in which some styles have been fashionable, for where a style is fashionable, the less informed in learned circles will see no merit in building or design out of it.

We may ask ourselves, could any method of enshrining a beautiful idea in architecture or art be more inviting than that of the Adelphi Adams, and of the period of Reynolds, of Flaxman, of the Wedgewoods, and all the eminent men of that time whom I have no space to catalogue. Can you on looking back see any reason why such a fashion ceased, and that shown in the Houses of Parliament for a time arise, and Pugin,* Sir C. Barry, and kindred artists be in vogue? We all know Pugin's arguments in favour of the Gothic revival, and if my memory rightly serves me, one of the most celebrated art thinkers and writers that ever arose, whilst in some respects following the same line of thought as Mr. Pugin, said hard things about him and the "houses." Of course, you know I allude to Mr. Ruskin, who has been a power in the influence that at one time changed the mode of thought and fashion in art. The action of the Royal Academy during the century has been rather that of a body with an unsettled purpose.

In its early days composition, design, and the more intellectual branches of the art were represented. Amongst its roll of members we often find the names of eminent composer-artists such as Flaxman, Macleise, and Dyce. The main object of the majority seems to have been simply to encourage mechanical and technical excellence until quite recently, under the present President, who with some few others has encouraged the study of the architectonic arts. The Academy has not, however (notwithstanding the recent advances in the architectural school), as yet during the present century shown us even the elements of a school of national artist-composers, great as some of its individuals are in separate branches of art. About half a century ago there arose the school of design at South Kensington, but I cannot think the influence of that expensive machine has been other than dangerous at times.† It has given us cheap drawing schools, but is national design, as national design, developed at all in proportion to the influence of the great and expensive machinery? My own impression is that nearly all modern developments and improvements are from minds that were outside its influence. I cannot, therefore, consider it a large factor in the changes that have taken place.

Many of us can recollect the influence that the Lille competition and the publication of Viollet le Duc's dictionary had for a period on

* Probably the Oxford movement assisted this, but was not the cause.—N. H. J. W.

† One instance alone shows a mischievous tendency, the establishment of a school of design at Bombay, which did something to injure the previous Indian tradition.—N. H. J. W.

our fashions. The Early French style adopted by Burges and Clutton,—the successful competitors for Lille Cathedral,—began to dominate, and I think you can find that adaptations of this style became so prevalent that nearly every architect practised it more or less.

We all know of work in that style by Clutton, by Burges (who never entirely deserted it), by Street, and by a host of followers, with a result that, personally, I sometimes think, was lamentable; for the host of followers seem to have delighted in the eccentricities, rather than the merits, of the style, and many of the arts were involved in its study and practice for a considerable period.

Later on, the competition for the Law Courts perhaps did much to produce a change in this, and we saw many of the competitors working from English models, although the successful architect never completely escaped from his French 'convictions.'

The youngest of us have seen through the change, from Decorated to Perpendicular, the devotion to the so-called Jacobean and Queen Anne, and our present rising fancy, if there is one dominant, for a mixed Renaissance of a very indefinite character.

It would be superfluous before the present audience to go into greater details, you all know the names of the leading men of this century, and their changes of style, and many of you can perhaps give a reason for these changes as well as the architect or artist himself.

This brings me to the second part of my subject. Why have these changes taken place? Why, if one of the antique styles died for centuries, and one of the Medieval styles for one hundred years, and was consequent and consonant to its predecessor, must we have now twenty or thirty different, and often incongruous, styles adopted in the same period?

What is the cause, not the accidental,—but the essential,—cause of this? Is it that there is no dominant national or religious character to enshrine, no dominant thought requiring a dominant idiom, no great and leading poetical aspiration in us, no really important idea for us as a nation to represent? So that we have fallen from the regions of the ideal, and are become more professional men and few poets! For I take it that architecture and art in their perfection are but concrete renderings of the author's finer imaginings.

The language, the idiom in which he spoke in ancient days, embodied an idea of which he was a part,—it was almost a "chironomia,"—and we even now, when gazing at times on these ancient works, seem to feel the author's emotions, and to be inspired by the same sublime ideas.

We appreciate at evening the grand outlines of their buildings as they appear like dreams, their masses showing dimly against the setting sun, and in the daylight we dwell on the sweet intentions or bold determination of their details or mouldings. We read their language, but have little occasion to speak it as they spoke it, and too great a love of various knowledge to limit ourselves as they were limited,—to the perfect expression of a few ideas; we forget that in this limitation of action there is an increase of power.

My argument may thus be condensed,—the higher architecture is an art, and like the other arts is a language* for the expression of thought; in this it distinguishes itself entirely from the science of building; perhaps to many my definition would be more acceptable if I were to say that it is a language combining science and art. In ancient times it expressed the ideas of the period in the idiom of the period.

In these times what is its position, what expression of living national or local idea is there in the Houses of Parliament, the Law Courts, the Meat Market, in the various new Board schools or workhouses? You may answer, little; but tell me to look to the railways and their stations, the City warehouses and those real expressions of living national architecture, the ships, but for my own part in these last only do I find what I desiderate. If, then, there is neither dominant idea nor dominant idiom, what is the architect to do? and the most rational answer to this, in my own mind, is that he must either express his own ideas, embody his own fancies, or represent the ideas of some living energy to which his mind is affiliated.

When I said that we were now more pro-

* Of course, it is not a language, but like it, in being a method of expression.—N. H. J. W.

fessional men than poets, it was not my intention to imply that there are no poets left,—no architects whose works speak of their nobility of aspiration or intelligence. Far from it. There are some few. It would be invidious to choose examples amongst the living, but I may mention the names of two who have not long passed away, and with whom I was intimate; and so far as I had opportunities of forming an opinion, I think they had minds so full of sympathy and intelligence that they would have been marked men, matter in what method they expressed themselves. I allude to Burges and Sedding, and I would take them as exponents of the two ideas I have mentioned,—Burges of the first, and Sedding of the second. Burges imbued his sensitive and poetical mind in Medieval lore; he was almost at home in its ideas when an accident led him to study early French architecture, and he learnt to speak in an idiom of his own formed upon that basis. He cared not to speak much in any other way; if he did, he did it with that difficulty with which one speaks a foreign tongue, and you all know at sight Burges' works, and from them Burges' ideas; they are not, as far as I can appreciate anything, more than an individual expression, but they expressed the man, his intelligence, his great information, his power of adapting that information, and his poetical disposition.

Sedding affords us a complete contrast; intelligent, fairly learned, of a refined and poetical mind, he rather represented an idea than himself. He did not work long enough in any style to form for his own a distinct idiom, although he managed by his ability and sympathy to express himself in many ways; his individuality was never so apparent in his work as was that of Burges.

This, then, I suppose is the highest point in which the architectural arts can now aspire as national arts. What might be done by the nation, or even by the City of London, or the various large parishes, is one thing,—what might be done had they unity and honesty of purpose is magnificent to think of; but what is done amounts, I fear, to little more than a series of jobs in which those capable of intrigue have had far greater chances of success than men of reflective, conscientious, and poetical dispositions.

Look at the majority of public buildings, the workhouses, and the Board-schools, and tell me do they represent in any way the best or the second-best architectural genius of their period. You, who can form a fair opinion, tell me,—am I right or wrong.

Returning, then, to my subject, I fear this change of fashion, then, is unavoidable, we shall not have a nineteenth-century style. The era will pass without any distinct architectural expression like the period of a nation, if such a society can be so-called, of mixed languages. But what are the advantages of this disadvantageous position, as we are soon to enter a new era—the twentieth century? History never repeats itself, yet its life and ideas are the products of its predecessors. I will return to this point presently.

I daresay most of you will agree with me now in the statement that this is the first century in the history of the world's civilisation unmarked by any dominant architectural style.

If the history of a country is written in its monuments, what will the historians of future centuries say of this? Will they be right in saying that it was a century of "Fashion," of vacillating thought and of changing or unsettled purpose, in which everything was tried and nothing stuck to? One cannot tell, but this we know, that if as a nation, as a people, we have made no great and distinct monumental mark, as individuals we may still have character and purpose.

Perhaps, then, as a necessity of the position in which we live, if we differ in our characters and purposes, the great knowledge of the various styles which have been diffused by the successive study of them will be of some use to us and to coming men, from which each mind can adopt that best suited to its bent. Wren and Inigo Jones did this as Burges and Sedding did. Moreover, this knowledge of the character and the details of each style enables us by comparison to form a clear and intelligent knowledge of the capacities of each, as though we could speak many languages and choose that which best expresses our thoughts, even if we lacked a mother tongue. Of course, a mind allied to very firm convictions and of a strong character may out of this knowledge evolve a style which may embrace the thoughts

of an age, and become that of a coming era, but I think, as yet, we are looking for this mind. At any rate, when such an one arises there is a vast store of knowledge in the Art literature of this century, so collected and ordered that he will not require mental food. He will have this advantage over those who have preceded him, in any period, for never has there been so vast a store-house, nor so much accumulated store, so readily obtainable, and to this cyclopaedic accumulated store of Art knowledge the Architectural Association has been no small contributor.

Mr. Owen Fleming, in proposing a vote of thanks to Mr. Westlake for his somewhat philosophic paper, and to Mr. Goldsmith for reading it, said that the paper was rather difficult to discuss; in fact, he did not think there were very many points in the paper which one could discuss in any detail. There was the large question as to whether the architects of the nineteenth century were inventing a new style; and as to that question he was getting tired of hearing the public talking so much about "a new style." In the *Standard* the other day there was a leading article commenting upon the election of Mr. Jackson to the honourable position of Associate of the Royal Academy. He was sure they were all glad that Mr. Jackson had obtained that position, which he ought to have obtained long ago. The *Standard* said that architects did not appeal very much to the general public unless they invented a new style. That statement seemed to him to show an entire misconception of architecture as a whole. Architects never had invented, and, he ventured to say, never would invent, a style. To talk of *inventing* a style of architecture was to show a complete ignorance of the subject. To his mind, a style was that which grew out of the natural necessities of building, and out of the position that a people held in the civilisation of the world. It was frequently urged against architects that this nineteenth century was an age of individualism and eclecticism. That was so, no doubt, to an extent; but he thought that we English of the present day were not competent judges whether we had a definite style or not. Four or five centuries hence the historian who wrote the history of the nineteenth century would be able to find out the prevailing characteristics of nineteenth-century architecture, just as we had discovered the characteristics of the architecture of the Greeks or Venetians, or of that of the thirteenth or seventeenth century. Each century had its own individual style, but he did not think that any of the persons who created that style were aware of what they were doing; they acted just as they felt prompted to act, without any consciousness of "inventing."

Mr. Paul Waterhouse, M.A., in seconding the vote of thanks, said the subject which had been touched upon in the paper and commented upon by the last speaker was a very deep one, and one which exercised the minds of architects a great deal; still more did it exercise the minds of those who, without being architects, took a great interest in architecture. Architects were perhaps, as a rule, too hasty to theorise about their art. The remarks made by Mr. Fleming as to the possibility of a future historian recognising in the architecture of the present day chronological characteristics which we of the present time could not see, contained, he thought, the germ of a very great truth. All the original styles of the world had been the outcome of national characteristics and geographical conditions. As the original styles were exhausted, or, perhaps, not exhausted, but rather fulfilled, in their original form, the world had been obliged to modify them, and very little good architecture, perhaps, had been produced since the year 1400 (or, say, 1500), in which there had not been a more or less conscious imitation of the styles of the past. But if they were to consider, for instance, the stream of revival which first began in Italy about the year 1425, they would see that that stream flowed in certain countries in Europe, more or less continuously, down to the beginning of the present century, perhaps even longer. He supposed there had been no break in the string of those who had been following in the wake of the Renaissance movement, first started in Italy, and carried on in Italy, France, and other countries for four centuries. And yet an expert in architecture could, by studying the buildings of those countries during that period, pick out the half or quarter of a century to which a building belonged. He thought we

made a great mistake in comparing the conditions of to-day with those of the past. Those who cried out for a new style asked whether the world was so played out that it could not bring a new style into existence? But the conditions had altered; and why? If they looked at the architecture of those countries where the means of communication were good, a similarity of architecture was to be seen. In England, for instance, there was a distinct architecture of districts, due to the fact of easy communication within those districts. As communication in the world increased, of course the natural result followed that similarity of architecture took place. That was due not merely to the fact that architects were necessarily plagiarists, but to the more important fact that association played so great a part in our satisfaction with architectural design. They could not get away from the feeling of association. There was something absolutely repugnant in the idea of novelty for novelty's sake in architecture, except in the matter of grouping and the modification of detail; and thus it was that when communication became more or less universal, architects were universally imbued with the associations of surrounding architecture, and leaned upon them; and their critics leaned upon them too.

Mr. C. H. Brodie said he would like to refer back to Mr. Westlake the question whether he, as an artist, would be satisfied with the effect produced by buildings which so entirely spoke their purpose as some of our railway-stations, for instance, and some of our ships?

Mr. Leonard Stokes said he was not quite sure that he gathered what Mr. Waterhouse intended to say; but if he meant that communication governed architecture, or, rather, if he meant that because it was easy to get from one place to another, therefore the architecture of all districts should be the same in character, he (the speaker) could not agree with him. If they happened to be in a stone district, and were, by means of a railway or a canal, able to bring bricks into the district from a brick district, he thought it would be wrong, from an architectural point of view, to import bricks into the stone district, and build a red-brick mansion, for instance, with terra-cotta dressings. He thought the proper thing to do was to build in stone, provided it was good stone, if they were in a stone district. No doubt Mr. Waterhouse agreed with him, and would not wish to see architecture too much alike all the world over. For his own part, he hoped that such a thing would never be brought about. He felt that one great charm of architecture was that it did adapt itself so admirably to local facts and difficulties: in flint districts they had flint churches, in brick districts brick churches, and in stone districts stone churches. The old architects made good use of their materials, whatever they were, and he thought it would be a great pity if the day arrived when, because one might happen to like terra-cotta, which he (the speaker) did not, that therefore it should be used everywhere, regardless of local circumstances and traditions.

Mr. Waterhouse said he respectfully disagreed with the deductions which Mr. Stokes had drawn from his remarks.

Mr. F. T. W. Goldsmith said he took it to be Mr. Brodie's wish that the question he had put should be conveyed to Mr. Westlake; but as he (the speaker) was in some sort Mr. Westlake's champion in his absence, he wished to say that he did not think that the question quite embodied the idea which Mr. Westlake meant to convey by his paper. He did not think Mr. Westlake meant that they were to design their buildings with an entire absence of decorative detail, but rather that they were to design them in such a way as to indicate clearly their different purposes and the period when they were built. Mr. Stokes had remarked that he would be sorry to see architecture alike all the world over, but the tendency was in that direction. Old customs and influences, which they clung to with affection owing to their associations, were gradually being swept away in the face of what was called modern civilisation. He did not think it was a thing to be regretted if they took it in the proper spirit,—in the spirit which animated the architects of the Renaissance,—for we found that during that period, in France and Italy particularly, many almost identical designs were carried out, executed, however, with different materials and with details differing according to the idiosyncrasies of the architect. He thought that it would be well for them if they were to attempt to carry

out the ideas suggested by Mr. Westlake with singleness of purpose, and he must say that he had a great admiration for a building which was built "up to date." A modern city warehouse, for instance, in which economy of space and suitability of plan had been studied, and in which everything, such as matters of lighting, &c., had been carefully thought out, was capable of being made, in a degree, as good and true a piece of architecture as a Gothic cathedral or Renaissance palace. He did not wish to institute comparisons, but he thought that if modern problems were approached in the same consistent spirit that the old men would have approached them, whether in Gothic or Renaissance times, whether in the manner of Pugin or of Sedding, the result could not but be satisfactory. He thought Mr. Westlake was quite right in contending for absolute honesty of purpose in building, and that every new building should be erected, not in the spirit of the thirteenth or any other century, but in the spirit of 1892.

Mr. E. Woodthorpe, M.A., said he quite agreed with Mr. Waterhouse's remarks. In the present age of steam and railways, we were so easily brought into contact with other countries,—facilities for travel were so great,—that they got ideas from all countries in the world, and a great many of them imbibed different ideas, some from the Renaissance, and some from the Gothic. The ancients of the earlier centuries had more or less copied one another. He himself did not believe in originality in architecture at all. He had never seen anything that was quite original,—not even in the work of Sir Christopher Wren, for nearly all the detail of Wren's work was to be found in Italy; as far as he could see, that great man and very successful architect had all the details at his fingers' ends and in his head, and had been able to put them together in a different way. To take a modern building, he had been to the Law Courts a great many times, but he had not seen any single bit of detail that was absolutely original; and nearly all our finest buildings were more or less imitations of other buildings. He thought that the Victorian age would some centuries hence be recognised as the greatest age of architecture that ever had been. He liked to see the individuality of thought which was shown by our buildings in the streets of the City and in other parts of London. If, however, we went to Paris, we saw very beautiful public buildings, because the Government spent a great deal of money on them, while the Government of this country would not spend money on art of any kind, and had no Department of Architecture. In Paris the Government took the public improvements in hand, and they also helped to educate the architects. The streets of Paris were very much more uniform, and the public places much better laid out, but the streets of Paris were not nearly so pretty or picturesque, and did not possess so much individuality as the streets of London. He thought the English architecture of the present day was *par excellence* that of the country-house style, initiated by Mr. Norman Shaw. In France, however, the architects did not seem to have any idea of any style adapted to a small country house.

The President, in putting the vote of thanks, said he took it that Mr. Westlake's paper was not meant to have any very distinct end in view. Mr. Westlake had not set himself to teach any very definite lesson. It was, however, a very philosophical consideration of fashion in architecture. One of the influences which guided design in architecture at the present time was fashion, whether they liked to admit it or not; and none of them could escape from fashion. He supposed not even the strongest designer in architecture could get away from the fashion of the moment, although he might guide it and mould it, to a certain extent, to his own ideas. In former ages tradition exercised a much greater influence on design, but since that was dropped, and we began to copy previous styles, more or less, that influence had been lost. Besides the influence of fashion, there now only remained to them the primary influences of materials and situation, and the circumstances generally with which architects had to comply. Mr. Westlake's paper was intended to deal exclusively with the question of fashion in architecture. A good deal of discussion had turned upon some remarks made by Mr. Waterhouse as to the influence of facilities of inter-communication on architecture. He did not understand Mr. Water-

hose to say that such facilities ought not to influence architecture, but that they were bound to influence it, as they influenced language and even the character of men. Mr. Woodthorpe had spoken of the question of originality in architecture. He did not think that Mr. Woodthorpe meant to say that he altogether disliked originality in architecture. He (the speaker) took it that he only meant the originality which was forced and for its own sake.

Mr. Woodthorpe said what he said was that he did not believe that there was anything in architecture perfectly original.

The vote of thanks having been passed, the meeting terminated.

HEREFORD CATHEDRAL.*

H general outline as well as in detail the Cathedral at Hereford bears strong evidence of its Norman foundation, and the "sturdiness,"—if it may be so termed,—of its exterior is largely due to the considerable remains of the earlier church which we find in the interior. Although there are vague accounts of a round church,—planned after the fashion of the basilica of Charlamagne at Aix-la-Chapelle,—having been erected by Bishop Losing in Early Norman times, there are now no traces above ground, and nothing in the Norman work at present existing to suggest that such a form had either been in existence or incorporated with the later work. If, indeed, it ever existed its destruction has been complete, and the present work of the Norman period is distinctly English in its form and treatment. The form and character of this Norman church is very clearly shown by the ground plan. A nave of eight bays with aisles, a choir of three also with aisles, a central tower, transept, and a sacristy on the east side of the south transept formed the chief parts of the Norman church, finished by Robert de Bethune (1131-1148). The east end was not treated as one large apse with an surrounding ambulatory, as at Peterborough, Norwich, and Gloucester, but each alley had its own apse, a small one at the end of each aisle, and a larger one projecting eastward from the present eastern arch of the presbytery. Of this church, the apses eastward have gone, and the greater part of the aisles of the choir, and both those of the nave; the north transept has been for the most part remodelled and extended, and the westernmost bay of the nave has entirely disappeared. In 1780 the western tower fell and rinded the front, and Wyatt, who had already been busy with deeds of Vandalism at Salisbury, was called in and rebuilt the west front, but shortened the nave by a bay, and availed himself of this opportunity to remove all the Norman work above the nave arcade and substitute a design,—if it be worthy the name,—of his own. The gradual developments which took place after the Norman period bear, as is natural, a strong resemblance to similar alterations which were going on at other buildings of the same class during the same time. The alterations, as in other cathedrals, took the form of eastward extension, and the rebuilding of the aisles was no doubt considered necessary owing to the gloom of the Norman work, which, even with the later windows, is still a characteristic of the Hereford Presbytery. The work attributed to De Vere (1186-1199) is, as may be concluded by its date, of Transitional character, and bears a strong likeness to the well-known work at Glastonbury Abbey. These alterations entailed the sweeping away of the three Norman apses already mentioned, and De Vere, not contented with a simple elongation of the presbytery aisles, doubled them, thus making two side chapels in each transept (for such it in fact was). How the centre portion was treated is mere conjecture, but the late Sir G. G. Scott, in his paper read before the Archaeological Institute in 1877, suggests that the central part projected one bay beyond the sides. One peculiar feature in this work of De Vere's was the placing of columns in the centre of the central division. When we consider the distinctly unsightly appearance that the central column even now presents, placed as it is in the centre of the east arch of the presbytery, there can be

* This series of illustrations of the Cathedrals of England and Wales was begun in our issue of January 3, 1891. A list of those already illustrated, with particulars of future arrangements, will be found on page 112.

Hereford Cathedral

Doorway from Cloisters to Chapter House

but little doubt that the portion we have now was only the commencement of a larger scheme, which included the rebuilding of the presbytery and dividing the eastern wall into two arches instead of one, as was the case later at Chichester, Lichfield, and Exeter. This scheme, however, was destined never to be realised, and the building which followed partook more of the character of alterations on the old lines than of additions or new schemes involving alteration of plan. The Early English Lady-chapel was an extension of De Vere's work (if we are to accept Sir Gilbert Scott's theory), but its having been raised on a crypt adds interest to this part of the church, as being a unique example of its date. The great work of the latter half of the thirteenth century and the beginning of the fourteenth was the rebuilding of the north transept. This very beautiful part of the church has always been associated with the name of Bishop Aquablanca (1240-1268), whose tomb is one of the finest in the Cathedral. The Norman work of the transept was pulled down entirely, with the exception of the arches leading into the aisles of nave and choir. The new transept was of two bays with an eastern aisle, this aisle having a story over, now used as a library, and approached from the north aisle of the Presbytery by a staircase turret. This transept is well known from the peculiarity of its "straight-sided" arches, and the great length of its windows in the western wall. The triforium stage is very elaborately diapered, but this part of the design suffers from the thinness of its tracery, which is very striking as seen from below.

The Decorated period has left its mark in the beautiful central tower, and in the aisles and eastern chapels. These latter should be considered first, as being probably the earlier parts. It amounted chiefly to a remodelling of De Vere's work. The bases of his piers and responds were allowed to remain, and are still

visible, and, upon the former, octagonal columns were erected to carry the vaulting, and the windows were altered throughout. The aisles of the nave seem to have been rebuilt at the same period, and the windows are all of Decorated design.

The central tower, one of the glories of the Cathedral, is a fine example of Decorated work, and covered with a profusion of half flower ornament. Like the central tower of Salisbury, it probably owes something of its design to the earlier lantern of Pershore Abbey, not in this case far distant. The likeness is most noticeable in the disposition of the upper windows, and the character and position of the dividing pilasters and bands of ornament. Allowing for the alteration of detail consequent on development of style, the resemblance is striking. Pinnacles placed diagonally take the place of the partly-engaged octagonal turrets which make Salisbury's resemblance to Pershore more apparent, and large angle pinnacles rise above these, leading to the great central spire which formerly existed. It is shown,—although only as a timber one covered with lead,—in old prints of the Cathedral. Hereford, however, before the catastrophe of 1786, possessed two towers, that at the west end being, if we are to credit the old prints, of a very similar design to the existing central one, but rising only one stage above the nave leads. This was, in all probability, used as a belfry; whereas the central tower was a lantern. It is now open to the church as far as the heltry stage, and exhibits what has been called "pillar construction," as may still be seen in the upper stage at Lichfield and Wells, an expedient adopted for lessening the weight on the arches below. This is well shown in a section in Britton's book on the Cathedral.

The only other portions of the Cathedral of Decorated date are the inner north porch (as

distinct from Bishop Booth's addition) and what remains of the chapter-house. The north porch, especially in the doorways, has some very delicate detail, and what remains of the chapter-house shows it to have been a very beautiful piece of design. We here give an elevation of the entrance to it from the cloister, from a drawing by Mr. H. D. Walton. The chapter-house itself was, as will be seen by the plan, a decagon, each side (except the one occupied by the entrance) being sub-divided into five panels or seats. Remains of three sides only are left, and even these only as far as the window-sills, and in a very ruined state.

The remaining portions of the Cathedral are additions made in the fifteenth and sixteenth centuries. The Chantry-chapel of Bishop Audley (1492-1525) is placed on the south side of the Lady-chapel, and is in the form of a semi-octagon, two stories in height, with an elaborately panelled screen towards the Lady-chapel. Bishop Booth (1516-1535) lengthened the great north porch, and his design, although later in date, somewhat resembles the porch in the centre of the west front at Peterborough Cathedral. It is a very bold piece of Perpendicular work, the outer arch having richly-panelled spandrels and a large five-light window over. Octagonal turrets flank the entrance on either side, and contain staircases which lead to the room over the porch. An earlier addition of the Perpendicular period is the chapel of Bishop Stanbury (1453-1474), approached from the north aisle of the presbytery, and richly panelled and vaulted. Some additions were made to the Norman sacristy, on the east side of the south transept, in Tudor times, lengthening it a bay eastward, and placing a turret in the angle leading to an upper story. It was used for some time as a chapter-house, but is now a vestry.

The cloisters are on the south side of the nave, and of three walks, two,—the east and south,—remain, and are of late Perpendicular date. Against the south wall, towards its east end, are some remains of two Norman chapels dedicated to SS. Katherine and Margaret. A second cloister, known as the Vicar's Cloister, connects the Vicar's College with the south-east transept. The arrangement here is interesting to compare with Chichester, as showing the probable arrangement there before the destruction of the south walk, and its connection with the cloister of the Vicar's Choral.

It now only remains to notice the objects of interest in the Cathedral. A very large and interesting series of episcopal and military effigies exist here. Amongst the former, the beautiful tomb of Bishop Aquablanca, in the north aisle of the choir, stands first, with its delicate detail and simplicity of design. Near it is the base of the shrine known as the Cantilupe shrine, but thought by some to be the remains of the shrine of St. Ethelbert. It consists of two stages, the lower having a series of cinquefoiled niches and fourteen figures of Templars in chain armour, and the upper an open arcade, the slab inside still bearing the matrix of the brass of an episcopal figure having traces of the arms of the See (those of Cantilupe), and another space formerly occupied by a brass figure of St. Ethelbert, now in the sacristy east of the south transept. The traces of where the shrine fitted in on the top are still visible. The material is a fine sandstone.

Amongst the other monuments worth particular notice are those of Bishop Charlton in the north transept (here illustrated),* and Bishop Stanbury's tomb on the north side of the Presbytery opposite his chapel, with some good heraldic work, one of which bears the arms of the See.

Another good monument is that of Sir Richard Pembridge in the nave,* formerly at the Greyfriars' Monastery, but removed here at the Suppression. He was a Knight of the Garter in the time of Edward III., and died 1375. Hard by is the Norman font,* a circular bowl ornamented with mutilated figures of the twelve Apostles. On the opposite side of the church, near the porch to which he added, is the tomb and effigy of Bishop Booth.

On the north side of the Lady-Chapel is a fine monument hitherto ascribed to Hamphrey de Bohun, and so called in the reference on the plan, but said in the guide to the Cathedral, by Rev. Francis T. Havergal, to be the monument of Peter Baron de Grandison who died 1358. There is a very fine recumbent effigy, and, on the canopy, statuary representing

Villa, South-hill Park, Bromley, Kent.

the crowning of the Virgin in the centre, with figures of King Ethelbert and St. John the Baptist on one side, and St. Thomas à Beckett and Bishop Thomas de Cantilupe on the other.

The choir-stalls are largely ancient, with good canopy work and quaint misereres. The screen and reredos are, however, modern, the former of metal, from the design of the late Sir G. G. Scott, and the latter one of the additions made during the restoration by the late Mr. Cottingham. Immediately north of the altar is placed the ancient bishop's chair, attributed to the twelfth century. Scattered about the eastern end of the Cathedral are several fragments of stained glass, some of the best, apparently of

Hereford Cathedral.—The Arms of the See from Bp. Stanbury's Tomb.

early fourteenth century date, being in one of the lancets on the south side of the Lady-Chapel, west of the Andley Chapel, having a Majesty and the four evangelistic symbols, besides other fragments of interest. There are also some figures of saints in the windows of the eastern transepts, but not of a very high order of merit, although apparently of fourteenth-century date.

The ground-plan of the Cathedral which we publish to day has been reduced from a very carefully plotted quarter-scale plan by Mr. William E. Martin, and kindly placed at our disposal by Mr. Kempson, of Hereford. To this have been added the cloisters and chapter-house, as they exist at the present time. We have to acknowledge also much help and valuable information received from Mr. St. John Hope and Mr. Gordon Hills. A paper by the latter in the Archaeological Association "Proceedings" of 1871 is a very valuable and exhaustive account of the building.

ILLUSTRATIONS OF OLD CHESTER.

I.—FIREPLACE IN BISHOP LLOYD'S PALACE.

This fine apartment, originally forming one of a suite in Bishop Lloyd's Palace, has evidently been approached by a handsome staircase and hall, now removed, except the large window and ornamental plaster ceiling. The room is about 32 ft. by 17 ft. by 13 ft. 6 in. high to the ceiling. The floor is of oak. The panelling is deal painted, which appears to have been general throughout the street. It extends along the side opposite by the fireplace, and about half the opposite side.

In the north wall are three windows, which, being rather small, do not light the room sufficiently; between the windows are panels. The south wall, with the entrance doorway, has been brought forward into the room, reducing its length about 6 ft., and is perfectly plain. The fireplace is entirely of red sandstone, and is surmounted by a broken pediment and phoenix, and is carried above the line of ceiling, which is coved to receive it. The cove is enriched. The plaster ceiling is delicately treated, but has been much injured by repeated coatings of distemper, otherwise the room is in very good preservation.

The adjoining room, with which this communicated, will form the subject of another illustration in the series.

T. P. Ivison.

VILLA, SOUTH-HILL PARK, BROMLEY, KENT.

This villa, built as a private residence at Bromley, is faced with red bricks up to first floor, and rough-cast and half-timber work above same. The position is a high one, and the oriels and turrets command good views of the adjoining country. The cost was about 2,200*l.*, Messrs. W. A. Williams & Hopton, of Bromley and London, being the architects.

The contractors are Messrs. Baxter, Payne, & Lepper, of Bromley.

HOUSE, No. 79, FORE-STREET, REDRUTH, CORNWALL.

The rebuilding of these premises has recently been completed, local stone being used for the walling, with Portland stone dressings, cornices, strings, &c. The works have been carried out by Mr. Arthur Carkeek, of Redruth, from the designs and under the supervision of Mr. Hubert A. Gregg, A.R.I.B.A., of London.

THE CITY ARCHITECTSHIP, ABERDEEN.—Ballie Rust will, it is understood, at once intimate his resignation as a member of the Town Council in order to become a candidate for the City Architectship. Messrs. Matthews & Mackenzie, architects, are also candidates for the office.—*Aberdeen Free Press.*

COMPETITIONS.

TRUANTS' SCHOOLS, LICHFIELD.—In the competition for the Midland Truants' Schools, to be erected at Liebfeld, the plans sent in by Mr. R. Stevenson, Barton-on-Trent, under motto of "Adaptability with Economy," have been accepted, and he has been appointed to carry out the work. Mr. E. R. Robson was the assessor in the competition.

CHACEWATER CHURCH RESTORATION.—The *Cornwall Gazette* says that plans for the restoration of Chacewater Church have been submitted by six architects. These are now under the consideration of Prebendary Hingeston-Randolph, who has kindly undertaken to act as assessor. Should his opinion confirm the selection made by the committee, it is hoped that the work will at once be opened to tender, and the building in a contractor's hands in the early spring. So far 1,100*l.* has been contributed, but it is to be hoped that the additional sum required will be subscribed before the completion of the work.

ARCHITECTURAL SOCIETIES.

EDINBURGH ARCHITECTURAL ASSOCIATION.—A meeting of this Association was held on the 28th ult., Mr. John Kinross, the President, in the chair. A letter was read from the First Commissioner of Works regarding the condition of Linnithgow Palace, and notice was given of the following motion, to be submitted to the next meeting of the Association:—"That this Association, in acknowledging the communication from the First Commissioner of Her Majesty's Works of date December 29 last, intimating that he had caused a sum of 250*l.* to be provided in the estimate of the Department for the ensuing year in order to admit of the more urgent and special repairs of the Palace of Linnithgow being carried out at an early date," begs to thank the First Commissioner for having taken action in the matter, and to express its satisfaction that the immediate necessity for certain repairs has thus been recognised; but, looking to the exceptional importance of the Palace in regard both to the history and architecture of Scotland, the Association feels that the thorough repair of the entire fabric is the only proper course, and begs respectfully to represent that such thorough repair can only be properly carried out by replacing the burnt timbers and flooring, reglazing the windows, and covering the whole with a roof, so that the walls may be firmly tied together, and the whole rendered wind and water tight." The meeting then proceeded to consider the following motion, moved by Mr. G. S. Aitken:—"That this Association, in view of the recent architectural changes made in the approach to the Register House, is of opinion that the Wellington statue in front thereof should be removed, and that for the following reasons, viz.:—(1) It is an obstruction to the thoroughfare; (2) it is out of scale with Adam's fine building; (3) it is incongruous with its surroundings; (4) its merits as a work of art are not advantageously displayed in its present position." After some discussion, the matter was remitted to the Council of the Association for further consideration.—Mr. Hippolyte J. Blanc then read an interesting paper on "Heriot's Hospital and Contemporary Work."

GLASGOW ARCHITECTURAL ASSOCIATION.—The fifth lecture of the session was delivered by Mr. James Lindsay, A.R.I.B.A., on the 28th ult., his subject being "Approximate Estimating." The President, Mr. Wm. J. Anderson, occupied the chair. The lecturer's endeavour was to give some helpful hints to architects called on to approximately state the cost of some building without awaiting contractors' exact estimates. The capabilities of the cubing system were discussed. If from some existing building of a similar character to the one proposed is obtained its price per cubic foot, that applied to the bulk, as found from plans of the other contemplated, ought to approximate pretty nearly to its cost. The difficulty was to find the nearest precedent, and even when found error was made when simple contraction of bulk was expected proportionately to reduce the expense. The features in which lie the chief expense must be reduced rather than the mere walling, roofing, and flooring. Another system,—superficial measurement,—was described, with illustrations on the blackboard. At the close of the lecture a discussion followed, and the customary thanks were voted to Mr. Lindsay.

LEEDS AND YORKSHIRE ARCHITECTURAL SOCIETY.—At a meeting of the Leeds and Yorkshire Architectural Society on Monday night, Mr. F. W. Bedford read a paper entitled "Some Account of the Arts in Southern Italy and Sicily." Mr. W. H. Thorp, President of the Society, introduced Mr. Bedford, who, he explained, had spent a considerable time studying the architecture of Spain, Southern Italy, and Sicily. Mr. Bedford illustrated his lecture with photographic views thrown upon a screen, and the audience were much interested, especially in the very complete Pompeian series which the lecturer possesses.

THE SOCIETY OF ENGINEERS.

The first ordinary meeting of the Society of Engineers for the present year was held on Monday evening last, at the Town Hall, Westminster. Mr. W. N. Colam, the President for 1891, first occupied the chair, and presented the premiums of books awarded for papers read during his year of office, viz.:—The "President's Premium" to Mr. G. M. Lawford for his paper on "The Drainage of Town Houses," The "Bessemer Premium" to Mr. J. H. Paul for his paper on "Corrosion in Steam-Bollers," A "Society's Premium" to Mr. John Kerr for his paper on "Portable and Pioneer Railways."

Mr. Colam introduced the President for the present year, Mr. Joseph William Wilson, jun., to the meeting, and retired from the chair, receiving a hearty and unanimous vote of thanks for his services during the past year.

Mr. Wilson then took the chair, and upon his proposition, seconded by Mr. Colam, a vote of condolence with the Queen and the Prince and Princess of Wales in their recent bereavement was agreed to.

Mr. Wilson then proceeded to deliver his inaugural address. After returning thanks to the members for electing him as their President, and calling upon them for their co-operation in advancing the growing prosperity of the Society, he reviewed the work done under its auspices during the past year, during which time the number of members of all classes had increased more than 9 per cent.; Sir George Barclay Bruce, Past President of the Institute of Civil Engineers, having been elected to the vacancy in the roll of Honorary Members occasioned by the lamented death of Earl Granville. The chief points of interest in the papers read and discussed during the year were then touched upon, and reference was made to the professional visits undertaken during the summer, which included those to the Ice Works of the Linde British Refrigeration Company, at Shadwell; the City and South London Electric Railway Company's Stockwell Depot; the Royal Engineers School of Military Engineering, at Chatham; the Shortlands and Nubeah Railway Works; and the Crystal Palace Gas Company's Works at Lower Sydenham. The President then referred to the growth of the population of the world and the corresponding development of engineering enterprise; and to the present unsatisfactory condition of the London sewage question, in reference to which he had received from Sir Robert Rawlinson an epitome of his solution of the sewage disposal as being "Out of the River Thames and into the Sea over Maplin Sands." The work of the recent International Congress of Hygiene and Demography, especially in reference to the section of "Engineering in relation to Hygiene" was touched upon, and it was felt that, although much had been done, much still remained to be accomplished in relation to not only sewerage disposal, but also the adequate supply of water to, and the prevention of smoke in, London. The President then enumerated the proposed railways in and around London; and, pointing out the great need that existed for these and other methods of relieving the overgrown street traffic, urged the necessity for a conference of competent authorities in order to decide upon some definite scheme of gradual re-organisation for existing London, with a due regard to its systematic onward development. He then dealt with increasing railway speeds and the connexion of the question with the recent Norwood Bridge accident, and the consequent re-construction of many railway bridges on the lines throughout the country; and he advocated a more general adoption of the plan utilised on the Forth Bridge of laying the rails in iron troughs so as to avoid the lamentable accidents at present produced by a train leaving the metals when crossing a bridge and immediately

crashing through the floor. The rapid increase in third-class passengers, and the gradual disappearance of second-class carriages, and the approaching abandonment of the remainder of the broad-gauge system were touched upon, and Mr. Wilson proceeded to consider the important engineering development of subaqueous tunnelling. Tunnels had already been successfully carried beneath the St. Clair River in America, and the Severn and Mersey Rivers in England, and the Blackwall Tunnel beneath the Thames was about to be commenced; besides which there were many such works proposed in various parts of the world; the most important schemes being for tunnels beneath the sea, of which that designed by Sir Douglas Fox for connecting Prince Edward's Island with New Brunswick was likely to be the first actually constructed; and he proceeded to give particulars of this, with approximate estimates for the various diameters designed for alternative conditions of traffic. Extracts from the latest reports of Sir John Fowler and Sir Benjamin Baker upon the maintenance and present satisfactory condition of the Forth Bridge were given, and allusion was made to the approaching completion of the Manchester Ship Canal, the Tower Bridge, and the Liverpool Overhead Railway, and the commencement of the Dover Harbour Completion Works, and the Harbour and Improvement Works at Ramsgate; and, after referring to the Crystal Palace Electrical Exhibition, which promised to outshine all previous Exhibitions, and where the development of electrical machinery was so prominent a feature, the President concluded by dealing with the question of engineering education, with which he had been intimately associated during the last twenty years; emphasising the fact that the true solution of the question is to be found only in a judicious and simultaneous blending of theory and practice, under the highest personal supervision; and that success would be ensured to the engineer if he would but "deserve it" by an honest and unwearied application of all his energies of mind and body to the requirements of his great profession throughout his career.

THE LONDON COUNTY COUNCIL.

The usual weekly meeting of the London County Council was held on Tuesday last, the Chairman, Sir John Lubbock, presiding. The greater part of the sitting was taken up by a discussion on the incidence of local taxation.

Appointment of an Assistant Medical Officer of Health.—On the recommendation of the General Purposes Committee, Dr. W. H. Hamer was appointed Assistant Medical Officer of Health, at the commencing salary of 500*l.* a year, rising to 600*l.*

The Valuation of Land.—The Special Committee on the Valuation of Land presented a report recommending the appointment of a central assessment committee under the direction of the County Council, to have the same powers as the surveyor of taxes under the Act of 1863, together with other powers giving them authority to secure through the local assessment committees uniformity of assessment throughout the metropolis, and the separate assessment of all land in the county, irrespective of buildings and improvements, and authorised to appoint an assessment clerk to act as their agent. The Committee believed that even under existing Acts all land ought to be rated on its value, and recognised the fact that land not yet built upon had not in practice been rated according to its value, and they proposed that legal advice should be taken as to whether such practices were legal, and could only be altered by new legislation. In the event of counsel advising that such legislation was required, the Committee recommended that application should be made to Parliament to obtain powers authorising rating authorities and assessment committees to calculate for rating purposes, not only the annual rent, but also the capital value of land, and to assess the property either on the rent "which a tenant might reasonably be expected to pay," or on a statutory percentage of the capital value. The Committee further recommended that this report should be referred to the Parliamentary Committee with instructions to take measures for obtaining from Parliament during the present Session such powers as might be required to carry out the foregoing recommendations. The recommendations were adopted.

Enlargement of Banstead Asylum.—On the recommendation of the Asylums Committee, it was resolved to provide further infirmary accommodation at Banstead Asylum, at an estimated cost of 14,000*l.*, from plans prepared by Mr. G. T. Hine, the architect of the Claybury Asylum, now building.

Regulations for Ensuring the Public Safety in Theatres.—The Theatres and Music-halls Committee brought up a series of regulations for ensuring the safety of visitors to theatres, music-halls, &c. The consideration of the subject was postponed for a week, and,

After transacting other business, the Council adjourned.

ARCHAEOLOGICAL SOCIETIES.

LANCASHIRE AND CHESHIRE ANTIQUARIAN SOCIETY.—The annual meeting of the Lancashire and Cheshire Antiquarian Society was held on the 29th ult. in Chetham's College, Manchester, presided over by W. E. A. Axon. Mr. W. Harrison (in the absence of the hon. secretary, Mr. G. C. Yates, F.S.A.) read the annual report, which stated that the steady growth in the number of members maintained until last year had been arrested, but in other respects the success which had attended previous years had continued. The total number of members now was 337—283 ordinary, 49 life, and 5 honorary members. The Duke of Devonshire was unanimously elected President of the Society, and Mr. T. Letherbrow and Mr. G. C. Yates were re-elected treasurer and secretary respectively.

LEICESTER ARCHITECTURAL AND ARCHAEOLOGICAL SOCIETY.—The annual meeting of this Society was held on the 25th ult. Mr. W. J. Freer, hon. sec., read the thirty-seventh annual report, which mentioned the fact that seventeen new members had been elected.

Books.

The Maintenance of Macadamised Roads. THOMAS CODRINGTON. Second Edition. London: Spon, 125, Strand.

AS a reliable handbook Mr. Codrington's "Maintenance of Macadamised Roads" has been universally recognised since its publication twelve years ago. The exhaustion of that edition has consequently produced a second, for which we have been waiting with some degree of expectation. In the meantime Mr. Codrington, as one of the Engineering Inspectors of the Local Government Board, made a "Report on Road Maintenance" to that Board, which was published "By Authority," and sold to the public in the form of a pamphlet at the time of the birth of the first County Councils. This second edition incorporates in some measure the contents of that pamphlet, which brought road-matters a little more up to date, but incorporates little else. What the cause for this may be we know not, but it cannot be otherwise than a regrettable circumstance that the issue of a new edition of this deservedly popular work was not made the occasion for introducing much that would have added to its value.

It may be interesting to know that the cantonniers,—the men who are charged with the manual labour connected with the maintenance of the roads in the cantons of France,—wear blue jackets and leather hats, "around which shall be a band of copper, 0.25 in. long and 0.555 in. broad;" that their punishment for a first offence of absence is the loss of three days' pay; for the second similar offence, a loss of six days' pay, and for the third offence dismissal; that from May 1 to September 1 they begin work at 5 a.m. and cease at 7 p.m.; and that they have to plant a staff on the roadside within a short distance of where they are working, so that a man can be found in case he has gone for a doze into a shady and adjacent wood. All this, and more, is included in the "Regulations for Cantonniers," which forms Appendix I. of the volume under notice. A perusal of those "Regulations" may afford some faint guide for a frame on which to weave a code of laws for roadmen; but what it chiefly does is to furnish grounds for doubt whether such stringent semi-military regulations would be acceptable to, or accepted by, the class of man who it is understood is to be the future model roadman of this country. Nevertheless, there is something to note in them, and it was well to append them to the work. The magnitude of the subject, from a financial point of view

may be appreciated from the following statement:—

"The annual taxation returns now show a total expenditure in England and Wales of upwards of 5,500,000. a year on highways, street improvements, and rural roads. Of this amount, 2,000,000 is expended by highway authorities in rural districts, almost entirely on macadamised roads. The other 3,500,000, is expended in the metropolis and by urban sanitary authorities."

A very sensible proportion of this three-and-a-quarter millions is, of course, also expended on macadamised streets in the towns and cities of the country. Why, in treating of the value of a binding material, a quotation from Mr. Deacon's paper in the Proceedings of the Institute of Civil Engineers has been placed under the head of rolling instead of nnder that of binding, it is not easy to discern, nor why it is there alluded to as a *binding* instead of a *binding* for macadam.

We are glad to see a little,—though a very little,—more information about the machine tests adopted in France by the road authorities, and hope that the time may not be far distant when the Local Government Board, or the County Councils' Association, or some large Municipal or County Council, whose expenditure on these matters is very considerable, will take up this branch of the subject, purchase or construct machines, either on the French or any other suitable designs, and carry out tests, which are bound to be of very great assistance to them.

To this part of the work a little more care in the revision of proof would have prevented the publication of such peculiar formulae as:—"Grammes of detritus: 20 = 20; coefficient, and 3,000; crushing weight per square centimetre = 20; coefficient."

The author ought to have been aware that the stone of Mount Sirel is not a hard trap. An error of this kind is important, as it much disturbs the value of the subsequent information relating to the cost of crushing by machinery, the details of cost given being naturally assumed by a reader to be those for breaking a hard trap, which is not the case. We are aware that quarry owners might reasonably object to furnishing for publication the details of cost of the operations which go on in their respective quarries, but the way in which this branch of chapter iii., viz., "Stone-breaking by Machinery," has been treated by the author is altogether inadequate to its importance; in a great measure it is a piece of ancient history.

The fact of the "Cost of Road Material" having been condensed into a page and a half, as in the first edition, will also give a correct notion of the adequacy of treatment of that part of the subject.

There are some useful observations on the merits of the artificial application of water to roads, and as this matter is one on which the author has on several occasions had to adjudicate as an arbitrator, it is well to know his published opinion, as follows:—

"For the sake of the road itself, a road, except one of a silicious nature, seldom requires watering in this country." The contention of urban surveyors on this point of dispute between them and county surveyors would not, therefore, be deemed by him to be of great weight.

A small amount of additional information is given respecting the cost of road maintenance in the metropolis, and a good deal more about the cost of roads elsewhere, and this chapter is on the whole more complete and better revised than most other portions.

The section which relates especially to road management,—i.e., the *systems* of road management,—has also received beneficial additions, and we fully endorse the strictures passed on contracting for road management. With a good surveyor,—i.e., a man who knows and does his work and is honest,—no contract for maintenance can be necessary, nor can a contract in such a case be other than a discreditable extravagance.

In spite of the deficiencies and blemishes to which we have been compelled to draw attention, this is a work far ahead of any other of its kind. It will still probably hold its own as the best handbook on the subject.

The Art and Craft of Cabinet-making. By DAVID DENNING. London: Whittaker & Co. This useful work forms one of Messrs. Whittaker's series of practical manuals on the arts, sciences, manufactures, and industries, and the author states in his preface that his inten-

tion has been to supply "amateurs and young professional cabinet-makers with a reliable guide to the construction of cabinet-making." This the author may be said to have done in a very clear and concise manner, and the chapters dealing with the craftsmanship of his subject may be praised without reservation. The title is a taking one, as at the present time the connexion between artists and craftsmen is receiving the attention of the former in the attempt to make the crafts fine arts. This book may be confidently recommended to the furniture-building architects of the day. The descriptions of the use of tools, the materials, and the methods of workshop practice are admirably explained, and the knowledge of these principles of handicraft cannot fail to assist these architects in their ardent wooing of the craftsman. It cannot be claimed, however, that Mr. Denning's hook will throw much light upon the methods of designing really (not so-called) artistic furniture; for the promise which the title of the book holds out is not redeemed in the text. The book contains many illustrations of articles of furniture, most of which seem to be reminiscences of Tottenham-coort-road. The principles of good design do not appear to have been grasped by the author, and many of his remarks in this direction might easily be misleading. The perusal of Mr. Denning's hook emphasises the gulf existing now-a-days between the designer and the craftsman who executes the work, each failing at times to comprehend the difficulties arising in the province of the other, and the question naturally arises as to whether it is possible, with our existing institutions and their developments, that the good old days shall return, and the craftsman be an artist who is equally alive to beauty of form and colour, and the precision of craftsmanship necessary for its execution.

The London Householder's Chart: Public Health Act, 1891. By T. MILLER MAQUIRE, LL.D., Barrister-at-Law. London: Simpkin Marshall & Co.

THIS is little more than a pamphlet in size, but may be a very useful one to many householders. It contains a brief statement as to the working of the Public Health Act as it will affect householders, directing them what to do and to whom to apply in specified cases, and also to whom and to what extent they are liable for infringements of the Act &c. There is a list also of the districts in which the Vestry is the Sanitary Authority, and those in which the District Board is the Sanitary Authority; an existing irregularity of administration which is a puzzle to many. It will be found a very useful little manual of facts put into a small compass.

The Metropolitan and Provincial Local Government Annual and Diary, 1892. London: S. ENCUMBE-ROGERS, Dorset House, Salisbury-square, E.C.

THIS is the first appearance of what is likely to prove an exceedingly useful and convenient publication. The object of the editor, Mr. Edgumbe-Rogers, as he tells us in the preface, has been to give within the two covers of this book (the price of which is 1s. 6d.) information "which previously could only be obtained by buying some four or five different volumes ranging in price from 2s. to 15s., at a total cost of £2." The first in order of the many useful features of this diary is "The Local Government Remembrancer," which sets forth the duties to be discharged by public bodies and officials in each month of the year. Then follows a list of the chief officials of the Local Government Board, and this, in turn, is succeeded by lists of the members and chief officers of the London County Council, the Metropolitan Asylums Board, the School Board for London, and the Corporation of London; then comes a list of the various District Boards of Works and Vestries, with the names of their officers, and a variety of other information. The country section is commenced by a list of associations connected with local government, with their chief officers. Then follow the Municipal Corporations, with the names of the new Mayors, the Town Clerks, and Surveyors. The County Councils, with the names and addresses of the Clerks and Surveyors, and the country Unions, with the names and addresses of Clerks and the Masters, are given in a clear form. Everything appears to be up to date. Among the forty-one distinct features of the book are to be found

information about the City Companies, the District Surveyors, burial boards, cemeteries, coroners, sick asylums, county-courts, police-courts, baths and washhouses, public libraries, gas, water, and electric light companies; public parks, and port sanitary authorities. The hook, which includes a diary of three days to the page, may be strongly commended to the attention of all who are engaged in the work of local government, and will be especially useful to the intelligent ratepayer.

Correspondence.

To the Editor of THE BUILDER.

THE JEW'S HOUSE, LINCOLN.

SIR,—The reason why the "Jew's House" at Lincoln, of which you have recently given an illustration from Mr. Powell's drawing (January 9), is so called, is simply because it was the house of a Jew. Lincoln has two such houses, of nearly the same date, i.e., about the middle of the twelfth century. That represented in Mr. Powell's drawing is the more perfect, but the other is the more historically interesting. It was the home of "Aaron the Jew," the prototype of the Isaac of York of Sir Walter Scott's "Ivanhoe," one of the chief, if not the very chief, of the money-lenders of Henry II.'s time, whose name is of very frequent occurrence in the legal documents of the period. The other house (that of your drawing) which stands some way farther down the almost precipitous "Steep-hill" on the opposite side of the way, though built a hundred years before her time, was in the latter part of the thirteenth century the property of a Jewess named Belaset (Belle assez?), of Wallingford. This lady in 1271, betrothed her daughter Judith to Aaron, the son of Benjamin, endowing the young pair with twenty marks sterling, and a copy of the Hebrew Bible, written on calfskin. The marriage took place four years later, in 1275, and the wedding-feast, of which we have a record, may probably have been held in this very house. Fifteen years later, in 1290, the same year in which the Jews were expelled from England, Belaset was hanged on the charge of clipping the King's coin. Belaset's message having escheated to the crown, was granted to Walter le Fevre of Follethly, from whom it passed by gift to Canon William de Thornton, Prebendary of Stow Longa, and was presented by him to the Dean and Chapter. On the surrender of the Chapter Estates to the Ecclesiastical Commissioners, the Jew's House became the property of that body. Applications have been recently made to the Commissioners to redress some of the damage caused by the neglect and wanton mischief of former years, and maintain a precious relic of the Domestic Architecture of our forefathers in its integrity, but they have obtained little attention. The house is thus described by Mr. Hudson Turner ("Domestic Architecture in England," vol. i., p. 7):—"A building at Lincoln, known as the Jew's House, is a fine specimen of the period. The principal dwelling-room is on the first floor, where there is a fireplace on the side towards the street. The chimney is corbelled out over the door, the lower part with the corbels forming an arched canopy over the doorway, which is richly ornamented." He adds: "There is another house in the same street," that known as the house of Aaron the Jew, "of equal antiquity, but in a less perfect state." Both houses are described more fully on pp. 41, 42. Mr. H. Turner writes of Belaset's House, "it is small, and seems to have consisted of two rooms only, one on the ground floor, and one above" (not quite accurate: there was a hack room as well as front room). "These may, however, have been originally divided by partitions." His concluding remark that "the interior has entirely lost all original character," I am happy to say, is not strictly accurate. In the northern division of the house, now occupied as a butcher's shop, in both stories a perfectly plain round-headed Norman archway, tall for its width, forms the communication between the front and back rooms, and in the north wall of the lower room is a broad, shallow Norman recess. From all of these the wall-paper and plaster by which they were obscured was stripped off, and the stonework cleaned and left bare on a recent change of tenant. Of Aaron's House Mr. Turner says:—"The same arrangement of the arch of the doorway carrying the fireplace is found here also. The Norman ornamented string, on a level with the floor, may be traced along two sides

of this house, which stands at a corner, and some windows" (only one now) "may be distinguished, but less perfect than those of the first house." I may add that a blacklead pencil drawing of this house by Mr. J. C. Buckler, executed in the exquisitely-delicate style in vogue seventy or eighty years back,—now, to my regret, quite out of fashion,—is to be found in the collection of the British Museum, in a volume containing drawings of the monumental slabs ejected from Lincoln Minster at the time of the disastrous repaving at the close of the last century and placed in the cloisters. This drawing, which is undated, depicts the house in a much more perfect state than now, with two of its Transition Norman windows on the south front in a perfect state. At a repair of the house in 1878 a similar window was discovered on the west face, and carefully restored by the Minster masons under the direction of the clerk of the works.

It is noticeable that the few examples of town houses of the twelfth century remaining in this country are almost without exception traditionally assigned to members of the Jewish community. Besides the two at Lincoln there is a very remarkable Jew's house at Bury St. Edmunds, known as "Moyses' (the Vulgate spelling of Moses) Hall," of stately character than its fellows. The reason is that when houses in towns were, as a rule, constructed of wood and plaster, the Jews built theirs of stone as a security for their persons and their property, especially their hags and chests of coin, from the assaults and plunder to which they were continually exposed. "It is certain," writes Mr. Turner, "that in all early deeds relative to the transfer of tenements once held by Jews, those tenements are usually described as built of stone" (p. 47). "Examples, these," says Mr. Freeman, "of the stately houses of these favoured chattels of the King to which men pointed with envy as rivaling the King's own palaces" ("Towns and Districts," p. 215).

EDMUND VENABLES.

The Precentory, Lincoln, January 26, 1892.

CONCRETE FOR ARTISANS' DWELLINGS.

SIR,—I am very much obliged by your insertion of my inquiry as to laying flooring on concrete, and to those who gave the valuable suggestions in reply. The great importance at the present time of the question of housing the labouring classes in cities will, I trust, be a sufficient excuse for troubling you with a question or two more, which may elicit from some of your readers their experiences for the benefit of those who, like the writer, are endeavouring to solve the question of economical, and yet substantial, labourers' tenements in their own localities.

It is proposed to replace joists on upper stories by slabs of coke breeze concrete, the walls being levelled off for each story at underside of floor concrete, which would be then laid on the walls through their full thickness, and the walls of next story carried up from top surfaces of the slabs. On these slabs the flooring would be nailed.

1st. Should the breeze be used just as it is got from the gas-works, or is it necessary to remove any of the very fine part of it, or to add any other material to it, and in what proportions should it be mixed with Portland cement for this particular purpose?

2nd. What is the largest size of floor that is shown by practical experience to be safe without any support, except on the walls as above described, and using slabs of 5 in. or 6 in. thick?

3rd. If breeze is used for the walls, which would vary from 5 in. to 9 in. thick, would it be necessary to add any other material? and what proportion of cement should be used for wall work?

SCRYVEOR.

FLOORING-BOARDS ON CONCRETE.

SIR,—I had some 1 in. yellow deal flooring nailed to 2 in. of coke breeze concrete, on a bed of brick rubbish and Portland cement concrete (6 to 1) five years ago. The whole of the concrete was left for a month to get thoroughly dry before the floor boards were nailed, and I saw this flooring about a month ago. It has stood perfectly, and is as solid to walk upon as on the day it was laid. The boards were not, and ought not to be, tongued.

C. F. M.

SIR,—I would advise "Surveyor" not to lay tongued-wood floor direct on to flat surface, either of breeze or other concrete, for the following reasons: If nailed to the concrete without intervening air space, dry-rot is almost sure to follow; and if nailed to fillets embedded in the ordinary ballast concrete without intervening space, the same result will ensue.

Providing "Surveyor" wishes to do without wood fillets, sleepers can be formed of breeze concrete, keeping the surface not less than 1 in. above the

general surface of concrete floor, and making provision for the admission and circulation of air.

In no case should floor-boards be "cut down" directly to the concrete-floors are laid, and nailed down later on, as suggested by "Another Surveyor," as the boards will become saturated on the underside by the moisture emitted from the concrete during the process of drying, and when nailed down considerable shrinkage will ensue.

The most satisfactory results will be gained by allowing the concrete to dry thoroughly, or as much as possible, before the boards are laid.

"Another Surveyor" suggests that he is not sure "that coke-breeze is a safe material to place even near flues, that it is a very perfect conductor of heat, and that the heat will accumulate in it sufficiently to char any wooden skirting," which appears to me to be entirely contrary to facts.

I have used breeze concrete most extensively for years, and have put it to the severest tests in every way, and found it both a non-conductor and non-absorbent of heat, and most fire-resisting and incombustible,—in fact, much more so than ordinary ballast concrete, as if heat is applied to the latter the "aggregate" will immediately crack and fly to pieces.

I have no doubt "Another Surveyor" is cognisant of the use of "Wright's" fireproof bricks for fixing wood skirtings, &c., round fire-flues and similar situations, which have had the test of at least ten years without causing any catastrophe, and from the facts mentioned above there is no possibility of any heat from the grates or stoves being communicated to the concrete if carried into the fireplaces sufficiently to char any woodwork placed in juxtaposition.

It is admitted that breeze concrete is lighter than ballast concrete by about 25 per cent., but there is no ordinary concrete made that is water-tight, or will prevent the percolation of water through it.

The experience of "Another Surveyor" in regard to coke-breeze concrete scaling off from below the flanges of the iron joists is unfortunate, and I would suggest that, instead of using coke as an aggregate, he should use coke-breeze mixed with the usual proportion of Portland cement, and keep the soffit of the concrete at least an inch below soffit of joist; he will then find the soffit of the concrete throughout perfectly sound, which can be plastered on direct, and he thorough good work without the needless expense of battens and lathing.

I have encased girders up to 26 in. wide in a similar way with same satisfactory results.

"EXPERIENCE."

** "Experience" is a correspondent who has a right to the signature, but we may point out that the "experiences" of others is tending to show that boards may be laid on concrete with proper care, without dry-rot supervening (see as one example the letter of "C. F. M." above); and the plan of laying the boards with a space between them and the concrete, supposed to be necessary, keeps up that system of inaccessible hollows in house-building, which it is desirable on sanitary grounds to get rid of entirely.—E.U.

MONUMENTS TO ARCHITECTS.

SIR,—May I, with your kind indulgence, ask through your columns whether any of your readers are aware of the names of any English architects, besides Sir Charles Barry, G. E. Street, and Professor Cockerell, who have had statues or sculptured memorials, funerary or otherwise, erected in their honour? O. F.

BERLIN WATERWORKS.

SIR,—I venture to bring to your notice an error in your last week's "Notes." You refer to Herr Osten as "the engineer" of the Berlin water-works. The engineer, who has held this position ever since the waterworks were built, is Mr. Henry Gill, M.Inst.C.E., an account of whose paper on "Water-meters," read at the Institution of Civil Engineers, a few weeks ago, was published in your columns. Herr Osten only holds the position of chief assistant-engineer. I trust you will see your way to correcting your slip of last week. GEORGE H. GILL.

OLD TOBACCO-PIPES.—In digging ground for the foundations of the Patent Office extension buildings, an unusually large number of seventeenth-century tobacco-pipes have been found. They lay, all together, about 14 ft. deep in what had been the garden of a house in Took's-court, and close to the southern wall of the Staple Inn block, which was re-built in 1699, as the date over its doorway testifies. They are made of fine white clay, with straight stems, in some cases 12 in. long; a few are glazed, and have initial letters on the wide foot under the bowl. Whilst after the customary type of a thick stem and a deep bowl, not much larger than the stem, the pipes have bowls of varying outline, many of them, indeed, showing well-moulded shapes. Out of these we have seen a good collection could be made of these humble specimens of plastic art. In the basement of the house in Took's-court was found the ornamented leaden cistern, bearing date "1675," to which we recently referred (see the *Builder*, vol. lxi., fol. 161).

The Student's Column.

WARMING BUILDINGS BY HOT WATER.

VI.

AIR IN PIPES (concluded). WATER SUPPLY.

(HORTICULTURAL WORKS)

IR tubes can be made of almost any material; copper tube, composition tube, or iron pipe. The former is very usually adopted when convenient, as it does not perish readily, and its rigid nature prevents injury by blows, which the compo pipe could not withstand. Composition pipe is, however, used to a considerable extent, owing to its cheapness, the easier way in which it can be worked (bent, &c.), and it can be more easily obtained if the material for the air-tube has to be purchased in the country. Iron pipe is sometimes used, but it entails more labour, cutting and screwing, is more clumsy looking, and no more effective than copper.

The size for the tube is small, varying from 1/2 in. to 3/4 in., according to the engineer's ideas or requirements. A very small pipe is sufficient, in fact, a pin-hole would permit of the air escaping, but a very small hole or tube bears a risk of becoming stopped. There is one essential feature to be observed when putting up air-tubes, which is that they must not on any account be dipped anywhere in their course. That is, from the point where they are connected to the hot-water pipe upwards, they must be carried in an ascending direction. If it is necessary to carry the pipe horizontally, then it is permissible, although it would be better if it could be given an ascending direction, however slight, but on no account must the pipe descend anywhere, or its purpose will not be fulfilled.

Supposing an air-pipe was erected, as Fig. 21. This would have a dip or descent in the pipe

where marked a. Now, this dip would not be found objectionable when first charging and testing the apparatus, but when the fire had been alight some time the little vapour that escapes by this pipe would cause a collection of water to occur at a, with no means of removing it. This collection of water, when once formed, would afterwards prevent the escape of air that is perpetually being given off by the water as it changes temperature, and the result would be the volume of air collected becoming great enough to stop circulation by locating itself in the extremity of the water-pipes where the air-tube is connected. The common term expressing this state of affairs is to describe the pipes as being "air-locked," and this is really the case, as the collection of water at a will quite prevent the air passing out from b unless the water was heated to boiling-point, when the steam would, doubtless (depending upon the depth of the dip), effect relief. We could not, however, depend upon raising the water to boiling temperature for this purpose, and it must somehow be arranged to carry the pipe in an ascending direction and not dip it anywhere. This is always possible, the pipe being so small as to permit of its being placed anywhere without being unsightly or objectionable in any way.

This pipe is always connected to the water-pipe by a union-joint; this admits of its being simply disconnected and removed if required. It frequently happens that these pipes have to be taken down, as insects, fine leaf debris, and other substances, find a collecting-point there, sufficient to quite stop the pipe up sometimes, and this has to be removed and the pipe cleared. The air-pipes are usually terminated inside the house if convenient, they are then less liable to stoppage. If they terminate outside, care should be exercised to see that no part of the pipe containing water be placed out of the house, or the first severe frost may freeze the water within it, and be an objection in several ways.

The upper extremities of these pipes are

usually turned over, as shown at fig. 21; this assists in preventing falling matter lodging within the pipes, and so bringing about a stoppage. When two branch services of hot-water pipes terminate near one another, the air-tubes can be joined, if a saving of pipe can be so effected, but both before and after the junction the same care must be used to see that the pipes rise more or less throughout their whole extent.

WATER-SUPPLY.

It is, of course, necessary to provide some convenient means of, not only filling the apparatus when it is newly erected, but (more important) of regularly replenishing and making good the loss of water by evaporation. Sometimes a draw-off tap is inserted in the apparatus, which the gardener resorts to when warm or tepid water is required for watering purposes, but this arrangement necessitates some special provisions, and the loss by evaporation only will be spoken of first.

It is, of course, understood that an apparatus, such as which we are speaking of, with open pipes at the extremities, loses water by evaporation very freely when it is in use; the evaporation being brought about by the heating of the water, as every one is aware. If it were not for this, a simple hole at some point would suffice for the first filling, but as the subsequent loss referred to necessitates moderately frequent attention (varying with the size of the apparatus, the power of the boiler, and other circumstances), a provision must be made for convenient replenishment, and at the same time it should be arranged so that the gardener or attendant can see at a glance when water is needed.

This is all fulfilled by an ordinary supply cistern,—a square cast-iron cistern of somewhat small size, placed in any convenient spot just above the highest point of the circulating pipes. No gain,—rather the reverse,—is effected by placing it higher. By keeping it low it is easily looked into, and the want of water seen in a moment. By keeping the bottom of the supply-cistern above the highest circulating pipe, we know that the pipes are full while there is water in the cistern, however little it may be, assuming nothing is amiss with the apparatus in other respects. With a cistern placed in this manner, the water is added, as required, by simply pouring it in from a can.

The important feature in connexion with the supply-cistern is that it should bear some relation to the size of the apparatus. The reason for this is, that when the apparatus is charged, it is, of course, filled with cold water. Now water, as explained in the earlier papers, expands to a most noticeable extent when heated, and the exact extent of this expansive or swelling property is one in twenty-four when heated from freezing to boiling temperature. This amounts to an increase of bulk, so that a quantity of very cold water occupying 24 cubic inches would be found to fill the vessel to 25 cubic inches when heated to 212 deg. In the works under discussion, we do not get such extremes of temperature, and a difference of about 130 deg., viz., from 50 deg. to 180 deg., is about the maximum, and the increase in bulk in this case would be only about one in thirty-six.

The object in dwelling upon this question is to point out that if a supply-cistern be put to the apparatus, and the apparatus then charged and the fire lighted, we shall get an overflow of water when it becomes heated and expanded, unless the cistern be of sufficient capacity to allow for this increase of bulk. The proper calculation to settle the size of the cistern is to use one capable of holding one-thirtieth of the whole contents of the apparatus. (Allow a trifle over half-a-gallon for every foot length of 4-in. pipe; 10 ft. of 4-in. pipe will hold 5.433 gallons.) When the apparatus is first filled, the cold water should not reach higher than about $\frac{1}{2}$ in. above the bottom of the cistern; the cistern will then nearly fill as the water reaches its highest temperature.

Some gardeners (and some engineers) do not trouble about this variation in bulk, and the allowance it necessitates; they use a small cistern, and when charging fill it up. As the water heats they let it overflow, until the expansion ceases, and the water level then remains fairly constant, unless the water cools down again. If the apparatus is one that has regular and skilled attention it may be taken for granted that the water will not cool down again until the fires are drawn in the warm weather, and not even then, if there is a

tropical house being heated. It will be seen that the variation in the bulk of water is in ratio with its heating and cooling, and if the boiler fire is kept going night and day, and the water thus always kept hot, the bulk will not vary to any important extent. The expanded water will not contract so long as heat is imparted to it from the fire, which, as just stated, is not allowed to go out all the winter months, under any circumstances.

The supply cistern should always have a lid to prevent dirt, insects, and leaves from falling in and stopping the supply pipe. Dirt is very usually a conspicuous feature in these works when they have had a little use; the causes just named contribute some, but the bulk (and the quantity is large sometimes) is due to the supply water being furnished from ditches or some such rather impure source. In towns the water used is generally from a company's mains, or, at any rate, clean water is abundant, but in country places it is not so conveniently accessible for the gardener's use, and recourse is had to rain or surface water. This water answers excellently, but has generally some suspended matter in it which collects at all available points in the apparatus. It is this matter when deposited in the boiler that requires removing periodically.

The supply pipe from the cistern to the radiating pipes is usually $\frac{1}{2}$ in., sometimes $\frac{3}{4}$ in., but considering the short length generally required, the former size might be used in every instance. It is less likely to get stopped. This pipe should have a dip, or syphon (inverted) in it, the object of this being to prevent the heated water finding its way into the supply cistern.

