JOURNAL

JOURNAL OF THE BRITISH MEDICAL ASSOCIATION

BRISTOL PART

VOLUME I FOR 1888

LONDON

PRINTED AND PUBLISHED BY THE BRITISH MEDICAL ASSOCIATION, 5, AVENUE ROAD, LONDON, W.

INDEX TO VOLUME I FOR 1888.

- A.
Aarau Cantonal School, dental inspection at, 934
Abbeyleix, epidemic of fever at, 1179
Abdomen, treatment of gunshot wounds of, 922
Abdominal section in tubercular peritonitis, 24;
penetrating wounds of stomach and meso-colon
treated by, 79; three unusual cases of, 128; rup-
tured extra-uterine gestation successfully treated
by, 129; for peritonitis, 861; for ruptured uterus,
971; on a new-born child, *ib.*; in extra-uterine
gestation, two hours and a half after rupture,
1152; pancreatic cyst cured by, 1297
Abercrombie, Dr. J., a fatal case of hemiplegia in a
child, 76
Aberdeen and infectious diseases, 92; sanitation in,
153; medical officer of health of, 432, 657; notes
from, 1073
— University. See University
Abernethy on tumours, 475
Abortion, Pathology and Treatment of, Dr. L.
Phillips, *rev.*, 702
— pathology of in relation to treatment,
681; after removal of ovaries, 861; after treat-
ment of, 902; payment for attendance on a case
of, 1192; in double uterus, 1217; treatment of,
1367
Abraham, Dr. P. S., epithelioma of larynx, 137
Abscess, spinal, note on the treatment of, 130, 1061;
of brain in a ewe, 134; between liver and dia-
phragm, 194; in the tibia, 355; cerebral in con-
nection with otitis media, 530, 534, 614, 636; of
antrum, treatment of, 647; of brain, 700, 744;
cerebral successfully treated by operation, 848,
857; of liver, 1224; abdominal following enteric
fever, 1338
Abscesses, multiple of liver and lungs, 251; multi-
ple in sucklings, 753; abdominal, air in, 1277
Abyssinia, small-pox in, 755
Academy of Medicine, Belgian, report on hypno-
tism, 567
— French, election of corre-
sponding members, *etc.*, 632
— in Ireland, Royal, candidates
for presidentship of, 1239
— Section of
Anatomy and Physiology, notes of some nervous
and arterial anomalies, 302; an effect produced by
direct stimulation of the heart, *ib.*; first dorsal
interosseous muscle supplied by the median nerve,
ib.; on the distribution of the cutaneous nerves
on the dorsum of the human hand, *ib.*; brain
growth and cranio-cerebral topography, 801;
sacro-iliac joints in a pregnant woman, 802;
homology and innervation of the achselbogen and
pectoralis quartus and the nature of the lateral
cutaneous nerve of the thorax, *ib.*; history of the
nerve to the anconeus, *ib.*
— Section of
Medicine, argyriasis, 137; cerebral tumour, *ib.*;
nervous diseases, congenital spastic paraplegia,
ataxic paraplegia, 354; heredity in hemorrhagic
purpura, 355; case of pneumothorax, 699; etiology
and classification of the anæmia of puberty, *ib.*;
gastric epilepsy, 700; migrainous headache, 1222;
saccharin in chronic cystitis, 1223; rare form of
mental disease, *ib.*
— Section of
Obstetrics, suppurating ovarian cyst, 21; placen-
tal cyst, 22; uterine hemorrhage of five years'
standing caused by an enlarged and cystic ovary,
removal of ovary, recovery, *ib.*; pudendal hæmato-
cele, *ib.*; specimens, 469; removal of fibroid, *ib.*;
report of the Rotunda Hospital, *ib.*
— Section of
Pathology, dysentery, 250; sclerosis of brain and
spinal cord, *ib.*; suicidal wound of the heart with
a pin, *ib.*; multiple abscesses of the liver and
lungs, *ib.*; hydatid cyst of the deltoid muscle,
537; rupture of the trachea with fracture of the
sternum and rib, *ib.*; ulcerative endocarditis, *ib.*;
intra-uterine amputation, *ib.*; carcinoma of
liver, 853; acute pulmonary tuberculosis, *ib.*;
chronic Bright's disease, *ib.*; chronic Bright's dis-
ease with cerebral hæmorrhage, 859; corneal
tumour, *ib.*; unreduced dislocation backward of
the bones of the forearm, 1275; acute lobar pneu-
monia and chronic Bright's disease, *ib.*; unreduced
dislocation of the elbow, 1276; intestinal obstruc-
tion, *ib.*; secondary cancer of the lung, *ib.*; pul-
monary artery with two valves, *ib.*; peritonitis
from perforation, 1338; pyæmia of dental origin,
1339; microscopic appearances in locomotor
ataxy, *ib.*; separation of the coracoid epiphysis of
the scapula, *ib.*; cirrhosis of the liver and portal
thrombosis, *ib.*
Academy of Medicine in Ireland, Royal, Section of
State Medicine, president's address, 419; the
Coachford poisoning case, *ib.*; distribution of
enteric fever in the city of Dublin, 962; hypno-
tism, *ib.*; Glengarriff as a winter health-
resort, *ib.*
— Section of
Surgery, president's address, 22; trephining in
brain disease, *ib.*; serious brain symptoms follow-
ing pyæmia, *ib.*; penetrating wounds of stomach
and transverse meso-colon successfully treated by
abdominal section, 79; foreign body in the eso-
phagus, 80; the treatment of advanced conditions
of equino-varus, 301; the surgery of the thyroid
gland, *ib.*; aneurial hæmorrhage treated by
secondary trephining, 747; traumatic subdural
abscess of the brain and its treatment by treph-
ining and aspiration, 748; case of traumatic
aphasia successfully treated by trephining and
removal of blood-clot from the interior of the
cerebrum, *ib.*; on suprapubic lithotomy and vesi-
cal suture, 1166; suprapubic lithotomy, *ib.*; vesi-
cal tumour removed by suprapubic cystotomy,
ib.; punctured wound of the peritoneum, with
protrusion of the intestine, recovery after opera-
tion, 1276; enterectomy and enteropathy, 1277
Accident to Dr. Nelson, 493
Accidental Injuries: their Relief and Immediate
treatment, Mr. J. Cantlie, *rev.*, 22
Accidents, shooting, how they occur, 43, 102, 159;
how to prevent, 230; at the opening of the Glas-
gow Exhibition, 1075; from lightning and thun-
derstorms, 1305
Accommodation, diphtheritic, paralysis of, 1875
Acetic acid and ergot in *post-partum* hæmorrhage,
295, 743
Acetonæmia in diabetes mellitus induced by the
shock of a strangulated femoral hernia, 908
Achselbogen and pectoralis quartus, homology and
innervation of, 802
Acid, action of antipyrin in migraine that of an,
1007
Acids, treatment of the paroxysms of migraine by,
73
Acland, Sir H., operation on, 543; proposed banquet
to, 918
Aconite, poisoning by, 694
Aconitin, the dose of, 786
Acromegaly, a case of, 855
Act, a model, 30
— the Allotments, Local Government Board order
under, 1251
— Dentists, prosecution under, 105
— Habitual Drunkards, 706
— Labourers, in Clonmel, 358; in Celbridge
Union, 760
— the Margarine, in operation, 882; conviction
under, 884
— Pharmacy, amendment of the, and the Parlia-
mentary Bills Committee of the British Medical
Association, 425
— Public Health, important decision under, 723
— Sale of Food and Drugs, in Yorkshire, 47; nul-
lifying the, 90
— Vaccination, prosecution under, 1131
— Vivisection, and the inoculation of animals,
29)
- Action, disgraceful, against a medical man, 105
Acts, Contagious Diseases, in India, 1300
Adam, Dr. J., a case of melancholia presenting some
exceptional features; prolonged refusal of food
and forced alimentation, 343
Adams, Mr. A. P., obituary notice of, 621
— Mr. W., on the successful treatment of
"hammer toe" by the subcutaneous division of
the lateral ligaments, 645
Addison's disease. See Disease
Additions, recent, to the materia medica, 23
Address on the therapeutica of the uric acid dia-
thesis, by Dr. I. B. Yeo, 16, 67; on surgical in-
stinct, by Mr. W. D. Spanton, 169; on the medical
student and his environment, by Mr. E. Owen,
175; on diphtheritic and related forms of para-
lysis, by Dr. J. S. Bristowe, 225; on our hospitals
and the interests of patients and pupils, by Dr. E.
D. Mapother, 231; on the relations of gynaecology
to general therapeutics, by Dr. A. W. Edis, 291;
on the value of practical studies, by Professor W.
Rutherford, 1002; on pernicious anæmia with
jaundice and cases simulating it, by Dr. J. S.
Bristowe, 1149; on the social position of the
medical profession, by Dr. T. W. Thursfield, 1269
— change of, 675; wanted an, 1032
Adenoma of pituitary body in an ewe, 134; seba-
ceum, 251; of the pinna, 589
Admiralty examination, 1307
Adolescents, acute bronchocele of, 1374
Adrenals, disease of, without bronzing, 645
Adult, epileptiform seizures caused by oxyurides
vermiculares in an, 1056
Adulteration, of wine, 323; of pepper, 331; of milk,
conviction for, 567, 605, 772; legalised, of wine, 1284
Adults, congenital heart disease in, 958
Advertisement, a flaming, 615
Advertisements in local papers, 560; quack, 1397
Advertising in newspapers, 162
Advice and medicine 61, 616
Affleck, Dr. J. O., the clinical value of temperature
observations in certain acute and chronic diseases,
593
Africa, South, hydrophobia in, 48
Aged Persons, report of Collective Investigation
Committee on, 511
Agreements with unqualified practitioners, 105;
form of with assistants, 217, 327
Ague, a case of "quintan," 343, 501, 623
Aid in convalescence, 1174
Ainhum, 195
Air, exhaled, toxicity of, 210; testing the compe-
tency of the valves of the heart by means of, 883;
in abdominal abscesses, 1277
Air-passages, removal of puff and dart needle from,
195; transmission of tubercle by the, 433; malig-
nant disease of, 746
Aitken, Sir W., on the Animal Alkaloids, the
Ptomaines, Leucomaines, and Extractives in their
Pathological Relations, *rev.*, 81; portrait of, 631;
degree of LL.D. conferred on by University of
Edinburgh, 867
Alasio, "A Pearl of the Riviera," Dr. J. Schneer,
rev., 650
Albinism, 595
Albumen in urine, undescribed fallacy in testing
for by nitric acid, 355
Albuminuria, bearing of on life assurance, 248; a
frequent result of sewage poisoning, 451; in en-
teric fever, 906
Albuminous food in obesity, 1300
Alcohol, in ophthalmia neonatorum, 244; ophthal-
moplegia externa due to, 464; therapeutics with-
out, 515, 635; medical declaration concerning, 105
Alcoholism, strychnine in, 90; nuxvomica in, 243;
hereditary, experiments on, 1083; relation to
inbreeding, 1320; and amenorrhæa, 1323
Alexander, Dr. W., a method of treating incontinen-
ce of urine in the female in cases hitherto
considered to be beyond the resources of surgery,
1015

- Allerson, Dr., calculus in a tonsil, 801
 Alexander, Dr. W., obituary notice of, 988
 Algeria, inoculation for small pox in, 313
 Algiers, medical practice in, 54
 Alkaloid, new, in tea, 1395
 Alkaloids, the Aniline, the Ptomaline, Leuco-
 maline, and Extractives in their Pathological Re-
 lations, Sir W. Aitken, *rev.*, 81
 Allan, Dr. J., nitrate of silver in erysipelas, 549;
 treatment of carbuncle, 900
 Allbutt, Mr. H. A., proceeding of against the
 General Medical Council, 1350
 — Dr. T. C., the Local Government Bill and
 sanitary administration, 984
 Allen, Professor, diseased suprarenal body, 594
 — Dr. J. H. L., Napier and Kiriapapanga
 (Hawkes Bay Province, New Zealand) as health
 resorts for pulmonary invalids, 293
 Allen's hot-water and ice bottles, 913
 Allingham, Mr. H. W., treatment of loose cartilage
 in knee-joint, 301; on the causes of failure to find
 the colon in lumbar colotomy, 591, 835; the in-
 teral semilunar cartilage of the knee-joint
 sutured to the head of the tibia, 1110
 Allotments Act. *See Act*
 Alopecia, obtrinate, 55; case of, 80; areata, 906
 Alopecia, medicine and politics in, 1126
 Altitudes, high, pulmonary consumption treated by
 residence in, 1009, 1088, 1195
 Alum in typhoid fever, 256
 Alyph, measles and whooping-cough at, 34
 Amalgamation of medical schools in Dublin, 1024,
 1133
 Amblyopia, toxic, 219
 Ambulance class at Tobermory, 605
 — competition trophy, 443
 — instruction for the police, 1042
 — Lectures, Dr. J. M. Martin, *rev.*, 82
 — lectures to ladies, 223
 — movement at Hawarden, 32
 — service for Paris, 932
 — work in civil practice, 345
 Amenorrhœa, permanganate of potassium in, 56
 associated with alcoholism, 1383
 America, practice in, 773, 831, 1043
 Ammonia, picro-nitrate of in malarial fever, 313;
 treatment of snake-bite by, 549
 Amputation of thigh, 23; at the hip-joint for sar-
 coma of femur, 468; intra-uterine, 537; at
 shoulder-joint, 890; by Berger's method, 861
 Amylene hydrate as a hypnotic, 549
 Anatomy, Inspector of in Dublin, 205
 Anæmia of puberty, the etiology and classification
 of, 688, 699; acute saline transfusions in, 693;
 pernicious, with jaundice, and cases simulating it,
 1149; a case of pernicious treated by repeated
 transfusions, 1336
 Anæsthesia and respiration, 323; during strabismus
 operations, 349; local, 430
 Anæsthetic mixture, a pleasant, 19; canadol as a,
 1184; methylene as a, 1211, 1301
 Anæsthetics, 595; Guide to the Administration of,
 Mr. H. Davis, *rev.*, 912; administration of, Dr. J.
 A. Junker on, 1112
 Analysis, of St. Lucie rum, 210; in auscultation,
 801, 1086; of water, law as to, 1071
 Anatomical peculiarities in relation to disease, 409
 Anatomy, the Comparative, of Domesticated Ani-
 mals, Mr. J. McFadyen, *rev.*, 912
 Anatomy, Pathological Studies in, Drs. N. Wolfen-
 den and S. Martin, *rev.*, 1220
 Anchylostomiasis, 1367
 Anconous, history of the nerve to, 802
 Anderson, Dr. J., case of unilateral sweating, 193; a
 case of sub-retinal effusion in chronic nephritis
 in a child, 248
 — Dr. M.C., cancer of the pylorus, 633
 Anderson's College Dispensary. *See Dispensary*
 Aneurysms, thoracic, 24, 195; orbital, 125; abdo-
 minal, *ib.*; popliteal, ligature of superficial
 femoral artery for, 467; of thoracic aorta, 595; of
 aortic arch, *ib.*; innominate, distal ligature for,
 712; of arch of the aorta, congenital malformation
 of pulmonary valves simulating, 609; of the in-
 nominate artery, 1161; of axillary artery, electro-
 lysis in, 1222
 Angioma, of the epiglottis, 150; of the larynx, 584
 Angiomata of the mouth and tongue, 29
 Animal Magnetism, M.M. A. Binet and C. Féré, *rev.*,
 473
 Animals, the inoculation of and the Virulence Act,
 920; and man, diphtheria in, 961
 Ankylosis of atlas and occiput, 700
 Annacker, Dr. A., Martin's method of dealing with
 the placenta and sac in laparotomy for extra-
 uterine pregnancy, 290
 Annales des Maladies de l'Oreille, du Larynx, etc.,
 A. Gouguenheim, *rev.*, 424
 Anolyne, antipyrin as an, 622
 Anorexia, menthol in, 423
 Antagonism, the law of, 915
 Antharobin, a substitute for chrysoarobin, 1231
 Anthropometry, practical, 740
 Antifebrin, clinical remarks on, 350; in epilepsy,
 819
 Antipyrin, foreign opinions of, 32; in hay fever, 40;
 in nervous drowsiness, *ib.*; effects on blood, 55;
 in migraine, 75; in epilepsy, 100; hypodermic
 injection of, 101; antiseptic powers of, 157; action
 of, 209; in labour, 210, 931; idiosyncrasy with re-
 gard to, 213, 258, 260, 645, 1147; in a uterine
 emissions, 374; failure of in epilepsy, 500; toxic
 effects of, 555; as an anodyne, 622; ill effects of,
 661; impure, 707; action of in migraine that of
 an acid, 1007; notes on, 1052; in hæmorrhage and
 ulcers of the leg, 1075; contra-indications of, 1185;
 in cerebro-spinal meningitis, 1218; Bishop's
 granular effervescence, 1281; in eye surgery, 1300
 Antipyretic, strophanthus as an, 757
 Antipyretics and febrile states, 1114; action of on
 the liver, 1184; Dr. D. MacAllister on, 1330,
 1373
 Antirabic inoculations in Italy, 29
 Antiscap, vaginal, 980
 Antiseptic Methods, Principles of applied to Ob-
 stetric Practice, Dr. P. Bar, *rev.*, 195
 Antiseptic, lozenges, 100; acidified corrosive subli-
 mate as an, 148, 295; naphthol as an, 491; agents,
 chemical incompatibility of, 898; chloroform-
 water as an, 970; salutar as an, 1054; naphthol β
 as an, 1185; for midwives, 1419
 Antiseptics in midwifery, 1420
 Antisepticism, dangers of, 1084; value of in internal
 urethrology, 1165
 Antivaccinationist's mare's nest, 312
 Antrum, treatment of abscess of, 647; operative
 treatment of empyema of, 1030
 Aorta, thoracic, aneurysm of, 596; aneurysm of
 arch of, *ib.*; congenital malformation of pulmonary
 valves simulating aneurysm of arch of, 909
 Aperients, use of in scarlet fever, 1195
 Aphasia, puerperal, 237, 415; sensory, 339; trau-
 matic treated by trephining, 748
 Apomorphine, treatment of poisoning by nitre by,
 110
 Apoplexy, case of, 596
 Apostoli, Dr. G., on some new applications of the
 induced or faradic current in gynecology, 63; the
 electrical treatment of uterine fibroids, 439, 1362;
 and electrolysis, 557; notes of a case of hydro-
 salpinx, new mode of electrical treatment, 998;
 at Brighton, 1020; treatment of uterine myomata
 by the method of, 1065; Dr. Tivy on three cases
 of uterine fibroids treated by the method of, 1376
 Apothecaries' Hall, Dublin, opening of School of
 Pharmacy by, 483; and the King and Queen's
 College of Physicians, 551, 559
 Apothecaries' Society of London, pass lists, 53, 276,
 499, 771, 990, 1192; and illegal practice, 380, 1303;
 the arts examination of, 622; admission of women
 to examinations, 809, 967; and the title of its new
 licence, 1086, 1169, 1250; and alleged illegal
 practice, 1394
 Apparatus, Gärtners', for the therapeutic utiliza-
 tion of muscular work, 35; orthopedic, 656; elec-
 tric exhibition of, 802; life-saving fire, exhibition
 of, 1385
 Appeal, an, 385, 726, 817, 944, 1044, 1096, 1368
 Appendages, uterine, *See Uterine*
 Appleby, Dr. F. H., presentation to, 1350
 Appleford, Mr. S. H., case of alcoholic paralysis,
 with phthisis terminating in fatal left hemiplegia,

END OF VOLUME I FOR 1888.