In the first papers it was explained that the circulation of water by convection currents was due to the heated particles of water taking an ascending motion by the superior descending force exerted by the colder particles. Now, this action will take place in a single pipe from a boiler; the heated particles going up the centre and the cold particles descending close to the inner surface of the pipe. This action is very free, and, although of no use for practical purposes, it is quite sufficient to admit of the rapid transference of hot water from the pipes into the supply cistern, if the pipe was carried in a straight line from one to the other without the dip just shown to.

This dip as shown in fig. 22 is merely the supply pipe carried down about 6 in. or 8 in.

FIG. 22.

below the circulating pipes and then it ascends, entering the return pipe below as illustrated. By this arrangement, the heated water to find its way into the supply cistern would have to first take a descending and downward direction, and this it will not do; and although the supply pipe is open and clear right through, no hot water will enter it so long as the dip exists.

OBITUARY.

MR. PHILIP C. HARDWICK, F.S.A., F.R.I.B.A.—We regret to learn from the *Times* that Mr. Philip C. Hardwick died after a long and painful illness on the 27th ult. He was born in 1822, and, after having been trained under Mr. Edward Blore, he joined his father in architectural work in 1842. Among the many useful works to which he devoted himself mention may be made of the Artists' Benevolent Institution, of which he was the honorary treasurer, and to which he rendered invaluable service. He was architect to the Bank of England, to St. Bartholomew's Hospital, to the Goldsmiths' Company, to the Merchant Taylors' Company, to Greenwich Hospital, and to the Charterhouse, and was surveyor to the Portman Estate. Among his principal works are the central hall of Euston Station, added to his father's building; the Great Western Hotel at Paddington Station; the Ship Hotel, Greenwich; Adair house; Madresfield court; Addington-mansion; and the New Charterhouse School buildings at Goldingham. Besides these he designed a very large number of banks and office buildings in the City and elsewhere. He was one of the competitors selected to send in

designs for the Albert Memorial, and he was also invited to compete for the Law Courts, but declined. In 1884, when the designs for the rebuilding of the War Office were under consideration, he, together with Mr. Ewan Christian, was appointed to the committee of selection as a professional adviser.

MR. JOHN E. PRICE, F.S.A.—As the *City Press* remarks, London archaeologists have sustained a grievous loss by the decease, which occurred a few days ago, of Mr. John Edward Price, F.S.A., of Harvey-road, Leytonstone. Mr. Price, who was in his fifty-second year, had been in failing health for some months. He had long been a keen student of archaeology, taking in this respect after his father, whom he invariably accompanied on his visits to spots where Roman and other remains had been discovered. For a long while Mr. Price was in business, but, the study of archaeology proving more attractive to him, he severed his partnership, thenceforward devoting the whole of his time and attention to his literary labours. In the world of archaeology he was regarded as a high authority on Roman relics in London. Mr. Price was the author of innumerable pamphlets and works hearing directly or indirectly on the hobby of his life. Possibly the work by which he will be chiefly remembered in four years is the one he wrote nearly six years ago for the Library Committee of the Corporation, the title being "An Account of the Guildhall." The deceased for a number of years had rendered substantial assistance to the Library Committee in connexion with the acquisition and arrangement of articles now on view at the Museum at Guildhall, a museum that now contains not a few of the relics of the Roman occupation of London. His efforts had succeeded in collecting. Some years ago Mr. Price held the post of secretary of the London and Middlesex Archaeological Society.

DR. G. G. ZERFFI.—The death, in his seventy-second year, from pneumonia following on influenza, of Dr. G. G. Zerffi occurred on the 23rd ult. at Chiswick. Dr. Zerffi was for upwards of twenty-four years Lecturer in Lectures on Ornament at the Science and Art Department, South Kensington, and was expected to have resumed his lectures from week to week since his illness. He wrote, amongst other works, "A Manual of the Historical Development of Art," "Spiritualism and Animal Magnetism," and "Studies in the Science of General History," and was a well-known lecturer on historical subjects. He was a member of the Councils of the Royal Society of Literature and of the Royal Historical Society. According to the *Times*, Dr. Zerffi was a Hungarian by birth, and took part in the Hungarian Revolution of 1848, serving as a captain in the 2nd Corps of the revolutionary army. He also edited the *Ungary*, published at Pesth. He became naturalised soon after taking up his residence in this country some forty years ago.

GENERAL BUILDING NEWS.

RESTORATION OF PETERBOROUGH CATHEDRAL.—This work, which has been in progress for the past ten years, is, says the *Leeds Mercury*, now rapidly approaching completion. The workmen have finished off the first set of stalls on the south side of the choir, and so much progress has been made that service will be resumed beneath the lantern in about a week or a fortnight. The altar will be placed as far back as the new pavement will permit, and the workmen will continue their work behind it. The new marble mosaic pavement, too, which is a gift by Dean Angles, is rapidly approaching completion. The designers,—Italian artists,—are now engaged on the second elevation eastward. The development of the pattern as it progresses shows a magnificent conception of design and colouring.

LECTURE HALL, SALISBURY.—On the 27th ult. a lecture hall was opened at the rear of the Congregational Church, Fisherton, Salisbury. The dimensions of the hall are 45 ft. by 25 ft. On either side are two class-rooms, 15 ft. by 15 ft. These class-rooms are shut off from the hall by movable partitions, and when these are taken away the room is capable of seating 450 persons. The hall itself will accommodate about 250. It is also intended to erect three other class-rooms and a kitchen at the farther end of the hall. The material used was red brick and stone work for the windows, with a wood-block floor and rough rolled cathedral glass. Mr. E. Witt was the builder, and the architect was Mr. Stevens, of Dorchester.

CHURCH AND SCHOOLS, BRIGHTON.—In a limited competition for a church and schools, Florence-road, Brighton, the designs submitted by Mr. George Baines, architect, were adopted. The church will seat 524, and 154 more in a future end and gallery; total, 678. The school will seat 250. There are also seven other vestries and class-rooms. The style is Late Gothic, and the walls are faced with flints, with red brick and terra-cotta dressings. The front gable of the church will be flanked by two turrets, one 85 ft. high.

PROPOSED RECONSTRUCTION OF THE FREE EAST CHURCH, ABERDEEN.—According to the *Aberdeen Free Press*, there is a proposal at present under the consideration of the congregation of the Free East

Church for the purchase of the buildings of the Free South Church, soon to be vacated by the congregation therein assembling, and by whom the church at the lower end of the Rosemount Viaduct has been erected from designs by Mr. Mackenzie, architect. It is proposed to make certain structural alterations in the Free East Church, and to convert the structure of the South Church, divided into two floors, into class-rooms, assisted by a tower hall, &c. In the words of the report prepared by Mr. William Kelly, architect, who has been consulted on the subject: "The present session-houses of both churches and the vestry of the Free South Church would be removed. Within the East Church the present entrance lobby and the staircases to the gallery would be cleared out, and the area added to the church. The main entrance to the East Church buildings, as altered, would be by a porch in the centre of the north gable of the South Church, leading by a vestibule 9 ft. fin. wide to an inner vestibule or hall, lighted principally from the roof. Direct access from this vestibule would be had to the church and to the various halls and rooms on the ground floor. In the centre of the vestibule would be placed the staircases to the first or gallery floor, leading upon a passage 9 ft. wide, which would be carried round the vestibule at the present gallery floor level. From the passage just mentioned there would be direct access to the gallery of the church, to the large hall, and to a couple of cloak-rooms on the first floor. The structural alterations within the East Church include the formation of windows under the side gable of the building up of the doors in the north and south walls, and the formation of a porch door at the north-east corner, corresponding with the present porch door at the vestry entrance. These alterations would greatly increase the light under the galleries, and would remove the draughts caused by the opening of the present entrance and exit doors. On the gallery floor the only structural alterations proposed are the formation of a passage for access, and the connection of the church galleries with those of the vestibule. It is proposed to improve the whole of the seating. The number of sittings in the church would remain as at present, but the pews in the area would be widened. It is proposed to divide the remainder of the space within the South Church into two floors. The lower floor would contain office-bearers' room, cloak-room, small hall (or session house), 28 ft. by 21 ft., and two large class-rooms, besides storage accommodation. On the upper floor would be the church hall (43 ft. square and having a height of about 20 ft.), capable of seating an audience of 350 to 400." The cost of the work is estimated to be about 2,350*l.*

SCHOOLS, WIGAN.—A new infants' school and class-rooms are to be built to the present Church Schools of St. Catherine, Whalley, Wigan. The architects are Messrs. Heaton & Ralph, of Wigan. The Church Schools of St. Paul's, Gosse-green, Wigan, are also to be largely added to and altered, under the direction of the same architects.

SCHOOLS, NORTHLEET.—The present Board Schools being inadequate for the number of children attending, a new school is about to be erected in the High-street for 500 boys. The *Greenwood Journal* says that the Board have selected the plans of Messrs. Walford & Legg, architects, submitted in competition.

HOSPITAL, TORBAY.—The Governors of Torbay Hospital held their annual meeting on the 28th ult., and decided to accept the sum of 47,000 bequeathed to the hospital under the will of the late Miss L. A. Warrington. It has long been desired, says the *Western Morning News*, to rebuild the hospital. This will now be possible, the chief condition of the legacy being that the work shall be done after the plans and under the supervision of Messrs. Habershon & Fawcner, architects, and that one of the wards in the new building shall be named "The Lavinia A. Warrington Ward."

SANITARY AND ENGINEERING NEWS.

CRANLEIGH SEWAGE PURIFICATION.—A Local Government Board Inquiry was held on 14th ult. before Mr. E. C. Walton, C.E., to consider the application of the Hambleton P.S.A. for a loan to carry out works of sewage disposal for the parish of Cranleigh, the treatment of the sewage on land having proved an expensive failure. Mr. C. Nicholson, C.E., of 16, Great George-street, Westminster, who had prepared the scheme, explained that the method of disposing of the sewage was that known as the "intermittent" system, by which the sewage was first treated in tanks and then passed through polarite filter-beds.

SEWAGE PURIFICATION WORKS AT SALE.—An inquiry was held at Sale, near Manchester, on the 21st ult., by Mr. R. G. Walton, C.E., who has recently been appointed one of the inspectors of the Local Government Board. The application was from the Sale Local Board for power to purchase additional land and erect a pumping-station and large sewage purification works for the treatment of the sewage of Sale by the polarite and ferrozene process of the International Water and Sewage Purification Company, Limited. The works will be of very considerable extent, and will include 2,300

square yards of polarite filter-beds. The plans have been prepared by Mr. McBeath, the Surveyor to the Local Board. Mr. Charles H. Beloe, the Consulting Engineer of the International Company, gave evidence to the effect that the plans were well adapted to carry out the objects of the company.

SEWERAGE AT LIANDRAFF YARD.—At a special meeting of the Cardiff Rural Sanitary Authority on the 30th ult., the tender of Mr. J. Straghan, contractor, Cardiff, was accepted for the sewerage of Liandraff Yard and Maindy, for the sum of 2,743*l.* 12*s.* The building-by-laws, as amended under the Public Health Acts Amendment Act, 1890, so as to apply to the whole of the district of the Authority, were also considered.

CLOMEL WATERWORKS.—A Local Government Board inquiry was held on the 20th ult. to consider objections from persons interested against the execution of works outside the district. The Clomel Corporation are about to carry out water-works at an estimated cost of 14,437*l.* The Government Engineer sat on Tuesday, February 2, to decide the value of the various lands required for the works. Tenders have been received for the iron pipes and valves, and the tender of the Stanton Iron Works Company, Limited, for 4,848*l.* 1*s.* has been accepted. The works will commence immediately. The engineer to the scheme is Mr. W. H. Radford, of Nottingham.

FOREIGN AND COLONIAL.

FRANCE.—At Pantin, near Paris, an excavation has been discovered, lined with marble slabs, in which have been found jewels, arms, a helmet surmounted by a Roman eagle, an alabaster vase, and various other objects apparently connected with the Roman occupation of Gaul. M. Fagel, the sculptor, has just completed the monument in commemoration of the battle of Watignies, the plans of which were prepared by M. Dutrieux. The monument will be inaugurated shortly. A serious fire has destroyed the fine chateau belonging to M. Guisot de Lagarde, near Toulouse. The chateau contained a valuable library, and a rich collection of furniture and works of art.—There has been found, in the district of Chalons-sur-Marne, a sepulchre of the neolithic age, containing skeletons, flint hatchets, needles formed of wolves' teeth, and fossil shells of the Tertiary epoch, arrows and other weapons.

A monument at Vannes, to Le Sage, the author of "Gil Blas," is to be inaugurated in May.—On April 3 next the Minister of Public Works is to go to the department of La Manche to open the new line of railway between Vere and Saint Lot.—It is announced that part of the ancient church of Val-les-Bains (Ardeche) has fallen.—M. Auguste Génin has been commissioned by the Minister of Public Instruction to make a journey to Mexico with the object of carrying on further researches into its archeology and ethnography.—For some days past dealers in works of art have been offering for sale pictures and studies by M. Puviss de Chavannes. These, executed about twenty years ago, have been stolen from his studio, and the artist has begged the Parisian press to put the public on their guard against purchasing such works. He intends to have all such works seized by the police as soon as information is obtained of any of them being offered for sale.—The death is announced of M. Emile Allard, a retired Inspecteur-Général des Ponts et Chaussées. We learn also of the decease of M. Foulhoux, architect-in-chief on the Indo-Chinese station, to whom we owe most of the work done at Saigon. He had published some interesting studies on Annamite architecture.—In the Palais de Justice at Lyons has been placed a portrait of M. Devienne, formerly first President of the Cour de Cassation. He was born at Lyons in 1802.—The Académie des Beaux-Arts has appointed MM. Dumet and Gruzer on the committee to judge the competition opened by the town of Nantes for the construction of a museum of painting in that town.

The committee charged to prepare a list of candidates for the chair left vacant by the death of M. Alphonse bas put forward, as candidate in the first rank, M. Georges Lafenestre, in the second rank M. Georges Berger, in the third M. Michel, in the fourth M. Corroyer, and in the fifth rank M. Charles Yvernat. The names follow of M. Philippe Gilles and M. Roger Ballu. The election will have been made by the time these lines appear.

DENMARK AND NORWAY.—The new church of Jesus in Copenhagen, to which we recently referred, has just been consecrated with great ceremony, the Danish Royal family being present, although, as yet, the exterior is not quite finished, and it will take some three years to complete the tower. It is the gift of the well-known Meenias and philanthropist, Herr Carl Jacobsen, the Copenhagen brewer; the cost, when completed, is estimated at 50,000*l.* In front of the entrance stands a bronze cast of Michelangelo's "Moses," whilst the façade is ornamented with statues of Christ and four Evangelists. It is stated that the church, when finished, although comparatively small, will be the finest structure of its kind in Scandinavia.

A monumental building to be used for military offices will shortly be completed in Copenhagen. It is three storeys in height, the materials used in the

construction being red bricks, sandstone, and granite.—A new cement company, the Danish Portland Cement Company, Limited, has been constituted, in order to work a deposit of cement near Aalborg.—At the last meeting of the Danish Old Norse Record Society, Dr. Müller, the distinguished archaeologist, presented his new work on the Bronze Age in Denmark, being an important link in the Danish historical culture.—The large new Masonic Hall in Christiania is now approaching completion. Work is now carried on with the new Customs House to be built in Christiania, but with some difficulty, owing to the entrance of sea-water.—A large market building, with fifty-six shops, has just been opened in Christiania, constructed of iron and glass. It is lighted by electricity.

MISCELLANEOUS.

LECTURES TO ROYAL ACADEMY STUDENTS ON SCULPTURE.—The following lectures have been arranged for:—"Three lectures on 'Archaic compared with Archaistic Sculpture,'" by Dr. A. S. Murray, of the British Museum, to be delivered on February 15, February 18, and February 22; and three lectures on "Michael Angelo" (continued from last year), by Professor J. H. Middleton, to be delivered on February 21, March 4, and March 7.

THE SURVEYORS' INSTITUTION.—Of the candidates who presented themselves at the Students' Preliminary Examination of the Institution, held concurrently in London and Manchester on the 26th and 27th ult., the following satisfied the Examiners:—Messrs. G. J. P. Adams, H. C. Adams, A. Arnold, P. C. Beasley, G. Bekon, jun., H. O. Ball, F. R. Betenson, R. Bonella, A. Bruce, C. V. Cable, S. G. Carnell, A. S. Cartwright, J. A. Chubb, J. W. Clayton, R. W. Clutterbuck, H. L. Cowell, W. S. Cowper, H. H. Crawford, S. J. Cribb, D. B. Davies, W. J. Davies, G. P. Deasy, E. A. Duer, C. R. Finch, H. E. Folkes, J. G. Garner, H. A. Glover, C. H. Godfrey, W. Harris, W. H. Hicks, W. H. Hull, W. Jarmain, D. H. Jelouit, W. T. Lamprell, W. B. Leans, S. B. Lee, F. P. Lightfoot, E. C. Lyons, F. C. T. Mann, A. J. Martin, T. C. Nevett, H. A. Newbronner, S. H. Page, W. H. Pain, W. Parks, J. W. Paul, J. A. Peppercorn, F. J. Phillips, F. F. Rootham, C. S. Sandford, A. S. E. Sedgwick, H. E. B. Sewell, A. P. Skant, A. G. Skingle, A. G. Smith, R. W. Smith, A. C. Stander, C. W. Stupart, W. S. Walker, H. J. Watson, H. B. Whitty, and S. A. Wilde.

PROPERTIES FOR SALE.—In course of the Spring at the Mart, will be offered for sale (by Messrs. E. & H. Lumley) Killeen Castle, with its demesne of 1,000 acres, in county Meath. This stone-built castle was erected, according to Lewis's Topographical Dictionary of Ireland, in 1180, by Hugh de Lacy, who built also those of Clonard, Delvin, and, as some maintain, Trim, in this county. The castle, being now in good repair, was enlarged by Johnston to meet more modern requirements. King John is known to have been for a while in Meath, and at Killeen Castle they show "King John's tower" which he is said to have occupied in the year 1210. The estate, for the most part, there being no tenantry, is let at from 3*l.* to 4*l.* per acre annually for the rearing and fattening of stock. The church of St. Mary, rebuilt by Sir Christopher Plunket (died 1415), contains ruins of ancient tombs, with figures clad in episcopal robes; Tegbarne was of opinion that Killeen is identical with Colgan, famous for the burial therein of seven bishops. St. Endeus founded an abbey here, and a nursery for his sister, St. Fancha (Cerecha), its first abbess. Joan, only daughter and heir of Sir Lucas Cusac, brought the barony of Killeen in marriage, 1468, to Sir Christopher Plunket, whose descendant Lucas, tenth lord baron Killeen, was elevated Earl of Fingall in 1628.—By direction of Mr. Whitehead, who has established a new torpedo factory at Weymouth, his Sussex estate at Paddockhurst, in Balcombe, Worth, and Ardingley parishes. This property, valued in all at 250,000*l.*, consists of 3,000 acres, whereof one-third is under separate cultivation. The house, since enlarged, was built thirty years ago, with stone quarried on the land. A homestead, known as New House, is of Elizabethan's day, and is conjectured to have been designed by the architect of Wakehurst Place, in the neighbourhood, in Surrey.—And on 26th inst., at the Mart, the block lately erected along the southern side of Coventry-street, Haymarket, having a frontage of 51 ft. between Arundel-place and Oxendon-street. The block includes five splendid chambers on the four floors over the four shops; it is held from the freeholder for a term of which 92½ years are unexpired, at an annual ground-rent of 800*l.* The premises are severally let for an aggregate rental of 2,270*l.* per annum. 'Tis side of the street, so named after Henry, son of the Lord Grey, Coventry,—was pulled down in 1831-2, and with it No. 21, whereat Davies Wisshart established himself as a tobacco and snuff dealer, by sign of the Highlander, Thistle, and Crown, in 1720. The Civil Service Stores, Haymarket, stand on the site of Coventry House. Next northwards, occupying the whole south side of Coventry-

* Pressed at head of list.

COMPETITIONS, CONTRACTS, AND PUBLIC APPOINTMENTS.

COMPETITIONS.

Table with 4 columns: Nature of Work, By whom Advertised, Premium, Design to be delivered. Includes 'Technical School Building' and 'Revision to accommodate 10,000 persons'.

CONTRACTS.

Table with 4 columns: Nature of Work or Materials, By whom Required, Architect, Surveyor or Engineer, Tender to be delivered. Includes 'Sewerage Works', 'Works and Materials', 'Distillery', 'Public Baths', 'Road Works', 'Furnace', 'Works and Materials'.

CONTRACTS.—Continued.

Table with 5 columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, Tenders to be delivered. Includes '12,000 Tons Stone for Moss Landing', 'Ever Hospital, Langfield, Yorks', 'Public Baths', 'Free Library', 'Electrical Condensers and Galvanic', 'Revision of Schools, East Bonford', 'Warning and Ventilating Tower Hall', 'Works and Materials for One Year', 'Enlargement of Vestry, Cambora', 'Wesleyan Chapel, Brentwood', 'Six Terrace Houses, Cross Green, Oley', 'Co-operative Homes, Low Waltham, Leeds'.

PUBLIC APPOINTMENTS.

Table with 4 columns: Nature of Appointment, By whom Advertised, Salary, Application to be in. Includes 'Surveyor', 'Assistant Surveyor', 'Sanitary Inspector'.

Those marked with an Asterisk (*) are advertised in this Number. Competitions, p. iv. Contracts, pp. iv, vi, & vii. Public Appointments, p. xii.

street (prior Piccadilly), and over against Piccadilly Hall, was Shaver's Hall, erected circa 1620, which, with its bowling-alley, orchards, courts, &c., covered about 2 1/2 acres, according to a survey made in 1650. The tennis-court cited in the survey is, perhaps, that in James-street; to which we adverted in a "Note" on July 30, 1887, nearly opposite to the doorway of "Hickford's" auction-rooms, 47, 49, George I., for the Shaver's Hall ground is set out as "abutting on the Earl of Suffolk's brick wall south." Henry, fifth Lord Arundell of Wardour (ob. 1726), married a daughter of Colonel Thomas Panton, the gambler (ob. 1681) and last proprietor of Piccadilly Hall.

CONCRETE-MIXING MACHINE.—Concrete machines are frequently a part of a builder's plant used in house-building in Paris. They are usually of the vertical type, but Messrs. Casier, Rickers, & Co., of Saint Denis, have recently introduced a horizontal machine which, it is claimed, will supply large quantities of concrete of good quality. It consists of an inclined wrought-iron cylinder supported by rollers held in the framing. The cylinder is caused to revolve by geared wheels driven by a belt from a counter-shaft. There are forty paddles inside the cylinder to cause the concrete to become more thoroughly mixed. The materials are introduced through a hopper at the upper end, and there is a suitable receptacle for the concrete at the lower end. The capacity of this machine is 654 cubic yards of concrete per day, and it is driven by a 10-horse-power portable engine. The cylinder revolves ten times per minute. The stones and cement are brought to the machine in trucks, and are shot in from a platform provided. As the trucks hold a definite quantity, no further measurement is required. The water is measured by a suitable valve.

THE LAND SALES OF 1891.—The Estates Gazette contains a review of the land sales effected in 1891, from which it appears that in England there has been a great falling off in the returns of sales in 1891, more noticeable in several of the home counties than elsewhere, although the average price per acre is only 2L. short of that of 1890; but in Scotland and Wales there was a most decided improvement in the number of properties sold, although the average prices are very low, in the former country especially, due principally to the sale of two very large estates, one of which of some 72,000 acres in Ross-shire only realising about 2L. 10s. per acre, which, of course, materially had the effect of lowering the averages in the other counties. The following is a statement of areas of land sold and the price realised per acre:—In England, 49,592a. 3r. 29p. sold for a total of 2,106,683L, which is an average of 43L. per acre. In Scotland, 98,457a. 0r. 14p. fetched 425,062L, or at the rate of 4L. an acre. In Wales, 8,903a. 2r. 15p. realised 163,377L, equal to 18L. per acre.

THE "CROSS-BONES" BURIAL-GROUND, SOUTHWARK.—In a "Note" on July 27, 1885, we directed attention to this burial-ground in Union-street (corner of Red Cross-street) Borough. A few months afterwards, Sir James Bacon, who was then Vice-Chancellor, dismissed with costs a summons under the Vendor and Purchaser Act, 1874, in re Trustees of St. Saviour's Rectory, Southwark, to Messrs. Oyer. The purchasers had bought of the rectory

trustees, for 2,300L., what was described in the particulars of sale as "valuable freehold building-land in Union-street, Borough, occupying the large area of about 13,000 ft., adapted for a builder, contractor, timber-yard, &c." An Act of 1883, to abolish church-rates in St. Saviour's parish transferred this land from the parish "wardens" to the trustees, and empowered the latter to sell it, or grant building leases in respect thereof. Section 5 of the Act of 1884 for the prevention of building on such grounds, contains an exception of any burial-ground disposed of under any Act of Parliament; and this section was cited in the conditions of sale. The purchasers, stating they had intended to buy for building purposes, declined, on their side, to complete the sale. A summons taken out by the vendors was adjourned into court, with the result stated. Meantime the ground has been occupied by three persons, who for some while past have there carried on a sort of fair, with all latest "improvements" in shape of steam-organs and roundabouts, shooting galleries, &c., which proved, as alleged, a source of great disturbance and annoyance to the neighbourhood. Arraigned on indictment, the defendants were found guilty at the London County Sessions, on Friday last week, fined in sums of 25L. and 40s., and bound over to keep the peace. The area we speak of may possibly have taken its name from a carving on the stone that formerly stood over its entrance,—see the interleaved copy of Manning and Bray's "Survey" in the Guildhall Library. It formed a place of interment for the inmates of the licensed houses, or bordellos, on Binkside, in the liberty of the Clink, and belonged to the estate of the see of Winchester. A large number were buried here at the time of the Plague; as many as, it is said, 600 in one week. Circa 1708, the bishop gave a lease for three lives to the parish. A subsequent lease for three lives and sixty-one years (June 9, 1820) was enfranchised by the wardens for 3,338L. On October 31, 1853, two burials (the last) took place, with the prescribed service and payment of fees as in the case of consecrated ground. On November 8, 1854, the wardens granted a twenty-six and a half years' lease, at 50L. rent, the Vestry consenting. In 1791 were rebuilt on the southern side, the parochial schools, established, at first, in Montague-close, and then removed for a while to Angel-court.

A MONSTER BUILDING.—Chicago journals state that the Society of Oddfellows in that city has plans prepared for a building to be erected on a site in the central part of the town, 177 ft. by 120 ft. in area, and having ten stories. The central portion, moreover, will have ten additional stories, crowned with a tower, making the number here twenty-two in all. The tower portion will contain 133 offices, situated above the lower part of the building. There are to be eighteen lifts and four grand staircases. The summit of the tower, 70 ft. square, will be situated 450 ft. above the street. The two first stories will be arranged for offices. The architects who have prepared the plans of the building are Messrs. Adler & Sullivan, and its cost is estimated at 1,222,000L.

THE ENGLISH IRON TRADE.—The disorganisation in trade produced by the fall in warrants continues to become more pronounced. Although

Scotch warrants remain stationary, both Cleveland and hematite warrants have suffered considerable reduction. Scotch makers' iron is more active, but quotations generally are lower. The North of England pig-iron trade is practically at a standstill, and in all the other crude iron centres a depressed tone is observable. Tin-plates are still quiet, and manufactured iron is only in moderate request. In the steel trade makers are a trifle brighter, and a better demand is noticeable for rails. Shipbuilders are less active, and engineers are not so busy. The coal trade generally is quieter.—Iron.

LIVERPOOL ENGINEERING SOCIETY.—The seventh ordinary meeting of this Society for the present session was held at the Royal Institution, Colquhoun-street, on the 27th ult., Mr. John T. Wood, President, in the chair. The principal portion of the evening was devoted to an adjourned discussion upon a paper entitled "Transatlantic Lines and Steamships," read by Mr. A. J. Maginnis, M.Inst. N.A., at the previous meeting. The discussion, which was a very interesting one, dealt principally with the various improvements in the design and construction of Atlantic liners and their machinery during the last few years. The speakers included the President, Messrs. F. Hindlestone, Henry H. West, T. L. Miller, Jennings Campbell, and others. Mr. Maginnis, having replied on the points raised during the discussion, a vote of thanks was accorded to him by acclamation for his paper.

THE TELFORD PARK ESTATE.—Messrs. E. E. Crosser & Co. announce in our advertisement columns the sale of a portion of the well-known Telford Park estate, which is freehold, and extends from Stratham Hill to Tooting Bee Common.

LEGAL.

CASE UNDER THE EMPLOYERS' LIABILITY ACT.

WILLETS v. WATT AND CO.

This was an appeal from the County Court of Stafford, holden at West Bromwich, and was heard in the Queen's Bench Division on the 22nd ult., before Mr. Justice Hawkins and Mr. Justice Wills. It raised a question as to what was the meaning of the word "way" in the first section of the Employers' Liability Act. It appeared that the defendants had large works, and that there was a yard in them 50 yards by 250 ft. The surface of the yard was covered more or less with machinery and tanks, which were not always lying in the same place. In the yard there was a well which had not been uncovered for seven years, but on the day of the accident, some water being required for testing an iron cylinder, it was uncovered and left so. Half an hour later the plaintiff, while going across the yard between the bits of machinery, for the purpose of seeing whether more steam was wanted, fell into the well, which was in his direct line of way, and injured his arm and head. For these injuries he brought this action, and in the particulars, claimed damages by reason of a defect in the "ways." The jury awarded him 150L.

Against this judgment Mr. Hugo Young, for the defendants, appealed, and argued that no defect in

the way had been shown. "Way" meant a passage marked out in a particular direction, and there was no special or usual passage across this yard—

Mr. Justice Hawkins, in giving judgment, said—Judgment ought to be entered for the defendants on the ground that it is not a way within the section. I think, if it can be considered a way

under the section, it was, under the circumstances, defective. The question is—Is it a "way connected with and used in the business of the employer?" I take Mr. Justice Field's definition in M'Griffin v. Palmer's Shipbuilding Company. The learned Judge, after stating the facts, continued—In my opinion the question is, was it a way which was habitually used, or pointed out, or intended to be used as a way from one part of the works to another? "Way" does not mean every piece of ground that may be used for passage.

Mr. Justice Wills.—The word "way" does not stand alone in the Act; it is coupled with the words "connected with and used in the business of the employer." This shows the word "way" means a line of passage more or less habitually used. Under some circumstances, no doubt, a way, even though used for the first time, may come within the description in the Act. If the plaintiff's contention is correct, every line from one part of the works to another where the workmen passed would be a way. There was no evidence that this line of passage was habitually used as a way. The fact that obstacles were placed there temporarily does not define the passage as a way.—Times.

MEETINGS.

SATURDAY, FEBRUARY 6.

Architectural Association.—Visit to the new Metropolitan Life Assurance Building in Moorgate-street, and to the tower and spire of Bow Church.
Society of Architects (Carpenters' Hall).—Address to be delivered by Dr. Geo. Reid. 8 p.m.
Royal Institution.—Professor J. A. Fleming on "The Induction Coil and Alternate-Current Transformer." 8 p.m.

MONDAY, FEBRUARY 8.

Royal Institute of British Architects.—(1) To receive the announcement of the name of the person the Council propose to submit to Her Majesty the Queen as the recipient of the Royal Gold Medal. (2) Mr. Edwin T. Hall on "London Building Legislation." 8 p.m.
Society of Arts (Antient Lectures).—Professor George Forbes on "Developments of Electrical Distribution." 8 p.m.
Clerks of Works Association (Carpenters' Hall).—Paper by Mr. G. Calvert. 8 p.m.
Liverpool Architectural Society.—The Rev. F. F. Gostling on "Babylonia and Assyria as a Home of Early Literature and Science." 8 p.m.

TUESDAY, FEBRUARY 9.

Institution of Civil Engineers.—Discussion on Mr. A. H. Curtis's paper on "Gold Quartz Reduction." 8 p.m.
Sanitary Institute (Lectures for Sanitary Officers).—Professor H. Robinson on "House Drainage." 8 p.m.
Sheffield Society of Architects and Surveyors.—Mr. W. Randolph on "Town Churches." 8 p.m.

WEDNESDAY, FEBRUARY 10.

British Museum.—Miss Eugénie Sellers on "Greek Sculpture." "Egean Work." 1.30 p.m.
Carpenters' Hall, London Wall.—Professor W. H. Corfield on "Water Supply, Drinking Water, and Pollution of Water." 8 p.m. (Admission Free.)
Sanitary Institute.—Papers on "Refuse Disposal" by Mr. Charles Jones and Mr. James Ransell. 8 p.m.
Society of Arts.—Mr. E. Price Edwards on "Burning Oil for Lightness and Lighthouses." 8 p.m.
Liverpool Engineering Society.—Mr. Thomas Morris on "Engineers' Tests of Iron and Steel." 8 p.m.

THURSDAY, FEBRUARY 11.

Royal Academy of Arts.—Professor Alchison, A.R.A., on "Saracenic and Turkish Architecture." 8 p.m.
British Museum.—Miss Millington-Lathbury on "Mysteries and Oracles" as illustrated by the Greek monuments in the Museum. 2.45 p.m.
Society of Antiquaries.—8.30 p.m.
Institution of Electrical Engineers.—(1) Mr. Alexander Siemens on "Some Experimental Investigations of Alternating Currents." (2) Mr. W. H. Prece on "Insulated Conductors for Electric Lighting and other purposes." 8 p.m.
Society of Arts (India Section).—Lord Lamington on "Recent Travels in Indo-China." 1.30 p.m.
Edinburgh Architectural Association.—Mr. Eneas F. Mackay on "The Architecture of Scottish Towns, as Illustrating Scottish History." 8 p.m.
Dunedin Institute of Architecture.—Mr. John Honeyman on "Glasgow Cathedral." 8 p.m.

FRIDAY, FEBRUARY 12.

Sanitary Institute (Lectures for Sanitary Officers).—Professor H. Robinson on "Sewage Disposal." 8 p.m.

Institution of Civil Engineers (Students' Meeting).—Mr. H. B. Ransom on "Fly-wheels and Governors." 7.30 p.m.
Royal Institution.—Mr. G. J. Symons on "Rain, Snow, and Hail." 9 p.m.

RECENT PATENTS:

ABSTRACTS OF SPECIFICATIONS.

21,191.—PORTABLE BUILDINGS: E. E. Allen.—This patent relates chiefly to portable buildings. Sheets 8 ft. 6 in. long and 8 ft. 6 in. to 8 ft. 8 in. wide, composed of three thicknesses of thin wood, are formed in the lining of the buildings, the grain of the central layer being arranged at right angles to the other two layers thus making large and very strong sheets not liable to split. With the above sheets are combined sheets of galvanised corrugated iron, placing between them inodoriferous felt or silicate cotton, and rivetting or otherwise attaching them by turning over edges of the iron, or enclosing them in a light wooden frame. Similar sections or sheets are formed with slight modifications for the roofs and floors of the building. Compound standards are constructed as set out in the specification and are used for the purpose of securing the sections together. The inventor claims the saving of bulk and weight for transport, and time and labour in erecting the building.

13,106.—ROOFING: J. A. Main.—This claim is for an improved method of supporting "putting" bars on the rafters of roofs, though the invention is also applicable to other parts of the building.

13,349.—BRICK-MAKING MACHINES: R. Mountain.—This is an invention referring to machines where the moulds or blocks are made in revolving barrels. The barrel is preferably provided with several moulds, uniformly distributed over the circumference of the barrel. At one side of the barrel is provided a mixer and into which the clay is fed, and thence pushed forward to enter and fill the moulds as they successively come opposite the mill or mixer. The bottom of the moulds are formed as moveable rectangular pistons. By means of mechanism described these pistons are moved radially in the moulds. Without the barrel a die or top piston is provided moveable within radially placed guides for the purpose of pressing the brick in the mould, and at a suitable position past this die there is a delivery table on to which the formed bricks are delivered. Mechanism for locking the barrel truly in position is also described.

13,423.—BUILDING CEMENTS: F. J. Reynolds and J. Brown.—This invention claims the preparation of a cement more efficient, harder, and more durable than those in ordinary use. Lime, well calcined, is incorporated with carbonate of potash and reduced to powder in the form of a hydrate, and when required for use is treated with a combined acarieous and metallic solution such as iron, copper, or other metal as described. The inventor states that mortars made of the above with any kind of hard gritty substance will harden under water.

10,754.—BRACE BITS: T. O. Smith.—This patent refers to an improved adjustable attachment to brace bits provided with an adjustable countersinking blade, the whole device being fixed to the bit by means of screw pins as described. The specification also describes a hole-boring and countersinking device for attachment to brace-bits, consisting of an adjustable block provided with a mutilated conically-shaped cutting head for countersinking the block being provided with a screw adjustable stop to regulate the depth of countersinking required.

NEW APPLICATIONS FOR PATENTS.

January 18.—939, A. Baxter, Connecting Earthenware Sanitary Appliances, &c., to Metal Pipes.—864, A. Young and R. Chesney, Lock.

January 19.—1,023, S. Middleton, Operating Window-shades.—1,024, J. Evans, Apparatus for Utilising Waste Heat for Heating Buildings.—1,029, G. and C. Collason, Joint for Hot-water Pipes.—1,041, S. Rolison, Generating Electricity for Buildings.—1,052, J. Chappell, Parquet and Block Flooring.—1,053, J. Schindler, Chimney-cowl.—1,062, J. Barber, Device for Curving Smoky Chimneys.—1,092, T. Brown, Chimney-pots and Tall-boys for Chimneys.—1,095, G. Williamson, Kitchen-ranges.

January 20.—H. Hansen and Others, Hoods or Cows for Ventilating or other Shafts.—114, W. Copping, Bolts or Fastenings for Emergency Doors of Public Buildings.—1,121, W. Turner, Gun-pot.—1,119, A. Fowler, Automatically-flushed Water-closets.—1,132, D. Shaw, Gully-pipes.

January 21.—154, W. Riley, Construction of Knobs or Door-handles, and Adjusting and Holding them upon the Spindles.—1,170, J. Leech and J. Lewis, Fastening of Sash Windows.—1,195, A. Willard, Artificial Stone.—1,196, J. Banks, Flush and other Bolts.—1,200, R. Frost, A Joint for Pipes or Tubes in Stone-ware or Metal.—1,233, J. Smeaton, Water-closets.

January 22.—1,381, H. Dowty, Hot-water Pipes and Connections.—1,324, H. Browne, Fire-grates.—1,294, E. Brooks, Safety Fastener for Sash Windows, which opens or closes.—1,313, A. Ransome, Pelling and Cutting Timber.

January 23.—1,336, E. Mooney, Earthenware Gully-traps.—1,342, E. Elmer, Electric Water-closets.—1,343, J. Hunt, Automatic Ventilator and Foul-air Removing Boards.—1,357, H. Wethered, Ventilation of Closets and Water-closets.

PROVISIONAL SPECIFICATIONS ACCEPTED.

17,105, J. Wally, Fastening of Stable-doors.—21,038, R. Roberts, Accessories for Water-closets.—21,043, G. Johnson, Drain-pipe Junctions.—21,054, W. Hicks, Water-waste Preventing Siphon-flushing Cistern.—22,209, J. A. Buckett, Water-closets.—22,265, T. Serrate, Jar-nut, Brick, &c.—22,356, S. Hawke, Fastenings for Windows and Doors.—22,492, J. G. H. B. B. Water-closets.—22,534, J. R. Edford, Siphon-flushing Apparatus.—22,610, A. & W. Gill, Paints and Lacquers.—22,773, C. Ennis, Electric Bells and Indicators.—22,793,

P. Fowler, Fireplaces.—22,800, M. Williams, Oil Paints and Paint Medium.—71, W. Oberstern, Ventilator for Shop Window.—72, A. Davidson, and E. Thorn, Veneer, Fabrics or Materials for Decorative Purposes.—109, S. Dix, Water-closets.—337, T. Halliwell, Glazing Blinds.—364, H. Conolly, Water-closets.

COMPLETE SPECIFICATIONS ACCEPTED.

(Open to Opposition for Two Months.)

4,364, W. Munns, Shutter-fastening Device.—4,750, The Society Anonyme des Ardouettes, De Deville and Heyden, Material suitable for Building, &c., from Waste Pieces or Debris of Slate.—4,779, T. James, Glazed Panels for Furniture and Interior Decorative Work.—5,068, F. Ostry, Kilns for Use in the Manufacture of Pottery, &c., and other Similar Goods.—6,203, W. Hughes, Opening and Closing of Windows.

SOME RECENT SALES OF PROPERTY:

ESTATE EXCHANGE REPORT.

JANUARY 25.—By Surridge & Son: 6 to 9, Curlew-st., Hoxleydown, 12 yrs., gr. 3l., r. 104l., 350l.
JANUARY 26.—By A. Robertson: 48 to 60 (even), 710l.; 27 and 28A, Richmond-st., n. t. 25 yrs., gr. 40l., 400l. 10s., 170l.—By Messrs. Aldridge: 9 and 11, New-road, Sulhurst, n. t. 74 yrs., gr. 8l., 45l.—By T. G. Wharton: F.R. of 34l., with reversion in 30 yrs., Bromley-by-Bow, 800l.—By Archer, Butler, & Waghorn: 10, Wilton-cres., Belgavia, n. t. 32 yrs., gr. 1l., r. 315l., 4,100l.—By Orpitt: 5000, & Orpitt: "The Farmer's Arms," Amwlch, Anglesea, n. t. 12 yrs., gr. 20l., 60l.; "The Clarendon Arms," Beer House, Birmingham, n. t. 6 yrs., at 50l.; "The Junction Inn," and 40 to 45, Cromwell-st., f. Dudley, Worcester, 950l.; "The Bridge Inn," Swindon, n. t. 2 yrs., at 30l., 300l.; 81 and 82, Heath-st., and "The Forge Hammer" Beer House, f. Wolverhampton, 930l.

JANUARY 27.—By J. A. & W. Tharp: 1 to 9, Beaconsfield-ter., Leytonstone, f. r. 226l., 2,865l.; 9 to 12, Barclay-ter., f. r. 119l., 1,332l., 1, 2, 9, and 10, Denmark-ter., f. r. 125l., 1,200l.; 2 to 7, Laying-ter., f. r. 183l., 2,000l.

The Electrical Exhibition at Sydenham.

ON Saturday last the Lord Mayor and Lady Mayoress visited the Crystal Palace. This second opening of the Exhibition has had the effect of stimulating the efforts of exhibitors, and many of the stalls which have hitherto remained almost empty since the first opening in January are now fairly complete. In exhibitions of this class the readiness of manufacturers to advertise their wares is made use of to instruct the public, and with this latter aim the catalogue has been drawn up.

The exhibits are divided into sections,—“Phenomena and Laws of Electricity,” “Electrical Measurements,” “Batteries,” “Motors,” &c.—seventeen sections in all; with two or three pages of what, after revision, may be accurate popular explanation, as a preface to each section. The idea is a good one could the Exhibition be arranged on the same plan, but that is obviously impossible; no exhibitor could be expected to distribute his goods over a dozen stalls, where they would be mixed with those of some fifty other firms; consequently, to follow out the catalogue plan, one would have to go through the Exhibition seventeen times,—an appalling prospect.

From this general scheme the Government exhibits of telegraphic instruments is exempted. Here we have chronologically-arranged specimens of the principal apparatus used from 1837, down to the present day.

Amongst them is a delightful placard of 1837, announcing the opening of the first telegraphic office, and engaging to send messages “with most confiding secrecy” at a shilling each. From this placard it appears that people were willing then to pay a shilling to see the telegraph in operation (as we should now to see, or hear, a phonograph).

Those were the ages of faith. No one then doubted the material existence of electricity, and the very rats at which the “fluid” travels is given.

The Postal Telegraph Department, moreover, not only arranges the exhibits well, but gives a concise but intelligible account of what Clerk Maxwell, as a boy, used to call the “go of it” in the majority of cases.

Leaving the Government stall we come at once to Mr. James White's exhibit of Sir William Thomson's measuring instruments, including current meters which will measure any current from the hundredth of an ampere to a thousand amperes, watt meters, an improved rheostat, and the exquisitely delicate siphon recorder for submarine telegraphy.

On the right is an interesting exhibit of the Maquay Electric Light Syndicate of portable lamps, driven by primary batteries, in which the tiny filament is raised to a very high degree of incandescence.

One of these lamps is burning under water, showing that it may be used as a diver's lamp; with this we may contrast the Mining and General Electric Lamp Company's hand-lamps on the opposite side of the Nave, which are driven by lithium cells and have a switch connected with resistances so that the brightness of the light may be varied.

A recess between the Medieval and Renaissance Courts has been appropriately fitted up by Messrs. Banham & Froud as the chancel of a church electrically lighted. The advantages of the electric light in church are as obvious as in the theatre, but we fear it will make its way there slowly; wax candles on the altar are likely to survive for reasons of ritual long after they cease to be used elsewhere, as a stone sacrificial knife existed long after the Stone Age.

The stand of the Consolidated Telephone Company, No. 7, and No. 104, that of the National Telephone Company, will be attractive to all who are interested,—and who is not?—in this marvellous application of electricity to the service of man. Here will be found numerous compact and beautifully-finished instruments, receivers, and transmitters, including the pretty little watch receiver. The National Telephone Company also exhibits a multiple switchboard, so that visitors can form an idea of what takes place daily in a Central Exchange. Its instruments are in communication with London, Manchester, Liverpool, and other towns, not only illustrating the great advance of late in

long-distance telephoning, but giving its customers an opportunity in the Music-room, No. 191, of, in effect, attending various London and provincial theatres.

For those who live far from a Central Lighting Station, who prefer additional cost of up-keep to heavy initial expense, and who consider that the constant re-charging of primary cells is less troublesome than the occasional attention required by a gas or petroleum engine, the Weymersch Battery Syndicate, Stand 113, provide primary batteries which claim a high degree of constancy for many hours.

Messrs. Rashleigh, Phipps, & Dawson have a prettily-arranged stall in the North Nave, with all the latest improvements in electric fittings, and some quaint and fanciful allegorical designs; they also light and contribute part of the decorations to some rooms in the South Gallery, artistically furnished by Messrs. Godfrey Giles & Co.; they use, with good results, translucent plates of ivory to soften the light, or bead ray-diffusers to distribute it effectually over a room. The electrical effects introduced into the Pantomime are also arranged by this firm.

In the south nave the most conspicuous object is an electric crane shown by Messrs. Crompton & Co., and near it the search light exhibited by the same firm flashes its rays on the fountain which is playing close by. They also exhibit a four-pole machine capable of supplying over 8,000 lamps, besides other dynamos, some specially designed to give heavy currents for electric plating or for the new process of electric welding. A completely-furnished municipal testing laboratory for testing meters and for faults in insulation should attract the attention of County Councillors, actual or potential, as also should their model of the system of mains; while builders and architects will be interested in the ornamental mouldings, picture-rails, cornices, &c., designed for carrying and concealing the house wires. Of more technical interest are their twisted armature bars to reduce Foucault currents, their cut-outs and heavy discharge switches.

The beautifully-furnished show-rooms in the Western Gallery, decorated by Messrs. Wallace & Co., are also lighted by Messrs. Crompton & Co.

Messrs. Swinburne & Co.'s stand will be one of the most remarkable in the Exhibition when their transformer, giving 0.2 ampere and 100,000 volts, can be seen regularly in action. It has been working for some time at Teddington, where it sparks a distance of 6 in. in air, establishing an arc which can be drawn out to almost any length, and sends a current through substances hitherto regarded as amongst the best insulators, heating them as currents of ordinary voltage do conductors. There is, of course, a display of "hedgehog" transformers, with their accompanying condensers, so valuable in conjunction with open circuit converters.

Considerable interest will be taken in the General Electric Company's (No. 7, south nave) exhibition of apparatus for heating and cooking by electricity. Though it is admitted that the production of heat by electrical means is expensive, yet for some purposes this disadvantage is more than compensated for by the economy in its use, the heat being obtained exactly where, and only while, it is wanted. In most of these appliances the resistances which can be heated by an electric current are embedded in enamel. The electric cigar lighter has a platinum wire coil embedded in asbestos, which is raised to incandescence by the current, and would certainly be useful in a house where reliance on the electric light has made people careless in the supply of matches. The lady, too, whose dismay at finding her room lighted by electricity and warmed by hot-water pipes Mr. Du Maurier has lately depicted in *Punch*, should present her hostess with a pair of electric hair curlers, so should modern science remedy the "disadvantages of modern science." We question, however, whether electrically-heated foot-warmers have any future before them. The expense here is a fatal objection; one does not want a foot-warmer for five seconds or for five minutes only. At this stall also may be seen an improved automatic cut-out, and ampere-meters and voltmeters on Donnisson's system.

The most remarkable of Messrs. Woodhouse & Rawson's exhibits is the "Kingdon" alternator, in which, as in a transformer, the coils of both field-magnets and armature are stationary; the current is produced by the revolution of inductor blocks, which thus vary the induction in the armature. The mechanical advantages of having the moving parts of iron only are obvious, and the clearance can be made very small.

Messrs. Siemens Brothers contribute, besides the usual measuring instruments, batteries, &c., a carbon contact switch for heavy currents, a model of the cable steamer *Paradise*, and an apparatus for illustrating the curves formed by the vibrations of the diaphragm of a telephone. Their most sensational exhibit, however, is the 52,000 volt-transformer; but this will have to take a second place when Messrs. Swinburne & Co.'s 100,000 volt is at work.

The Brush Electrical Engineering Company exhibit an electrical tramcar which is so placed that it is impossible to see anything of the motor which should drive it,—tramcars can be seen without visiting Sydenham. They have also a number of the well-known Brush machines of various sizes, several of which are of the old discarded pattern with channelled instead of laminated armature cores. Two or three Morley alternators are also shown, one of which is apparently taken to pieces the better to show the construction; we say *apparently*, for the parts of this machine never were, or could be, put together,—the armature belongs to a much smaller machine than the field magnets; we find from the catalogue that this is not due to an oversight, as we at first imagined, but that the firm have deliberately chosen to exhibit different parts of two machines, the out-put of one being half as much again as the other; but the purpose of this arrangement remains a mystery.

For the system of concentric wiring shown by Messrs. Andrews & Co., Stand No. 102, it is claimed that the leads and house wires occupy less space, that wood casing is un-

necessary, and that joints can be made with less skilled labour than on the ordinary plan. On the other hand, it seems that a fault is more difficult to find, or, when found, to remedy. The advantage of a short circuit, and fuses going, whenever there is the slightest fault, will hardly be so clear to others as it is to Messrs. Andrews, but the saving of space is a real gain, and if the wires can be run, and bent round corners, without bringing the inner wire into contact with the outer, there may be some field for this system.

The specialty of Messrs. Frank Suter & Co., No. 151, North Nave, is their appliance for picture lighting by means of reflectors, so that the direct glare of the lamps may not dazzle the eyes of the spectator; but their prettiest exhibit is a little glow-lamp of frosted glass shaped like the flame of a candle and mounted on a candle-like support; at a short distance these lamps may easily be mistaken for very bright and steady candles.

In the machine-room, where the dynamos are at work, the great improvement in dynamo design since the exhibition of 1881, or even since the South Kensington Exhibition of 1885, strikes even a casual observer.

The modern machine is much more compact, makes less noise, and has a far greater output; the sparking at the brushes is imperceptible (except in one Brush, and, of course, the Thomson-Houston machines); many of the machines are direct-driven, saving the waste of space and energy implied by the older belt and pulley method. The number of gas-engines used is also a prominent feature of this exhibition, and it is noteworthy that here they work almost in silence, which they can seldom be persuaded to do in any private installation. The absence of belts and shafting noticeable throughout the Palace, and not merely in the machine-room, is a striking illustration of the advance made in the electrical transmission of power; nearly all the machinery in motion which is not driven directly by an engine being actuated by an electric motor.

Visitors to the Frankfort Exhibition were attracted to the Thomson-Houston machine by the blaze of the commutator sparking, due to the spherical armature being wound in three sections only, and the curious crackling noise as it is blown out by the air blast. The makers apparently do not care for this sort of advertisement, for in the present exhibition the commutator is turned away from the spectators and the noise lost in the general hum of the machinery.

The South Gallery is chiefly given up to examples of domestic lighting to which we have already referred, and to medical batteries and belts, of which the less said the better. The Consolidated Telephone Company have here a supplementary stand, but at several of the stalls the exhibits are only indirectly electrical, as No. 221 N., Cash & Co.'s exhibit of bleached shellac varnishes, &c.; Wake & Sanders's mica exhibition at 206 A.; and (No. 227) Britannia Rubber and Kamptulicon Company.

The exhibit of Messrs. Johnson & Phillips, though conspicuous, is not at first sight obviously connected with electricity. The prominent objects on their stand, No. 10, South Gallery, are some large buoys and grapnels, which are used in laying and picking up cables. Less easily seen are a set of linesman's tools, and specimens of switches, resistances, &c. They also show D.P. accumulator cells designed to bear a high rate of discharge without injury to the plates.

In the Machine Room, No. 60, this firm also exhibits a number of Mr. Kapp's dynamos, both direct and alternating, including a large eight-pole dynamo of 130 kilowatts output, coupled with a Davey-Paxman triple expansion engine. Mr. Kapp, who in the earlier days of electrical engineering had much to do with the designing of Messrs. Crompton's dynamos, claims for his own a very high efficiency, due to the care with which the proportions have been worked out beforehand.

The steam and gas engines in the machine-room, though indispensable for the production

of the electric light, can scarcely be regarded as themselves part of an "electrical" exhibition, and we may be pardoned if we pass them by with a mere nod of recognition. Even less claim to the title of electrical has the stand of Messrs. Chubb & Son, where safes and locks are shown on the strength of the addition of an electrical alarm. Similarly a diver's dress is displayed by Mr. Applegarth, with the addition of an electric lamp in the helmet; but all these have a better claim than the Homacoustic Speaking Tube Company, who introduce their speaking tubes, by adding to them an electric bell call.

To sum up, the general effect of the exhibition, especially at night, is very good. The blaze of light from the stands, softened and freed from glare by every kind of shade and screen, contrasts well with the harsher white light of the arc lamps, which, burning with a steadiness unhoped for ten years back, and hung too high to clash with the milder glow lamps, illuminate the rest of the Palace. There is every reason, in spite of the absence of many important firms, to expect the exhibition to be a success. The Palace Company and the exhibitors mutually assist each other, the former supplying a roof and appropriate surroundings, and a certain number of habitual visitors; the latter decorating and beautifying the Palace, and attracting many visitors who would otherwise never think of going down to Sydenham.

Amongst the firms who do not seem to appreciate the advantages offered them may be mentioned Messrs. Mather & Platt, Paterson & Cooper, Latimer, Clark, Muirhead, & Co., Gooden, Parsons, and Ferranti & Co., but we understand on good authority that the last-named firm has, though late, repented of its determination, and we may expect to find it in the next edition of the catalogue.

NOTES.

REERENCE has been made once or twice in our columns to the large and highly-finished model of the Parthenon, constructed in Paris a year or two ago under the direction of M. Chipiez, and which has since been purchased for and erected in an Art Museum in New York. The model itself we have not had the opportunity of seeing, but from the fine set of photographs of it which have been taken in New York we fear that the American institution which has purchased it has obtained a representation or restoration of the celebrated temple which is in some important points very far from accuracy. In the first place, M. Chipiez has chosen to insert seated winged sphinxes at the bases of the pediment, and a very large acroterion, flanked by winged genii, at the apex. The sphinxes, or something of the kind, may be probable, though there is no authority for them; the acroterion and its figures in some sort also, but the genii are represented as apparently silver figures, or burnished metal of some kind, and in this respect and in their attitude have a somewhat tinsel and Parisian appearance. A more important point, which is demonstrably wrong, is that the entasis of the columns is greatly exaggerated. The actual deflection from the straight line in the columns amounts roughly to about $\frac{1}{2}$ in. in a height of over 31 ft. It is not visible to the eye even on the building, except to those who know it is there and fancy they see it. Yet it is so exaggerated in the model that it is distinctly visible in a photograph which reduces the columns to about $3\frac{1}{2}$ in. in height, and must represent a deflection from the straight line of 4 in. or 5 in. But the most extraordinary blunder is that the metope sculptures are in their wrong places. Beneath the pediment sculpture of the east front are shown the metope sculptures which belong to the west front, and *vice-versa!* This is a curious example of the light-hearted indifference of French archaeologists to accuracy in matters of this kind. All the infor-

mation as to the real positions which were occupied by the metope sculptures is easily accessible at the British Museum, but we presume it could not be supposed possible that a French *savant* could learn anything from English sources. It is a pleasant consideration for the New York people, who have probably paid a large sum for a model of the Parthenon containing, besides minor inaccuracies, a serious blunder which the most ordinary care and investigation might have prevented.

THE promoters and framers of the new proposed Glasgow Building Regulations Bill seem rather to have laid themselves open to opposition by the sweeping nature of their clauses and the rather high-handed manner in which it seems intended to carry them out. The measure is no doubt a very well-intended one, but it has obviously been framed in the first instance without sufficient regard to what is fairly practicable under present circumstances. A good many modifications have been made in the direction of a more moderate policy: but we agree with some of the critics of the measure in thinking that one of the first points to be considered in connexion with such a Bill should have been the provision of a better-constituted authority for the administration of building legislation. It is perfectly evident from what is stated (and not contradicted) in the Glasgow press, that the Dean of Guild Court, with its constant change of direct personal authority owing to the system of election of a new Dean of Guild every two years or so, is on this if not on other accounts a most unfit authority to deal with permanent building legislation. On the other hand it is perfectly evident that a good deal of the opposition comes from landlords and others who are concerned for their own pockets more than for the public good. A proposed By-law that no building should exceed the height of the street on which it abutted has provoked violent opposition, and is characterised in a leader in the *Glasgow Herald* as "absurd," while a memorial from the Glasgow Institute of Architects speaks of it as injurious and uncalled-for, and one which would lower the value of some of the most important sites in the city. Such a By-law certainly should not be passed without the reservation of a dispensing power in special cases; but in the main a restriction of height of buildings in proportion to width of streets is in accordance with the best sanitary opinions of the day, and the Glasgow Institute of Architects must be rather behind the age if they are not aware of this. Such legislation is distinctly for the good of the city community generally, as promoting both the health and the pleasant aspect of a city, and the act that it will prevent some owners of sites from making as much out of them as they otherwise would is an entirely secondary matter in relation to wider public interests. The clause has, it appears, been entirely removed in deference to what we should call mis- and rather ignorant criticism. For our part, we hope the principle will not be lost sight of, and that it will be retained in some form or other in the final arrangement of the new regulations.

THE strike of engineers on the Tyne, &c., still continues, and a good deal is being made of the fact that in some cases the notices were given by the employers, the dispute being generally referred to at meetings of the men as a "lock-out." Sir C. Almer, at whose establishment the dispute practically commenced, protests against this being altogether misleading, and states that the whole trouble might have been avoided had the fitters agreed to have the questions at issue submitted to arbitration. The effect of these unlooked-for stoppages in the shipbuilding industry is to increase the difficulty of estimating the cost of and probable time occupied in constructing vessels. This was demonstrated by the managing director of the Thames Iron-

works Company (and also by the First Lord of the Admiralty and the Director of Naval Construction), on the occasion of the launching of the cruiser *Grafton*. During the construction of this vessel, the gates of the builders' yard were picketed for eighteen months, so that the men employed were unable to go to and from their work without running considerable risks. Again, at the Newcastle Chamber of Commerce last week, Sir B. C. Browne, a large employer of labour in the disaffected district, stated that when the dispute occurred between the carpenters and joiners a year or two ago, an order for a steamer went to Scandinavia which would have been given to his firm but for the stoppage. The question then at issue was very similar to that which has brought about the present deadlock, and the recurrence of strikes of this nature must produce hesitation as to the acceptance of large contracts, possibly to the permanent injury of the whole district. It seems strange that the men cannot recognise this, and make an effort to adjust their differences amicably. Certainly ship-building proper is not so much affected at present, but what has been said of ship-building applies equally to ship-engineering.

THE correspondence which has recently taken place in the *Times* on the subject of professional persons taking commissions without the knowledge of their principals, has done no more than again call attention in a public manner to what is well known to nine out of every ten men of business. But until agents are prohibited by law from taking commissions without the knowledge of their principals, this practice will flourish. The competition of the present day is so keen that men will do anything to gain business. It must be admitted also that in some respects the giving and taking of commissions behind the back of the principals is not so injurious to their interests as might at first be supposed. Thus, if an estate-agent gives back part of the commission on the sale of an estate to the solicitor who has introduced the business, the principal does not suffer, since if this part of the commission which he has paid did not go into the solicitor's pocket it would have remained in that of the estate-agent. We do not defend the practice, for its indirect results are often bad; but, on the other hand, it is desirable that the public should not be under the impression that they will get much direct advantage by its legal abolition.

THE destruction by fire of the Hotel Royal at New York directs attention to the dangerous character of these large buildings, a subject to which we referred in a recent "Note" in regard to the action of certain insurance companies in Chicago. Such a building as a large hotel of great height is not safe without a watchman constantly on guard throughout the night, and it is essential also that means of escape should be easy and numerous. We are aware that it is easier to give the latter advice than it is to carry it out, and those who erect these buildings will certainly try if possible to avoid everything which does not tend to profit. It has been pretty well demonstrated, indeed, that enormous buildings of a public kind, such as hotels, will have to be periodically inspected by the public authorities under legislative directions, if there is to be real security for the members of the community by whom they are used. We have fortunately been free in this country from such calamities as that which has just occurred at New York, but it may well serve as a warning to us to be on our guard.

IT was gravely announced in an evening paper a few days ago that the Midland Railway Company contemplate introducing dining and sleeping cars on their long-distance trains. This information would appear to be some years behind-hand, but the words "third-class" had probably escaped either the scissors or the paste-brush, as we understand that this enterprising

company are about to try the experiment of running third-class sleeping-cars on some of their trains. The rapid advance in the matter of accommodation is one of the most remarkable features of railway development in this country, and to the Midland Company much of the credit for this must be given. That their policy of making things as comfortable as possible for their patrons is a wise one, is evident from the increasing prosperity of the line, as measured by the gross receipts; although the expenditure it entails apparently tends to keep down the amount available for dividend. The past half-year has been one of the most successful in the history of the company, which has now reached a position second only to the London and North-Western as regards traffic receipts. But in spite of the increase in gross earnings, the dividend declared is at the same rate as that for the corresponding period last year, with a smaller balance to be carried forward. The announcement to which we have alluded may, therefore, be received with some disfavour by shareholders who have an eye to economy; but the travelling public are too quick to appreciate any additional comforts that are offered them for there to be much room for distrusting the action of the directors,—especially in view of the increasing competition for the passenger traffic to and from the north. Another effect of this announcement will be to make the less-favoured third-class travellers on some of the southern lines devoutly wish that similar incentives were at work on their side of the Thames. The contrast in accommodation is striking enough already.

DR. A. KÖRTE, in a letter to the *Berliner Philologische Wochenschrift* (February 6), suggests an addition to the list of the supposed hypæthral temples of antiquity. The temple of Apollo at Delphi was not included in the instances cited by Dr. Dörpfeld in his recent article on the subject ("Athen. Mitteil.," xvi, pp. 334-344). The reason given by Dr. Körte for supposing the temple to be hypæthral is curious and ingenious. In a passage in Diodorus (xvi, 27),—a passage which, by the by, seems so far to have escaped the attention of the warmest supporters of the theory,—there occurs the following statement:—"An omen occurred to him (i.e., Philomenus), also in the Sanctuary of Apollo,—an eagle that was hovering over the temple of the god swooped down to the earth in pursuit of the doves that were reared in the sanctuary and caught some of them from the very altars." Dr. Körte thinks that, if the eagle came down straight, as birds of prey usually do, he must have descended through a hypæthral opening. The passage is certainly worth noting, but it does not seem to us absolutely conclusive. An eagle might appear to be hovering over the actual temple (*ὑπερμαρτύριον τῶν ἱερῶν*) to one standing outside it, and yet come down straight enough and alight on an altar *outside* the temple but within the sanctuary (*ἐν τῷ ἱερῷ*).

SINCE the publication of Mr. J. G. Frazer's "Golden Bough," the Temple of Diana at Nemi has become a reality to many to whom it was before a bare name, if so much. Probably, however, there are still some who are not aware that the antiquities discovered there by Lord Savile, in his recent excavations, are now lodged in the Art Museum of Nottingham Castle. If sufficient subscribers are forthcoming (200 is the minimum) Mr. Wallis, the Director of the Museum, proposes to publish a descriptive catalogue of these antiquities in quarto size, with illustrations and views. Lord Savile is to contribute an account of the discovery of the temple, of which there will be a ground-plan, and all the principal objects found will be reproduced in photo-mezzotype. These objects range in date from B.C. 300 to B.C. 80. The coins are an unusually complete sequence, beginning from the "æse rude," and containing fine examples of every type and fraction

of the Roman "as." There are few sculptures, but one portrait bust and stele, inscribed (of Fundelia C. F. Rufa), to judge from the specimen illustration, is certainly a very fine piece of work. There are also a multitude of terra-cottas, personal ornaments, sacrificial utensils, and many architectural details. Among the bronzes are many statuettes of nymphs and priestesses of Diana, and a remarkable sacrificial ladle inscribed Diana in archaic characters.

WHEN, at the beginning of this century, iron pipes were placed down the face of the Castle rock of Edinburgh, to carry off the sewage, it was thought to be a great improvement upon the state of matters which previously existed. The advance of civilisation is conducive to fastidiousness, and now the exposed pipes cannot be tolerated, and are in course of being removed. The sewage will then be carried off by hidden conduits.

THE space in the Scottish National Gallery is now too restricted to allow of a proper display of the existing art treasures. No room can be found for some recent bequests, and works offered by the Royal Scottish Academy have been refused,—works which are, undoubtedly, superior in art-work and public interest to many of those now in the Gallery. The Government have given a grant of 1,000*l.* a year for the purchase of pictures, and it is obvious that more extended premises are required, so that the new works acquired from the grant and those gifted to the nation may be made available for public delectation and instruction. Two courses are open,—either (1) that the Royal Scottish Academy shall be required to vacate the portion of the premises allotted to them, and he provided for elsewhere, whereby the National Gallery would be doubled in space capacity; or (2) that the present building be given up entirely to the Academy, and a new National Gallery erected. In the event of the latter course being resolved upon, it is suggested that the National Monument on the Calton Hill should be completed and made available for the display of the national art treasures. To finish the National Monument according to the original conception would require a larger sum of money than it is probable will be forthcoming, but a modification of the too ambitious design might be carried out at a moderate cost, and a building produced worthy of the site and suitable for the purposes of an art gallery. Indeed, such a design was prepared, and exhibited, by the late Mr. Dick Peddie, and in that design he made use of the existing pillars which form a conspicuous feature in the Scottish capital. Mr. Dick Peddie did not carry the rows of Doric columns along the flanks of the building, and the eastern portico was much simplified. When it is kept in view that, through the munificence of Mr. Findlay, Scotland has been supplied with a National Portrait Gallery (in which, by the way, are placed several portraits which formerly occupied space in the National Gallery), it would not be too much to expect that Government should provide funds for the proper housing of the present collection, and of future additions thereto. Were this done we have reason to believe that donations of works would flow in which are now withheld.

IN one of the cellars of the British Museum there are now being put together some fragments of a very interesting terra-cotta cornice of probably the sixth century B.C., found at Civita Lavinia by Lord Savile. The corona of the cornice is faced with thin plaques of terra-cotta with low relief ornament and with many traces of colour. The peculiar point about it is that the terra-cotta veneer forms at its lower edge a serrated ornament or fringe which is visible both at front and back, and in fact reminds one not a little of the fascia formed of hoarding, with the ends cut into ornamental

shapes, which are often seen in railway-station verandahs and other such erections: another instance that there is nothing new under the sun. This terra-cotta fringe is painted and ornamented both on the back and front. Above the cornice are disproportionately large antefixæ formed of heads with a large open-work ornament making a kind of nimbus round them.

SARACENIC ARCHITECTURE.*

BY PROFESSOR AITCHISON, A.R.A.

I MUST now transport you to Persia, not because the Persian buildings we have delineated are in regular sequence in those described in the last lecture, nor are even of antecedent date, but merely to show the peculiar forms that Moslem art took in that country, which was the first they conquered. The peculiar form of arch was, in all probability, first adopted to save centring; the springing of the arch was probably carried to the slipping-point, and then continued in a nearly straight line until it touched the centre line. It much resembles the four-centred Tudor arch, and is now said to be struck by a reel of string, the marking-point being held in the hand, and moved as the string unrolls until it reaches the centre line, the reel being held by a pin running through its middle and placed in the centre of the small radius. We know more about the modern method of building in Persia than about any other contemporaneous work in the East, through the sagacity and perseverance of Mr. C. Purdon Clarke. He saw much work done in Persia, had some done under him, secured a large number of the architects' pattern-books, and discovered some of the rules by which the architects work; and these rules are understood by the builders and workmen. Probably something of the same sort prevailed in Medieval times in Europe.

In Persia the only drawings required are plans, with details for stalactites, inscriptions, and other ornaments. The drawings are made on squared paper mounted on hoards and varnished; the solid parts or walls are shown by tinting the whole or portions of the squares with Indian ink. Every room and opening has its height proportioned to its width by a fixed rule, and a similar rule is observed as regards the formation of stalactites, so that, given the plan of the stalactites, the builder can lay down the lines, and the plasterers can properly finish them. I think all the architectural students will be interested in knowing how these mysterious creations of the Saracens' mind are now formed. A stalactite dome or ceiling is done thus,—the floor of the chamber to be thus ornamented is levelled and strewn with ashes and then struck with a rule; on this a coating of plaster of Paris is laid and floated; the builder then sets out the full-size plan from the architect's drawing on the plaster floor, making the lines with a blackened cord, as our carpenters do with a chalked line; his men then cut a V-shaped groove in the plaster with the black line for its centre, and when the plaster cuttings are swept off the whole is saturated with hot melted suet, to prevent the castings from it sticking to the mould; the first or lowest plan of the stalactite ceiling is then run, taken up and cut into the shapes marked by the projecting V ridge; each piece is then fixed in its place by plaster on the wall and supported by ties made of bits of stick or reeds secured to the wall and the plaster slabs by dabs of plaster. The plasterer then works down the stalactites to their proper shape, which he knows by heart, and then another line of plan is cast and put up in the same way, the great pendant stalactites being supported by iron cable chains made rigid with plaster. I went over to Paris early in 1878 to see this work done by the Shah's men in a little pavilion he had erected in the grounds of the Exhibition, but when I got there all the stalactites were just done.

I look on the discovery of the Persian architects' pattern-hooks as the most curious and important discovery, to us, that has been made in this century, as regards the habits and practices of the past, as it is quite within the range of possibility that this practice has descended from Saracen times. As far as I understand the matter, the

* Being the third Royal Academy Lecture on Architecture this session. Delivered on Monday evening, February 1.

pattern-hooks contained plans of buildings the architects had designed, and possibly others, and all the well-known domes and stalactites, so that the employer had only to choose his plan, or to state what additions he required to it, or on what scale he wanted his mansion or palace built, and to choose the pattern of the stalactites, domes, wood, and plaster-work. Occasionally the architect had original designs of his own for new arrangements of domes, stalactites, plaster-work, doors, shades, and wood-work, and we may be sure that a wealthy and tasteful employer would require larger reception-rooms than ordinary, magnificently enriched, and would prefer having the last fashion, or a new one, for his mansion and rooms.

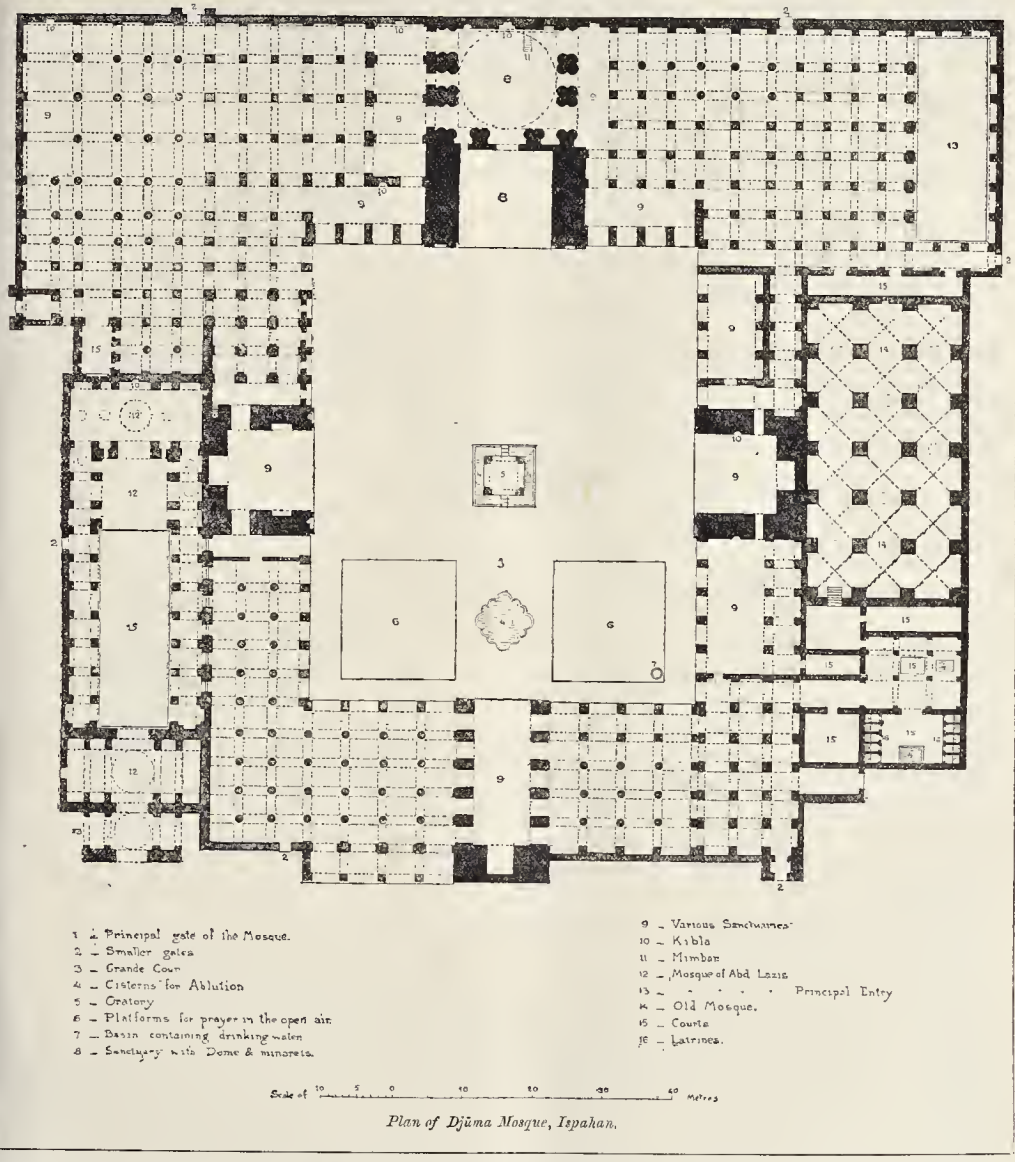

Besides the peculiar forms of the arches and dome, and the stalactite enrichments, there are two striking features about Moslem art in Persia, one architectural and one decorative. The architectural peculiarity is this: That frontispieces of oblong shape are erected to mark entrances; in these are large four-centred arches, with recesses at the back, mostly covered with half-domes, carried on squinches, and frequently enriched with stalactites. These frontispieces are also found in the centres of each front of the courts of mosques, and greatly resemble the ancient Roman exedrae. The only modern instance of a similar feature that I know in Europe is the triclinalium of Pope Leo III., close by the Scala Santa, in the Lateran Piazza. Whether you like this feature or not, it must be admitted that it is a striking one.

Isfahan, from which most of the illustrations are taken, is situated midway between the head of the Persian Gulf and the Caspian, a little to the eastward of the head of the Persian Gulf, and is in that division of Persia called Irak-ajem. The air is said to be so dry there that iron does not rust. A mosque seems to have been built there in the Kaliph Mansur's time, which has been replaced by the Mesjid-i-Djinnah, though a crypt of Mansur's time is said to be under it. The reason that nothing earlier than the sixteenth century remains is possibly due to Isfahan being taken by the troops of the destroyer Genghis-Khan, and subsequently to its being stormed by that scourge of God, Tamerlane. He admitted the town to capitulation and tribute, but, from the excesses of his collectors, a riot took place, in which most of his people were killed, and the Persians then defended the town, and it was taken by storm. Afterwards, in cold blood, Tamerlane sent his men to butcher 70,000 of the people, whose heads were formed into a pyramid on the plain in front of the town. He seems to have been in an amiable humour, as on like occasions he was wont to build towers, whose walls were composed of living persons laid in mud. Though the Saracens occasionally ground the corn for their army with rivers reddened with their conquered enemies' blood, there are no accounts of atrocities quite equal to those of the Monguls.

The great frontispiece in front of the vestibule of the sanctuary, at the mosque of Mesjid-i-Shah at Isfahan, is oblong, 75 ft. wide, and 108 ft. high. The arch within it is about 57 ft. wide, and 79 ft. high to the crown. The frontispiece is flanked by two cylindrical minarets, and has a dome behind it, which towers above the frontispiece. The dome covers the space in front of the niche.

The decorative peculiarity is the use of brilliantly-coloured enamelled bricks or tiles for facing, ornamented with scrolls. Almost all important external work is so finished, including domes. The patterns on domes are made by inlaying or by cutting plain-coloured tiles into the required patterns. In the tile work at the Alhambra the texts are inlaid. The effect of a whole building executed in brilliantly-coloured pottery must be very splendid. There is a great opportunity in London and in all manufacturing towns for the use of this material, which would have the advantage of substituting for the dingy brick or stone a beautifully-coloured front; it would greatly add to the brightness of the streets and could be easily cleaned by a hose.

When the western part of Persia, with its capital Medain, fell into the hands of the Saracens (in 15 or 16 A.H., 636 A.D.) in the second year of the reign of the Kaliph Omar and about two years after the great battle of Cadesyia, the Saracens had no architecture of their own, and had come upon the architecture of a civilised people. Here was the palace of Cheroes with its white pavilion; one of it

grand halls was used by the conquerors for a mosque. The whole of Persia was conquered in Omar's time, about 633 A.D. The Persian Empire, however, extended to the Oxus and the Indus, and this part was not conquered till the reign of Moawia.

About fifteen miles above Medain the second Abbasside Kaliph Mansur founded Baghdad in 145 A.H., 762 A.D., and Medain was destroyed, at least as far as the Saracens could destroy it, to supply materials for the new city of Baghdad. An arch near the Tigris resisted all their efforts, and was to be seen from the Tigris some forty years ago, but has, I believe, since fallen. (Photograph, taken about forty years ago, exhibited.)

The great congregational, or Friday, mosque at Ispahan, Mesjid-i-Djuma, also called the old mosque, is said to have been originally built by the Kaliph Mansur, though it has been altered and added to since, if not rebuilt. It is situate not far from the north gate Tokhtahi, in that part of the town that is to the north of the river Zendebroud, some 2,228 yards above the mosque of Mesjid-i-Shah. The mosque is about 482 ft. long by 496 ft. wide over all; but it is not a perfect oblong square, but is slightly

T-shaped, and seems to be a collection of at least ten mosques, though it is in many respects like the early congregational mosques that were described in the last lecture. That which looks like the original mosque is of a more strongly-marked T shape, the sanctuaries on the Kibla wall forming the head of the T; there is a large oblong courtyard with triple aisles to the right and left, and with five aisles on the side opposite to the main sanctuary forming the upright of the T. It looks as if the external mosques had been subsequently added, a covered one on the right with courts, and an open one on the left of the side cloisters. The court itself is an oblong square, about 213 ft. by 180 ft., with a basin of water in the middle, with an oratory over it, with two paved spaces about one step high, and a basin, with a jet of water. This court looks on plan as if it had been laid over the centre of a Latin cross, allowing the ends of the four arms to project beyond it; the bulk of the supports of the mosque are piers, but there are, some columns, twenty-nine in the left sanctuary, and eight in the right, and there are forty-three in the left hand and back cloisters. The court itself may also have been used as an open-air mosque, as

the two raised spaces, about a step high, may have been used instead of Dikkas, or trilunes.

In Egyptian mosques, the niche is invariably semi-circular, although you will recollect that it was not introduced until the year 53 of the Hegira, and the use of this semi-circular niche is confined to mosques, and is carefully avoided in lay buildings; but in Persia, a square recess or half of a stepped square is used indifferently with the semi-circle; to take the niche wall, beginning at the left, there is a narrow sanctuary and niche, then there are the nine aisles, only these are arched both ways, then another narrow sanctuary touching the vast piers of the main one, which is domed; to the right another narrow sanctuary, then ten more aisles, and an open court, equal in width to three aisles; the left side goes into the flank, up to the arm of the cross, and is twelve bays deep from the niche wall,—the left side is only eight bays deep. Behind the piers that form the sanctuary-side of the court are two spaces right and left of the recess; that to the left is a sanctuary with a niche; on the right flank of the court are two small mosques; both arms of the cross have prayer niches. The two outside

mosques have been mentioned before. The vaulted mosque on the extreme right is groined, and has immense piers, about 6 ft. 8 in. square, though the span of the arches is but about 16 ft. 6 in.; possibly these piers are very high. There is only one pulpit, at the right side of the niche in the central sanctuary. The court looking to the sanctuary consists of a central frontispiece, containing a four-centred arch, about 43 ft. span, with an archivolte running down to the plinth; beyond are wide piers, panelled, with arches and square panels alternating, and the whole is framed by a wide border, on which are inscriptions; behind are two cylindrical minarets, like Egyptian columns, with stalactite cornices, and with their thinner cylinders above partly ruined. At the back is a pointed bulbous dome, with an inscribed band. The recess is domed on a series of large arched semi-domes. This side of the court is made up by arcades of four arches, two stories high, on each side, that rise to about half the height of the frontispiece; each arch is framed by vertical and horizontal bands. The left side of the court has also a frontispiece in the middle, and two-story arcades on either side of six arches each, only the pieces enclosing the single arcades, next the frontispiece, are higher, so as to make a sort of stepped frontispiece; the half dome of this is carried on Persian stalactites. The front of the frontispiece seems to be of plain brick, but the spandrels are in patterns, while all the rest is faced with enamelled brickwork on a marble plinth. The central basin, with the oratory over it, is formed of four piers, with slender columns between on the long sides, carried by four-centred arches over the water, and is reached by steps. The flat roof has projecting eaves, carried by cantilevers. The whole of the court is paved. The interior of the mosque is mainly stuccoed.

The external arrangement of the architecture of the court is precisely similar to that used in all comparatively recent Persian buildings, whether they be khans, colleges, palaces, or mosques,—*viz.*, two-storied arcaded buildings, with four-centred arches, with a frontispiece in the middle.

Nearly in the centre of that part of Ispahan that is on the north side of the river Zendeherund is a group of buildings, consisting of the palaces of the Shah, the bazars, and the horse-course, set out nearly due north and south; this block is connected with the southern part of the town by a grand cloistered avenue, in the middle of which is the bridge over the river; on the east side of this avenue the grounds of the palaces abut. At the south end of the group is the great mosque Mesjid-i-Shah, whose kibia is nearly south-west. The entrance to the mosque is in the middle of the south end of the hazaar, which surrounds the horse-course, and to get the entrance to the court of the mosque in the middle, too, the north angle of the mosque is cut off. It was built by the great Shah Abbas I., who took Baghdad. He was born in 1557 A.D., and died in 1628 A.D.

This mosque is like the later ones in Cairo, almost without columns, and has a central court with four arms, like the mosque of Sultan Ihsan at Cairo, only in that case the arms take up a larger proportion of the sides of the court, while in this mosque the widths of the openings of the arms are about a quarter of the length of the side. The arm forming the mosque at Sultan Ihsan's is 98 ft. 6 in. wide, while here it is but 56 ft., and is divided from the sanctuary by a wall, the main entrance to Mesjid-i-Shah being in the centre of the horse-course, and the exit being in the centre of the court. The two axes of the doorways make an angle. The same device was used here that Sir John Soane used in the passage to the Rotunda at the Bank of England. The mosque is very nearly an oblong square, with the north corner cut off, and is 341 ft. deep and 423 ft. wide; the supports are wholly walls and piers, except six octagonal columns that divide the side sanctuaries into two aisles each. At the niche end there are two open-air mosques, one to the right and one to the left, with basins of water for ablution. These two open mosques have two half-round niches to each; the domed sanctuaries on either side of the central one have rectangular niches, and the centre sanctuary has a stepped half-square for its mebrat, and is almost cut off from the side sanctuaries by the huge piers that support the great dome. There are certainly five separate mosques, if not nine, four with half-round niches and five with square ones.

The Persians were mostly Shi'as,—*i.e.*, of the main heretical sect,—and the Shi'as creed is now

the national faith. The Shi'as believe the first three Kaliphs,—Abu Degr, Omar, and Othman,—were wrongly elected; and, therefore, do not acknowledge them; they say the Kaliphate could only descend through the family of the Apostle, and consequently by Ali, who married Mohammed's daughter, Fatima, and that Hasan and Hosen, the Apostle's grandsons, were the legal successors; to show their contempt for the first three Kaliphs they tattoo A and O on their heels. By this means Harun, in the "Arabian Nights," knew that the corpse was not that of Aladdin Abushshamat, who was supposed to have been hanged. There may be peculiarities about these Shi'as mosques. A graphic description of the sort of mystery play of the death of Hosen now performed in Persia was given in a magazine a year or two ago. The mosque has two minarets flanking the frontispiece of the main entrance in the horse-course, and the court of the mosque has in the centre of each of its four sides a frontispiece; between each side frontispiece are triple arcades, two stories high, and each flank of the entrance side has five arcades. The entrance to the sanctuary has a frontispiece flanked by two cylindrical minarets, and beyond them rises a bulbous dome on a drum pierced by windows filled with lattices. The spaces between this frontispiece and the flanks are filled with arcaded walls faced with enamelled bricks, divided into two unequal compartments; the division is marked by ornamental panels on a white ground, all the rest of the court having a blue ground. In each of the spaces are arches; those next the frontispiece are about 34 ft. 6 in. wide and 36 ft. high. Within this is another parallel arch, recessed, leaving a margin of 5 ft. all round; the outer arches go up to the crowning hand, or flat cornice, and are, therefore, in one height. The arches at the end are in two storeys, and are simple combinations of the arcades of the flanks.

The real dome is about 71 ft. in diameter inside, carried on squinches, and 124 ft. from the pavement to the crown; this carries a timber roof, which, with the masonry filling up the lower part of the hulls, support the bulbous dome; this is about 90 ft. in diameter externally at its widest part, and 164 ft. to its apex from the pavement; beneath it is a circular drum, pierced with eight windows, with lattices, and stands on an octagonal platform, the face of which is arcaded. The angles of the recesses are brought into the half-circle by means of squinches, and the present one in the horse-course is carried in the same way, only the form is hidden by its stalactite decoration. The decoration of the mosque is superb; above the marble or alabaster plinth, which is about 7 ft. high, the whole of the facing is of enamelled pottery; the ornament mainly consists of coloured scrolls on an azure ground; the minarets have a green ground, covered with a large pattern of crosses set anglewise; the crosses have a line of dull red as an outline, while at a little distance inside the form is repeated by black dots, and inside this again with white ones; the capital or gallery is of a golden yellow with an inscribed band, with the letters in black and the panels above, and those of the stalactites have blue panels with white flowers in the centres; the outside of the dome is enamelled and diapered in colours, with a flower in the middle of each diaper; below the dome is a band of blue, with an inscription, and below this inscription the whole drum is of enamelled bricks down to the octagonal platform; the walls, arches, and semi-domes of the frontispiece have an azure ground, enriched with coloured patterns, and the top of the semi-domes is of golden-yellow with slight coloured patterns. The view on entering the court must be magnificent, with this splendour of colour, and the vast archway over 60 ft. wide, and nearly 100 ft. high, facing you with its grandeur enhanced by the low buildings on the flanks, while through the two-fold gloom of the recess, and the sanctuary, the light of heaven is seen through the piercings of the lattice over the mebrat. It may not be quite equal in monumental grandeur of colour to the superb friezes of Darius' Palace at Susa, now in the Louvre, with the green-headed troops of the White Nile, but it still keeps up the traditional glory of the enamelled ware of Mesopotamia. The inside is also covered with enamelled pottery, except the plinth, which is of some marble like agate, and when lit up with thousands of lamps must have the appearance of fairyland. I did not

see the tiled mosque of Ahmed at Constantinople lit up.

It must be remembered that this Mosque of Mesjid-i-Shah was built late in the sixteenth century, and has remarkably few stalactites; these are mainly confined to the cornices of the minarets and that part of the entrance that abuts on the horse-course. Almost all the other domes and semi-domes have interesting arches. The brick stalactites of the half dome of the recess fronting the horse-course are cut in the elongated voussiors of the inner shell of the half dome. The thrust of the great half dome of the sanctuary must be very great, for though it has a radius of nearly 100 ft., with a centre nearly 40 ft. below the springing, the top abutment is nearly 11 ft. thick, besides being weighted with the parapet, while the bottom abutment is 13 ft. thick, though it is loaded with the weight of the drum and dome in addition. The proportions are not quite to one's taste, the bulk of the openings being squat; the best piece is the frontispiece of the sanctuary, but though the height of this is not more than an additional fifth of its width, the opening of the grand archway itself is about three-fifths of its height. The minarets, which are, to all intents, columns on tall square pedestals, are about 5½ diameters high, but the wooden balustrade and roof increase this to about 6½; the finials are but small cylindrical shafts, with flat bulbous domes, and contrast very unfavourably with the elegant minarets of Cairo. The four-centred arches of the openings are not agreeable, but the most probable cause of the shape was to get rid of centreing; the whole of modern Persian architecture has an air of being done by rule, and no very good rule either, and lacks altogether the apparent spontaneity and artistic invention of the architecture of Cairo. The grand exedra, too, lose much by being nearly alike on all the four sides of the court. Still, in spite of all adverse criticism, the effect of these magnificent exedrae must surpass anything else in the world. The same style was pursued, and is, to some extent, pursued to this day in every building, though it became duller and more mechanical the later it was in date, and the taste in colour diminished till quite modern work is garish and vulgar when seen in the light of this country.

A few monuments, however, that have been delineated deserve mention. The principal one is the blue or orthodox mosque of the Sunnis at Tabriz, the ancient Tauris, in Azerbaijan, midway between the west side of the Caspian and Lake Van. This mosque was ruined by an earthquake in 1721; it was built by Djehan Shah, one of the Mongol Princes of the dynasty of the black sheep, in the fifteenth century; it was called the blue mosque from the prevalence of blue in its enamelled brick decoration. Its plan has a strong family resemblance to that of Sta. Sophia at Salonica, only its sanctuary is rectangular, with a small, half-round niche in a rectangular recess. The narthex goes round three sides, as at Sta. Sophia; the main dome, which has fallen, was about 54 ft. internal diameter; the front was flanked by two minarets at the extreme angles; the frontispiece to the central entrance, which still remains, has its half-dome carried on squinches; the internal plinth is said to have been of a sort of agate. Sultaniah, in the north-east corner of Irak-Ajemi, was built by Argon Khan in 1290 A.D., one of the descendants of Genghis Khan; his brother and successor, Oldjaitou Mohammed Khoda-Bendeh, carried on the work with great vigour. In 1305 A.D., the town was called Sultaniah in honour of the birth of his son, and Khoda-Bendeh then built his own tomb-mosque, which consists of an octagonal chamber, with a dome, and the tomb-chamber behind it. This has a half-octagon niche, and a small dome over the tomb. The building is a square of about 120 ft., with the back angles cut off; above, the front angles are cut off, too, making an octagonal base for the dome. The main dome is about 79 ft. internal diameter, with a total external height of 177 ft.

The exterior has a stalactite cornice with a triple arcade below it on each face of the octagon; the arcade consists of one wide central arch with a narrow one on each side; this arcade forms an ambulatory, with a balustrade for protection; the entrance-front is square, with staircases and recesses in each of the square angles, lit by two narrow pointed windows at two levels. In the middle of each of the square sides there is a small doorway enclosed in a frontispiece, with an arch over it

Ruined Tower at Reï, Persia.

reaching to the string of the arcades; within this arch, above the door, is a triplet window. The angles are splayed horizontally with a parallel splay just below the bottom of the arcades; the other faces below the open ambulatory are arcaded. Above the top splay of the stalactite cornice rises at each angle a cylindrical minaret, whose finials are gone; these rise nearly to the height of the top of the dome; the dome and minarets are plastered and ornamented with patterns in blue and white enamelled bricks. This tomb-mosque is supposed to have been damaged on the town being taken by Tamerlane, and since his day the town has fallen into ruins. Reï, the ancient Ragae, where Alexander the Great gave up the pursuit of Darius, is close to Teheran, under Mount Demavend, and near the Caspian; here are the ruins of a brick tower of victory, from which the Persian conquests used to be announced. It is curious as a structure, and also as being characteristic of structures commonly found among the Moslem buildings of India. It is about 50 ft. in diameter, with walls about 6 ft. thick. Externally it is fluted with twenty-two V-shaped flutes, which run up to the cornice, which consists of one tier of Persian stalactites in the flutes, and two tiers of semi-domes above, each tier projecting over the other, with a plain band above, containing an inscription in Cufic characters. The tower is supposed to have been crowned with a dome, and to have had between them and the dome a passage between them and the dome for the proclamation of victory. The dome has unfortunately fallen in. The doorway is formed by a high four-centred pointed arch in a frontispiece, which occupies the space of two flutes; above the arch of the doorway are three ranks

of Persian stalactites. The tower is about 68 ft. high to the bottom of the inscribed band, of which only enough is left to show that it was inscribed in Cufic characters. The battlements were reached by a corkscrew staircase in one of the V-shaped solids nearly opposite the door. Other circular towers of masonry, once domed, but unfluted, are found in the neighbourhood.

Near Ispahan is a little oratory or tomb-mosque flanked by an enormously tall cylindrical minaret known as that of Shah Rostan, who lived in the fifteenth century. The minaret is known to be Moslem from its Cufic inscription; it is 17 ft. in diameter, with a double newel staircase entered from opposite sides, so it looks as if it were originally much used; possibly it acted as a tower of victory as well as a minaret. It resembles a slender Egyptian shaft with a cavetto capital in outline, only instead of leaves there are two vertical bands with knots at the bottom; the finial at the top is ruined, and the wooden balustrade has disappeared. There are traces that show that its decoration was of enamelled bricks, the enamel of which has perished; the height, exclusive of the finial, is 128 ft., the minute oratory is but 26 ft. 3 in. square, with a doorway and external niche, and is crowned with a dome; the point of the dome only reaches to about half the height of the minaret; so they look like the giant and the dwarf. The oratory has one of its angles chamfered, and its faces are perfectly plain; the height of each side is about the same as its width, and is then splayed off into an octagonal band whose height is about a half of its width; at some distance back on this octagonal platform is the dome, which has a doorway level with the battlements, and one window above it

which appears to be the sole opening for light. It is a quaint-looking little building, and the two make an eccentric looking group, unlike the usual Persian architecture.

Many of the tombs in different parts of the country are hexagonal or octagonal; the octagonal ones have borders round the sides which enclose one four-centred pointed arch on each face; the hexagonal ones have each side divided into a wide and two narrow blind arcades, the middle one arched in one height, and the side ones in two. From the centre of the platform formed by the flat roof of the polygon, rises a tall circular or polygonal drum covered with a tall roof or steeple, or with a bulbous dome, somewhat reminding one of St. George at Ezra in the Hauran, without the sanctuary. Some of these tombs have quite a Gothic air.

MAGAZINES AND REVIEWS.

THE *Fortnightly Review* contains an article by Sir John Lubbock on "The Government of London," chiefly with the view of submitting some points in regard to the London County Council, for the consideration of ratepayers and new candidates. Among the points to which Sir John Lubbock draws attention are the desirability in some cases of reducing the numbers on committees; the status of the Chairman, whether his office is to be analogous to that of the Speaker in the House of Commons, or to that of a leader of the Government (his opinion inclining to the former theory); the desirability of giving the Finance Committee in all cases the first consideration and recommendation as to any special expenditure; the limitation and definition of the duties of the County Council, on which the ideas of some members are far too extensive; and the housing of the working classes. Sir John Lubbock concludes with the hope that it will soon be possible to secure a suitable site for Municipal Offices, considering that with an adequate building specially planned, concentration, convenience, and economy would result.

In the *Art Journal* Mr. Aymer Vallance continues his articles on "The Furnishing and Decoration of the House" treating of "Walls, Windows and Stairs." The illustrations of wall-coverings show the efforts that are now being made to get hold of some new ideas in wall-papers,—efforts which are too obvious, and in which the semi-naturalistic treatment employed in some instances is not by any means decorative in the best sense. The Dean of Gloucester contributes an article, illustrated by some excellent little sketches of the cathedral and bits of the town; the artist's name is not given,—an odd omission in an art journal.

In the *Magazine of Art*, Mr. R. T. Blomfield, in continuing his articles on artistic houses, points out the danger of dilettantism in substituting a mere collecting mania for artistic creation. The public, he observes at the close, have this matter in their own hands: "It is for them to treat architecture as a serious art and to set a higher value on courage, independence and individuality in design, than on unscrupulous cleverness in hitting off the fashion. Plain work, even savage barbarous work, anything is better than fashionable work." It is possible, however, to push this last dictum too far. The article is illustrated by interiors of houses by Mr. Norman Shaw, Mr. Jackson and Mr. Macartney. Considering the stand made in the article in favour of originality, there seems a good deal of modern-antique in the examples. "The Ornamentation of Early Firearms" is an interesting subject, treated by Mr. Greener, with numerous illustrations. An article on the "Reynolds Centenary" is illustrated by some sketches of places connected with Reynolds's life, chiefly from Plympton, his birthplace.

The *Antiquary* has a neat and pointed article on the ivy dispute re Kirkestall Abbey, upholding the removers of ivy, and observing that "artists" (i.e. painters) who make such a fuss about the removal of the ivy, in most cases care nothing about the architecture, or about any other art than their own, which is assisted by ivy; whereby also, we may add, they are saved the trouble of trying to draw the architecture, in which they are seldom successful. Mr. R. J. Preston contributes some notes, with sketches, on "Some Cornish Beach Ends." Otherwise the number for February is as well and usefully filled as usual.

The *Gazette des Beaux Arts* contains an article on "Les Sarcophages de Sidon," by M. T. Reinach, with some fine illustrations,

There is an article of rather special interest on "Ingues Samin," a little-known architect and sculptor in wood of the latter part of the sixteenth century. An illustration is given of his design for the façade of the Palais de Justice at Besançon.

The *Contemporary Review* contains an article of some importance on the "Unhealthiness of Cities," by Sir Francis Peck and Mr. Edwin T. Hall, to which (from internal evidence) we shall probably not be wrong in concluding that the last-named gentleman is the larger contributor. It deals first with "sewer-gas," suggesting the principle of having inlets of fresh air at the highest point of a sewer system, and exhaust shafts at the lowest point, in order to draw the air in the same direction with the sewage flow and get the assistance of the latter. Against this must be put the fact that the air in sewers naturally tends to ascend, and it would require rather a quicker current than usual to counterbalance this tendency. However, the suggestion is worth consideration; the main object being to ensure that inlets shall always be inlets, and not inlets or outlets at various times. Other subjects dealt with in the article are "London Fog," "Poisonous Ground Air," "Jerry Building," and "Sanitary House Planning and Construction." In this latter portion of the article we observe the caution that "all cisterns should be well covered" to exclude vermin, dust, &c. To this should have been added the caution that such cover should be easily removable and the cistern easily accessible so as to be readily inspected. In another paragraph, we are glad to see, the authors call attention to the importance of doing away with unventilated hollow spaces hidden from light, as a matter important to the sanitary condition of a house.

In the *Nineteenth Century* the "London Water Supply" is the subject of a paper by Sir John Lubbock, whose main conclusions are that the question is one of vital and pressing importance; that the population of the Thames Valley is rapidly increasing, and the limits of the present water supply nearly reached; that it will shortly be necessary to go elsewhere for a fresh supply; and, last but not least, that unless we do so soon we may find that the available areas have been appropriated by other cities, and that we are too late; "which is what we urged in nearly the same words a good many months ago. Sir John Lubbock is opposed to the idea of buying up the water companies, but suggests additional supply either by the companies with the aid of the Council, or by the Council by arrangement with the companies; and that an agreement should be made with the companies for dividing future profits equitably between them and the ratepayers. The article is a sensible and judicious one in general, and deserves attention.

In the *Century* Mr. Sillman continues "The Italian old masters" with an article on "Titian," very short and slight for so great a subject, and giving the impression of having been merely written to accompany three engravings from Titian's works. An article on "Pioneer Days in San Francisco," by Mr. J. W. Farmer, is illustrated by sketches of the original streets, the first hotel, &c., which throw an interesting light on the local colouring of Bret Harte's stories of towns in a similar embry stage, and seem made to illustrate the scenes in "Red Dog" or "Tattleville."

Harper's Magazine has an article by Mr. Julian Ralph on Chicago as "the main exhibit" of the 1893 exhibition. The article is not calculated to tempt European visitors. The position and the marvellous prosperity of Chicago within so short a time are picturesquely set forth; but we are given also the picture of Chicago as a place of absolute turmoil of money-making, where no one has time to be civil; where if you ask the way you must run by the side of your man to get his answer, for no one has time to stop in the street in Chicago; where to ask a necessary question of a ticket-taker or tram conductor is to expose yourself to gratuitous insolence; and where an average of six hundred people are annually killed by railways on level street crossings. This is not the testimony of a prejudiced "Britisher," but of an American writer in an American magazine; and judging from his account we should imagine that to cultivated Europeans Chicago must prove the most detestable of all the large cities of the world.

The *Atlantic Monthly* has an interesting sketch of "A Venetian printer and publisher of the sixteenth century," one Gabriele Giolito

to wit, derived from recent investigations by Signor Salvatore Brongi.

In the *New Review* Mr. Spielman suggests the founding of the proposed National Gallery of British Art in the rear of the National Gallery, on the site of the barracks, and with a new street opened to westward of the block. We doubt whether the site can be acquired, otherwise its contiguity to the National Gallery would in itself be an advantage rather than the reverse; but then the question would arise whether the works by English painters now in the National Gallery are or are not to be considered part of the "National Gallery of British Art." The trustees of the National Gallery would probably demur, and there would be dissensions.

The *Quarterly Statement* of the Palestine Exploration Fund contains an article by Mr. Flinders Petrie on the "Tomb-cutters' Cubits at Jerusalem," an attempt to investigate the length of the cubit by a comparison of the measurements of different sides of the tombs where it may be expected that exact multiples of the "foot-rule" of the period would be found. This practically enforces a suggestion we have already made, that the exact proportion in length and breadth of some ancient structures may merely have arisen from the natural use of so many lengths of a measuring rule in each direction, and not from any theory of proportion.

In *Temple Bar* is an article on Benjamin Robert Haydon, chiefly in relation to Tom Taylor's biography, which may serve to recall the name of a painter who is little heard of by the younger generation, and who, whether in regard to his talents or his tragic career, should not be forgotten. The article in *Macmillan* on "The Beautiful and the True" seems rather high-sounding than valuable or pointed; one has had enough of "the beautiful" with the definite article. The *English Illustrated Magazine* includes an interesting article on "The London and North-Western Locomotive Works at Crewe," by Mr. C. J. Bowen Cooke (Assistant Running Superintendent); an article on Brahan Castle by the Marchioness of Tweeddale, with illustrations by Mr. T. Riley, and one on "The Mosques of Tlemcen," written and illustrated by Mr. Edgar Barclay, but the illustrations (as might perhaps be expected) are of pictorial rather than architectural interest. The *Ludgate Monthly* gives a short article on Malling Abbey, with some sketches (not very first-rate), and *All the Year Round* makes a concession to the increasing popularity of archaeology by an article on "A Dead City of Etruria," which is, however, picturesque and chatty rather than archaeological.

ROYAL INSTITUTE OF BRITISH ARCHITECTS:

LONDON BUILDING LEGISLATION.

The seventh general meeting of this Institute for the present session was held on Monday evening last, the President, Mr. J. Macvicar Anderson, in the chair.

Obituary.

The minutes of the previous meeting having been read and confirmed,

The President said:—Since our last meeting, an architect whose name was well-known has passed away. I do not think we should be content with a mere official or formal notification of his death, and therefore I refer to it specially. Mr. Philip Hardwick was a man whose works were important and numerous, and he occupied a distinguished position. It is with grief that we have heard that his latter days were embittered by a painful illness. He was a man who, while in practice,—for it is now some years since he retired,—was looked upon as an able architect and an honourable man, and it is with great regret that I have to announce his decease.

Nomination of the Recipient of the Royal Gold Medal for 1892.

The Secretary, Mr. William H. White, having read By-law 64, regarding the award of the Royal Gold Medal,

The President said:—I beg to announce that the Council propose to submit to her Majesty the Queen the name of M. César Daly, Hon. Corr. Member, Paris, for his writings in connexion with architecture. I cannot refrain from reading an extract from a letter I have

received from M. Daly this morning. He writes:—

"The Secretaries of the Institute have officially informed me of the Council's very flattering decision of presenting my name before her Majesty the Queen, as a worthy recipient for the Royal Medal to be given in 1892. . . . I beg you to receive my most grateful acknowledgment for this kindness and honour. You know already the strong ties which bind my youngest nephews with Bridges and Englishmen; but the favourable vote of the Council binds my old age to the old country by a new tie that no strain will ever weaken. By their generous and large feeling in favour of architectural progress through the whole world, and their decision of seeking the worthy amongst all nations, the English Institute has created a sort of architectural senate, of which every architect must be highly flattered to become a member."

It is some satisfaction, gentlemen, to find that those abroad who are nominated for the reception of this honour from her Majesty so highly and thoroughly appreciate the honour.

London Building Legislation.

Mr. Edwin T. Hall, Fellow, then read a paper on "London Building Legislation." In his opening remarks he referred to the great importance of the subject, especially as the codification and amendment of the Metropolitan Building Acts was now occupying the attention of the Government and the London County Council. He desired to expound the views of the Practice Standing Committee, who for the past two years had had the matter before them, and whose suggestions for a Draft Bill had been approved by the Council of the Institute. The Committee had throughout realised that the question must be approached in a public spirit, with the endeavour to ensure safe and sanitary building with as few restrictions as possible on artistic design. The main lines of the suggestions had been issued with the notice convening the meeting; and, having drawn attention to the importance of excluding the construction of roads, drains, and bridges, &c., from a Building Act, Mr. Hall proceeded to treat with the details of the draft. Great attention had been given to definitions. Many subjects defined by the committee were not defined in the existing Acts, while new definitions had been given to many others; among the former were,—building, structure, wall-sign, warehouse, domestic building, living-room, flat, business offices, story, topmost story, floor area, superficies, cubic contents, and fire-resisting; and the latter included public building, site, base of the wall, foundation, builder, street (instead of roadway), and centre of street.

Several of the existing exemptions to the Act, he pointed out, were manifestly opposed to the public interest, and therefore recommended to be removed or limited in scope, while new exemptions of very small buildings from the general rules of the Act were suggested, but placed under the control of the District Surveyor. An important addition to the Act was the section dealing with the "alteration in purpose or character of a building," and a new section also provided for the restoration of buildings of architectural, archaeological, or historical interest, while the section for "rebuilding old buildings" was varied. With reference to foundations and sites, several alterations were suggested. The existing rule as to the thickness of concrete under a wall was inadequate; the suggested section said the thickness of good concrete shall vary according to the height and class of building, and allowed of the omission of concrete, with the approval of the District Surveyor, where the site was "a natural bed of solid gravel or chalk of not less than 3 ft. in thickness." The subject of recesses and openings in external walls had received careful attention, and it was proposed to modify the law by enacting that the recesses and openings in any story shall not exceed one-half of the superficies of the wall of such story in which they are made; "this limit not to apply to that portion of an external wall between its base and 30 ft. above the level of the public footway immediately in front of the centre of the façade, or where there is no such footway, then above the actual level of the ground before excavation. Turning to party-walls, a principle had been adopted for fire prevention and stability which, it was hoped, would commend itself to all; the theory of ownership in the existing Acts was not interfered with, but the new principle of construction was that there shall be in the centre of the new party-wall a continuous backbone of brickwork, the thickness of which neither owner shall diminish. On its own side only of this backbone could the flues of any

building be placed. Applying the principle, it was proposed that in no case shall the back of a recess be within 4 in. of the centre of the wall. As to the formation and superficial limits of recesses in party-walls, the new section provided that the recesses shall be arched or corbelled over in the height of the story in which they are made, and that their extent shall be measured by width, not area, and that the "width shall not exceed one-half the whole length of the wall of the story in which they are made." As to the section governing uniting buildings, a discretion to the County Council was suggested to consent to the uniting of buildings which were not wholly in the same occupation. In the case of floors of fire-resisting materials such uniting might, he thought, within limits be permitted with perfect propriety. The new section forbade openings in "any party-wall or any two external walls dividing buildings," and further provided that "no opening in such wall or walls on any one floor" shall be "nearer than 25 ft. to any other opening on the same floor;" and the existing section, requiring openings in party or dividing walls to be stopped up, had been made much stronger. Under the heading of "Miscellaneous," an effort had been made to get rid of the public danger arising from advertisements on combustible hoardings "on the face or in front of the external wall of any finished building." Mr. Hall next dealt with "Timber in external walls," bressumers, the height of party-walls above roofs,—treating the last-mentioned at considerable length,—and then turned to the payment of the cost of party-walls and the question of stories in the roof. A new section for "Chimney-shafts from furnaces" incorporated the essentials of the existing rules which the County Council adopted in sanctioning such shafts, while in the rules as to other chimneys and flues many variations in detail had been made. Considerable alterations had also been made as to the construction of habitable rooms, the minimum height, except in the roof, being increased from 7 ft. to 8 ft., and minimum areas of windows, of dormers, lantern-lights, &c., had been fixed. The Draft next embraced all the building regulations of the Public Health Act for underground rooms let as separate dwellings, and added regulations for other underground rooms not so let; and he considered it a matter of congratulation for the Institute that the Government in framing that Act had adopted so many improvements suggested by the Institute. Projections beyond the general line of building had also received careful attention. The sections had been drawn anew, and it was affirmed that cornices of shops might to a specified extent overhang the public way, but no other part of a shop front encroach on it. Permission for bay windows and similar projections over building-owner's own land was given, thus legalising what was a pretty general practice; while adjoining owners were protected by the condition that no such projection shall come within 2 ft. of the centre of a party-wall, nor shall it extend outside a line drawn at an angle of 30 deg. from the point in the front of the building where it touches the centre line of the division of the properties. It was a pleasure to note that the County Council, too, in their amendments, had a section with the object to concede greater freedom of design to architects, or rather building-owners; this section allowed, under restrictions, projecting oriel windows or turrets not only over the building owner's land, but 12 in. over the public way. The County Council had apparently considered overhanging constructions only in relation to the public way, for, though right and proper so considered, the limit for oriels and turrets not to be lower than a certain height above the level of the footway was unnecessary and undesirable where they were over the building-owner's own land. The author then dealt with a sub-section designed to ensure the construction of party-walls in buildings subsequently converted into two or more buildings, and a section to secure fire-resisting construction in a building erected or converted into two or more divisions, intended for or adapted to be used as flats, or as warehouses, or which is let or occupied in two or more such divisions, with reference to which an incidental change of great importance was made. The old sub-section said: "Sets of chambers or rooms tenanted by different persons shall in certain buildings be deemed to be separate buildings." The new section assumed a building to be that which it was

popularly understood to be, viz., a cube resting on the ground and covered by a roof. Having described the suggested regulations as to "gress from certain buildings" referred to, and the incorporation of section 29 of the London County Council (General Powers) Act, Mr. Hall proceeded to treat of those to govern lift-shafts. Lifts, in the suggestions of the Committee, were divided into three classes,—(1) those which were inside a building with fire-resisting floors containing flats or business offices; (2) those outside the external wall; and (3) those inside warehouses which pass through fire-resisting floors, and where it is not the practice to enclose the lifts with walls. In the first class it was suggested that the lift be separated from flats or offices by brick walls, and all openings into the shafts from within the entrance doors of flats must have an iron door in addition to a wooden one. In the second class the enclosures to the shafts or for cylinders, balance weights, or gearing, were to be either of brickwork, ironwork, or other fire-resisting material approved by the District Surveyor; if the floors of the building are required by the Act to be of fire-resisting construction, then any openings into the shafts from within the entrance doors of the flats, or from any warehouse or business offices, are required to have an iron door as above. In the third class all openings in the floors must have a horizontal door, hatchway, or other cover of iron or other fire-resisting material as specified. With reference to the present maximum of heights of buildings in the 1890 Act, that maximum was proposed to be reduced to 75 ft., and the height of two stories in the roof limited to 20 ft. The provision for open spaces at the rear and sides of dwelling-houses was next dealt with; and, having referred to the many points of view from which this question had to be considered, and the dangers of insufficient space, Mr. Hall said the London County Council were now going to an extreme in proposing to require an open space at the rear, not only of domestic, but of all buildings, which space between the opposite backs of two buildings were to be practically double the width required between the opposite fronts of buildings. Proceeding to analyse the working of the proposed section, he assumed there were three buildings which were parallelograms,—i.e., with no back additions. Two faced each other: their front walls were 75 ft. high, and they were separated by a street 70 ft. wide; the third was behind, and backed on to the second; between the second and the third was also a road 70 ft. wide. By the operation of the section there must be above the ground-floor of the building 90 ft. between the backs of the blocks, and the external walls forming the backs cannot be more than 45 ft. high, while the front walls, 70 ft. apart, may be 75 ft. high. Could there, asked Mr. Hall, be any justification whatever for such a consequence? The section would afford room for much litigation and its ultimate abrogation by evasion. Which was the front of a building? Or, given two good roads, why should a building have a back at all? Moreover, if the case were bad when there was a back street, it was worse when there was none; for if the depth of a site be 55 ft., the building might then be 45 ft. deep; but the application of the County Council's rule would only permit the rear wall to be 10 ft. high, and the front wall to be 50 ft. high, and that with a sky-line of dull and dreary monotony in a street 70 ft. wide. The varied problems of open spaces had all received careful attention, and he thought upon further consideration the County Council would agree that the necessities of the case were met by the suggestions in the Institute Draft. Mr. Hall then referred to a new section dealing with drains and sanitary apparatus, &c., which left all details to by-laws; and he gave an epitome of matters relating to the construction of public buildings, concluding his paper by alluding to questions which had been settled in principle, but not yet formulated by the committee,—among others the making of by-laws, the machinery for settling disputes by the award of the Surveyors, the Tribunal of Appeal, and the duties and remuneration of District Surveyors.

The President, in inviting discussion, said that Mr. Hall had given them a lucid explanation of a very voluminous document. As he saw present several gentlemen who were practically acquainted with all the intricacies of the subject, he trusted that they would have an interesting discussion.

Mr. H. H. Collins said that at that advanced period of the evening he felt he could do little more than propose a hearty vote of thanks to Mr. Hall for his admirable paper. Most of the suggestions made in the draft Bill of the Institute had occupied the attention of various other bodies; but he was very glad that the Practice Standing Committee of the Institute had considered the matter, not with the view of framing a new Bill, but with the view to the codification and amendment of the existing law. In a large number of bodies with which they were all more or less connected, it seemed to have been the idea that a new Bill should be proposed, and he was fearful when he came into the room that evening that he should hear an exposition of new ideas, new notions, and new provisions embodied in Mr. Hall's paper. He was glad that that was not so, for he was sure that an Act which had borne the hard test of thirty-six years' wear, and which had not been found wanting in its main principles, was one which deserved to be retained. He did not think it was desirable to have over-legislation in building matters. They did not want to go to school again. Architects, builders, and clerks of works had their minds now pretty well saturated with existing legislation, and he thought that, with some amendment of the existing laws, they would be able to jog on again very comfortably for another thirty-six years. The way in which Mr. Hall had treated his subject had disarmed criticism. In reading a book entitled "Called Back" a short time ago, various criticisms of the proposals therein set forth by the author arose to his mind on almost every page; but on succeeding pages the very objections which had occurred to the reader had been anticipated and met by the author. That was very much what had occurred with Mr. Hall's paper. As it proceeded he (the speaker) saw objections to what was proposed; but when Mr. Hall got a little further those objections were met. With regard to the point about the extension of the footings of party-walls upon each side, the thing was absolutely impossible to carry out in practice, and if it were carried out it would have the effect of leaving an unsanitary space at the side of each house. He was very glad that Mr. Hall had criticised the curious proposal of the County Council as to space at the rear of buildings. If that requirement were worked out to its logical conclusion, it would involve nothing less than confiscation, and it should not be entertained for one moment. He did not think that the House of Commons would be at all likely to agree to any such legislation. He therefore warned all who were promoting this legislation not to overload their ship, or they would be in danger of getting on the rocks and going to pieces. That was so in 1884, when the Bill then introduced contained many of the present amendments. One after another these were eliminated, until at last the Metropolitan Board of Works found that their measure was so emasculated that they preferred to abandon it altogether. He was glad to see that in the new Bill they were seeking to ensure not only safety in case of fire, but the health of the people who might have to live in the buildings erected. He had much pleasure in proposing a vote of thanks to Mr. Hall for his able paper.

Mr. Arthur Baker said he regretted to have heard very little in the proposals before the meeting as to fireproof construction. At Kensington there was just now in course of construction an enormous brick and stone building standing entirely upon iron legs. He hoped that when they got a new Building Act such a structure as that would be impossible. Such buildings were most dangerous, and ought to be prohibited.

Mr. Alexander Payne said that whatever might be their views on the provisions of the proposed new Bill, they would all agree that Mr. Hall was deserving of their very hearty thanks, and he therefore had much pleasure in seconding the proposal made by Mr. Collins. The amount of work which Mr. Hall had done was very great, and the amount of detail which he had gone into was appalling. From his (the speaker's) own experience as one of those who had to assist in the administration of the existing Act and its amending Acts, he knew what a very difficult thing it was, in the first place to know what the Act meant, and in the second place to know how the lawyers would interpret it, and it would be no easy task to clear up all existing difficulties by the proposed new Act.

Mr. Ralph Nevill said he had heard with very great satisfaction that very strict rules were to be laid down in the proposed Bill with regard to the thickness of the walls of the flues of kitcheners. But the remarks which had been made as to the necessity of thick walls behind flues were applicable not only to kitcheners, but to many of the new-fashioned grates, which were almost equally dangerous when placed against thin walls. As to projecting windows, he rather gathered that Mr. Hall saw no objection to projecting windows being brought out over a building-owner's own land beyond the line of frontage, not only at a height above the pavement, but down to the ground; but that seemed to be very objectionable. If a bow-window might be brought out down to the ground beyond the line of frontage, why might not the whole building be brought out? He did not know whether the Institute Committee had yet taken into consideration the schedules of the old Act, but they were certainly open to amendment. He had had a good deal of experience in concrete building, and he had always been very much annoyed by the very foolish provision for stepping concrete foundations. Such a provision might have been applicable to lime concrete, but it was wholly unnecessary in the case of concrete made of silentic or Portland cement, which rapidly became as hard as stone.

Mr. Edmund Woodthorpe said he should be glad to support the vote of thanks to Mr. Hall, knowing the immense amount of labour that he had spent on the subject during the last two years. With regard to the question of lifts, or rather lift openings, he thought that some special attention should be given to the subject, with a view to the prevention of fire. The need of every possible precaution in regard to them had been shown by the disastrous fire in the hotel at New York. Another point needing attention was that where, as was frequently the case in the City, the lower floors were used for the storage of inflammable goods, and the upper floor as a residence for the housekeepers or caretakers, special means should be taken to make that part of the building fireproof, and it should be reached by a fireproof staircase entirely cut off from the warehouse buildings, so as to allow a means of escape in case of fire.

Mr. Arthur Cawston said that when a modern half-timbered building originally erected when there were no other buildings near it needed restoration or rebuilding, it would, perhaps, be desirable only to sanction its rebuilding when there were no other buildings erected close up to it. As to the fronts of warehouse buildings having a certain proportion of brickwork or stone to window openings, why should not such fronts, if necessary, be entirely of iron and glass? He thought the proposal that no external wall should be used as a party-wall, except under the conditions specified in the Institute's suggestions, rather a hard one on the owner of the wall. A great incentive to the spread of fire in warehouse and factory buildings was the use of match-board lining to the walls, with the inevitable hollow spaces behind it. Such walls should always be plastered, or left with the brickwork face.

Mr. Bernard Dicksee suggested that with regard to wooden bay-windows, the County Council might be relieved of a large amount of labour if such windows were allowed to be erected on certain conditions, as, for instance, if they did not come nearer than 10 ft. to the adjoining property, or project more than 3 ft. or 4 ft. Another point that he thought might be introduced into the new Act was that District Surveyors should be given full control over the house drainage, and that it should not be left in the hands of the Vestry Surveyors. Very often the latter knew nothing of drains at all: they were mostly road men.

Mr. Hall explained that in the proposed new Act the drainage, and everything within the control of the house, would be under the control of the District Surveyor.

Mr. Dicksee, continuing, said he thought that the definition of a building in the proposed new Bill was a little too all-inclusive. It seemed to him that it would include everything, from a pill-box to a cathedral. He thought it would include a tent, but he thought that the definition of a building should not cover things of that kind.

Mr. H. H. Statham said he also had some objection to offer to the definition of the term "building," but it was not the same objection as that of the last speaker. He thought that the "suggestions" of the Institute there

was some confusion between the terms "building" and "shed." A "building" was defined as including every erection comprising a cubical space defined by walls, piers, posts or other structures, and a roof or other covering, whether such erection was wholly enclosed or not; and then, later on, it was proposed that "sheds" which were not enclosed, but which were open on one or more sides, might be erected if the roofs were covered with fire-resisting material. What was the differentiation here between "shed" and "building"? And was a "shed" only one of the varieties included under the general term "building"? As to back-to-back houses, which had been incidentally spoken of with favour by one of the speakers, he hoped they would hear no more advocacy of them in that assembly. As to fire-proof construction, he thought a little further definition was required, especially with regard to the mention of stone as a fire-proof material, for although stone would not burn, it would crack and fly. It was also worth consideration whether the use of "oak" beams might not be specified in certain positions, not merely "wooden" beams, for, on the testimony of Captain Shaw, an oak post or beam took a long time to burn through, and although it might get charred on the outside, it would not be consumed, or materially weakened under the action of fire for a long time.

Mr. J. Douglass Mathews said that, with regard to By-laws, there was great danger that they would embody various whims or fancies not at all to be desired in the interests of the public. Mr. Hall had flattered the District Surveyors by proposing to give them a great deal of discretionary power, but they (the District Surveyors) wished to be vested with as little discretionary power as possible.

Mr. Thomas Blashill said that with regard to the proportion of openings to solids in front of buildings, fronts entirely of iron and glass were prohibited because of the danger of the spread of fire. He defended the proposals of the County Council as to space in the rear of buildings, and contended that Mr. Hall's unfavourable illustration was that of an extreme case. Of course the provision of increased space was made primarily in the interests of health. With regard to the definition of the term "building," he did not see why it should not include a tent, because tradesmen and others frequently rigged up tents at the back of their premises, and used them for the storage or exhibition of goods.

Mr. John Slater said it was gratifying to him to find that many suggestions which he had made in a paper he read before the Institute two years ago had been embodied in the Institute's draft Bill. But he agreed with Mr. Statham's criticisms, especially as to fireproof construction, and deprecated the use of iron without fire-resisting casing; and he was convinced that the schedules and definitions would need much more careful consideration.

Mr. T. M. Rickman and the President having made a few remarks, Mr. Hall replied to some points raised in the discussion, and the meeting terminated.

Illustrations.

HOUSES, QUEEN'S-GATE.

THIS is an illustration showing the work that has been carried out in refronting two houses at Queen's-gate, South Kensington, after removing the stucco, cement cornices, and enrichments on the existing front. One has been recessed with red brick and terracotta enrichments, and the other with red brick and Portland stone dressings.

Considerable structural alterations have also been made in the interior of the building. Bath-rooms, lifts, and other modern requirements have been added, and a considerable portion of the old building has been removed from the rear to give direct light into the hall and principal staircase. The stone stairs immediately in front of the entrance-door have been removed, and the hall considerably widened, with a new oak staircase approached through an oak colonnade. The hall and dining-room have been lined with a high wainscot dado. The ceilings to the principal rooms have been enriched with ribs in geometrical forms, supported by deep modelled friezes.

The kitchen has been removed from the body of the building and placed at the rear, with offices adjoining; and a large billiard-room

placed in the basement, having a separate staircase from the hall.

The work has been carried out by Mr. J. Douglas, under the superintendence of Mr. Fred G. Knight, architect.

EAST WINDOW, S. MARY'S CHURCH, LEIGH, LANCASHIRE.

In the principal lights are standing figures under canopies, with small subjects in the bases. A figure of Our Lord in Majesty occupies the centre light, and in the side lights are the four Archangels. The small subjects or scenes below bear reference to the figures above them. Thus, in the centre light is the Resurrection; below the figure of Raphael, "Tobit drawing the fish from the water at the angel's command"; below S. Gabriel, "The Annunciation to the B. Virgin"; under S. Michael is depicted his combat with the dragon; and in the fourth light S. Uriel explains to Esdras his vision. The row of traceries immediately above these lights represent the nine orders of angels, supplemented by virgins. The remaining pieces of tracery are filled with figures of prophets and angels.

The work is broadly treated, as demanded by the scale of the building and the size of the window (the principal lights being over 2 ft. in width), with large masses of silvery-white glass and simple colour. It may be noted that the wings of the Archangels, which come out so darkly in reproduction, are in a pale golden stain.* The artists are Messrs. Shrigley & Hunt, of Lancaster and London, and the drawing was exhibited in the Royal Academy last year.

DESIGN FOR A PUBLIC LIBRARY FOR A COUNTY TOWN.

In this design, the elevations of which were hung in last year's Academy exhibition, the designer sought to get interest and effect out of the necessary features of the building rather than introduce unnecessary ones. The material was to have been red brick and Bath stone, with green slates, finished with a stone ridge. The angle turret at the corner was crowned with an oak and shingle flèche covered with copper. This turret contained the librarian's private stair, which gave him access from his flat on the top floor to the reading-rooms and reference-library on the first floor, to the lending-library on the ground floor, to the caretaker's rooms in the basement, and also into the street. The site was a corner one, with light only on two sides; the back was, therefore, lighted by a long well, and the windows in the front made as large as possible without being unsightly, and glazed with iron casement frames.

A. BARTLETT.

HOUSE AT WOKINGHAM.

This is one of three houses being built at Wokingham. Messrs. Bottrill & Son, of Reading, are the builders, and the architect is Mr. Ernest Newton. The house is built with local red bricks and tiles.

A PAINTER'S HOUSE AND STUDIO.

This is a design for a small house and studio; the house to contain dining-room, drawing-room, hall, offices, &c., and on the first floor, four bedrooms, bath-room, &c. There is no room over the studio. From the verandah there are doors to both studio and drawing-room, so that there should be free circulation at receptions. The approximate cost was 1,500l.

FRED. M. SIMPSON.

COMPETITIONS.

CHACEWATER CHURCH, CORNWALL.—The competition for rebuilding the Parish Church, Chacewater, Cornwall, has resulted in the selection of the designs sent in by Mr. Edmund Sedding, of Plymouth. There were six sets of plans sent in for it, and various were the ways suggested for treating the hideous building, which was erected early in the present century, with accommodation for 1,500 persons. The church has for some time been closed as unfit for public worship, the roof and other parts being in a bad state, so it is intended to commence the work in March.

* All colours tending to yellow or gold are liable to come out dark in photographing.

equally pleasing design. The general contract has been carried out by Messrs. Cubitt & Co.

A visit was then made to the tower and St. Mary-le-Bow, which is now undergoing restoration under the superintendence of Messrs. Tress & Innes. The opportunity of investigating this interesting work of Wren's was much appreciated.

SHEFFIELD SOCIETY OF ARCHITECTS AND SURVEYORS.

The monthly meeting of this Society was held at the School of Art on Tuesday evening last, Mr. Innocent, the President, in the chair.

Mr. W. Randolph read a paper on "Town Churches, Ancient and Modern." He referred to the absence of a matured type of Town Church in Medieval England. Our country churches were adopted fifty years ago as models for the orthodox church of the Gothic Revival. Exceptions in favour of a broader treatment were instanced in the works of Pugin and a few other architects, but no general movement was apparent till about 1850, when both the art and the literature of the Revival began to witness the influence of foreign studies. After dealing with the brickwork and church furniture of North Germany and the Netherlands, the lecturer passed on to English precedents. The last portion of the paper was devoted to showing how the character of church work since the middle of the century had been widened under such influences as had been reviewed.

The lecture was illustrated by photos, diagrams, and sketches.

NATIONAL ASSOCIATION OF MASTER BUILDERS OF GREAT BRITAIN.

This Association held its twenty-eighth half-yearly meeting, in the rooms of the Central Association of Master Builders of London, on Tuesday, the 26th ult.

Mr. J. C. White, of Liverpool, the President, presided, and representatives from London, Liverpool, Manchester, Birmingham, Bristol, Hull, the Potteries, Cambridge, and Preston were present.

The report and accounts for the past half-year were read and adopted.

The following Officers and Council were appointed for the ensuing year:—President, Mr. J. C. White, Liverpool; Vice-Presidents, Messrs. Robt. Dennett, Nottingham, and John Bowen, Birmingham. Hon. Vice-Presidents, Messrs. Stanley G. Bird, London; Robt. Neill, jun., Manchester; and Mr. J. Howard Colls, London. Hon. Treasurer, Mr. Jos. Stevenson Jones, Liverpool. Hon. Auditor, Mr. C. W. Green, Liverpool. Council: Birmingham, Messrs. C. H. Barnsley and W. Sapote; Bolton, Mr. Jos. Hy. Marsden; Bradford, Messrs. William Moulson and William Holdsworth; Bristol, Mr. A. Krauss; Cambridge, Mr. A. G. Bell; Derby, Mr. John Walker; Edinburgh, Mr. Thomas Bonnar; Glasgow, Mr. R. Bennett; Hull, Mr. R. Beevers; Leeds, Mr. C. Tomlinson; Lincoln, Mr. Wm. Hy. Close; Liverpool, Messrs. A. G. White and J. B. Johnson; London, Mr. Thos. F. Rider; Manchester, Mr. Wm. Southern and Alderman Wm. Brown; Northampton, Mr. W. H. Smith; Potteries, Mr. Jas. Bowden; Wigan, Mr. Chas. E. Holmes; and Wolverhampton, Mr. J. Bradney. The Presidents of the Local Associations are also Members of the Council, *ex-officio*.

Several matters of great interest and importance to the building trades were discussed, and the meeting was brought to a close by a vote of thanks to the President.

It was decided to hold the next half-yearly meeting at Newcastle-on-Tyne.

THE ENGLISH IRON TRADE.—The English iron market, although practically unchanged, exhibits a slightly improved tone. The Glasgow warrant-market is dull; but more movement is noticeable in Scotch makers' iron, with most brands showing considerable reductions. In the Cleveland market prices are stronger. The hematite pig-iron trade remains depressed. The tin-plate market is dull. Manufactured iron is only in limited inquiry. The steel trade shows little alteration; the demand for heavy sections of rails is a little fuller. Ship-builders, with the exception of west-coast yards, are quiet. Engineurs are only moderately employed; the strike on the Tyne exhibits no sign of conclusion. The coal trade is rather quiet; the Durham miners are preparing to resist the proposed 10 per cent. reduction.—*Iron*.

THE ARCHITECTURAL ASSOCIATION SPRING VISITS:

THE METROPOLITAN LIFE ASSURANCE BUILDINGS.

The block of buildings in Moorgate-street which has been erected for the Metropolitan Life Assurance Society, from the designs of Messrs. Aston Webb and Ingress Bell, was visited on Saturday afternoon by a large party of members of the Architectural Association, under the guidance of the Junior Honorary Secretary, Mr. F. T. W. Goldsmith, the occasion being the first spring visit of the present session. In the unavoidable absence of the architects, the buildings were carefully described by the Clerk of the Works, Mr. Warburton. These two buildings now occupy the site of three houses which have been removed. The offices of the Society occupy the basement, ground, and first floors of the corner building, and the rest of the premises is devoted to offices, access to the upper portion over the insurance office being gained from Coleman-street, at the back. The principal point of interest in the rooms of the Society, which are fitted throughout with Spanish mahogany, is the graceful design of which is materially enhanced by the high character of the workmanship. The chief office occupies the whole of the front of the corner building with corner

entrances, a smaller room for committees, and two rooms for the actuary and assistant actuary, occupy the remainder of the ground floor. The first floor contains a large board room facing Moorgate-street, with doctor's and dressing-rooms, a small room, and a luncheon-room adjacent. The board-room has a low mahogany dado, and the upper portion of the wall is divided into panels by light moulded plaster ribs, and these panels are to be covered with embossed Japanese paper, which will doubtless give a rich effect. The ceiling is executed in Jackson's fibrous plaster, and the same material has been used in the valances of the windows, of exceedingly delicate design, though the use of the material in this position is somewhat open to question. It is to be hoped that the dummy door on the left-hand side of the entrance is not really intended, and that the balance of the decoration will be maintained without resort to this old-fashioned architectural sham. The barrel-vault shaped ceiling of the staircase, gracefully modelled *in situ* received much attention. The façades of the building have been executed in Portland stone, with polished Cornish granite base, and the elaborate detail of the windows is emphasised by the deep bands of plain surface between them. The treatment effectually disguises the fact of the existence of two buildings. The dreary monotony of Moorgate-street is now broken by this interesting addition to city architecture, and it is to be hoped that this building may be followed by many more of an

For view of the corner building see *Builder* for 17, 1892.

THE INSTITUTE OF BUILDERS.

The eighth annual general meeting of the Institute of Builders was held at the offices, 31 and 32, Bedford-street, Strand, W.C., on Tuesday last, the President, Mr. H. T. Ashby, being in the chair.

The Secretary, Mr. Richard S. Henshaw, read the following report, which was adopted unanimously:—

"1.—The Council have the pleasure to present their Eighth Annual Report, and in so doing regret having to record the death of one of the Members of the Institute, Mr. William Henry Cowlin, of Bristol, late President of the National Association of Master Builders of Great Britain, and a Director of the Builders' Accident Insurance, Limited.

"2. The building trade of the year was seriously interfered with by the prolonged strike and lock-out of the carpenters and joiners, lasting as it did for nearly six months.

"3. The Council in their last Report, stated that they had appointed a Committee to consider the draft 'General Conditions of Contract,' proposed by the Royal Institute of British Architects to take the place of those formally agreed between the Royal Institute and the 'Builders' Society.' The Committee devoted much time to the consideration of the proposed Conditions, and after fourteen sittings reported to the Council, who adopted the report, and forwarded the revised Conditions to the Royal Institute. The Council are now awaiting further communications on the subject.

"4. The Council appointed a Committee to consider the Building By-laws proposed by the London County Council. The Committee formulated their objections to the By-laws and in due course presented them to the Home Secretary.

"5. The London Building Law (Consolidation) Bill, prepared by the Government, is now being carefully considered by the Parliamentary Committee, who will comply with the request of the Secretary of the Local Government Board to report to him the views of the Institute upon the Bill.

"6. The Council have the pleasure to present the audited accounts of the Institute, and the Library and Benevolent Funds for the year 1891.

"7. In accordance with the Articles of Association, the President, Mr. H. T. Ashby; one of the Vice-Presidents, Mr. Robert Scall, Junior; the Treasurer, Mr. G. Plucknett; one of the Auditors, Mr. H. J. Sanders; and four members of the Council,—Mr. John T. Chappell, Mr. W. H. Clarke, Mr. Basil F. Ellis, and Mr. Woodman Hill,—retire, but are eligible for re-election.

Mr. Herbert Henry Bartlett was elected President; Mr. R. Neill, jun., and Mr. John M. Burt were respectively re-elected and elected Vice-Presidents; Mr. George Plucknett and Mr. H. J. Sanders were re-elected Treasurer and Auditor respectively; and Mr. J. T. Chappell and Mr. Woodman Hill were re-elected, and Mr. Benjamin Hannen, jun., Mr. William Scrivener and Mr. G. Williams were elected, members of the Council.

A vote of thanks to the President for his services during the past year concluded the proceedings.

THE LONDON COUNTY COUNCIL:

NEW THEATRE REGULATIONS.

The usual weekly meeting of the London County Council was held on Tuesday afternoon last, the Chairman, Sir John Lubbock, presiding.

Regulations for Ensuring the Public Safety in Theatres.—The Theatres and Music-halls Committee reported that, in the interest of the public safety, they had, after much consideration, drawn up a set of regulations for theatres and music-halls in lieu of those now in existence. These regulations have been framed under the Metropolitan Management and Building Acts Amendment Act, 1878, with respect to the requirements for the protection from fire of theatres, houses, rooms, and other places of public resort within the administrative county of London, and are divided into three parts, viz., Part I., relating to Structural Matters; Part II., General; and Part III., Electric Lighting. It is provided that "these regulations shall, unless otherwise specified, apply to all theatres, houses, rooms, or other places of public resort within the administrative county of London, to be kept open for the public performance of stage-plays, and to all houses, rooms, or other places of public resort within the said county, to be kept open for public dancing, music, or other public entertainment of the like kind, under the authority of letters patent from her Majesty the Queen, her heirs or successors, or of licences by the Lord Chamberlain of her Majesty's household, or by the London County Council, other than letters patent, or licences which may have been granted for the first time before the passing of the above-mentioned Act." The following are the regulations relating to structural matters, in the form in which they were amended and

finally agreed to, *seriatim*, after some discussion:—

"1. **Applications and Drawings.**—Every person who for the first time after the making of these regulations shall be desirous of obtaining a licence to open any such premises within the said County, shall first make an application in writing to the Clerk of the Council for a certificate under the above Act.

Such application shall contain a statement as to the nature and extent of the interest of such person in such premises, and the character of the entertainment for which such premises are proposed to be used, and be accompanied by complete plans, elevations and sections, drawn on tracing linen, to a scale of one-eighth of an inch to a foot; and by a block plan showing the position of such premises in relation to any adjacent premises, and to the public thoroughfares upon which the site of such premises abuts, drawn to a scale of not less than $\frac{1}{8}$ th of an inch to a foot.

Such drawings shall be coloured to distinguish the materials employed in the construction of the building; the width of all staircases, corridors, gangways, and doorways, together with the heights of the tiers, and other parts of the building.

The thicknesses of the walls, and scantlings of the various materials, shall be clearly shown by figured dimensions; and the cardinal points shall be marked upon each plan.

Such drawings shall be accompanied by a specification of the works to be executed, describing the materials to be employed and the mode of construction to be adopted, together with such other particulars as may be required by the Council to judge whether the requirements of these regulations will, when such premises have been completed, have been complied with.

Such drawings shall also show the respective numbers of persons to be accommodated in the various parts of such premises, and the area to be assigned to each person, which shall not be less than 1 ft. 8 in. by 1 ft. 6 in. in the galleries, and not less than 2 ft. 4 in. by 1 ft. 8 in. in other parts of such premises.

"2. **Site.**—One-half at least of the total length of the boundaries of the site of any such premises which consist of an entire building, and in case of a room or other such premises not consisting of an entire building, one-half at least of the total length of the boundaries of the site of the building of which such room or other such premises form part, shall abut upon public thoroughfares, of which one thoroughfare at least shall be not less than 40 ft. wide, and of the remainder none shall be less than 20 ft. wide if a cartway, or 20 ft. wide if a footway.

"3. **Passage or way.**—In compliance with Regulation No. 10, an additional passage or way should be necessary, if may be provided by means of a private passage or way.

Such passage or way shall not be less than 10 ft. in width, and under the complete control of the owner of such premises, and no door, window, or other opening of the adjoining premises shall communicate therewith, or overlook any portion of such passage or way.

"4. **Windows overlooking site.**—No such premises shall be erected upon a site within 20 ft. of any windows or other openings belonging to any other premises overlooking the site.

"5. **Walls.**—All such premises shall be enclosed with proper external or party-walls of brick or stone. The thickness of such walls shall not be less than the thickness prescribed by the Metropolitan Building Act, 1859, for walls of similar height and length in buildings of the warehouse class.

"6. **Dressing-rooms.**—Dressing-rooms shall be arranged in a separate block of buildings, or divided from the place of public resort by party-walls, with only such means of communication therewith as may be approved by the Council.

All such dressing-rooms shall be constructed of fire-resisting materials, and connected with an independent exit leading directly into a thoroughfare or street.