BRITISH MEDICAL JOURNAL.

BEING THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION.

EDITED FOR THE ASSOCIATION BY ERNEST HART.

LONDON: SATURDAY, JANUARY 7, 1888.

A LECTURE

TUMOURS OF THE BLADDER.

Delivered at University College Hospital, November 21st, 1887.

By SIR HENRY THOMPSON, M.B., F.R.C.S.,

Consulting Surgeon and Professor of Clinical Surgery to the Hospital, etc.

PART I.

AFTER remarking on the extremely narrow limits which this subject occupied a few years ago, compared with that which it has at the present day, the lecturer continued:—With regard to the varieties of tumour which affect the bladder, they are to be classified as in other parts of the body, according to their histological characters, and also to their tendency to invade surrounding structures and reproduce themselves elsewhere.

Until recently, most vesical tumours were supposed to belong to that class of growths roughly indicated as "cancerous." And besides these, a single species was familiarly recognised under the term "villous," although by some this was also relegated to the preceding class, as "villous cancer," without any warrant, however, for doing so. It was well known to be a bleeding tumour, which sooner or later produced a fatal result by its single irrepresible function of continuous blood-letting. This so-called "villous growth" is, in fact, of all varieties that which most commonly affects the bladder, and it will form the most prominent in the series now presented, but under another name—that of papilloma.

First, however, I shall briefly mention as the least complex form of growth springing from the vesical mucous membrane, the simple mucous polypus, that formation of which the well known nasal polypus is the type. It is very rarely found in the bladder, and has at present been only met with in that of the young child. Nothing more will be said of it here.

Secondly, we come to the growth just referred to as papilloma; it is so called because its distinctive structure is that of an outgrowth from the mucous membrane in the form of papillæ, more or less covered with a well defined epithelium, spheroidal or more commonly cylindrical, each papilla being provided with a considerable blood-vessel. The structure, indeed, is normal in its elements, and the arrangement of these is normal also, inasmuch as the papilla is simply a very slender fold or extension of mucous membrane. A section of the mucous coat from an empty healthy bladder, made immediately after death, will furnish the same appearance in every respect. I show you here an admirable section taken from the monkey in the condition named, which, of course, is not attainable with a human subject. It is not distinguishable from papilloma. To return; when these papillæ are long, slender, and filamentous, floating in the urine, springing together in a group from a circumscribed base or stalk, they are termed "fimbriated papilloma." If the organ containing such a growth is examined in air instead of under water, the fimbriæ collapse, adhere, and form a soft, rounded, scarlet mass, which is quite characteristic. Unting the filaments, especially at the base, there are always some connective tissues interspersed, and mostly some non-stripped muscular fibres also. Then sometimes the outgrowth springing from a pedicle expands so as to form a small polypoid mass, much firmer than the nasal variety just alluded to. It may grow to a large size, and whether small or large there may be two or more springing from the same base.

When there is a larger proportion of the fibrous structures named, associated to form the growth, and it is denser in structure than those first described, I have employed the term "fibrous papilloma" to denote it.

Fibrous papilloma thus understood is, of course, related through in-

sensible gradations to the fimbriated variety, although the two are essentially distinct in their nature, since the fimbriated variety may continue, increasing in size for years while still retaining its simple structure, and it does not necessarily acquire density with age. A characteristic fibrous papilloma is a growth chiefly solid, and as such may form a considerable mass, with only a small proportion of fimbriated papillæ on its surface. And here let me tell you that these fimbriated papillæ may be found attached to the surface of any vesical tumour, even to some forms of malignant growth, apparently as accidental adjuncts, the true character of the tumour being unaltered thereby. And this is a matter of importance in relation to diagnosis, and obviously indicates the necessity for caution in forecasting the result of operation, since a specimen of papilloma in the urine, while it proves the presence of that growth in the bladder, does not absolutely bar the possibility that a more serious growth may be there also.

Next, occasionally we find a tumour springing generally from a wide base, rounded in form, firm in consistence, not large, although one or two such have been met with, doubtless after a considerable term of growth, the chief constituent of which is organic muscular fibre, such as that which constitutes the contractile coat of the bladder itself. This is termed myoma. It may be more or less intermixed with bands of connective tissue, and it may have fringes of papilloma on the surface, but the distinctive character found on examination determines its classification as a muscular growth.

In carefully examining the foregoing tumours under the microscope, a few examples are met with in which may be observed a large quantity of small nucleated cells interspersed, or grouped among the constituents of the fibrous stroma forming the denser portions of the tumour; and sometimes cells of irregular form, not apparently belonging to any normal type. And such a structure always arouses suspicion that the growth is not so innocent in its tendency as papilloma, and may not improbably be reproduced after removal. It suffices for the present to speak of these as forming an intermediate or transition class, and thus we approach the borders of the next group.

This is that important class of growths the structure of which is largely composed of epithelium in varied or modified forms; and their tendency is to invade and infiltrate by rapid increase, all adjacent structures. Among them, epithelioma may be first named, as it appears not infrequently to affect the bladder, and its course is probably not more rapid there than it is in other parts of the body. Scirrhus is somewhat more rare, and progresses more slowly than the preceding. The more rapidly developed and larger growths formerly grouped as encephaloid, and now defined as round-celled and spindle-celled sarcomata, are certainly rare in the adult; they occasionally affect the prostate and bladder of children who appear not to be subject to the other forms of malignant disease in those organs. Lastly, may be named, as the rarest of all, the dermoid tumour, which has been on two or three occasions met with in the bladder.

Now the symptoms of vesical tumour present nothing special at the outset; a little undue frequency of micturition is then commonly the only sign, and excites no suspicion as to the real cause. But early in the progress of papilloma there is an important sign, characteristic of it throughout its entire course, and common to most other tumours at a late period, namely, the appearance of blood in the urine. A single hæmorrhage occurs after exercise, thus resembling that from calculus, hence its presence is often suspected, but with certain differences which you may advantageously note. First, the hæmorrhage from papilloma is generally much more abundant than that of calculus; and secondly it is mostly unaccompanied by pain and irritation of the bladder. As the case advances, hæmorrhage becomes more frequent; pain, however, is still rarely complained of unless obstruction to the outflow of urine is occasioned by clots. Such a history should always arouse great suspicion. The symptoms described have very commonly, until recent time, been attributed to "congestion of the kidney," a rare, if not unknown occurrence, without the presence of other symptoms than those which have been named. And a careful inquiry should be made in order to determine the diagnosis. En-

deavour first to learn whether the patient has ever observed that the act of micturition sometimes commences by passing urine a natural appearance, but becoming stained or mixed with florid blood towards the close. If so, the source is vesical, possibly prostatic, at all events not renal, but is more probably the result of tumour. When blood comes from the kidney, it is almost invariably mixed with the urine, and unless it is very recent indeed, it is brownish, not florid in tint. Occasionally, although very rarely, florid blood may appear first and clear urine afterwards, but the reverse is the almost invariable rule.

Secondly, a microscopic examination of *débris*, passed in the urine must be diligently made, and before long the characteristic appearance of papillomatous structure will, if present, generally be discovered. The bladder may be washed out with plain water, especially after an examination by sounding, in order to obtain the evidence in question. For the nature of the structure sought, see Fig. 1; which

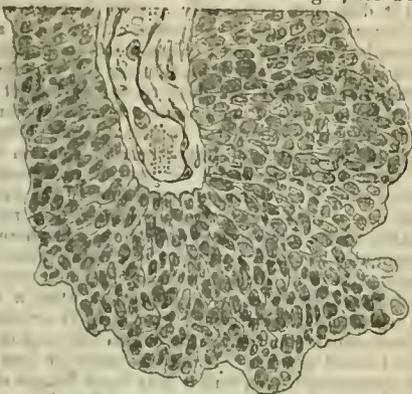

Fig. 1.

shows a typical specimen, such as may be often found, and a glance at which enables you to affirm without hesitation, the presence of a papillomatous growth in the passages, and its site may be safely assumed to be the bladder, where the symptoms described are present.¹

But, you may say: Why not sound the bladder, as we do for a stone, and determine the question thus? For this reason, that the question is not thus determinable. The soft, filmy tissues, even when springing from a thick base, cannot be felt floating in a fluid medium, and yield no evidence to the sound. Nor does rectal examination afford a sign unless the bladder is distended by the growth, when the organ feels rounded, but very soft, as if filled with fluid. On the other hand, when there is a cancerous growth involving the bladder to a notable extent, a well-defined mass of irregular outline and of hard, unyielding consistence, almost invariably presents itself to the finger in the bowel. Whenever this is met with, a condition so different from the rounded and yielding mass presented by senile enlargement of the prostate, there need be little doubt as to the very grave fact indicated, namely, the presence of scirrhous occupying the walls of the bladder itself, and therefore irremovable by art. If on this point you are in any doubt, you may with the short beaked sound obtain further evidence by examining the rectum with the finger at the same time when carcinoma in any form may usually be thus detected. Having verified its presence, we make no attempt at removal; nothing can be gained by dealing thus with any portion of such a tumour.

How we are to treat the non-malignant growths will be discussed next.

(To be concluded.)

¹ The portion from which the figure was drawn was, among others, shown under the microscope at the lecture; the epithelium is columnar, and very abundant.

TESTIMONIAL TO DR. BODINGTON.—Dr. Fowler Bodington, formerly President of the Birmingham Medical Institute, of the Midland Medical Society, and of the Birmingham and Midland Counties Branch of the British Medical Association, who is on the eve of leaving for British Columbia, where he intends to begin practice, has been presented with an address, largely signed by the members of the medical profession in Birmingham, expressive of the high regard and esteem in which he has been held for many years by all those who have had professional and social relations with him, of the credit and distinction with which he has filled the various offices, and heartily wishing him full success and prosperity in his new sphere of duty. Among the signatories we observe the names of Sir Walter Foster, M.P., Dr. Wade, Dr. Fournier, Dr. Jordan, Mr. Lawson Tait, and Dr. Alfred Carter.

LETTSONIAN LECTURES

SOME POINTS IN THE SURGERY OF THE URINARY ORGANS.

Delivered before the Medical Society of London, January, 1888.

By REGINALD HARRISON, F.R.C.S.,

Surgeon to the Liverpool Royal Infirmary; and Lecturer on Clinical Surgery in the Victoria University.

LECTURE I.

URINE FEVER AND TOXIC URINE.—THE FORMATION OF STRICTURE TISSUE IN REFERENCE SPECIALLY TO THE TREATMENT OF URETHRAL STRICTURE.

MR. PRESIDENT AND FELLOWS,—Let me, in the first place, thank you for permitting me to address your ancient and learned Society in the capacity of Lettsomanian Lecturer for the present session. At the same time, and with a full consciousness of my inability to approach you as I would desire, let me also ask your indulgence whilst I attempt to follow in the direction selected by many who, in preceding me in this chair, have so largely contributed to the practical advancement of medicine and surgery.

As I have already indicated, I propose making some observations relative to certain points arising out of the surgery of the urinary organs. It is now some years since my attention was directed to the circumstances under which fever was occasionally seen in connection with various lesions involving the urinary tract. It appeared to me that the subject had scarcely received the attention it deserved, and that a further knowledge of the etiology of what I would speak of as urine fever, as opposed to ordinary wound fever, might be of service to us as practical surgeons.

Let me, for the sake of clearness and comparison, briefly illustrate in a familiar way what I mean, and then I can the more easily deduce the points upon which I desire to lay stress this evening.

In surgical practice we have long been accustomed to recognise, after injuries and operations, a form of excitement which is generally known as wound or traumatic fever. It varies in degree according to circumstances, is generally attended with some elevation of temperature, and it usually declines without proving either serious or fatal. Since the due recognition of these principles upon which Listerism is based, the development of this kind of fever has been considerably restricted, if not entirely abolished.

In striking contrast with this we have a distinctive form of fever, not unlike ague in many important respects, which is also seen in lesions involving the urinary tract. Let us take, for example, the simple operation of internal urethrotomy. Here an incision, limited to a few lines in length, is made in the urethra, which the patient for some two or three hours is probably unconscious of. Then he is seized with a rigor, which terminates in fever and an elevation of temperature. As a rule, these symptoms decline in the course of a few hours, possibly to be repeated. More rarely the rigor and fever are followed by suppression of urine, convulsions, and speedy death; *post-mortem* examination failing to discover any reasonable or recognised explanation for these phenomena. The symptoms, though, as a rule, in only slight degree, more frequently follow internal urethrotomy, accidental wounds of the urethra, and the introduction of a catheter or a bougie. Even the last mentioned operation, simple as it usually is, has proved fatal in the course of a few hours, with little or nothing to show for an explanation. Here then, as I have said before, we have a train of symptoms resembling ague, which are only called into existence in connection with lesions involving the urinary tract. In order that I may be perfectly understood as to the phenomena referred to, let me briefly illustrate the kind of case alluded to by narratives from my own practice.

Some years ago, in a case of extremely tight stricture, I performed an internal urethrotomy on a young and otherwise healthy male; three hours afterwards he had a rigor, followed by high temperature, convulsions, and suppression of urine; and in forty-six hours he was dead. *Post-mortem* examination failed to prove anything except that the operation had been properly performed.

In the course of last year I saw a boy, aged 11 years, who, having ruptured his urethra by a fall, had retention of urine for thirty hours

before I visited him in consultation. A catheter was then passed with some difficulty along the lacerated canal and retained, the retention being in this way relieved. On the following morning he was visited, and found to have passed a restless night, with a temperature of 102° F. About four o'clock the same day his usual medical attendant, Dr. Davies, was summoned, and found the patient in severe convulsions, and absolutely unconscious. The temperature was then 105° F. He could not swallow; the fits recurred with much violence, attended with episthomonos, and he became comatose, and died at midnight, that is, to say, about twenty-four hours after I first saw him and the catheter was passed.

I could not help observing that so long as this patient had retention he was comparatively safe; when, however, an opportunity was afforded to the urine of coming and continuing in contact with the laceration in the urethra by means of the retained catheter, then a process of acute poisoning seemed to commence, which speedily terminated in death.

In 1874, a healthy middle-aged man was under my care for a tight urethral stricture, for which, in the course of treatment preliminary to dilatation, a metal instrument carefully passed was followed by some very slight bleeding. Four hours after this he had a rigor, and his temperature went up to 103° F.; this was followed by a succession of rigors, at intervals of from eight to twelve hours, with occasional vomitings. For over fifty hours the amount of urine excreted was only four ounces. During this period the pulse was quick and thready, the tongue dry and brown; there was a tendency to drowsiness, with occasional delirium, and death appeared to be imminent. After remaining in this serious condition for ten days, he ultimately completely recovered, though he complained of muscular pains and much prostration for some time afterwards.

Illustrations such as these, and others that I could quote, seemed to indicate that the presence of urine in a wound, under certain circumstances, was capable of generating an aguish form of pyrexia, which I shall speak of henceforth as urine fever. I am aware that some authorities are accustomed to speak of all the phenomena I have just illustrated under the one name of urethral fever. Such a term, I think, is misleading, inasmuch as it seems to connect the symptoms produced with the precise part, rather than with the process, for wherever throughout the urinary tract urine can be placed under certain conditions, there can all the phenomena usually associated with the term urethral fever be produced. With the view of endeavouring to throw some light on the causation of this, I determined some years ago to investigate (1) the relationship between urine and a wound which leads to the development of urine fever; and (2) the probable nature of the influence or material producing it. To the elucidation of these two important practical points I would now desire to direct your attention.

In the first place, it appeared to me that the development of urine fever might be traceable to the kind of contact that existed between a wound and the urine. I thought I would test it in the following way. Taking a number of cases of subpubic urethral stricture, which were unfitted for treatment by dilatation, I adopted the following procedure:

Internal urethrotomy having been performed, and all obstruction being removed, so that a full sized grooved staff could be passed into the bladder, the patient was placed in the lithotomy position; and a median cystotomy was performed, quite independent of the previous internal operation, so as to admit a full-sized drainage tube, such as I usually employ for this purpose, to be passed into the bladder. By this combination of internal and external urethrotomy I treated a considerable number of urethral strictures of the worst type with results which time has already shown have been eminently satisfactory, both so far as the immediate comfort of the patient was concerned and the permanency of the relief that was afforded.