All such dressing-rooms shall be ventilated to the outer air by windows in the external walls.

The walls of all such dressing-rooms shall be hung, for decorative purposes, only with materials completely adhering to the surface of such walls.

No such dressing-rooms shall be situated more than one story below the street level.

Sufficient and separate male and female accommodation, properly ventilated to the outer air, shall be provided for the use of the male and female artistes.

"7. **No theatre under or over any other building.**—No theatre shall be constructed underneath, or on the top of, any part of any other building.

"8. **Number of tiers.**—No such premises shall have more than three tiers or horizontal divisions, including the gallery, above the level of the pit.

Where the front seats of the gallery are separated from the gallery by a partition, such seats shall not count as a separate tier.

"9. **Height of tiers.**—Where the first tier or balcony extends over the pit, stalls, or area, the height between the floor of the pit and the first tier shall not be at any part less than 10 ft., and the height between the floor of the highest part of the gallery and the lowest part of the ceiling over the same shall not be less than 12 ft.

"10. **Floor of pit.**—In all such premises the floor of the highest part of the pit, or of the stalls where there is no pit, shall not be more than 6 in. above the level of the street adjoining the principal entrance to the pit, and the lowest part of the floor of the pit or stalls shall not be more than 15 ft. below such level.

"11. **Entrances and exits.**—Two separate exits, not leading into the same thoroughfare or way, shall be provided to every tier or floor of such premises. If any tier or floor shall be divided into two parts, two separate exits, not leading into the same thoroughfare or way, shall be provided to each of such parts.

Such exits shall be arranged so as to afford a ready means of egress from both sides of each tier or floor, and shall lead directly into a thoroughfare or way.

"12. **Vestibules.**—Where vestibules are provided, not more than three tiers or floors (or where such tiers or

floors are divided into two or more parts, such parts of tiers or floors) shall communicate with one vestibule.

The width of each vestibule shall be at least one-third greater than the united width of all the doorways or passages that lead thereto.

No such openings shall exceed 3 ft. in width and 6 ft. 6 in. in height, and each of such openings shall be closed by a wrought-iron door not less than $\frac{1}{2}$ in. in thickness in the panel, hung in a wrought-iron frame, so as to close without a spring.

No openings formed in the proscenium-wall shall, at the lowest part, be at a higher level than the floor of the stage.

"13. **Proscenium-opening.**—The proscenium opening shall be provided with a fire-resisting screen to be used as a drop-curtain, of such pattern, construction, and material, and with such arrangements for pouring water upon the surface of the screen as may be approved by the Council.

"14. **Roof over stage.**—The height of the wall-plate carrying the rafters of the roof over the stage shall not be less than twice the height of the proscenium, and the height from the level of the stage to the top of the rafters shall be not less than 12 ft. in thickness, and such opening shall be covered with a lantern light, glazed on the top and sides, and be fitted with suitable exhaust cowls.

"15. **Corridors, lobby, passages, and staircases.**—Every staircase, lobby, passage, or passage intended for the use of not more than 100 persons, and all such openings shall be formed of fire-resisting materials and shall not be less than 4 ft. 6 in. wide; but if accommodating a larger number of persons, the width of the accommodation of a larger number of the audience than 100 persons, it shall be increased in width by 6 in. for every additional 100 persons until a maximum width of 9 ft. be obtained.

"16. **Staircases.**—Every staircase for the use of the audience shall have steps turned (the newel posts and spandrel) steps of York or other stone or fire-resisting materials, to be approved by the Council, with treads not less than 11 in. wide and with risers not more than 6 in. high, without winders, in flights of not more than twelve or less than three steps each.

The treads of each flight of steps shall be of uniform width, and be pined into brick walls at both ends. The several flights of such steps shall be supported, and enclosed upon all sides by brick walls not less than 9 in. thick, to be carried down to the level of the footways.

No staircase shall have more than two flights of twelve or less steps each without a turn.

All landings shall be 6 in. thick, be square upon plan, and have brick arches 9 in. deep turned under them in the middle of such landings.

Every staircase shall have a roof of fire-resisting materials to be approved by the Council.

A continuous handrail shall be fixed on both sides of all steps, without winders, supported by strong metal brackets built into the wall.

Such handrails shall be chased into the walls, where the thickness of the walls will permit, but in all cases 6 in. above the top of the steps, the newel posts shall be chased so as to allow the handrail to turn without projecting on the landing.

"17. **Gangways.**—A clear passage or gangway not less than 3 ft. wide shall be formed at the sides and in the rear of the seating in every part of such premises.

Such passages or gangways shall at all times be kept entirely free from chairs, flap-seats, or other obstructions, whether permanent or temporary.

"18. **Ironwork.**—All constructional ironwork in such premises shall be embedded in fire-resisting materials in a manner to be approved by the Council.

"19. **Workshops, &c.**—All workshops, stores, rooms, wardrobe or painting rooms, in connection with such premises, shall be separated from such premises by brick walls not less than 9 in. thick.

All openings in such walls shall be closed with self-closing wrought-iron doors hung in a wrought-iron frame.

All such doors, if consisting of a single fold, shall be made to overlap, when closed, the door frame at least 3 in. and, if made of two folds, such folds shall overlap each other, when closed, at least 3 in. on each side.

All floors and ceilings of such rooms shall be formed of fire-resisting materials.

"20. **Lime-light tanks, boilers, and dynamos.**—All lime-light tanks, boilers with engines, and dynamos with engines shall be each placed in a ventilated chamber or enclosure of proof construction.

Such chambers or buildings shall be separated from such premises, and from each other, by brick walls and fireproof floors without openings, and shall be enclosed upon all sides by brick walls of not less than 9 in. thickness, and shall have floors and ceilings of fire-resisting materials.

All openings from such docks, stores, or rooms shall be closed with self-closing wrought-iron doors, hung in wrought-iron frames.

"21. **Scene Dock.**—All scene docks or stages and property rooms in connexion with such premises shall be enclosed by brick walls not less than 9 in. thick, and shall have floors and ceilings of fire-resisting materials.

All openings from such docks, stores, or rooms shall be closed with self-closing wrought-iron doors, hung in wrought-iron frames.

All such doors, if consisting of a single fold, shall be

* In these regulations the expression "such premises" means a theatre, house, room, or other place of public resort to be kept open for any of the purposes aforesaid.

made to overlap, when closed, the door-frame at least 3 in. and, if made in two folds, such folds shall overlap each other, when closed, at least 3 in. on each side.

22. Enclosures.—No enclosure shall be provided upon any premises where the public can assemble for any other purpose than to view the performance, except so far as the Council shall consider necessary for the provision of refreshment-bars, or, in the case of a theatre, for the provision of a foyer, or smoking-room.

23. Skylights.—All skylights, and the sloping sides of lantern lights, shall be protected by galvanised iron-work, securely fixed on the outside of such skylights or lantern lights.

24. Gas.—All such premises when lighted by gas shall have separate and distinct gas services and meters as follows:—(a) To the stage; (b) To the auditorium; (c) To the staircases, corridors, and exits.

Such meters shall be placed in properly ventilated chambers of fireproof construction.

All gas-brackets shall be fixed without joints; and all burners within reach of the audience shall be fitted with secret taps, and be efficiently protected by glass or wire globes.

All gas-burners within 9 ft. of the ceiling shall have hanging shades of non-inflammable material to distribute the light.

All gas-pipes shall be made of iron or brass. Where there is a stage or wings with scenery, the floodlights or floats shall be protected by fixed iron-wire guards, and the burners shall be provided with glass chimneys.

The rows and lines, and gas-burners in the wings which must commence 4 ft. at least from the level of the stage, shall be protected by fixed iron-wire guards.

All battens shall be hung by at least three wire ropes, and be protected at the back by a solid metal guard, and wire fixed to a stiff iron frame, at such a distance from the gas-jets that no part of the scenery or decoration can be touched thereto.

All movable lights shall be fitted with flexible tubes, and the gas in every case shall be turned off by the tap on the tube, as well as by that on the flexible tube.

All flexible tubes shall be of sufficient strength to resist pressure from without.

An indicating gas-plate shall be provided at a convenient place at the side of the stage.

25. Doors and fastenings.—All doorways used by the public shall be at least 6 ft. 6 in. wide in the clear, with the doors hung in two folds made to open outwards towards the thoroughfare or way.

All internal doors shall be so hung as not to obstruct, when open, any gangway, passage, staircase, or landing.

No door shall open inwards, and shall be fitted with a square landing at least the width of the doorway shall be provided between such steps and such doorway.

All exit doors having fastenings shall be fastened by automatic bolts only, of a pattern to be approved by the Council; but where such doors are also to be used by the public for entrances, they shall be fastened with screw-pieces or lever bolts only, of a pattern to be approved in each case by the Council, and fitted with lever handles at a height of 3 ft. 6 in. from the floor.

All doors used for entrances, and all gates, shall be opened in both ways, and shall, when opened inwards, be locked back against the wall in such a manner as to require a key to release them.

All barriers and internal doors shall be made to open outwards, with no other fastenings than automatic bolts.

No locks, monkey-tail, flush, or barrel bolts, or locking bars, or other obstructions to exit, shall be used on any doors, gates, or barriers.

26. Ventilation.—All parts of such premises shall be so constructed as to be sufficiently ventilated in a manner to be approved by the Council.

All openings for ventilation shall be shown on the plans, and described in the specification, which shall be submitted to the Council for its approval.

27. Warming.—No fireplace shall be formed in any portion of the auditorium or stage of such premises.

All open fireplaces or stoves in any other part of such premises shall be protected by strong fixed iron-wire guards and fenders, part of which may be made to open for all such purposes.

All heating apparatus shall be placed in a position to be approved by the Council, and enclosed upon all sides by brick walls not less than 9 in. thick, and shall be properly ventilated.

All hot-water pipes or coils shall, where necessary, be incased in the walls, or otherwise arranged so as not to diminish the clear width of the gangways.

Where such premises are heated by artificial means, they shall be inadmissible, and either hot-air or the low-pressure hot-water circulation system shall be adopted, throughout the system shall be of galvanised wrought-iron, with the exception of those in immediate contact with the boiler, which may be either of galvanised wrought iron or copper.

The boiler shall be made of wrought iron, copper, or solid steel, and shall be provided with a dead weight or other approved safety-valve, which must be attached to the boiler by an independent galvanised wrought iron or copper pipe, and must not under any circumstances be fixed to the circulating pipes, and must be placed in such a position as will ensure protection from soot and dirt.

The term low pressure shall be understood to mean the pressure due to the vertical head of water between the boiler and the supply cistern.

28. Water supply.—All such premises containing a superficial area for the accommodation of the public of 1000 ft. and upwards shall be provided with a sufficient number of hydrants, each of a diameter of not less than 1 in., to be connected by a 3-in. main with a water company's high pressure street main.

Each of such hydrants shall be provided with at least 30-ft. length of hose, with fittings of the Metropolitan Fire Brigade pattern.

In all such premises, where there is no constant supply of water, there shall be provided on the top of the premises, or at some other place to be approved by the Council, two cisterns, to be kept always filled with water.

Such cisterns shall be each capable of containing at least 250 gallons of water for every 100 persons of the audience to be accommodated in the building.

Such cisterns shall be properly protected from all danger from frost.

Fire-mains shall be connected with such cisterns to hydrants to be fixed in such places and manner as may be approved by the Council.

29. Addition or Alteration to Premises.—Notice shall be given to the Clerk of the Council of any intended structural addition to, or alteration of, any such premises, in respect of which the Council may have granted a certificate under the said Act of 1875, to the effect that such premises were, on their original completion, in accordance with the Council's regulations.

Such notice shall be accompanied by plans, elevations and sections, block plan, and specification of the works to be executed similar to those required in the case of premises to be certified for the first time by the Council, and showing such intended addition or alteration.

The Council will, if necessary, cause a fresh survey of such premises to be made.

No doors, bolts or other fastenings, obstructions to the means of egress, flap seats, or other means of diminishing or stopping up the gangways, shall be put, nor shall any alterations of a like nature be made to such premises without the previous consent of the Council being obtained thereto.

Railway and other Schemes.—On the recommendation of the Parliamentary Committee, it was decided to petition against various railway and other schemes affecting the Metropolis, including the Manchester, Sheffield, and Lincolnshire Company's proposed new trunk-line to London.

Gower-street.—Amongst other recommendations of the Improvements Committee which were agreed to was one approving of an arrangement for removing the bar at the top of Gower-street, so as to open up another direct line of communication between Emston-road and Holborn. The land occupied by the roadway between University College and University College Hospital is, it seems, the property of the Hospital authorities, who are willing to sell it for 15,000*l.* The Council propose to contribute 10,000*l.* towards the cost, the Vestry contributing the remaining 5,000*l.*

After transacting other business, the Council adjourned.

Correspondence.

To the Editor of THE BUILDER.

DR. TEALE ON "DUST."

SIR,—In your article of February 6 upon my lecture at the Society of Arts upon "Dust and Fresh Air," you throw doubts upon some of the points I contended for. Upon these kindly permit me to make some comments.

1. "The windows to be formed with the greater portion fixed, and only a tall, narrow sash hinged to open as a casement, and protected in the same way as closet-doors and boxes." My proposal is,—that, in an ordinary window, one half should be fixed, the other half should open as a casement inwards, but that in the case of a wide window the two outer thirds should be fixed, and the centre third should open on hinges. The casement should not open in one tall piece, but in two portions, or even in the case of very tall windows in three portions, in order to avoid the clumsiness and inaccuracy of the ordinary fittings of French windows. This hinged window is not protected against ingress of wind and soot after the manner of drawers and closets, but by very accurate fittings against a "double rebated frame," after the manner of a jeweller's case.

2. "The adoption of this principle would mean a practical stoppage of direct fresh air through open windows." Not at all. The windows can be opened whenever it is wished to have extra fresh air; as in summer, when few fires are burning, and there is but little soot in the atmosphere. But no one in London would have a window open night and day, because of the dirt and dust; whereas with the "Hardy diffuser" and screen we have virtually an open window, with most of the dirt screened off,—day in and day out, year in and year out.

3. "For the exclusion of dust from the house we think Mr. Teale's method can hardly be regarded as 'within the region of practical politics.'" Well, I can only say that I have had the system practically at work in my consulting rooms and in my lodgings for patients for several years, and that I am quite satisfied as to its value, practicability, and effectiveness. Neither is it very costly.

Let me repeat, what I said at the end of my lecture, my conviction, from long observation, that by far the most serious part of the dirt in a house consists of soot drawn in through the windows.

T. PRIDGIN TEALE.

* * Dr. Teale's letter at all events confirms our opinion that his system of complete dust

exclusion applied to closets and boxes cannot be applied to houses in the same complete manner. Dr. Teale does not live in London; every architect and architectural draughtsman who works in London knows that when the drawing-office windows are opened in summer for air and coolness, there has to be a constant dusting of the drawing-board to keep it clean. Nor do we speak of summer only; windows ought to be frequently opened in winter, and what becomes of straining the dust out? You cannot treat a dwelling-house like a cupboard or a chest.—Ed.

CONCRETE FOR ARTISANS' DWELLINGS.

SIR,—Breeze from gasworks is very far from being the best material for concrete floors, especially of large span, its use being confined chiefly to short spans, with a free use of iron or steel girders. Breeze is improved,—so far as strength goes,—by washing, but it is even then too sandy and deficient in strength to make good concrete. It requires a greater proportion of Portland cement than many other aggregates to make, in comparison, concrete capable of withstanding moderate tensile and compressive strains. Where the materials are of a suitable nature, floors of 12 ft. to 20 ft. span may be constructed in one slab, but a judicious use of iron or steel girders, and spans of 10 ft. or thereabouts,—if the floors are quite flat on the under side,—are the best to adopt in a general way.

Breeze is not a good aggregate for walls, and assuming it was obtainable for nothing, would, if measured by strength, be probably the most costly of any in use.

As there appear to be conflicting opinions with regard to the susceptibility of deal floors laid on concrete to dry-rot, I have sent you a piece of deal, half an inch in thickness, which formed part of a ceiling floor nailed down to concrete nearly eight years ago, and which is as sound now as on the day it was fixed. The advantage of nailing floor-boards to the concrete, beside that of no intervening space for mice and other house pests, is, that much thinner flooring is required, for it is well-known that if supported on joists 12 in. apart, a floor is unsafe when it is worn to about half an inch in thickness, but if laid on solid concrete, the whole thickness is available for wear.

The great point is for the concrete to be thoroughly dry before the floorboards are nailed thereto, but it takes a long while,—months, indeed,—to arrive at a fit condition to case with wood.

My own experience points to forming the mass of concrete at the earliest opportunity, leaving about 1½ in. or 2 in. in thickness of coke breeze (or fine crushed or broken soft brick debris, screened through a half-inch sieve, is quite equal thereto when breeze is unavailable), to be laid down at last and carefully levelled. Even this should have a month allowed it to dry, and be exposed to all the wind and air possible, not covered up, as "Another Surveyor" suggests, which not only retards the concrete from drying, but saturates the wood flooring.

THOMAS POTTER.

Atexford.

SIR,—I cannot see how the 1-in. space, which "Experience" recommends between the floor-boards and the concrete, is to be properly ventilated on the upper floors of an ordinary building. The imperfect jointing of the floor-boards is, of course, what would actually ventilate this space in many cases; but we have no right to trust to this. A few years ago I saw dry rot break out on the upper floors of a building where something like a 6-in. space had been left. The upholsterer had bordered the rooms with linoleum, and the margins went wrong in about three months.

I do see, and have felt for many years, that a layer of either one or more inches of what must be very dirty air is a nasty dangerous thing to live over. You, Sir, dealt with this most trenchantly in your paper at the Health Congress last year, and my heart went out to you for exposing one of my pet horrors; a horror from which hardly any house is free. Our noses are all night long within about 2 ft. of the abomination. Supposing it possible to ventilate the space, it still remains a "run" for vermin and a home for microbes of every sort.

"C. F. M." seems to have gone nearer than anyone else to ridding us of this danger. His 2-in. screed of coke breeze and cement seems to me excellent. Nails can be driven everywhere into it, ordinary inch floor-boards can be used instead of 1½-in. wood blocks (which, spite of all efforts to the contrary, give trouble from shrinkage and absence of nails), and the dirty, stagnant, stratum of air disappears.

I wish the London School Board would give "C. F. M."s" plan a trial in a few of their buildings. A five-years' test in an isolated case is not entirely sufficient.

Of the combustibile character of coke-breeze concrete, I have had, as I stated, ocular evidence. The layer of coke breeze and cement had been carried into the fireplaces, and became almost red hot from the heat of an ordinary fire. The heat travelled *via* the coke breeze through a 9-in. brick

back, and made havoc with the decorations in the adjoining room, the paint becoming completely frizzled. Luckily, the skirting was of cement. So hot was the concrete that, after taking out the stove, nothing could be done for several hours; the concrete would not cool down! It seems to me a farce to call coke and cement fireproof.

"Experience" says that ballast concrete is not fireproof,—and that it is even less so than is the coke mixture. But can he quote any instance in which the latter has been put to the test of a big fire? And is it not well known that the former was so tested at a serious fire in the Borough some few years ago, and that it gave admirable results?

I know Wright's fireproof fixing blocks, having introduced them into quite a dozen buildings. They are much better than wood bricks; they do not shrink; and will, of course, resist fire for a very long time where the wood bricks would not. Did "Experience" ever try how one of these fireproof blocks behaves in a fire? A friend of mine, who received a sample block, had the curiosity,—cruelty, I had almost said,—to put it in the fire, and thus made both fuel and fun of it. Nevertheless, I think them very good things indeed in the right place,—not in the fireplace.

Of course I did not advise that the floor-boards be "cut down" until the concrete was practically dry. What I meant was, that they should be cut down at that stage, and nailed down as late as possible.

"Experience" advises coke breeze instead of coke for the "aggregate." The scaling off, about which I wrote, occurred where coke breeze had been so used.

"Experience" suggests keeping the layer 1 in. down to prevent such scaling. But this means either adding 1 in. to the layer of stagnant air above the concrete, or of making the concrete 1 in. thicker than is actually necessary for strength.

I do not like battening the soffit, but for a good job,—a richer job than artisans' dwellings,—I should always hatten and lath, whatever the concrete; in no other way that I have seen can a fireproof building hope to be at all sound proof. I am afraid, Sir, that when the absolutely solid floor comes into general use our clients will still not be happy, but will say that they preferred the risk of their old condition to living in a sort of drum, upon which every passing footstep overhead heats a tattoo. "ANOTHER SURVEYOR."

February 8, 1892.

MATCH-BOARDING ON NEW BRICK WALLS, AND OAK-BLOCK FLOORING ON CONCRETE.

SIR,—I should be much obliged if any reader would tell me, through the medium of your columns, how long a time should be allowed to elapse before putting match-board lining on new brick walls built in the winter months. The match-boarding is to be kept 1 in. from the brickwork, with perforations to admit air.

Also, how long a time is required for a bed of Portland cement concrete, 6 in. thick and laid on the ground, to become thoroughly dry and fit to receive oak-block flooring? INQUIRER.

The Student's Column.

WARMING BUILDINGS BY HOT WATER. VII.

WATER SUPPLY (concluded). DIRT IN BOILERS AND PIPES. (HORTICULTURAL WORKS.)

THE necessity for a dip or siphon in the cold-supply pipe was pointed out in the last paper, and it was shown how it was effected by merely carrying the service down a few inches below the circulating pipes and then ascending into the under side of the return. This is the most simple way, but does not give very easy access to the dipped part of the pipe if it gets stopped with dirt, as it is likely to do. Some, therefore, prefer to set the pipe as fig. 23; this answers the same purpose and just as effectively, and it is frequently suggested that a plug be put at the point marked *, so that any deposited matter may be easily removed without disconnection of the pipe. This is especially desirable for those works which are fed with surface water.

Occasionally the two methods of dipping the pipe are resorted to as fig. 24. There is, however, but rarely occasion for this.

A very useful appliance for small apparatus is an expansion box end, as fig. 25. This is put at the extremity of the pipes furthest from the boiler, the flow and return being connected at the points shown. This article fills the duties of a supply cistern, a siphon (the connecting-piece which unites the flow and return at their furthest extremities) and a substantial support for the pipes. These expansion boxes are now made in a variety of sizes and styles, but the one here shown, by the enlargement at the top, admits of a hall-valve being fitted

within it, if needed. It should have been mentioned that this appliance also does away with the necessity of an air-pipe that would be otherwise required at that point.

The point at which the cold-supply pipe (from a cistern) is connected into the apparatus is generally near the boiler into the return service. It does not matter much where it is situated, if the apparatus is heating a conservatory or any glass-house without divisions; but

FIG. 23. FIG. 24. FIG. 25.

when there are two or several houses heated from one boiler, the cold supply must be kept near the boiler, as otherwise, in shutting off the circulation from one or more of the houses, we should possibly shut off the water-supply as well, and this would not do.

When means are provided for drawing warm water from the apparatus for watering purposes there must also be some arrangement for automatic self-filling, as it would cause a great deal of trouble to replenish by hand every time the tap was applied to. No doubt this is done sometimes, but the more usual practice is to introduce a hall-valve into the supply cistern, assuming there is a storage cistern somewhere that will furnish the required quantity.

If surface water is used, dipped from a pond or ditch, then the hall-valve and automatic replenishment will probably not be feasible. Of course, warm water for watering purposes need not necessarily be drawn from the apparatus, and there are a number of gardeners, if not the majority, who are averse to it. In drawing water it naturally follows that the pipes are cooled down somewhat by the bulk of cold water that is introduced, and this is an objectionable feature, although care may be used only to draw water in the warmest hours of the day (winter day). A common means of providing warm water is to carry one or two pipes through a tank, and so heat its contents. There is no objection to this method, for although the water in the tank may take a good while to heat, and have a cooling influence upon the apparatus in the first instance, there is but little expenditure of heat when once it is all heated.

It is necessary to notice one particular feature that is manifested when water is regularly withdrawn (which means the frequent changing of the water in the apparatus), and this is the accumulation of incrustated lime deposit that occurs when hard water is used. In the usual way it is soft water, rain-water, collected in tubs or in ponds or ditches, that is supplied to the apparatus, particularly in country places; but in towns, and also when a hall-valve is used, the water supply is generally from a water company's mains. In the southern half of England the water furnished from this source is almost invariably what is known as "hard," that is, having lime in solution. The lime thus held in a dissolved state within it, as a rule, due to the water having originally come from or through chalk strata, and, far from being noticeable, the water is usually conspicuous by its clearness and crystal-like appearance.

This lime or chalk matter (calcic bicarbonate), so soluble in water, is, as before mentioned, quite invisible and unnoticeable to the eye, but when the water is heated, a change in the state of the lime is effected, and instead of being in the fluid or gaseous state just referred to, it, by losing carbonic acid, is at once converted into a visible, hard, and solid substance (calcic carbonate), a sort of limestone. The amount of this substance obtained by heating one charge of water in the apparatus would be scarcely perceptible, and the heating and re-heating of the same water would never result in giving us more; but if the water is changed,—that is, new water introduced,—we get another precipitation of lime deposit when it is heated. By the time the water has been changed a

great number of times the accumulated matter will have become, perhaps, $\frac{1}{4}$ in. or $\frac{1}{2}$ in. in thickness, and unless it be soon removed a fracture will occur in the boiler-plate. The fracture is brought about by the deposit, which is generally very dense and hard, keeping the water away from the iron, and the boiler-plate perishes by the action of the fire. The action of the fire has no ill-effect while water is directly in contact with the opposite side of the boiler-plate; but it has, as every one knows, a rapidly destructive effect upon iron-plate that is unprotected.

It is necessary to speak of this peculiar result with hard water, when water is drawn from an apparatus causing the contents to be frequently changed, for the deposit must one day become of sufficient thickness to do harm if not removed. When it is known that water is going to be drawn from an apparatus, it is usual to order manlids of a proper size and number for the removal of this hard scale, for it may need a tool to be inserted to loosen it, even if an anti-incrustation fluid be used when cleaning it out.

In the worst of cases, however, the hard deposit trouble never assumes the state in these works that it does in domestic supply boilers, for when using these in hard water districts, we get a $\frac{1}{2}$ -in. deposit of "fur" in three to six months; and frequently a boiler will crack, from this cause, within a year, if it is not cleaned out. In horticultural works,—and, in fact, all heating works,—it is best to do without drawing water from the apparatus (except for the periodical emptying and cleaning) if anyway possible.

In concluding the subject of water supply, it remains to be explained that with an apparatus from which no boiler is drawn it is not generally recommended to use a hall-valve to the supply cistern with the view of automatically replenishing the loss of water by evaporation. The quantity of water lost this way is really very small (unless the apparatus happens to be a rather extensive one), and consequently the services of the hall-valve are in very little request. This usually results in it becoming stuck or out of gear by mere want of use,—a weakness that these articles are subject to. Of course, a hall-valve can be used, if looked to now and again, but it must not be implicitly relied upon.

It will be gathered from the information given that the use of surface water, whatever care be used, introduces a deal of dirt matter into the apparatus, and this must be removed periodically. Its removal in sufficient quantity it will bring about the destruction of the boiler-plate, in almost the same way as the hard deposit just referred to.

In a saddle-boiler, which has but one return-pipe entering it at the side, there will always be found a collection of dirt at the bottom, on the side opposite to that which the return-pipe enters. This, it will be understood, is due to the rapid movement of the water keeping the dirt clear at the point where it flows into the boiler, but it thus causes the collection to settle and form on the opposite side, where the action of the water is less strong. When a saddle-boiler has but one return and is fed with water from impure sources, the fracture, when it takes place, will almost always be at the point just explained, and that part of the boiler will be found choked up with dirt.

The dirt will also settle in pipes that are run horizontally; the more horizontal they are the easier for the dirt to rest within them; and the lowest pipes may be expected to have the larger share. This dirt is removed by a periodical flushing of the apparatus, and this suffices for all general purposes, as it is not so inclined to cake and become hard in the pipes as it does in the boiler with the fire acting upon it. Provision is made for this flushing when setting the boilers; pipes being connected into low points of the boiler, which not only admit of the issue of the water flushed through, but also admit of a cane or other instrument being passed in to disturb any sedimentary matter in the boiler that may not yield to the flushing process.

BIRMINGHAM ENGINEERING STUDENTS.—A meeting of the Association of Birmingham Students of the Institution of Civil Engineers was held on the 4th inst. at the Midland Institute, the President, Mr. J. Edward Wilcox, A.M.Inst.C.E., being in the chair. A paper was read by Mr. T. Rooke, Student Inst.C.E., "On the Design and Construction of Dynamos," which was followed by an interesting discussion.

OBITUARY.

MR. M. H. BLANCHARD.—We regret to hear that Mr. M. H. Blanchard, formerly of 74, Blackfriars-road, London, terra-cotta manufacturer, died on the 1st inst., at his residence, Bishop's Walkham, Hants, after three days' illness, of influenza. He was one of the earliest revivalists of terra-cotta, and obtained the prize medal of the 1851 Exhibition for material and workmanship in terra-cotta. He carried out some of the most extensive terra-cotta works throughout the country, including, we believe, the South Kensington Museum and the Horticultural Gardens. His latest novelty was a terra-cotta staircase and floor, which were tested by fire on December 17 last, with satisfactory results, under the circumstances detailed in the *Builder* for January 2 last, p. 18. Mr. Blanchard was born November 9, 1816. His remains were interred on the 5th inst. at Northwood Cemetery.

GENERAL BUILDING NEWS.

PROPOSED RESTORATION OF LICHFIELD CATHEDRAL.—On the 3rd inst. a public meeting, convened by the Dean and Chapter, was held in the School of Art at Lichfield to consider the subject of the needful restoration of Lichfield Cathedral. The Dean and Chapter a short time ago issued an appeal asking for nearly 20,000*l.* for this purpose. About 80,000*l.* has, in past years, been expended on the renovation of the Cathedral, but other repairs remain to be taken in hand, and that without delay, says the *Lichfield Diocesan Calendar*, if the fabric is to be maintained, in some places with safety, in others in its integrity. These are as follows, and they are stated in the order of the urgency with which they are respectively executed:—(a) Structural repair in central tower and spire, parts of which are in such a state as to threaten their stability. (b) Resetting of glass in two windows, with new mullions, and repair of buttresses in Lady Chapel. (c) Restoration to original design of buttresses in south transept, with repairs urgently needed. (d) Renovation of north transept, with fresh windows as originally constructed. (e) Repairs of parapets and clerestory in the choir and Lady Chapel. (f) Repair of north aisle of nave, and other like work elsewhere. Besides these repairs, which press for attention at the very earliest opportunity, the raising of the roofs to the original pitch has been urged by the architect, Mr. J. O. Scott. This operation, which would not in the least degree, it is stated, interfere with the beautiful groining as seen from the inside, would involve probably a further outlay of about 5,000*l.* But besides these external reparations, some outlay in the interior is almost a necessity. A reredos of lasting material, probably of mosaic, ought to be placed in the Lady Chapel; the two western windows in which require to be filled with stained glass in some degree corresponding to the beauty of the other seven. The present doors, fixed inside the three main entrances keeping out draughts, are hardly such as befit the dignity of a cathedral. Proper fittings are required for the prebendaries' vestry and sacristy; and the present music-room would amply repay the cost of opening out its fair proportions. The nave also ought to be seated throughout with oak benches, of the same character as those which are already provided. On the Rev. Canon Lonsdale having entered into an unstated explanation of the work required to be done, Colonel T. J. Levitt proposed:—"That this meeting having had brought before it the present condition of the fabric of Lichfield Cathedral, and the urgent necessity of undertaking its repair, desires to express its earnest hope that the appeal issued by the Dean and Chapter for this purpose may be liberally met throughout the diocese and elsewhere, and pledges itself to do the utmost to support the effort about to be made." The resolution, having been seconded, was carried unanimously. Over 1,000*l.* was subscribed in the room.

NEW SCHOOLS, COLLEGE OF SURGEONS, DUBLIN.—On the 1st inst., the new schools which have been built in connexion with the Royal College of Surgeons, Stephen's-green, Dublin, were opened by the President of the College, Dr. Croly. The schools constitute a new wing at the rear of the College, and include a dissecting-room, a smaller dissecting-room for lady students, a chemical laboratory, and a lecture theatre. The architects were Sir Thomas Deane & Son, and the work was executed by Messrs. H. & J. Martin. The principal dissecting-room is 74 ft. in length by 64 ft. wide and about 22 ft. in height. The roof, of which the central portion is higher and is glazed, is supported by metal columns and beams; it is composed of asphalted concrete and is fireproof. The floor is of concrete asphalted, and is also fireproof. The ladies' dissecting-room is about 30 ft. square. The chemical laboratory is 64 ft. by 28 ft. All the rooms are provided with electric lamps supplied by the Electric Engineering Company of Ireland, and are heated by hot-water pipes supplied by Messrs. Magahey, of Belfast. There is also a bone-room, in which specimens of human bones are preserved for purposes of study, and a lift extends through the

rooms by means of which the dead subjects are raised from a cellar below.

NEW FREE CHURCH, NEAR EDINBURGH.—A new church, to be called the Restalrig Free Church, has just been erected at Parson's-green, on a triangular plot of ground between the Fortholme and Willowbrae-roads. The church has been designed by Messrs. Sydney Mitchell & Wilson, and is in the Early Gothic style. Its length is 100 ft., its breadth 25 ft., and the axis is placed east and west. There being a rapid fall of the ground to the east, advantage has been taken thereof to construct a hall under the main building capable of holding 300 people. The church consists of a nave and aisles, transepts, and chancel. Externally, at the north-east angle, is an oblong tower, with corbelled parapet, over which rises a hexagonal spire. The entrance is placed in a narthex, at the west end of the building, and above it is a six-light window, with pointed lancets and cusped circles. In the transepts the windows consist of five simple lancets grouped under an arch; the aisle windows are small with square heads; and the clerestory range consists of two-light windows arranged in pairs. The chancel is lighted from the south side by a window of the clerestory order. The church is built of red Corsehill stone, and the columns of the nave bays and the sides of the windows are of the same material. The internal walls are plastered and painted,—the upper part of yellowish-green and the under a dull red. The roof is of timber, practically of open construction; the pews are of pine. The aisles, separated from the nave by four bays, are not seated, being used solely as passages. There are no galleries. The chancel is separated from the nave by a carved wooden screen. The lower walls of the chancel are draped with deep blue hangings; on the upper portion the mural decorations are in the same tint as the rest of the church. The pulpit, an octagon of carved wood, is placed at the south angle of the chancel. The church is seated for about 600 people. The heating is accomplished by means of high-pressure hot-water pipes; and the artificial lighting by wrought-iron gas coronae hung from the centre of the nave-roof. In the transepts and chancel there are wrought-iron wall brackets. The bust of the late Mr. Smith, who left funds to defray the cost of the building, has been executed in marble, by Mr. D. W. Stevenson, sculptor. The church has cost about 5,700*l.*

MISSION CHURCH, WESTBURY-PARK, BRISTOL.—On the 6th inst., the Dean of Bristol (Dr. Picon) laid the foundation-stone of a new mission church at Westbury-park. The proposed building will consist of a nave 32 ft. wide and four bays in length, and will provide accommodation for 250 people. The style is to be fourteenth-century Gothic, and the principal feature will be the east window, which will be tracery. The building will be of brown Pennant with freestone dressing, and Brossley tiles will be used for the roof. The side walls will be low, so as to have a high-pitched roof. The church will be heated with hot-water pipes. Provision is made for an extension of the building by the addition of three more bays, and when this is done accommodation will be provided for 500 persons. There will also be a timber porch and a bell-cot added when the extension takes place. The architects are Messrs. Crisp & Outley, of Bristol.

UNITED METHODIST CHURCH, ILLIGAN, CORNWALL.—The new United Methodist Free Church which has been recently erected at Paynter's Lane-end, Redruth, and which was opened on the 3rd inst., stands on a site at the junction of roads leading from Redruth, Pool, Illogan, and Tehidy. The site is the gift of Lord Robartes. The building is in the Romanesque style. The outside measurements are 49 ft. in width by 62 ft. in length, and 27 ft. in height from the floor to the crown of the semi-circular ceiling. The front is of Plymouth limestone, with granite dressing, and the principal features in the design are three deeply-recessed arches supported on pilasters. Under the centre arch there is a bold geometrical window of granite, and the entrance doors, with circular windows over, are in the other recesses; the pilasters and arches are also continued around the sides of the building. The seats are arranged in amphitheatre form, and accommodation is provided at the orchestra end for a large choir and also for an organ, and on either side are vestries for minister and choir. The orchestra is spanned by a moulded segmental arch supported on Corinthian pilasters, the mouldings and pilasters being continued the whole width of the end. The orchestra is lit by two circular-headed windows, and a quatre-foil. The ceiling is segmental, springing from a cornice and frieze moulded into panels. The pews are of red deal framing and pitch-pine standard ends and panelling. The rostrum and orchestra front are of pitch-pine and mahogany. The main entrances open into lobbies, with tiled floors and pitch-pine screens. The cost of the work is about 1,000*l.*, and it has been designed and superintended by Mr. Sampson Hill, architect, of Chacewater, for carpentry and joinery, and Mr. W. H. Gray, of Illogan, for the masonry. The windows of front and orchestra are of cathedral glass, in lead lights, made by Messrs. Solomon & Co., of Truro.

SANITARY AND ENGINEERING NEWS.

SANITARY ASSURANCE ASSOCIATION.—The fifteenth annual meeting of this Association was held on the 8th inst., at the offices, 5, Argyl-place, W., the President, Surgeon-General Cornish, C.I.E., in the chair. Mr. Joseph Hadley, secretary, read the annual report, from which we quote the following:—"The properties inspected and certified during the year have as usual been of the most varied character, and the Council has again to report that in no case of first inspection has the sanitary condition been such as could be certified without alteration, though there is evidence on every hand of continued improvement, and with newly-built property fewer alterations have to be insisted on before granting sanitary certificates." The balance-sheet showed that the income of the year had been 46*l.* 3*s.* 8*d.*, and after meeting all liabilities a balance was carried forward.—On the motion of the President, seconded by Mr. Andrew Stirling, the report was unanimously adopted.—Surgeon-General Cornish and Mr. Henry Rutherford, barrister-at-law, were re-elected members of the Executive Council. The President was re-elected, and Sir Joseph Fayer, K.C.S.I., M.D., F.R.S., and Professor Roger Smith were re-elected vice-presidents.

RAWDON SEWERAGE.—A Local Government Board inquiry was held by Colonel Ducat, R.E., on the 27th ult., into the application of the Rawdon Local Board for the issue of a provisional order to take land compulsorily for sewage disposal purposes. There was opposition from the owners of the land. It is proposed to sewer the whole district of the Rawdon Local Board, and purify the sewage by chemical precipitation, followed by filtration through sand. The area of land required to be taken is 16*ac.* 2*r.* 10*a.* The cost of the works is estimated at from 8,500*l.* to 10,000*l.* Mr. W. H. Radford, of Nottingham, is the engineer of the scheme.

FOREIGN AND COLONIAL.

FRANCE.—Messrs. Dutert, Rauin, Boitte, Formigé, Nénot, and Ancelet have been appointed by the Académie des Beaux-Arts as jurors for the Prix de Rome competition of this year.—M. Hardy, Diocesan architect at Cambrai and Naney, has been appointed Diocesan architect at Limoges in place of the late M. Bailly.—The Société Centrale des Architectes has appointed five members as a Committee of research to study the best lines on which to require a diploma for persons practising architecture.—It is announced as almost certain that the Opéra Comique will shortly be rebuilt on the former site of the Salle Favart, burned a few years ago. The scheme will be submitted to Parliament and can be commenced in two months if approved.—The scheme for the Metropolitan Railway is to be submitted to the Chamber of Deputies early in March.—The death is announced of M. Alfred Arago, son of the celebrated naturalist, at the age of seventy-seven. He was a pupil of Paul Delarocche, and from 1841 to 1852 exhibited various historical paintings. In the latter year he was attached to the Government as "Inspecteur Général des Beaux-Arts," and became a "Chef de Division des Beaux-Arts" in 1870.—The Civil Tribunal of the Seine has given its judgment in regard to the Meissonnier dispute, and has pronounced for the division of his works among the inheritors, and against their sale.—The new Hôtel des Téléphones at Gutenberg is shortly to be opened. The building is entirely constructed of brick and iron.—The well-known pavilion at Saint Adresse, near Havre, successively inhabited by Alphonse Karr, Alexandre Dumas, and Victor Hugo, is in course of demolition.—M. Lambart, the sculptor of the Voltaire statue at Ferney, has offered to execute gratuitously a bust of Louis Favre, the engineer of the St. Gothard Tunnel works. It will be erected at Geneva, opposite the post-office.—A dispute arose last year between the Bishops of Verdun and Saint Dié, about the Joan of Arc monument. The former wished the heroine to be glorified at Vaucouleurs, which is in his diocese, while the latter wished it to be at Domrémy, in his diocese. They have come to an agreement at last on the understanding that there should be a Joan of Arc monument in each town.—The Académie des Beaux-Arts proceeded to the election of a successor to M. Alphand. M. Lafenestre was elected by 20 votes out of 48. M. Michel had 9, M. Georges Berger 6, M. Corroyer 2, and M. Philippe Gille 1.—A competition is to be opened for the pictorial decoration of two new rooms in the Hôtel de Ville at Paris, adjoining the Galerie des Fêtes.

SWEDEN.—The funds accumulated for the building of the new Swedish Houses of Parliament now amount to 300,000*l.*—An aquarium is to be built in Stockholm at a cost of 2,000*l.*—The designs for the new Opera House to be built in Stockholm have been approved by the Crown authorities, some slight alterations having been made in the plans for reasons of greater safety.—Arrangements are being made for the building of a new theatre at Carlstad, at a cost of about 5,000*l.*—A German

COMPETITIONS, CONTRACTS, AND PUBLIC APPOINTMENTS.

COMPETITIONS.

Table with 4 columns: Nature of Work, By whom Advertised, Premium, Designs to be delivered. Includes entries for Public Hall and Offices, Cemetery Buildings, and School Buildings.

CONTRACTS.

Table with 4 columns: Nature of Work or Materials, By whom Required, Architect, Surveyor or Engineer, Tenders to be delivered. Includes entries for Water Supply Works, Sewerage Works, Roadmaking and Paving Works, and various other construction contracts.

CONTRACTS.—Continued.

Continuation of the Contracts table, listing various works and materials with their respective architects, surveyors, and tender dates.

PUBLIC APPOINTMENTS.

Table with 4 columns: Nature of Appointment, By whom Advertised, Salary, Applications to be in. Lists appointments for Surveyor, Assistant in Borough Surveyor's Office, and Assistant Surveyor.

Those marked with an Asterisk (*) are advertised in this Number. Competition, p. iv. Contracts, pp. iv, vi, viii, & ix. Public Appointments, p. xx.

architect, Herr F. Seesselberg, of Veersens, has obtained official sanction to prepare plans, &c., of the Cathedral of Lund, and of two other old churches in the province of Scania. — A monumental chapel is to be erected at Filipstad over the remains of John Ericsson, the famous inventor, the Swedish Riksdag having voted £1,000 for the purpose. — The Stockholm Building Board has elected Colonel A. M. Lindgren its chairman for the current year. The board is most active in enforcing its new regulations. The other day a builder was prohibited, through a report of the Sanitary Board, from letting a house that had not been dried for the stipulated time. — The board of the Academy of Arts to be built in Stockholm has submitted the designs for the building prepared by Professors Dahl and Grundström, and Messrs. C. Miller and E. Lallerstedt, to the Government for approval. The principal façade shows a lofty, imposing, central structure, with two lower wings, rising from a terrace approached by a monumental flight of steps. As regards the interior, the chief consideration has been the exhibition-rooms and the hall for teaching. On leaving the flight of steps referred to, a gallery is entered running right through the transverse section of the building, intended for the exhibition of sculpture, behind which is a smaller one for the same purpose, covered with a glass roof. On both sides of this hall are situated open courts, upon which but other exhibition rooms, stairways, and the hall for teaching. There are in all fourteen exhibition rooms, whereas in the old building there are only two. The great festival hall will be situated on the second floor. — Some more stringent regulations than the present are to be added to the Stockholm Building Regulations, with the object of affording greater protection to men at work on the roofs of houses. Larger and stronger footboards are to be provided, as well as a solid wire rope running along the middle of the roof. — New waterworks are to be constructed in the town of Östorsund at a cost of about £5,000. — A Royal Commission has recommended the painting of three huge wall frescoes in the National Museum, one by Baron G. Cederström and two by Herr C. Larsson, but the subjects have not yet been decided. — Of late there has been considerable agitation in the Swedish press against the paving of the streets of Stockholm with granite, making that city "the noisiest in Europe." Wood-paving is recommended (London being cited as an example) for its noiselessness, durability, and cleanliness. Wood, too, would, of course, be very cheap in Sweden. — The laying down of asphalt on the Vase Bridge has been a complete failure, the company having the work in hand and having adopted a new method as regards the foundation, which has proved worthless. The whole work has to be done over again.

* This last seems an extraordinary recommendation. The one serious objection to wood-paving in cities is its insanitary and dirt-holding character.

MISCELLANEOUS.

SIM'S IMPROVED CASEMENT WINDOW.—This is a form of casement invented by Mr. Sim, architect, of Montrose, which contains an improvement of some importance. Mr. Sim's casement is hung to open inwards, but the bottom rail of the window, when closed, descends below the rebate of the sill in the same way as a lifting-sash window. To open the window it is raised by a handle fixed on the bottom rail, the hinges being specially constructed to allow of lifting, and the sash can then be swung inwards, the weight being taken by a gun-metal plate beneath the bottom corner of the sash, which is also shod with gun-metal. The fastening of the window is also new, effective, and simple; it consists of a gun-metal wedge fixed on the upper part of the vertical rail, which slips behind a spring fixed vertically on the window frame, the wedge driving the spring out a little and being thus securely held between it and the frame. The action of dropping the sash into its place when closed automatically fastens it by this spring arrangement. We have examined only a model on a small scale, and of course the method is open to the objection that the lifting would be inconvenient in the case of a heavy sash of large size; but the objection is not important in regard to house-windows of average size.

A WORKMEN'S SANITARY CONGRESS.—The French labour party have determined that their Ninth Annual and National Congress shall be devoted to the discussion of one single subject. It was, of course, somewhat embarrassing to decide which question should thus be considered, to the exclusion of all others; but it was ultimately resolved to give the preference to hygiene in its relations to the working classes. The debates of the Congress will be divided into three different phases of this great subject. First will be taken the problem of food-supply, especially in reference to the laws of March 27, 1851, and May 5, 1855. The workers will demand that the quality of the bread they eat shall be as carefully guaranteed by the State as the quality of the gold of which the current coinage is made. The second question relates to the sanitation of the worker's home, when the utility will be dwelt on. The last subject is the sanitation of the workshop and factory, when the decree of 1810 will be denounced in no measured terms. According to this law the public are protected against dangerous industries, but not the workers. Thus, lead works are put in the second category, because they do not give rise to injurious emanations, and are only injurious to the workmen themselves. Such will be the general scope of the Congress; but before the delegates of the trade unions and the workmen's societies who form the labour party discuss these problems they will invite the best-known scientific authorities on hygiene to deliver addresses to the

Congress so as to enlighten the delegates as to the technicalities at issue. This precautionary measure is at once as wise as it is modest, and denotes considerable discretion and tact on the part of the workmen. They will find a scientific basis for their demands and make their wants known to men of science. —Lancet.

AUTOMATIC "IN-AND-OUT" TURNSTILE.—Mr. G. Williamson, of Hunslet, Leeds, sends us particulars of a four-armed turnstile so contrived that one arm acts as a coin-freed ingress and the other arm as an outlet, thus requiring only one turnstile instead of two. The ingress arm is locked till the insertion of a coin in a slot, when it opens sufficiently to allow one person to pass, and automatically adjusts itself to the locked position again. According to the description, the other arm can be pushed for an outlet without the necessity of unlocking the ingress arm, and sets itself automatically again to the locked position. We do not see from the description what is to prevent one person inside from opening the turnstile for another outside without the ceremony of putting in the coin, but we have not seen the machine at work; this may be provided for.

GLASGOW BUILDINGS REGULATION BILL.—A sort of small civil war has sprung up in Glasgow over the Town Council's Buildings Regulation Bill. Drastic in its proposals, that measure has seriously alarmed a great number of persons interested in the property of the city, and various public bodies have actively taken part in the fray. The Measurers and the master plumbers, for instance, are for the Council, while arrayed against it are the Landlords' Association, the Institute of Architects, and the Promoters' Committee. So strong, in fact, has been the opposition that the Buildings Regulation Committee have had to yield on a number of points, such as the re-erection of burned buildings, hollow squares, the making of by-laws, the height of buildings, compensation for property taken down, and so on. It is to be hoped that in making the useful concessions to those whose pockets will be affected, care will be taken not to obliterate the good features of the Bill. A measure that will check the jerry-builder and secure proper sanitation should have the support of every loyal and sensible citizen. —Scottish Leader.

LONDON AND COUNTY BANKING COMPANY.—The directors of this Company, in submitting the balance-sheet for the half-year ending December 31st last, report that the net profits of the half-year amounted to 217,239l. 10s. 7d. They recommend a dividend at the rate of 11 per cent. for the half-year, making a total dividend of 22 per cent. for the year. The balance-sheet, which will be found in our advertising columns, was adopted at the annual general meeting of the Bank, held on the 4th inst.

SAFETY OF RAILWAY BRIDGES IN AMERICA.—According to the Engineering Record of New York (January 23, 1892), the subject of railway bridge

LONDON.—For alterations and additions to the Hallwell School, Canning Town, for Mr. West Ham School Board, Messrs. J. T. Newman & Jacques, Architects to the Board, 2, Fenchurch, E.C. 1.

The Builder Cathedral Series.

SERIES of Illustrations of all the English and Welsh Cathedrals is now being published in "The Builder," and will be continued, in the first issue of every month, until completed.

The Illustrations to each can include an exterior view, reproduced from a drawing especially prepared for the purpose; and a ground plan, to a large scale, shaded to indicate the date and style of the several parts.

There is also a short descriptive article, having reference to the Church and its surroundings, with sketches of some of the details, &c.

No trouble or expense is being spared to make this series in every respect artistic and instructive; and as it is cordially offered to all lovers of Ecclesiastical Architecture.

Power Distribution from Central Stations.

At the annual meeting of the Institution of Mechanical Engineers, just held, Mr. Joseph Parry, the Water Engineer to the Corporation of Liverpool, gave some interesting particulars of the recent endeavour of that Corporation to extend the area of operations of the water service by introducing a system of low-pressure power supply. Although the information given by Mr. Parry might have been cast into better shape, it is nevertheless valuable as giving authentic data on ordinary commercial working; which is a very different thing from trial-trip results. It may be stated that the average rate of water supply per head per day, for all purposes, is, in Liverpool, twenty-one and a quarter gallons.

The distribution of power from central stations is the coming engineering problem, or until we extend the "factory system,"—the great modern illustration of the fable of the bundle of sticks,—to the production of power, our civilisation will have lagged behind in one important particular. Efforts are being made in this direction, but on a small and unimportant scale compared with the importance of the subject. Perhaps, however, these tentative methods are the best; certainly they are the safest. No one knows yet which is the best vehicle for power: steam, gas, water, air, or electricity. The New York installation is the most notorious effort made to use the former. Great things were expected of this, but it is a fact that about eighteen months ago there was something very like a howl of public indignation, ascending from the press and elsewhere, against this company; and that the way along the streets was frequently blocked by earth disturbances, which had every appearance of being due to boiling rings, but were in reality, we were informed, simply caused by the disrupted pipes of the steam-supply company's mains. Expansion and contraction of the mains through variations in temperature is a most fruitful

source of trouble in steam distribution: condensation is another. The steam motor, too, gives off heat, and is ill-smelling. On the other hand, when steam has to be the prime source of power there is at least one conversion the less. Steam distribution from a central station does not, however, appear likely at present to be extended in this country.

Gas is, of course, at present the chief agent in the distribution of power from central stations. The great economy of the gas-engine has led to its introduction of late in many situations where a few years back it would have been looked upon as out of the question, even by the most staunch of its supporters for smaller uses. As an instance we may mention that one of the new machine shops at Armstrong's enormous works at Elswick is being run, or, at any rate, was to be run, entirely by gas-engines, and there are gas-engines at work of 170 indicated h.p., the fuel consumption, it being claimed, being equal to 1 lb. of coal per hour per indicated h.p. This, of course, is far ahead of anything yet done by the steam-engine. But these latter cases, after all, do not come under the category of "power distribution," for the engines are mostly supplied with Dowson gas, which, as is well known, is made in separate producers, just as, in the ordinary way, steam for engines is generated from separate boilers. Nevertheless, even when using the expensive illuminating gas of the companies, the gas-engine fairly holds its own in many positions. If the demand ever lead to the distribution of purely power or heating gas, then we may expect to see the gas-engine almost make a clean sweep (and, indeed, many other clean sweeps will be made if that time ever arrive); unless, of course, corresponding advances are made in other quarters. The gas-engine, however, is hot and malodorous, like its brother the steam-motor. It also makes a most irritating noise, and is difficult to start, but improvements have been made in the latter respect of late.

Distribution of power by hydraulic means has been successfully installed, notably in London; but the applications have been chiefly in passenger-lifts and the hoisting of goods. The great thing to be desired in the

application of water power is a means by which the quantity of water used may be apportioned to the load. At present we know of no satisfactory device for compassing this end, or, we hasten to add,—with a wholesome dread of expostulation from the many inventors at work in this field,—we know of no satisfactory device the merits of which have been adequately recognised.

A great struggle has been made lately by the advocates of the compressed-air system; and that struggle has ended in their defeat. Birmingham offers, perhaps, a more favourable field for the application of a power-distribution-scheme than any other town or city in the kingdom, inasmuch as there are more small industries, using small motors, there than in any other equal area. In Paris, the Popp compressed-air system, first started for simply working clocks, has been a success. One chief point against compressed air is that in compression heat is given off, and in expansion heat has to be replaced. This, of course, represents a loss of efficiency, and, in some cases, much inconvenience through ice forming in the engine. In the Birmingham scheme an effort was made to get over this difficulty by heating the air before using by means of stoves which were fed by waste heat. This does not appear to have been very successful, and there were also serious troubles, owing to leakage in mains, due to expansion and contraction. It is but fair to compressed air, however, to say that those connected with the scheme complain that their hands were fettered by official restrictions. Whatever may be the merits of the case in this respect, the Birmingham failure cannot but be a serious discouragement to the advocates of this means of power distribution.

Electricity comes next on our list. Perhaps the easiest thing to say about it at present is that it is too dear; but that is largely due to commercial or financial rather than physical causes. The Liverpool Electric Supply Company offer power at the rate of 5d. per indicated horse-power per hour. Such a price puts electricity out of the running, excepting for very small applications such as those of dentistry, sewing-machines, or other light and delicate applications. It may be said in favour of electricity that there is more

hopes for improvement than in any other of the methods of distributing power above enumerated. We can see nearer to the end with water, steam, air, and gas,—we have named them in what we consider the order of precedence in this respect,—than we can with electricity. There is a vast undiscovered country round which thousands of able explorers are ever wandering, watchful and eager to obtain entrance. Let but one lucky individual, a Thompson, a Crookes, or a Tesla, find the pass, and the armies of applied science will flock in to conquer the domain for the occupation of industrial enterprise. As it stands, however, electricity offers an admirable means of power distribution. So much attention has been directed to its adaptation for lighting purposes, that its perhaps more important function has been neglected. The efficiency of the electric motor is very high, and it is a pity that even such knowledge as we have does not receive more frequent application.

To return to Mr. Parry's paper, which deals with Liverpool in particular, we find that in that city, steam, water, gas, and electricity have all been utilised, to a greater or less extent, for the distribution of power: but, up to the present, only water and gas have found any fairly extended practical application. The figures Mr. Parry quotes were obtained in the course of an investigation he made about two years ago for the purpose of reporting to the Corporation of Liverpool on a proposal of the Hydraulic Power Company to extend their mains outside of an area within which they had been allowed to supply power. Liverpool offers a favourable field for the application of the central station system, more especially in the working of cranes and lifts. The weight of goods handled in one year exceeds 14 million tons, and the work required for this is of an intermittent character.

The number of hydraulic machines now worked by direct pressure from the Corporations mains is 162. The Mersey Dock and Harbour Board have, of course, a system of their own. The majority of these motors are for lifting goods, but organ-blowers stand second on the list, so it will be seen that many of the installations are small; indeed, the total consumption of water per annum does not exceed 125,600,000 gallons, of which 118,000,000 gallons are used for lifts and elevators. The pressure varies from 50 lb. to 80 lb. per square inch. The great bulk of the loading and unloading is still done by steam; but gas-engines are coming into use, and are in some cases taking the place of steam. There are 650 now in use in Liverpool, of which city we are at present alone speaking.

The average amount paid per annum for working a goods hoist from the Corporation mains is 13s., or 10d. per hoist per working day. With an available pressure of 60 lb. per square inch, properly utilised, and at the present rate of 7d. per 1,000 gallons, the cost of lifting is 1d. per 50 foot-tons. In cases where the waste water can be used there is an important saving in this respect; for instance, at the Exchange Station, the Lancashire and Yorkshire Railway Company work elevators and fill the hoilers of their locomotives with the exhaust water. In a table Mr. Parry gives some figures which would be more valuable were there a little further explanation of the working conditions. We are told, however, that in the lifts instanced in this table counterbalance weights are not used, so that the weight of ram and platform has to be added in order to arrive at the gross weight lifted: also that none of the hydraulic machines are fitted with devices for varying the expenditure of water. Proceeding at once to the vital question of money expenditure, we find that, in three cases taken, the cost in lift A is 1-79d. per 50 foot-tons, in lift B is 5-95d. per 50 foot-tons, and in C is 3-05d. per 50 foot-tons. It would have been of value had the author of the paper helped us by some explanation of the vast difference between, say, 13d. and 6d. spent for the same total work done. In the absence of positive information, we can only conjecture that the more

economical lift was working up to or near its full capacity, whilst the wasteful one was very lightly loaded. Thus, if in both cases the lifts were of one ton capacity, and A was taking only one 6 or 7 cwt. bale at each journey, while B was carrying a ton each time, it would approximately account for the difference in economy, for it takes practically as much water to send a hydraulic lift up empty or lightly loaded as when full. That is the chief point to remember in connexion with hydraulic lifts. Of course the discrepancy may have been due to cut leathers, a scored ram, or leaky valves. In that case the waste should be set down to negligence of the user; but when it occurs through light loads it will be inherent in the system, until someone introduces a cheap and practically effective method of apportioning the water used to the useful work done.

Turning to another of Mr. Parry's tables we find the cost given of working warehouse hoists by steam, gas, and compressed air. Here again we have wide variations in charges with the use of the same description of power, any explanation of which we have not been able to find in the paper. A 12 nominal h.p. engine works at the rate of 0-62d. per indicated h.p. per hour. An 8 nominal h.p., at 1d. per i.h.p. per hour. Here is a very wide difference, not to be accounted for by any of the details given. The cost appears to include coal, stores, water, wages, and repairs. It is a great pity, too, that Mr. Parry did not adhere to his original unit of work of 50 foot-tons, instead of complicating the matter by indicated horse-power, in which there are so many uncertain factors, including that totally unknown quantity, the friction of the machine, to be added. The foot-ton is a simple and certain quantity. Two gas-engines are instanced. These cost, respectively, 33d. and 52d. per i.h.p. per hour. Two compressed air-lifts cost 1-00d. and 0-40d. per i.h.p. per hour, respectively. We quote the above figures, because they are the unbiased results of actual commercial working, and will prove useful if taken as rough guides.

There is in the paper another table, in which further information is given of two other gas-engines working hoists. These engines were started in the morning and kept running all day, whether the lifts were in use or not. They were probably engines of the older pattern. The results of five trials are given, and cost for gas varied between 0-285d. per fifty foot-tons and 1-450d. per fifty foot-tons. The economy varied inversely as the total work done, nearly, and we should judge by the figures that by far the greater part of the excess of 50 per cent. of cost (in the latter case over the former) would be done away with if the gas-engine had been stopped and started as the work was required. It would therefore seem that for intermittent work care should be taken to provide a modern, easily-started gas-engine.

Further results of trials made by Mr. Parry have been published as an appendix to his paper. From this we see that in the case of three steam-hoists the best average result was a cost of 0-0689d. per foot-ton; whilst on a gas-engine the equivalent cost was 0-0512d. Here, however, fuller details are required to make an exact comparison.

Finally, Mr. Parry compares high and low pressure water-service for power purposes. Low-pressure (50 to 80 lbs.) water from the Liverpool public mains is charged at the uniform rate of 7d. per 1,000 gallons, whilst the Hydraulic Power Company charge a varying rate for their high-pressure (700 lbs.) water, according to the quantity used: thus, for 1,000 gallons the rate would be 10s. per 1,000, which equals 2l. for the total quantity. Equivalent power from the Corporation's mains would cost 1l. 7s. 2d. For a total of 10,000 gallons (7s. per 1,000) used, the total cost would be about equal as between high and low pressure; but above that, the high-pressure water is cheaper. When we come to 300,000 gallons, the rate of high-pressure water is 2s. 10d. per 1,000. For that total (300,000 gallons) the cost would be

42l. 10s. for high-pressure water, whilst the Corporation would charge 102l. 1s. 8d. for the same power supplied. Mr. Parry's comment on this part of the question may be quoted. "It is obvious that ordinary water-mains laid for domestic and manufacturing services can be utilised only to a very limited extent for power purposes, and that the relatively low pressure they carry cannot be economically applied as a motive power for driving large machinery. With a pressure of 700 lb. per square inch a main 6 in. diameter will carry about 100-h.p. To obtain the same power from a main conveying water at the pressure ordinarily available for town supplies the diameter of the pipe required would be 21 in. Pressure from the mains of corporations and water companies cannot compete with high-pressure water from mains specially laid for hydraulic purposes when the power water is sold at rates not exceeding 3s. per thousand gallons."

THE ORIGINAL DUCAL PALACE AT VENICE.

FROM AN ITALIAN CORRESPONDENT.

THE recent restorations carried on under the guidance of Signor Forcellini, architect, have contributed to spread a considerable amount of new information with reference to the construction and the history of the Ducal Palace in Venice, and have likewise aided Signor Galli in discovering whether, previous to the existence of the present Ducal Palace as it now stands, there was not another in existence, and also what was its form and its site. The study of Signor Galli is very interesting, and the results which he has obtained are calculated to awaken the curiosity of the archaeological and architectural world.

As is well known, the construction of the Ducal Palace at Venice may be regarded as distributed over five epochs: from the time of Angelo Partecipazio (814) to Sebastiano Ziani (1173), from Sebastiano Ziani to Bartolomeo Gradenigo (1340), from Bartolomeo Gradenigo to Francesco Foscarelli (1425), from Francesco Foscarelli to Giovanni Morecenigo (1484), and from Giovanni Morecenigo down to our own time.

During the successive Governments of all these doges, therefore, the Ducal Palace continued to undergo a gradual transformation. Hence the question: How much is there left of the Palace such as it was in the first period? Filiosi, Cicognara, Daru, Selvatico, Zanotto, Lorenzi, Pulin, and all who have written on the subject, held that of the Ducal Palace erected by Partecipazio not a single stone was left, nor can anything about it be discovered.

But now recent observations have completely upset this theory. The façade of the basilica is on the west side of the Piazza San Marco, and further back on the Piazzetta are the "Gran Porta della Carta" and the western front of the Palace. In the rear on the south side of the basilica, between this and the Porta della Carta, extending for a few metres, are two walls forming a right-angle. In the angle, after being converted into a room, was placed some centuries ago the treasury of the church; but there is nothing in the interior to show that that portion of the building was erected to contain it. By careful observation we discover that the wall is thickened in order to make the room square; therefore an old wall existed previously which was not built for the treasury room. Let us hear this in mind. From the exterior we gather other elements which give us ground for belief in the pre-existence of a construction which differed from the present one. The decorated cornices which surround the angle are as ancient as those of the vestibule of the basilica, but their projection shows that they were not placed there before this portion of the building in the eleventh and twelfth centuries (as well as the church) was veneered with marble. Hence the most superficial examination is enough to convince one that this brick-work angle was not originally annexed to the church,—that is to say,

not connected in any organic way with its structure.

We must now trace in the mind's eye the lines of this angle; the walls become delineated, the buildings reassume their shape, and we can imagine that previous to the eleventh century, when the church was in the shape of a basilica, that church was detached from the Palace; detached from the south side, which ran in a straight line; detached from the two chapels (Zen and

built the wall between the new chapel and the angle which was subsequently used for the treasury. Probably it was he who pulled down the thick wall (*ee*) which started from the ducal palace, and stretched straight in front of the original chapel of St. Mark, as far as the basilica. Let us bear in mind the length of this wall (*e*); this same length carried to the wall of the basilica in an eastern direction, gives another side (*mm*), which terminates at the pilaster of the inside southern dome, and previous to the eleventh century formed a part of the wall of the brick basilica. This length, if carried parallel to the first side (*nn*) will meet the thick wall which we saw rising from the sanctuary of the relics, and is a sufficient explanation of it. The remaining side is constructed from the wall (*f a*), which even now enclosed the Palace, and turns at that angle from which we took our starting-point. We thus proceed from the fixed and ancient points, and we have a square. This is the discovery of one of the first portions of the Ducal Palace, and of one of its defences.

Signor Galli says that it clearly follows that the northern wall of the Palace (814) ran precisely on the line which bounds it even now, and leads to the large gate called the Porta della Carta, having joined which it extended to the west, forming a tower. When the church was built (829), dangers from without still existed, internal animosities were still kept up; therefore the defences of the communal palace could not have been diminished. If they were anxious to erect the basilica to the patron saint, "juxta Palatium," how could it be placed up against the wall of the latter? Would not the projecting tower have been an obstacle in the front? It would have been necessary to find some other means; it would have been necessary to place the basilica not along the wall of the Palace, but along the wall of the most prominent part, that is the portion on the northern side of the tower. This explains the line of the whole basilica at a distance from the Palace; here is [where the northern side of the tower stood. The result of the researches in the interior is that the tower must have been rectangular with sides of about 14 metres and an area of over 200 square metres. As to the façade of the Palace,—the one on the Piazzetta,—this appears to have been constructed in two different epochs. The portion from the angle on the quay to the eighth column was built between 1340 and 1370. The portion from the eighth column to the great entrance-gate, or, rather, to the supposed tower, was built by decree of 1422, hence we read, "On March 27, 1424, they commenced to pull down the old palace in order to re-erect it," this being under the Government of Francesco Foscari. Almost sixty years therefore passed, from 1370 to 1424, during which the first portion of the new palace, as it is now seen, and the last portion of the old one, had stood together on the western side.

Let us now glance at the Porta della Carta; its history may be suggestive. Sansovino speaks of this celebrated gate as erected by the Buonos in 1438, but previous to that time did there exist a great palace gate? And what was its position? In order to discover it, excavations were undertaken. These excavations were carried 2 or 3 metres along the front of the column which marked the division between the "new" and the "old" palace, and at a depth of 40 centimètres a pavement was discovered. Signor Galli followed its traces, and succeeded in discovering that that pavement led to a wall the height of which was 2 metres. This is a very important point, and worthy of notice. From the line of the present columns it was 170 metres distant. It was a buttress of oblique wall, consisting of masses of stone taken from the Euganean hills, placed roughly, but regularly, so that it appeared as though intended to serve as a parapet, and to be in sight. It ran towards the north. In front of the fifteenth column (always reckoning from the angle of the quay), the wall turned and crossed the Piazzetta in

an oblique line* towards the Piazzza; but after a few metres it continued on the original line, along the pillars of the portico, passing along the front of the Porta della Carta, and ending at the projection of the angle which now forms a portion of the treasury of St. Mark, namely, the southern side of the ancient tower. In front of the Palace then there was a canal (this canal no longer exists) and the entrance-gate which, according to the most careful observations, must in ancient times have occupied the same position as the present Porta della Carta, and have been provided with a drawbridge.

All this renders it obvious that the arrangement of the Palace must have been originally different from what it is now. As a matter of fact, the researches which have been made to discover the truth of such a supposition have shown that the ancient palace did not possess any projecting portico. A large stone wall was discovered on its outer surface, and filled in roughly, the extremity of which was behind the seventh column, where a much wider pilaster than any other is to be found, and where the above-mentioned canal commenced. The limit of the gate and the height of the wall clearly indicate that before the erection of any gallery or portico that line constituted one of the extremities of the Palace.

To resume, the main dates stand thus:—
814. Angelo Partecipazio builds the Palace.
946. Partially burned under Candiano IV., it was not restored until the time of Pietro Orseolo I. This is the original one restored.
1,000. Deacon Giovanni, speaking of Angelo Partecipazio, says "qui palatii mamentis fuerat fabricator," therefore Partecipazio's Palace in its general formation was still in existence.

1,105. The Palace partially burned was restored by Ordelaaffo Palieri. The restoration refers, therefore, to the ancient remnant.

1,172. Ziani, according to one of the chronicles, renovates and enlarges the Palace, in such a way, adds another chronicle of older date, as to be regarded as the founder; "et fuit tempore sui principatus inchoatum palatium Venetiarum." Therefore, the old palace was preserved down to the time of Ziani, together with the projecting tower, the gate attached to the drawbridge and the surrounding wall, and it was opened to the boats by means of a 7-metre canal (the measurement has been taken from a series of observations which I cannot offer in a brief survey like the present).

Other researches have brought to light that in the space comprised by the transverse foundations,—or, in other words, from the thick seventh column as far as the quay,—there was no palace existing previous to 1173. The older palace ended here; the great stone wall was one of its extremities, as I have observed, and the tower above-named standing within the angle raised on high its castellated walls. The importance of Professor Galli's studies is confirmed (if it needed confirmation) by a manuscript existing at Oxford, and written by three monks of the fourteenth century (English, perhaps), who went from Venice to the East, and on their return home wrote their account of the journey, "qui parole de la grand Armente de Persie et des Tartares et d'Ynde et de grand merveilles qui p. tout le mond aont." In this account they described the Church of St. Mark, the Ducal Palace and the Piazzetta, nor did they forget to put the date, 1360. This manuscript belongs to an epoch too distant from the original Ducal Palace, but in some points it may be considered as precious since it confirms the studies and researches made on the angle wall containing the Treasury, it shows the existence of the tower and a castellated wall, viz., the same one that enclosed the ancient palace of 814. The general external appearance of the original Ducal Palace was that of a very strong castle; nor need we be astonished at this, as in Venice many of the most important buildings had the same

* Our readers should refer to the plan of the Piazzza of St. Mark, but most of them will doubtless remember it.

Putti), which stood on the angle on that side. And is it possible that that angle (*a b*), projecting from the Palace with an immensely thick wall, would have been erected in so much isolation, standing solitary in space, without rhyme or reason? Then, as Signor Galli justly observed, a story told of Candiano IV., flying from the burning Palace, and saved by taking shelter in the court of the church, would be unintelligible: nor would the older chronicles be intelligible, especially the one discovered by Signor Galli as contemporaneous with the foundation of the basilica, which describes it as "Juxta Palatium;" nor other more recent ones,—one, for instance, about Dandolo, in which the basilica is stated to have stood in an angle of the Palace: "in angulo ducalis palatii condita est."

But Professor F. A. Gfrüerer, who, referring to the subjection of Venice to the Byzantines, takes as the starting-point of this subjection the translation (or removal) of the body of St. Mark, on the basis of a statement of Deacon Giovanni considers that the first church of the Evangelist was not a separate building but a part of the Palace, namely, a chapel standing in an angle of the ducal palace. In that case it is certain that the Zen Chapel originally had nothing to do with the present basilica of St. Mark; and it is further certain that originally, not only when the church was enlarged in the shape of a Greek cross, but when built in brick, the site of the present baptistry was either left vacant or contained no buildings annexed to the church. The baptistry owes its origin to the Doge Dandolo (fourteenth century), who must have

appearance, from Ca Foscari and Ca d'Oro of the sixteenth century back to Ca Loredan Da Mosto and Pisaro (later on converted into the Fondaco dei Turchi) of the twelfth century. A. M.

NOTES.

T seems to be a recognised function of the House of Lords to utter from time to time a note of warning on the subject of London smoke and fog, coupled with the suggestion of heroic remedies the adoption of which is to be pressed upon the legislature as a public duty, without much consideration either of the scientific possibilities of the course recommended, or of the practical working of the legislation to be set in operation. Viscount Midleton's speech on Friday the 12th was in the traditional style of utterances of this kind in the Upper House. A Royal Commission was to be appointed (which after many months would probably tell us only what we know already), and the inhabitants of London were to be subjected to a system of house-to-house visitation on the part of officials who were to see that they burned only one kind of coal and used only an approved pattern of grate. Lord Salisbury's comment on the speech was a model of common sense. After drawing attention once more to the fact (which anti-fog agitators apparently wilfully keep out of sight) that the fogs to which London and its neighbourhood is liable arise in the main from natural causes which we cannot contend with, he proceeded to say that—

"He quite agreed with his noble friend that there were certain remedies which might be adopted if they were willing to carry out a particularly drastic line of legislation. By far the most effective remedy they had heard of was that everybody should be forbidden to use any fuel except anthracite coal. The result, however, of such a prohibition would naturally be to increase enormously the price of that class of coal, and likewise to condemn the population to give up the use of open grates. In his opinion, it was very doubtful whether the people of London would condemn themselves and their children to sit by a flameless fire. Such were the difficulties which attached to remedies of this character. He believed that as far as scientific investigation had gone there was not much to ascertain either as to the nature of the London fog or as to the remedies to be applied to it. The main difficulty was political, because they would be requiring from the owners of the million and a half chimneys in London a sacrifice which they could not expect from the people of a free country. Moreover, such a remedy would require the establishment of a gigantic system of inspection. Was it possible to conceive a state of things in which inspectors should be going into every house in London to see whether the grates were properly made or whether proper fuel were being burnt in them? The burden thus entailed upon the inhabitants of the metropolis would be worse than the results from any London fog."

That is the plain common sense of the matter. People are naturally liable, when under the infliction of a London fog impregnated with smoke, to curse their existence for the moment and to feel that "somebody ought to be hanged for this." But if the whole population of London were condemned to sit by black and cheerless fires, under the penalty of an inspector demanding entrance to their Penates at any moment to report them for a fine, we should soon have a more dire outcry on the other side. One course, however, we will suggest, which it may be possible to carry out, which need not involve discomfort or serious expense, and for which it might be practicable to legislate. This would be, to enforce, within the boundaries of London, the use of gas for cooking. A considerable proportion of what may be called "private smoke" arises from kitchen fires, even in winter, and in summer of course they form the principal source of it. The adoption of gas would relieve us from this proportion of smoke, and though it would entail a certain expense in the installation, it is in the long run cheaper than coal cooking, besides having many other advantages in point of convenience. Lord Salisbury would be willing to assent to the appointment of a Committee of the House to consider the question; and if such a Com-

mittee is formed, we commend to their attention the possibility of enforcing cooking by gas, as one practicable method of lessening the amount of London smoke.

SUCH disputes as the London Coal Porters' strike touch the general community more nearly than some labour disputes of far greater magnitude. When supplies of food or fuel are stopped,—as in this case or in that of the great dock strike,—public interest is strongly aroused, and much gratification is felt when the dispute is settled. It is very fortunate that the coal strike terminated so speedily, or the hardships of many in the metropolis would have been considerably aggravated by the return of winter this week, had the strike been prolonged. The work of the railway companies, too, would soon have been seriously hampered by their sidings being blocked with coal. The question at issue seems to have been the now oft-recurring one of whether masters are to have the power to employ free labour or not. No fewer than fifty-nine strikes last year had their origin in the refusal of trades unionists to work with non-unionists, although, of this number, 57.6 per cent. were unsuccessful. The Secretary of the Society of Coal Merchants, in his statement of the causes of the dispute, said that the Committee had always set their faces against any discrimination between unionists and non-unionists; but a clause in a circular issued by him in the name of the Society last week, requesting merchants not to engage anyone unless he could produce a satisfactory reference from his last employer, was regarded by the unionists as a breach of this rule. In fact, peace was only restored on the Society passing a resolution recommending its members to fill up vacancies from the best men who applied, whether they had been on strike or not. A considerable section of the strikers have since been roundly abusing their officers for their efforts in the cause of peace, and for some time they refused to return to work. Of course, the resolution just quoted did not bind the masters to immediately re-instate every man who had left his employment, but this is what the malcontents among the unionists seem to have expected their President to have demanded. The order of the Council for a general resumption of work is being obeyed with such very bad grace that it may be that we are not yet out of the wood in this matter.

THE National Association for the Promotion of Technical and Secondary Education has issued an address to the electors for the new County Council for London. This address points out that the only two counties which are doing nothing for technical education are Middlesex and London, and that the amount of money available for this purpose in London is 163,000*l.* a year. The appeal is well timed, and it is very desirable that candidates should declare their views on this question. It may be doubted whether the money is quite wisely spent by some County Councils: there is a good deal of groping in the dark. But in London the need for technical education is so clear, and it could so easily be carried out, that there can be no doubt that the new Council should at once take up this subject. This object will be much surer of attainment if electors will consider the matter and obtain pledges from candidates. No new rates are required,—the money is ready, and its use for the purpose for which it was intended will conduce to the welfare of London and of its trade. Lord Lingen has, in a letter to the *Times*, endeavoured to excuse the London County Council on the plea that the use of this money for the purposes of technical education was permissive only, and that it was reasonable to throw it into the general funds of the Council. There is no doubt, however, that the Government did intend that this sum should be used for technical education, though they wisely left the matter very much at large, so as in no way to fetter

the action of local authorities. Lord Cranbrook's answer in the House of Lords on Monday last to Lord Cowper's inquiry as to the permanence of this grant indicates plainly that the Government will still continue to make this grant for the purposes of technical education. Under these circumstances it is clear that not only should London follow the example of other local bodies in regard to technical education, but that in those parts of the country where the grant is considered as temporary only, it should be looked on as permanent, and be used accordingly.

THE excavations now in progress on the site of the Athenian Agora seem likely to be productive of unusual practical gain to the community. Dr. Dörpfeld has long had his eye on the ancient aqueduct of Peisistratos, by which water was brought from the Ilissos to the Agora, the supply being rendered available at the so-called Enneakrunos fountain. Four years ago Dr. Dörpfeld pointed out to us *in situ* what,—from somewhat complex *a priori* reasoning, and certain marks of boring in the rocks near the Pnyx,—marks noticeable only to the trained eye,—he believed to be the course of the aqueduct. This belief is now (we learn from the *Athenaeum*, February 13), conviction. During the last fortnight, in digging near the Areopagos, the excavators have come upon a substantial bank of polygonal stonework, which supported the north side of the great Panathenian road. Close to this wall a reservoir has been found, and two or three paces away remains of the ancient aqueduct are to be seen. The modern Athenian has already utilised the water-course of Hadrian, and he hopes to do the like with the ancient aqueduct of Peisistratos. Be that as it may, the discovery both of the lie of the Panathenian road and the position of the Enneakrunos is of the first importance to Athenian topography. Everyone who has mentally, or in print, drawn a plan of the Athenian Agora will have to look to his imaginings if the cold light of fact, and it is not too much to hope that this same cold light may lay for ever the ghost of the "Enneakrunos Episode," which has so long troubled the dreams of archaeologists.

NOT less interesting is the news that Dr. Waldstein has obtained for the American School of Classical Studies at Athens permission from the Greek Government to excavate during a term of seven years the site of Sparta, with Amyclæ and other adjacent Laconian places. If America has lost Delphi, Sparta is a good second in interest. We owe to the neighbourhood of Sparta the unique collection of archaic grave-reliefs, now for the most part housed in the local museum there. Vaphio, near Amyclæ, has yielded the gold cups which have taught us so much that was unexpected as to pre-Dorian art. Popular expectation will look to Sparta for statues of Helen and Menelaus, Leda and the Dioscuri: science will look for the ground-plans of some of the countless buildings, civic and religions, mentioned by Pausanias; also for inscriptions, for votive offerings that will throw some light on ancient pre-historic cults that may tell us of Amyclæ before the Dorians destroyed it, of Hyakinthos who came before Apollo, of Alexandra before she became Cassandra. English and Germans, as well as Americans, will congratulate Dr. Waldstein on his good fortune, and will eagerly look to see where he first puts in his spade.

TUESDAY next is the one-hundredth anniversary of the death, at 47, Leicester-square, of Sir Joshua Reynolds. Most of the houses he occupied in London can yet be traced. After his father's death, in 1746, he settled in London. Returning from Italy at the end of 1752 (see Northcote's "Life"),

* Mrs. Thrale records that Johnson's essay upon Procrastination, in "The Rambler," was hurriedly written in Sir Joshua's parlour. The essay appeared on Saturday, June 29, 1751.

he, by advice of his early friend and patron, the first Lord Edgecumbe, came to town, and lived in a house by St. Peter's-court, on the western side of St. Martin's-lane, over against May's-buildings. Thence he removed to No. 5, Great Newport-street, northern side, originally the central portion of a house since sub-divided into Nos. 4, 5, and 6. The then garden has been covered by a picture-gallery. Here Reynolds raised his charges to twenty-five, fifty, and one hundred guineas for a head, a half-length, and a whole-length respectively. In 1761 he bought a house in Leicester-square, now occupied by Messrs. Puttick & Simpson, the auctioneers. On July 20, 1762, Dr. Johnson writes to B. Retti at Milan: "Mr. Reynolds gets six thousands a year. . . ." Six years later he is knighted, and elected first President of the Royal Academy. The large sale-room at the back of No. 47, Leicester-square, is commonly taken for his painting-room there. But we are authoritatively informed that that apartment was built about fifty years ago, for purposes of the Western Literary and Scientific Institution. Reynolds's studio was a back room, beyond the present lobby, octagonal in shape, and about 15 ft. high. The railings of the main staircase are, we understand, of the painter's time; they are curved out at the foot, to afford more space for the ladies' hooped dresses. This house was afterwards inhabited by the fifth Earl of Inchiquin and first Marquess of Thomond, who, in 1762, had married, for his second wife, Mary, daughter of John Palmer, of Torrington, a niece of Sir Joshua Reynolds first met Dr. Johnson at the house, in what was then Castle-street, Oxford Market, of the Misses Cotterell, and attracted the attention of Johnson (who lived in Castle-street) by replying to the ladies that the death of a friend to whom they owed obligations had, at any rate, relieved them of a burden of gratitude.

THE proposed Berlin Cathedral is again being talked about in the German capital, the interest in the subject having been revived by the Emperor, who has expressed a wish to inaugurate the "Dom" on his first birthday in the new century. Professor J. Raschdorff has, apparently, during the months he has been in oblivion, had some steady work done in the reduction of his last design to a less extensive and cheaper one, and we hear that a very complete set of drawings of this "reduced" scheme will be put before the Prussian Houses of Parliament, when the vote for the first 15,000*l.*, of an estimated total of 500,000*l.* will be asked for by the Government. Of the 30,000*l.* voted some years back for the preliminary office work, some 20,000*l.* yet remains unspent, but this sum is to be applied for the erection of a provisional wooden or iron church, for the use of the Court whilst the cathedral is in course of erection on the site of the present church. The 15,000*l.* referred to above is intended for the preliminary foundation work which the Emperor and his architect would like to see commenced this summer. We, however, scarcely believe that the money will have more chance of being granted this session than in the one of last year in which it was refused. The old objections relating to site, architect, plan, and architecture, are making Raschdorff's Cathedral scheme more unpopular every year, and the provincial representatives in the House are not much in favour of their constituents having to pay for what they regard as an unnecessary luxury in the capital. If the Landtag will not vote the money, and the Emperor wishes to stick to site and architect, he can however still have recourse to his privy purse, or to his power of granting a public lottery.

THE Sandwich Corporation have invited tenders for the construction of an iron swing-bridge,—in place of the present wooden one,—across the river Wansum or Stour. The existing bridge, being opposite to the Davis, or David's, Gate, stands midway

between the ancient ferryway at Key or Fisher Gate (east), and the site of St. Mary Gate (west). The first bridge at this spot was built in pursuance of an Act passed in 1754, and consisted of two arches with a lift-bridge between them. An illustration of it will be found in W. Boy's "History of Sandwich" (1792). In Hasted's "Kent" (1799) the bridge is described as having been "lately rebuilt with great improvements." On crossing the bridge one is in Stonar, the supposed Lapis Tituli of the Roman occupation in Thanet, and sees stretching before him into the distance northwards the straight level road to Ebbsfleet, and so on to Ramsgate. The Canterbury Gate in the walls of Sandwich was pulled down in 1784, and three others shortly afterwards, so that there now remain only the Fisher Gate and the David's Gate with its two conically-roofed turrets,—the one the Barbican, the other the Custom House, a favourite "hit" of old Sandwich.

ON March 21 last we adverted, in a "Note," to the impending demolition of the Skinners' Company's Almshouses (as rebuilt in 1729), founded by Sir Andrew Judd, Knight, in Great St. Helen's. In that same place a fine specimen of our old merchants' houses will soon, in all likelihood, be destroyed; for its site is about to be put up at auction on a building-lease for a term of eighty years, and the materials are included in the letting. The house, marked by its handsome elevation, of red brick, is numbered 8 and 9, in Great St. Helen's, and is that which Sir John Lawrence built in 1640, employing, it is said, Inigo Jones as his architect. The pilasters have stone capitals, the second floor window-sills project boldly beyond the deep vousoirs beneath; on the front are

A L 1646.

In No. 9, are a good mantelpiece, and a handsome Jacobean staircase. Lawrence was elected Lord Mayor in 1664. He erected a white marble altar tomb to his wife Ahigail (1682) in St. Helen's Church; where Judd was buried (1558); and there, against a pillar in the chancel, was set up, over his seat, a carving of his coat-arms. The Grace collection contains a copy of Prattent's small print, 1796, and a drawing, 1856, by T. Hosmer Shepherd, of this house. An adjoining house, No. 10, was, reputedly, a home of Anne Boleyn's father, and is believed to have been one of the oldest private residences of its kind in London. We also find that the lease, for about fifty-two years unexpired, of No. 18, St. James's-square, corner of King-street, was announced for sale by auction at the Mart on Thursday last. Here Lord Castlereagh resided for a while, and on more occasions than one was made to feel his unpopularity with the mob. Converted into residential chambers, at rents amounting to 1,270*l.* per annum, it is now held at a ground-rent of 100*l.* a year.

WE are very glad to see that (as we report in another column) the London County Council propose to acquire power for the decent preservation and protection of York Water Gate, at the bottom of Buckingham-street, Strand, on the edge of the Embankment garden. The neglected condition of this monument has long been a reproach to those who own it or claim to be its owners. There is, it is stated, no "beneficial ownership" in the gate, and this, perhaps, accounts not only for the neglect which it has suffered, but for the fact that it has come down to the present day at all. If the Council acquire the powers they seek, as we hope they will, we trust that their professional advisers will be conservative in their treatment of the monument. From the fact that it is at present partly situated in a hollow, owing to the formation of the Embankment and its garden, it has been proposed to lift the whole thing bodily, but objections more or less weighty have been urged against this course being taken. Without altering the level of the gateway, it might perhaps

be utilised as an entrance to the garden from Buckingham-street. The gateway is generally (and we believe rightly) attributed to Inigo Jones, although it has been ascribed to Nicholas Stone, who was probably only the executive master mason. On this point we may refer our readers to an article in the *Builder* for June 21, 1879, p. 677.

IN his last four weeks' report on the sanitary condition of Kensington, Dr. Orme Dudfield, the Medical Officer of Health for that district, makes some strong remarks, in the spirit of which we entirely concur, in regard to the power still left to the Water Companies, though under certain salutary restrictions, of cutting off the water supply from premises in default of payment of water-rent. Commenting on the clause in section 48 of the new Act, which rules that "an occupied house without a proper and sufficient supply of water shall be a nuisance liable to be dealt with summarily under this Act," Dr. Dudfield observes that,—

"It does seem absurd in these days of sanitary progress, that the Companies should have the power to cut off the supply, and so create a nuisance liable to be dealt with summarily under this Act." The position of the Sanitary Authority, moreover, it being their duty to take proceedings for the abatement of the nuisance thus created,—a duty which in effect makes them the agents of the Company to secure payment of the rate,—is undignified, not to say ridiculous. Surely it is time that steps were taken to correct such an anomalous state of affairs, affecting, as it does, a question of prime importance from the public health point of view."

THE water-supply of Chicago was cut off on two occasions last January, by what is known in America as "anchor ice," which appears to be similar to the "ground ice" of this country. The ice lodged round the intakes in the lake, and in one case the flow of water was stopped until a fire float had cleared the gates by means of sinking hose to the spot and pumping through it. At another intake an arrangement had been specially provided for the purpose. This consisted of a perforated pipe, which surrounded the intake, and by means of which compressed air was forced into the water to prevent ice accumulating. This apparatus is said to have been ineffective, but it is questionable whether the obstruction was not caused by ice piling up round the gates, the water having been very low at the time. In that case the compressed air would naturally have been insufficient.

WE hear that Sir John Codd, the eminent engineer and past President of the Institution of Civil Engineers, has been elected a member of the Athenæum Club under the special rule which empowers the Committee to elect from time to time such eminent persons as they may select for that honour.

THE *Transactions* of the Edinburgh Architectural Association, Part IV. of the first volume, contains a great deal of information about Scotch castles and mansions visited by the Association at different times during the past three or four years, a paper on each being read by the member who conducted the visit. The buildings treated of include the Parliament House and Argyle Tower, Edinburgh Castle; Kinross House, Tullibole House, Drum House, Dirleton Castle, Linlithgow Palace, Norham Castle, Bonhard House, and others.

A NEW monthly review, under the title *Natural Science*, and devoted more especially to biology and geology, is to be issued by Messrs. Macmillan next month.

THERE is to be an International Exhibition this year in the Isle of Maa, of all places. The site is at Belle Vue, near Douglas, and the Exhibition is to include industrial and fine art exhibits, with a special division for "women's industries."

A CORRESPONDENT writes to us complaining very strongly of the absence of attendants at the stalls of the Crystal Palace Electrical Exhibition from whom any information can be got, and the difficulty of persuading the few who are there to give any information as to the exhibits of their firms. The managers of the Exhibition of course cannot exercise any control over exhibitors in this respect. We can only appeal to the exhibitors themselves, in their own interests, to assist the visitors as far as possible by giving information as to the machines they exhibit.

WE wish to call the attention of patentees and inventors who may send us descriptions and illustrations of their inventions for criticism, to the importance of sending technical diagrams (if only sketches) showing the method of working and of construction, especially in the case of patents involving mechanical action. Descriptions of such things are frequently sent to us accompanied merely by pictorial representations, which may do very well to catch the public eye in an advertisement, but which are totally useless in the way of conveying any real information upon which an opinion as to the value of the invention can be formed.

SARACENIC ARCHITECTURE.*

BY PROFESSOR AITCHISON, A.B.A.

THE Saracen architecture of Spain has a double, if not a triple, claim on our attention; it includes the finest early mosque in Europe, whose interior is at once the most striking and unique of modern buildings. This mosque, too, affords us some hints of how, and from what, some of the peculiarities of Saracen art were developed, while the Alhambra shows one branch of Saracen art carried to its ultimate conclusion. We may be proud of that splendid monograph that saw the light through the patriotism of our countryman, Owen Jones, in spite of the discouragement of Government,—I mean "the Alhambra," by him and Jules Goury, though we must not forget the gratitude we owe to Murphy for his work on the Arabian antiquities of Spain.

It is necessary, I think, to say a few words on such parts of Spanish and Saracen history as may enable you to comprehend some of the causes that produced these results, one of which was the falling of Spain under the sway of such patrons of the fine arts as the Omiades.

Those portions of Spain that were held by Carthage fell into the hands of the Romans during and shortly after the third Punic war, and all Spain and Portugal fell into their hands about the time of Augustus, and became a portion of the Roman Empire. Roman towns, with their temples, were built, as well as magnificent villas. Corduba on the Baetis, now Cordova on the Guadalquivir, was called the "Patrician colony," as it was peopled by decayed Roman patricians.

On the conversion of the Roman Empire to Christianity, cathedrals, churches, and monasteries were built there as elsewhere. Spain was afterwards overrun by the Huns, the Swedes, the Vandals, and the Visigoths, the Vandals having left their name in Andalusia. These savages were also converted to Christianity, so there were Roman, Byzantine, and Romanesque buildings, and not to speak of the use made of the columns of these buildings by the Saracens, their ornament and some of their architectural features had great influence on Saracenic buildings. Musa-Ibn-Nuseyr, who is said to have been a descendant of a Christian student of a Nestorian seminary on the Euphrates, and who is well known to us as the principal actor in the story of the "City of Brass," had conquered Barbary, and was invited into Spain in Weld I.'s reign; he deputed his freedman Tariq with a handful of troops to reconnoitre it. Tariq landed in July, 710 A.D., at Cape, now called Gibraltar, from Tariq (Jebel-Tariq, the hill of Tariq), and successfully plundered the neighbourhood. Reinforcements were sent him, and he defeated the Gothic army on the River Guadalete. Malaga and Granada were taken, Cordova besieged, and Tariq proceeded

Cordova Cathedral: Capilla de Villa Viciosa.

to Toledo, then the capital of Spain, which was deserted by all but the Jews, who fraternised with the invaders. In some of the expeditions to the hills the "Table of Solomon" was taken, set with pearls, rubies, and all sorts of jewels, and with 360 feet. Musa landed in 712 A.D., and, with Tariq, proceeded to conquer the remainder of the country; and practically all Spain and Portugal were conquered, except the Crags of the Asturias. Subsequently the Saracens passed the Pyrenees, and took the south part of France, until an Abd-al-Rahman was conquered by Charles Martell (732 A.D.) at the battle of Tours; and subsequently Charles Martell wrested Avignon from the Saracens, and they were driven back to Narbonne. This took place about 737 A.D., in the reign of the Kaliph Hisham I.; subsequently Spain almost fell into anarchy. The Berbers, who came over in large numbers with the Saracens, were looked down on, and so were the new converts, and the old tribal feuds

broke out again. Tyranny was producing its baneful effects throughout the Moslem dominions. An indulgence in luxury, indolence, and dissipation were unfitting the leading families for rule; while able Generals and Governors were murdered, imprisoned, or grossly insulted and degraded by the Kaliphs. The consequences were soon felt; able men were driven into opposition,—a new claimant for the Kaliphate was found in Abul Abbas, "the bloodthirsty," a descendant of the Prophet's uncle, El Abbas, who after the defeat and death of Merwan II. (750 A.D.) became the first Abbasside Kaliph. It was difficult to destroy the main descendants of the Omiades, so an amnesty was proclaimed, and about ninety of them were invited to a banquet and there butchered. The uncle of the Kaliph, the originator of this piece of treachery, with his followers, had a carpet spread over the slaughtered victims, and finished their banquet. This reminds one of Cæsar Borgia's banquet at

LONGITUDINAL SECTION.

Mosque at Cordova.

strongly Byzantine in character, though slightly marked by some foreign influence; and there is a tradition that the Mehrab and its mosaics were done by Byzantine workmen sent from Constantinople. The peculiar cusped arches of the sanctuary, and the Emir's pews (La Villa Viciosa), one tier riding on those below, are possibly original.

San Cristo de la Luz, at Toledo, originally a mosque, has much the same character, with peculiar ribbed domical vaults, like that of the Mehrab at Cordova. The ribs of this last form in plan a Solomon's Seal. The south part of the mosque, with the Mehrab, Maksudrah, and the back chambers, are supposed to have been built between 961-76 A.D., nearly a century after Titlun's mosque at Cairo (878 A.D.). These cusped arches of the Maksudrah and the Villa Viciosa, however, had an important effect on the subsequent Moslem architecture of Spain, for to the last cusping was a favourite device. The ceilings of the mosque were originally of wood, arched, panelled, and enriched with inlay and gilding.

We heard before how the Kaliph Othman built himself a splendid palace at Medina, and every succeeding Kaliph did the same. Moavia's was at Damascus, and that of the Abbassides at Baghdad, and there is little doubt that the Viceroys had splendid palaces at their seats of Government. We know that Mamun held his court at Merv, but probably there is nothing left of any of these palaces. The Spanish Kaliphs were not behind-hand, and the description left us would make us believe that the Spanish one near Cordova was not inferior to the others.

A palace usually included a fortress, round which a town was sure to spring up. This one, called Medinet Azabra, was on the banks of the Guadalquivir, five or six miles below Cordova, was finished in 936 A.D., for Abd-al-Rahman III., and is said to have contained, besides the barracks and a mosque, a mint; coins with this mint mark upon them alone attest its reality. The palace is said to have been 4,000 ft. in length, by 2,000 ft. in width, and naturally consisted mainly of gardens; but 4,300 columns of precious marbles are said to have supported the roofs of its halls; 1,013 came from Africa, 19 from Rome, and 140 were presented by the Byzantine Emperor. The halls were lined and paved with marbles; the roofs were of cedar, ornamented with interlaced work and gilding, but without a trace or an illustration to judge by,—it is mere talk.

The Omiad Kaliphate of the West ended with Hisham III. (1031 A.D.). After that their kingdom was split into pieces, and ruled by independent rulers, was then successively overrun by the Almoravides and Almohades, religious sects almost wholly composed of Berber tribes. Their dominion was, however, brief, from 1073 to 1228 A.D., when Mohammed-ibn-Yusuf-ibn-Hud, descended from the Kings of Saragossa, overcame the Almohades, and ruled for a time over the best part of Murcia, Andalusia, and a bit of Alicante, but the Spaniards were fast narrowing the dominions under Moslem sway.

The first Royal Palace of the Alhambra is supposed to have been built between 1232 and 1272 A.D., by Mohammed Ibn-Yusuf called Ibn-al-Ahmar, who reigned as Mohammed I. of Granada; he was a descendant of Sa'd-Ibn-Obada, one of the companions of the Prophet; he began to reign after the power of the Almohades was broken, and the greater part of Spain had been wrested from the Moslems by the Spaniards, and was a vassal of Ferdinand III. of Castile. His son, Abdallah, Mohammed II., added to the palace built by his father, and is said to have lavished treasures on the artists who decorated its gilded saloons; he died in 1302 A.D., and successive sovereigns enlarged and decorated the palace. I think that it is only necessary to add that Granada was ceded to Ferdinand and Isabella in 1492. If we could learn the studies pursued by the Saracen or Moorish architects, masons, plasterers, and decorators of that day, it would be useful and interesting, but as we cannot we must try and pick up what we can from the buildings themselves.

The hill on which stands the fortress of the Alhambra is now reached by steep but excellent roads, deliciously shaded by overhanging trees, whose foliage is sometimes so dense that the sun does not pierce it, and sometimes sufficiently open to make a spangled pattern on the road, with channels of clear running water on either side. If its fortress be

Singalia, only he did not use his slaughtered victims as a table for his own banquet. Afterwards those that had escaped were hunted down.

The Omiad Abd-al-Rahman, an ambitious youth, and a grandson of the Kaliph Hisham, made his escape by swimming the Euphrates, and got safely into Africa, where he passed some five years, always intriguing for sway when he had a chance, but without success; he was eventually invited to Spain by the followers of the Omiades there, and landed in 755 A.D., and after two successful battles he became the first Kaliph of Spain. His bitterest enemy, the Kaliph Mansur pronounced the highest eulogy on him. On Mansur asking his courtiers, "Who was the greatest man of Islam?" they naturally said "he was," but he replied "No, Abd-al-Rahman is. He was a penniless refugee, without friends or an army, and he is now the ruler of Spain, with the largest revenue of any potentate in the world."

I make a few extracts from an article on the mosque at Cordova by Professor Middleton, in which he gives from Arab sources the eloquent speech Abd-al-Rahman made to his Court, when he was about commencing the splendid mosque at Cordova (786 A.D.). This was to surpass anything before built, and was to be the rival of the Kaaba, and thus save the pilgrims of Spain and Barbary from the tedious and dangerous journey to Mecca. Abd-al-Rahman, after extolling the charms and advantages of Islam over the wretchedness and corruption of Christianity, spoke thus of his proposed mosque:—"We will raise at Ala a shrine only equalled by the holy building at Jerusalem. . . . Let us raise the Kaaba of the West on the very site of a Christian church, which we must needs destroy in order that the Cross may fall amid ruins, and El-

Islam may rise up all radiant. Let its plan be like that of the Basilicas of the Crucified, that the house of God may crush the house of idols. Let it have an atrium, a portico, aisles, and sanctuary, all within an enclosure of four angles, and four sides, like the Holy House of Mecca." The Arab historians say that Abd-al-Rahman took the most enthusiastic interest in his new mosque, visited the works every day, and drew out a great part of the ornamentation with his own hands, and undoubtedly supplied the ancient columns and marbles.

The building of the mosque was carried on by his son Hisham, who devoted his fifth of the plunder of Narbonne and Carassonne to the work; it was completed in 796 A.D., Hisham dying in the June of that year, so it is not certain that it was opened by him or by his son Al-Hakem I. It is said to have cost a million and a half sterling of our money. In it was the Koran, written by the Kaliph Othman, who was reading it when he was assassinated, so that it got stained with his blood; this was torn up by the Christian soldiers, when Cordova was given up to Alfonso in 1146 A.D. This mosque, called Aljama de Medina Andalus, was subsequently enlarged southwards by El-Hakem II. (961-76 A.D.), who built the Mehrab and the Maksudrah, the enclosed sanctuary. The mosque was finished, with its nineteen aisles, thirty-six bays deep, by Mohammed-al-Mansur, the Vizer of Hisham II., though practically the Kaliph, and called Mohammed I., between 976 and 1001 A.D. Supposing Abd-al-Rahman I. was a draughtsman and designer, and did design some of the ornament of his original mosque, I doubt if any of it remains; all the capitals appear to be Roman, Byzantine, or Romanesque; all the ornamentation of the enclosure to the sanctuary and the Mehrab are

The Alhambra: Transverse Section of part of the Court of the Fish-pond (the section to right of the large basin is a repetition of that on the left.

entered by the Gate of Justice, you come on to the unfinished Renaissance palace of Charles the V., with its circular open court or bull-ring, the north side of which touches the Saracen palace. The palace of the Alhambra has the appearance of having been added to at various times; the centre is about 168 ft. north and south, and 107 ft. wide; it mainly consists of a large open court, with a piece of water in the middle, called the Court of the Fish-pond, with cloisters at each end; beyond the north cloister is the Hall of the Bark, a narrow hall like the narthex of a Christian church; this Court of the Fish-pond has no cloisters on its sides, but only suites of narrow chambers; at the back of the Hall of the Bark is a large building, nearly square, 59 ft. long, north and south, 55 ft. wide, forming internally a single chamber, about 38 ft. square, called the Hall of the Ambassadors. To the left of the Court of the Fish-pond is a building about 92 ft. wide, east and west, and 130 ft. long, containing the mosque and its court, and chambers, probably for the Mollahs; there is a niche near the mosque, not shown on the plan; the mosque itself probably had one, but it may possibly have been obliterated by the Christian sovereigns. To the right of the Hall of the Fish-pond, northwards, are the baths and a pavilion for music; and on the same side, southwards, is the Court of the Lions, so called from a fountain supported on the backs of marble lions; this court at the Crystal Palace is about half the size of the original; the court, with its dependencies, is about 103 ft. from north to south, 165 ft. from east to west; to the north of the centre is a projecting building about 63 ft. by 40 ft., containing the Hall of the Two Sisters; opposite in the part already mentioned is the Hall of the Abenserrages.

Aysha and Zoraya, two of the wives of Mulay Ali Abul Hasan, the King or Sultan of Granada, who reigned between 1470 and 1493, quarrelled, and had their partisans; the tribe of the Beni Serraj (the Abenserrages) supported Zoraya, and their head men were said to have been butchered in this hall. The total area of the part of the palace now existing, exclusive of the parts restored or rebuilt by the Catholic kings, contains but 52,625 superficial feet, including the open courts.

We must bear in mind that all the decoration of this palace is in plaster, once painted and gilt, except the enamelled tiles of the dados and floors. It would be very interesting to know what the costly stucco of Othman's Palace at Medina was like, and it is not impossible that, if the Arabs were to allow excavations to be made at Medina, some fragments of it might be found; however, we may

be sure that it bore very little resemblance to that at the Alhambra. The Saracens made great strides in geometry when they began to study it, and may be called the inventors of æsthetic geometry.

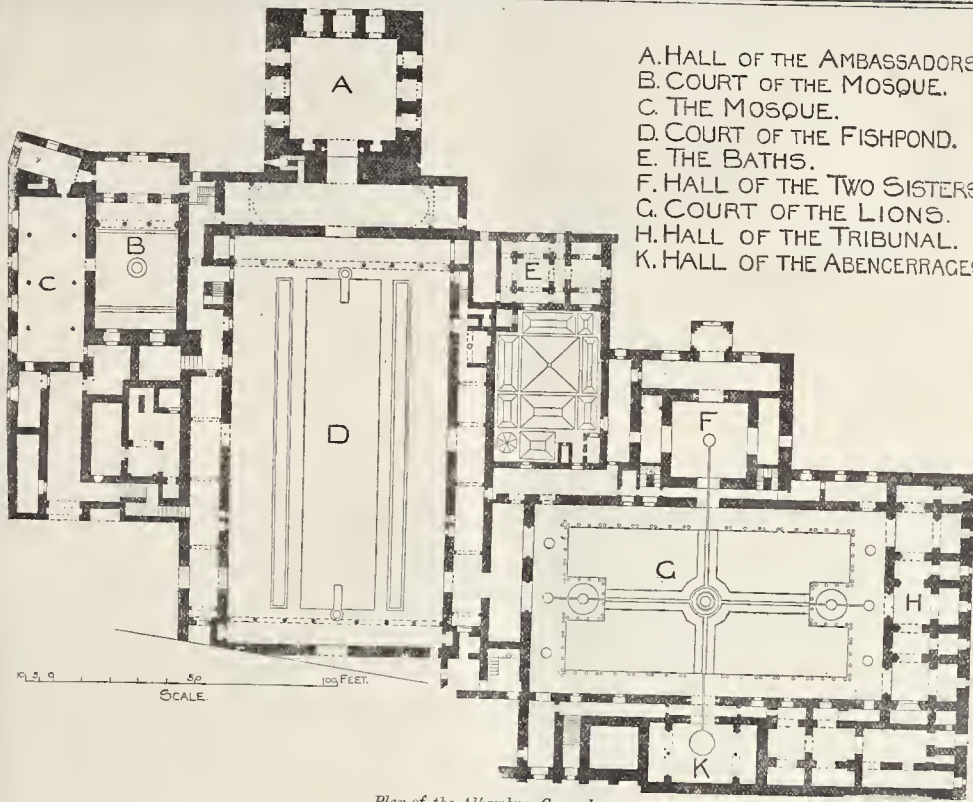

Welid I. (705-715 A.D.) is said to have founded universities, and Cordova was, from the days of Ahd-al-Rabman I., one of the greatest, if not the greatest, university in the world. The main subjects taught, besides Moslem theology and jurisprudence, were medicine and mathematics. Between 808 and 813 A.D. Musa's treatise on quadratic equations was published, and, we may be sure, gave a great impetus to the study of mathematics. Architects are mentioned in the "Arabian Nights," but they are mostly called mathematicians and geometers.

To speak of the architecture of the Alhambra first, although most of us know very little of the requirements of an Oriental palace, we can form some judgment of the skill exhibited in the planning, for when the arrangement is characterised by simplicity, it is the marked attribute of a good plan. The Court of the Fish-pond is adapted to be lined by troops, so as to impress ambassadors, and the narrow vestibule to be passed through would enhance the effect of the hall; while the Court of the Lions, at the end of which the Sultan sat to administer justice, is surrounded by cloisters to afford shelter to the suitors. The narrow passages in front of the other two halls were convenient for their service. There were many reasons for the exteriors of buildings being plain and almost repellant; among so turbulent a people every large building might be wanted as a place of safety in a riot,—it might even have to be used as a temporary fortress; while in the case of the Sultan's palace, the chances of its being wanted for such purposes were at least doubled. But besides this there was a desire not to provoke envy; the effects of the evil eye were greatly dreaded by every Moslem, so we can only expect to get architectural fronts in courtyards, and these are generally well, and sometimes elegantly, proportioned. The front of the cloister at the north end of the Court of the Fishpond is particularly graceful. There are the six slender white marble columns, and the two half ones carrying elegant arches only just pointed enough to prevent their looking flattened, delicately cusped and gracefully corbelled out beyond the piers on the capitals, and with a vertical panels from the columns, held together by a horizontal band below the frieze; the spandrels and upper part above the arches are dispersed; while the centre arch is wider and stilted, runs right up to the horizontal band,

and has floral spandrels of much smaller pattern than the diapers, but overlaid by a very large scroll. There is very little architecture in the world that would take the palm from this, merely looked on as a piece of proportion.

The proportions of halls are to our eyes rather excessive in height; but we not only have to consider the need of air in a hot climate, but the passion the natives had for a "mighty contiguity of shade." In the Hall of the Ambassadors, however, the width is but three-fifths of the height. The borseboe arch, supposed to be an invention of the Eastern Christians, but said to be found in the Pantheon at Rome, is mostly abandoned, or is so slight as to be imperceptible except in the case of the niche, where it is possibly kept from religious conservation or from a cherished recollection of the great one at Cordova, then in the hands of the Christians. The capitals of the columns are original and graceful inventions,—not equal, I admit, to good floral capitals of the Greek, Roman, or Renaissance artists, but superior to most, if not to all, Gothic ones. The capitals are mostly cushion-shaped, but the stalactite ones are an original creation of the Saracens, which are not so interesting, but have a better outline. I must confess that the stalactite arches and domes with their vague outlines do not excite my admiration, and though I am astonished at the domes, I hate their maddening complexity, and their trick of looking without support. Gothic stone pendants are certainly not more agreeable to look at, but they have the merit of being really constructive. Doubtless, the vagueness of outline in the stalactite arches and domes, and their complexity and mystery, had a charm for the Oriental mind. The Western Medievals were certainly saturated with Saracen thought, work, methods, and manufactures, and they loved complexity, and had learned, most probably from the Saracens, that marvellous effects could be got by the ordered repetition of simple parts. The Saracens were never masters of profiling, and the Spanish ones never admired a firm outline. We see as early as the great mosque at Cordova how fond they were of ugly cusped arches,—cusped, too, on the intrados and extrados, and intersecting one another. At the Alhambra, this passion is carried to excess. The outlines, it is true, are not so ugly as those at Cordova, but they lack the barbaric vigour, and sometimes are almost as imbecile as the ornamented mouldings that are put in modern pianos.

It is impossible to speak of Saracen decoration without considering its colour, for it was made for the colour, and without it is but poor stuff. I will first speak of the tile dados:

- A. HALL OF THE AMBASSADORS.
- B. COURT OF THE MOSQUE.
- C. THE MOSQUE.
- D. COURT OF THE FISHPOND.
- E. THE BATHS.
- F. HALL OF THE TWO SISTERS.
- G. COURT OF THE LIONS.
- H. HALL OF THE TRIBUNAL.
- K. HALL OF THE ABENCERRAGES

Plan of the Alhambra, Granada.

these are mostly bad; they have all the faults of oddness or complexity of pattern, without being redeemed by the colour, though there are a few almost wholly made up of blues, greens, and white, with a touch of yellow, which fall just short of being delightful; and there are a few pieces of tolerably agreeable colour, with quaint patterns that are certainly striking. One of these patterns is made up of a sort of rough sketch of a swallow flying, seen from underneath, and this 'nit' is used in pairs, kissing; one pair is green and one black, or dark blue, on a white ground; one pair has the lines of the wings horizontal and the other has them vertical. Admirable borders are made of black bearded hattlements on a white ground, and there are some very pretty ones made of texts from the Koran, cut in black tile and inlaid on a white ground.

The ornamental plaster-work is made up of checkers and curious Saracen geometrical forms, sometimes over scrolls and sometimes merely filled up with flowers and leaves in low relief, with diapers superposed, sometimes many deep; by the apposite juxtaposition of blue, red, and gold, the two former tempered with white, the whole mass at a certain distance forms a warm grey, a blue grey, or a red grey, and when you are slightly closer the least change of position brings out a new pattern of a different colour, in a way that is absolutely magical. On a sunshiny day I could watch the changes of pattern and tint at the Alhambra Court of the Crystal Palace by the hour.

The main ideas that underlie Saracen decoration seem to me to have been two-fold—what may be called a poetical passion for flowers, and an intellectual interest in the creation of new geometrical forms, too often of maddening intricacy. It seems natural that people who came from sandy deserts should passionately admire flowers, and even if the decorators themselves had never seen a desert, their constant perusal of the Koran would suggest it; for besides the black-eyed honris of paradise, there is a constant reference to gardens with rivers flowing beneath them, to shady trees, to flowers, and fruit. Where the flowers, plants, and fruit they chose to copy or conventionalise

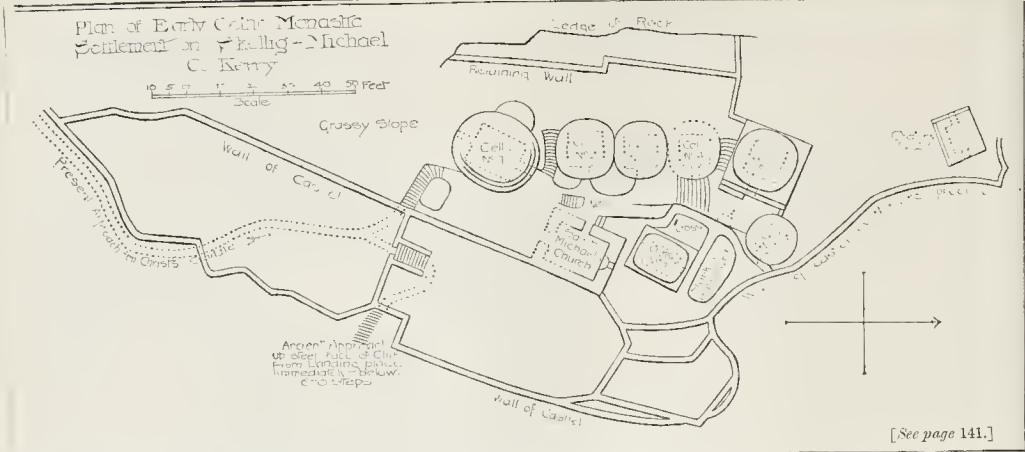

came from, I know not, but the bulk of them are like nothing else one has seen, and no travelled botanist seems ever to have attempted a solution. It is only natural that the Saracens, who had made great advances in geometry, should have delighted in their own geometrical puzzles, for though they cultivated their intellect at the expense of their taste, they had an excellent excuse. No mosque could have in it the representation of any living thing, and no pious Moslem could tolerate such representations in the decoration of his house, furniture, or utensils, so architects and decorators must have been hard put to it to gratify their employers' taste for richness and magnificence. They might, it is true, have elaborated a new system of floral decoration, though hitherto that has been dull when not associated with animals or man, but they took up with studies that were rather intellectual than artistic. They found the solution of these problems in aesthetic geometry, and this, to some extent, supplied the want of the human figure, for the beholder, when tired of the mere gorgeonsness, could endeavour to solve the geometric puzzle. When once the Saracens had started on this line, there was the pride of the inventor on the one side, and the pride of the possessor in having a new invention of his own race, on the other. If these geometric ornaments had been much nglier than they are, the Saracens could have made Touchstone's boast,—“An ill-favoured thing, Sir, but mine own.”—just as some people in England admire the engine-turning of a watch, and think it is artistic ornament. Their ornament seems to me, as a rule, to treat floral forms in a coarse and commonplace way; there is none of the style and precionsness of nature in them.

The best Greek, Roman, and Renaissance sculptors and decorators extracted, as it were, the essence of floral beauty, while I have never seen a single piece of floral ornament from the Alhambra,—except, perhaps, the capitals,—that I should care to possess. It must, however, not be forgotten that the object was to make a snpth mass of coloured decoration, so that if we merely look at the ornament as means to an end, elegance of floral form was of secondary

importance. As a mass, however, these forms occasionally have a very bad fault,—they look as if they were crawling, which is as agreeable to look at as a pan of live eels. Some of their patterns, however, are superb, both in composition and colour. I may instance that on the panels of the Hall of the Ambassadors, composed of two similar meanders reversed, touching one another and interlacing; the pointed ovals formed by the meanders have heart-shaped pieces at the bottom from which spring two of those Saracen twin leaves, the upper leaves having scrolls; a single leaf springs from each of these, crosses the meander and goes into the adjoining heart; in the space of the oval thus left is a reversed shield covered with floral ornament on a small scale; the bands of the meander have wide edges, and the centre is filled in with a text in cursive characters; the whole ground is red; the grounds of the meanders, shields, and leaves are blue; the leaves are ribbed, and all the inscriptions, ribs, and patterns on the shield and edges of the meanders are gold. The branching leaves hind each alternate oval together and break up the monotony of the meander, and the whole is a broken surface of gold and blue, with a few hits of red as jewels; while the hearts, the top of the oval, and a piece of the shield are of massive gold. Naturally imitation has had a great deal to do with the emergence of their style of ornament; the strongly-ribbed leaves of Byzantine carving seem to have taken the fancy of the Saracens; almost all underlying leaves are so treated, and some look as if these were meant for the edges of leaves not yet quite unfolded; these edges or ribs are blue if the leaf is white, but if the leaf be red or blue the ribs are gilt, thus texture is got, and also those broken bits of colour which are very valuable as contrasts to larger masses of pure colour and gold.

The Byzantines seem to have taken a good many interlaced patterns from the ropes and wickerwork of the Northern nations, besides those they had from Greece and Rome; these were greatly adopted by the Saracens, and were made more intricate.

I mentioned that in the great mosque at Cordova the arches were mostly rusticated by

[See page 141.]

projecting stone voussours alternating with red brick, the ornament being confined to the stone rustications. This characteristic method of decoration is continued at the Alhambra, only the ornament is pure Saracenic and is applied to every voussour, as may be seen in the flat arches of the court of the mosque. The horseshoe arch of the niche has every voussour carved, and their circular heads form the cusping of the extrados of the arch, the intrados being ornamented with crockets, and the whole was painted and gilt.

The later Saracens of Spain had no feeling for plainness, nor did they appreciate its value in heightening the effect of the ornamented parts, as the Greeks did; for every square inch is covered with ornament, except the marble shafts of columns, which were gilt; but they understood the value of gradation better than any other people have done.

Considering that by their religion the Saracens were debarred from using human or animal forms, we must admire the consummate art with which they covered the whole of their interiors with arabesques, and yet varied the patterns and relief so that the patterns fulfilled the duties of separation and prevented the eye from being satiated and disgusted with their monotony.

Little as I admire their stalaecties, it must be admitted that by these they were enabled to accentuate certain parts, and thus redeem the whole from distressing uniformity of relief. Hate Saracenic ornament as you may, every glint of decoration must admit that the Saracens knew every trick of the trade,—large surfaces of flat ornament are redeemed from dulness by projecting shields or panels, whose ornament is large enough to give a marked preponderance of accent. I believe they were the inventors of superposed ornament, which was used with such effect in inscriptions, and you may note with what art they used the different sorts of writing. A band of the stiff and monumental *Cufic* is often followed by another in the African or in cursive letters. I should only weary you if I attempted to describe the thousand devices by which they secured the desired effect. One phase of the subject has particularly struck me,—the enormous variety of patterns and ornament. It seems unlikely, if not impossible, that any body of men could be gifted with so much off-hand invention. We may be sure that these fighting despots, whose power and life were held by the slightest tenure, were not to be put off by the architect, mason, plasterer, or decorator saying he had to design the building, the construction, the carving, the plastering, or the painted ornament. The Sultan, or ruler, or captain probably sent for the architect at his sitting in the morning, gave him a sheet of parchment, and told him to make his design then and there, and if it was approved, a sum of money was handed to him, and he was told to hire men, and to begin at once: probably to carry on the work night and day. I imagine that the palaces built in one night by Jims, Ons, and Marids were suggested by this practice. The same thing possibly happened to the plasterer, the painter, and the goldsmith who did the gilding, only the employer probably did not have a design, but merely mentioned the sort of effect he

wanted. Yet the decoration of each hall must have been under the guidance of one master mind; it could not have been done in pieces haphazard. The whole of each hall is so designed as to be properly effective as a whole, with certain parts more accentuated than others; I therefore come to the conclusion that the decoration of halls like those of the Alhambra, though probably on a smaller scale, was common; that the master plasterer had one or more designs for halls of a certain size and character, and that he had a staff of men who knew the exact relief required for each part, and that he worked in conjunction with a master painter and goldsmith, who also had staffs who knew exactly what ornament, and what colours, and what gilding to use to this particular plaster pattern. Some of the patterns of the plaster-work may have been kept in stock, but this cannot always have been the case, for some were evidently carved. We see the slabs put up, with the main lines of the patterns only marked on them, in the Court of the Lions and elsewhere.

The late Mr. Lundgren, the artist, told a curious story about plastering. He went to India after the Mutiny to make sketches of the natives, and while in the Punjab with his interpreter, they went into an unfinished tomb for shelter from a storm; the ceiling appeared to be just plastered, and there was an old tub in the tomb; a man with three laths came in and measured the length and breadth of the tomb, he then got on the tub, broke the ends of the laths into different shaped points, and set out some triangles on the ceiling; he then began at one end and modelled with the laths a most elaborate floral pattern in the wet plaster. Lundgren stayed there till the plasterer left, and told his interpreter that this plasterer was the cleverest man he ever met with; the interpreter said, on the contrary, "He is an idiot." Lundgren replied, "I have been a painter for forty years, and I could not do such a thing straight off." The interpreter said, "His father was a clever man,—he could do five patterns; he had three sons,—one could do three patterns, one two, and this idiot could only learn to do one." On this, Lundgren said, "Oh! if he has been all his life doing this one pattern it is not so extraordinary as I supposed."

Illustrations.

STAIRCASE, RENISHAW HALL.

RENISHAW HALL, Derbyshire, originally built in Elizabeth's reign (about 1600), was largely added to at the beginning and end of the eighteenth century. It has always belonged to the Sitwells, the present owner being Sir Geo. R. Sitwell, Bart. The new staircase is erected in the room to the left of the hall, which was originally, probably, the huttery, the staircase being formerly where the drawing-room corridor is now. The walls of this corridor and the ground-floor walls of staircase hall, jambs of arches, &c., are panelled in deal painted white. The staircase itself, including the panelling up the stairs, and on the first floor, &c., is of oak. The door (existing) seen

through the arch on the first floor, has new pediment, &c.; it leads to the private drawing-room over the library. The hall is paved with 14 in. squares of black and white marble; the hearth and between the arches being small diamonds of the same materials.

The deal panelling was made by Mr. Geo. Stevenson, of Ekeington; the staircase, &c., by Mr. Franklin, of Deddington, Oxon, the "hedges" round the tops of the newels being carved by Mr. J. E. Knox, of Kennington. The architect was Mr. Fred. M. Simpson, of Westminster, S.W. The library (part of the old house) has a fine Elizabethan plaster ceiling and frieze.

MOSQUE OF SHAH ABBAS, ISPAHAN.

THE plan and section of this mosque, given here, formed two of the diagrams to Professor Aitchison's third Royal Academy lecture, printed in full in our last issue. His description of the building will be found on page 118 ante.*

The section, as will be seen, is taken right through the centre or backbone of the plan, the turn or angle formed in the back portion of the plan being laid out in one plane on the section.

HANOVER SCHOOLS, GILBERT-STREET, GROSVENOR-SQUARE.

THE new Hanover Schools were erected in 1889 for the Hanover parish in conjunction with the parish of St. George's, Hanover-square, to take the place of the old schools in South Molton-street, which had become inadequate.

The site was a free gift in perpetuo to the parish by the Duke of Westminster.

The drawing from which we illustrate the building was hung in the Royal Academy in 1889.

The contract was carried out by Messrs. Turtle & Appleton, of Wandsworth, from designs by Mr. W. D. Caröe.

Accommodation is provided for 110 boys, 110 girls, 150 infants, with master and mistress's residences.

NEW CHURCH, LONG CLAWSON, LEICESTERSHIRE.

THE existing Church of St. Remigius, Long Clawson, being in a dilapidated condition, and devoid of any architectural or archaeological detail, it has been decided to pull down the old church and erect a new one, as shown in our illustration. The old church has had north and south transepts, as well as nave and chancel abutting up to its central tower; and in designing the new church the architect has adhered to the original architectural outline and grouping.

The cost of the new church will be about 5,500*l.*, exclusive of taking down and re-hanging the five bells, which is being done by Messrs. Taylor & Sons, of Loughborough.

Mr. John Howitt, F.R.I.B.A., of Nottingham, is the architect.

* The drawings being in use for the Professor's lectures, we were not able to give the illustration last week.

SKELLIG [MICHAEL.

AN account was given in the *Builder* for Sept. 12, 1891, of the visit paid last summer to the ancient Celtic monastery on Skellig Michael by the Royal Society of Antiquaries of Ireland and the Cambrian Archaeological Association. We now illustrate the very interesting remains at this place by a plan of the monastic buildings, two views, and a measured drawing of one of the oratories. The main outline of the plan is taken from the one in Lord Dunsraven's "Notes on Irish Architecture," and the additions were sketched in on the spot last August. The views are reproduced from photographs done by Dr. Norman, of Bath, who has kindly given permission to use them.*

The Great Skellig, or Skellig Michael, is a rocky island in the Atlantic, off the west coast of Kerry, $8\frac{1}{2}$ miles from Bolus Head, which is the nearest point on the mainland. The 6-in. ordnance-map shows the size and shape of the rock, and the position of all the buildings upon it. The island has an area of a little over 44 acres, and consists of two conical peaks rising, respectively, to heights of 714 ft. and 611 ft. above the sea, and joined together at their bases. Between the two peaks is a grassy valley, 422 ft. above the sea, called, on account of its peculiar shape, "Christ's Saddle." There are two lighthouses at the southern end of the island, which are approached from the landing-place at the northern end of the island by a zig-zag road along the edge of the cliff. The monastic buildings are situated just below the summit of the lower of the two peaks, on its eastern side, at a height of 543 ft. above the sea, advantage having been taken of the only piece of ground which is sufficiently level for the purpose.

The present path up to the monastery is through the valley called "Christ's Saddle," which is reached by pursuing the road from the landing-place to the lighthouses for a short distance southwards, and then turning off to the west. The old route was straight up the almost perpendicular face of the cliff from the landing-place, but the lower part has now been cut away in order to make the road to the lighthouse.

At the back the monastic settlement is protected by a retaining wall and the rounded ledge of rock which rises up behind it to the westwards. Beyond this ledge of rock, further west, is a sheer precipice down to the sea. In front, where the slope is less steep, the settlement is surrounded by a dry-built stone wall, forming a sufficiently strong defence in case of attack.

The whole area enclosed measures about 300 ft. long by 100 ft. wide, and the buildings within occupy a space of 150 ft. by 50 ft. The earlier remains consist of six beehive cells, two oratories, two wells, five ancient burial-grounds, and several rude crosses. The church of St. Michael is of later date, and is built with mortar, whereas all the other structures are of dry rubble. The ground, which is highest next the retaining wall at the back, and slopes down towards the east, has been artificially levelled up in a series of steps, so as to form a more suitable foundation for the different buildings. The raised ground is in each case faced with low retaining walls, and rude flights of stairs lead from one level to the next. The photographic view in which the cross appears is taken from a point between cell No. 2 and St. Michael's Church looking northwards, and shows the flight of nine steps leading from the space in front of cells Nos. 1 to 4 to that in front of cell No. 5.

The other view shows the interior of the ruined church of St. Michael, with the Lemon Rock and the coast of Kerry in the distance. It will be noticed that the side wall of the church is built directly over the wall of the chapel or fortress, on the edge of the cliff, and there is an uninterrupted view of the sea below.

Whatever may be the actual date of the remains on Skellig Michael (and it can hardly be later than the eighth century), the type of Christian structure here found is the earliest of which we have any knowledge in Great Britain, exhibiting as it does transitional features between the Pagan and subsequent methods of building, and showing the evolution of the stone-roofed church from the pre-Christian beehive cell. The most primitive form of the clochaun, or beehive cell, is probably that which

View on Skellig Michael, showing the Cross and some of the Cells.

Skellig Michael: Remains of the Church.

is circular in plan both inside and out. The cells on Skellig Michael are an advance upon this in being rectangular inside, although still retaining the rounded shape outside, but in the oratories an entirely new departure is taken in the adoption of the square corners altogether. The drawing of oratory No. 2 shows the Irish stone-roofed church in this its first stage of development, after emancipating itself from the Pagan traditional methods of building, an advance in style which was eventually to culminate in the design of Cormac's Chapel at Cashel. The oratory is in such a position that it requires a steady nerve to stand beside it and look over the edge of the retaining wall at the sea, hundreds of feet below. One is lost in admiration for the skill and daring of the monkish builders who, with their lives in their hands, could construct a wall actually sloping outwards over empty space, like one side of the Leaning Tower of Pisa. The character of the masonry of this wall is almost identical with that of the celebrated Staigue Fort, co. Kerry. Another resemblance to the Staigue Fort that will not escape the notice of the keen observer is in the ingenious contrivance for relieving the weight on the horizontal lintel of the doorway of cell No. 1, by placing a second lintel above with a small intervening space. Yet, whilst we are struck by constructive features that the Skellig Michael remains possess in common with the Pagan fortresses, the Christian character of the buildings is rendered sufficiently obvious by the crosses over the doorways formed of quartz pebbles, showing up white against a background of dark coloured slate.

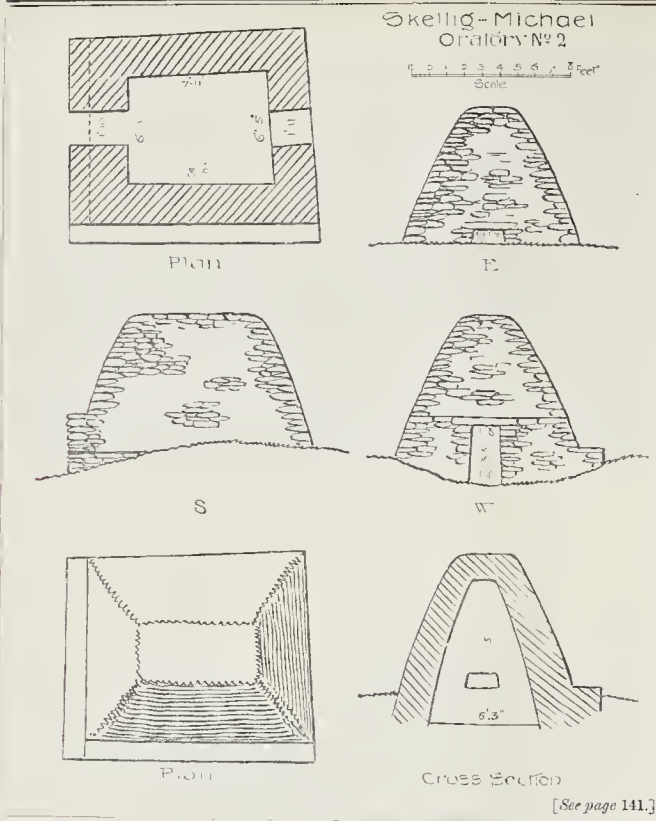

DEMONSTRATIONS ON GREEK SCULPTURE AT THE BRITISH MUSEUM.

MISS EUGÉNIE SELLENS gave on the 10th inst. the first of a course of six demonstration lectures on Greek sculpture in relief.

Miss Sellers said that Greek sculpture begins with intense realism, which is in itself hostile to decorative schemes. For example, in the little pediment of poros stone at Athens which represents Herakles slaying the Hydra, there is no centre-figure; while the chariot of Herakles, with complete disregard for decorative effect, is turned away from the centre ready for the homeward journey when the contest is over. Again, in the Harpy Tomb in the British Museum, there is no adequate centre, and the Harpies that should frame in the composition, fly away from the centre, realistically portraying the idea of souls passing away in death.

Passing to the consideration of the sculptures of the Temple of Ægina, Miss Sellers incidentally claimed these for Attica, basing her claim on the close resemblance between them and the bronze helmeted head in the Akropolis museum and the beautiful archaic head of a youth, now at Copenhagen, which was found at Athens; and further bearing in mind the fact that Pausanias, — to whom we owe the term "Æginetan art," — had seen scarcely any archaic art, all the statues that recent excavations on the Akropolis have reclaimed being in his day buried under the walls built by Kimon and Perikles. But Ægina still had its archaic sculptures; hence the term *Æginetan* came to be synonymous with *archaic*.

* Copies of all the views taken by Dr. Norman during the Kerry excursions can be obtained from Mr. W. Middleton Ashman, 12a, Old Bond-street, Bath.

In the pediments of Egina the sculptor began to feel the need of a centre, and we find him balancing his figures one against the other with perfect symmetry, but with the unsatisfactory result that they have somewhat the air of ornaments neatly arranged upon a shelf.

In the second lecture, last Wednesday, it was shown that the same principle applies to the pediment sculpture of the Temple of Zeus at Olympia. Again we have the central figure with figures symmetrically arranged on either side; but, for all the beauty of the individual figures, the whole lacks harmony and fusion. As in the old porous stone pediment, chariots form part of the scheme; but this time they are turned inwards, without regard to realism, and stand stiffly on either side of the centre.

In the Parth-non, the central composition of the western pediment shows a great advance. This time, the chariot horses that frame the centre are represented in active movement. But the angles still have that obtrusive symmetry which deprives the grouping of any charm. It is, however, in the eastern pediment where we have figures combined in groups which are themselves subordinate to the central group, that the Greeks approached most nearly to that combination of living forms into patterns which characterises, for example, the work of Donatello in his famous gallery of singing boys.

Miss Sellers here discussed at some length the various interpretations which have been given from time to time of the figures of the East pediment. She would revert to the old interpretation of Nux for the figure commonly called Selene; for in vase paintings it is Nux that drives while Selene rides.* The group often called "the Fates," which have been interpreted by Dr. Waldstein as Hestia, Gaia, and Thala-sa, she unhesitatingly calls "the Charities," thus obtaining a group of three whose attributes as well as whose attitudes would be closely symmetrical with the figures on the other side if interpreted as the Horai and Dionysus (rather than Olympos)—a combination that appears in the representation of the marriage of Peleus and Thetis in the François vase.

*The head of the "Selene" horse quite allows of the supposition of a rider instead of a driver.—Ed.

Finally, in the Parthenon frieze,—for all the flow and movement of the sides,—the centre is certainly weak. Mr. Murray suggests that the gods and goddesses are to be conceived as sitting in a semi-circle in a different plane from the procession, which advances in front of them from both sides,—an explanation, by the way, which Miss Sellers applies to the interpretation of the west side of the Harpy Tomb, where, as here, the artist has tried to represent two sides of one scene at the same time,—but no archaeological knowledge gets rid of the fact that the eye, in travelling rapidly on with the procession, is checked by the disagreeable impression of those five inadequate vertical figures, on whom the gods are turning their backs.

ARCHITECTURAL SOCIETIES

LEEDS AND YORKSHIRE ARCHITECTURAL SOCIETY.—A social gathering of the members of this Society was held on the 15th instant, in the Law Institute, Albion-place, Leeds. A collection of drawings and sketches of architectural subjects was hung on the walls. Mr. Frank Bedford showed the collection of sketches of Italian and Spanish architecture he had executed while on a tour of study on the Continent, and Mr. H. V. Lancaster, who has also studied and sketched abroad, exhibited some drawings. Other sketches were also shown by Mr. W. J. Mettam and Mr. Carby Hall (secretary). Specimens of wood and ivory turning, by Mr. H. B. Buckley, were also exhibited.

EDINBURGH ARCHITECTURAL ASSOCIATION.—On the 11th inst. the Edinburgh Architectural Society met in the hall, 42, George-street, Edinburgh, under the chairmanship of Mr. John Kinross. Mr. James Bruce, W.S., Edinburgh, moved that the Association, in acknowledging the communication from the First Commissioner of Her Majesty's Board of Works, intimating that he had caused a sum of 250*l.* to be provided for the "urgent and special repair of the Palace of Linlithgow," thanked him for having taken action in the matter, but felt that the thorough repair of the entire fabric was the only proper course, and begged to represent "that such thorough repair could

only be carried out by replacing the burnt timbers and flooring, re-glazing the windows, and covering the whole with a roof, so that the walls might be firmly tied together, and the whole rendered wind and water tight." He said that the sum of 250*l.* was utterly inadequate for the purpose they aimed at, and they, as Sootsmen, should insist upon that palace being put into proper order.—Mr. Ross seconded the motion, which was supported by several members, and agreed to.—The Council of the Association, under remit from the last meeting on Mr. G. S. Aitken's motion regarding the removal of the Wellington statue, recommended that the Association should take no further steps in the matter. This recommendation was unanimously adopted.—Sheriff Mackay then read a paper on "The Architecture of Scottish Towns as illustrating Scottish History." Taking the four periods of Scottish history—the Celtic-Roman, the Celtic-Saxon, the Scottish-Norman or Feudal, and the British or Modern,—he described the known architectural characteristics of each. The Celts, he said, had no architecture prior to the Roman invasion, and it was not until after that event that there occurred the transition from the Scottish manner of building with wood to the Roman manner of building with stone. The Roman influence, however, upon town architecture was nil. The Celtic-Saxon period was the era of the origin of the earliest Scottish towns,—their sites being fixed near castles, river mouths, and (at a later date) cathedrals or churches,—but scarcely a vestige of their style of architecture remained. The third period was contemporaneous with the form of Gothic or Norman architecture prevailing from the time of David I. to the Reformation, which put an end to the feudal character of the Church, and to the Revolution, which put an end to feudalism in the State. The signs of advance in architecture were seen in churches, colleges, palaces, and private houses. In the last or modern period the Revolution settlement, and the Union in 1707, led to the development of Scottish burghs. After the Rebellion of 1745 the feudal burghs burst their bonds, new towns and new architecture afterwards arose, and, as time went on, a higher standard of comfort, produced by increased wealth, preceded a higher standard of art.

GLASGOW ARCHITECTURAL ASSOCIATION.—The usual monthly meeting of this society was held on the 9th inst., the Honorary President, Mr. W. Forrest-Salmon, in the chair, when a demonstration was given by Mr. Francis H. Newbery upon "The Architecture of the Human Figure, and its Application." He referred to the besetting weakness of architects' undue regard for precedent, exemplified chiefly, perhaps, in their reproduction of the Classic orders by means of a unit of measurement,—the module,—found in the half-diameter of the column. For encouragement he instanced the modern development of sculpture and figure-painting. At one time the human form was studied in the same exact but, withal, mechanical way. It had been discovered that in Egyptian representations of the figure the unit was the middle finger. In Greece the principle was further elaborated, and the palm, and then the head, taken as the multiple for all the proportions of the body. Leonardo da Vinci, a great artist, did not scorn the aid given by a knowledge of the normal proportions of the body as codified, but he went further, and to acquaintance with antique canon added the study of nature at first hand. Mr. Newbery's "application" was that, beyond the precise analysis of past styles, the architect must appreciate the human figure, Nature's supreme example in proportion, symmetry, and beauty of line, if his architecture is to advance from academic correctness to the artistic realisation of Nature's principle in its proportion. The demonstration was given on the blackboard.—Mr. Kerppe opened the discussion which followed, and at its close a hearty vote of thanks was awarded Mr. Newbery.

CHICAGO EXHIBITION.—We are officially informed that the British railways have undertaken to carry goods for British exhibitors at the Chicago Exhibition, to and from the port of shipment, at half rates. The American railways will charge their usual rates to Chicago, but will bring back the goods free at the close of the Exhibition. Many of the principal steamship companies have reduced their rates considerably, and will take freight for the Exhibition at 1*l.*s. per ton. Many of them have also consented to adopt a reduced passenger tariff for exhibitors and their *esposas*, certified as such under the authority of the Royal Commission.

COMPETITIONS.

THE COXLEDGE ASYLUM EXTENSION.—On Wednesday afternoon, at a meeting of the Coxledge Asylum Committee of the Corporation of Newcastle, it was announced that the professional assessor, Mr. G. T. Hine, had reported that eighteen sets,—with four alternative plans, making twenty-two in all,—had been sent in. The successful competitors were, in his opinion, to be placed in the following order:—1. Motto, "Norstan," Mr. J. W. Dyson, Grainger-street. 2. "Compact," Messrs. Montgomery and Carr, Grainger-street. 3. "Order," Mr. W. L. Newcombe, Pilgrim-street. 4. "Northumbria" (second plan), Messrs. R. Knill Freeman and S. R. Robins, Grainger-street. The committee are to meet again shortly to consider the report of Mr. Hine. The cost of the extension is expected to range from 70,000l. to 80,000l. The competition was confined to Newcastle architects.