After a number of trials of this kind, I soon found that as was my drainage, so was my freedom from fever; urine fever only occurred where the former was imperfect. When urine, even in very small quantities, was pent up in a recent wound, fever resembling ague invariably followed. When, on the other hand, urine was allowed to escape freely and continuously, as after a lateral lithotomy, no such symptoms were developed. But, further than this, in connection with the operative treatment of stricture, it was observed with much uniformity that, in cases where it was impossible to obtain perfect urine drainage, the urine might, so to speak, be sterilised by local or general measures. This tended considerably to prevent the urine undergoing changes and yielding products which were calculated by their absorption to produce this special kind of fever. For instance, I found that after an internal urethrotomy, certain antiseptic precautions, directed towards the wound as well as the bladder, for the

purpose of acting upon the contents of the latter, considerably reduced both the frequency of these attacks as well as their severity. This was chiefly noticeable in connection with the use of solutions of corrosive sublimate for irrigating the wound, as well as for retaining within the bladder. Further, it was impossible not to recognise the importance of certain drugs, which by their elimination in some degree through the urine, seemed to render the latter less capable of exciting a specific fever where it remained in contact with a recent wound. This was most marked in the case of quinine, which is so largely eliminated by the urinary apparatus. In some cases of internal urethrotomy that were observed, the production or not of urine fever could be largely influenced by the administration of quinine. As bearing upon the sterilisation of urine in connection with operative procedures on the urinary apparatus, I will refer to a passage from a recent writer who, in bearing testimony to the value of boracic acid as a prophylactic against urethral fever, states that in some forty urethrotomies, he had had but one case of urethral fever, and that occurred in an instance, where the precaution of sterilising the urine by the administration of boracic acid had been accidentally omitted. The consequence of this was a violent chill on the third day after the operation, with a high temperature. These observations, then, taken collectively, seemed to me clearly to indicate that the kind of contact between fresh urine and a recently made wound was in itself sufficient to determine the occurrence of urine fever as a consequence.

I will now pass on to notice, in the second place, the probable nature of the influence or material by which the fever is actually produced.

During the last few years some important investigations have been made relative to the development of animal alkaloids, both in the dead and living, by Messrs. Gautier, Peter, and Bouchar, in France; and by Drs. Lander Brunton and A. M. Brown, in this country. An address of much interest on this subject, in its relation to practical medicine, has also been recently delivered by Sir William Aitken. To all these gentlemen we are indebted for much valuable information. From these investigations I do not think there can be any doubt in coming to the conclusion that the secretions of living beings are capable of forming leucomaines, alkaloid bodies having poisonous properties, and that many phenomena connected both with health and disease may thus be accounted for. For, as Gautier remarks,¹ "Of all the extractive composite residua, the alkaloids of animal origin are worthy of the deepest interest. It is only now that they have become familiar to us. They claim our special study from the fact of their constant presence in normal secretions, and must be classed with the most active agents known." From my observations in connection with the surgery of these parts, it seems probable that the development of urine fever is really due to the absorption of some such poisonous compound as an alkaloid which is derived either from urine, or tissue, or wound decomposition, or from all combined, and I would base this conclusion not from any chemical discovery that, so far as I know, has hitherto been made, but from the following deductions which seem to be warrantable from what I have already stated:

1. That the presence of urine in relation with a recent wound is necessary for the production of what I have spoken of as urine fever.
2. That mere contact of urine with a wound is not sufficient for its production.
3. That the retention of fresh urine within the area of a recent wound is almost invariably followed by its development in a greater or lesser degree.
4. That where urine is placed under such circumstances as have been last mentioned, the liability to the development of urine fever is greatly diminished when it is sterilised by local or general means.
5. That the retention of fresh urine, blood, and the debris of damaged tissue in the confines of a recent wound for a certain time, at a temperature of somewhere about 100° F., could hardly be possible without chemical changes taking place in the constituents referred to.
6. That there is a common origin for urine fever is rendered probable by the uniformity of the symptoms attending it, which, though differing in degree, are identical, whether following a surgical operation or an accidental wound.

As some may not be prepared to accept from me, though fortified with the reasons I have urged, that urine or urethral fever is the product of a definite poison introduced into the system, let me occupy your time for a few moments, while I quote from the last essay² of

¹ Professor Armand Gautier's *Introduction to the Animal Alkaloids*, by Dr. A. M. Brown.

² *Medicine of the Future*: Address written for the Annual Meeting of the British Medical Association, 1886.

one of the most original thinkers the medical world ever produced, I refer to the late Dr. Austin Flint, of New York.

"Analytical chemistry," he observes, "carries investigation beyond the limits of microscopical observation. The latter, at the present moment, both in pathology and physiology, seems to promise most; but is it not a rational anticipation to look for future results from chemical analysis of the components of the body, in health and disease, which in brilliancy and practical utility may surpass those of the labours in this field of investigation during the past half century? The medical semi-centenarian can recall the enthusiasm aroused by the labours of Liebig. Histology is now in the ascendant, but is it safe to predict that before the lapse of another half century there will be another era in organic chemistry, and that light will penetrate dark recesses which histology cannot reach?.....The supreme objects of study in pathology at the present time are the discovery of micro-organisms and their natural history. But these agents it is probable are pathogenetic, not directly, but indirectly, by means of the toxic products of their activity. What are these products, and how do they give rise to the phenomena of disease? We may ask the same question of certain of the poisons introduced from without the body. How is it that fractional quantities of morphine, hyoscyamin, strychnine, aconitine, atropine, and other alkaloids, produce their lethal effects? It conveys no adequate information to say that they act upon the nervous system. This is merely the statement of a fact, not an explanation. For the latter we must look to the organic chemistry of the future."

But objection may be raised against the views I am advocating relative to the way in which urine or urethral fever is developed, by the fact that it sometimes arises under circumstances where it may be difficult to prove that any actual breach of surface in the urinary tract has been inflicted. For instance, as I have already said in illustration, some degree of urine fever frequently follows the passing of instruments along the urethra, as in the treatment of urethral stricture. It would not be difficult to illustrate every degree of this complication, from the most transient rigor with slight febrile excitement, to the severest form of septic intoxication, rapidly terminating in death. And this leads me to speak of the influence of the epithelial lining of the urethra making the canal water-tight, or, more correctly speaking, urine-tight. And out of this will necessarily arise some remarks on the pathology of urethral stricture and abscess with extravasation of urine. Let me take an illustration of what I mean by the protecting power of the epithelial lining. A patient with a stricture, I will say, has a catheter or bougie passed; this may be followed in the course of a short time with a rigor and some fever, and no further inconvenience is experienced. What has actually taken place is that the epithelial lining has been scraped off at one or more points, and this has permitted urine leakage and absorption to take place at the points injured. If further proof of this be required, take instances where prolonged attempts to pass catheters in cases of urethral stricture have been made, and proved futile. Then, in consequence of the degree of retention, and as an alternative, an aspirator needle is introduced above the pube, and the urine is drawn off in this way without coming in contact, or remaining so, with any portion of the urethra which may have been wounded by the attempts made to give relief by catheterism. I have never known rigors or fever follow the relief of retention by suprapubic aspiration, though the amount to which the urethra has been lacerated by attempts at catheterism has been considerable as well as sanguinary. There can be no other explanation for the absence of characteristic rigors and fever under these circumstances than the fact that urine has not been allowed to come and remain in contact with a freshly-made wound. And in connection with this point I cannot help remarking that in the protecting power which the epithelial lining of the urinary apparatus exercises we probably have an explanation of certain phenomena which have been observed but not accounted for. Some have concluded that the bladder is capable of absorbing some of its contents, whilst others, on the contrary, not only have denied the possibility of such an inference being drawn, but have pointed out how serious might be the consequences if there was any liability to such a contingency. It seems that both of these conclusions may be true, and the explanation I would offer is that, by injury to, or disease of, its epithelial coat, the bladder may be rendered capable of absorbing what it contains, to the detriment of the individual, as we see in those cases now often referred to by the name of catheter fever. In recognising the power of the epithelium to prevent or permit absorption, I am in agreement with other observers, amongst whom I may mention Dr. London, of Carlsbad, who has made some investigations upon this point.³ Further, it is important to notice that when a urine

³ Berlin. Klin. Wochen., No. 11, 1881.

fistula is transformed into a permanent urine channel, as after Cock's operation, we find the passage becomes lined like the urethra with epithelium, and thus it acquires the power of transmitting urine without leakage. We could not have more positive evidence than this in support of the view that the epithelial coat is a necessary part of any canal which has to perform the function of transmitting urine.

Applying, however, these remarks to the pathology of urethral stricture, let us see how this is brought about, and how the protecting influence of the urethral epithelium may thus be demonstrated.

A stricture of the urethra is generally considered to be due to more or less prolonged inflammation of the lining membrane of the canal, which ultimately leads to the deposition of organised lymph in the peri-urethral tissues. This ultimately is converted into a dense connective tissue, which subsequently shows a remarkable tendency to become contractile. Thus the escape of urine from the bladder is interfered with by the degree to which these contractile masses prevent the expansion of the canal to anything like its normal extent. Now all this may be very true on the whole, but it does not enter into details with which we should be acquainted for the prevention and treatment of the disorder.

It will be convenient to take an illustration for the purpose of tracing more gradually the process of stricture-making, as a consequence of a specific urethritis or gonorrhœa, which is generally admitted to be the common cause of the former affection. The acute form of the disorder, unless care be taken, is very apt to become merged into the condition commonly known as chronic granular urethritis. By the latter term we are to understand that at one or more spots within the urethra the epithelium has become so damaged, as a consequence of the prolonged inflammation, that it ceases to render the canal urine-tight, and a slow process of escape of some of the constituents of the urine into the tissues comprising the urethra and surrounding it, takes place. As a consequence of this, and to prevent urine further soaking into the tissues, inflammatory exudation is excited, and barriers of lymph, which ultimately become organised, are thrown out opposite the places where the leakages take place. Thus splints of plastic tissue are formed, corresponding with the spot or spots where the epithelium has been so damaged by persisting inflammation as to cease to discharge its normal function. In this strengthening of the urethra we recognise, in the first instance, a conservative action; eventually, however, as in other compensating processes, certain inconveniences follow which constitute, as it were, an independent disease. In addition to the careful observations which have been made relative to the pathology of gleet, and the changes that are induced by chronic inflammation in the epithelial lining of the urethra by Dr. Oberlander, of Dresden, there are other considerations which seem to indicate that an excessive form of plastic exudation in the tissues around the urethra is probably excited by the interstitial leakage or exosmosis of some of the constituents of the urine through the walls of the canal.

Amongst those I would mention are: (1) That though the mucous membrane is the tissue chiefly involved in the primary inflammation, it is, as a rule, only secondarily implicated in the stricture-forming process. In many instances it will be found after death that the dimensions of the mucous membrane are not permanently altered, and that it is possible to split a stricture without necessarily damaging the lining membrane of the canal. (2) That the plastic exudation which makes up a stricture differs from other exudations provoked in other parts of the body by inflammation in the degree of its density and tendency to contract. There is no tissue I am acquainted with in the human body, except, perhaps, that found after scalds and burns, where the original tissues are entirely destroyed, which is so tenacious and resisting as that constituting the usual form of urethral stricture, nor do I know of any other canal or duct which, either as a consequence of injury or disease, is liable to be involved in such changes as a strictured urethra represents. (3) The character of the cicatrix which is formed in connection with ruptures and lacerations of the urethra unmistakably shows the effect produced in the healing process of a recent wound, which is constantly submitted to the action of more or less pent-up urine. Here we have a cicatrix formed which of all strictures is the most resisting and contractile. At the present time, when we are so much occupied in devising means for the radical cure of hernia, one cannot help sometimes thinking and wishing that it were possible to transplant the process of tissue thickening and contraction, as observed in connection with the formation of traumatic urethral strictures, to the parts constituting the weak points we are desirous of consolidating in the abdominal parietes. Here it would be serviceable instead of being detrimental.

Further, the form in which stricture tissue is deposited, and ultimately

⁴ Vierteljahr. für Dermatologie und Syphilis. Wien, 1887.

exercises contractile pressure on the urethral passage, is strongly suggestive that in the first instance it served the purpose of strengthening the wall of the canal, and thus preventing further leakage of some of the constituents of the urine taking place at points where the epithelial coat had been more or less permanently damaged. Most strictures are the result of organised lymph which has been deposited in the submucous tissue in an irregular form. An annular stricture is comparatively rare, except when due to traumatic causes, such, for instance, as an injury to the whole calibre of the urethra.

It may, however, be urged that the view I am advocating is open to objection on the grounds that urine leakage is invariably followed by acute forms of inflammation, such as we see when extravasation has taken place. In reply to this, I would say that so far as I have been able to observe the process of urine transition through the mucous membrane of the urethra, which has been deprived of the protecting influence of its epithelial lining, is extremely gradual, so far as the process is concerned, and does not necessarily imply that all the constituents of the urine are distributed amongst parts which are not adapted to receive them. Where a pathological process is slow, time is permitted for that adaptation which the human tissues are proved to be so capable of. But the exudation which a damaged epithelium may permit of does not necessarily imply that all the constituents of the urine are thus brought into contact with the tissues under circumstances where the most active and destructive forms of inflammatory mischief must inevitably be aroused. Some years ago, I recorded the following case, which at the time seemed to me of much importance in reference to the subject now under consideration. It was as follows: The case was one of stricture, with extravasation of urine, occurring in a person suffering from Bright's disease of the kidneys. Though the extravasation had come on suddenly, and had existed for twenty-four hours unrelieved, there were no signs of acute inflammatory action and commencing gangrene, such as are usually expected. However, the tension being considerable, I incised the parts involved in the extravasation. As the fluid escaped from the incisions, I noticed that it had not that strong ammoniacal odour which is so perceptible in such cases. Subsequently I treated the stricture, which was exceedingly tight, and kept in abeyance the more threatening urinary symptoms. I was somewhat puzzled for an explanation, as I felt sure that the case was one of extravasation, and not acute scrotal oedema. How was it, then, that extravasation and confined urine failed to excite gangrene? I collected some of the urine as it trickled through the wounds, and compared it with some subsequently drawn off by the catheter. I found them identical, and in both there was an almost complete absence of urea. This, then, to my mind solved the mystery, and explained that as there was no urea to decompose, there was no source for the production of the ammonia by which the destruction of tissues in connection with extravasated urine is mainly effected. By the absence of urea the urine was rendered chemically harmless to the tissues with which it came in contact. In the same way, and by a process of leakage, I apprehend may be explained some of those rare cases which have been described as scrotal or perineal urinary cysts, where a urinous fluid, with little or no direct connection with the urethra is retained within a fairly well-developed envelope.

In illustration of the formation of stricture by urine leakage, due to epithelial desquamation or abrasion, I would point especially to those cases of multiple stricture caused by spots of induration in various parts of the canal. In a patient who was recently under my care, almost the whole length of the urethra was strictured by a series of nodular deposits, chiefly in relation with the floor of the canal. These could only be explained on the supposition that the urethra had almost entirely lost its normal power of conducting urine in the course of a long gleet, and that these numerous centres of induration and contraction marked the spots where leakage of some of the constituents of the urine had been permitted to take place. It will not be necessary for me to extend these views for the purpose of explaining certain facts observed in connection with peri-urethral abscess and extravasation of urine, which in practice we are all familiar with. What applies to the plastic form of exudation applies equally to the suppurative. In this way, however, is explained the fact that in these cases, when suppuration occurs, and the matter is evacuated by incision from the perineum, the urethra is found passing through the abscess cavity, completely isolated, and without showing any direct connection with the suppurating focus. It is under these circumstances that the unsupported canal occasionally gives way under the expulsive powers of micturition, and the urine is first forced into the abscess cavity prepared to receive it, and subsequently amongst those tissues, where it may be the more easily extravasated.

There are one or two practical points relative to the treatment of

stricture and injuries of the urethra arising out of what I have thus ventured to bring under your notice, to which I should like to refer before concluding. In the first place, the knowledge that certain relations between a wound and the urine may cause and keep up urine fever will prove of service to us in practice, as I will illustrate in the following way. Not long ago I treated a case of urethral stricture by Holt's method of rapid division. Contrary to my usual experience of the operation, the patient had a severe rigor three hours afterwards, and a temperature of 105° F. On the following day this was repeated with, in addition, almost complete suppression of urine. As it appeared to me that the patient would die if he absorbed any more toxic material from the wound, I had him placed in the lithotomy position, and passing a grooved staff, I performed a free median cystotomy, and put a drainage tube into the bladder. I should add that there was nothing to indicate that suppuration had occurred; the time was too short for its development, the symptoms being clearly due to urine poisoning. After this was done there was neither rigor nor fever, and urine was again rapidly excreted. By thus suddenly altering the relations of the wound with the urine, the whole complexion of the case was immediately changed for the better, and the patient made a good recovery.

In the next place, a due recognition of the function of the epithelial lining of the urethra shows that there is a right and a wrong way in making use of dilatation in the treatment of strictures. I am sure that more good follows the daily introduction of a bougie which passes quite easily, than where a larger size is less frequently used, but where, in fact, the principle of the mechanical wedge is aimed at by the process. In this way rigors and other inconveniences associated with the treatment of stricture by bougies is avoided. I have made a large number of observations bearing upon this subject.