BOROUGH LUNATIC ASYLUM, SUNDERLAND.—At the meeting of the Sunderland Town Council on the 10th inst., the Visiting Committee of the Borough Lunatic Asylum recommended:—That the common corporate seal be affixed to agreement for purchase of land at Ryhope as the site for the Borough Lunatic Asylum. That the Town Clerk take all necessary steps for obtaining the approval of a Secretary of State to such agreement. That Mr. C. H. Howell, architect to the Commissioners in Lunacy, the assessor, having reported that, after a careful examination of the drawings submitted for the proposed Borough Lunatic Asylum, he is of opinion that the designs marked as follows should be awarded the prizes in the undermentioned order:—1st, Scio; 2nd, Turpi Secernis Honestam; 3rd, X. The Committee have so awarded them, and they recommend that No. 1 plan, "Scio," be adopted for the asylum and forwarded to the Commissioners in Lunacy, subject to an arrangement being previously made with the author thereof as to the architect's commission, &c."—Ald. Shadforth moved the adoption of the report, and proposed that the first should be adopted as the plan for the asylum.—Mr. Bruce seconded the motion.—Ald. Swan moved that the matter be adjourned for a fortnight, so that the members of the Council should have an opportunity of seeing the plans.—Mr. W. Sanderson seconded the amendment, which was put and lost.—Ald. Swan then moved that the Council ought not to be asked to approve of anything which they knew nothing about, and under the circumstances he suggested that a special meeting of the Council be held on Wednesday, the 17th, to consider the matter. This was agreed to.

THE LONDON COUNTY COUNCIL.

THE usual weekly meeting of the London County Council was held on Tuesday afternoon last at Spring-gardens, the Chairman, Sir John Lubbock, presiding.

Tenders.—Tenders were received for the construction of the Hackney-wick, &c., relief sewer, and for the erection of a new Fire Brigade Station at East Dulwich. The lists will be found on another page.

Proposed Appointment of a Parks Superintendent.—The General Purposes Committee presented the following report:—

"Under the resolution of the Council of November 3 last, an advertisement was issued inviting applications for the post of Superintendent of the Council's parks and open spaces, at a salary of 700l. a year. The applications were in the first instance considered by the Parks Committee, who at our request submitted to us the names of the three candidates whom they considered the most suitable for the appointment. The three candidates selected by the Parks Committee were Lieut.-Colonel P. Bailey, Colonel I. C. Walker, and Mr. C. J. Ponsonby. Having seen the three selected candidates, and weighed their respective merits and qualifications, we recommend—

"That Colonel Inches Campbell Walker be appointed Superintendent of Parks and Open Spaces, at a salary of 700l. a year, upon the following conditions—That he do hold his office during the pleasure of the Council; that he be required to give his whole time to the duties of his office, and he not allowed to take any private business; that any fees received by him either as a witness or in any other capacity be paid to the Council; and further, that he do accept the condition that on retirement he shall not be entitled and shall not make any claim to any superannuation or pension, and that he will submit to any general scheme which the Council may adopt with respect to insurance for pensions or superannuation."

Mr. Corbett moved, as an amendment,

"That, as it was stated in the advertisement for a Parks Superintendent that the age of candidates must not in any case exceed fifty years, and as two of the selected candidates exceed that age, the question be referred back to the Committee for further consideration."

In the course of the long and somewhat acrimonious discussion which ensued, the Parks Committee was criticised by some of the members for not having stated in their report that two of the candidates, Col. Walker and Lieut.-Col. Bailey, were beyond the prescribed age. Whether the strict limitation of age was desirable or not, it was contended that to adopt the recommendation of the Committee would be to break faith with other applicants for the appointment. Apart from this irregularity, however, many members objected to any such appointment,—to the creation of any such office. They urged that the existing Park Superintendents having charge of individual parks had shown themselves to be men fully competent for their posts. This was not denied by the Committee and its supporters, but it was urged that admirably as the individual Park Superintendents fulfilled their duties, the proposed new officer was much wanted in the interest of efficiency, economy, and uniformity of administration. To this it was replied that Messrs. Sexby and Nairn, two officers in the employment of the Council,—one in the Architect's department and one in the Clerk's department,—had managed the work of supervision very well. On behalf of the Committee it was rejoined that the existing state of things had only been made passably satisfactory through the untiring vigilance and unremitting supervision of members of the Committee. Some of the members of the Council who were not on the Committee advocated the appointment of a general superintendent of parks and open spaces, on the ground that there had been great mistakes made in the laying-out of the new park at Dulwich,—mistakes which they feared would be repeated in Waterlow and other parks. On being put to the vote, Mr. Corbett's amendment was carried by a large majority over the recommendation of the Committee. On being put as a substantive motion, several new amendments were proposed and lost. One of these amendments was to the effect that Mr. Ponsonby, who, it was said, fulfilled all the required conditions, should be appointed to the post. It was stated that, while possessing all the knowledge of forestry possessed by the other two candidates named, he was under fifty years of age, and had a knowledge of horticulture and landscape-gardening. This amendment was lost by a large majority, and ultimately Mr. Corbett's amendment was adopted as a substantive motion. The question was therefore referred back.

Appeal by the School Board against an Order of the Shoreditch Vestry.—The Report of the General Purposes Committee also contained the following paragraph:—

"We have to report that, acting as the Statutory Appeal Committee appointed under Section 212 of the Metropolis Management Act, 1855, we have heard an appeal by the School Board for London against an order of the Vestry of Shoreditch, requiring certain water-closets proposed to be erected at the Board schools in Shap-street, Kingsland-road, to be separately drained with a separate trap, pan, and water supply for each water-closet. Having heard the parties for and against, we came to the conclusion that the order of the Vestry should be varied, and we accordingly passed the following resolution:—

"That the order be varied by allowing the construction of the water-closets as proposed by the School Board, provided that the Board construct the water-closets so that the flushing of the troughs shall take place automatically at intervals of every half-hour during the day, commencing with school hour, and ending half an hour after."

The Bar at the Top of Gower-street.—The Improvements Committee again brought up their report on this subject, which was not adopted at last week's meeting, as we inadvertently stated on p. 125, ante. The following is the text of the report, which we did not print last week:—

"We have received a letter from the Vestry of St. Pancras stating that the authorities of University College and Hospital are willing to give up for the sum of 15,000l. the land in front of the Hospital, with a view to the opening up of the line of communication north and south through Gower-street, and asking the Council to contribute 10,000l. towards the cost. The land referred to has an area of 1 rood 4 poles 27 yards, is situated between Grafton-street and University-street, and divides University Hospital from University College. The

Hospital authorities claim the ownership to the land, and though they permit it to be used by foot passengers (save on one day in the year) they can at any time close it to traffic, and utilise the land for building purposes. Indeed, public right of way across it, and we are, therefore, anxious to reconstruct their Hospital, and in the event of their so doing it is open to them to use the land which they now offer to sell, and thus prevent the opening up of Gower-street. We have satisfied ourselves that the authorities possess the freehold of the land to the exclusion of any public right of way across it, and we are, therefore, of opinion that the present opportunity for acquiring it should be seized. The Vestry has agreed, in the event of the Council contributing the 10,000l., to undertake all further expenditure, including the cost of making the roads and footways over the land. The price asked for the land may, from one point of view, appear somewhat excessive, but we would point out that in the event of the Hospital authorities acquiring the property on the west side instead of this area, they would certainly have to expend a larger sum than 15,000l. The removal of the bar in Gower-street and the opening up of a direct line of communication between New Oxford-street and Euston-road would be a great public advantage, and in harmony with the avowed policy of the Council respecting the removal of gates and bars. We can confidently advise the Council to accede to the request of the Vestry, particularly as if this opportunity be suffered to pass, it may never occur again. We recommend,—

"That, subject to an estimate being submitted to the Council by the Finance Committee, as required by the statute, the Council do contribute 10,000l. towards the cost of opening up the line of communication north and south through Gower-street, such contribution to be made on the usual conditions with regard to contributions to improvements undertaken by local authorities."

The recommendation was now agreed to without discussion.

York Water-gate.—The second report of the Parks and Open Spaces Committee contained the following paragraph:—

"We have had our attention called to the partially dilapidated condition of the York Water-gate at the bottom of Buckingham-street and adjoining the Victoria-embankment-gardens, and also to the untidy condition of the ground around it. There is no beneficial ownership in the gate, and the persons who are, or claim to be, in possession of it consequently take no steps to keep it in proper order. We have no desire to alter the ownership of the gate, but having regard to its position as a monument of the past and an object of public and architectural interest, we think that the Council would be quite justified, as it forms a feature of the Victoria-embankment-gardens, in undertaking its future maintenance. We therefore recommend,—

"That the Council do direct the Parliamentary Committee to insert a clause in the next General Powers Bill to enable it to maintain the York Water-gate next the Victoria-embankment-gardens."

The recommendation was adopted *nem. con.*

The Inhabited House Duty.—Mr. Beachcroft moved:—

"That, in the opinion of the Council, the Inhabited House Duty should cease to be an Imperial tax, and should be substituted for the share of the Probate Duty grant now carried to the local taxation account, so that the amount actually leviable in respect of house duty in the County of London may be appropriated to the County Fund, and that a representation to this effect be made to the Chancellor of the Exchequer."

After some discussion, the motion was referred to the Local Government and Taxation Committee, and the Council adjourned shortly after six o'clock, having got through its business an hour earlier than usual.

THE SANITARY INSPECTORS' ASSOCIATION.

The ordinary monthly meeting of this Association was held on the 6th inst. at Carpenters' Hall, London-wall, when an address was delivered by the Medical Officer of Health of the Staffordshire County Council, Dr. Geo. Reid, D.P.H., an hon. member of the Association. Mr. Hugh Alexander, Chairman of the Council, presided, and there was a good attendance of members.

The lecturer selected for his subject "Infection and Disinfection," and, in his treatment of it, he limited himself almost exclusively to two salient points,—(1) the nature of contagion and its phenomena, and (2) methods of prevention by disinfectants. We had long passed, he said, the epoch of curious hypotheses as to the causes of infection, and we now knew that certain kinds of disease were propagated by low forms of animal life, which were known as germs. The existence and the various shapes and forms of these organisms,

* See Builder for October 31, and November 7, 1891.

though mostly so minute as to be invisible to the naked eye, had been in various ways demonstrated. These organisms, or their spores, which were more difficult to kill than mairre germs, often clung for a long time to clothing, remaining perhaps for a considerable period in a state of suspended animation for want of proper food. It was still a moot question whether such germs had a spontaneous origin or were only to be found after an antecedent case of sporadic disease, and as there were facts to support both theories of origin, it might be possible that they had a double development. Whatever might be the truth as to their origin there was no doubt that an atmosphere of dirt, moisture, and a certain temperature were necessary conditions of their existence. As fish could not live in water without air, so these morhific germs could not live in the air without filth; and ozone, as their distinguished President so often maintained, was fatal to them. Armed with that knowledge, and knowing also where to look for the conditions of filth, the Inspector would be in a position to fight the evil and to conquer it. An infected person was a centre of contagion, and from him, by means of the breath, emanations of the skin, secretions, contact with clothing or through water, milk, food, or air, it might be communicated indefinitely from person to person. The different ways in which the same or different diseases had been communicated in observed cases were illustrated by diagrams. Disease in animals played an important part in the spread of epidemics, particularly tuberculosis, diphtheria, and scarlet-fever. Entering upon the second portion of the subject, the lecturer explained by means of a table the effects of dry and moist heat at different degrees of temperature upon the bacilli, and stated the various times required to destroy life in them under the different conditions. Moist heat at 212 degrees Fahrenheit effectually destroyed germs after five minutes exposure, which would require from one to four hours with an exposure up to 220 degrees, in dry heat; the former was therefore to be preferred to the latter. It was fortunate that they now knew enough of the habits of the enemy to follow him to his haunts and combat him successfully, but they were heavily handicapped in the fight by the ignorance of the public and the apathy of local authorities.

On the conclusion of the lecture, a vote of thanks was proposed by Mr. F. G. Bell (Epping), and a discussion took place in which the Chairman, Mr. West (Walthamstow), Mr. Dee (Westminster), and other members took part. The motion having been carried by acclamation Dr. Reid briefly replied in acknowledgment.

CLERKS OF WORKS' ASSOCIATION: ANNUAL DINNER.

The ninth annual dinner of the Clerks of Works' Association of Great Britain was held on Monday evening last in the Venetian Saloon of the Holborn Restaurant, Mr. Aston Webb, F.R.I.B.A., in the chair, supported by Mr. P. T. Bagdallay, F.R.I.B.A., President of the Architectural Association; Mr. Wyatt Papworth, F.R.I.B.A.; Mr. T. H. Watson, F.R.I.B.A.; Mr. C. Stanley Peach, F.R.I.B.A.; Mr. Thomas F. Rider (Rider & Sons), Mr. Joseph Randall, Mr. Edwin Brooks, Mr. J. Merifield, Mr. J. Brady, Mr. F. Dashwood, and many other gentlemen.

The Chairman, in proposing "The Queen and Royal Family," feelingly alluded to their recent bereavement. It was sometimes said, he continued, that the Victorian Age would not be remembered much as an age of art, but that its chief claim to remembrance would be its scientific and engineering achievements. Without wishing to decry the latter, he thought that there was something to be said on behalf of architecture, for an age which had produced the Houses of Parliament and other prominent public buildings, and which had produced architects such as Sir Charles Barry, Sir Gilbert Scott, George Edmund Street, Alfred Waterhouse, Norman Shaw, and many others whom he might name, could not be said to be undistinguished in architecture.

The Chairman next proposed "The Army, Navy, and Reserve Forces," coupled with the name of Sergeant J. M. Jefferson, who briefly responded.

Mr. G. Dalton, in a humorous speech, proposed "The Architects and Surveyors," coupled with the names of Mr. C. Stanley Peach, F.R.I.B.A., and Mr. Stanley Clarke, both of whom, in replying, spoke of the indebtedness of professional men to clerks of works.

The Chairman, in proposing the principal toast of the evening, "The Clerks of Works' Association," said that he was glad to find that the position of the Association was a most favourable one. He understood that it now numbered 130 members, and

that it had been established ten years. The members had gradually increased, and during the past year there had been an increase of ten. The Association appeared to be in the happy position of having an income slightly in excess of its expenditure, and to be able to place to reserve something every year, although there was no absolute necessity for them to do so. The advantages of the Association were thoroughly known and appreciated by the members of the architectural profession. The register of competent clerks of works which the Association kept was one which was now pretty well known and resorted to by most architects in search of capable clerks of works. The Association was to be congratulated on the publication of its useful little *Journal*, which contained a great deal of valuable practical information. Another advantage which had been gained by the establishment of the Association was the opportunities which it afforded of enabling the members to make each other's personal acquaintance and to exchange opinions and experiences. He did not know whether the Association had in connection with it any benefit society or club, for mutual assistance in case of illness, accident, or other misfortune, but if they had not, they had possibly already given attention to the subject. He was very glad to notice, in reading their *Journal*, that they were fully alive to the importance of technical education, and that they were co-operating with Prof. Banister Fletcher and the Carpenters' Company, in that desirable work. He would impress upon them all, and especially upon their younger members, the great importance, and, indeed, the absolute necessity, of keeping abreast of the times. Every decade of the present century had brought forth some invention, some improvement, some important progress, and it therefore behoved clerks of works, as well as architects and builders, to make themselves conversant with every new thing, as far as they possibly could do so. He had been asked to say something on the question of salary, but that was a rather delicate matter. He was not one who thought that the salaries of clerks of works were always adequate, but he did not think it would be possible, with advantage to themselves, to fix a uniform salary, which all should receive. As he apprehended, the Association had no such object in view; it was, in fact, a trade union. He believed that a thoroughly capable and experienced clerk of works would generally be able to obtain employment at such a salary as his merits entitled him to receive. He thought there were indications that the position of clerks of works would before many years be much better than it was at the present time, for it was probable, and even possible, that their functions would be greatly extended. There were growing signs of the tendency to divide the work of erecting a building into the several trades, and the general contractor seemed to be on the wane. If that were so the probabilities were that the clerk of works would become more and more in request, and he would have greater and greater responsibilities thrown upon him. With the toast he had much pleasure in coupling the name of Mr. J. Brady, the President of the Association.

Mr. Brady, in responding, said that with regard to the subject of a benefit club or society, they had considered that matter at first, and determined to exclude it from their programme, wishing to make membership of the Association independent of all pecuniary considerations, save, of course, the payment of the annual subscription. But they did not, in the least wish to disparage other societies which adopted a different course on that matter.

Mr. F. Dashwood, secretary, in a humorous speech proposed "The Worshipful Company of Carpenters," coupled with the name of Professor Banister Fletcher, who, in replying, referred to some criticisms which had appeared in the Association's *Journal* concerning the examinations at Carpenters' Hall.

Other toasts followed, including "The Hon. Treasurer" (Mr. J. Oldrid Scott, who was, we regret to learn, unable to be present through illness); "The Press" (coupled with the name of our representative); "The Visitors" (coupled with the name of Mr. P. T. Bagdallay, President of the Architectural Association); and "The Chairman" (proposed by Mr. R. Wheeler).

BRETT'S AUTOMATIC REVERSIBLE SASH.—This sash, the invention of Mr. A. Cutting, is a form of reversible sash-action which has the merit of being exceedingly simple in its working, containing nothing that is liable to get out of order. In place of the rebate at the edge, there is a loosely-fitted lath of brass or other metal working in a slot in the side of the sash, and when the sash is closed, fitting loosely into another slot in the frame. A small bar on this lath projects through the frame at each side, and by a knob or handle can be raised and by the same action drawn inward obliquely towards the centre of the window, when the lath leaves the window-frame slot, and the sash is free to swing round on centre bearings. On returning the sash to its place the metal lath drops automatically downward and outward, by its own weight, into its place, being guided outward by the oblique line of the slots in which the bars carrying the handles work. The make of the sash is very inexpensive.

Correspondence.

To the Editor of THE BUILDER.

COKE BREEZE CONCRETE.

SIR,—I am much surprised at the opinion expressed by Mr. Potter in your last issue as to the suitability of coke breeze for concrete, and as to the strength of concrete made with it. The use of breeze for concrete is not known in my neighbourhood, though there is plenty of breeze to be had, hence my wish to get practical opinions about it. I proposed to use it for the floor-slabs and walls of artisans' dwellings in consequence of seeing in one of the papers of the Royal Engineers a report of experiments on concrete beams from which it appeared that a beam made with "gasworks breeze" was much stronger than one made with "gravel screened to 1 in. and washed," the proportion of cement being the same in each case,—perhaps some other experiences of the use of breeze for concrete will be given. I regret that my inquiry as to the sizes of rooms that can be spanned by flat slabs of concrete without iron joists, and with practical safety, has not received any replies than that kindly given by Mr. Potter, as this is a point upon which definite practical experience would be of great value, and especially so as it may now, I think, be taken as experimentally proved that durable floors can be formed by nailing deal flooring direct on such concrete slabs, without leaving air-spaces, and so doing away with timber joists entirely. If, as Mr. Potter states, breeze is a bad material for making a strong concrete, his suggestion of forming the lower portion of the floor-slabs of an aggregate that would make a stronger concrete, and putting a layer of 1½ in. of breeze concrete over it to nail into, is good, but I cannot see the use of postponing the laying of this layer until after the lower portion is dry; on the contrary, it seems to me, that it would be very much better to lay, say, 4½ in. of the strong concrete, roughly levelled, and at once lay on it the breeze concrete, properly levelled off to receive the boards, so that the two layers would be practically incorporated into one mass, and the whole would dry out together. In the records of some experiments on concrete floor-slabs, it is stated that they were wetted daily for one week after they were laid. Is this an advantageous thing to do? Perhaps some further and more definite practical experiences may be given by your readers on this important subject. In the particular case in which I am interested the rooms are 13 ft. by 14 ft., surrounded by 8 in. walls.

1. Can such sub-rooms be safely spanned by 6 in. slabs of coke breeze concrete, gauged, say, 3 to 1 of best Portland cement,—on which the flooring would be nailed?
2. If not, would the necessary strength be secured by using broken brick or other material, instead of breeze, for, say, 4½ in. thick of the slabs, as suggested above? SURVEYOR.

AIR-BOUND PIPES.

SIR,—Can any of your readers instruct me how to cure above? The cold man outside my house is only a three-eighth pipe, whilst my service from it up to cistern is ½ in., with branches half-way up to lavatories, &c. The hot-water pipes from cylinder to bath, &c., have no after circulation. When the hot-water taps are turned, lowering the water in cylinder and cistern, a terrific noise, like a horn, sets up, and continues till it is relieved by turning the cold on also, and letting it run for some time; the cold pipe vibrating violently.

What is the cause, and what is the simplest cure? FOGHORN.

** From the above letter we gather that the service of water to "Foghorn's" residence is constant and not intermittent; what is generally known as "constant supply." This being the case, the cause of the noise is not far to seek, although it is due to something that might not in the general way be readily thought of. The noise and the vibration engendered proceeds from the ball-valve in the cold-water cistern.

This peculiar trouble is not very frequently experienced, and it does not follow that it proceeds from the same cause in every instance, but on the few occasions it has come to our notice it has in each case proceeded from the ball-valve, and has been easily remedied. If the cistern has a stop-cock, and then (while the noise and vibration are proceeding) places his ear as near as he conveniently can to the ball-valve in the cold-water cistern, he will doubtless come to the conclusion that this is the seat of the trouble. He rightly likens it to a foghorn, for the noise is due to a similar cause,—viz. the passage of a fluid through a narrow aperture at high pressure. If there is any doubt, let him either lift the ball of the valve to close it or press it down to fully open it, and the noise will cease if the trouble proceeds from the cause that our experience has shown us.

The remedy is to change the ball-valve for one of a different pattern, or to check the pressure of the water before it arrives at the ball-valve. This latter could be done by inserting a stop-cock and partially

closing it, or choking the pipe in some way, or reducing the passage way in the tail part (not the outlet) of the ball-valve; but in adopting a remedy every consideration must be given as to what "Foghorn's" water company will be agreeable to.

It will be plainly seen that the opening of a cold-water tap must relieve the pressure at the ball-valve, for the cold-water taps are all in direct connexion with the supply-pipe, and take the water at a lower point. This relief, as "Foghorn" states, proves sufficient to cause a cessation of the noise. It is, of course, understood that this trouble is due to the water flowing in from the main the instant water is drawn from the cold-water cistern. This scarcely ever permits of the ball-valve opening to its full extent; if it did, then there would be no troublesome noises (assuming the ball-valve was of sufficient size)—no more than happens when the cistern is filled once or twice a day upon the intermittent system. This, it must be repeated, is the probable cause, to the best of our experience, but it does not follow that it is the correct solution in every case.

The Student's Column.

WARMING BUILDINGS BY HOT WATER. VIII.

EXAMPLE WORKS (HORTICULTURAL.)

It must be clearly understood that these examples do not represent copies from which other works can be carried out, as in the first place the sketches are merely imaginary requirements. But in explaining these, the principle and general idea of the work can be correctly described, and this is all that is needed. When an apparatus has to be put up it is best when, or after, viewing the place in plan the arrangement of pipes, their disposition and quantity, without reference to any suggested examples, as in no two cases are the requirements exactly alike. This may sound as if the examples about to be given would convey no useful information, but this is not the case, for without dealing with a few complete works it is hard to convey to the inexperienced mind the connexion between the different separate subjects treated.

FIG. 26.

The first example, fig. 26, shows about the most simple apparatus we have with a boiler in which coke or coal fuel is used. This does not represent the smallest style of boiler by any means, but the whole erection is simplicity itself. This simple structure is due in a great measure to the boiler, which is of the "Loughborough" pattern. This boiler, which has now been in use some little time (and will be referred to more fully presently), is of a shape which permits its being built in the substance of one of the walls of the greenhouse or conservatory. By this method of fixing the front of the boiler, with its feeding and stoking doors, and the smoke-nozzle, are outside the building, while the back of the boiler, with the connexions, show inside, so that the whole of the pipes can be used for radiating purposes. Ordinarily, a certain amount of pipe has to exist between the boiler and the house, and which has to be carefully covered or it will cause a waste of heat. It will be noticed that the design of the boiler is such that, although some part of it is within the house, yet all attention, stoking, &c., is done outside.

From the back of the boiler are carried flow and return pipes having a slight rise towards the further extremity, where they terminate in an expansion box, as referred to in the last article. The pipes in a small apparatus like this would probably not exceed 3 in. diameter. The usual size for all medium and large-sized works is 4 in. This is an apparatus that is considered sufficiently simple for an amateur to erect himself, the pipe joints being made with indiarubber rings. (These will be spoken of later.) It can be just as easily carried round three sides of a house as along one side only, if the necessary quantity of pipe and bends are provided. No air-pipe would be needed if the

expansion box is used and the pipes have a rise all the way. If more than two pipes be needed, the connexions can be effected, as will be shown presently.

FIG. 27.

The next example, fig. 27, shows an apparatus to heat a small glass-house, the boiler situated outside the house somewhere; but we may assume it is not far away. It would also probably be somewhere below the house level. If this were a conservatory attached to a residence, the boiler might be in a cellar or basement-room near. In this case, the boiler would be of the independent kind, with the flow-pipe leaving the top (or the side, near the top) and the return entering at a low point, as fig. 28.

FIG. 28.

FIG. 29.

The difference, however, between these pipes in this case, and that last explained, is that they should not be of full size,—viz., 3 in. or 4 in., until they enter the place to be heated.

Between the boiler and the radiating pipes in an apparatus like this the pipes would not require to be larger than 1½ in. Probably 1 in. would do, if the boiler was below, and the radiating pipes were not extensive, say not more than 40 ft. in all. This effects a saving in cost, and a deal of heat would be lost from these pipes, if large, and not carefully covered. Pipes which are not required for radiating purposes should always be covered with a poor heat conducting material, and, of course, it costs more to cover large pipes than small, and the large pipes answer no good purpose in a small apparatus like this.

The pipes now referred to, between boiler and radiating pipes, as they are small, would be of wrought iron, and in ordering the boiler, and also the cast pipe connexions, this must be remembered and prepared for, as otherwise no provision will be made for pipes that are to be screwed in. Both boiler and pipe makers will arrange for this if instructed. These pipes are run in the same manner as already described, that is, ascending everywhere.

The illustration shows the connecting pipes from the boiler entering the house at such a point that the radiating pipes have to branch off in different directions. Of course, if the connecting pipes can be brought in and connected to either extremity of the radiating pipes it would be better, but this example is given to show how branched services should be treated when needed.

There is nothing complex in connecting the branch services, especially in a small work like this. If a tee-piece be put at the angle where the connecting-pipes come, instead of the usual bend, a cap or socket drilled and tapped and fitted to the projecting end of the tee is all

that is needed for the reception of the wrought-pipe. This practically leaves the two branches of the radiating pipes open for the water to circulate which way it chooses, as fig. 29. If the branches are of about equal lengths and working under the same conditions, the circulation may be expected to be fairly equal each way. If, however, as here shown, the branches are of unequal length, we may probably get unequal results, the shortest most likely "taking the lead," as it is termed, to the prejudice of the longer service, which will appear to be acting very sluggishly. In a larger apparatus any irregularity in the working of the different branches is controlled by stop-valves which have to be provided; but in this we can get sufficiently equal results by giving a little greater rise to the long branch than to the short one.

Air-tubes would have to be connected at each extremity as shown, these extending two or three feet above the level of the supply-cistern; ½ in.-tube would be quite large enough. The water-supply would be furnished by a small cistern placed in the most convenient position just above the level of the radiating-pipes. It is usually arranged for this cistern to be placed out of sight, behind rockery or plant staging. Of course, an expansion-box at each extremity would be very suitable, and dispense with the air-tubes, and supply-cistern, and provide the end supports, as already explained.

Sometimes it is desired to have three or four pipes on one side of the house, but only two on the other. The greater number of pipes would be upon the exposed side, the lesser number on the wall side, but this quantity is not usually required for greenhouses or conservatories, unless they are very wide or roomy. If three pipes are required, it is usually the flow that has the extra pipe, the return being single. The extra pipe is connected by a branch pipe, as

FIG. 30.

fig. 30. If four pipes are needed, they are not placed one above the other, as three pipes very commonly are; they are generally placed two and two, and they then consist of two flows and two returns, the flows on top, the returns below.

In fixing the boiler of this example apparatus, it is to be supposed that if placed in a cellar or basement-room, it can be connected with one of the residence chimneys by a pipe. The size of this pipe will be governed by the size of the smoke nozzle on the boiler; the makers putting that size which is most suitable. If the apparatus is to be a permanent affair the smoke-pipe should be of cast-iron, and although coke may be the usual fuel it is best to provide soot-doors in all the elbows used. This gives access for sweeping should it ever be needed, or should access be required for any other purpose. Wrought-iron smoke-pipe answers very well in dry situations, and if the fire is not let out all the warm weather. If the conditions are different to this, it will soon fall even if it be galvanised.

To effect the proper working of the furnace, the pipe joints and the connexion of the smoke-pipe with the chimney should be air-tight, so that we may consider that all the air entering the chimney has to first pass through the fire. Most boilers will, however, work without such precautions as this; but if it is possible to fix the boiler in this air-tight manner, it is best to do so. In fitting up the flue-pipe a damper must be put close down by the boiler, where it can be conveniently used. The fire-doors of the boiler are usually provided with a sort of hit-and-miss ventilator to fulfil the purpose of a damper; but an additional damper in the flue-pipe should be provided, and it should be a well-fitting one, if the boiler is to be regulated with any degree of nicety.

It will have been noticed that the boiler shown is of the upright variety, which, like the "Loughborough," is capable of taking a charge of fuel to last through the night without attention. This is an essential feature if the greenhouse has anything else but hardy plants in it. If the conservatory is heated for the sake of the plants, the night is the time when the boiler should be at its best. If, on the other hand, heat is only needed to make the conservatory com-

fortable for occupation during the day, the night cold is not so much thought of; of course, in this latter case, only evergreen shrubs, &c., would be placed in it.

OBITUARY.

MR. JOHN CHESSEB.—The death is announced at Dorlin, Corstorphine, of Mr. John Chesseb, architect, late Superintendent of Works to George Heriot's Trust. Born at Dalmeiny, the deceased, on acquiring a knowledge of the joiner trade, crossed the Border, and while yet a young man held the post of master of works during the erection of some public buildings in Lincolshire. On the death of his father he returned to Dalmeiny, and succeeded him as Superintendent of Works on the estate of the late Earl of Rosebery. In 1858 Mr. Chesseb was appointed Superintendent of Works to the Governors of Heriot's Hospital, in room of the late Mr. Alexander Black, and he continued to act in that capacity until about three years ago, when, on account of failing health, he resigned, and was granted a retiring allowance. During Mr. Chesseb's term of office a large amount of Heriot Hospital ground had been feued, and in this connexion the late Superintendent of Works rendered valuable service, not only in connexion with the feuing of the land, but in preparing the ground and elevation plans. He also drew the plans for a number of the more recent Heriot Schools, the reorganisation of the Hospital School, and the reconstruction and extension of the Heriot-Watt College. The deceased, who is survived by a widow and grown-up family, was in his 73rd year.—*Scotsman.*

GENERAL BUILDING NEWS.

WILLIS'S ROOMS, ST. JAMES'S.—This historical building (originally "Almack's") is now in course of alteration, and before many weeks are over will have been completely changed. The block of buildings has been acquired by Messrs. Robinson & Fisher, the auctioneers, of Old Bond-street, whose present premises are not sufficient for their business. The ground-floor is being converted into shops with mezzanines over, and the old ball-rooms will become sale-rooms for pictures and works of art. It is thought that this alteration in King-street, which is generally recognised as a centre for dealers in works of art, will help to further centralise the trade. A considerable portion of the block, at the end nearest St. James's-street, is being altered to form suitable premises for a first-class restaurant or a dining-club. The front to King-street will be refaced, and will have a more architectural treatment than heretofore. The alterations, of which we hope shortly to illustrate the plans and elevations, are being carried out by Messrs. W. Johnson & Co., and the designs and under the direction of Messrs. J. T. Wimpey & Arber, architects.

RESTORATION OF BOURN ABBEY.—The ancient Abbey at Bourn is to be immediately restored. The work will be carried out in sections. Some months ago a committee was formed, having as its secretary Mr. R. M. Mills, who is a munificent subscriber to the cost. It is now announced that the response to the appeal made has been sufficient to justify the committee in giving instructions for the work to be immediately commenced.—*Leeds Mercury.*

NEW BANK, LEEDS.—A branch of the London and Midland bank was opened in Kirkgate a few years ago, and in 1890 designs were prepared by Mr. William Bakewell, architect, of Leeds, for a new bank, which was opened at the commencement of this year, on a site opposite the market. The facade is executed in stone from the quarries at Idle and Morley. The building is classical in character, with Corinthian columns and pilasters. The pediment over the entrance is surmounted by a statue of "Minerva," and the tympanum of the pediment is enriched with carving; the arms of London and Leeds are carved in the sunk panels on each pedestal. The interior of the banking room has a dado, 5 ft. high, executed in walnut; the walls above are lined with Italian marble. The floor of the bank is laid with mosaic pavement. The banking room is warmed by hot-water coils; the fresh air is admitted and passed through the coils of hot-water pipes. The vitiated air is extracted by a shaft prepared for the purpose. The strong-rooms are placed in the basement; and a hydraulic elevator is provided for the service of the bank. The contractors for the work are Messrs. Nicholson & Son, Barrard Bros, Moore & Heywood, Emley, De Grolle Houdret, Appleyard, Schroeder, Nutt, Faylor, Oldroyd, Churton, Barratt & Russell, Ratcliff & Horner, Chatwood, and Elgood. Mr. Charles Goulden has acted as clerk of the works.

NEW CHANCEL, PARISH CHURCH, EMSWORTH, HANTS.—On the 6th inst. the consecration took place of the new chancel just added to St. James's Parish Church, Emsworth. In November, 1890, the plans of Sir Arthur Blomfield, A.R.A.,

the Diocesan Architect, for the extension of the church at the east end, were approved, and on July 8 last the foundation-stone of the chancel was laid. The total cost of the work has been about £2,500. The addition of the chancel has restored the church to something of its original form. When first built, about fifty years since, its ground-plan was cruciform, but the extension of the aisles to the outer walls of the transepts made it almost square. The new extension converts the church to the form of a Greek cross, and increases the sitting accommodation to just over 500. The style of the building is Late Norman, and the external walls are of flint with Bath stone dressings. Three bold arches have been cut in the old east wall communicating with the chancel, organ-chamber (on the north), and vestry (on the south), while between these three sections other arches have been constructed. The new transepts and organ-chamber are each 25 ft. in width, and the vestry and organ-chamber are each 22 ft. by 17 ft. The former is approached from the nave by three steps, and separated from it by a low wall of stone. The altar is raised three steps above the choir level, and above the carved-oak table the east wall is pierced by three narrow windows filled with stained glass, the subjects of which are the "Crucifixion," the "Virgin Mother," and "St. James." A tessellated pavement has been provided in this part of the church. On the south side of the altar a sedilia, piscina, and credence table have been cut. The choir stalls and clergy seats are of pitch-pine, and accommodation is given for twenty-two choristers. Adjoining the northern pillar of the chancel arch is a pulpit, carved in alabaster, colored in marble, and the body of the church has been repaired with wood blocks, and the old pews have given place to pitch-pine seats. The organ has been removed from the western end of the south aisle to the new organ-chamber, where room has been left for its extension. The windows have been filled with cathedral tinted glass, and the stained-glass window which formerly occupied the east end has been placed in another part of the church. A new heating system has been introduced.

TOWN HALL, CLECKHEATON.—On the 10th inst. Cleckheaton Town Hall, which has been erected in the centre of the town, was formally opened. The building is in the Queen Anne style, and has been built from the designs of Messrs. Mawson & Hudson, architects, of Bradford. The interior arrangements of the building include a large hall, which is planned to accommodate 1,000 persons and 100 more in the orchestra, the latter having ample retiring-rooms. The Board-room is on the same floor. The Local Board offices are all situated on the ground floor underneath the large hall, and provision has been made for their enlargement at any future time if necessary. The basement is devoted to workshops for the gas and water departments of the Board, kitchen, &c., from which there is a lift in connexion with the large hall, and the entire building is lighted by electricity. The principal features of the facade are a massive tower, rising to a height of nearly 100 ft., and capped by a turret, a projecting oriel window which lights the principal room in the suite allotted to the Local Board, and a gable at the south corner with bay windows. The contractors for the work were:—Messrs. Mawson, Messrs. Holdsworth Bros., Cleckheaton; stonemason and carpenter, Mr. W. Isherwood; painter, Mr. T. W. Craig; Cleckheaton; plasterers, Messrs. Metcalfe & Lockwood, Staincliffe; ironfounder, Mr. Robert Hird; painter and decorator, Mr. Squire Nutter, Cleckheaton; slaters, Messrs. Albert Hill & Son; electric lighting, Messrs. J. H. Holmes & Co., Newcastle-on-Tyne.

PROPOSED RESTORATION OF ST. MARGARET'S CHURCH, WETTON.—It is proposed to restore the Church of St. Margaret, Wetton, Staffordshire, by the provision of new roof and ceiling, which are at present dilapidated and unsafe; new floor; the old being damp and rotten; the removal of an end gallery and partition, so opening up the Medieval tower arch at present buried thereby; a new heating apparatus; the entire reseating of the church in lieu of the old deal pews; rebuilding of the organ; and making safe the interior of the tower, which contains bells of the dates 1699, 1709, and 1815. Plans have been submitted by Messrs. W. Sugden & Son, architects, Leek, and adopted.

CHURCH OF ST. ANNE, AMBERGATE, DERBYSHIRE.—The new Church of St. Anne, at Ambergate, was opened on the 13th inst. by the Bishop of Southwell. The structure will accommodate 250 worshippers, and there is a schoolroom below. Mr. A. Coke Hill, of Derby, was the architect, and Mr. J. Glossop, of Ambergate, the contractor. The church is in the Early English style, with nave, chancel, organ-chamber, choir vestry, and clergy vestry, with bell turret. The roof is covered with red tiles, while the walls are of Ambergate stone, lined with red brick.

BISHOPHOPE PALACE.—Alterations (are being made at the Archbishop of York's Palace, Bishopthorpe. The old wooden floor in the chapel has been taken out, and a fireproof one substituted. Messrs. Mark Fawcett & Co. have been entrusted with the work. Mr. Ewan Christian is the architect.

FOREIGN AND COLONIAL.

FRANCE.—The Jury of Architecture of the Ecole des Beaux-Arts has given judgment on the competition opened for "Un Hôtel Général d'Association des Etudiants," awarding a medal to M. Lajoie, pupil of M. Laloux.—It is announced that the City of Paris is about to purchase, at the price of a million francs, the celebrated Hotel of the Archbishops of Sens, which will become a kind of dependency of the Carnavalet Museum.—The Louvre has acquired the original model executed by Rude for the bronze statue erected at Fixin (Côte d'Or) to the memory of Napoleon.—On April 21 a new art exhibition organised by the "Union Libérale des Artistes Français" is to be opened in the Palais des Arts Libéraux. It will remain open till June 20. The fine collection of the fatness of the late M. Maillot du Boulay, formerly curator of antiquities at Rouen, has been acquired for the Louvre.—The "Nord" Railway Company proposes to commence shortly the arrangements for penetrating further into Paris with auxiliary lines serving the Halles Centrales and the Paris Opéra.—A fire which might have had serious consequences broke out last Saturday at the Sévres Manufactory. The collections escaped, however, and the injury was only to material of the value of 50,000 fr. or thereabouts.—The work of dismantling the fortifications of Arras has been stopped by a general strike of the workmen engaged.—An international exhibition is to be opened at Bordeaux during this year.—At Tours there is to be an exhibition in May, chiefly connected with public instruction, hygiene &c. It will be open till August.—An industrial and artistic exhibition is to be held at Cannes in the months of March and April, and at Reims there is to be an art exhibition in the autumn, opening October 1.—M. Gerôme, the painter, has just finished a bust of Philippe Roussseau, to be set up in the garden of the Museum at Evreux.—M. André, the architect, has been commissioned by the Municipality of Lyons to design the monument to be erected there to the memory of the lyric poet Dupont.—The Minister of Public Instruction has appointed M. Degré Professor of Architecture at the Ecole Nationale des Beaux-Arts at Dijon.—The jury of architecture of the Ecole des Beaux-Arts has awarded the Edmond Labarre prize to M. Bardey, pupil of M. Guadet.—M. Maggesi, Honorary Director of the School of Sculpture at Bordeaux, has just died in that city. He was born at Carrara in 1807, and exhibited in the Salons of 1838, 1844, 1845, and 1857, and settled at Bordeaux in 1862. Among his numerous works are the marble statues of Montaigne and Montesquieu in the Place des Quinconces at Bordeaux; and eight busts or statues in the Museum at Bordeaux, especially "Jupiter Olympius" and "Giotto." The Cathedral of St. André is to be seen in the form which he executed for Cardinal de Cheverus. He also executed some of the colossal statues placed on the Palais de Justice, and the fine bust of the architect Louis which decorates the foyer of the theatre at Bordeaux.—The Minister of Public Instruction has granted a credit of 40,000 francs for the restoration of the ancient theatre at Orange. M. Fornigé is the architect entrusted with the work.

BERLIN.—The members of the Prussian Royal Academy had a special meeting to celebrate the Emperor's birthday. Herr Professor Oetzer (Hon. Corresponding Member of the I.R.A.) was the guest of the day. In a lengthy harangue he treated of matters pertaining to the gradual development of church-building in Berlin. It may be noted that no less than twenty-five Protestant churches have been built or commenced within the city and suburbs of Berlin since the day on which Emperor William II. ascended the throne. Anton von Werner will for the coming year 1892-3 again hold the president's chair in the "Verein Berliner Kuenstler." There was a close contest with a second candidate, Herr Karl Becker, President of the Prussian Royal Academy, who obtained 103 votes to Anton von Werner's 105. If Herr Becker had been elected the unpleasant relations between the Society and the Academy would probably have now seen an end, especially as the "Academy party" is gradually growing weaker, but surely not stronger.—During a business meeting of the "Verein Berliner Kuenstler" a large participation at the Chicago show was decided on. Berlin will be well represented as regards to quantity if not quality of work. Munich will send only a small collection of South German works of art, but it is to be a very select one.—The "vereinigting Berliner Architekten" intends exhibiting at Chicago as a body, and will send a fairly representative collection of architectural work done in the city by its members. Each member of the Society has been invited to prepare drawings of work he has carried out during the last decade, special conditions as regards the scale of the drawings, and the different sizes of sheets, being added. The drawings are to become the property of the "Vereinigting," who, will on their return from the Chicago show use them as a basis for a larger collection of members' work planned some time back. This latter collection of members' work will be kept up to date by the regular contributions of drawings of all the more important

buildings erected year after year, will some day be a valuable one for the historians of the future. — Herr Kayser, at a meeting of the "Vereinigung Berliner Architekten," reported on the progress made by the special committee of members of the society occupied with framing a new code of building regulations intended to replace the very unpopular one at present in force. When ready the different paragraphs of the new code are to be put before the authorities in the form of propositions, and it is hoped that they will be passed with but few alterations as early as 1893. — The proposal to erect a so-called Provincial Museum in Berlin, which has been before the municipal authorities for some time, has found favour. The financial part of the question has been solved, and a site for the new museum selected in the city proper. A competition for a suitable design for the building (which is to cover some 2,000 square metres of ground) is to be opened at once; three premiums (250, 75, and 50) are to be awarded. — The two Court playhouses, the opera-house and the theatre, will be subjected to some extensive alterations in accordance with the requirements of the Prussian police regulations relating to the protection of human life in theatres. In the budget put before the Prussian Parliament a vote of 25,000l. is asked for this purpose, and will have to be granted, as the houses would otherwise have to be closed. The regulations require the alterations to be complete by October, 1893. — The large building of the Imperial Bank of Germany (the "Reichsbank"), generally considered to be one of the finest in the city, is to be extended. The foundations for a new wing are to be taken in hand at once, and the new rooms are to be occupied in 1894. — At the "Kunstgewerbe Museum" a special exhibition of Japanese work has been opened for a charitable purpose (relief works in Japan). Some thirty private collectors, among them a number of the members of the Royal Family, headed by the Emperor, have lent objects of interest. — Messrs. Hennicke & v. d. Hude, a firm of architects of old standing and repute, have dissolved partnership. Among the work done by the firm we note the Lessing Theatre and Central Hotel, both in Berlin. — An exceedingly popular member of the profession, Herr Giesenberg, the manager and junior partner of Messrs. Ende & Boeckmann, died last month of a tedious illness of some duration. He had been senior assistant to the late Professor Lucie at the time of the erection of the Frankfort Opera House, and had, after the death of his chief, which occurred during the time of the erection, — the completion and entire interior decoration of this building in his hands. In 1884 he was one of the four winners called off in the great competition for the so-called "Museum Island" design.

MISCELLANEOUS.

NATIONAL REGISTRATION OF PLUMBERS. — A meeting of the local district council was held at the Guildhall (by kind permission of the Mayor) on the 8th inst., under the presidency of Mr. T. J. Pope, architect. There was a good attendance of representatives, and the following, amongst other resolutions, was adopted: — "That the council, recognising the close connexion between the public health and the plumber, and thus the necessity in the public interest for members of the craft of plumbing to be properly acquainted with the laws of sanitation, expresses its warm approval of the efforts being made by the Worshipful Company of Plumbers to obtain the sanction of Parliament to a Bill for the registration of plumbers and for the efficient examination of all entering the trade, and desires that local members of Parliament be requested to support the same." It was also resolved to form a local committee, composed of five members and a secretary, the public and master operative plumbers being equally represented, at Bath, Cheltenham, and Gloucester.

ROYAL METEOROLOGICAL SOCIETY. — The usual monthly meeting of this Society was held on Wednesday evening last, at the Institution of Civil Engineers, 25, Great George-street, Westminster, Dr. C. Theodore Williams, President, in the chair. Four papers were read, the first one being on "The Untenability of an Atmospheric Hypothesis of Epidemics," by the Hon. Rolfe Russell, M.A., F.R.Met.Soc. The author is of opinion that no kind of epidemic or plague is conveyed by the general atmosphere, but that all epidemics are caused by human conditions and communications capable of control. In this paper he investigates the manner of the propagation of influenza, and gives the dates of the outbreaks in 1890 at a large number of islands and other places in various parts of the world. Mr. Russell says that there is no definite or known atmospheric quality or movement in which the hypothesis of atmospheric conveyance rests, and when closely approached it is found to be no more available than a phantom. Whether lower or upper currents have ever taken a leap to cross Europe from east to west, or adjusted their progress to the varying rate of human intercourse. Like other maladies of high infective capacity, influenza has spread most easily, other things being equal, in cold, calm weather, when ven-

tilation in houses and railway-cars is at a minimum, and when perhaps the breathing organs are most open to attack. But large and rapid communications seem to be of much more importance than mere climatic conditions. Across frozen and snow-covered countries and tropical regions it is conveyed at a speed corresponding, not with the movements of the atmosphere, but with the movements of population and merchandise. Its indifference to soil and air, apart from human habits depending on these, seems to eliminate all considerations of outside natural surroundings, and to leave only personal infectiveness, with all which this implies of subtle transmission, to account for its propagation. In the second paper, on "The Origin of Influenza Epidemics," by Mr. H. Harries, F.R.Met.Soc., another theory was propounded. The author has made an investigation into the facts connected with the great eruption of Krakatoa in 1883, and the atmospheric phenomena which were the direct outcome of that catastrophe. He has come to the conclusion that the dust derived from the interior of the earth may be considered the principal factor concerned in the propagation of the recent influenza epidemics, and that, as this volcanic dust invaded the lower levels of the atmosphere, so a peculiar form of sickness assailed man and beast. The third paper was a "Report on the Phenological Observations for 1891," by Mr. E. Mawley, F.R.Met.Soc.; and the fourth a "Note on a Lightning Discharge at Thornbury, Gloucestershire, on July 22, 1891," by Dr. E. H. Cook.

"FAIR FROD" SYSTEM. — We have received a description and illustrations of what is called "FAIR FROD" system of ventilation, the main object of which is to prevent the condensation of moisture on the interior surface of shop-windows, by which they are often obscured. The device consists simply of fresh-air inlets arranged below the window and foul-air outlets above it, and would doubtless achieve the end principally aimed at by the author, Mr. G. C. Vernon Inkpen. The system, as a means of ventilation, would have but small effect, as the action would be confined almost entirely to the portion of the shop atmosphere immediately contiguous to the window. A patent has been granted for this invention, but, as in England, such a grant is no evidence of validity, we do not hesitate to express our doubt as to the invention possessing sufficient novelty to maintain the patent.

AUTOMATIC "IN-AND-OUT" TURNSTILE. — Mr. G. Williamson, the patentee of this turnstile, which we noticed briefly last week, sends us a sketch diagram of the mechanism, from which we see that we misunderstood the description formerly sent, and did not do justice to the ingenuity and usefulness of the turnstile. The ingress and egress are through the same opening, the space occupied by the opposite arm being permanently blocked in the usual manner for egress turnstiles, the motion being capable of reversal for ingress on the insertion of the coin. The method by which the turnstile sets itself, after the insertion of the coin has allowed it to pass a quarter revolution, is ingenious and simple, the only weak point being the dependence on the action of a spring, which is always an undesirable element in mechanism, though it cannot always be dispensed with.

LIVERPOOL ENGINEERING SOCIETY. — The eighth ordinary meeting of this Society for the present session was held on February 10, at the Royal Institution. Mr. Thomas Morris, F.G.S., read a paper entitled "Engineers' Tests for Iron considered," and Suggestions for Standard uniform Tests." The author showed by tables of numerous engineers' tests how engineers would ask for different tensile strains for the same class of work, adding that the iron must be equal to some known "brand," as though the iron produced in the localities named was uniform in quality. He paid a high tribute to the reduction of area test, as being one that gave more consolation to the engineer in case of work coming to grief than any other test specified. The elongation test, which he said was only another form of test for ductility, was not to be depended upon with the same ease and comfort as contraction of area, and the manner in which the former test was specified by nearly all engineers was anything but creditable. He treated the "limit of elasticity test" with disfavour almost amounting to ridicule. His suggestions for "standard uniform tests and conditions" were put in the simplest form, and were thoroughly explained to those present. The discussion was adjourned to the next meeting.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY. — At the meeting of this Society on Wednesday evening last a paper on "Gas Producers" was read by Mr. R. Booth, M.I.M.E. The author first of all dealt with the increased attention which has lately been given to the economical use of fuel, and the possibilities which lay ready to hand for avoiding smoke and mitigating the fog nuisance by means of the use of gasiferous fuel. He pointed out that it had been satisfactorily proved that the discharge of black smoke from factory chimneys could be entirely obviated by using gas instead of solid fuel, but the application of gas to domestic purposes did not come within the scope of his paper. He then proceeded to compare the chemical and physical

problems presented by the two systems of burning coal from a broad point of view, pointing out that the process of combustion was by no means a simple one, — that while, considered as a process of oxidation, the amount of heat was invariably, the intensity varied with the rate at which the oxidation took place.

A PERFECT SCREW. — What is claimed to be a perfect screw has recently been made by Professor Rowlands, of the Johns Hopkins University, in the United States. This screw forms part of a dividing machine of wonderful accuracy which the Professor has devised. It is 17 in. long, 1 1/2 in. in diameter, and has twenty threads to the inch. It is described as being made of "Jessop tool steel," from which we gather that the material has been sent from Sheffield. It was cut in a lathe and then ground with fine emery for three weeks in oil and water kept at a constant temperature. The dividing machine will rule 100,000 lines to the inch on highly polished speculum metal; and it is said a 1,000,000 lines to the inch can be ruled if required; 110,000 lines to the inch have been done. The cutting part is a diamond.

THE ENGLISH IRON TRADE. — The English iron market remains in a quiescent state. There is still great want of animation on the Scotch warrant market, and in the Cleveland district there is a lessened demand for crude material. The hematite pig-iron trade is still depressed. Manufactured iron is in limited inquiry, and Welsh hars are slightly lower than last week. The tin-plate market remains dull. In steel there is an increased call for heavy sections, which have again been advanced, but other descriptions exhibit little alteration. Shipbuilding is tolerably active, except on the north-east coast. Engineers are only moderately employed; the strike on the Tyne still shows no signs of termination. The coal trade is quiet. — Iron.

THE BROOKLYN BRIDGE has long been insufficient for the traffic between Manhattan and Long Island, and a Bill is now being brought forward in the New York State Legislature by which the East River Bridge Company and the Union Elevated Railway Company seek power to build two bridges across the strait which is called by New Yorkers the East River. Twenty-five million dollars is the capital set apart for the undertaking.

LEGAL.

CASE UNDER METROPOLIS MANAGEMENT ACT, 1873.

HOUSE FRONTING MORE THAN ONE STREET-CROWN LANDS.

MR. JAMES POLLOCK, builder, Nottingham, was summoned at the Woolwich Police-court, on the 6th instant, by the London County Council, for not setting back the external fence of the forecourt or other space in front of a house on the east side of a footway leading from Chislehurst Park to Lee.

Mr. Chilvers, from the Solicitor's department, supported the summons, and called a surveyor, who proved the erection of the fence at less than the prescribed distance from the centre of the footway. The witness on cross-examination admitted the house fronted Chislehurst Park, and only had a flank wall abutting on the footway.

Mr. Sampson, solicitor for the defence, submitted that sections 6 and 8 of the above-named Act applied only to the forecourt or other space in front of a house, and not to a piece of land at the side; and, further, that as the land on which the fence was erected was Crown property, the Council could not proceed without the consent of her Majesty's Commissioners of Woods and Forests, as provided by section 27 of the Act.

Mr. Chilvers contended that that section did not apply to a Crown lessee, and that the summons was in respect of the fence and not the land; also that in the lease held by defendant it was provided that the powers of the late Metropolitan Board of Works should be complied with.

The magistrate, Mr. Marsham, held that a house could front three or four roads, and that a Crown-lessee was not exempt; and he ordered the fence to be set back in a month, and allowed 2l. 2s. for costs; but, on application, he granted a special case.

MEETINGS.

SATURDAY, FEBRUARY 20.

Architectural Association. — Visit to the Imperial Institute, South Kensington, by permission of the architect, Mr. T. E. Collcutt. 3 p.m.

MONDAY, FEBRUARY 22.

Royal Institute of British Architects. — Messrs. R. Herbert Carpenter, F.S.A., James Powell, N. H. J. Westlake, F.S.A., and Clement Heaton on "Painted and Stained Glass." 8 p.m.

Royal Academy of Arts. — Dr. A. S. Murray on "Archæic Compared with Archæistic Sculpture." III. 8 p.m.

Liverpool Architectural Society. — Mr. James Dod on "Light and Air."

COMPETITIONS, CONTRACTS, AND PUBLIC APPOINTMENTS.

COMPETITIONS.—Continued.

Table with columns: Nature of Work, By whom Advertised, Premium, Designs to be delivered, and Tenders to be delivered. Includes entries for Intermediate School, Bridge, and various construction projects.

CONTRACTS.

Table with columns: Nature of Work or Materials, By whom Required, Architect, Surveyor or Engineer, and Tenders to be delivered. Lists various construction contracts and their specifications.

CONTRACTS.—Continued.

Table with columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, and Tenders to be delivered. Continues the list of construction contracts.

PUBLIC APPOINTMENTS.

Table with columns: Nature of Appointment, By whom Advertised, Salary, and Applications to be taken. Lists various public appointments and their details.

Those marked with an Asterisk (*) are advertised in this Number. Competitions, p. iv. Contracts, pp. lv, vi, viii, ix, & xviii. Public Appointments, p. xx.

TUESDAY, FEBRUARY 23.

Institution of Civil Engineers.—(1) Mr. W. T. Douglas on "The Bishop Rock Lighthouses." (2) Mr. David C. Salmon on "The Illumination by Gas of Tory Island Lighthouse, Co. Donegal." 8 p.m. The meeting will be adjourned at 9 p.m., when the President and Council will hold a reception in the library.

Society of Arts (Applied Art Section).—Mr. J. William Tonks on "Artistic Treatment of Jewellery: Jewel and Address Caskets." 8 p.m.

Builders' Clerks' Benevolent Institution.—Twenty-fifth Annual General Meeting of Donors and Subscribers. 7.30 p.m.

Sanitary Institute (Lectures for Sanitary Officers).—Mr. J. Wright Clarke on "Details of Plumbers' Work." 8 p.m.

Wednesday, February 24.

British Museum.—Miss Eugénie Sellers on "Greek Sculpture: Sculptures from Bassae." III, 2.30 p.m.

Society of Arts.—Mr. Ernest Hart on "Ancient and Modern Art Pottery of Japan." 8 p.m.

Liverpool Engineering Society.—Adjourned Discussion on Mr. Thomas Morris's paper on "Engineers' Tests for Iron considered, and Suggestions for Standard Uniform Tests." 8 p.m.

Thursday, February 25.

Society of Antiquaries.—8.30 p.m.

Institution of Electrical Engineers.—8 p.m.

Friday, February 26.

Royal Academy of Arts.—Professor J. H. Middleton on "Michael Angelo." 6 p.m.

Institution of Civil Engineers (Students' Meeting).—Mr. G. H. Shellfield on "The Construction and Efficiency of Locomotive Boilers." 7.30 p.m.

Sanitary Institute (Lectures for Sanitary Officers).—Mr. Charles Jones on "Scavenging, Disposal of Refuse." 8 p.m.

Institute of Certified Carpenters.—7.30 p.m.

RECENT PATENTS.

3,797.—CEMENT: G. H. Skelley.—This patent refers to a process of manufacturing Portland Cement from chalk to be found in large quantities near Hull and other places. An ordinary wash-mill in combination with an edge-runner mill made with specially constructed heavy runners, is employed. The chalk is weighed into the required quantities before it is passed to the edge-

runner mill, where it is mixed with a proportion of water and ground into a thin paste of required consistency, and then is passed to a wash-mill, in which it is mixed with a certain proportion of clay. The manufacture is then proceeded with in the ordinary manner. The inventor claims that cement made in this way can be produced at much less than the usual cost.

3,877.—WINDOW VENTILATION: C. R. Green.—This patent refers to an improved method of window ventilation effected by means of a series of holes bored in the sash-frame where the top sash shuts against it when closed. Further arrangements for fitting out the invention are fully described in the specification.

3,908.—FIREPLACES: J. W. Lewis.—This invention relates to the construction and arrangement of the back parts of domestic fireplaces so that the firebrick back block may be used separately from, and if desired much thicker than, the back block. Means are described for connecting the same together and to the firebox.

4,424.—VENTILATORS: A. V. Kershaw.—The inventor claims that an improved ventilator for the admission of fresh air is made by combining two forms of inlet ventilation, the one part after the form of the Sheringham or box inlet, and the other part the application to the same of the inventor's patent diffusers. The said inlet ventilator consists of a frame for building or being in wall, of a face-plate with sides hinged at foot, or sliding in and out of frame, for opening and closing, and of the above patent diffusers.

14,576.—GLAZING BARS: J. Jefferys.—This refers to an improvement in glazing bars for fixing glass on roofs, &c., to form a water-tight covering, and consists of the combination of two separate bars to form a channelled sash bar, the insertion of an elastic packing between the two bars to equalize the pressure, and an arrangement for securing an even line when seen from below.

18,757.—FIREPLACES: A. C. Freeman.—This specification relates to what is described as an improved method of inducing and increasing up-draught and preventing down-draught in fireplaces. This is effected by providing a front cover or screen of sheet-metal (iron plate) as described. Above the same is a bar or rod which may be elongated by a screw, socket, fitting or by a slide arrangement for the purpose of adjusting the height between the screen itself and the mantelpiece, to which a screw clamp or like fitting may be applied in connexion with the adjustable rod.

NEW APPLICATIONS FOR LETTERS PATENTS.

February 7.—1,929, E. Stewart, Ventilating Sewers &c., and Disinfecting or Deodorizing the Gases therefrom.—1,942, S. Renschel, Fastening Devices for Handles of Furniture, &c.—1,945, A. Smith and J. Emery, Centrifugal Revolving Ball in Taps.

SUBSCRIBERS IN LONDON AND THE SUBURBS, by preparing at the Publishing Office, 19a, per annum (or 4s. 9d. per quarter), can accept receiving "The Builder" by Friday Morning's post.

The Builder Cathedral Series.

SERIES of Illustrations of all the English and Welsh Cathedrals is now being published in "The Builder," and will be continued, in the first issue of every month, until completed.
 The Illustrations in each case include an exterior view, reproduced from a drawing specially prepared for the purpose; and a ground plan, to a large scale, etched to indicate the date and style of the several parts.
 There is also a short descriptive article, having reference to the Church and its surroundings, with sketches of some of the details, &c.
 No trouble or expense is being spared to make this series in every sense artistic and interesting, and as each it is cordially offered to all lovers of Ecclesiastical Architecture.

1. CANTERBURY	Jan. 3.	7. SALESBURY	July 4.
2. LICHFIELD	Feb. 7.	8. BISTON	Aug. 1.
3. ST. ALBAN'S	Mar. 7.	9. NORWICH	Sept. 5.
4. PETERBOURGH	April 4.	10. BUCKINGHAM	Oct. 3.
5. WILLS	May 2.	11. LINCOLN	Nov. 7.
6. EXETER	June 6.	12. GLOUCESTER	Dec. 5.

1892.
 13. ST. PAUL'S Jan. 2. 16. ELY April 2.
 14. Hereford Feb. 6. 17. Llandaff May 7.
 15. CHESTER Mar. 5. 18. Oxford June 4.
 (Further arrangements will be duly announced.)
 Price FOURPENCE each (by post 4½), except Nos. 1 and 2, which are out of print; but the view, plan, and description of CANTERBURY and of LICHFIELD have been re-printed, and they can now be had, price ONE SHILLING each set; by post, 1s. 2d.

Formal Gardens.

THE appearance of another book on gardens by an architect* is a further instance of the interest now taken in this subject by the members of the "art or profession" of

architecture, and of a growing determination on their part to have the design of the garden, so far as it is connected with a building, in their own hands. Mr. Blomfield's book, however, though a small one in size, is not to be considered quite on the same platform as the late J. D. Sedding's "Garden-craft," which we noticed a short time since. Sedding's work, charming and suggestive as it is, is more a rhapsody than a treatise from which any principle or aim can be deduced; it was obviously written quickly and easily, and, as we observed at the time, though delightful reading, there is not much to be learned from it. Mr. Blomfield's book, begun we believe a good while before the other, is closely reasoned and gives evidence of a considerable amount of study of the older literary works on the subject. The illustrations, reproduced from sketches by Mr. F. Inigo Thomas, are very pretty examples of book-illustration on a small scale. Four of them, by the kindness of the publishers, are reproduced with this article.

The main object of the book is to recommend the treatment of the garden in connexion with a residence as a piece of design, on more or less architectural principles, and to discredit the principles and practice of the landscape-gardener. This latter personage is doing penance, and is likely to do penance for some time to come, in all treatment of the subject by artists. He has had, it must be admitted, a very long innings, has imposed himself on society in a triumphant style, and has little right to complain that it is his turn to be shunted. Nor need landscape gardeners, as a race, altogether despair of the resuscita-

tion of their mystery, though not in the present generation. Many have been the changes in fashion in regard to gardens, followed dutifully by wealthy planters of parks, without any too curious inquiry into the philosophy of the matter; and what has happened before may happen again. Nor is it certain that landscape gardeners have deserved all the abuse they now get, or that formality may not be carried too far. But for the present it is clear that the landscape gardener will have to stand aside; society having (as they say of an officer dismissed from the army) "no further occasion for his services."

The main sins of the landscape gardener are twofold. First, that he deliberately adopts the principle of the false or imitative picturesque; secondly, that he ignores the architecture of the house, and designs his garden quite irrespective of it. The first is the more heinous offence of the two, as involving a broad principle of falsity. Because Nature in her irregularity of woodland and glade is charming, we are to make artificially a similar irregularity in the garden. Paths are to wind about as if in accidental meandering, and clumps of trees or hushes are to be carefully, but as if carelessly, placed here and there to give colour to the windings of the walks, as if they were compelled to bend from their course to avoid obstacles which have been purposely contrived beforehand. There is not the slightest difference in principle between this process and the now exploded one of making artificial ruins, which was current in the last century. Because the ruined remains of part of an old abbey are picturesque and suggest poetic association with the past, therefore, if there are no genuine ruins about, we may deliberately create some. The common-sense of the present day revolts at this; but it is only the same principle carried further. The only real difference lies in the fact that the sham ruin is a palpable imposture built up of artificial materials, while the sham landscape is created of materials which are in themselves the work of nature, though artificially disposed, and the imposture is less easily seen through. Once seen through, its charm, if not gone, is at least largely discounted. Besides, there is nothing of a professional

mystery in it, after all. Anyone can do it who chooses to exercise himself in that way. Any one can plant his garden irregularly, and say, here I will have a clump of trees, here a winding walk, here a piece of pond which shall be arranged to look like the end of a large lake of which the remainder is hidden by the trees. Of course the amateur will not do it quite according to the devices of the professional landscape gardener; but then those devices are worth nothing except to the landscape gardener. They are his creed, but not ours, unless we tamely allow him to impose them on us. As we had occasion to remark when reviewing a landscape-gardening book some little time since, we are told certain trees must be placed in a certain way, &c.; but *why* must they? Simply that it is the landscape gardener's notion, which has nothing to do with either nature or art, but is a kind of hybrid concoction in obedience to arbitrary rules. It is his way of doing the trick; but if we do not want the trick at all, what then?

There may no doubt be such a thing as judiciously clearing out or planting up a park for certain ends of effect; but a park is not a garden. The essential error in treating a garden in this mock-natural manner, as stated by Mr. Blomfield, is of two kinds; in reference to what is outside and what is inside the garden; the landscape without and the habitation within (for we are considering the garden specially as an appanage of the habitation). As regards what is without, it is no business of the garden to imitate or blend with that; the garden is an enclosed space or "paradise," separated from the wildness of natural landscape, and intended as a place of retirement for man, in which he may follow the bent of his own devices and make a design after his own pleasure. Now a design which pretends not to be a design merely stultifies itself. As Mr. Blomfield observes "Any one who loves natural scenery will want the real thing; he will hardly be content to sit in his rockery and suppose himself to be among the mountains." A garden is an artificial enclosure, and what we look for in it is an artificial design and not an attempt to make it look like nature. And this argument has double force when we consider that the garden is

* "The Formal Garden in England." By Reginald Blomfield and F. Inigo Thomas. London: Macmillan & Co. 1892.

immediately connected with the architecture of the house, which is necessarily an artificial design. A house growing out of a "wilderness" is a thing out of place, coming abruptly out of the ground, with nothing to lead up to or form a base to it. The laying-out and planning of the garden should have a direct reference to the style and to the laying-out of the house. It is a pendant to the architecture. In the mock-natural landscape garden it is impossible this can be the case, for the characteristic of this type of garden is a studied irregularity: the clumps of trees must be disposed as if to persuade the eye that they naturally grew there; the walks must take all kinds of apparently accidental curves and windings. There is something absolutely repelling to the architectural eye in the plan of one of these gardens, with its walks deliberately laid out in broken-backed curves.

There are certain points, no doubt, in the book before us, which are pressed a little too far, both in the direction of formality and in the condemnation of informality. It may be questioned (as indeed Mr. Blomfield hints) whether the title "The Formal Garden" is altogether the best one, the word "formal" having an acquired secondary sense which is the reverse of complimentary; though we are not prepared to suggest a better title for the present purpose. But the tendency of some of the examples and of some of the remarks is a little too much in favour of a degree of artificiality in the garden design which some may think deserving of the worse meaning of the word "formal." Mr. Blomfield condemns indeed the sheer pattern-making of the Dutch system, observing that the votaries of this style seem to have forgotten that, after all, a garden was a thing compounded of natural growths, of herbage and flowers. But he appears to defend the artificial clipping of trees rather further than

we should be disposed to follow him. It is quite true, as Mr. Blomfield says, that it is really no more unnatural to clip trees than to clip grass; but to clip them into imitative shapes is another matter, and though the author admits that this was carried to excess under William and Mary, he seems to have a kindness for it which we cannot feel. It is interesting and pleasant in the garden of an old house, where it belongs to and recalls the taste of the period to which the house belongs, and has an association of old times about it; but we should be very sorry to see it revived in modern gardens. It is an artificiality precisely the opposite to that of the landscape gardener, and (to our thinking) equally false in taste. We doubt whether even the cutting of shrubs or small trees into purely geometrical shapes, such as cones and obelisks, is not over formal. At all events it is certain that a garden treated with this extreme degree of symmetry requires fine weather and warm sunshine to look at home; it is a melancholy spectacle in winter. Then again we are disposed to think that some places may be found for landscape-gardening, on a small scale and without an actual pretence of naturalness, in gardens which have no connexion with architecture; those which form a secluded portion of a park for instance. Mr. Blomfield is sarcastic over Battersea Park, which we always thought rather a wilderness of a place; but the enclosed quasi-garden portions of Birkenhead Park, which have no relation to any architecture, but are merely secluded portions railed off from the open park for special treatment, realise a very charming effect with their plantations and small glades and water, which can hardly be said to pretend to pass for natural, though irregular in their lines; and we doubt whether a treatment of the whole as a single formal garden open to the eye at all parts would have given

as much pleasure or beauty, on the whole, within such a confined space of ground. The vice of twisting the water about so as to carry it out of sight from every point of view is a piece of trickery, certainly, that cannot be defended, nor the use of a bridge where one could as easily walk round the end of the pond; but (in spite of principles) it is a very pretty spot. Then we think also that the author rather fails to recognise the real merits of Repton, who lived in a bad day and practised in a bad style, but who may be called a genius in his way, and was at least far above his immediate predecessors and followers in power and perception in dealing with estates according to the method then in vogue. Mr. Blomfield talks of Repton having ruined this and that place; but we do not feel quite so sure about this; and in regard to his sins in cutting down avenues, it should be remembered that it is one thing to admire one fine avenue, and another to go, as Repton did, all over the country from one "seat" to another, and find everywhere the eternal avenue, as if nothing could be done without it. At all events, we do not think Repton was a man to be dismissed with a sneer. A man may be a genius, though working in a bad style. There is no doubt Bernini's style was execrable; Adam's was formal and tame; Street's Gothic Law Courts are a mistake; but Bernini, Adam, and Street were all remarkable men in their way, and so we take it was Repton.