Thirdly, when a stricture has become or is so contractile and dense as to render dilatation out of the question, if not impossible, then, I believe, the open method of treatment is the safest and affords the best permanent results. In fact, excepting the earlier forms of stricture, which are satisfactorily treated by dilatation, the open method has furnished the largest proportion of permanent cures that have come under my observation in the collecting and noting of many hundred cases of stricture taken indiscriminately. And in reference to this point, I must take exception to a statement which is frequently made, to the purport, "once stricture, always stricture." I could furnish many examples following the open treatment which are quite at variance with such a conclusion. In order that I may not be misunderstood in using the word "cure," I mean that a contractile stricture necessitating the constant use of the bougie has been so influenced by what has been done as to render any further use of this instrument unnecessary, and that, after a lapse of time of some years duration, the urethra can be proved both to be structurally and functionally normal. The majority of these cases have occurred where the perineum has been opened for stricture complicated with abscess and extravasation of urine. Here it by no means unfrequently happens, if the artificial drainage made by the surgeon is free and direct, that a healthy scar, such as we see after lithotomy, takes the place of the dense contractile stricture which has sloughed by the acuteness of the inflammation that has been aroused. I should meet with no difficulty in fully illustrating this point. By the open treatment of stricture, of course I mean the perineal section of Syme, or a modification of it, to meet some special circumstances, such as the double operation of external and internal urethrotomy combined, as I have already described. It must, however, be borne in mind that a perineal section is seldom resorted to until the urethra is largely impregnated, so to speak, with old cicatricial tissue of a contractile nature. Hence, although you may put into the urethra by your operation a longitudinal splice of good sound tissue, such as fills up the wound made in lithotomy, and so bring up the canal to its normal dimensions, you do not succeed in removing the tissue, which you have merely divided; this still remains behind, to contract and to mar to some extent results which, under other conditions, would be obtained. Still, in spite of the impossibility of removing the cicatricial tissue by a mere section of it, the results of perineal section, so far as I have observed them in cases where dilatation was insufficient, have proved both safe and satisfactory. The conditions, however, which the operation must necessarily fulfil are complete division of the stricture and thorough urine drainage. The difference between the wound of a lateral lithotomy and a perineal section is only this, that in one case you operate upon sound textures, whilst in the other they have been rendered permanently and almost hopelessly contractile. Still, on the other hand, when the conditions I have mentioned are fulfilled, the cicatricial splice of sound tissue which perineal sec-

tion introduces into a bad stricture often proves of the greatest and most permanent advantage in cases suited for this proceeding.

Fourthly, that in wounds of the urethra—made either accidentally or in the course of surgical operations, which, by the nature of circumstances, have to be treated without due regard for urine drainage—means should be more systematically taken to prevent the development of urine fever, as well as the formation of a dense contractile cicatrix. I found, after repeated trials, in the case of internal urethrotomies, that much might be done by irrigation, locally and through the agency of drugs, which were largely eliminated by the urine in promoting these objects.

Lastly, we must remember that the prevention of stricture is within our scope. If, as I have urged, the dense cicatricial material which constitutes a stricture is the result of urine leakage occurring in the process of a chronic inflammatory affection in the interior of the canal in one instance, whilst in another it is brought about by the constant contact of the excretion with an internal wound, as in accidental rupture of the urethra, then the importance in one case of irrigation as a part of the treatment, and free urine drainage in the other, is at once evident.

It is, however, in connection with ruptures of the urethra, such as are caused by blows and falls on the perineum, where the canal is more or less lacerated, that we see exemplified the most disastrous effects of permitting a wound to heal subject to the irritation that constant contact with pent-up urine is capable of exercising. Fortunately, as a rule in these cases, retention of urine for a time averts the liability to acute septic intoxication, such as I have already illustrated in an earlier part of this lecture. Though the future of these cases relative to the kind and degree of stricture that follows is in some measure determined by the character of the injury inflicted upon the urethra—whether, for instance, the canal is entirely torn across, or partially, either obliquely, longitudinally, or transversely—I have not the least doubt, from a careful observation of a considerable number of these cases, that those do best which are treated by perineal section and drainage without reference to the question of extravasation. When a catheter can be passed under these circumstances, and there is no evidence of urinary extravasation, it is often, I admit, very tempting to be content with this procedure, and to wait until there are further indications as to the necessity for incision. Such a course is almost invariably followed by the formation of a stricture of the most dense and contractile nature. Where incision is practised, as in those instances where there is evidence of extravasation and the laceration proves to be only of a partial nature, the wound heals with a scar which shows but little tendency to subsequent contraction. In these cases we have remarkable illustrations of the damage that the presence of urine under certain circumstances is capable of exerting whilst the process of repair in a wound is going on. And what applies to the healing of wounds inflicted accidentally upon the urethra internally applies equally to others similarly inflicted on the canal for surgical purposes. I have elsewhere stated that for many years past I have taken some pains in collecting and noting cases of urethral strictures, with the view of estimating the permanency or otherwise of the treatment to which the patient may have been previously submitted by various surgeons. The testimony that I have thus gathered from the examination of many hundred cases is certainly not favourable either to the permanency or the character of the relief that internal urethrotomy usually affords. Amongst the worst cases of stricture that I have thus met with have been those which have been treated by an internal section. If there is any force in the observations I have brought before the Society this evening, I do not think there should be any difficulty in explaining how this happens, and of recognising the importance of applying to the treatment of wounds of all kinds involving the urethra those principles which are the basis of Listerism, namely, drainage and cleanliness. There is no part of the human body to which disregard of these conditions is more likely to be attended with disastrous consequences, whether we have regard to the present or to the future. In conclusion, gentlemen. Most speakers commence their discourse with a text, I prefer concluding with one. Urine can spoil tissue as well as blood.

SEAMEN'S HOSPITAL SOCIETY.—Lord Charles Beresford has consented to take the chair at the annual court of governors of this corporation on a day to be fixed in February next. Owing to the increasing area over which the shipping of the port of London now extends, this charity has established dispensaries for seamen at the Docks and at Gravesend. The maintenance of the 258 beds at Greenwich, as well as the dispensaries, necessitate an expenditure of £12,000 per annum.

HARVEIAN LECTURES ON LUPUS.

Delivered before the Harveian Society, December, 1887.

By JONATHAN HUTCHINSON, F.R.C.S., F.R.S., LL.D.,
Emeritus Professor of Surgery at the London Hospital.

LECTURE I.—COMMON LUPUS—THE HEAD OF A FAMILY, AND NOT A SOLITARY DISEASE.

Characteristics of the Lupus Process.—Its Power of Infection by Continuity, by Contiguity, and through Vascular Channels to distant parts.—Importance of the Subject in reference to General Pathology.—Satellites and their Meaning.—Different forms of Lupus on different parts of the Body.—Differences in relation to Age and State of Health.—Relations of Lupus to Tuberculosis, to Scrofula, to Chilblains, and to Cancer.—Justification of the term Scrofula as distinct from Tuberculosis.—Morbid Anatomy of Lupus.—The Bacillus.—Description of the different Varieties of Common Lupus, and Definitions of the Terms proposed to be Used.

EVERYONE knows lupus. In student-life, we all early learnt to recognise lupus; for its frequency, its conspicuousness, and its very definite features, rendered its diagnosis both easy and attractive. Nor, for many of us, have the questions as to its nature and affinities failed in interest as we have advanced in life. Lupus has been well and ably studied by many competent observers, and no atlas of portraits has been published which has failed to portray it in at least two or three of its principal forms. Our clinical knowledge respecting it is now well advanced, and I purpose in the present lecture to endeavour to place before you a summary of it, not without the hope of being able to gain therefrom some little further insight as regards the disease itself, and the valuable illustrations which it affords of the general laws of pathogenesis.

We shall find, I believe, as we proceed with the examination of the facts as to common lupus, that not only does it present some important varieties, but that there are a number of other maladies, some of them already named and others as yet undescribed, which stand in close relationship with it, and partake, indeed, of its nature. Before proceeding in this direction, it is needful, however, that we should recapitulate the chief clinical facts as to the type form of the malady. This type form we find in "common lupus."

All observers are agreed that lupus is a disease which usually begins in early life, and which, although it may affect mucous membranes, almost always has its first development in the skin. It prefers exposed parts, and attacks the face out of all proportion to other regions. It is insidious in commencement and very slow in progress. Its characteristic feature is the formation in the corium of a peculiar effusion, or cell growth, which is visible to the naked eye through the transparent cuticle. This growth is of a brownish-yellow tint, and semi-transparent, being aptly compared to apple-jelly. It is present in greater or less abundance in all cases of common lupus, but may easily be obscured by the products of inflammation. The recognition of this apple-jelly growth, in however small a quantity, denotes the disease conclusively as lupus, for nothing exactly like it is ever seen in any other disease. It often happens that we succeed in finding it at only one part of a large lupus patch, or in only one patch, where there are several which do not show it; but I may repeat that, whenever it is thus sparingly present, it is yet sufficient to justify the diagnosis as regards the whole of the diseased processes which it attends. Whether this growth is present in the very earliest stage of the disease, or whether that be not rather simply one of inflammation, is not yet known, but it is certainly the condition which first justifies the application of the name "lupus," and it is often recognised while the disease is as yet on an exceedingly small scale. Many facts as to the causes of lupus—such, for instance, as its frequently beginning after slight injuries to the part—would suggest the belief that a stage of congestion and cell effusion, undistinguished from common inflammation, usually precedes for a short period the characteristic growth. There are, further, no facts whatever which would support a belief that lupus ever takes its origin from contagion. Whether or not it begins by inflammation, there is no doubt that it is very apt in all its stages to be complicated by it. Although a few cases are seen in which the growth, through a long course of years, pursues its quiet course of gradual extension, without

ulceration, and almost without inflammatory redness or swelling, they are exceptional; and in a large majority, at one or other period, the tissues break down and ulcers form, attended usually by the formation of papillary granulation masses, covered by crusts of pus and epidermic scales. Most of the distinctive terms employed in reference to lupus by the older surgeons have reference simply to the presence or absence of inflammation. We may disuse with advantage the old terms exedens and non-exedens, exulcerans, hypertrophicus, serpiginosus, exfoliatus, and the like, and speak simply of inflamed lupus and non-inflamed lupus, for all the epithets alluded to generally refer to peculiarities produced by more or less active inflammation. The same case may vary in respect to them in different parts at the same time, and at different times in the same part. They have, too, been used by different authorities with very varying meanings. I much fear that, before I have done, you will accuse me of introducing new names whilst I disuse the old; but I hope to be able to convince you that those which I shall propose are based upon real and permanent clinical distinctions. If a man has a large family, he must, for convenience sake, give to each child a distinctive name. It is so with lupus. The diseases to be grouped under that name are related—closely related, but they are yet different—and it is necessary that we should distinguish them.

It will be convenient that I should here introduce to your notice a schedule of the various forms of lupus which we meet with in practice. I shall not now discuss its details, but it may be well to state that where I have joined two substantives together as a name for a sub-species of the malady, it is with the intention of asserting that the disease so named partakes of the characters of both. Thus acne-lupus is not a lupus resembling acne, nor an acne looking like lupus, but is acne and lupus in combination. It occurs at the age at which acne is common, and in the subjects of common acne, differing from it only in that some of the pustules become the site of lupus-processes. So with eczema-lupus: the disease begins as eczema, and throughout looks like it, but it has these peculiarities, that it is well nigh incurable, slowly advances at its edges, and heals in the centre, leaving a scar. It is an eczema which produces the results of lupus, and therefore clearly partakes of its nature. I cannot but think that this plan of joining substantives, each one having already a well known meaning, conveys what it is intended to imply with far less trouble to others than can possibly be attained by coming uncouth adjectives, which are at the best more or less inappropriate.

The Lupus Family.

General Definition.—Serpiginous, infective, scar-leaving inflammations of skin and mucous membrane.

Principal Forms.

Struma-lupus (with subcutaneous abscesses and gland disease).

LUPUS VULGARIS.

Distinctive Features.

- a. Apple-jelly-growth usually present and characteristic
- b. Non-symmetry the rule
- c. Tendency to ulcerate
- d. Common in children
- e. Affects the two sexes almost equally
- f. Not closely allied to chilblains
- g. Very seldom fatal

Clinical Groups.

- 1. Single patch.
- 2. Multiple.
- 3. Of hands and feet.
- 4. Necrogenic lupus.
- 5. Of mucous membranes.
- 6. Of septum nasi.
- 7. Lupus mutilans.
- 8. Lupus with elephantiasis.

Common lupus (its typical forms)

- Acne-lupus (very rare).
- Eczema-lupus (very rare).
- Psoriasis-lupus (very rare).
- Nevus-lupus (very rare).
- Lupus lymphaticus (very rare).

Hyposis and the Rhino-scleroma of Hebra are probably allied diseases.

The term lupus hypertrophicus or the adjective hypertrophicus, in connection with lupus, has been used in such different senses by different authors, that I think it would be much safer to discard it. The older writers, I think, generally employed it in cases in which there was an unusually solid oedema or elephantoid hypertrophy. Hebra and Kaposi have used it for cases in which the papillary outgrowth was well marked and large; and, lastly, I find that Dr. Sangster has availed himself of it for a case in which the scar is very thick and fibrous. It is quite clear that there is no variety of lupus by which this adjective can, with any clinical usefulness, be applied. Overgrowth of papillae, hypertrophic induration of scar, and elephantoid oedema are conditions which may be present in certain parts of any given case of lupus and wholly absent in others, and they certainly do not differentiate any special variety of the disease.

Principal Forms.

Seborrhea-lupus (=lupus sebaceus)

LUPUS ERYTHEMATOSUS.

Distinctive Features.

- a. Little or no apple-jelly growth
- b. Symmetry the rule
- c. Non-tendency to ulcerate
- d. Not seen in childhood
- e. Far more common in women than in men
- f. Closely allied to chilblains
- g. Sometimes fatal

Clinical Groups.

- 1. Restricted to face.
- 2. Face and extremities.
- 3. General diffusion
- 4. With recurring erythema.

Erythema lupus (its typical forms)

- Chilblain-lupus.
- Sunblain-lupus.
- Acne rosacea-lupus (very rare).
- Psoriasis-lupus (very rare).

Kaposi's disease is probably a "family form" of lupus erythematosus. In dividing lupus into two great groups, as vulgaris and erythematosus; I yet wish it to be clearly understood that they are closely allied. There are numerous connecting links, and cases often occur which it is impossible to assign exclusively to either.

Amongst the qualifying adjectives which have been used for lupus, we can well spare that of "serpiginosus." It is of the very essence of all lupus to be serpiginosus, and if any form of new growth or inflammatory action were shown to be not so, it would certainly *de facto* lose all claim to rank with the lupus family. In all its varieties, and in all stages of its development, the lupus patch gradually spreads at its edges. It is necessary to consider this tendency to creep on into all adjacent parts in a little detail, for it is a most important feature. It proves that lupus action is attended by the production, in the part affected, of elements which are infective to those with which they are in contact. In this power of infection by continuity of tissue, we have one of its most characteristic features, and we have also an important guide to its treatment. Not only, however, do we witness the gradual extension of lupus patches by growth into continuous parts, but we observe almost invariably another phenomenon of a slightly different order. This is the production of other foci of diseased action not continuous with the original patch. To these when they are, as is usual, very near to the first, we may suitably give the name satellites, and may imply by it that we believe that they originate, as the moon from the earth, from materies directly detached from the larger mass near to which they are seen. We have in them an example of infection by contiguity, and the infective material has no doubt spread either in the perivascular spaces, or along the lymphatic channels. The phenomenon is exactly parallel to what we witness in the case of cancer of the skin, in which the production of satellite nodules of smaller size near to the parent one is very common. Their nearness proves their relationship. It is not a matter of chance where they are formed, nor are they arranged with anything like symmetry in the two halves of the body. No, they come as a rule near to the patch of which they are the product. In many instances the satellites and their parent, by gradual extension at their borders, tend to coalesce. The term disseminate lupus has been employed for cases in which the crop of satellites is very abundant, but as they are present to some extent in almost all cases, it is scarcely necessary. Although, as first asserted, it is the rule for secondary lupus growths to occur near to the border of the original patch, yet this position is not invariable, and we sometimes observe them at considerable distances from it. Thus a patient may have primary lupus on the nose, and may have secondary patches on the arm or leg. Must we, when that occurs, seek some other explanation of their production, and assume that they are developed independently of the original patch? Such a step is not necessary, for we encounter precisely the same occurrence in the case of cancer. No one doubts that when a growth develops itself in the femur after scirrhus of the breast, that such growth is due to the transference of germinative material from the mammary gland to the bone. Nor is there any reason to doubt that such distant transference is possible also in the case of lupus. Both in cancer and lupus proximity of infection is the rule, but distant infection is possible, and not very rare, and the two are to be explained in the same way. Let me here in passing remark that neither in common lupus nor in cancer does the distant infection show any tendency to arrange its products in a symmetrical pattern in the two halves of the body. In other words, the distant tissues show little or no preference or selective power as regards the germ elements which are afloat. It is almost a matter of chance

where these may develop. I shall have to ask attention in another lecture to the fact that this rule is to some extent reversed in the case of lupus erythematosus.

Permit me to pause here to remark that, although I have been obliged to mention cancer as the most instructive parallel to lupus in respect to infection by continuity, the production of satellites, and of scattered secondary growths at a great distance, yet these features are by no means the exclusive property of new growths. They do not prove, although to some extent they may seem to imply, an association between lupus and malignant neoplasms. Infection of the individual, in all of the three methods mentioned, is probably a possibility in all types of inflammatory action, though it is seen with much greater energy in some than in others. Near to a boil other boils occur; one patch of eczema, if neglected, tends to produce others; indeed, the facts as to multiplicity of lesions following local ones which are constantly under our observation in so many diseases are probably all of them to be explained in the same way. Those which we witness in the rare cases in which cicatricial keloid becomes multiple are of especial interest, because amounting almost to a demonstration of the law. We witness in them excellent illustrations of blood infection by a morbid growth not usually supposed to be malignant, and at the same time the preferential selection by certain predisposed sites. If a patient who has old and perfectly healthy scars becomes the subject of a new wound the scars of which take on keloid growth, his old scars may become infected and grow on a like pattern. This I have myself observed more than once, and an instance of it is recorded by Mr. Clutton. It is not easy to suggest any other explanation of the phenomenon than that the keloid growth sheds into the blood certain elements which find their proper nidus for development only in scar-tissue. I suspect that this is the only way by which keloid becomes multiple; but, in citing it as I have now done as evidence in support of my theory, I am bound to admit that it is not the ordinary rule for old scars to become thus infected. Even when it does happen we usually observe many of the old scars to escape. The case which I first published as illustrating the fact was, however, a very definite one. A man who had been frequently cupped, and whose cupping scars were perfectly soft and healthy, was long afterwards very severely scalded over his shoulder, and the scald became the site of an enormous keloid growth. At this stage many of his cupping scars developed little buttons of keloid.

We have, then, described common lupus as a slow process of cell growth in the true skin with infection by continuity, by contiguity, and in some instances to distant parts through the vascular channels. We have said that it is to be recognised by these qualities as regards its mode of advance, and above all by the visible presence of a new material, like apple-jelly, which is easily appreciated by the unassisted eye, and which is absolutely pathognomonic. I wish to make the distinct claims for all affections of the skin, which show these features that they belong to the lupus family, and in so doing, I by no means insist upon the last named. There are a great many cases of common lupus in which the apple-jelly cannot be seen and many more cognate affections in which it is never visibly present. In order, however, that we may increase the means at our disposal for deciding as to what should and what should not be admitted to be either true lupus or nearly cognate with it, it may be well to mention a few other common features of lupus-disease. None of them approach in importance those already stated, but some are still of considerable value.

The lupus process, although very slow, yet always tends to come to an end after a time, and it always, when it does thus end, leaves the structures disorganised and in a state of scar. The kind of scar is often peculiar. It is thick and firm and is seamed with white, so as to have suggested a comparison to veal. These peculiarities are probably due to the fact that the scarring has taken place without complete removal of the lupoid cell-material. By degrees this removal will become complete, and then the scar will become supple and thin. In many instances it is supple and thin from the first. It is by no means necessary to the production of scar after lupus that there shall have been ulceration. The scar may be wholly subcuticular, and is so in many instances, the disease having disorganised the corium, but left the cuticle almost uninjured. A tendency to the production of scars is invariable in lupus, but there are many slight cases in which the recognition of scar is difficult. An absence of tendency to infect lymphatic glands must be noted in all forms of lupus, and with it an absence of tendency to travel deeply or to involve parts other than the skin. It is essentially a disease of skin and mucous membrane, and does not, with the rarest exceptions, attack other tissues. When ulceration has occurred there is usually a remarkable proclivity to the formation of granulations which assume papillary forms and over which scar-tissue readily develops. The removal of lupus-crusts is almost always at-

tended by bleeding, for these papillary outgrowths are united to the partly organised crust, and are very easily torn.

Lupus-disease in all excepting its most quiet and absolutely non-inflammatory forms is very liable to be attacked by erysipelas. Some patients have many such attacks, and although not infrequently they are excited by the use of caustics, yet they are often spontaneous. As a rule, but by no means invariably, the erysipelas is mild. It may, I think, be added to the minor characteristics of lupus that its processes, although slowly retrograde in the structures first attacked, always spread so much in the adjacent ones that nothing of the nature of a complete spontaneous cure ever results. This statement may possibly have a few exceptions, but they are very few.

Having thus endeavoured to trace the characteristic features of the lupus process in general, it may next be convenient to enumerate some of the modifications which it assumes in different regions of the body, and parts of the surface. As will be conjectured from what I have already advanced, these differences have chiefly reference to different degrees of inflammatory action. In some parts lupus almost invariably inflames and ulcerates. It is rare indeed to find a patch of non-ulcerated lupus on the nose; and, should such be encountered, we may feel quite sure that the condition is only temporary. The same remark applies to the extremities. On the hands and feet lupus is always inflamed more or less, the degree varying with the season and weather. Often, indeed, it is difficult to diagnose lupus on the feet, so great is the excess of inflammatory material by which it is concealed. I have not in many instances, indeed, recognised the apple-jelly stage, and when it is shown it is never present long, being soon superseded by a mass of fungating granulations. It is, in fact, a clinical fact that lupus-ulcers on the feet very often escape diagnosis, so wide is their difference in appearance from the typical form of the disease. Often, however, the diagnosis is set at rest by the discovery, on other parts of the body, of patches which show the characteristic conditions.

The part in which it is most common to see lupus without any inflammation and absolutely quiet is, I think, the cheek. Here we sometimes see what I have called single-patch-lupus, slowly progressive at its edge, but without satellites, and without any trace of crust or even of congestion. The subjects of such conditions are almost always near middle life and in tolerably good health. If the patient be young, or the strength feeble, lupus is almost certain sooner or later to inflame and ulcerate.

There are certain regions of the body which are almost exempt from the attacks of lupus. It is in the main a disease of exposed parts, particularly of parts exposed to cold and wind. The face and the extremities are its most frequent sites. Excepting when it has passed by extension from the limbs or neck, it is very seldom seen on the trunk, and it scarcely ever originates there. The more protected the part as regards warmth, the less is it likely to be the seat of lupus. The genitals in both sexes, the cleft of the nates, and the armpits are almost wholly exempt. This is by no means true of the syphilitic imitations of lupus, which not infrequently display themselves in these regions.

When lupus attacks the lips, and extends to the prolabium, it is almost always attended by much swelling and ulcerative destruction of parts. The explanation of this is, no doubt, that the disease affects the skin surface on the one side, and the mucous on the other, and hence much loss of tissue. The same is observed when the *ala nasi* are affected, destruction of the parts being then almost certain. It will easily be realised that the conditions are very different from those which obtain on a flat surface, as the cheek.

Thus, I think, it may be with justice held that many and very important differences which are observed in the lupus process are due not to essential difference in the nature of the disease, but simply to the peculiarities of the part attacked. Anyone who will inspect a considerable series of cases side by side, or examine a collection of portraits, will easily satisfy himself of this, and will observe that the disease may in one and the same patient earn for itself different names, according to the part affected. It is almost always "exedens" when it attacks the nose, often "hypertrophic" on the lower part of the face, and always "serpiginous" on the neck.

I do not wish, however, for one moment to attempt to explain all the varying features of lupus by reference to the part affected. Many of them have reference rather to the peculiarities of the individual, to his age, and to the state of his general health. Without venturing in much detail upon this topic, I may repeat a statement already made, that the younger the patient the greater is the probability that lupus will inflame and ulcerate, and the greater by very far the risk that its infective material will become diffused, and its manifestations multiple and distant. It is rare in those of middle age to see lupus show itself in more than one place, and the disease at this period of life is

almost always very slow in its advance. As old age approaches, we sometimes witness a sort of return to the liabilities of youth, and lupus originating then may prove very troublesome. It is so, however, only in that it may rather rapidly spread and resist treatment, not, I think, in the way of general infection.

Before quite leaving this part of my subject, I will venture to ask your attention to some statistics as to the parts most usually affected. They confirm in a very definite manner the statements which I have made as to local exposure constituting an extremely important predisposing cause.

From the analysis of 56 cases in which I find the parts affected specified in my notes, it is shown to have occurred on the face in 41, and on the extremities in 15. In 5 of those in which the face suffered, there were one or more patches on the limbs also. In 15 the disease was on the nose only, and in 9 on the cheek only. My notes do not state with sufficient precision on what part the disease commenced, but only the parts affected when the patient came under my observation. We may probably assume that in all cases in which the nose is mentioned it began there, for it is almost unknown for the nose to suffer secondarily, whereas it often causes the infection of other parts. In the table which I have displayed I have given more detailed statement.

Nose and cheeks ...	8	} 41
Cheek alone ...	9	
Nose alone ...	15	
Nose and lips ...	1	
Chin ...	2	
Face and limbs ...	4	
Cheek and neck ...	1	} 15
Nose and foot ...	1	
Leg ...	2	
Fingers and hand...	6	
Forearm... ..	3	
Each hand and arm	1	
Arm	3	

As a good example of the influence of local conditions in modifying the disease, I may mention that lupus assumes somewhat peculiar features when it occurs on the buttock. Its cause in this position is frequently the irritation of riding. I well remember, when a student at St. Bartholomew's, the case of a young man (I think a groom) who had a patch the size of the palm of a hand on one buttock. Mr. Stanley amused himself by making his friends write their diagnosis of this sore on a paper which hung at the head of the man's bed, and I think there were at least half a dozen different opinions there recorded. For some it was simply a "saddle sore," others regarded it as syphilis, others as impetigo, and, lastly, some, who I have no doubt were quite correct, called it lupus. I have seen several such sores since then, and they are all of the same characters. Their peculiarities are—extremely slow advance at the margin, and a very thick, almost brawny, cicatrix in the centre. These peculiarities are no doubt due to peculiar conditions as regards pressure and friction to which these sores are exposed.

An example of this form of lupus has been admirably studied by Dr. Sangster, who has recorded his results in the twenty-ninth volume of the *Pathological Transactions*. His patient was an engine fitter, aged 24, but as the disease had begun when he was 10 years old, it had, in its origin at least, nothing to do with his occupation. The patient was in excellent health, but a paternal aunt was said to have died of consumption. Although the disease had been fourteen years in progress, the patch did not measure more than four inches across. It was hard and cicatricial in the centre, like "bacon rind," but had a somewhat inflamed and crusted edge. Its complete excision as a measure of treatment gave Dr. Sangster an opportunity for a microscopic examination of it in its various parts, and of this he availed himself with zeal. The paper is illustrated by some excellent drawings. I will quote the summary of the microscopic appearances in Dr. Sangster's own words.

"1. Changes (cell-germination proliferation) are observable in the epidermal structures before the lupus cell-growth can be made out in the corium.

"2. The lupus cell-growth in the corium appears first in clusters round the blood-vessels.

"3. When the clusters occur in the neighbourhood of epidermal cells they are accompanied by what appears to be an irritative germination of the latter.

"4. Where the cell infiltration is great it replaces all superficial structures below the rete Malpighii; the hair follicles, sweat glands, etc., disappearing as a result of degenerative change.

"5. The rete Malpighii covering extensive cell infiltration is in a state of extreme activity, simulating appearances seen in epithelioma.

"6. In the cicatricial stage there are seen only lupus "nests" lying in meshes of fibrous tissue, covered by an irregular Malpighian layer, with flattened cells representing a stratum corneum."

Some differences are to be observed as regards the parts affected at different ages. Thus I think that the mucous surfaces are never attacked in very early life."

A discussion as to the relations of differences in lupus to different states of health brings us at once to the all-important question as to its relationships to tuberculosis. All who have observed the disease have been struck by its frequent association with feeble health and with what, until lately, we have known as scrofula. On the other hand all have acknowledged that there are startling exceptions, in which the disease shows itself in those who appear to enjoy great vigour of constitution. The names given by authors, however, sufficiently attest the general assertion that almost all observers have regarded lupus as frequently of a scrofulous type. I am desirous for the moment to avoid reference to histological questions, and to discuss the subject solely on its clinical evidence. It is certainly not common for lupus patients to have definite evidences of tuberculosis of the viscera. I have in the course of many years' experience known two or three who were the subjects of lupus become affected by aggressive phthisis, but they have been very exceptional. The same may be said, but with more numerous exceptions, as to the occurrence of gland disease or other forms of struma. The lupus patient does not, as a rule, suffer from any other form of disease. More than thirty years ago I collected and tabulated with considerable care a long series of cases of lupus, with the hope of showing by statistics its relation to struma as well in the patient's family as himself. Nearly all my patients were at that time of the hospital class. My statistics did not prove much, and I have not felt encouraged to continue their collation during later years. Nothing is easier than by statistics to show, in reference to any given disease occurring amongst the English poor, either the frequent history of tuberculosis or the reverse. All depends upon the patience and perseverance of the investigator. Most patients begin by denying that any relatives have died of consumption, and most will, if time be allowed, succeed in remembering that such has been the case. More definite facts may be obtained if we restrict ourselves to the causes of death in the patient's parents and amongst his brothers and sisters; but here still are numberless fallacies, and, after all, we know well that such tendencies often overpass a generation. Briefly, I may say that my statistics did not prove the history of scrofula nearly so frequently as the impressions formed by memory would have led me to expect. Out of nearly seventy cases I found the occurrence of other evidences of scrofula in the patient is only 28 per cent., and the history of such disease in any near relative in only 35 per cent. No fewer than 50 per cent. appeared, so far as I could ascertain, to be themselves in good health, and to come of families against which nothing could be established. It is to be remembered also that the impressions formed by casual observations

² The following statistics are compiled from a series of hospital cases, which I tabulated more than thirty years ago, and do not include my more recent experience. They are sufficient for the present purpose. Of 141 cases, 59 were males and 83 females. Of 67 cases in which the age at which the disease began is noted. In one case at the age of 1, at 2 in 3, at 3 in 3, at 5 in 2, at 6 in 2, at 7 in 2, at 8 in 3, at 9 in 1, at 10 in 4. Thus in the first decade we have 30, or nearly half.

At 11, 2; 12, 5; 13, 3; 15, 1; 16, 3; 17, 1; 18, 1; 19, 1; 20, 1; 23, 8; 24, 2; 26, 2; 30, 1; 32, 1; 33, 1; 35, 1; 40, 3; 42, 1; 44, 1; 48, 1; 49, 1; 52, 1; 56, 1; between 10 and 20, 18; between 20 and 30, 8; after 30, 4. Thus after the first decade we have a total of 37.

In reference to the proportion of lupus cases to other forms of skin disease, I may quote the following statement from Sir Erasmus Wilson, who found in 10,000 cases of skin diseases occurring among the wealthier classes—

Lupus "strumousus" (= vulgaris)	77
Lupus erythematosus	78
The misleading character of statistical statements is well illustrated by the fact that Sir Erasmus found lupus erythematosus rather more frequent than lupus vulgaris. No one believes that it really is so, and the subjoined statement will show how the facts on this point stand in Vienna:		
Kaposi, in 6 years' hospital experience—		
Lupus erythematosus,	29	7 males
		15 females
Lupus vulgaris,	279	132 males,
		147 females.

The startling difference in the proportionate frequency of the two diseases in Wilson's experience and in that of Kaposi, I believe, to be explained by the circumstances that one drew his conclusions from private practice and the other that of a hospital. Lupus erythematosus being an almost incurable disease, it follows that it is likely to be sent to private consultants, whilst cases of lupus vulgaris more usually remain under the care of the family surgeon. My own experience during recent years has, I believe, been very similar to that of Sir Erasmus, and would show lupus erythematosus apparently as common as lupus vulgaris.

are liable to some error, inasmuch as lupus produces deformities of the visage, and scars in the neck which are precisely of the kind to suggest the offhand suspicion of scrofula. This may easily happen in cases in which, excepting the lupus itself, there may be an entire absence of all evidence of such taint.²

In spite of my own statistics, however, I cannot avoid the belief that lupus is, in very many instances, a scrofulous disease; but at the same time I am inclined to the belief that, in most instances, the tendency to disease of this type having begun in the skin, restricts itself to it, and shows little or no tendency to attack internal organs. I well remember a family of three sisters, whom I know intimately in youth, and whose history may illustrate my meaning. The eldest of these had her neck dreadfully scarred by strumous abscesses in childhood, but she subsequently enjoyed excellent health through a long and vigorous life. The second, always delicate, died of phthisis at 50; and the third, who had never ailed anything else, lost her nose from lupus at about 45. There was a history of tuberculosis in the mother's family.

The more definite the exemption from tuberculous antecedents or concomitants, the more likely it is, I think, that any individual case of lupus will prove non-inflammatory; but there are exceptions on all hands, and I dare not assert anything in this matter with confidence. If the mucous membranes suffer, there is, I think, almost invariably a tuberculous family history. On the other hand, I must admit that the evidences as to family history of phthisis is as strong, or even stronger in the case of lupus erythematosus, as it is in common lupus.

There is another peculiarity of personal health, which is of much importance, in predisposing to certain forms of lupus. I refer to the proclivity to chilblains. The tendency on the part of the tissues to inflame and become irritable, under the intermittent influence of cold and damp, which constitutes the chilblain proclivity, is so marked in many cases of lupus, that this disease might almost be regarded as being a modified chilblain. This statement concerns the erythematosus form more frequently than it does the common lupus, but it is not without its importance as regards the latter.

In what I have been saying I have been speaking of scrofula and tuberculosis as if they were interchangeable terms, or, if not so, as if scrofula still enjoyed an existence, and had not been wholly merged by modern discoveries. It is desirable to explain a little on this point. Those who hold with the greatest firmness the modern doctrine that a bacillus is the one and the only cause of true tuberculosis yet admit that peculiarities in the state of health of the recipient are of very great importance in favouring the development of the parasite. For them tuberculosis is a disease of infection from without, and can never be self-produced; but still only those of certain idiosyncrasy or diathesis are capable of readily receiving the contagion. We have then two things—contagion and proclivity. It follows, I think, that it is quite possible that the state of system which constitutes proclivity may in itself and without tuberculous infection originate some forms of disease. Nothing is more probable than that persons vulnerable in the direction of easily affording a nidus for the tubercle bacillus may also be liable to peculiar forms of common inflammation. That such is the case I would submit we know well by experience. In such patients wounds, bruises, and chilled parts repair badly and are very apt to inflame. If exposed to cold, chronic catarrhs or states of local inflammation may readily follow. Thus ophthalmic surgeons recognise a scrofulous ophthalmia which they do not regard as tuberculous, but which occurs in patients who have tuberculous susceptibilities. I would venture to suggest that the terms struma and scrofula are very suitable for the designation of all such specialised types of common inflammation as we encounter in those who would easily become tuberculous if exposed to contagion, but who have not as yet had the

¹ I have, since this lecture was given, collated for statistical purposes some more recent notes which I had by me. The following statements will, I believe, convey a truthful impression of them. In rather more than half my cases the notes expressly state that the patient appeared to be in very good health, and had at no time suffered from any debilitating diseases.

² In nearly half special inquiries on this head failed to disclose any particular delicacy or ill-health on the part of the brothers and sisters, or of the parents.

³ In only 9 per cent. was there reason to suspect phthisis in the individual, and in several of these the evidence was but slight. In nearly 30 per cent. there were enlarged lymphatic glands, but in some of these clearly the gland disease was secondary to the lupus. I am well aware that results of statistical inquiry have been published which differ considerably from mine.

⁴ Lelour (*Annales de Dermatologie et Syphilis*, vol. vii) brings considerable clinical evidence to prove that the two diseases are practically identical. Of 17 hospital cases treated by him in 1855, 10 showed unmistakable signs of lung tuberculosis, another suffered from white swelling of the knee. In two of them he proved the presence of tubercle bacilli in the lupus tissues, though inoculation experiments on the peritoneum of dogs failed. In one case lupus of the hand was attended by scrofulous lymphangitis (and formation of "tubercular gummata" along the lymphatics of the arm), followed by tuberculosis of the lung on the affected side. In four cases lymphatic oedema ("white erysipelas") accompanied lupus of the skin, and constitutional disturbance and phthisis resulted.

bacillus implanted. Whatever results from the implantation of the bacillus we may name tuberculosis, whatever results from the constitutional state alone we may denominate scrofula.