To return to the book before us, the second and third chapters give an interesting historical sketch of "The Formal Garden in England," in which a great deal of curious antiquarian information, illustrated from various old prints, is compressed into a small space, followed by a chapter on "the end" of that institution, accompanied by the sarcasms of Pope and the mild fatuities of Addison. It is perhaps hardly correct to say that Milton of all men loved the formal garden. His

"trim gardens" suggests the idea, but in his later great poem he makes it one of the beauties of Paradise that the scene had nothing to do with "nice art" but with "nature hoon."

Wild without rule or art, enormous hills."

"Enormous" is no doubt used in a quasi-Latin sense, the absence of *norma* or rule. The succeeding chapter deals with "Courts, Terraces, and Walks" in a fashion partly historical, partly critical. Concerning the critical portion we entirely concur in the importance of a terrace near the house, as a base for it to rise from, and in the fine effect of a "fore-court," now too often represented only by the carriage "sweep" and the oval of green grass in the centre of it. The charm of the fore-court of Ham House we alluded to not long since. Fully do we agree also in the recommendation of a liberal breadth for walks. Nothing more tends to give meanness even to an otherwise stately garden than cramped and narrow proportions in the walks. A charming specimen of the fine effect of the fore-court in a comparatively small and unpretending mansion is given in the view of Ambrosden (fig. 25).

In the following chapter on "Knots, Parterres, and Grass-work," we hope that we are not intended to admire the examples from Markham, with the apparent interlocking of the horders, as bad in garden design as German "interpenetration" in architecture: but we do not notice any protest against it. In regard to grass-work it is suggested that the lawn-tennis court presents some opportunities,—

"that is, if the scale given by the dimensions of the court itself are" (query—"is?") "sufficiently adhered to, and the features introduced are kept sufficiently large and simple. To make the court a really valuable part of the garden it is not enough to lay out a sufficient expanse of grass, which loses itself at the earliest opportunity in shrubs and flower-beds. The court should be taken as a definite problem, and designed as an integral part of the garden. And this applies to all grass-work. The mistake of the landscapist is that he considers grass only as a background, not as a very beautiful thing in itself. Grass-work ought to be designed with reference to its own particular beauty. The turf of an English garden is probably the most perfect in the world, certainly it is far more beautiful than any to be found on the Continent, and even the French admitted this two hundred years ago. It is wifely throwing away a most valuable means of delight to treat grass-work as a mere affair of haphazard convenience."

In the chapter on "Fish-ponds, Pleaching, arbours, Hedges" &c. the author refers to the decline of the old fish-pond under the influence of Le Nôtre, to make way for the vast sheets of water which formed an essential feature in his system. "Great canals and basins took its place, and the transition from this to the artificial lakes of the landscapist-gardener was easy." The long canal form of ornamental water is however to our thinking a very fine incident in a garden; it has this advantage over a broad sheet of water, that it gives distance and perspective of water-reflections without interfering with the sense of repose, enclosure, and privacy in a garden. The view given of the canal-like fish-pond at Wrest, with its parallel lines of thick hedge on each side, forms a charming example of this. "Pleaching," a revived old English word, signifies, according to the author, "the trimming of the small boughs and foliage of trees or hedges to bring them to a regular shape"; but we doubt if this is the old meaning. Walker's dictionary gives "to bend, to interweave," with the note "obsolete"; but Lord Tennyson (who, though not a dictionary-maker, is one of the first authorities on the true use of old English words) revived it in a well-known passage which confirms Walker's reading—

"Round these grow, self-pleached deep,
Bramble-roses, faint and pale,
And long purples of the dale."

Mr. Blomfield distinguishes it from "plash," which refers to the half-cutting of the larger branches and bending them down to form a hedge." We rather think it will be found that "pleach" and "plash" are two forms of the same word. The illustrations,

from Markham's "Country Farm," of hedges cut into elaborate ornamental outlines at the top, are curious, but we should have liked to have seen them condemned; the weak garden-owner may take them as models, to the astonishment and alarm of his visitors.

Chapter viii. is devoted to the interesting and fruitful subject of "Garden Architecture," on which a book might be written; books have indeed been written on it, and bulky ones, but no good one that we know of; they are mostly advertisements of designs for lodges and entrance-gates. Many remains of old garden architecture are delightful in their combined dignity and simplicity. "Rustic bridges" were unknown in those better times. The two great stumbling-blocks are rusticity on the one hand, which is quite out of place in the formal garden,—it is the landscapist gardener's pet "fad"; and "classic" pretension on the other hand; gardener's lodges in the shape of Greek temples, &c. These are not out of keeping with the garden so much as with the purpose to which they are put, making them cottage-homes inside and temples outside. Gate-piers in the seventeenth century are well worth study; the same general idea runs through many of them, but constantly varied in little details, though without any attempt at strange or sensational

more fatal than to put up commonplace reproductions of well-worn works.

In the concluding chapter are some remarks on the treatment of gardens in London squares which deserve special consideration. A London square, the author observes, is an entirely artificial affair, bounded by rectangular blocks of buildings.

"In Bloomsbury, till within the last few years, there existed a good old-fashioned square garden, laid out in four simple grass plots, with a lime walk and a border of flowers running round the sides. It was restful and pleasant to look at. The grass plots were good for lawn-tennis and the lime walks kindly to the citizen; but the landscapist gardener appeared on the scene and speedily put all this to rights. He cut up the grass plots and destroyed two sides of the lime walk, and heaped up some mounds, and made the most curiously unreasonable paths; and then charged a handsome sum for having destroyed one of the few Square gardens in London with any pretence to design."

We think we know the garden, and sympathise. The present treatment, with its feeble "mounds," is puerile. But there is something to be said on both sides, where a wealth of tree foliage exists. Has Mr. Blomfield ever noticed the effect of the mass of foliage in Brunswick-square gardens on a bright day in spring or early summer? We doubt whether any parterre would compensate for that.

In regard to one point touched on in the general criticism of landscape-gardening in the earlier part of the book, we do not quite agree with the author in condemning the idea (carried out, as he observes, by Barry in his well-known scheme at Trentham) of treating the park immediately outside the garden enclosure in a partially formal manner, so as to lead out by stages to the informality of natural landscape. It may be carried out so as to appear too pedantic and contrived, but there is something in the idea. Hampton Court is an example. Outside the semicircular fence enclosing the formal garden we have only trees, meadows, and water, and trees and water laid out in formal avenues and canals. The contrast with the formal garden within the fence is quite sufficient to mark off the garden as the more artificialised portion, and we should certainly

GATE PIERS: CANONS ASHBY: NORTHANTS

treatment. Canons Ashby, of which we give an illustration, is a good example; notice the admirable effect of the consoles at the back of the piers, breaking the harsh angle between them and the wall. Tissington gate is a characteristic specimen, but to our thinking owes its picturesqueness rather to age and association than to the actual merit of the design: it would look rather bald and heavy if executed as a new work in freshly-hewn stone. The gate from Pitmidden, Aberdeenshire, of which an illustration is given in the book, with its double returned flight of steps and the fountain-niche in the centre of the inner retaining wall, and the gate-piers flanked by a short length of balustrade on each side, is one of the pleasantest examples of the combination of simplicity, dignity, and picturesque character in this kind of work. The sundial is one of the most beautiful and suggestive features that can be introduced in a garden; we give the illustration of the one from Wrest. In regard to statuary, we think Mr. Blomfield is right in condemning marble for this country; it is only suited to a bright southern climate, and gets stained and looks unhappy and starved in a rainy climate. Portland stone is preferable, but the author especially recommends the revival of the old use of lead for such garden statuary, which weathers into a silvery grey, rather improving than deteriorating with time, as far at least as appearance goes. We give the example of the little leaden cupid from Melbourne. Statuary is a beautiful addition to a garden; but let it be good statuary. Nothing is more easy or

LEAD FIGURE OF CUPID MELBOURNE: DERBY

lose a fine palatial effect in the loss of the formal arrangement of the avenues and canals.

One other criticism we have to make. Had Dante lived in the age of printing, he would

certainly have had a place in one of the circles of his "Inferno" reserved for authors who issue books without an index, who would probably have been condemned for ever to search for references which they could not find. By his prudence in living after Dante, Mr. Blomfield has escaped this inconvenience; but we hope an index will be added in the next edition.

NOTES.

AT the meeting of the Hellenic Society on Monday last an interesting paper was read by Professor Percy Gardner, on "the Chariot Group of the Mausoleum," the object of which was to suggest that the two nearly perfect statues discovered by Sir Charles Newton among the other remains on the mausoleum site did not form part of the quadriga group on the top of the pyramid. That the statues do in all probability represent (according to their accepted nomenclature) Mausolus and Artemisia, Professor Gardner admits, but denies that they were placed in the chariot. The following are his principal arguments: Pliny describes the chariot but makes no mention of portrait-statues; such statues would probably not be placed at such a height that the portraiture would be lost, and even the figures themselves hidden behind the group of horses; the attitudes of the figures do not suggest the driving or controlling of horses, nor is the dress of the man such as would be worn in a chariot; and (which seems the most important argument) the figures are too small in scale for the wheel and the horses. The wheel of a chariot in Greek sculpture is usually about half the height of a man, and when figures are combined with horses, the figure is almost always, if not always, about the same height as the complete height of the horse, up to the top of the horse's head. These conditions of proportion would have required the figures to be about 14 ft. high, whereas in fact they are respectively 9 ft. 10 in. and 8 ft. 8 in. Mr. A. S. Murray, who is now engaged in setting up the remains of the quadriga and the figures in relation to one another (which was perhaps the reason the paper was read), replied in favour of his view, his most important arguments being that the stratification of the marble was similar in all the fragments, showing that they had come from the same locality in the quarry and presumably had been worked together; and that there is a break in the side of the statue of Mausolus just about the height where the chariot rail might be supposed to come. There is, of course, also the fact that the statues and the quadriga fragments were found close together on the site, but Professor Gardner replied that this, as is known in other instances, is no certain criterion as to their relative situations on the building. A glance at the remains, since the meeting, convinces us at least that Professor Gardner's argument about proportions is valid. The statues are decidedly too small in scale for the fragments of the horses; they would be thought so even in modern art, still more in Greek art, where the horse is always smaller in comparison with the human figure than in modern art. Mr. Murray's arguments must not be overlooked, but if the figures did belong to the quadriga they were out of scale to a degree of which we believe there is no other example in Greek art. If, however, these dignified and highly-finished statues were not in the place which has been supposed, there appears to be no fitting site for them in Pullan's restoration of the Mausoleum, so that the question affects the architectural as well as the sculptural restoration of the monument. We may take the opportunity of observing that two things are much wanted at the Hellenic Society's meetings, viz., ventilation and punctuality. Of the former there is none; and as to the latter, the meeting is always kept waiting from ten minutes to a quarter of an hour after the stated time, before the chair is taken.

THE subject of "Stained Glass" drew a large meeting at the Institute on Monday evening, and the large collection of diagrams of stained-glass designs exhibited was an element of considerable interest; but nothing very new was said about stained glass either in the papers or in the discussion, in spite of a return to the old and (we thought) exploded system of "calling on" selected speakers by name. This system certainly has the advantage that it stops the mouths of certain irrepressible gentlemen who are always wanting to hear the sound of their own voices, but otherwise it is a principle rather at variance with freedom of discussion, and its advantage was not very obvious on Monday night, when one artist admitted that he had nothing to say, and another appeared to think the chief object of the meeting was to hear him speak, and had eventually to be stopped by the Chairman. Among points which might have been noticed in discussion and were not, we may call attention to the unfortunate suggestion made in our paper, that for the treatment of the extremities of the figure in stained glass we should study Botticelli, *i.e.*, conventionalise some one else's convention. Certainly the wiser course would be to begin at Nature and do our own conventionalising so far as it is necessary. Among the remarks made on iron work not a word was said about a point that has excited a good deal of controversy in some quarters lately, whether the heavy supporting iron work should not rightly be *outside* the window and not in, and he so treated as to be a decorative feature externally; a view of the matter on which there is a good deal to be said. There are, we believe, Mediaeval examples of this. Another matter which requires criticising, and to which not the slightest reference was made, is the perpetual repetition in stained glass of details imitated from stonework; the eternal "canopy" which seems to sum up the idea of so many designers for filling up the head of a window, and which is not only uninteresting but is entirely unfitted for glass work. Now and then we see a window in which there has been some attempt at the design of an ornamental filling specially suitable for glass, but in the majority of cases it is just the same recipe, the figure of a saint in coloured robes below, and the imitation architectural canopy above. Stained glass should have its own forms of ornament, which are essentially distinct from those of architectural masonry. Speaking of the coloured robes reminds us, too, how little attempt has been made, and how much might be made, to adapt the idealised or conventionalised nude figure to treatment in glass, in combination with decorative detail. All these matters might have raised points for really new discussion, in place of some of the rather worn-out enthusiasm about "jewelled effects," &c., of which we have heard often enough by this time.

AFACULTY has been obtained (as recorded on another page) for the removal of human remains from St. Helen's, Bishopsgate, with which it is impossible to deal otherwise, with proper regard to sanitary precaution. This course will probably have to be adopted in other city churches from time to time. It is natural that descendants of those who have been interred in a church and to whom monuments have been erected in it should feel grieved at the necessity, but there are cases in which it is a necessity, and sentiment must give way to sanitation. We hope the same course will be taken with the remains under St. Mary Woolnoth, instead of adopting the insane project of pulling down this, one of the most characteristic buildings in London, which has been mooted in some quarters. The absurdity is the greater inasmuch as, even if the church were destroyed, the mass of human remains would have to be removed all the same, for the safety of the city.

IT has long been held that section 157 of the Public Health Act, 1875, which authorises Local Sanitary Authorities to

make By-laws with respect to certain structural arrangements of new buildings, does not authorise the making of a By-law with respect to the height of rooms, and, accordingly, in the Public Health Acts Amendment Act, 1890, a section (No. 23) has been introduced extending the powers under the Act of 1875 so as to enable any Sanitary Authority, after having formally adopted the Act, to make By-laws with respect to, *inter alia*, the height of rooms intended for human habitation. In many old codes of building By-laws a clause has been introduced with this object; but, owing to its having been declared by the Law Officers to the Crown to be *ultra vires*, it has been used only with the greatest caution. Such clause has usually prescribed a minimum height for any habitable room, and has then prescribed a further minimum height for any habitable room situated either wholly or partly in the roof. There is obviously much inconsistency in determining, for purposes of health, a minimum height for any room intended for human habitation and immediately afterwards fixing a smaller minimum height for another room intended for the same purpose but happening to be in the roof of the building. If a certain minimum height,—say, 8 ft.—is requisite in order to secure adequate breathing-space in a room having a rectangular section, it is clear that a similar height throughout only half the area of the room when situated in the roof must be inadequate, and yet this is what has commonly been demanded. Now that the Legislature has specially authorised the making of by-laws for regulating the height of habitable rooms, the subject has received the consideration of the advisers of the Local Government Board, and a memorandum signed by Dr. George Buchanan, F.R.S., the Medical Officer of the Board, and Mr. Gordon Smith, their architect, has recently been prepared for the guidance of those sanitary authorities who may contemplate making such a By-law. It is recommended in this mem. that the minimum height for a habitable room should be 9 ft., though 8 ft. 6 in. is regarded as permissible, and even 8 ft. would not be refused; but it is suggested that no By-law proposing less than 8 ft. of height should be submitted for the Board's approval. For rooms in the roof it is pointed out that no part of any room should be less than 5 ft. in height, thus doing away with the unsatisfactory arrangement of having part of the floor so circumstanced that the sloping ceiling under the rafters comes down to meet the floor at an acute angle; there must be, in attic rooms intended for human habitation, vertical sides at least 5 ft. high. For the rest the room must be of such a height as will give a mean height over the whole floor-area of not less than 8 ft., or whatever greater height may be determined upon. There can be no doubt that more decisive legislation on this subject is called for, and it is to be hoped that the point will receive attention in framing the new Metropolitan Building Act.

THE action of the Amalgamated Society of Engineers, in regard to the strike in the North, has been condemned in outspoken fashion by some of the affiliated societies. Although the dispute is now affecting some 18,000 men,—the majority of whom are idle against their will,—the engineers stubbornly refused to submit the question at issue to arbitration, until unusual pressure was brought to bear upon them by the Federation of Engineering and Shipbuilding Trades of the United Kingdom. This body urged them to show more willingness to come to a peaceful settlement, and, although they were at first told that their advice was "a scandal to trades unionism," it eventually received more reasonable consideration. Happily, the Unions are not all so averse to conciliatory measures. The following passage occurs in the last "Monthly Report of the United Society of Boiler-makers and Iron Ship-builders":—"Let us always, if possible, ad-

just our differences by peaceful means; and this is possible in ninety-nine cases out of every hundred if there is a desire to do so." The desires of the disputants in this case have inclined in quite an opposite direction, and the interests of their employers have been so entirely ignored, that the latter have been goaded into adopting a rather uncompromising attitude. Messrs. Palmer & Co.—at whose yard the dispute arose,—have had to send work away from Jarrow to Glasgow for I.L.M.S. *Revenge*, and other work is in like manner being lost to the district. In accepting a proposal from the societies interested for a conference, the employers have stipulated that the discussion must take cognisance of the original dispute; whereas the engineers characteristically desired it to be confined, in the first instance, to the lock-out, which was really the inevitable outcome of that dispute.

THE case of Hart v. The Monarch Land Company, Limited, tried this week before Mr. Justice Mathew and a special jury, shows the difficulty in which owners of property are placed when they have to rely solely on the opinion of experts. The action was brought to recover damages for injuries done to the Star Music Hall by the erection of some model dwellings which abutted on the east wall of the hall, and which, by placing too great weight on this wall, caused the front wall to crack. On the one hand, various architects and surveyors state that in their opinion the cracks were caused by the defendants' buildings. On the other hand, an equally numerous body of experts asserted that in their opinion the causes of the damage were certain defects and weaknesses in the wall itself. Each of these adverse opinions was, no doubt, put forward quite honestly; the mistake which professional witnesses make is in adhering too confidently to matters of opinion as if they were matters of fact. It is this which brings professional witnesses into disrepute. In the present case, the jury agreed with the plaintiff's witnesses, or it may be they gave him the benefit of the conflict of evidence. When in doubt, and for the plaintiff, is a maxim dear to the jurymen's heart. But such a dispute as this ought to have been kept out of the law courts: a competent architect with a judicial mind might surely have settled the matter after an examination of the buildings.

THE London School Board have again been in litigation against one of the holders of their schools, on the ground of fraud and wilful deviation from the contract. The result was a verdict for the defendant. Nothing could be more ill-advised than to claim damages on such a serious ground as this without very complete proof. Mere carelessness, however reprehensible, is entirely different from fraud. The contract in question made the builder liable for four years if fraud and wilful deviation could be proved. It is businesslike for a public body to have a clause making the builder liable for bad workmanship and materials for a stated period after the end of the contract, for the deviation from the contract is not always ascertainable. But it is thoroughly unbusinesslike to bring actions for fraud unless there is proof positive; to do so in an uncertain manner is simply to throw good money after bad.

WE have repeatedly expressed our opinion that London, in considering its future water-supply, ought to aim at finally abandoning direct supply from the Thames; and in support of this opinion from the medical point of view we may draw the attention of our readers to the following remarks in the last issue of the *Lancet* :—

"While recognising to the utmost the value of modern improvements, we find ourselves unable to abandon our old belief that the Thames affords a most unsatisfactory water-supply. The Thames drains a large and highly populous area, and pollutions of all kinds pass inevitably into it. Every storm of rain carried down in muddy streams the washings of towns, villages, manured fields, and

pigstyes. In spite of all care human sewage certainly finds its way into the stream even at distances not far above the intakes of the great companies. At the mouth of the Wey, close to Shepperton, a cluster of houses with cesspools certainly pollute the water, for the cesspools fill during flood time and empty as the water recedes. Such at least was the state of things at the time of our last inspection, and we have no reason to suppose that any change has been effected. This, at all times unpleasant, might evidently become a source of urgent danger if a single case of cholera or choleraic diarrhoea occurred in one of the cottages. In the same way barges and even house-boats, in spite of the prohibitions of the Thames Conservancy, might evidently and at any time communicate some deadly pollution to the water-supply. London would then be protected only by the filters, and surely nobody would drink with comfort water which, having received the cholera virus, had been purified solely by passage through sand. As to other pollutions, we have ourselves seen the putrid bodies of dead dogs floating in the river within half a mile above the intakes of the companies."

PROFESSOR HAMMER has been making an investigation of the different slide rules in the Stuttgart Technical School, and has published the results of his inquiry in the German surveyors' organ, *Zeitschrift für Vermessungswesen*. For simple multiplications or with multiplications with three factors, the 25 centimetre slide rule gives an approximation of within about 0.1 to 0.2 per cent. of accuracy. Professor Hammer tested a number of German celluloid slide rules, and found the mean error in simple multiplication to be $\frac{1}{1000}$ with rapid reading. The less portable office slide rules in use in Germany are the 50 centimetre slide rule, giving an accuracy of 0.08 per cent. with rapid reading; others of various dimensions, such as the Landsberg 723 m.m. long; and Beyerlen's calculating circle, which represents a length of 754 m.m., and with which the accuracy is 0.07 to 0.05 per cent. The Fuller and Thacher rules are used in England and the United States respectively. Mr. Hammer made careful tests with the former, with the result that it was found to give a mean error of 0.008 per cent., which showed that the accuracy claimed by the makers, — i.e., $\frac{1}{10000}$ is not too much. Still, more nearly accurate results were obtained with the Thacher rule, the mean error with careful adjustment being 0.0031 per cent., or approximately $\frac{1}{30000}$ with careful reading.

THE Middlesex County Council intend to enlarge, at an estimated cost of 20,000*l.*, the Council Chamber and Sessions House at the Westminster Guildhall. The present octagonal building, of brick with stone Doric portico, was erected in 1804-5, after C. P. Cockerell's designs. The site is that of a meat market, built in the Sanctuary in 1751, and which had been established, as we read, as early as 1568. It appears, too, that the market stood over part of the foundations of the Sanctuary church, whose remains, supposed to be of Edward the Confessor's time, were drawn and described by Dr. Stukeley, — see *Archeologia*, Vol. I.* Maitland (1756) gives an account of "a prodigious strong stone building . . . 72½ ft. the length of each side, and the walls in thickness no less than 25 ft.," and identifies a portion of it with the bell-tower which Edward III. built here for the use, it appears, of the Minster. This is "the strong clochard of stone and timber, covered with lead," mentioned by Stow as having been erected in Little Sanctuary by that sovereign. For the bell-tower they removed the outer staircase at the church's south-eastern angle, and built another on the eastern side, as shown in the drawing and plans made by Stukeley. Part of the fabric was afterwards converted into the "Three Tuns" tavern; all above ground had disappeared by the year 1760. The original "Quaker" tavern gave place to an extension of the market area.

AT a sitting of the Consistory Court, in St. Paul's, on the 18th inst., Dr. Tristram, Q.C., Chancellor of the Diocese, granted

* His view, with plans, of the upper and lower churches are reproduced in Allen's "London," 1823.

faculties in respect of certain London churches. The works for restoring St. Helen's, by Mr. Pearson, R.A., reveal the existence of a large amount of human remains beneath the floor, which we gather is to be replaced with another and levelled. It was stated that of 4,335 interments during the period 1652-1833 one-third were made inside of the church. In view of Dr. Sedgwick Saunders' evidence, and the opinion of the medical adviser to the Home Office, the Court agreed to issue a faculty for a removal, generally, of the remains to the City of London Cemetery at Ilford, or elsewhere, as may in particular instances be desired, but with exception for non-interference with the McDougal (1835), Robinson and wife (1599, 1592), and Sir Julius Caesar (1636) vaults, upon representations by the respective relatives and descendants. The exception extends also to the Sir John Spencer (1609), Sir William Pickering and his son (1542-74), Sir Thomas Gresham (1579), Sir John Lawrence (Dame Abigail, 1682), Sir John Crosby, and Sir Francis Baconroft (above ground, 1723; he died 1726) vaults and tombs.* Towards the cost of the repairs, calculated at about 7,000*l.*, the Merchant Taylors, as patrons, contribute, we believe, 2,000*l.*, and the Charity Commissioners 4,092*l.* out of the common fund set up under the City of London Parochial Charities Act, 1883. Another faculty, following that of August 18 last, for laying out and planting the churchyard of St. Botolph-without-Aldgate, provides for the non-disturbance of the Sidney family monument (1801), and for the levelling and filling of the John Gibbon vault (1765) at the north end, with the removal of the memorial slabs to against the church wall. In the case of Christ Church, Spitalfields, Dr. Tristram said he would grant a faculty—its conditions to be based upon a visit he would make to the ground—for converting the graveyard into an open space, in pursuance of a resolution of the Vestry, passed last December, to profit by the Metropolitan Open Spaces Act. It was stated in Court that the Metropolitan Public Gardens Association are prepared to expend 450*l.* upon the work.

THE Dudley Gallery Water-Colour Exhibition is not a very interesting one as a whole, but contains some works of marked character. Among these are Mr. G. Marks's very beautiful little landscape studies, which give the idea of large paintings reduced to a small scale (Nos. 192, 193, 197, 200, 201); "Lengthening Shadows" (201) the smallest of all, an evening view in a harvest field, is particularly fine. Among larger works Mr. J. Carlisle has a fine landscape, "Until the Evening" (21), a cold spring sunset with a ploughed field in the foreground; "Allington Gorse" (42) is another good work by the same hand. Mr. Sidney Evans exhibits two small drawings of Eton (81 and 87) of very artistic quality; Mr. Henry Bailey's "A Rich Harvest" (92) is fine in sentiment and composition, though rather weak in handling; Miss Skidmore's "The Glow of Eventide" (136) is fine in feeling, and Mr. Fulwood's "Whispers of Gloaming" (150) is noticeable for colour. Mr. Harry Goodwin is rather palpably imitating the style of his brother in some of his views of special localities, such as "Winter Sunset, Hastings" (341), in which however he is not much behind Mr. A. Goodwin, and his "Lucerne Twilight" (162), more in a style of his own, is one of the most striking pieces of colour in the room. We rather quarrel with Mr. F. G. Coleridge, in his various sketches about Salisbury, for not doing more justice to the cathedral; in the "Canon's Garden, Salisbury" (172), the building, which occupies a considerable part of the middle distance, is incorrectly and very weakly treated, becoming a mere wash of brown, and there is no indication (otherwise) of any mistiness in the atmosphere to excuse

* The dates are those of the deaths of the persons named. For an account, with illustrations, of their monuments, and of the church, see the *Builder*, March 15, 1884, and June 29, 1883.

this silhouette kind of treatment. Signor Giampietri, as usual, treats ancient architecture admirably, especially in his "Roman Forum, Remains of Fourth Century" (110), which is perfect as a representation of antique remains of this class. Mr. Barnett Stuart has some interesting representations of ancient architectural remains in various parts of the world,—“Temple Gateway, Kioto” (129), the “Sanchi Tope” (186), the “Caves of Ellora” (224), and the strange scene of the “Approach to Ming Tombs, Pekin” (343), with its elephants and other creatures rudely carved on either side of the road, like a hurlesque on the Egyptian avenues of Sphinxes. Mr. T. A. de Moleyns has some “colour notions” in his slight sketches of foreign town scenes, but the best, the “Rath-Haus, Basle” (137) is spoiled by the buildings being out of perpendicular. Mr. W. Tyndale gives a good architectural picture in “Pont Flamand, Bruges” (138); Mr. L. Block’s studies of old books (158, 163) are admirable hits of still life; and the studies of shipping by Miss Nora Davison—especially “A Farewell Visit” (69) and “From the Far North” (90)—show great truth of perception, and a very original style of handling. We have not too many good painters of shipping (as distinct from sea), and Miss Davison seems to have a style and handling of her own in this class of subject.

WHILE Londoners grumble (often in a very exaggerated strain) at the inaction of municipal authorities in clearing away snow, it appears that the Parisians have had an opposite reason for complaint. According to a sarcastic paragraph in *La Semaine des Constructeurs*, the energy of the “Ponts et Chaussées” in washing away snow by the application of jets of water has threatened to render Paris a kind of Venice:—

“On a canalisé le boulevard Saint-Germain, la rue de Rivoli, l’avenue de l’Opéra, toutes les grandes artères ou commencement déjà à circuler des bateaux . . . d’ailleurs à fonds plats; le service de navigation est chargé de l’entretien de ces voies. On ajoute que les plaques du Jardin d’Acclimatation vont être dressés sous la haute surveillance du sympathique directeur de cet établissement, M. Geoffroy St. Hilaire. On les destine à traîner la gondole du Président de la République. L’administration compte sur un effet saisissant.”

THERE appears to have been a very odd kind of critical objection raised in Glasgow on the passing by the Town Council of the draft Building Regulations Bill in its final form. The complaint is that the Bill will raise the cost of house building. Of course it will; who ever heard of a Building Regulation Bill that did not, if it were worth anything, raise the cost of house building? The necessity for such Bills arises from the tendency of speculating builders to build as cheaply and as badly as possible, and it is to prevent them doing so for the future. The champions of the existing state of things in Glasgow speak with sympathy for the poor builders, who wish to build houses that will pay. No doubt they do, but they are not to indulge this desire at the expense of the public health. The public pays in the long run, not the builders; and the Glasgow public, if it has any common sense, will be willing to pay higher for better and more sanitary building.

CANTERBURY CATHEDRAL.—The Dean of Canterbury writes to the *Times* (Wednesday) in regard to what is being done at the Cathedral:—“The north and south walls of the nave of Canterbury Cathedral have for a century and more been out of the perpendicular, each leaning slightly outside, from the pressure of the roof. When a new roof was put upon the nave, forty or fifty years ago, much was done to correct the pressure, but some months ago we asked Mr. Christian, the architect of the Ecclesiastical Commissioners, carefully to examine these walls and see if they had moved at all. He reported that they were perfectly safe and had not moved; but that it might be as well to brace them together for more perfect security. He gave us drawings for the braces, which are now being put in position, and will tie the two walls together. What we are doing is thus simply a matter of precaution.”

SARACENIC ARCHITECTURE.*

BY PROFESSOR AITCHISON, A.R.A.

It will now, I think, be opportune to give a general review of Saracenic architecture. When I proposed to take up this subject, I intended to include Ottoman architecture, but I felt that in one sense Ottoman architecture should not be included, for though certain Saracenic forms and ornament were retained, it was in fact a branch of Byzantine architecture. Most of the early mosque builders at Constantinople, after the Ottoman conquest, were Byzantines, and when they were not, the main problem the architects had to solve was to improve on the methods adopted at Sta. Sophia; so that in reality it would be extraneous to the main purpose of these lectures.

The research into the origin of Saracenic architecture has been the cause of a certain satisfaction to me in respect to our art,—I use the word art in its most comprehensive sense, just as we speak of the art of the goldsmith and the potter. The Saracens in a century could conquer more of the world than ever belonged to the Egyptians, Chaldeans, the Persians, the Greeks, or the Romans, but with all their resistless energy, and with most of the architecture of the world before them, they could not for four or five hundred years elaborate a Saracenic style; in spite, too, of an influx of wealth, and of a demand for buildings, that was unprecedented. I do not think they were great constructors. At least there seems to be nothing that they built which could vie with the domes and vaults of Rome, or the dome of Byzantium. And in point of durability their works seem to have fallen short of those of Greece, Rome, and Persia. They do not appear either to have originated any great novelty or advancement in what I may call constructive planning. They added a few distinguished picturesque features, and they perfected,—we may almost say invented,—a new scheme of decoration. We know nothing of the causes that produce architects, or poets, or astronomers, but we fancy that certain conditions will produce architecture, and all, or almost all, these conditions were found in the Saracens. They were more magnificently generous than any people of whom we have any knowledge,—in fact, to be called generous was, in their eyes, the summing up of all the virtues. At first they were ascetics, but at a very early period, after their emergence from Arabia, they gave up asceticism, and were more celebrated for the gorgeous magnificence of their buildings, dress, houses, and furniture, than Persian kings or Byzantine emperors. Founding mosques, hospitals, khans, and fountains, were looked on as claims to paradise, and, when the rulers were Turks, they were great tomb builders. Free education was as great a programme with them as it is with us, and the meanest freedman, or the poorest heggar, was admitted to the Society of Kaliphs and Emirs, if he was a Hadji, a holy man, or was distinguished in the arts or sciences. Many of Kaliphs cultivated the arts and sciences with success, while music and poetry excited the most passionate enthusiasm in all the Saracens.

There was, too, in the mind of every Moslem a strong belief in the marvellous and the weird, in all sorts of spiritual beings, good, bad, and indifferent; in astrology, in incantation, and in amulets and talismans. Hidden treasures of fabulous values must have been common, when a wealthy world had been conquered in less than a century, so a shrewd man might easily get a reputation for his divining rod, talisman, or incantation; and with what wonders had this simple people been confronted; many of them had seen the deserted or buried temples of Egypt, the deserted palaces in Persia, the sculptured caves in India, and fountains of fire. The strange beasts, birds, and fishes of many countries had met their eyes, and they were familiar with the learning of Greece, Rome, Egypt, and India, not to speak of glimpses of the Chinese.

Bactria which they conquered was a Greek Kingdom, and even to this day, it is said, that half the words of the Afghan tribes are ancient Greek. Many of the Saracens had visited Ceylon, Sumatra, Java, Borneo, and probably the islands of Japan, if not Australia itself. Homer had been read, for we find the cannibal of Sumatra, called Fenion; evidently the shot of a Saracen at Polyphemus. Early people can no more copy than children can; certain strong

* Being the fifth Royal Academy Lecture on Architecture this season. Delivered on Monday evening, February 8.

characteristics strike both savages and children, and both only portray, as well as they can, the salient features that have struck them. This trait appears to me to be very characteristic. The Saracen style, and we must allow something for national characteristics and personal peculiarities. Striking features of the architecture of the countries they had conquered were used in a new way, and where the Moorish element was largely mingled with the Saracen, as in Spain, a passion for vague outline is a marked characteristic, and all else was derived from the profound study and love of geometry; this, however, seems to me to have been chiefly confined to ornament; they seem to me never to have worked out a logical style irrespective of ornament. One part of Kaloun’s mosque is almost purely Romanesque, another small piece is Gothic; the later mosques, if you exclude the ornament, are two-storied warehouses or mansions with lines of recessed windows; and this seems to me the most persistent type. When they made a grand success, as at the mosque of Sultan Hasan, they did not make continued efforts to perfect it. I admit that this would have been difficult to improve on; as it is, it looks like the isolated effect of one genius.

We learnt from Abd-al-Rahman himself that the aisles of Christian basilicas had struck him, and he evidently thought he could not have too many aisles, nor could they be too long. He made in his mosque eleven aisles, more than 200 ft. deep, and his successors increased the number to nineteen and the depth to 350 ft.; but take the 200 ft., there was an effect produced that is unrivalled, an effect like that of a pine-tree forest, at once suggesting an infinity of number and homeless space; for the limits are shrouded in mist and gloom.

Doubtless Abd-al-Rahman I. had seen Acha’s mosque at Kairouan, but we must be all the more thankful to him for appreciating what was fine, and seeking to perpetuate it. Two hundred years later on, we have the arches of Makarrah and the Villa Viciosa cusped on the intrados and extrados, which in some form or other persisted in Spain and Barbary till the end of the Moslem sway. Similar features are found at San Cristo de la Lnz, and Sta. Maria della Bianca, at Toledo, yet we know not where these cusped arches came from. They may have been a pure invention of the Saracens.

We next come to those two curious monuments near Baghdad, the tombs of Ezekiel and Zobeida. Zobeida was alive in 833 A.D., and at Mamun’s wedding; therefore, if it was her tomb it was after that date. As to the domes, they are not confined to Saracenic architecture, though they are one of its most characteristic features, for they abounded in Persian and Byzantine times, not to speak of Rome itself.

If M. Choisy is wrong, and the Persian domes were not of the days of Achæmenides, where did Agrippa’s architect get his idea of the dome of the Pantheon from? for this was erected in 27 B.C., and the Sasanian dynasty did not begin till the third century A.D. Where did the minarets come from I do not know, but they might have been suggested, and probably were, by Byzantine watch-towers, for if they were suggested by the isolated columns of Persepolis, they took an entirely different shape, except in Persia and very late in Cairo, but they are at once the most striking, original, and well-designed features of Saracenic architecture. I am equally ignorant of when they were first used—the one at the mosque of Amr in, I should fancy, early, and so is the one at the mosque of Tilm.

The most striking ornament is the stalactite. The author of the theory I mentioned in my first lecture is of opinion that they had their origin in Persia. In the Cavetto of the crowning member of doorways in the days of Achæmenides there is an ornament consisting of three ranges of leaves, and each leaf has a semi-circular top. When seen in a drawing to a small scale, this ornament is not to be distinguished from the Saracenic stalactites over door-heads; and a great part of Saracenic stalactites in Persia are merely niches superposed. I believe the dome over the fountain in the mosque of Tilm contains the first example of stalactites, but all we know of its date is a remark in Mr. Poole’s “Art of the Saracens in Egypt,” where he says it was at least a century after Tilm’s death in 883, or in 983, but, as a rule, those peculiarities that made the true Saracenic style are not observed till about the twelfth century.

The main peculiarity to be noticed is the founding of all ornament on elaborate geo-

metrical framework, and as often as not the geometrical framework was the only ornament. It is not flattering to one's national vanity to find that every hook on Saracenic architecture is a French one, except Murphy's and Owen Jones's on the Saracenic work of Spain, and Mr. Poole's on "The Art of the Saracens in Egypt." Pascal Coste is our sheet-anchor, and Girault de Prangez and Prisse d'Arvennes, the bowlers. M. Jules Bourgoïn has published a charming hook called "Les Arts Arabes," to show the different patterns founded on geometrical figures that are to be found in Egypt and Syria. In the book there is an essay on the methods of design employed, which he calls "aesthetic geometry." He is, however, a man of few words, and so imbued with this aesthetic geometry that he treats it much as Sir Isaac Newton did Euclid, when, after reading the statement at the head of each proposition, he said it was ridiculous to attempt to prove what was self-evident. M. Bourgoïn gives a few examples worked out with the most concise descriptions, which leave us like the fishman, who was described as "a mark of inner-rogation standing prostrate." He also gives what he considers to be the key to each example.

As geometry is the foundation of architecture, the students may be safely advised not only to make themselves acquainted with the aesthetic geometry of the Saracens, but to work out every example he gives in the plates, seeing that it has been the foundation of a new style of ornament. I may add that any one who would publish a hook giving the geometrical solution of all the patterns would do a good work and earn the gratitude of those who desire to fathom this subject; he might, too, be the founder of a new style of ornament; as it is not likely that the Saracens exhausted all the capacities of geometry.

I will now speak of some of the architecture which has merits of its own, unconnected with this very elaborate aesthetic geometry. You may see in the plans of the Persian mosques, though their date is late, that they bear a strong resemblance, as far as their

court and transepts go, to the mosque of Sultan Hassan; and this is not surprising, as the idea is supposed to have been taken from some of the Persian palaces, but I do not think that this diminishes the credit we must award it. In the Pantheon at Rome we have without doubt the Roman rendering of some foreign colossal dome. The eye which lights it, and which is the main cause of its sublime effect, was due to an accident, that is, to its being built as the laconicum of Agrippa's baths, but to seize on a happy accident is one of the characteristics of genius. A witty architect once said, "All the finest things in the world originated in accident, and such accidents happen to every one, but the man of genius alone knows how to make use of them." Every one has seen a hungry dog gnawing a bone and an old tailor trying to thread his needle, but Dante alone has made these into immortal similes.

The sublime effect of the mosque of Sultan Hassan is solely due to its plan, its proportion, and its method of lighting. After passing through a dark, narrow, and tortuous passage, one emerges into the brilliant sunshine of the central court, and sees in the middle of each of the four sides a vaulted nave or transept, the faces of which come sheer down to the pavement, without a screen. The pointed arches of three of them are nearly twice their width up to the soffit of the crown. Some small doors and tiers of windows doubtless help to give scale. The sanctuary of the mosque has the same sort of pointed arch, whose height is but a third more than its width, and this vaulted sanctuary has for its only ornament a deep band of Cufic writing. The sanctuary is nearly as deep as it is high, and standing at the niche end you look out of the gloom into the blinding sunlight of the court; so you see that vastness, simplicity of form, and lighting are the main causes of the sublime in architecture. The main features of the design are doubtless taken from the old Persian palaces; almost all of them had a vaulted vestibule, that at Feruz Abad has a deep one, and there is one there in the centre of each end of the courtyard; at the same

place there is a fire temple, whose plan is precisely similar to that of the mosque of Sultan Hassan. The arched recesses of the courtyard of the Persian mosques are the same feature, and the frontispieces suggested by the doorways of the Achaemenid palaces give them greater dignity. It is only to be deplored that the hideous, four-centred arch has taken the place of some more dignified form.

The grand frontispieces were doubtless suggested by the vast doorways at Persepolis, and these were evidently taken from Egyptian doorways. The Persian minarets were, I think, imitations of the isolated columns of the palaces at Persepolis and elsewhere, and though the splendid enamelled pottery, with which Saracenic buildings of Persia are covered, took its rise from that of Babylonia and Assyria, it became Persian, and was not only much affected by the Saracens of Egypt, but was used by the Ottomans at Brusa and Constantinople.

The mosque of Edh-Dhahir Beybars outside the walls of Cairo, built about 1268 A.D., looks like a fortress; its front is about 351 ft. long, the walls are nearly 50 ft. high, crowned with bearded battlements; this sort of battlement, by the bye, was taken from the Persians; this front of Edh-Dhahir has a central projecting gate-tower, and two flat towers at the ends, the gateway having a pointed arch supported on columns, and its front is ornamented with two tiers of niches and some panels; the gate-tower is slightly higher than the walls, has bearded battlements, and a square tower over it, with square battlements; below the cornice of the wall are eight slightly-pointed windows on each side of the gate-tower, about 18 ft. from the ground to the sills; at the back of the gate-tower, at the other end of the mosque, is the dome over the hay in front of the niche.

The mosque of Sultan Barkuk, built about 1384 A.D., has his and his family's tomb at each end of the sanctuary. As far as its external features are concerned, it is a good type of a Cairene mosque, as many of the features persisted to the last, but, like that of Beybars I., it is not striped outside. The niche wall is about 236 ft. long, and 53 ft. high. The battlements

* The late W. W. Deane.

have disappeared, but were doubtless of the flower-de-luce pattern. In the centre of the wall there is a wide pier, with a square projection in the middle of it for the niche, over this is a little dome, that covers the bay in front of the niche. The dome is reeded, and on a pierced drum. The wall on either side of the central pier has three recesses, two stories high, in which are the windows. The upper windows are single, and slightly pointed; below are square-headed windows, with segmental discharging arches. The recesses for the windows are brought out flush with the piers by stalactites below the cornice. The walls which enclose the tombs at each end have a wide central pier, and two recesses with windows and stalactites like those in the other walls; above the cornice are truncated gables, the angles being moulded into grand toruses and cavettes, so as to bring the angles into an octagon for the dome to spring from. Each gable contains a triplet window, with three bulls'-eyes over it, but is not framed. The domes, which are about 50 ft. diameter externally, have a short drum pierced with windows, the external domes are chevronned. On the entrance side are two minarets about 150 ft. high; these are towers about 12 ft. 6 in. square, starting from the cornice of the building, and from this to the top of the first cornice of the minaret is about 34 ft., its cornice is a stalactite one, and resembles machicolations, and is crowned with a stone balustrade, in this stage are windows with balconies on stalactites, above the minaret is circular, with a deep stalactite cornice and a stone balustrade, the circular shaft is enriched with an interlaced rope ornament, leaving only plain narrow bands between it, the cornice, and the balustrade. Above the circular part is an open octagon turret on columns with trefoiled arches, crowned with a stalactite cornice, and above is the stone cup and ball, with a bronze finial and crescent. The tombs of the Mamluk Sultans are mostly domed, and are very picturesque, the domes being covered with every variety of ornament,—reeds, flutes, chevrons, geometric and floral patterns, the latter mostly overlaid with diapers,—and in the clear air and dry climate of Egypt these are not only delightful to look at, but answer the purpose of keeping the domes dry; here the ornament would perish by the wet and frost, and would, too, be wholly clogged up with soot and dust.

The university mosque of El Azhar can only be described as far as its courtyard goes, which is about 160 ft. by 124 ft.; it was founded in 971 A.D., but has been so altered and restored up to the middle of the last century that little of the original building remains. The court is surrounded with an arcade of Persian arches on marble columns; over this is another storey ornamented with niches, and very small windows with bulls'-eyes beneath them; it has a geometric frieze and pierced bearded battlements; over its entrance is a graceful minaret, and at the end of the same front another; originally the wall seems to have been striped and subsequently plastered over.

I must not omit the charming little mosque of Kaif Bey, 1472 A.D. Its flank is not straight, but one end projects considerably, and its entrance is at the narrow return end. The walls are striped and mainly ornamented with windows in recesses, their tops brought out flush with stalactites, and the whole building is crowned with flower-de-luce battlements; on the flank by the entrance-angle, the first floor has a triple arcade to an open belvedere, and this has a double arcade on the entrance front; but this is over the fountain which externally forms part of the mosque. Beyond is the high recess for the doorway, Persian fashion, that looks as if it had been built separately, as the courses do not match. Just beyond the door recess, the minaret springs from behind the battlements. Over the projecting flank is the dome covered with a geometric star ornament, filled in with foliage (a beautiful water-colour drawing of it by Mr. Spiers is on the table); except for its minaret and dome, you would never take it for a mosque, but all the ornamented parts have a quaint kind of elegance.

The mosque of Sidi Amar Abada, at Kairouan, shown in Mr. Alexander Graham's hook on Tunisia, forms a picturesque group, with its five domes, three of which are on stepped square bases.

The Persian mosques must have been very striking; at that of Shah Abbas you come into a court 170 ft. deep and 223 ft. wide, with low sides, not more than 42 ft. high, in the centre,

opposite you, the vast frontispiece, 95 ft. wide, towers up to a height of 105 ft., and is flanked by the cylindrical minarets, with the top of the dome just peering over the frontispiece; the deep shadow of the recess, when the sun is high, must greatly add to its impressiveness, and when we picture to ourselves that the whole courtyard is faced with enamelled bricks in gorgeous colours, it must surpass anything we have seen in magnificence.

I am painfully aware of the dulness of descriptions, but to fully illustrate all I have to say would take years to do; I will not, however, trespass on your patience much longer. I did mention the trefoiled-headed recesses that are often used to mark doorways. Their effect is both striking and unusual to our eyes, and I think with a little study, might be introduced here, and would greatly relieve the dull monotony of fronts. There are a few small architectural exhibits in Egypt that are marked by extreme care, delicacy, and originality of proportion, that are well worth profound study. Our best architects are very careful and painstaking about some of their smaller works, and often introduce delicious little bits. The study of these Saracenic motives would, I think, greatly aid them. The Saracen architects were not nearly so much fettered by rules of proportion as we are, and rightly thought that the object was to please the tasteful; I think that the late Professor de Morgan's dictum, which he applied to mathematics, is quite as applicable to architecture, "that rules are excellent things for those who can do without them." There is a doorway at Cairo in M. Bourgois's book that illustrates in its details what I have been saying, and I may remark that the Saracen notion of marking the entrance by a grand feature was a happy one. A narrow band, consisting of two beads and fillets with a space between them, forming a guilloche as at intervals, is used as a dado, leaving wide jambs to the doorway; it then rises up so as to form an oblong enclosure, high enough to frame in a small mezzanine window; the door jambs are quite plain, but the course at the top of the door is made into two delicate corbels, one on each side; above this is a deep enriched lintel, nearly as deep as the jambs are wide; the frame runs out on either side below the lintel, till it is in a line with the jambs of the door; and from this the frame runs up again on both sides, and across over the lintel, and again over the discharging arch, thus making two panels of unequal heights. The parts below the segment of the discharging arch is recessed

and ornamented. The arch has vousoirs of the wildest shape, in two kinds of marble; above it, in the centre, is the little half-story window, the moulded band, that frames the doorway, going round it, leaving a square panel on either side. A little above the framing of the door is a square panel, not so wide as the frame of the doorway, with a large circular panel in it, which, with the spandrels, are ornamented. The rectilinear patterns are of the most recondite Saracenic geometry, and are intermingled with floral patterns; but an equivalent in colour or texture would answer the same purpose, at any rate, if the shape of the vousoirs were kept. There is also a little wooden shop-front at Tantah that is replete with exquisite grace. It consists of the square framework of a doorway, and two windows, grouped with the door; the height of the doorway is about two and two-thirds of its width, and the windows are about two and a-half times their width. Some woodwork is fitted into the doorway and windows to make the openings "rastremati," as the Italians say,—i.e., narrower at the top; the heads are flat ellipses, and at the springings there are peculiar hooked corbels; round the frame of the door is a narrow piece of lattice. Two pieces of panelled woodwork go from the windows to the fronts of the adjoining houses; above, under the bressummer, is a broad band of intricate panelling in the centre, with the ends filled with lattices. I should say that the bottoms of the windows are filled in with turned balusters. You may think the upper lattices, from their position, more quaint than beautiful; but the exquisite-ness of the lower part is certainly due, and due only, to a certain originality and a most refined and cultivated taste.

I have mainly confined myself to mosques, except in the case of the Alhambra, not because there are no other Saracenic buildings, but because I thought that these more completely show the peculiarities of the style, but there are khans (the Xenodochia of the Byzantines), colleges, fountains, palaces, baths, houses, &c. The khans are curious, but are hardly of much use to us in England; they are fortified places where merchants, with strings of camels, mules, and horses, can put them up, lock up their goods, and have a small living-room for themselves; the palaces are mostly those adapted to a burning climate, and to Oriental potentates; it is curious that some features are precisely the same as in the days of the Achæmenides,—i.e., the structure consists of a roof, supported on

slender columns, open between, the enclosures being made by curtains or hangings.

The arrangements of a good house are always more or less interesting, and there are two or three requirements to be noted in Moslem houses. Well-to-do people mostly keep a horse, a mule, or a donkey to ride on; the donkey is not the dull, slow animal in a hot climate that it is here, but, if of a good breed, it goes like the "blinding lightning." Well-to-do people bake their own bread, and, from keeping their women separate, may enjoy the society of whom they please. The Viceroy of Egypt would probably admit to his saloon and table a beggar who was a Hadji, he certainly would if he were an agreeable person as well; a Hadji being one who has performed the pilgrimage to Mecca, run seven times round the Kaaba, and kissed the black stone, and run up to the top of Mount Arafat, and had his head shaved. When I was in Cairo I visited a house, then deserted, that was said to have belonged to the Sheykh-el-Islim, the chief mufti, or doctor of the law, a title that was first conferred by Mohammed II, when he took Constantinople. There is generally a stone seat for the porter outside the door, called a mastaba, the entrance-passage makes a sharp turn, so that no one can see inside, and the entrance is generally into the court, in which is an open pavilion, raised above the ground, a sort of summer-house or belvedere; there is often another on the first-floor of the house. The floor of the grand reception-room is on two levels, mostly paved with marble, with mosaic borders; in the middle is a plashing fountain, rising from the middle of a basin, mostly octagonal, often with little ones at the angles, with jets falling into the middle basin, like the font in the Baptistery at Florence. Over it, above the roof, is a latticed dome, and just beyond the fountain is the step up to the carpeted dais; you leave your shoes on the lower level. On either side of this dais, and sometimes at the end, are slightly raised seats covered with cushions that form the divans. The walls are lined with marble, sometimes inlaid, sometimes bordered with mosaic, and sometimes they are covered with enamelled tiles, and this is finished by a wood shelf, on which the fine crockery is put, so that if any of the pieces fall, they may fall on the cushions. There are, too, cupboards for keeping the cushions, &c.; these are closed by doors, but some have fantastically-pierced openings for bottles and vases. In the lower part of the saloon are often stepped fountains in the middle of each side, down which water trickles. Above the shelf there were, in this house, hunting-scenes on the walls; on one side of the dais there is often a projecting lattice, or bow-window, in which the porous water-bottles stand, commonly called meshrebiyas, or drinking places; the saloon is mostly very lofty, and, whenever there is a recess or a break, the woodwork comes down in long stalactites; the ceiling is mostly flat, and the beams round and not far apart, the ends of the beams are brought into the square next the walls by stalactites; between the bearers the ceiling is panelled, and the whole covered with elaborate patterns, coloured and gilt; if one side looks into the garden, the lower window is often a plain lead light with circular panes of clear glass; above are the windows of pierced plaster, filled with stained glass that look like jewels. We know these saloons well from the pictures of the late John Lewis and Mr. Dillon. All architecture and decoration is, as a rule, confined to the inside; the house is mostly of stone to the top of the ground story, above of lath and plaster on a bressummer, carried on heavy stone corbels, often peculiarly moulded, looking as if folding-wedges had been driven in between the mouldings, and this part has windows filled with flat lattices, generally with one latticed bay-window, the eaves of this are decorated with pierced woodwork like our railway stations, often in two or three ranges, the bottoms coming below one another; the eaves generally project considerably for shade, and are carried on slight framed gallow pieces, with the double or triple rows of delicate pierced leaf-boards. These, of course, cast long, sharp, fantastic shadows. Some of these pierced leaf-boards to the schools over the fountains are peculiarly graceful and effective. Here and there, however, there are bouses whose fronts have architectural pretensions, but I think mostly to the gardens or courtyards. Sometimes the architectural effect is confined to the ground story, and frequently to one feature. Sometimes a tall recess with an architrave runs up above the

bressummer, and has a lintel of its own, carried by short pannels on the corbels. The door is in this recess, with a half-story window over it, and with ornamental panels at the sides; the top is enriched with stalactites, and on either side of the architrave and beyond it there are sometimes panels of flat ornament; but when there is a makad or belvedere on the first-floor the whole front may be architecturally disposed. A low door mostly faces the entrance to the ground-floor magazine, which has as well plain segmental or square-headed windows, with iron gratings. Above the belvedere is open, standing on a central column, with enriched spandrels, and projecting eaves on corbels. The house door is reached by a flight of outside steps, and is enclosed in a recess running above the arches of the belvedere, with a trefoil head filled with stalactites like those to some of the mosques; the recess has often two tiers of windows. Above the door and in the spaces between the door and window and between the two windows are filled with ornamental panels.

In one of the streets in Cairo, called Khoul-el-Mokharbelyn, is a little oratory, called the Oratory of Abd-el-Rahman, who was lieutenant of the Janissaries from 1743 to 1751 A.D. The ground-floor is now used for shops, but from there being a semicircular niche in the back wall, it is most probable that it was originally an oratory; the present oratory is on the first-floor; the entrance doorway has a slightly pointed arch on columns; the lower fascia of the archivolts is godronned, the upper fascia is ornamented, and is carried up square as well, and connected at the top by a guilloche, so as to frame the doorway; above is an ornamental pierced stone balcony, carried on stalactites, in front of an opening used by the cryer to call the hour of prayer; the rest of the front is separated from this by a frame. The ground-floor has three square-headed windows; over them is a triple arcade, carried on columns with peculiarly cusped arches; the arcade contains three square-headed windows filled with iron gratings; above the framework of this is a deep oblong frame, rather within the one below, and is formed into three square panels over the centres of the arches, with blank spaces between; in each is a hull's-eye, with a frame round the circle, connected on the four centres with the outer frame, and with ornamental spandrels; there is no cornice above this, but the whole wall is finished with flower-de-luce battlements, banded below the flower. It was, as you have heard, designed for ecclesiastical purposes, and has only been turned, by decay of piety, into domestic use.

ROYAL INSTITUTE OF BRITISH ARCHITECTS:

STAINED AND PAINTED GLASS.

The eighth ordinary general meeting of this Institute for the present session was held on Monday evening last, the President, Mr. J. Macvicar Anderson, in the chair.

The minutes of the previous meeting having been confirmed,

The Chairman announced that letters had been received from the Home Secretary and Sir Francis Knollys on behalf of Her Majesty and the Prince and Princess of Wales in reply to the votes of condolence which had been sent by the Institute on the occasion of the lamented death of the Duke of Clarence.

The Honorary Secretary, Mr. Aston Webb, then read a long list of candidates recommended for admission as members of the Institute,—22 as Fellows, and 24 as Associates.

Two or three members attending for the first time since their election were formally introduced to the President; among them was the Bishop of Ely, Lord Alwyne Compton, of whom the President said that he was competent to form an express correct opinion on subjects of art and architecture.

Painted Glass.

The Chairman said that as they had four papers to be read, he would not detain them with any preliminary remarks, but would at once call upon Mr. Herbert Carpenter to read the first paper, of which the following is an abstract:—

Although the architect should be responsible for the whole internal effect of his design, it was not, in the author's opinion, necessary to determine exactly how far the stained-glass decoration should be under his control. He should, however, be able, without vexatious interference, so to direct those working with

him that the painted glass should in style and treatment harmonise with the architectural design of the building and with its decorative treatment. As an example of the satisfactory result of the co-operation of the architect and the artist in glass-painting, he referred to the case of Truro Cathedral, in which Mr. Pearson and Mr. Clayton had together produced a very beautiful and harmonious interior. Through successive centuries the relationship between architecture and glass-painting had been very intimate. In early Christian times the intense eastern sunlight, streaming through small window-openings filled with gem-like glass, afforded a striking and brilliant contrast to the large wall-spaces. As architecture travelled westwards and northwards into less sunny regions, in the eleventh and twelfth centuries, windows necessarily became larger but the "mosaic" glass, with its Byzantine ornamentation, was still used, the gorgeous and jewel-like effect of colour being emphasised and intensified by lines and points of white glass, and the bold, black geometrical forms of the frame-work. In the thirteenth century not only the gem-like glass, but silvery and brilliant pattern-glass, of white with a bluish tinge in it, was used, together with rich bands of pictorial figure-subjects, on a white ground. In the fourteenth century the mosaic glass, as such, went out of use in the great millioned windows, but its rich colours were retained, in combination with a lemon-yellow stain. The window tracery of this period was designed to frame the translucent pictures, though as time went on, and the masonry became more studied in design, the glass had to adapt itself to the masonry, rather than the masonry to the glass. As large windows multiplied, a large proportion of white or greenish-white or quarry-glass was employed. By very gradual changes the most characteristic English glass, that of the fifteenth and the early part of the sixteenth centuries, grew up, acquiring greater breadth than the gorgeously-tinted earlier glass, and infinite delicacy of drawing and tone, and combining with it especially painting on white glass with enamel colours and stains. At this time one mind and one idea inspired the designers both of the buildings and of their glass. After animadverting on Professor Moore's statement that nowhere, save in France, was there in glass-painting an actual spirit of original invention, the author spoke of the crude and incongruous designs or imitations of Medieval work in memorial windows erected in the last half century, as compared with those described to have existed in Long Melford Church or in the Grey Friars Church, London. It appeared to him that the principle of the memorial window was of inestimable value, not only artistically and historically, but as a link of the present with the past. Symbolism in stained glass he considered should be neither too patent nor yet too recondite.

With reference to modern painted glass he laid down the following postulates:—1. That the glass be brilliant, translucent, and jewel-like. 2. That the colours be, to a great extent, of pot-metal, of unequal tone and thickness. 3. That in each building its due proportion of white glass be fixed and adhered to throughout. 4. That the ironwork designed by the architect should be carefully considered in designing the glass, and that no sound ancient ironwork should be removed. 5. That the leading be an essential part of the design, to be shown on the glass-painter's sketch drawings. 6. That each window should form part of a complete scheme previously determined by the architect with the authorities of the church. 7. That the representation of sacred subjects should not be pictorial, nor realistic, nor sentimental, but should be treated in an architectural and conventional manner. 8. That a carefully-thought-out system of symbolism should be adopted. 9. That pictorial subjects extending over more than one light should only be selected when they lent themselves to arrangement in divisions. 10. That the series of figures or subjects be selected in proper doctrinal and historical gradation from west to east of the church. 11. That in memorial windows the kneeling figure should be introduced in the "predella" with a legible inscription. 12. That heraldry should be an essential part of the design, especially in memorial windows. 13. That in ancient churches, with windows of varying date, the glass should be assimilated in each case to the designs of the masonry. In conclusion, he urged that, as in architecture, so in the art of painted glass,

history and archaeology should not be disregarded, and that there should be no spasmodic attempts at originality.

Some Details and Technicalities of the Glass-Painter's Art.

This was the subject of the second paper read by Mr. James Powell. The following is an abstract.

In making a painted window, the first process is to prepare a small coloured sketch of the design, usually to a scale of one inch to a foot. On this drawing should be shown the ironwork, which should be so arranged as to assist and not interfere with the design of the glass.

The sketch having been approved, full-sized cartoons are prepared. For these, studies from the life are required, the hands and feet especially needing careful study. White subjects surrounded by colour should be drawn smaller than when against a white background. On these cartoons the ironwork and lead lines should be definitely shown, and upon the latter great pains should be bestowed, the lead lines being more conspicuous than the folds of the drapery. From the finished cartoon a tracing, called the "outline," is made on calico of all the lead lines, and from this the cutter cuts the glass in corresponding lines. Great discrimination is required in the choice of the glass, so that its varying thicknesses shall coincide with the light and shade of the figures. When the glass is cut, it is taken to the painting-room, and all the leading lines of the cartoon, and also the ornamental patterns of draperies or diapers of backgrounds are shown with enamel pigment. The glass, after having been fired in the kiln, is then fired with wax to a framed piece of plate-glass, so that it can be placed against the light on an easel. The paint (water-colour process) is then applied to the glass with a large flat brush, and worked flat or rough, according to the requirements of the design. The high lights are then removed with scrubs, or short hog hair brushes, and in the half-tones the pigment is reduced in density, and the shadows deepened by laying on another mat of colour. The glass is then again fired, and the above process repeated until the required strength is obtained, great care being taken to keep the shadows luminous. When the paint is finished, the silver stain is added, where required, to such parts as hair, embroidery of draperies, or foliage. The glass is next laid on its "outline" on the glazier's bench, and the leading is put in. Mr. Powell himself prefers flat lead, as being stronger than the round, and better for the cementing. The lead should be from $\frac{1}{2}$ in. to $\frac{3}{4}$ in. in width. After the window is soldered on both sides the leads are raised, and a cement of oil, lead, &c., is rubbed well in on both sides. The copper ties are then soldered on, and after a few days the cement has hardened and all is ready for fixing. As to materials used. Coloured glass is obtained by melting certain metallic oxides with the raw material or base. A good workman can so handle the melted glass as to produce variations of thickness, from which of course result varied tints of the same colour in one sheet. In some recent experiments the traditional charcoal yellow had been hit upon, and it had been found to be almost identical with the straw-yellow of the thirteenth century. Glasses made as above described are known as pot-metal colours. Flashed or cased glass, is used chiefly for ruby glass, the colouring matter of which is so dense that it is blown on a base of white glass; beautiful shades are also produced by casing the ruby with a hinc or yellow glass. One great advantage of the cased glass is that you can with hydrofluoric acid remove parts of the coloured film and expose the base colour underneath. This is especially useful in heraldic designs or the patterning of robes. The enamel used by the glass-painter for shading and outlines is a fusible glass containing a sufficient quantity of an infusible powder to produce the effect of opacity. The window may be painted entirely in water-colour, or it may be traced in oil-colour and matted in water-colour. The lead is first cast in short lengths, and then elongated by mechanical pressure. The leads used in old windows were usually very narrow, and were cast in their full length. A great deal of the old work had been re-leaded with wider lead than that originally used. The leading of the thirteenth and fourteenth centuries was mostly designed in diagonal lines, and this diamond form gave a perfect drain for the water. For a window designed in a strong

used; in the whiter windows less lead is required. To the ironwork the artist should pay special attention. Saddle-bars should not be more than 12 in. apart. The most useful arrangement for modern work, except in very narrow windows, is to have a double stanchion, with saddle-bars at distances varying from 10 in. to 12 in., according to the width of the light. If the architect wishes for outside iron as well the glass-painter need not grumble, for it enhances his work. Wire-guards are an abomination to the glass-painter and a detriment to the architect, and sheets of plate-glass outside look worse still. A lead across a broken pane is preferable to a wire-guard. The glass-painter should remember that a window is made to admit light, and white glass should predominate, though an east window requires more colour than a side window. On these points the architect should advise. Too many different colours should not be used in one window. The best decorative effects are produced with a simple scheme of colour. There should be harmony between the glass and its frame. This harmony is never wanting in the old work of the best periods, and hence it may be supposed that the architect must have had considerable supervision of the glass. The design of the glass should be in relation to that of the stone. Windows should not be crowded with too many figures. A better decorative effect might be produced by using more ornament and fewer figures. The scale of the figures used requires careful study, and as to this the architect should assist. Arms and legs should not be thrown behind mullion; large compositions of figures and canopies running across several lights should also be avoided. Lastly, a scheme should be carefully prepared for the subject of the window; and the glass-painter should work in harmony with the architect.

The Painted Windows at Fairford, Winchester, and King's College, Cambridge, as Models for Modern Work.

The third paper, by Mr. N. H. J. Westlake, F.S.A., was on the windows mentioned above.

After suggesting a few of the many questions which arise from a study of the ancient examples of painted glass, the author pointed out that the considerations in studying old work were, (1) The appropriateness of glass to the church so far as light is concerned. (2) The scale of the details in proportion to the building. (3) The composition and colour value. He intentionally omitted the theological scheme and iconography, because those ought to be settled beforehand by the theological and art authorities with the architect. The first consideration, he said, involved the questions of the size of the building, the size of the windows, the position and locality of the church, the amount of carving, painting, and other decorations, and the comfort of the congregation. At Fairford and at King's College, although the edifices were completely filled with painted glass, there was plenty of light. At Winchester the treatment was very similar to that at Fairford. At Fairford the openings were moderately large and plentiful, the glass fairly but not densely covered, and there was a great area of white in the canopies and draperies. At King's College the openings were larger and more numerous, there was less white, and the paintings were more dense. Chartres, he said, was an instance of a dark church,—the darkness not resulting from the amount of shadowing pigment on the glass, but from the smallness of the details, which involved so much lead and iron that a great area was rendered opaque. The architect could not dictate how much colour should be used until he knew whether all the windows were to be done. The proper character and quality of the painting on the glass, the quantity of pigment to be used, the amount of obscurity in painting on white and on colour, had been but slowly learnt by the artists in different countries. The earliest work was similar wherever found, but in the early years of the sixteenth century the northern countries used less pigment than the southern. English work of the best periods was as delicate and translucent as any; compare Fairford, King's College, and Winchester with the German and Flemish glass of St. Mary's, Shrewsbury, and Lichfield Cathedral. Between French and English work there was no great difference of tone. In the nave aisles of Cologne the covering of the glass was moderate; at Milan the covering was increased; at Florence, Bologna, Arezzo, and SS. Giovanni e Paolo, Venice, the glass was all more or less heavily painted. The painting at Fairford was often

unequal in tone, the inequality being in most instances intentional; e.g., the east window had more pigment than the aisle windows; but the diversity in covering the glass at Fairford was not so apparent or so necessary as in a large edifice like Winchester Cathedral. The windows from Winchester College (now at South Kensington) were a good example of the amount and character of the painting used in a chapel with plenty of large openings. In King's College the difference between the chapel glass and that in the large windows afforded an excellent comparison by which to acquire a knowledge of the painting of the glass under different conditions. Many of these windows, however, had been badly over-painted in restoration.

The Renaissance Period and the Use of Enamel.

The fourth and last paper was by Mr. Clement Heaton, who treated of the above-named subject. He said glass-painting originated from enamelled metal work, and in its early form was an assemblage of small pieces of glass, heavy in texture and strong in colour. As years went on it became lighter and lighter in general tone, the glass itself becoming thinner in substance and the colour less intense, while in all ways there was a progression towards lightness. A style of work was arrived at late in the fifteenth century containing principles which could not be departed from without loss of effect, and which he considered was in England more successful than in France. Admirable as this work was, it was not the highest development of glass painting. There was a limitation of design and conception, power of colour and drawing, compared with both earlier and later work. The earliest glass was geometrical in character, and the later Gothic purely architectural. The canopy work based on architectural models was monotonous through its endless repetition. In the sixteenth century, when new ideas came into France from Flanders and Italy, glass painting was thriving as regards technique, and the "Renaissance" was really in design alone; motifs of ornament from Flemish and Italian Renaissance were adapted and expressed in Gothic technique. In Rouen examples remained showing the transition; and the earliest of them exhibited this use of Renaissance detail, treated technically in the same manner as the Gothic canopies. In King's College Chapel, Cambridge, was a similar series of English examples, in which, however, the Italian influence appeared less direct. This was not surprising, as Leonardo da Vinci, Andrea del Sarto, Benvenuto Cellini, Rosso, and Primaticcio, and many other less-known Italian craftsmen, worked in France for a time. The art of glass painting was the more influenced because the line of separation between architect, sculptor, painter, and glass-painter was little marked. Jean Cousin was at once architect, sculptor, a prominent painter, glass-painter, and engraver, while he possessed enough knowledge of anatomy and geometry to write treatises thereon. It was to the breadth of study then in vogue that Mr. Heaton attributed the power of the work done from 1520 to 1550. The works of the Middle Renaissance showed a wondrous combination; the true principles of glass painting,—glorious colour, refinement, grace and power of drawing, vigour of design, and individuality of conception,—all might be found united in the same work, and that work such as only artists who knew all the techniques of glass painting could produce. After 1550 the glass painter aimed less at producing a beautiful glass painting than a picture full of strong contrasts in light and shade; the technique was interfered with to obtain such contrasts, and so the grace and the silveriness of the glass was lost and the colouration sacrificed. There were therefore three distinct phases of work to consider:—(1) Where sound principles and traditions were worked upon, but with limited artistic power; (2) where these same principles were used combined with great artistic power; and (3) where this power was misdirected and crippled by the abandonment of the true principles. Study of the second phase,—the most notable,—showed that certain principles must be adhered to, and that mere use of them, without individuality of conception and personal care, would only lead to monotony. The personal care of the artist must not stop at the design, but must be carried through every step of the work. The breadth of study among the artists of the Renaissance was well worthy of attention. M. Lucien Magne, who had closely

studied sixteenth-century glass, had written: "The first cause of the inferiority of modern work as compared with the old appears to me to be in the isolated instruction of the artist." Mr. Heaton then proceeded to mention the introductions in *technique* of the Renaissance. The pot-metal colours had been much extended in range, which was due to the system of plating; the silver stain was made to produce not only yellows, but orange and red; the brown painting colour was supplemented by a red; and finally transparent enamels were introduced about 1540. This last he made special mention of as being so influential and so specially a Renaissance feature. In the MS. of Theophilus,—twelfth to thirteenth century,—instructions were given for "placing gems on glass," and a description was added of how small pieces of glass were to be cut out, put on the white glass, and melted on to it. Various examples of this process were known, but the method was unsatisfactory; the use of fluoric acid had done away with the necessity of grinding the glass, but the use of transparent enamels had got over the difficulty of which all glass painters had been sensible. It was probable that the application of transparent enamels arose through the use of enamel in goldsmith's work, as was indicated by a recipe in Mrs. Merrifield's translation of the Bolognese MS. of the fifteenth century. Whether the idea came direct from Italy, or the French themselves adapted the enamel to glass from the enamelled jewellery and pottery, it was difficult to say. At Rouen there were several examples of the use of enamel in conjunction with pot metal glass; and enamel colour alone was used in the sixteenth century for panels and medallions, specimens of which could be seen in Rouen Museum, and some of a later date at South Kensington. It was also used by Giovanni da Udine in Florence about 1560, and in England in the time of Elizabeth. Although so extensively used it had sometimes been urged that its use was illegitimate, which was probably in consequence of its misuse and of ignorance in working it. Properly worked it was very reliable, as was proved by the fact that enamels done in 1540 were sound at the present day. As to the artistic use of enamel, any attempt to use enamel colour in large quantities and in rivalry to pot metal glass the author condemned. It was, so he said, an inferior result obtained in a roundabout way; but in conjunction with pot metal glass he considered it might be of great value if used with proper artistic discretion. For domestic use it could be a means of rendering colour in a fine way in harmony with modern interiors, which leaded colour was certainly not. It was an additional power, and as such required additional judgment in its use, while without artistic judgment and the restraint of good taste it would be more than likely to lead to very objectionable results.