It would be of great value if we could obtain any trustworthy evidence as to the frequency of the association of lupus with cancerous tendencies. As yet, however, none such are forthcoming. Many observers have noticed that there is in persons of middle age, who have suffered from lupus, a definite tendency for the scars to become attacked by cancer. I have myself witnessed this repeatedly. I have also, in several cases, seen cancer and lupus existing in different regions and independently in the same patient. The number of such facts is, however, not as yet sufficient to justify us in feeling confident that they are more than coincidences, however strong may, nevertheless, be our suspicions. The observation of histologists (Sangster and others) that, in lupus scars, there is often a definite tendency to down-growth of processes from the Malpighian layer, much after the pattern of epithelioma, is not without its interest in this connection.

A METHOD OF GRAPHICALLY RECORDING THE EXACT TIME-RELATIONS OF CARDIAC SOUNDS AND MURMURS.¹

By BYROM BRAMWELL, M.D., F.R.C.P. EDIN., F.R.S. EDIN.,

Assistant Physician to the Edinburgh Royal Infirmary, and Lecturer on the Principles and Practice of Medicine, and on Practical Medicine and Medical Diagnosis in the Extra-Academical School of Medicine, Edinburgh,

AND

R. MILNE MURRAY, M.B., F.R.C.P.,

Lecturer on Midwifery and Gynecology in the Extra-Academical School of Medicine, Edinburgh.

INTRODUCTORY STATEMENT BY DR. BYROM BRAMWELL.

In common with the great majority of physicians, I have been in the habit of thinking that the so-called presystolic mitral murmur is produced by a blood current flowing from the auricle to the ventricle through the stenosed mitral orifice; and I have repeatedly—both by (1) simple palpation with the flat hand; (2) combined auscultation and palpation; (3) combined binaural auscultation and inspection of the apex beat and movements of the cup of the stethoscope; and (4) combined binaural auscultation and inspection of the movement of the lever of a Galebin's cardiograph—investigated the relationship of the murmur to the cardiac impulse, with the result that, in the great majority of cases of presystolic murmur, which I have carefully and critically examined, I have satisfied myself (or, at all events, I have thought that I had satisfied myself) that the murmur does precede the first sound of the heart and the maximum impulse of the apex beat.

The publication of Dr. Dickinson's paper, in which he stated that, according to his observations, the murmur and impulse of the apex beat are synchronous, and in which he gave theoretical reasons² for believing that the murmur is ventricular systolic, and not auricular-systolic, seemed to show the hopelessness of getting all observers to agree even as to facts—to say nothing of the theoretical conclusions to be based on them—by means of our present methods of investigation, and to call for some new method by which the matter can be graphically demonstrated and finally and conclusively settled.

Some years ago, when the phonograph was first invented, the possibility of recording, on the same revolving drum, a tracing of the cardiac impulse (by means of a cardiograph) and a tracing of the cardiac sounds and murmurs (by means of a modified phonograph) had occurred to me.

The publication in the daily journals (just about the time when Dr. Dickinson's paper appeared) of the extraordinary results which Mr. Edison has obtained by means of his new modification of the phonograph, redirected my attention to the subject; and, with the object of bringing the matter to a practical conclusion, I explained exactly what I thought was wanted to my friend Dr. Milne Murray. Dr. Murray did not think that the phonograph or microphone, so far as their mechanism is at present known, could be made to record a tracing in the manner I desired; but he stated that he did not know the capabilities of Mr. Edison's new instrument, and he advised me to write to Mr. Edison himself.

¹ Communicated to the Royal Society of Edinburgh, on December 19th, 1887.

² It would be foreign to my present purpose to discuss the arguments which can be advanced both for and against the presystolic origin of the murmur of mitral stenosis. On some future occasion I may have to enter into some parts of the subject in detail. Suffice it for the present to say that the balance of evidence has seemed to me to be strongly in favour of the generally accepted or presystolic view.

This I have accordingly done. I have pointed out to Mr. Edison the immense practical advantages which would result if cardiac sounds and murmurs (and, indeed, all other stethoscopic phenomena) could be permanently recorded and phonographically stored up; and have begged him to direct his attention to the subject. I have told him that we physicians and clinical teachers desire two modifications of his instrument, namely:—

1. A phonograph (or phonographic stethoscope, as it might be termed) capable of receiving, recording, and reproducing cardiac sounds and murmurs. I trust that if Mr. Edison will direct his genius to the matter, he may be able to give us such an instrument. If the receiving portion could be adjusted to a limited area of the chest, and if the discharging portion could be made to reproduce its sound into the cup of a binaural stethoscope, the instrument would be exactly what is required. Its introduction would mark a new era in clinical medicine and in clinical teaching. By means of such an instrument, phonograms of all important and interesting cases could be stored up in our case books, and murmurs and other sound phenomena could be kept for any length of time, and reproduced whenever they were required. The teaching of auscultation would be materially simplified. And by means of a modification of the instrument it might perhaps be possible to magnify the sounds produced by such a phonograph, so as to make them audible to a large clinical class. In fact, the possibilities of such an ideal instrument are immense.

2. A phonograph capable of receiving cardiac sounds and murmurs, and of discharging its vibrations, not in the form of sounds, but in the form of movements, capable of being recorded on a revolving cylinder of smoked paper. Such an instrument would enable us absolutely and definitely to settle the systolic or presystolic rhythm of the murmur of mitral stenosis, and many other important questions connected with the physiology and pathology of the heart; for, by recording on the same drum a tracing of the apex impulse (by means of a cardiograph) and, immediately below it, a tracing of the sound phenomena (by means of such a modification of the phonograph), the exact relationship of sound to impulse, and to the different phases of the cardiac cycle, could be settled with certainty; in fact, with absolute mathematical precision.

Although much disappointed with Dr. Murray's opinion as to the possibility of graphically recording cardiac sounds and murmurs by means of the phonograph, I could not get rid of the idea; for some such instrument seemed so exactly what is required for determining the exact rhythm of the presystolic murmur on which my thoughts were at that time intent.

On further consideration the following modification of my original plan suggested itself to me: (1) To record on a revolving drum the cardiographic trace by means of a Marey's cardiograph. (2) To listen (the eyes being closed), by means of a flexible binaural stethoscope, to the cardiac sound or murmur the time of which it was desired to mark and ascertain. 3. To strike with the forefinger of the right hand the button of a second Marey's tambour (chest piece) at the moment when the murmur or sound was heard, and so to record it (by means of a second Marey's cardiograph) on the same revolving drum, immediately below the tracing of the impulse of the heart. In this way the impulse of the forefinger—in other words, the exact time occurrence of the murmur, less the "psychical loss" occupied by the passage, so to speak, of the murmur from the ear to the tip of the forefinger of the auscultator—could be exactly marked in relationship to the different parts of the heart's cycle, as traced on the drum by the cardiograph. If the levers of the two cardiographs (one worked by the apex beat, the other by the forefinger of the auscultator) were so adapted as to move in exactly the same vertical plane, the exact time relationship of the sound or murmur to the ventricular systole (or other phase of the cardiographic trace) could be determined, provided that the "psychical loss," previously alluded to, were accurately measured and deducted. (4) In order that the "psychical loss" might be accurately measured and deducted, time markings would have to be made on the revolving drum immediately below the tracings produced by the cardiographic levers; and (5) the exact time which elapses between a sound being made and its being signalled and inscribed on the revolving cylinder by the auscultator, would have to be accurately measured.

Dr. Milne Murray at once saw the feasibility of this modification, and very kindly promised not only to fit up the necessary apparatus, and to place the resources of his laboratory at my disposal, but, what was even more important, to share in the research and to aid me with his knowledge and advice. It is unnecessary to say that I eagerly availed myself of Dr. Murray's offer. My crude idea has in this manner been transformed into an actual working mechanism; and the research being supervised by Dr. Murray, who, in experimental tion of this description, has few, if any, equals, the reliability of any

results which are obtained is guaranteed, so far as it is possible to guarantee them.

Dr. Murray suggested that instead of the auscultator signalling the time of the murmur by touching the button of a second Marey's cardiograph, he should do so by means of a Morse's key and electric circuit.

To estimate the "psychical loss," a point about which I had no satisfactory notions, he at once suggested a most ingenious contrivance, which is in every way suited for its purpose. A lever is made to move and record its movement on a revolving drum, and a sound is produced in a telephone at one and the same moment by "making" or "breaking" the same electric circuit; in other words, by touching a Morse's key a sound in the telephone can be produced at will, and the exact time occurrence of that sound is at the same time automatically and, as it were, electrically recorded on a revolving cylinder.

By means of this contrivance the estimation of the exact "psychical loss" is a matter of the greatest simplicity. The individual whose "psychical loss" it is required to measure (the auscultator in the previous experiment), places the telephone to his left ear, and as soon as he hears the telephonic sound produced by a second individual, who is taking the observation, signals to the revolving drum by means of a Morse's key and electric circuit; in this way the auscultator inscribes, as it were, on the revolving cylinder of smoked paper the exact time when he hears the sound; and since the period at which the telephonic sound was actually produced has been already inscribed on the drum by the automatic arrangement previously described, the distance at which the auscultator's signal follows the telephonic signal of course equals the "psychical loss"—that is, the delay which occurs in the sound vibrations passing, as it were, through his psychomotor apparatus to the signal key.

By recording time markings on the drum below the tracings produced by the two signals, the exact duration of the "psychical loss" in fractions of a second can be exactly measured; and the necessary correction in the position of the signal representing the occurrence of the cardiac sound as measured in its relationship to the cardiographic tracing and cardiac cycle (for, in the previous observation, the same time markings were, it will be remembered, taken) can of course be at once made.

The more accurate account of the apparatus is given below by Dr. Milne Murray himself.

DESCRIPTION BY DR. MILNE MURRAY OF APPARATUS USED IN GRAPHICALLY RECORDING THE TIME OF CARDIAC SOUNDS AND MURMURS.

1. *Arrangement for Recording the Cardiac Movements and the Occurrence of the Murmur.*—The binaural stethoscope S., Fig. 1, is retained in position over the region of most audible sound, in the manner described, and attached to the ears of the auscultator, who sits with his back to the observer and the recording apparatus. The cardiograph C., is held in position over the apex beat, either by the patient or by an assistant. The movements of the cardiograph are conveyed to the recording tambour T., through the tube V., and are recorded by the uppermost pen (1). The right hand X., of the auscultator, is placed so as to close at will a properly adjusted Morse key, K., placed conveniently on a table by his side. This key completes the circuit of the battery, I., shown beside it, and actuates the signal magnet, M. The upstrokes of this pen (2) will therefore indicate the movement of the occurrence of the murmur listened to, as indicated by the signals of the auscultator. The magnet marked B. (tracing the third line) is in direct connection with a clock beating seconds, and that marked A. is in connection with a timing-spring beating fractions of seconds (in this case 1-15th).

2. *Arrangement for Determining the Time Intervening between the Reception of an Auditory Impression and the Transmission of a Signal by the Auscultator, that is, the "Psychical Loss" in the Observations.*—The pendulum F., makes contact with the platinum points at each swing, and closes the circuit of the cell E. This circuit includes the primary coil of the induction apparatus G., and the magnet C., acting on the pen 2. At each swing of the pendulum a current will pass through the coil G., and the moment of its passage will be recorded on the drum by the pen 2. This current will, moreover, induce a current in the secondary coil of G., with which the telephone H. is connected. This telephone is held to the ear, O., of the auscultator, who will thus listen to the clicks of the telephone produced by the induction currents in the secondary coil of G. The right hand X., of the auscultator, is conveniently placed on the key K., and with this he signals the moment when he hears the clicks in the telephone. These signals are marked on the drum by the magnet D. and the

pen 1, which are in the same circuit as the key. The loss of time between the reception of the auditory impression from the telephone and the transmission of a signal (in other words, the length of time required for the sensory impression at O., to be transformed, so to speak, into a muscular contraction at X.) will be measured by the distance between the up-stroke of 1 and 2. The pens 3 and 4 mark seconds and fractions of seconds in the same way as in the previous arrangement.

STATEMENT BY DRs. BYROM BRAMWELL AND MILNE MURRAY
OF THE RESULTS OBTAINED IN THEIR FIRST SERIES OF
EXPERIMENTS.

Our first observations were made on November 14th, in a case of typical presystolic murmur. In this and the subsequent experiments in this series Dr. Bramwell listened to the murmur and signalled it, while Dr. Murray superintended and worked the recording apparatus. For the purposes of description, and to avoid the needless repetition of names, we will term the former the auscultator and the latter the observer. The receiving tambour of the Marcy's cardiograph was

held in position over the apex beat by an assistant. The method of working was as follows:—

The patient was conveniently placed (seated or lying) at a distance of about four feet from, and facing, the recording drum. The cardiograph was then adjusted, so that a sufficiently satisfactory movement of the lever connected with the recording tambour was obtained. The assistant then took charge of the cardiograph, and kept it in accurate contact with the apex beat. The auscultator then seated himself in front of the patient, with his back to the recording drum, and by means of a binaural stethoscope determined the part of the chest where the murmur could be most distinctly heard.

In the case of presystolic murmurs, the area of which is often very limited, it is not usually possible to place the cup of the stethoscope over the exact point of maximum intensity of the murmur, for the receiving tambour of the cardiograph covers this spot; but in the two cases we have so far investigated, a position was easily obtained where the murmur was distinctly heard.

During the observation, the cup of the stethoscope may be held in position either by the patient, an assistant, or the auscultator him-

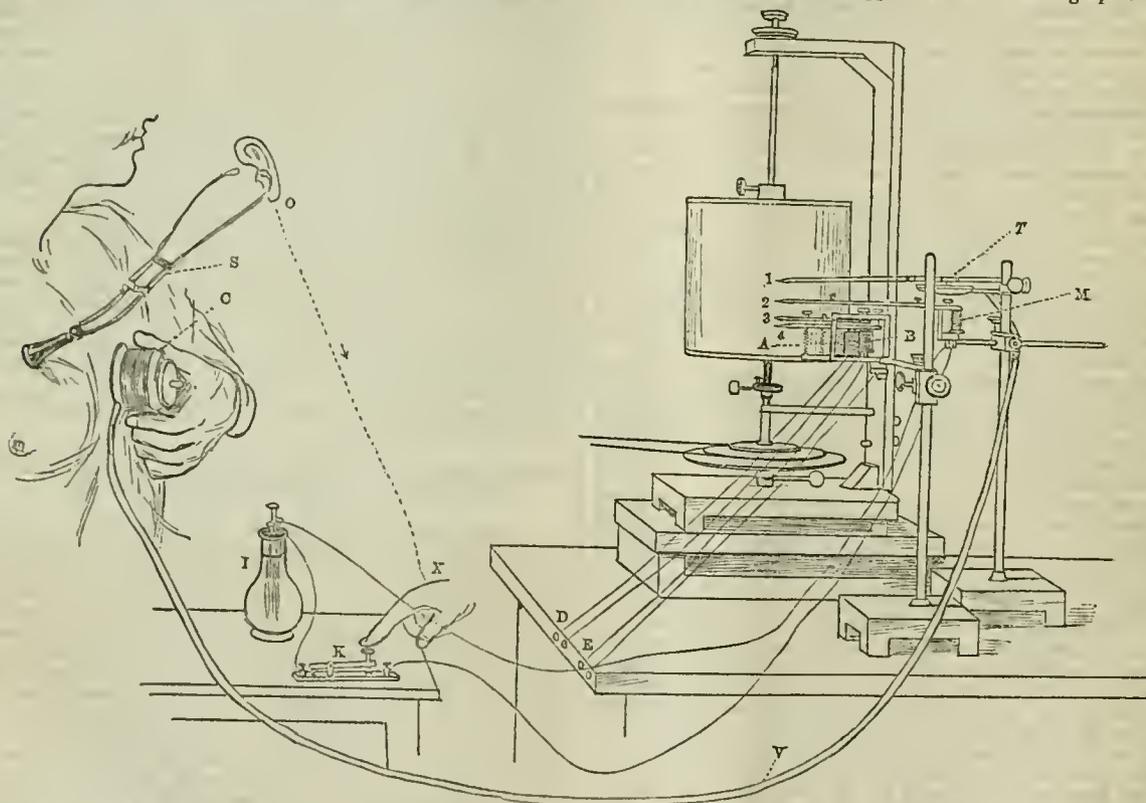

Fig. 1.—The apparatus used by Drs. Byrom Bramwell and Milne Murray, for graphically recording the exact time relations of cardiac sounds and murmurs. (For detailed description of the figure, see text.)

self. The advantage of having the end of the stethoscope held in position by an assistant or by the patient is that the auscultator is then altogether disconnected with the patient, except through the flexible tube of the binaural stethoscope, and there is, consequently, no possibility of his receiving any information with regard to the rhythm, systolic or otherwise, of the murmur by means of the tactile sense. The auscultator then closes his eyes, and concentrates his whole attention on the cardiac sound or murmur the time of which he desires to record, and proceeds to mark the time of the murmur by depressing with the forefinger the Morse's key, conveniently placed at his right hand.

After the auscultator has for some time signalled the murmur in this way (in other words, as soon as he proceeds to discharge and signal the time of the murmur in a regular and rhythmical manner,) and when the levers connected with the cardiograph and the auscultator are both working to the observer's satisfaction, the drum is started, allowed to make its circuit, and stopped. The observation is then completed. By this means four tracings are recorded on the smoked paper; the first or uppermost is the cardiographic trace; the

second shows the signals of the auscultator; the third the time in seconds, and the fourth or lowest trace, the time in fractions of seconds.

It must be understood that as yet we have made no attempt to time the duration of the sounds or murmurs which we have recorded. Whether this can be at all accurately done we do not at present know, but hope to determine in the course of our investigation. The duration, then, of the auscultator's signal may, so far as our present results go, be left entirely out of account. The commencement of the signal (the point at which the letter c is placed in Fig. 5) is the point to which importance is to be attached.

In this, our first experiment, several observations were made. The preliminary tracings were more or less imperfect, for the necessary adjustments, and the rate of revolution of the drum best fitted for all the requirements of the experiment, had to be ascertained by practice; but we finally obtained a satisfactory tracing, in which the auscultator's signal bore a definite and constant position to the ventricular systole, as traced by the cardiograph in successive cardiac cycles.

The "psychical loss" was then estimated in the following manner. The apparatus having been re-adjusted, the auscultator held the telephone to his left ear, and by means of his right forefinger (the eyes being closed) signalled to the recording apparatus the time when the telephonic sound was heard. The telephonic sounds were produced by the observer "making" or "breaking," by means of a Morse's key, an electric circuit at irregular intervals the exact time at which the telephonic sound occurred being, as previously mentioned, automatically inscribed on the revolving cylinder.

In this way, four tracings were again obtained on the smoked paper. The first or uppermost represented the auscultator's signal; the second the exact time of production of the telephone sound; the third, the time in seconds; and the fourth, the time in fractions of seconds. The psychical loss, estimated in this manner, was found on this occasion to be, roughly, about a fifth of a second. The auscultator was conscious of the very long psychical delay which occurred in signalling the intermittent telephonic sounds, produced at irregular intervals in this manner. The conditions were obviously quite different from the rhythmically and quickly recurring sounds produced in the human heart. It was, therefore, decided that, in future observations, the telephonic sounds should be produced in a rhythmic and regular manner.

The next observations were made on November 25th. On this occasion, two cases were examined. The first was another absolutely typical case of mitral stenosis (presystolic murmur). Several tracings were obtained, in which the murmur (as signalled by the auscultator) occupied a definite position in successive cardiac cycles (as traced by the cardiograph); and the position of the murmur corresponded exactly to the position of the murmur in the previous case of mitral stenosis.

In the present communication, we do not propose to make any further statement with regard to the position of the murmur in these two cases of mitral stenosis. The exact time relations of the murmur being in dispute, we intend to hold our judgment in suspense, until we have satisfied ourselves by repeated observations of numerous cases, that we have sufficient grounds for coming to a reliable conclusion on the point.

In the second case which was examined on this occasion (November 25th), there could be no possible doubt as to the nature of the clinical phenomena; and the tracings obtained, both of the aortic second sound, and of the telephonic sound which was artificially produced, in estimating the psychical loss, were so definite, so unexpected, and yet so mutually corroborative the one of the other; and the final result, as to the position of the second sound in the cardiac cycle was so absolutely in accord with all that is known of the physiology and pathology of the heart, that the reliability of the method, as a practical means of demonstrating the time relations of cardiac sounds and murmurs to the different parts of the cardiographic tracings is, we think, to a large extent established by this single series of observations alone.

The second case which we observed on November 25th, and to which

we now wish to refer in detail, was that of an intelligent man (W. K.), aged 41, a gentleman's servant, formerly a soldier, who consulted Dr. Byrom Bramwell at the out-patient department of the Edinburgh Royal Infirmary on November 5th, 1887.

The clinical details of the case are as follows. Four days previously, when playing at dominoes with his brother, he was suddenly seized with a localised epileptiform convulsion (attack of Jacksonian epilepsy), in which the head and eyes were twisted to the right side, and then affected with clonic spasms. Consciousness was retained during the attack, which lasted about a minute and a half. He was unable to see during the attack, in consequence, he thinks, of the eyes being turned so far upwards and to the right. The arm and leg were not affected.

On inquiry, it was ascertained that the patient had, previous to this attack, enjoyed excellent health; in fact, he stated that, with the exception of being occasionally laid up with the effects of drink, he had never known what it was to be ill. Some years ago, he used to drink and smoke very heavily; but, for the past eight or nine years, he has been perfectly steady in both respects. In particular, the patient stated that he never had syphilis, and that he had not suffered from

headache or vomiting. During the three weeks preceding the convulsive seizure, he had occasionally felt giddy. Four months ago, he "saw double" on three or four different occasions, but this double vision only lasted for a few minutes at a time. He had also, two or three times, seen bright flashes of light before both eyes. He stated that he had never had rheumatism; that he was not short of breath; and that he had neither pain nor uneasiness in the region of the heart; in short, he had no suspicion whatever that there was anything wrong with that organ.

On examination the optic discs were found to be normal, and there were ab-

solutely no physical signs of central nerve disease. On examining the heart, the apex beat was found to be ill-defined, in the erect position, beating behind the sixth rib, in the line of the nipple, or perhaps a little to the left of it. When the patient was lying on his back, the cardiac pulsation was abnormally forcible and heaving. The area of precordial dulness was distinctly increased, and there seemed to be a decided increase of the deep dulness over the ascending thoracic aorta. A well-marked double aortic murmur was audible up and down the sternum. At the second right interspace, the commencement of this murmur was accurately marked by a sharp, short, but loud and ringing, second sound, from which it (the murmur) tailed off. The heart's action was perfectly regular, and its frequency 72 per minute. The diastolic murmur was prolonged far into the diastole, which did not seem to be materially shortened, as it is in free aortic regurgitation. The radial pulse was moderately jerking, visible, and tortuous, but was not suggestive of free aortic regurgitation—an observation which was confirmed by the character of the sphygmographic tracing taken a few days subsequently. (See Fig. 3.) The cardiographic tracing shown in Fig. 4 was taken by Galabin's

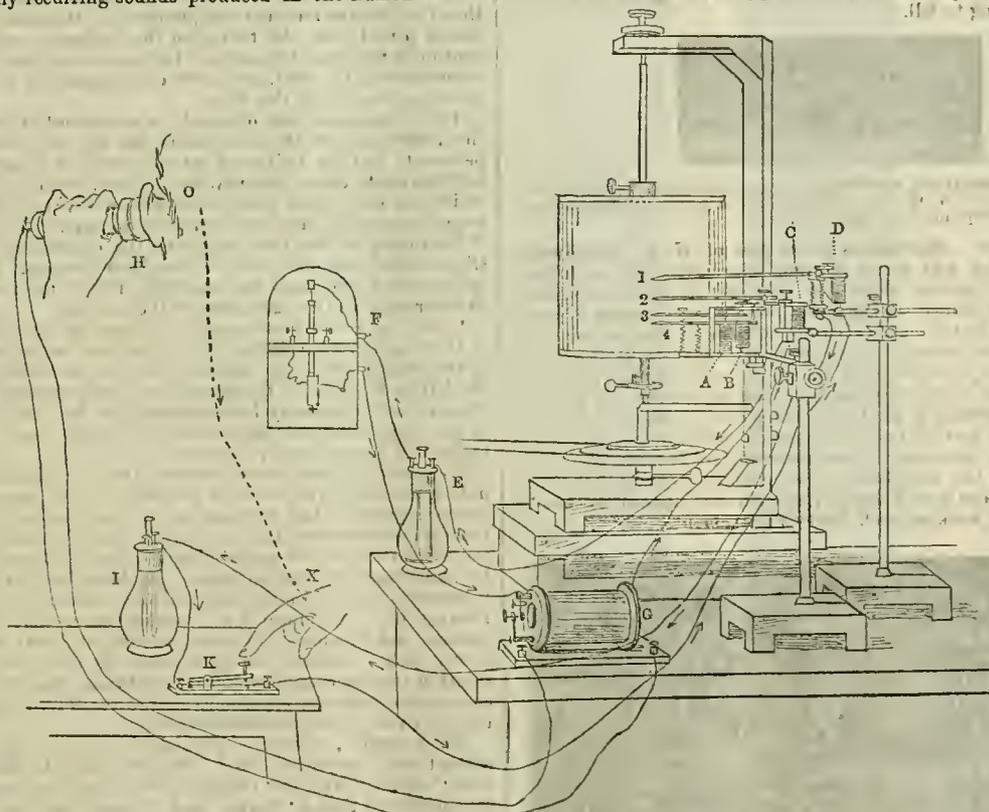

Fig. 2.—The apparatus used by Drs. Byrom Bramwell and Milne Murray, for estimating the "psychical loss." (For detailed description of the figure, see text.)

instrument on the same occasion as the sphygmogram, the heart's action at the time of the observation being somewhat accelerated and excited.

The diagnosis was dilatation (perhaps aneurysmal) of the ascending thoracic aorta, with some, though not free, aortic regurgitation. The cause of the attack of Jacksonian epilepsy need not be discussed here; but it was probably due to a small embolism, though the possibility of a commencing localised "coarse" cortical lesion cannot be absolutely excluded.)

Now this case seemed singularly well fitted for testing the capabilities of the method of timing cardiac sounds and murmurs which we are now describing, the apex beat being sufficiently well defined to give a decided systolic up-stroke corresponding to the ventricular systole, and the exact commencement of the diastolic murmur being most accurately and sharply defined by the short accentuated aortic sound, which occurs, as everyone admits, either immediately, or very shortly, after the termination of the ventricular systole—that is, when the lever of the cardiograph, which has been raised during the ventricular systole, is beginning to fall.

Fig. 3.—Sphygmogram (taken with Mahomed's modification of Marey's instrument) in the case of W. K. The tidal and diastolic waves are well-marked, and the pulse frequency is not increased.

The results of our observations in the case of W. K. (accentuated aortic second sound and aortic diastolic murmur) were as follow. The cardiographic tracing which was obtained by Marey's tambour apparatus, though amply sufficient for our present purpose (since it clearly shows the systolic and diastolic portions of the cardiac cycle and the point where systole commences and ends), is by no means equal to that which is obtained by Galabin's cardiograph. (The difference in the result is probably due to several circumstances, namely, (1) the inherent qualities of the two instruments; (2) the fact that the apex impulse was less distinct, the heart's action being much less forcible, when the laboratory observation was made; and (3) to the circumstance that the auscultator is accustomed to work with Galabin's cardiograph, and is well acquainted with its capabilities, but is not in the habit of working with Marey's instrument.)

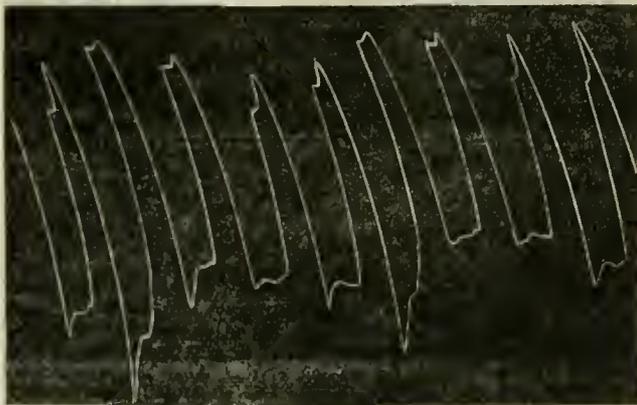

Fig. 4.—Cardiogram (taken with Galabin's cardiograph) in the case of W. K. When the tracing was taken the heart's action was somewhat excited and accelerated. The tracing shows powerful and well sustained ventricular contraction, some impediment to the passage of the blood from the ventricle into the aorta, and no marked rise of blood-pressure on the ventricle during its diastole.

A sufficiently satisfactory movement of the lever connected with the cardiograph having been obtained, the murmur was timed, signalled, and recorded with all the precautions previously described, the auscultator's attention being concentrated on the sharp accentuated second sound which marked the commencement of the murmur. The signal of the auscultator therefore represents the commencement of the aortic diastolic murmur, or the occurrence of the second (aortic) sound of the heart.

The timing in this case was very easy and very satisfactory, owing

to the sharpness and loudness of the sound to be observed, and the slowness (72 per minute) and regularity of the cardiac action.

The duration of the observation seemed to the auscultator inordinately long, and he was conscious towards its termination of a feeling of strain, and of cerebral surprise at the duration of the experiment, and of anxiety as to its result. The long duration of the experiment was due to the fact that the observer, being so pleased with the result, had not contented himself, as in former observations, with taking one tracing, but had three times raised and readjusted the drum, and had taken four successive tracings before giving the auscultator the signal to cease the auscultation by nudging him in the back. Exact reproductions of portions of these four tracings are shown in Fig. 5. The full length of each tracing was 19 inches; more than half (11½ inches) has consequently been cut off, so as to adapt the the woodcut to the size of the JOURNAL (8½ inches).

The total number of pulsations (cardiac cycles) recorded in the four tracings was twenty-eight, representing a period of nearly twenty-three seconds. The length of the observation was, however, very much longer than this, for the repeated readjustment of the drum occupied a much longer period than the taking of the tracings; and the auscultator continued to signal the murmur for some time both before the commencement of the first, and after the termination of the final, cardiac pulsation marked on the drum.

This experiment was obviously a severe test of the capabilities of the method and of the mechanism, for the long duration of the experiment, and the feeling of fatigue, cerebral surprise, and anxiety for the result, and expectancy for the termination of the observation, which the auscultator experienced towards the end of the experiment, might reasonably have been expected to interfere with the accuracy of his timing in the later stages of the observation; and to a very slight extent this does seem to have been the case. In the last three cycles traced, which are not shown in Fig. 5, the timing is not quite so accurate as in the other parts of the tracings.

It will be seen by reference to the tracing (Fig. 5) that the result in this case is very definite. The up strokes indicating the occurrence of the second sound, as signalled by the auscultator, and to which the letters C. point in the figure, practically occupy exactly the same place in each cardiac cycle throughout the four tracings. (The cause of the slight differences in position seen in successive cardiac beats or cycles will be explained presently.)

We observed with much surprise that the second sound, as signalled, exactly corresponds to the point of the cardiographic tracing which represents the termination of the systole; in other words, exactly corresponds to that part of the cycle in which we know that the second sound does actually take place. This result was difficult to understand, for no allowance or correction had been made for "psychical loss." In our previous observations we had roughly estimated the "psychical loss," which occurs in signalling intermittent and irregularly recurring sounds, at a fifth of a second; and if any such deduction had to be made in the present instance, the result of the observation would be an obvious absurdity, for it would cause us to place the occurrence of the second sound back, quite in the early part of the ventricular systole.

We proceeded, therefore, with much interest and anxiety to re-estimate the "psychical loss." With this object, Dr. Murray placed into "circuit," with the telephone and recording apparatus, a clock, so constructed that a "make" and "break" of the electric current, were effected every two seconds, the rhythm, however, being interrupted every tenth beat. In this way a "make" and "break" sound, separated by a short interval, were produced in the telephone, every two seconds, but interrupting every tenth beat, so to speak, and the exact period of occurrence of these "make" and "break" sounds was automatically recorded on the drum, as in previous experiments. The auscultator found that the signalling of the sounds produced in this way did not materially differ from the signalling of the intermittent and irregular sounds produced on the previous occasion; the sounds did not occur sufficiently rapidly to enable him to time them rhythmically, more especially since the interruption every tenth beat entirely disorganised the rhythm. In timing the sounds produced in this way, he had, he found, to watch for every separate sound, and to time it separately and individually, as if it had been produced in an altogether irregular and arrhythmical manner. As a matter of fact the "psychical loss," estimated in this way, was found to be exactly 3-15ths of a second.

We then determined to make the conditions, so far as possible, identical with those in the case of diastolic aortic murmur previously examined; in other words, to time a well defined sound, that is produced regularly, at the interval of a second. To effect this the clock, which in previous experiments had been used to mark the time in

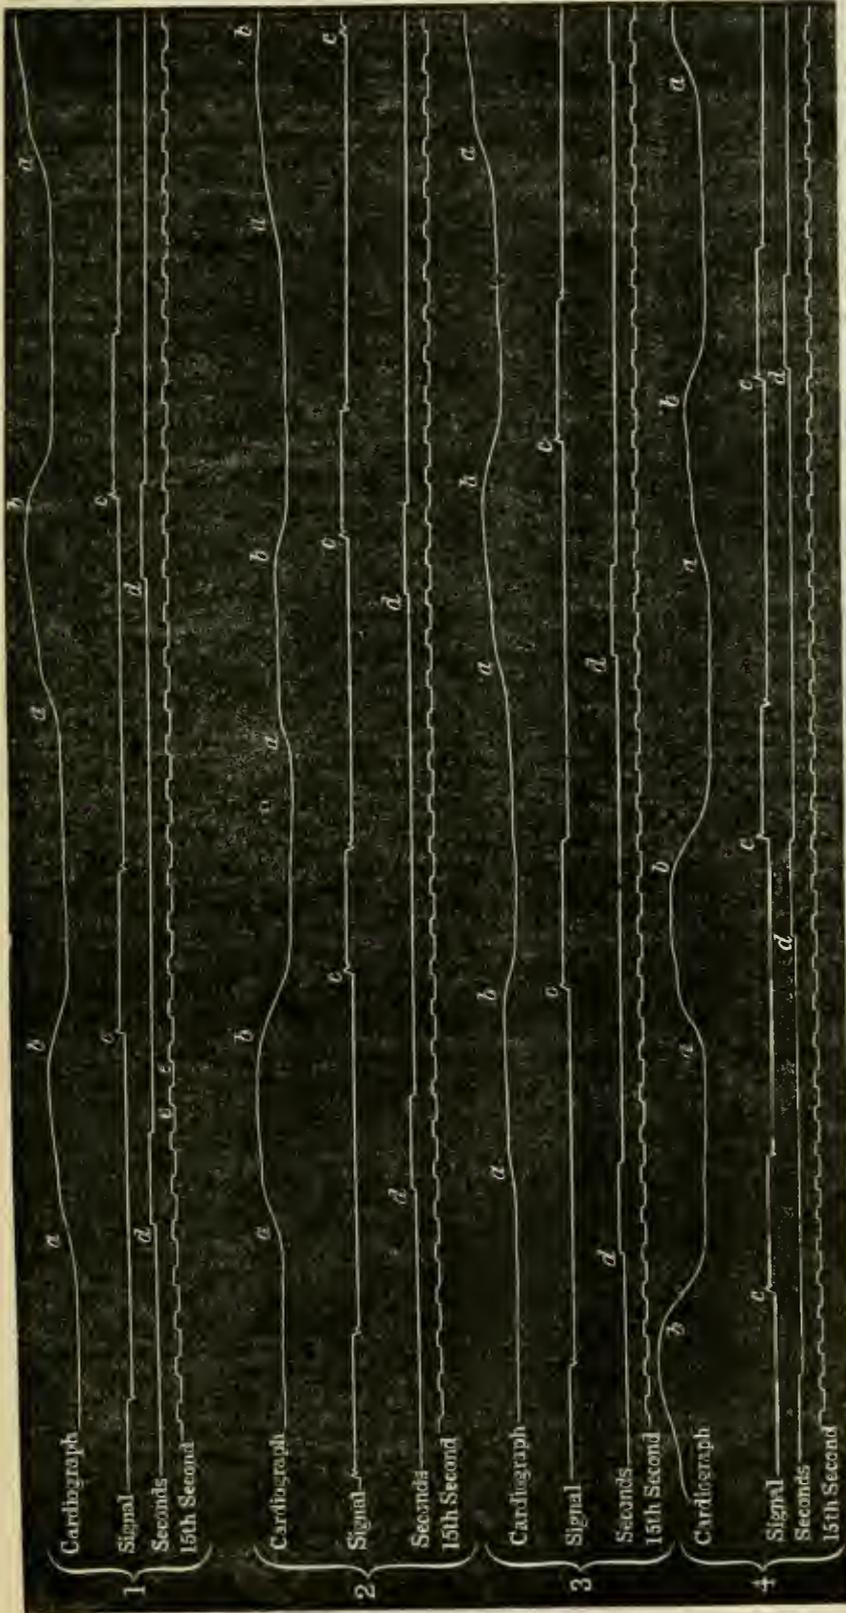

Fig. 5.—Facsimile of portions of four consecutive tracings in the case of W. K. The letters a, a point to the commencement, and b, b to the termination of the ventricular systole, as seen in the cardiographic tracing; c, c to the occurrence of the second aortic sound, as signalled by the auscultator; the spaces between the letters d, d, and e, e, in the third and fourth tracing indicate periods of a second and a fifteenth of a second, respectively.