The President, in inviting discussion, said they had with them so many distinguished artists who could speak with authority on the subject which was before them, that he proposed at once to call upon them to do so. He would ask their good friend and distinguished colleague, Mr. Alma Tadema, to move a vote of thanks to the authors of the papers.

Mr. Alma Tadema, R.A., said he felt honoured in being asked to move a vote of thanks to the readers of the papers. He had been very much interested in hearing so many artistic and technical views on a subject which had had so much influence on art and architecture. They would remember how Viollet-le-Duc was led to the pursuit of art by seeing the stained-glass windows of Notre Dame at Paris. He was quite convinced that the development of the art feeling of the people in France was greatly due to the people going in and out of the churches and seeing such wonderful windows, full of rich colour, and illustrating subjects which could not fail to influence them. It was therefore quite natural that the majority of the papers were devoted to the religious expression of stained glass. Perhaps the question of the use of stained-glass windows in domestic architecture had not been touched upon so much, though in modern times the architect must often have been asked for such windows. In towns, for instance, where one had a window opposite an ugly blank wall, it was a great advantage to have a stained-glass window. Of course, figures of saints and other things strictly belonging to religious art were a little out of

place, and, therefore, a purely decorative scheme of treating the glass would be preferable. Mr. Lafarge, in America, had applied himself to work of that kind with a very great deal of success, and he (the speaker) was the happy possessor of one of the finest specimens of his work. As they knew, he admired the old Romans very much, and he rather believed that they had stained glass, though not in our sense of the term. He knew that there was in Pompeii, in a little house, a piece of sheet-glass of a beautiful purple colour, built in the wall. In conclusion, he said he was quite sure he expressed the views of the meeting in proposing a hearty vote of thanks to the authors of the four most interesting papers which had been read that evening, and to whom they could not be grateful enough.

The Chairman said he hoped that the Bishop of Ely, out of the profundity of his knowledge, would be kind enough to second the vote of thanks.

The Bishop of Ely said he should have pleasure in seconding the vote of thanks to the authors of the papers, but he feared that it would be out of the shallowness of his knowledge, rather than out of its profundity. He had been exceedingly interested in hearing the four papers read; they were most instructive, and contained many most valuable hints. He was delighted to hear Mr. Powell denounce the practice of putting wires outside painted windows. That was a thing he had been fighting against for many years. An occasional crack would be far better than having the effect of the window always spoiled by the wires. There would be some reason in putting up the wires to protect an ancient window, but why should they put such wires in front of modern windows? He had seen many modern windows which he should be very glad to see broken. There was one point which was very often forgotten: that it was necessary that they should have light on certain parts of the interior of a building. Very often in the east end of a church painted glass was put in, and gradually worked in towards the west. The result, as a rule, was that the east end was perfectly dark, while the nave was so light that when standing in it the chance appeared to be a dark hole. He thought that was a great mistake. He thought it was possible to use a good deal of white glass in the eastern end of the building. He was not very fond himself of glass which was all white. He quite agreed with what Mr. Carpenter and Mr. Powell said, for he thought that the one effect of proper painted glass was colour, and the very white-tinted windows were unsatisfactory in that respect. Of course, he did not mean to depreciate good form and beauty of drawing, but he thought they might have that in combination with colour. As to the Romans making use of coloured glass, there was a passage in one of the old authors directing one how to make blue glass, and the reader was directed to take and grind down "sapphires." He thought that the "sapphires" in question must have been Roman blue glass; for, of course, they would not grind down gem sapphires. He had very great pleasure in seconding most heartily the vote of thanks to the four gentlemen who had so kindly favoured them with such interesting papers.

The President said he should next call upon one of their professional brethren,—one whom they were very glad to see with them that evening,—and who, he hoped, would allow them that opportunity of publicly congratulating him upon the honour which had been recently most deservedly conferred upon him. Of course, he referred to Mr. T. G. Jackson, who had recently been elected an Associate of the Royal Academy.

Mr. T. G. Jackson, A.R.A., who was heartily received, said that in the first place he must thank them very sincerely for the kind way in which they had received his name in connexion with the reference which the President had made to his recent election to the Academy. He was glad to have the opportunity of accepting their invitation to hear such admirable papers as those which had been read that evening. Benefit was always to be derived from such meetings, and he thought that the more opportunities artists of all kinds had of meeting together and discussing their different crafts, the more they were likely to advance art. The art of glass painting seemed to possess an unusual share of the perils which had assailed the art of architecture, one of the greatest of which was the danger of lapsing from art into archaeology. Glass painting was,

of course, exclusively a Mediaeval art, and could be best studied in the buildings of the Middle Ages; but in designing or considering the subject of stained glass, one of the difficulties that they had was, out of the mass of material, to select what was best suitable for their adoption and development. In England and France, having discovered, as they did very early, the means of making extremely rich and brilliant coloured glass, they seemed to have gone to the very extreme, and to have thought that they could not make the colours rich and heavy enough; but while one was impressed by the charm of such glass as that at Canterbury and Chartres, it would be impossible for us in the present day to attempt anything of the kind. It used to be said that we could not get the glass of the right quality; but he thought they might dismiss that altogether, because the production of any kind of glass was now quite within the power of modern chemistry. But something besides the glass was wanted, viz., the habit of mind which enabled the artists of old times to produce such designs as they did. We in the present day could not work in the simple, naïve manner which to them was natural, for in us it would be mere affectation; and without following their manner it would be impossible to produce glass like theirs. The most useful stained glass for our study was, he thought, the later glass, in which one got more perfect designs and a higher form of art, although, perhaps, not in the same gorgeous and transient effects of colour as in the early glass. For our modern purposes, he thought, the lighter glass was most useful. Many interiors owed a great deal of their charm to the pure light, or even the dusky light, which came in through windows glazed with ordinary glass. Nothing that had been done of late in Westminster Abbey in the way of filling the clearstory with painted glass compensated to his mind for the loss of the old wonderful light which used to steal in by the clearstory windows through the dusky and somewhat murky atmosphere that filled the Abbey, producing the most exquisite effects. That was now lost, and what had been done was, in his opinion, less rather than gain. In town churches there might, perhaps, be good reason for using stained glass more extensively, but in country churches stained glass must be very good indeed if it was to compensate for the loss of the blue sky and the green trees seen through the windows. He might, perhaps, mention one or two old examples where stained glass had been used in combination with ordinary glass with very happy effect. In both the great churches of Nuremberg, the Sebaldskirche and the Lorenzkirche, he thought there were windows which, in the lower part, were filled with richly coloured stained glass, but which was not carried right up to the head, but finished some part of the way up with a sort of canopy,—he forgot exactly how, but, at all events, there was a definite finishing, showing that it was never intended to go any higher,—the remainder of the window being filled in with ordinary white glass; the effect was admirable. Another instance, with which he was more familiar, was in one of the chapels at Oxford. In Wadham College Chapel there were on each side of the choir five transomed windows. The lower part below the tracemans was filled with painted glass and the upper part was filled with ordinary window glass, which was the original arrangement, and the effect seemed to him to be extremely pleasant. It dated from the year 1622. The chapel was perfectly light, and, at the same time, a very rich effect of colour was obtained by the amount of painted glass in the lower parts of the windows. Of course, if glass in such a position as that were painted very heavily, it would look dirty, but at Wadham College Chapel, to his mind, it was treated with great success.

Mr. Henry Holiday said he was glad to perceive the distinct advance which artistic opinion had made on the subject since it was before the Institute some years ago. It was now generally recognised that archaeology was not art, although it might greatly aid them in its study. They ought all to be ready to learn from the study of the past, but the duty of artists was not to imitate the work of the past. No great artist had ever succeeded in doing anything good by imitating that which had been done before him. Art was growth, and each artist at any of the old periods when great work was produced had done what he did, not as an imitator, but as a producer. Of

course it did not follow that every development was an improvement, but he thought that any artist worthy of the name would rather make a few technical errors in his art than produce lifeless work, for mere imitation must always be absolutely lifeless. All good artistic work must express the ideas of the artist and the ideas of his time. Thirteenth-century work was modern; so were Giotto and Michelangelo, and so must be every great artist. One great question which came home to the artist in dealing with the decorative arts was: How far could realism be united with true architectonic principles? There was a certain confusion of ideas often to be met with in discussing that subject with outsiders, who often seemed to think that if a piece of decorative art was not archaic in character it must be an imitation of an oil-painting. They all knew that what was known as the "Munich school" had wholly failed, by attempting to make stained-glass windows imitations of oil-paintings. They failed in the way that the Gobelin's tapestries failed,—in endeavouring to make one material imitate the effects of another material; they failed to get the effects of the other material, and they sacrificed all the beauty of the material with which they were dealing. The question, then, as he had said, arose, How far could an artist be realistic without failing in architectonic qualities? In his opinion, that was a question which would settle itself for each artist if he remembered that he had to consider his material, his situations, that he was working for a window and not painting on a wall, that he was working in transparent glass joined by leads and not with oil-paints. If he kept those things clearly in mind, then would he never fail by attempting to secure all the interest that could be obtained by imitating beautiful forms in outline and even beautiful forms in modelling. He would ask any one who had examined the frieze of the Parthenon whether he thought that the splendid decorative qualities of that frieze had been in the slightest degree sacrificed by its most beautiful imitation of the forms of horses and of human beings? In the thirteenth century, as well as at the present day, some of the greatest beauties of art had been obtained by what was to the artists of that day realism. If we compared the stained glass of that period with the miniature painting of that period we found precisely the same qualities in both. It was clear that they imitated to the best of their power. The fact that they could not imitate as accurately as we could detracted to some extent from the perfection of their forms; but, on the other hand, it left them a little freer to consider the mere technical qualities of the material, the jewelled beauty of the glass. But was there anything in the delicate play of tone about such figures as those of Mr. Burne-Jones, in the drawings exhibited, which would not add to rather than detract from the beauty of the glass for which they were prepared?

Mr. C. W. Whall said that an experimental practice which he himself adopted, and which he had not seen used elsewhere, was that of designing a window in glass itself. He made a sketch of the window in glass, cutting the pieces out on a small scale to an inch scale tracing.

Mr. Lewis F. Day said there was a suggestion that anything like originality must necessarily be spasmodic, and that if we were to do good work we ought to copy something old; but Mr. Holiday had practically answered that. With regard to the influence of style upon design in stained glass, he thought people in general, and perhaps architects in particular, were a little too much inclined to insist, for a church or whatever it might be, upon precisely the style in which the glass-workers of that particular period worked. Of course, every artist who designed stained glass, if he were an artist at all, did instinctively consider the style of his architecture, and he must do so; but that was quite a different thing from insisting that he should work in the style in which the glass-workers of that particular period worked. His own idea was that the artist in stained glass (as in anything else) should study the course of stained glass, and be perfect master of all that had been done in stained glass in every period. He should also study the styles of architecture. Being conversant with those two things, he should do the best he could with the glass, bearing in mind its surroundings. He did not think that necessarily meant that he was to do what was done by the glass-painters of that period. It was possible that the men in the thirteenth century did not

know so much about stained glass as the men in the fifteenth, and so on. We found that men insisted upon having Renaissance work, for instance, after the manner of artists who knew very little about glass. In the Renaissance there were stained glass artists who did glass that was almost as "mosaic" as thirteenth-century work.

The President, in putting the motion for a vote of thanks to the authors of the papers, said they owed a debt of gratitude to the Art Standing Committee, and more particularly to their Vice-Chairman, Mr. Carpenter, and one of their Honorary Secretaries, Mr. Caroe, for the great trouble they had taken to arrange that meeting.

The vote was passed by acclamation, and Mr. H. Herbert Carpenter, on behalf of the readers of papers, briefly returned thanks, and the meeting terminated with the announcement that the next business meeting of the Institute would be held on March 7, followed by a special general meeting to elect the Royal Gold Medalist for 1892 and to consider the amended paper of "Suggestions for the Conduct of Architectural Competitions."

ILLUSTRATIONS OF OLD CHESTER.*

II.—WATERGATE-STREET.

IN the sixteenth century, Watergate-street was of great commercial importance. Each side yet possesses immense bonded warehouses. When Chester was a thriving port, it was the principal street in the city, and contained several interesting mansions; in fact, it is the most picturesque and characteristic street in Old Chester. The Rows are especially interesting, although the purpose for which they were designed is doubtful. They form galleries or piazzas, one story above the street, to which they run parallel, and are approached by flights of steps at various places. At the Cross their elevation is about 10 ft. In front the Rows are generally open, and have a low railing. In the Rows are ranged the principal shops, and between these shops and the railings is the main thoroughfare of the citizens. Over all are dwellings, so the thoroughfare forms an agreeable promenade in all weathers. Underneath the Rows are other shops entered from the street. Various and contradictory are the theories of the origin of the Rows. The most rational contention appears to be that they were used as covered entrances to the residences of eminent Roman citizens, as, in the rear, remnants of extensive gardens are traceable. The Row, on the north side of Watergate-street, is a good example of the Rows as they existed in the last century; the south side possesses the greatest number of interesting buildings. Near the Cross is "God's Providence House" (restored). Two hundred years ago this was the residence of a family of distinction, evident from the armorial bearings carved on one of the beams. According to tradition this was the only house in the city which escaped the plague in the seventeenth century, and in gratitude for that deliverance the owner had carved on the front "God's Providence is mine Inheritance, 1632." Lower down on the same side,—under the Row,—is the old crypt, said to date from 1180, and adjoining this the remains of the town residence of Leach of Carden, a very fine example of old woodwork; the high hall and pendant still remain, and there is a noble fireplace of great height. At the back of this tenement is the "Lady's Bower."

Continuing downwards we reach "Bishop Lloyd's Palace," which is, without exception the most remarkable house in Chester, and, perhaps, has no equal in Great Britain. The origin of this house is not known. Bishop Lloyd died here about 1650. The date carved in one of the front panels and certain armorial bearings have an analogy to the bearings of his family. The centre gable of the three, seen to the right of the illustration, exhibits a profusion of grotesque ornament carved in oak. Under the windows are eight panels. The first contains "Adam and Eve in Paradise," and "Cain slaying Abel," next "Abraham offering Isaac"; the seventh has a curious representation of the Immaculate Conception; the eighth symbolises the completion of the sacrifice in Simeon's prophecy, "Yea, a sword shall pierce

* The first of this series of views was given in the *Builder* for February 6 last.

thine own heart also." The centre panel contains the arms of James I., the supposed arms and quarterings of Bishop Lloyd, and a Latin inscription with the date 1615. The supports in the row are profusely carved with indescribable forms of men and beasts, the three windows to the left belong to the room in which is placed the fireplace, already illustrated, the panels in this gable, which are now quite plain, are supposed originally to have been decorated similar to the last. A little lower down is a passage or entry called "Puppet Show Entry," chiefly memorable as the scene of a terrible explosion, which took place on December 5, 1772. Opposite formerly stood a fine old mansion of wood and plaster, the city residence of the Mainwaring's, a notable Chester family.

Continuing on the south side is the Yacht Inn, at the corner of Nicholas-street, of no architectural importance. At one time this was the first hotel in the city, and here Dean Swift lodged on one of his journeys into Ireland, and invited the dignitaries of the cathedral to a supper; but, to his great mortification, not one of them appeared. Disgusted, he scratched on one of the windows,—

"Rotten without and mouldering within,
The place and its clergy are both near akin."

Lower down, and up a narrow and inconvenient passage is "Stanley Palace," formerly the residence of the Earls of Derby. This is an elaborately carved three-gabled house, and is, perhaps, the oldest unmutated specimen of a timbered house in Chester. The date of its erection, 1591, is carved in front. Near to this is the Water-gate and the Roodee. Retracing on the opposite side is Stanley-place, the Old Linen Hall, and opposite the Yacht Inn is Trinity Church. Little, if any, of the original remains. In the entrance lies the defaced effigy of a knight in mail armour, Sir John Whitmore, of Thurston, in the reign of Edward III. The legend runs:

"Hic jacet Joannis de Whitmore, qui obiit
3 kal. Octob. A.D. 1374."

In Trinity-street, adjoining, stands the dissenting chapel, erected by Matthew Henry and his friends in 1700. Continuing east we enter the North Row, in which is situated the new Liberal Club, formerly the County Court-buildings. Two doors higher, 24, Watergate-row, contains an effective hall and staircase, on a small scale, the subject of one of our illustrations; and in the next Row (near St. Peter's Church) the Deva Tavern, in which there is a handsome oak mantelpiece, and below, on the same premises, is a curious chamber, entered from the street. T. P. IVISON.

STANFORD HALL, NOTTINGHAMSHIRE.*

THIS is the north view of Stanford Hall, the seat of R. Batcliff, Esq., to which considerable alterations and additions have recently been made.

The centre square block and the circular wing walls are the only portions of the old Hall. New offices entirely have been added on the east end, also fine oak stairs, conservatory, and reception rooms facing the south, and an addition to the drawing-room. On the west, the library has been enlarged, and new smoke-room, billiard-room, garden entrance, gun-room, lavatory, &c.

Messrs. Walker & Slater, of Derby, are the builders who carried out the works. The decorations and upholstery were executed by Messrs. Trollope & Sons. Mr. Westley H. Fletcher is the architect for the whole of the works.

EXAMPLES OF SARACENIC ARCHITECTURE AND ORNAMENT.

THE two plates showing portions of Saracenic architectural detail, and of mosaic and wall ornament, formed a portion of the illustrations to Professor Atchison's fifth Royal Academy lecture on Architecture, and are referred to in that lecture, which will be found in full on other pages.

LONDON COUNTY COUNCIL.—Under the title "Three Years' Work of the London County Council" the *Metropolitan* issues a small separate pamphlet giving a summary of the work of the Council from 1889 to 1892. It may be useful to electors at the present moment.

* This is correct, and not Leicestershire, as stated on the plate, which the architect tells us was a mistake on the original drawing.

THE ARCHITECTURAL ASSOCIATION :
DOMESTIC ELECTRIC LIGHTING.

The ordinary meeting of this Association was held on the 19th inst. in the Meeting-room of the Royal Institute of British Architects, 9, Conduit-street, the President, Mr. F. T. Bagallay, in the chair.

Mr. E. S. Gale, senior honorary secretary, read a letter which had been received from Sir Francis Knollys, on behalf of the Prince and Princess of Wales, thanking the members of the Association for their expression of sorrow at the recent death of the Duke of Clarence and Avondale.

Messrs. F. R. Betenson and E. F. Ware were then elected members of the Association.

Mr. Gale announced a donation to the Studio, by Mr. F. R. Farrow, of a set of plates on building construction. A vote of thanks was awarded to the donor.

Mr. Gale also announced that a member of the Association, who wished his name to remain unknown, had generously offered an annual prize of 5*l.* 5*s.* for measured drawings made under certain conditions.

The President proposed a vote of thanks to the anonymous donor, which was carried by acclamation.

Mr. Max Clarke then read a paper on "Domestic Electric Lighting." The following is an abstract of the paper:—

After some preliminary remarks, the lecturer said that the question naturally arose, "What had architects to do with electric lighting beyond seeing that there was light, and that it was properly disposed about the various apartments to be dealt with, and that the fittings or apparatus by which the light was brought to view were of what might be termed an "artistic" character? By some, the answer to that question would be, "Nothing whatever. When the building is sufficiently advanced, send for the electric light engineer; he will see to all that." And such was, no doubt, the course often adopted with regard to special branches of work. But while, perhaps, few architects went into the question of the size of the gas-pipes in which gas was laid on, or whether the pipes were run in the best way, it was desirable that they should know something about the capacity of electric-light wires, for although too high a pressure of gas in a gas-pipe would only have the effect of giving a bad and wasteful light, too strong a current of electricity in a wire might cause a building to be set on fire.

He took it for granted that everyone would admit that lighting by electricity was the light *par excellence* of the present age. No light was in any way to be compared to it, whether for public or domestic purposes,—for galleries where there were valuable pictures, for mansions where there were art treasures, and for the fire-side. For all, the incandescent electric light possessed every advantage, without any of the drawbacks of any of the other illuminants in use. He proposed to confine his remarks to incandescent lamps, and to saying nothing of the arc lamps used for lighting streets and railway termini.

The plant necessary for a domestic installation of electric lighting might be summed up as (1) the power,—water, steam, gas, or petroleum engines; (2) the generators, or dynamo-electric machines; (3) the accumulators, or storage batteries; (4) the wires or conductors; and (5) the lamps, which produce the light.

1. *The Power.*—A great deal of the cost of an installation hinged on the power. Sometimes water-power was to be had at a very low cost, while in factories and the like, as well as in many mansions and private houses, spare steam power was often available. In towns or anywhere where there was gas, the gas-engine was always available where steam could not be used, and for small installations the gas-engine was perhaps the best, as it was not very expensive in itself, required little attention, and could be put up in a small space. The great point to be borne in mind was to have the engine, of whatever sort or type it might be, well up to its work. An engine which was always worked much above its nominal power was more or less distressed, did not go so regularly, did not last so long, and needed more repairs than one well up to its work.

2. *The Generator, or dynamo electric machine,* briefly described, consisted in its simplest form, of a large magnet or of a number of magnets between the poles of which a number of coils of wire, usually of copper, wound upon an iron

core, were made to revolve. Each coil had its terminals connected to a separate strip of copper, these strips being arranged near one end round the shaft upon which the whole revolves, the coils and core so arranged being called the "armature," while the copper strips at the end were called the "commutator." Copper strips or brushes were held against the commutator, and as the current or electricity was generated in the coils of wire it was conveyed or driven into (Mr. Clarke said he hardly knew which) the commutator, collected by the brushes, and transmitted either to accumulators or direct to the lamps, the supposition being that the current flowed away through one brush and returned through the other. There were so many dynamos, all, no doubt, possessing merits of their own, that it was impossible to give within the limits of a short paper anything more than a general idea. As a rule, the magnets were made magnetic by being excited; in their normal state they were only bars of soft iron. The soft iron had a certain amount of what might be called latent electricity or magnetism in it, and when the armature was made to revolve a very slight current was produced; the current passed through the coils surrounding the soft iron bars, and the result was that the bars became electro-magnetic, gradually getting stronger, and when it could take up no more from the armature the full current was conducted along the cables for use. There were also machines producing what were called alternating currents, which at the present time were largely used. Professor Thomson's definition of a dynamo-electric machine was that it was "a machine for converting energy in the form of electric currents, or *vice versa*, by the operation of setting conductors (usually in the form of coils of copper wire) to rotate in a magnetic field." For the purposes of the present paper, then, the dynamo-electric machine might be taken as a machine for the manufacture of electricity. As before mentioned, there were many varieties of such machines. Those "wound in series" were best adapted for arc lamps; those wound "compound self-regulating" were best for incandescent lamps driven direct; and "shunt-wound" were best for charging accumulators.

3. *The Accumulators, or Secondary Batteries.* The accumulators, which were to electric lighting what gasometers were to gas-lighting, had an important part to play. By their use a serious drawback,—the liability of instantaneous failure of the light by the breakdown of some part of the machinery,—was got over, and they also rendered the light absolutely steady, which was not the case, as a rule, when the lamps were fed with the current direct from the dynamo,—at any rate not in small installations. The accumulators, the action of which was discovered by MM. Faure and Plante in 1860, though they were not brought into a practical form until within the last ten years, consist of plates of metal placed in boxes made of glass or wood,—usually the former,—the glass boxes or "cells" being filled with liquid. They were chemical batteries, in fact, but batteries possessing peculiar properties. The name, "secondary batteries," explained somewhat the difference between them and the ordinary battery. The secondary could not generate a current on its own account, but could only hold or retain one with which it had been supplied. Another difference was that there was no consumption of its elements during its work of charging and discharging, although there was an actual deterioration, which might perhaps be lessened by future improvements. The accumulators manufactured by the Electric Power Storage Company, Millwall, under various patents, were, the author understood, made in the following way:—Plates of prepared lead were perforated or indented all over, and the holes or indentations were filled with a composition consisting substantially of red lead for the positive or peroxide plates, and with litharge for the negative plates. The plates were then "formed" by means of the electric current, and then placed in the glass cells, so many positive and so many negative, all the positive being connected together and also all the negative. The cells were then connected up together, the positive plates of one cell to the negative of the next cell, and so on. The cells were then filled with a solution of sulphuric acid and water, in the proportion, roughly, of 1 of acid to 7 of water. The ends or terminals of the cells were attached to the wires from the dynamo, the action being that when the armature of the dynamo was

rotated, the current driven into the plates caused a chemical action to take place, the result of which we saw in the fact that when the dynamo was stopped, a current could be obtained from the cells sufficient to light the lamps without the intervention of the dynamo at all. The great advantage of the secondary battery was that the light could be used at any hour of the day or night, and the light was the very best that could be produced. But, as in every form of transformation of energy, there was a loss in using storage batteries, and they of course added to the cost of an installation. Completeness, however, must always be paid for, and private house lighting could never be thoroughly satisfactory without the use of accumulators. The loss entailed by their use amounted to about 20 per cent. of the energy stored. With regard to the maintenance of storage batteries, they could be kept in working order for from 11 to 15 per cent. per annum on their first cost. Accumulators should not be allowed to run down; they lasted longer when used regularly than when used and left uncharged intermittently. They should always be kept well charged, and when not in use charged, say, once a fortnight, until the bubbles rise to the surface of the liquid, which should always cover the surface of the plates, the evaporation being made up for by adding water. The cells should be kept in a cool place, not above 65 deg. Fah., and never in the hot engine-room. Ample provision should be made for the ventilation of the accumulator-room, so as to get rid of the disagreeable fumes of the acid solution. The number of cells required in an installation depends upon the description of lamp used,—how many volts it was made for. The size of the cells depended upon the number of lamps required to be in use at the same time. In an ordinary house, as a rule, less than twenty cells would be of no use, as the electro-motive-force of each cell never exceeds about two volts.

4. *Wiring.*—The work of "wiring," or putting in the mains to distribute the electricity to the various points where the light was required was the first item in which the cost of labour formed a consideration. What was required was the most perfect conductor, *ie.*, a conductor capable of conveying the current with the least possible loss, for there was always some loss. The metals which were good conductors were silver, copper, gold, zinc, platinum, iron, &c. Copper was usually used, it being comparatively cheap, very pliable, and lasting. Iron would do very well, but an iron wire to convey the same amount of current would have to be about six times the sectional area of a copper conductor. Therefore iron was not used except in some special instances. The copper conductor did not consist of one wire, but of a number of fine wires twisted together, which not only made the conductor more pliable, but gave a much greater surface-area, which was a *desideratum* for electricity was said to affect surface. Upon the purity and gauge of the copper wire, and the amount and quality of the insulating material, depended the good or bad results obtained in wiring a house, and upon them depended also very largely the question of cost. In many instances the estimate for wiring was based upon the number of lights. The cost of wiring varied from 17*s.* 3*d.* to 40*s.* per light. Either these figures did not represent work of the same quality, or the higher estimates must include more than a fair working profit. It was most important that the wires should be large enough to carry the requisite current, and, in the case of a private house or public building, to carry such additional current as might at any future time be added. People who had electric lighting in their houses were too fond of adding extra lights, until the wires were so hard-worked that they became hot, set the house on fire, and acquired a bad character. The Phoenix Fire Insurance Company had issued a set of regulations which were looked upon as a sort of standard; and the London County Council had just issued new regulations for lighting theatres and music-halls by the electric light, but he did not think that a single theatre in London complied with the standard in every particular. Great care must be taken with the joints in the wire: bad joints were a frequent source of danger. He was under the impression that wires well twisted together, and then carefully soldered, made a good joint, but the County Council's regulations (last item in clause 3) said that "joints in conductors shall be avoided" (there was a charming simplicity about that), "but

where unavoidable they shall be electrically and mechanically perfect. Soldering fluids shall not be used in making such joints." Did "soldering-fluids" mean the solder itself or the fluid put on as a flux? There was some ambiguity about the regulations. Wires should never be fixed behind plaster or in the thickness of the plaster, but they should be in wood casings, made with grooves to receive the wires. The London County Council regulation said that such casings should be of "hard wood." Such casings should always be screwed together; nails should not be allowed, as they were liable to damage the insulation or even the wires. It was absolutely necessary that the wires should be kept dry. Water was an admirable conductor, and if it got to the wires the current would go to earth. If the wires were fixed in inaccessible positions and damp got at them so as to cause a leak, the only way to get out of the difficulty was to cut off the wires and run new ones. In Messrs. Andrews's system of concentric wiring there was a copper conductor or wire, insulated, and then, wound round the insulating material was a series of iron wires forming the return, the latter not being covered in any way. It was said that that system did away with the necessity for casings, and had other advantages. The difficulty heretofore existing with the system had been as to making the branch joints, but Mr. Andrews claimed to have got over all trouble in that way now. There were several methods of arranging the wires between the dynamo or accumulators and the lamps. The most usual way, perhaps, was that known as "in parallel." Another plan was the "series" system, in which the lamps were arranged one after the other on the same wire, but that plan was more usual for arc lighting. Another method was that known as "the three-wire system" which had been adopted by the Parish of St. Pancras in their public supply installation, and by other companies. Switches were in electric lighting work what gascocks were in gasfitting work,—they were simply a means of turning the light on or off. The best switches were those known as the "quick-make, quick-break" switches, for it was of great importance and essential to safety that connexion should be made and broken instantly. The "cut-out" or safety fuse was a great safeguard in electric lighting,—in fact, the safeguard,—but in some cases it was much abused. In such cases, instead of being a trusted servant it was an insincere friend, lulling its users into a sense of false security, and then setting the house on fire. The idea was that each wire was intended to carry a certain amount of current in excess of what normally passed through it. When a too powerful current passed it heated the wire, sometimes melting it and causing a fire. To avoid that, at certain points short lengths of soft metal are fixed in suitable enclosures, and when the current became too strong, usually by accident, the soft metal melted, broke the connexion, and everything was right, except, of course, that all the lamps on that circuit went out. A new length of soft wire could easily be put in. The danger was when the soft metal was too large and would carry too much current; then it ceased to be a safety fuse, and became an element of danger. Every "cut-out" or safety fuse should be made exactly to suit its intended position, and should not be left to the discretion of the men who did the wiring, who often knew nothing about electric lighting. The "cut-outs" should be real ones, not shams, and had better be fixed on the switch-board or in some other accessible place, instead of on ceilings or high up on the walls, where they were difficult of access.

3. *Lamps*.—The lecturer next described the incandescent lamps, the cost of which he stated to be about 3s. 6d. each at present, though after the date of the expiry of the Edison-Swan patent, in December next, the price would perhaps be reduced to 2s. or less. The average life of an incandescent lamp was usually stated to be 1,000 hours; what was meant was probably that at their best they lasted as long as that. But sometimes the filament of carbon broke before they had been in use ten or twelve hours, though that was not usual if the current were steady, and did not vary its electromotive force. Jars or shocks would, of course, break the filaments, so that the lamps should not be hung on door-frames where the doors were likely to be banged or slammed. As an incandescent lamp became old it gave less light, and the glass became black inside, owing

to the deposit of minute pieces of the carbon filament. With regard to the design of fittings, much remained to be done by architects.

In conclusion, the lecturer referred to several practical points in some detail. Referring to some specimens exhibited, he said that the wooden casings for wires made by Mr. Fawkes, of Chelmsford, embodied an admirable idea. But where these casings were screwed up, the screws should be oiled before being driven, and not driven in too tight. After dealing with the question of the measurement of electricity, he entered into calculations of the cost of a 50-light installation, each light being equal to 16 candles. His estimate was as follows:—Engine, 1387; dynamo, 207; accumulators, 1264; fitting of engine, dynamo, &c., 204; wiring and switches, 207; fittings, 207; total, 3644. In planning the engine-room, it should be remembered that the longer the driving-helt the better, as it would run looser, last longer, and give less trouble. It should be at least 14 ft. long. No trouble should be spared in hedging the engine and dynamo so that they might be perfectly firm, and the dynamo must be completely insulated. Entering into figures, the lecturer calculated that the cost of working such an installation as he had described would be about 674 10s. per annum. For that sum they would get 20,857 hours' light of the very best sort, the cost per hour (*i.e.*, the cost per hour for every hour that one 16-candle lamp was alight) being a trifle over 3d., including depreciation of plant. The cost of an argand gas-burner would be about 4d. per hour. Time did not permit the lecturer to go into the cost of the light produced by any of the primary batteries before the public, which were generally, in his opinion, unsatisfactory for lighting purposes.

Mr. R. Langton Cole proposed a vote of thanks to Mr. Clarke for his interesting paper. It happened that he (the speaker) had been obliged to know a good deal about electric lighting, and he could therefore bear witness to the care and trouble the lecturer must have taken in bringing such a mass of detail before them. He thought the temperature of that apartment (the Institute meeting-room) was an eloquent testimony to the salutary value of the electric light, for though he had never felt cold in it before, he wished that he had not taken off his overcoat. As to the difficulty in securing good insulated wire, his advice was to get the "Silvertown" list,—and no doubt other makers issued similar lists. That list gave the size and class of insulation of all wires made, and the architect could specify the wire he wanted, and obtain samples direct from the makers to compare with those supplied by the contractor. Then there was the Electrical Standardizing Institution, which, for a small fee, would test wires or instruments submitted to them, and he saw no reason why architects' specifications should not contain a clause like that usually found in reference to Portland cement, thus:—"The wires shall be tested at the expense of the contractor." He thought Mr. Fawkes's moulded casings excellent, but it was curious that the covers were all screwed in the centre, although he quoted in his preface, the "Phœnix" rule, that all covers should be screwed at the sides. A small point about switches was that it was good to have a luminous tablet over them like those used on match-boxes; examples could be seen at the Crystal Palace Exhibition; and, as to cut-outs, it was just as well not to replace a burnt-out fuse without finding why it failed, as its failure was meant to be an indication that something was wrong. He quite agreed that every architect should design the fittings he required, but there were several points which must be attended to to ensure success.

Mr. C. Stanley Peach, in seconding the motion, said there could be no doubt that it was very desirable that architects in the present day should devote some attention to the study of electric lighting. He believed that electricity was at present merely in its infancy, and that there were many important developments before it.

Mr. Beresford Pite, in supporting the motion, said they were very much obliged to Mr. Clark for his paper, and to Mr. Langton Cole for his supplementary remarks. The profession was much indebted also to Mr. Cole for his writings in the "British Almanac and Companion." In the course of his remarks Mr. Pite strongly criticised the way in which some details of the electric-light fittings of the Insti-

tute meeting room had been carried out, to the disfigurement, as he thought, of the architectural details. He thought that some of these details might have been made far less obtrusive under proper direction.

Mr. A. H. Clark and another member having made a few remarks,

The President put the vote of thanks to the meeting, and Mr. Max Clarke having replied to several points raised in the course of the discussion, the meeting terminated.

Discussion Section.—The seventh meeting of the Discussion Section of the Association was held on the 17th inst., when Mr. W. Pywell, A.R.I.B.A., read a paper on "Flues and Fire-places." The Special Visitor for the evening was Mr. E. Priolean Warren. There was a good attendance, and an excellent discussion followed the reading of the paper, in which Messrs. A. H. Clark, T. E. Pryce, H. A. Satchell, and F. T. W. Goldsmith (chairman) joined. Mr. Warren then dealt with the subject very fully, and his practical and suggestive remarks were much appreciated. The paper was well illustrated, a capital collection of sketches and photographs being exhibited.

DEMONSTRATIONS ON GREEK SCULPTURE AT THE BRITISH MUSEUM.

In her third lecture,* Miss Eugénie Sellers dealt with the sculptures of the Temple of Apollo Epikourios at Bassæ, near Phigaleia. It has been generally held that this temple was built in gratitude to Apollo for the escape of the inhabitants from the great plague of 430; but, as Attic artists were employed upon it, it seems more likely that it was connected with a plague in the year 420, of which we have scantier notice, by which time the scene of the Peloponnesian War had shifted from the Peloponnese.

The plan of this temple is peculiar, for it has an inner cella, lying north and south, which is open to the sky, while it has been shown by Dr. Dörpfeld that it was usual for temples to be wholly closed and lighted only by the central door in front. But behind this cella is a small chamber, lying east and west, which is completely closed, save for a door in the eastern side. This must have been the original temple, containing the statue of Apollo, to which the cella served as a sort of courtyard. On the inner side of the cella are intertresses terminating in columns that have their origin in rough buttresses like those which prop the walls on the inner side of the court of the so-called palace of Priam at Hissarlik, and which were retained when later such a court formed the plan of a temple of a god.

The frieze, which is very high relief, runs round the inner side of the cella, where it would be seen in the full daylight. On two sides are represented the battle of the Centaurs and the Lapithæ, and on two that of the Greeks and the Amazons. The arrangement of the slabs is somewhat difficult. According to Mr. Murray, the group of Apollo in his chariot would form a centre-piece; but possibly its function is rather to form a link between the two subjects.

As a composition it is very successful. The subject lends itself to the formation of small groups, with interlacing lines—a scheme of decoration which suits the ribbon-like space of a frieze better than the rapid flow of the Parthenon frieze, with its somewhat inadequate centre. The figures are full of life and power, though the workmanship is often rude and coarse. The passion of the Centaurs, contrasting with the comparative lifelessness of the Centaurs with Greek sculptors to the variety of treatment of form offered by the contrast of male figures with those of women and of Centaurs.

BIRMINGHAM ASSOCIATION OF STUDENTS OF THE INSTITUTION OF CIVIL ENGINEERS.—A meeting of this Association was held on the 15th inst. at the Midland Institute, the President, Mr. J. Edward Willox, A.M.I.C.E., being in the chair. A paper was read by Mr. H. W. Butler, Student Inst. C.E., on "The Maintenance of Roads," which was followed by an interesting discussion.

* For brief notes of previous lectures see p. 142, ante.

THE ARCHITECTURAL ASSOCIATION'S
SPRING VISITS:
THE IMPERIAL INSTITUTE.

The Imperial Institute at South Kensington as usual attracted a large number of members of the Association on Saturday afternoon last, when, by the kindness of the architect, Mr. T. E. Collcutt, an excellent opportunity was afforded of carefully inspecting this interesting building. Considerable progress has been made since the visit of the Association last year; and, though glimpses of the finished work of the interior can now be obtained, the plant and scaffolding stand somewhat in the way of a definite opinion upon the finished aspect of the work. The building is expected to be opened sometime in June, and by then more than three-fourths of the proposed buildings will be nearly completed. The long gallery at the back of the building is in an advanced state, and the portions that will remain incomplete for a time are a wing at each end, the continuation of the central hall opposite the entrance, and the grand staircase. The scaffolding of the front elevation is gradually being removed, and gives a better opportunity of judging of the exterior. This is chiefly marked by the extreme delicacy of the detail, and, though it is generally most graceful, it is to be feared that the fineness of much of the detail will be materially obliterated by the sooty weathering which so soon overtakes every stone building of this murky metropolis. To the same cause must be ascribed the dead colour of the copper, which is largely used on the numerous cupolas. The prevailing fineness of detail is in the interior of the building seen to much greater advantage, and appears in this position to be much more suitably employed. The Hopton Wood stone lining to the corridors is distinctly pleasing in its effect, and the capital light provided throughout shows to the best advantage the care that has been provided upon the detail.

Messrs. Mowlem are the general contractors, and some excellent specimens of their work were seen. Mr. Wallace, the clerk of the works, conducted the party over the works. It may be mentioned that some of the corridors are laid with glass mosaic. This would have doubtless received more attention had the representative of the firm who laid it not been so conspicuously present.

BRITISH ARCHAEOLOGICAL ASSOCIATION.

At the meeting of this Association on the 17th inst., Mr. J. W. Grover, F.S.A., in the chair, Mr. Macmichael read some notes on hair-curlers of the seventeenth century, used for the preparation of the long ringlets or "heart breakers" worn by ladies, and the wigs worn by men, a large collection of the clay curlers being exhibited. Some notes on the ancient signs of London were also read. Mr. Marriage exhibited a fine example of Egyptian bronze. The Rev. W. S. Sykes exhibited a remarkable prehistoric hatchet, 14 in. long, formed of calliard, a white slate-stone of the locality. It has recently been found at the Crow's Nest Farm, Lawkland, Settle. The Rev. Carus V. Collier reported the opening of a harrow at Bradwell, Derbyshire. Three skeletons have already been found within it, two being on their sides with the knees bent up to the chins. They were surrounded by a low wall or cist of flat stones on their edges. Many bones visible in the part not excavated appear to be from older interments. A paper was then read by Dr. A. Fryer on the present condition of the ancient church of Perranzabuloe, Cornwall, which was excavated from beneath a great drift of sand. The ruins are very greatly reduced in height. The paper was illustrated by photographs. In the discussion which ensued, Mr. Loftus Brock, F.S.A., and others took part, and Mr. Langdon described the process by which a large portion of the locality has been invaded and covered by sand slowly blown from the sea-shore. Mr. Park Harrison then reported his recent discovery of traces of the old Saxon church, now Oxford Cathedral. Some of the shafts of what was believed to be a triforium of Norman date in the south transept are found to be grooved for the frames of windows, the grooves being continued through the bases and in some of the arches, but not in the capitals, which are probably Norman insertions in what appear to have been some of the earlier Saxon windows of the older church. Several drawings were exhib-

ited. The Chairman described some objects of antiquarian interest noted in his recent journey to the Azores and America.

THE LONDON COUNTY COUNCIL.

PRIOR to the commencement of the proceedings of the meeting of the London County Council on Tuesday last, the Chairman, Sir John Lubbock, unveiled a bust of the late Mr. J. F. B. Firth, the first Deputy Chairman of the Council. The bust, which is by Mr. Verheyden, stands in a corner of the Council Chamber.

The London Water Question.—The Chairman said that on Friday in last week it came to his knowledge that the Birmingham Corporation had put down their Water Bill for second reading on Monday last. The Council had passed a resolution to petition against the Bill, but he was not quite sure whether the Council desired to oppose the second reading. At the same time, having regard to the importance of the question, he thought he ought not to allow the second reading to pass unquestioned. He conferred, therefore, with the member in charge of the Bill, who consented most courteously to defer the second reading until next Monday. He (the Chairman) then asked the metropolitan members of Parliament, with some members of the Home Counties County Councils, to come to a conference in that chamber. They had a rather large meeting there on Monday, and considerable discussion took place on the question. He thought they all felt that if they were to proceed as against the Birmingham Bill it was desirable that they should do so with the support of the metropolitan members, or allow them to co-operate in the matter. Eventually the conference appointed a committee, comprising several members of the Council.—Mr. Lawson, M.P., Lord Compton, M.P., and Mr. Dickinson,—to confer with the Birmingham representatives, and it was hoped that some amicable agreement would be come to. While they did not wish to oppose any Bill which was promoted by Birmingham, they felt that, having regard to the recommendations of the Committee of the House of Commons on the London Water Question, they could not allow the present Bill to pass unquestioned.

Sewage Precipitation Operations during 1891.—The Main Drainage Committee's report contained the following:—

"We submit for the information of the Council a statement as to the results of the operations at the sewage precipitation works at Barking and Crossness during the year ended December 31, 1891.

At the Northern outfall at Barking Creek 30,172 millions of gallons of sewage have been treated by means of 8,516 tons of lime and 1,533 tons of sulphate of iron, which operation resulted in the production of 536,000 tons of sludge, which were sent to sea by means of the two steamers. During the summer 500 tons of manganate of soda, and 347 tons of sulphuric acid were employed in deodorising mainly that portion of sewage which was untreated by precipitation.

At the Southern outfall at Crossness 2,228 millions of gallons of sewage were only partially treated with 407 tons of lime and 113 tons of sulphate of iron which yielded 46,873 tons of sludge. If the ships had been available for carrying to sea a larger quantity of sludge than the above it could readily have been obtained at this station, but in consequence of the whole of the vessels' carrying capacity being required at the Northern outfall, precipitation operations at Crossness were entirely suspended on August 5. The untreated sewage discharged at Crossness during the summer was deodorised by means of 923 tons of manganate of soda and 532 tons of sulphuric acid.

In consequence of the better system of working at the Northern outfall during the latter portion of the year the percentage quantity of sludge (corrected to 90 per cent. moisture) obtained from the sewage rose from 0.28 per cent. in 1890 to 0.36 per cent. in 1891 for the whole year, which is in itself evidence of the better working of the system, as the theoretical quantity obtainable on the assumption that 30 grains per gallon are precipitated, is 0.43 per cent. In addition to the sludge at the Northern outfall, 2,691 tons of filth have been removed by means of the filth hoist and gratings and entirely consumed by means of the destructor; 5,196 tons of sand were also removed from the precipitating channels.

The cost for lime used at both outfalls during 1891 was about 3,184*l.*, and that for sulphate of iron about 3,184*l.*, as against 7,034*l.* for lime and 2,692*l.* for iron in 1890.

The cost of manganate of soda and sulphuric acid used at the outfalls and storm overflows was 27,525*l.*, the great bulk of which will be saved as soon as the precipitation operations are in full working order. The cost for the year 1890 was 24,560*l.*

The following is a comparative statement of the quantities of the materials used in the years 1890 and 1891:—

Northern Outfall:—		
	1890.	1891.
Quantity of sewage treated	35,003 mil. gals.	30,172 mil. gals.
Sludge obtained	449,500 tons.	536,000 tons.
Filth destroyed	—	2,691 "
Sand removed	—	5,196 "
Lime used	8,536 "	8,516 "
Iron used	1,563 "	1,533 "
Manganate of soda ..	427 "	500 "
Sulphuric acid	311 "	347 "

NOTE.—The works were in an incomplete condition during 1890, the improvements in methods for collection of sludge at the Northern outfall having been brought into action in August, 1891.

Southern Outfall:—		
	1890.	1891.
Quantity of sewage treated	3,370 mil. gals.	2,228 mil. gals.
Sludge obtained	61,735 tons.	46,873 tons.
Lime used	924 "	407 "
Iron used	113 "	113 "
Manganate of soda ..	1,054 "	923 "
Sulphuric acid	379 "	532 "

The report was agreed to, and after transacting other business, the Council adjourned.

COMPETITIONS.

DARWEN TECHNICAL SCHOOLS.—In reply to the advertisement for competitive plans, twenty-five sets were received. Mr. Murgatroyd, F.R.I.B.A., was called in by the Committee to make the selections. The design placed first is that of Mr. J. Lane Fox, of Dewsbury. The design placed second is by Messrs. Morley & Woodhouse, Bradford. The design placed third is by Messrs. Dunn & Watson, of London.

NEW POLICE-STATION, SHREWSBURY.—At a special meeting of the Shrewsbury Town Council, on the 22nd inst., Major-General Herbert moved that the plans of the new police-station, sent in by Mr. Johnson, of Westminster, and selected by the Watch Committee as the best, be adopted, and that Mr. Johnson be appointed the architect for the work, the cost of which will be about 3,000*l.*—Alderman Crump seconded the proposition, which was ultimately agreed to.

BUILDERS' CLERKS' BENEVOLENT INSTITUTION.

THE twenty-fifth annual general meeting of the donors and subscribers of this Institution was held on Tuesday evening last at the offices, 21, New Bridge-street, Blackfriars, the President-elect, Mr. Colin Grant Patrick, in the chair, supported by Messrs. E. Brooks (Treasurer), E. B. Gammon, W. D. Gilbert, E. W. Holland, F. S. Oldham, H. W. Parker, E. S. Rider, J. A. Robson, E. G. Roe, C. K. Turpin, T. H. Winy, and other gentlemen.

The retiring President, Mr. Benjamin Haanen, jun., was accorded a hearty vote of thanks by the Committee, at their meeting held just prior to the general meeting, and in vacating the chair he expressed his acknowledgements to the officers and Committee for the methodical, businesslike, and economical manner in which the work of the Institution is carried on.

The Secretary, Mr. H. J. Wheatley, having read the advertisement couvoning the meeting, the minutes of the last annual general meeting, and of a subsequent general meeting, were read and confirmed.

Mr. Wheatley next read the annual report of the Committee, which stated that the income for the past year amounted to 806*l.* 0*s.* 9*d.*, the largest total which it had yet been able to record. That amount was made up of 293*l.* 4*s.* in annual subscriptions, 406*l.* 18*s.* 6*d.* in donations, 103*l.* 16*s.* 1*d.* in dividends, and 2*l.* 2*s.* 2*d.* interest on deposit account. The sum expended was 455*l.* 0*s.* 1*d.*, including 340*l.* paid to pensioners and 15*l.* given in grants for temporary relief. During the year one of the pensioners (Mrs. Oliver) was removed by death, and another (Mrs. Hadriell) resigned, having re-married. The number of pensioners now on the books was sixteen, but the total number elected since the foundation of the Institution was 32; of these, 9 had died, while 7 had retired owing either to re-marriage or to improved circumstances in other respects. With reference to the orphan presentations (three in number) held by the Institution, the Committee report that the vacancy caused by the expiration of the term of Edith Friend was filled up during the year by the election of Cyril Ludford, who was now in the school. There was still a vacancy for another child, and the Committee were prepared to receive applications on behalf of orphans whose friends might wish to place them in nomination for the vacancy.* The Committee were also prepared to receive applications for two vacant pensions, the amounts granted being 25*l.* per annum to builders' clerks who might be eligible, and 20*l.* per annum to

* It may be as well to mention that only orphans of builders' clerks are eligible.

their widows. One applicant was already before the Committee. The thirteenth annual dinner of the Institution was held on April 6 last, under the presidency of Mr. Benjamin Hannen, jun., whose earnest appeal on behalf of the Institution was most heartily responded to, the sum of 433*l.* 16*s.* 6*d.* being obtained. The amount of 200*l.* placed on deposit in 1890 was last year brought into current account, and a further purchase of 500*l.* 2*s.* 6*d.* per cent. Consolidated Stock was effected, bringing up the total Stock now held by the Institution to 4,150*l.* The Committee expressed their hearty thanks to the retiring President for the very practical help rendered by him to the Institution during his year of office, and announced that Mr. C. Lin Grant Patrick had kindly consented to accept office as President of the Institution for the ensuing year. According to the Rules, one-third of the Committee retired, but were eligible for re-election. In conclusion, the Committee acknowledged the help so steadily afforded to the Institution by the builders, architects, and merchants connected with the building trade, and expressed the hope that their support of so useful a charity would be continued.

The Chairman, in moving the adoption of the report, said he had accepted the position of President of the Institution with great pleasure, and would do all he possibly could to further its interests during his year of office. The Institution was one which was particularly worthy of support, and he trusted that it would continue to prosper.

Mr. E. C. Koe, in seconding the motion, said he thought it was a matter of great satisfaction that the Institution was able to fund money from time to time. They were very desirous, indeed, of increasing their funded property, so that in times of depression the interest of their funds might enable them to meet their liabilities and carry on the work of the Institution without relying upon current donations or subscriptions.

The report was unananimously adopted. The new President having been elected, the other officers and the retiring members of the Committee were re-elected; and Messrs. S. J. Thacker and Thomas Stirling were re-elected auditors. Mr. Ernest S. Rider being also elected as an auditor in succession to his father, Mr. Thomas F. Rider, who has become one of the trustees of the Institution.

Heartly votes of thanks were accorded to the retiring President and other officers for their services during the past year, and it was announced that the annual dinner of the Association would be held on March 30.

Correspondence.

To the Editor of THE BUILDER.

CONCRETE FOR ARTISANS' DWELLINGS.

SIR,—I have no recollection of seeing any statement as to experiments made with concrete beams where it was definitely proved that coke-breeze concrete was superior to gravel; nor would such experiments be very conclusive evidence unless the quality and fitness of the gravel employed were known. Some descriptions of gravel used for concrete prove totally unfit for the purpose, although apparently otherwise. If "Surveyor" refers to Colonel Seddon's experiments some years ago, I believe he will find the results went to prove that broken bricks or brick ballast made the best concrete for large span floors, and that one experiment therewith, a floor 12 ft. 6 in. by 9 ft. 9 in. between supports, and 6 in. thick, carried a load of 8 cwt. per foot superficial before it collapsed. But there is another difficulty with concrete floors formed of huge monolithic slabs,—viz., their tendency to develop cracks or fissures on their under sides, and which it seems impossible to entirely prevent; and although it is assumed these do not lessen the strength of the floor, it is a doubtful point.

The objects of postponing the layer of coke breeze are:—1. The mass of concrete when first deposited in place is in a quaggy condition and not in a fit state for depositing thereon the floor layer and accurately levelling it ready for nailing boards thereto; some portions might get disturbed and disarrange the accuracy required. 2. It would cause delay in performing the straightening portion of the work; men would of necessity be moving about thereon, and the initial set of the cement would be protracted; concrete should be allowed to rest as quickly as possible after being deposited in place. 3. The surface should be true, smooth, and free from defects when the boards are nailed thereon; this is not likely to be the case if workmen have been tramping on the floors soon after completion, and for a considerable time longer, as would be the case if the floors were finished when the walls were the right height to receive them, let them be covered up over so carefully.

"Surveyor" asks if floors should be wotted directly after they are finished; it is desirable to do so, and keep them wet for several days, as the slower cement sets in reason, the better; but not, on the other hand, to deluge the concrete with water before it has obtained its initial set and disturb the particles of cement.

Colonel Seddon and others have proved that it is quite practicable to make floors of 14-ft. span or

more; but the point "Surveyor" appears to wish to ascertain is whether, in a general way, it is advisable. I think not; but I hope to see what others have to say relative thereto. I have made floors 12 feet by 10 feet clear of supports, and resting on walls on three sides only, without a failure.

With regard to coke breeze as an aggregate, it should be borne in mind that the good quality of concrete depends not only upon the affinity of the cement for the aggregate, but the inherent strength of the latter, and coke breeze does not stand high in this respect. If concrete made of one part of cement to seven parts of crushed bricks is broken asunder, it will be found that the fracture is a clean one,—i.e., the particles are not disturbed, but the brick aggregate is divided wherever the line of fracture occurs,—and this points, I suggest, to the desirability of balancing, where possible, the tensile strength of the aggregate and the adhesive strength of the matrix. Coke breeze, as a rule, contains a great deal of dirty matter,—the products of combustion possibly,—and to fit it for concrete this should all be washed out, incurring much labour; being very small, too, in size, it needs more cement than a larger aggregate to secure as good results. These two drawbacks explain my former assertion, that "measured by strength, it is, perhaps, the dearest of any." THOMAS POTTER, Maresfield.

LIVERPOOL MOTIVE POWER.

SIR,—When I revise, for publication in the "Proceedings" of the Mechanical Engineers, the paper on which you commented last week, I hope to explain some of the apparent inconsistencies and omissions to which you (writing upon a proof printed for the meeting) have called attention. It would have been much more satisfactory to me, and probably to everyone interested in the subject, if I had been able to reduce all the costs of work done to a common unit, and also to discuss the bearing of the facts upon the general question of distribution from a central station. But, if I had wanted to do this, the paper would not have been written, and a promise would have been broken.

Some day, if other engagements will permit, I hope to deal more fully and comprehensively with this important and interesting topic; and, meanwhile, you have exactly appreciated my object in publishing "authentic data" for the use and benefit of professional men, who generally experience great difficulty in getting anything but "trial-trip results." J. PARRY.

THE EXTINGUISHING OF FIRES.

SIR,—The use of mineral-oil lamps being so very general, the following incident may be suggestive to some of your readers:—

Last night, a large suspended oil-lamp fell in our library. The room was instantly "dark of fire." Some members of the staff showed much presence of mind, and rushed for "hand-grenades," the use of ten or twelve of which extinguished the fire in five minutes, confining the damage to the room in question, although the flames had reached from floor to ceiling.

The points to which I think attention might be invited are:—

1. The lamp should have "extinguished itself" in falling. It failed to do so.
2. The "finest water-white oil" (the quality used) is supposed only to ignite at a very high temperature (we won't dispute about a few degrees). This took fire at once.
3. The hand-grenades (which have been rather depreciated, and which may or may not be of value in the open air, when the gas generated is promptly dispersed) certainly acted with magical effect within the compass of a large room.

Your readers will draw their own conclusions. ROBERT JOHNSON, The Colonial College, Halesley Bay, Suffolk, February 19, 1892.

BOARD SCHOOL, GREENHEADS, LANCASHIRE.—On the 18th inst., the Dean of Manchester (Dr. MacLure) laid the memorial stone of a new board school to take the place of three school buildings which have been condemned as unsuitable in the neighbourhood of Greenheads. The principal front of the new buildings is to Webster-street, Greenheads. The walls externally are faced with Raddon stock bricks, being relieved with stone strings, heads, cornices, mullions, &c. An imposing feature is the central gable, and to the right and left dormers are placed, giving light to the covered portion of an upper playground. The main block of the building is placed in the centre of the site. Right and left are playgrounds for girls and infants, with entrances from Webster-street and Leaf-street. A coker's school-room and sallery will be provided. The whole of the space over the girls' department is utilised for a playground for the girls, a considerable portion at each end being covered. Accommodation is provided for 1,116 children. The works are being carried out by Messrs. William Southern & Sons, contractors, of Salford, from the designs and under the supervision of Messrs. Kayle & Bennett, architects, Manchester.

The Student's Column.

WARMING BUILDINGS BY HOT WATER.

IX.

EXAMPLE WORKS (HORTICULTURAL) (continued).

HIS next example, fig. 31, shows an apparatus heating two glass-houses, or what may more probably be the case,

one glass-house with a division in it. The two parts of the house are used for different purposes, one as a hot-house for tropical productions, &c., and the other as a greenhouse, for more hardy plants that perhaps only require warmth at night or in winter. The boiler would, in this case, be brick-set, and situated in a pit sunk below the greenhouse level. There is no objection to an independent boiler, but when a pit has to be sunk, it is less expensive to use the other kind, and there is less risk of loss of heat. We are supposing this glass-house is not against a residence, but is of the lean-to character, and placed out in the garden. Even if against a residence it is doubtful if the boiler could be conveniently placed in a cellar, as this apparatus would need the regular attention of a gardener. Boilers in cellars or basements-rooms are generally attached to less important works, and are attended to by a page-boy or female servant.

It was just mentioned that this example is of an apparatus heating a greenhouse of the lean-to shape, hounded on one side by a wall, as fig. 32. This lessens the quantity of pipe re-

quired, for on the wall side no actual loss of heat occurs, and by this arrangement a deal of protection is gained by having the wall facing north or north-east if any way possible.

In the first house the pipes (only the topmost flow-pipe is shown on fig. 31) enter at the point shown on the left-hand side, but it would be arranged for them to come in below the level of the path or floor. By this means the branch required for the front of the house (the side opposite the wall) can be first carried along the end below the floor-level without dipping down anywhere, and so miss the doorway, which is sure to exist, as shown in the illustration. The pipes which are carried below the floor-level are

shown broken or dotted; those above the floor-level, solid.

As the first house is devoted to plants requiring a high temperature, we may consider that pipes along the front only would hardly suffice; so a branch along the back, *i.e.*, the wall, is shown. This being the side requiring the least heat, two pipes will, probably, suffice (as shown at fig. 31). This would be one flow and one return. Along the front three pipes (perhaps four may be needed) are carried, but the portion below the floor-level along the end, need only be but two pipes, branched into three or four as soon as they rise above the floor-level.

The two pipes on the centre of the house are a flow and return, also carried beneath the floor-level.

All pipes beneath the floor-level are, as a rule, carried in brick channels, with a grating at top. By this means the pipes, although not exposed, contribute to the aggregate results, although not in proportion to pipes that are exposed, as the rule that is to be given will show. The gratings which cover these channel pipes must be easily removable, so that the pipes can be brushed and kept clean. A dirty pipe, even with a little dust, loses in efficiency, as dirt and dust, of whatever nature, are nearly always composed of poor conducting materials, and go far towards preventing the pipes losing their heat. If only 2 ft., or 3 ft., of pipes were carried below the floor-level, then they could be covered over entirely, as no great gain would be effected by placing such a small quantity in a channel. If pipes are covered entirely, then it must be with some poor conducting material, sand or dry earth will do.

It is desirable to point out that showing a certain number of pipes, and pipes in certain positions, does not indicate that the work should be always carried out in this manner. The illustration is merely to describe possible ways of doing the work, if such ways are considered the best to meet the conditions. But in the majority of cases it is not for the hot-water engineer to arrange the disposition of the pipes at all; he may settle the quantity, but the gardener is the person who settles general questions, and he will decide where the pipes may be run and where not. In works of fair size the engineer's first business should be to confer with the gardener. The pipes and their disposition can then be arranged to meet all requirements to suit the purposes to which the houses are to be put, also as to avoiding vine-roots, trees, &c., should such exist or be likely to exist. Many gardeners are very skilled in planning these works; it is, to all intents, part of their business, and usually forms part of their training.

Both the front and back services in the hot-houses are extended around and along the division, as far as the doorway. This may not always be necessary, although, as a rule, a tropical house wants a deal of pipe, and few

FIG. 33.

spaces are left empty. It is on this account a service is shown below the floor-level, up the pathway, although it is more often the inability to place the pipes against the walls, owing to

FIG. 34.

roots existing, that makes this plan necessary. Sometimes, if pipes cannot be carried close to the walls, they are run along the edge of the pathway, as fig. 33, or along the edge of a raised bed, as fig. 34.

The second house will probably be heated sufficiently by two pipes carried along the front, and extending to the division doorway and the end doorway as shown. These pipes are simply continuations of those along the front of the first house. To avoid ngly work just where the pipes pass through the division, there being three pipes in the first house and but two in the second, a box-end, as fig. 35, will be found very

FIG. 35.

useful. The illustration shows exactly how the connexion is made; the whole of the box is in the first house.

As illustrated, it is customary to have the tropical house nearest the boiler, as it requires the greatest heat; the houses (if there are more than two) succeeding this are then placed in order of precedence as to the heat required. This is the usual plan, although, like all other rules, it has exceptions. When there are two or more houses, however, it becomes necessary to introduce stop-valves to regulate the heat in any particular spot,—that is, to check or retard the circulation as required. This regulation is needed, as the most careful measurement and calculations will not result in a quantity of pipe that will do the work exactly, neither too little nor too much. Then, again, as the weather changes, and as the growth of the plants or fruit proceeds, regulation of the heat is needful, and at various other times. With one house only the regulation is effected by checking or urging the fire, but this does not do with several houses, as it is certain that the heat of all houses will not require regulating at the same time or to the same extent.

In the apparatus under discussion a stop-valve will be needed in the flow-pipe just inside the second house, where marked * on fig. 31, and as shown in the last illustration. This would provide a means of checking the second house without interfering with the heat of the first; this will suffice, and the reverse of this would never be required with the apparatus of this character. It might also be desirable to put a stop-valve in the service against the back wall in the first house, where marked *, to prevent this short and direct service from "leading" the circulation, to the detriment of the longer services in the other direction. This valve might, however, be dispensed with if the service was kept nearly flat and a good rise given to the other branch.

In the whole of this apparatus 4 in. pipe would be used. No gain would be effected by using a smaller pipe between the boiler and the circulating pipes, the distance being so short. Smaller pipes, say, 2 in.,—would be permissible if the distance was greater and the houses not very large. There is no need, however, for the stop-valves to be 4 in., they can be 2 in., the pipes being reduced to this size just where the valves come. This effects economy, as the valves are rather expensive. In larger works than this, it would be necessary not to use smaller pipes or valves than 4 in. anywhere, for, as explained in an earlier paper, the strength of the circulation, the motive-power, is very weak in horizontal works which are so deficient in vertical pipes, that is, of such little height. Air-tubes would be needed at each extremity and one on top of the box junction, fig. 35.

SURVEYORSHIPS.

LEICESTER.—The Leicester Corporation has, almost unanimously, increased the salary of Mr. E. G. Mawbey, the Borough Engineer, from 700l. to 1,000l. a year. Mr. Mawbey succeeded the late Mr. Joseph Gordon at Leicester about two years and a half ago, when that gentleman was appointed Chief Engineer to the London County Council.

THE CUTLERS' COMPANY.—Mr. Alex. R. Stenning, F.R.I.B.A., F.S.I., has been elected Surveyor to the Worshipful Company of Cutlers.

PULPIT, BRIDGESTONE.—An oak pulpit has been placed in Bridgestons Church, Devon, made by Messrs. Luscombe, of Exeter, from the design of Messrs. Tait & Harvey, The Close, Exeter.

GENERAL BUILDING NEWS.

PROPOSED RECONSTRUCTION OF GLASGOW COURT-HOUSE.—At a general meeting of the Glasgow Court-house Commissioners, held on the 18th inst., it was decided to adopt the plan prepared by Mr. Bell, of Messrs. Clarke & Bell, for the reconstruction of the Court-house and the provision of additional accommodation for the conduct of the business of the court. The plan deals with the premises at present occupied by the sheriffs, as well as those vacated by the Corporation, and involves the complete reconstruction of the building, at an estimated cost of 45,000l. The basement floor will be occupied mainly with fire-proof record rooms in connexion with the departments of the Sheriff-Clerk and the Justice of Peace Clerk. In addition it will contain a witness-room for the Justice of Peace Court, and there will be sixteen cells for the temporary detention of prisoners. In the Ingram street end of the ground floor accommodation will be provided for the Justice of Peace Court; and there will be rooms for the J.P. Clerk and Fiscal, as well as retiring-rooms for the justices. The Sheriff-Clerk's department will occupy the remainder of this floor, and here also will be refreshment-rooms and retiring-rooms for the agents. On the first floor there will be five courts for the Sheriffs-Substitute. Attached to each will be a retiring-room. Three spare court-rooms will be provided, in the view of the ultimate appointment of an additional Sheriff; in the meantime these would be available for other business. On this floor also will be placed the Sheriff-Principal's reception-room, the Ordinary Court, the Appeal Court, and the Jury Court rooms, with retiring-rooms for the judges in connexion with each. The Jury Court, where the criminal trials will take place, will have a gallery fitted up, to which independent access will be had by the general public. The Sheriff Small Debt Court will continue to occupy its present position on the second floor, but the main entrance will be from Hutcheson-street, and improved communication with other parts of the building will be provided. The Sheriffs-Fiscal's department will likewise be located on this floor, and eighteen large rooms will be set apart for the conduct of business; while, for the reception of prisoners awaiting examination, six cells will be provided. The remainder of the floor will be occupied with agents' retiring-rooms, witnesses' rooms, and the offices of the auditor. The attic floor will probably be occupied by the house of the caretaker, with additional retiring-rooms, lavatories, &c. There will be entrances in the centre, both from Wilson-street and Ingram-street, which will be connected by staircases with corridors running round the building on each floor, with access to the various departments. There will, in addition, be elevators at both ends, running to the top of the building.

BUSINESS PREMISES, CARDIFF.—Some new business premises for the Atlas Furnishing Company have just been erected in the Hayes, Cardiff. The frontage of the premises is over 100 ft., and the extreme depth measures 160 ft. The building contains a basement, ground, and four floors. The front elevation is worked in white brick, with carved Bath stone facings, with polished granite pillars. The new premises have a basement extending 150 ft. back, and above this is a glass-fronted shop. There are also suitable offices and waiting-rooms, and on either side is a doorway,—on the left leading to the warehouses, workshops, packing-rooms, and stables; and on the right to an area in which lavatories, &c., are placed. The staircase gives access to the show-rooms above and also to the basement warehouse. Iron pillars form a central support to each succeeding floor. Behind the show-rooms are the warehouses and workshops, stables, and coach-house. The former measures 60 ft. by 40 ft., the workshops being comprised in the two upper stories. The front building is supplied with a lift, and the workshops with hoists. The premises were designed by Mr. J. P. Jones, of Cardiff.

CONGREGATIONAL CHURCH, NEAR ST. HELENS.—The new Congregational church and schools at Blackbrook, St. Helens, which were commenced in August, 1890, have just been completed. The architectural design is Late Gothic in character, the plan of the church being cruciform, having chancel and transept. The outside of the building is composed of Monk & Newell's Ruskin brick, with red sandstone facings, and the inside is of white Cefn stone. There are several entrances, the main one being in the front and two on the sides. There are also rear entrances for the choir, &c. Internally, the clearstory is carried upon moulded arches, supported on octagon pillars having moulded caps and bases. On one side of the rostrum is the organ-chamber, and on the other side the vestry, with cloak room in the rear. The internal woodwork is of pitch-pine toned and varnished, and the rostrum is constructed of selected pitch-pine. The tracery windows are filled with tinted leadlights. The church stands back from the main road, and has a tower and spire 120 ft. high. A drinking-fountain is let into the boundary wall. The Sunday school building adjoining consists of an assembly room with accommodation for over 300 children, and boys' and girls' and infants' class-rooms. The architect has been Mr. Thomas W. Cubbon, of Birkenhead, and the con-

tractors Messrs. Hughes & Stirling, of Bootle. The work has been carried on under the supervision of Mr. A. Halsall.