Fig. 6.—Facsimile of a portion of the tracing obtained in the estimation of the "psychical loss," as described in the text. The letters a, a point to the time at which the telephonic sound was signalled by the auscultator; and the letters b, b to the time at which it actually occurred. The two arcs, it will be observed, are practically synchronous. The distance between c and e, in the third line, represents a period of two seconds.

seconds on the tracings, was put into circuit with the telephone and its recording lever; and the two seconds clock (that is, the clock which makes and breaks contact every two seconds, intermitting every tenth beat) was used as a time marker, though, with the telephone signal already marking seconds, this was not, of course, necessary. The result of this arrangement was the production in the telephone every second of a "make" sound and a "break" sound, separated by so short an interval that the sound vibrations appeared almost to run one into the other; the result produced very closely resembled a short, sharp cardiac murmur, occurring in a heart beating with absolute regularity sixty times a minute.

The auscultator, as soon as he listened to the sounds produced in this way, and before any tracing had been taken, expressed absolute satisfaction with the conditions. He stated that any "psychical loss," which was observed in timing these sounds would, he felt confident, apply to the observations made in the case of W. K. Further, it was obvious that the conditions exactly resembled the timing of a short, sharp systolic cardiac murmur, for the up stroke of the telephonic signal (which marked the occurrence of the telephonic sound) might be regarded as the systolic up stroke of the cardiographic lever, which marks the commencement of the ventricular systole, and therefore the commencement of a systolic murmur in a cardiographic tracing.

After careful adjustment of the telephonic lever and the signal lever of the auscultator, a tracing was taken with all the precautions previously described (the eyes of the auscultator being closed). The result (see fig. 5) was again a surprise, and an interesting physiological observation—which, so far as we know, has not been previously made—for it showed that, under the conditions of the experiment, there is absolutely no "psychical loss." The absence of any "psychical loss" under such conditions is a most important practical fact for the purposes of our present research; for it shows that in recording, by means of the apparatus which we have described, the sounds of a rhythmically contracting and slowly acting heart, the personal equation (as regards "psychical loss," but not, of course, as regards the auscultator's capability of perceiving cardiac sounds or murmurs) may be left out of account. Within what limits, as regards frequency of action (in other words, frequency of sound), this statement applies we do not at present know; but we hope in the course of a short time to be able to determine.

There are also several other interesting questions connected with this result (not, however, bearing directly upon our present research) which suggest themselves for solution, and which, if time permits, we hope to investigate:

The fact that there is no "psychical loss," under the conditions we have mentioned, confirms, in the most striking and absolute manner the reliability of the previous experiment, which had located the occurrence of the second sound just at the end of the ventricular systole. In fact, the two experiments are mutually confirmatory the one of the other; for the fact that the second sound does occur immediately, or almost immediately, after the ventricular contraction ceases, is, of course, one of the absolutely certain and fixed events in cardiac physiology.

These experiments seem to show that the method is a practical and satisfactory method, and well fitted to serve the purposes for which it is intended.

The explanation of the absence of any "psychical loss" in this experiment is not far to seek. It is obvious that the discharge of the motor centre concerned in the movement of the forefinger, which depresses the signal key, becomes rhythmical; and this rhythmical discharge of the "signal centre," as it may be termed, takes place synchronously with, or even rather tends, as some of our observations show (unless the attention of the auscultator be very closely concentrated on the sound) to anticipate the recurring sensory sensation (telephonic sound), with which it corresponds in time. It is quite obvious, therefore, that any given sensory impression or telephonic sound cannot regulate the motor discharge, with which it corresponds in time (and on the drum); but that the preceding sensory impression or telephonic sound guides the succeeding motor discharge; or, at all events, that the rhythmical recurrence of the motor discharges is regulated and guided by the rhythmically recurring sensory impressions which precede them.

Such a view explains the fact that the signal marking the occurrence of the second aortic sound, in the case of W. K. (the points at which the letter C. is placed) is not absolutely the same in each succeeding cardiac cycle. It will be seen that in some cycles it slightly precedes, while in others it slightly follows, the termination of the ventricular systole, as indicated by the cardiographic lever. The reason is, that (in consequence, no doubt, of the influence of respiration), the heart does not beat with the regularity of clockwork; that in a normal and apparently perfectly regularly beating heart, some cardiac cycles are longer, while some are shorter than others. We may, therefore, expect that if a short cardiac cycle, or a short ventricular systole, follows a long cycle, that the signal representing the second sound, since its time is regulated not by the second sound, with which it corresponds in time and on the drum, but by the preceding, or several preceding, second sounds (regulating the rhythmical contraction of what we may term the "signal centre"), will slightly succeed; while, in a long cardiac cycle, it will slightly precede the point in the cardiographic tracing at which it ought actually to be placed. Whether this is so or not we have not yet determined by actual exact measurement.

It will nevertheless be noted, that although successive cardiac cycles vary considerably in their duration, the relative position of the second sound, as signalled by the auscultator, to the termination of the ventricular systole, as recorded by the cardiograph, is practically maintained throughout the whole four tracings; in other words, the

² This fact was demonstrated by the authors of the paper to the members of the Edinburgh Pathological Club, on November 30th. Although the demonstration was made at 12 p.m., when the auscultator was exhausted by a hard day's work, and at the end of a meeting of four hours' duration, in which a good deal of tobacco was going the whole time, the result was perfectly satisfactory, the "psychical loss," under the same conditions, being again nil.

slight error in one cycle is not magnified in the next cycle, and that the relative position of these two points (second sound as signalled, and termination of systole as traced) is practically the same, both in the first and in the last cycles of the series; an argument, we think, in favour of the view that the preceding sensory impression (sound) regulates the occurrence of the succeeding motor discharge (signal).

The practical outcome of this, we fear, somewhat long explanation is, that the exact position—point of commencement—of a cardiac sound, or murmur, even granting that it is signalled with absolute precision, cannot by this method be absolutely and accurately determined from the observation of any single cardiac cycle alone; but that, by taking the average, so to speak, of a sufficiently long series of cycles, such location can be determined with very great exactitude, always, of course, granting that the auscultator signals correctly the exact commencement of the sound or murmur. Further, the error which, under such circumstances occurs in any individual cycle, in consequence of the diminished or increased length of that cycle as compared with the previous cycle, is so slight, that for practical purposes, for determining, whether a murmur is systolic, diastolic, or presystolic, it may be left out of account.

It must be remembered that these statements only apply, so far as our present observations enable us to judge, to a regular and rhythmically acting heart. To speak with absolute accuracy, we have only proved that they held good in timing a sound produced with exact regularity every second; but no one, we presume, will for a single moment be inclined to doubt that this limit, sixty times a minute, may be considerably extended in each direction. By future observation we hope to determine this point.

Further, we hope that by this method we may be able to demonstrate the exact rhythm of the murmur of mitral stenosis, presystolic murmur; and perhaps, after we have perfected our cardiographic apparatus and succeeded in recording on the drum a more simple and satisfactory tracing of the impulse of the heart, that we may be able to indicate the exact points, in the up and down strokes of the tracings, which mark the occurrence of the first and second sounds of the heart.

The apparatus seems also fitted to record other clinical phenomena, as, for example, the exact duration of the delayed sensation which occurs in some cases of nerve disease.

In conclusion, it is perhaps hardly necessary to state that this method of graphically recording the exact time relations of cardiac sounds and murmurs is not intended, nor indeed fitted, for ordinary every day clinical use. The apparatus is far too complicated and delicate for that. But, indeed, the ordinary method of auscultation, aided, if necessary, by the administration of digitalis or strophanthus, with the object of slowing, steadying, and strengthening the cardiac contractions, and so, of making the intensity and rhythm of the murmur more distinct, is, for practical purposes, all that the experienced observer requires. We hope, however, that the method which we have described may enable us to decide some of the questions which are at present in dispute.

Note.—Since this paper was written, Mr. Edison has kindly promised to direct his attention to this subject.

AN ADDRESS

ON

THE THERAPEUTICS OF THE URIC ACID DIATHESIS.

Delivered at the Opening of a Discussion on the Subject in the Section of Pharmacology and Therapeutics at the Annual Meeting of the British Medical Association, held in Dublin, August, 1887.

By I. BURNEY YEO, M.D., F.R.C.P.,

Professor of Clinical Therapeutics in King's College, London; and Physician to King's College Hospital.

I HAVE, in the first place, Mr. President, to thank you for the compliment you have paid me in inviting me to open this discussion.

The therapeutics of the uric acid diathesis is a very wide subject, and one surrounded by conflicting theories and divergent opinions; but it is within our power to limit this discussion to the consideration of certain definite questions of practical interest, in the examination of which we may hope to elicit, from the ripe experience and trained observation of the many distinguished physicians who are present here to-day, facts and suggestions of much value.

Organs of Sense:

Ophthalmia
 Conjunctivitis ("hot eye")
 Iritis, etc.
 Otitis (deafness).

Cutaneous Affections:

Eczema
 Psoriasis
 Prurigo (anal and vulvar)
 Acne.

PRINCIPAL PROPOSED REMEDIES FOR AFFECTIONS CONNECTED
 WITH THE URIC ACID DIATHESIS.

*Diet and Regimen:**Drugs.*

Colchicum
 Salicylates
 Benzoates
 Guaiacum
 Iodide of potassium.
 Arsenic
 Sulphur.

Alkalies and Alkaline Earths:

Salts of potassium, sodium, lithium, ammonium, calcium,
 and magnesium

Various Local Applications to Affected Joints:

- (a. Alkaline (bicarb. of soda), for example,
 Vichy
 b. Alkaline and aperient (carb. and sul-
 phate of soda), Carlsbad
 c. Chloride of sodium, Wiesbaden, Homburg
 d. Lime (earthy) waters, Contrexéville,
 Bath
 e. Indifferent (thermal), Buxton, Gastein
 f. Sulphur, Harrogate, Aix.

Water hot (and cold)

The treatment of the diathesis, rather than of its several morbid manifestations, must, in this discussion, chiefly occupy our attention.

In this, as in all other therapeutic questions, I would point out that we should always bear in mind that we have to deal with three elements or factors:—1, the pathogenic element; 2, the constitutional element; and, 3, the remedial element; and I would beg you to notice that the third is the only possible constant element.

The pathogenic factor may be present in all degrees of varying intensity; the constitutional element is, I need not say, extremely variable. The reactions of these two on one another may also vary greatly, leading frequently to the development of morbid conditions as different from one another as, for example, primary uratic nephritis and primary uratic arthritis.

The reactions of the third element, on the other two must also, of necessity, vary enormously.

Now, these considerations, although elementary, are frequently overlooked. Since these are the conditions of nearly every therapeutic problem, why should we look for constant uniformity in results? and why should we be discontented, or sceptical with regard to remedies because they do not always produce the same desired effect?

It is absolutely impossible, from the necessary conditions of the therapeutic problem, that they should do so. For example, in certain constitutions, a peculiar quality of the tissues may cause the uric acid deposit to cling to them with peculiar tenacity, while in others, for a like reason, they may part with it with unusual readiness. This obvious consideration must tend necessarily to disturb all experimental inquiries into the action of the various remedies proposed as eliminators of uric acid.

And now, without further preface, I will pass to the consideration of our remedies.

Diet and Regimen.—It is universally admitted that the treatment of the uric acid diathesis must take largely into account questions of diet and mode of life. Apart from the influence of heredity, which is the chief etiological factor in this diathesis, no other cause is so influential in its production as habitual excesses or errors in eating and drinking; and even when the hereditary tendency to this diathesis is strongly pronounced, very much may be accomplished by careful attention to dietetic rules, so as to keep in abeyance its more serious manifestations. It would, however, be a grave error to conclude that

all the victims of this diathesis merit the reproach of intemperance, or that they should all be submitted to the routine of a rigid abstinence. One of the greatest differences of opinion at present existing with regard to the most appropriate food for the gouty is that which has arisen in connection with Ebbstein's views on this subject. He maintains that one of the most compromising conditions that can affect a person predisposed to gout is obesity. He says: "The gouty who have grown old in spite of their disease are almost always those who have been able to keep obesity at arm's length;" and he considers the treatment of obesity an essential element in the treatment of gout. His method consists in allowing sufficient albuminous food for the physiological wants of the body—from seven to nine ounces of roast or boiled meat per diem. But, instead of avoiding fat, he encourages his gouty patients to take it, for he contends that the addition of a suitable amount of fat to the food is the best means of combating obesity. So far, he says, from increasing their fat, under this regimen they become thin, while their physical and intellectual faculties are improved. He explains this by the rapid manner in which fats allay the appetite or craving for food, and so prevents its excessive consumption. It also diminishes thirst and lessens the tendency to drink large quantities of fluid (which in German, means, beer!). Good fresh butter he considers the best form of fat. He allows from two to three and a half ounces a day. He forbids starchy matters, or limits their consumption to two and a half to three and a half ounces a day. He forbids sugar, farinaceous foods, and potatoes. He allows a moderate quantity of fruit and vegetables—peas, lentils, and beans in the form of *purées* (passed through a sieve), spinach, cauliflower, red cabbage, but forbids turnips.

It has been clearly established that in the uric acid diathesis no good results from abstinence from a moderate amount of animal food, and harm has no doubt occasionally been done by too severe a limitation in this respect, in the case of feeble persons. In opposition to this view, many object to a diet in which there is much fat or saccharine and starchy substances, on the grounds that, by affording the system material for combustion, these substances tend to check the metabolism of nitrogenous compounds and prevent their complete elimination. Senator says there should be a minimum of fat. He objects also particularly to yolk of egg, on account of the amount of fat and *lecithin* (an abundant source of phosphoric acid) it contains. Tea and coffee he forbids.

In these matters it has seemed to me that each patient requires a separate study, especially with regard to digestive peculiarities; and that our object should be, in accordance with and in subordination to certain generally admitted truths, to construct a diet which shall be readily digested, and which does not tend to excite acidity and undue fermentation in the alimentary tract; and that diet will differ with different persons. Whatever may have been the case with our predecessors who originated the gouty constitution, I am quite satisfied that in the present day, especially in the neurotic manifestations of this diathesis, we often encounter them in persons who are delicate feeders with small appetites, and who consume a minimum rather than a maximum amount of food.

A most important question in connection with the management of the gouty diathesis is the use of alcoholic drinks; in some persons, and especially in women, I am satisfied it is best to avoid them altogether; in others I have not found their moderate and discriminating use injurious. Of all alcoholic beverages, malt liquors are, I consider, most prejudicial in this diathesis, and bad quality wines. With regard to wines, I have had occasion to form a very decided opinion that it is not the name but the quality of the wine which is important. And no greater error has ever crept into medical practice than that exceedingly common one of advising everybody to drink light claret. A more injurious beverage than bad claret, or imperfectly matured claret—and speaking generally, all but the more expensive or most carefully selected clarets are bad—was never drunk. Cheap clarets consist of admixtures of the worst and most valueless wines that are grown on the surface of the globe. I repeat, it is the quality, not the name or even the quantity, of the wine taken, which is of chief importance to the subjects of this diathesis. Half a glass of bad sherry or claret or other wine will produce a decided disturbance of health, when considerable quantities of fine quality wines will pass through the system without injury.

I have made an observation, of the value of which I am more and more convinced: it is that the wines which act freely as diuretics are the wines which agree best with all persons. In some this will be champagne, in others claret, in others hock, and so on; but they are always, or nearly always, wines of good and often very fine quality. A very eminent physician of New York told me only a few weeks ago that he found champagne and port—carefully selected, I need not say

—the best remedies for his gout. I have certainly known many gouty persons who find champagne the wine that suits them best. For those who find a certain amount of wine a necessity, it is advisable that they should add to the wine they drink a small quantity of an alkaline water.

Some years ago I took to recommending *still* Moselle mixed with Apollinaris water for thirsty persons who required a "big drink." I find from the German wine merchants that these *still* wines, of the Moselle have been so largely recommended of late years to gouty persons that their price has advanced more than 25 per cent.

A great deal has been said about the importance of exercise for gouty persons, and no doubt a sufficiency of exercise is important to all persons. But gout is a disease which prevails amongst a class of persons who take a vast amount of physical exercise. Lord Beaconsfield's definition of the aristocracy as "People who live much in the open air and don't read," is, so far as the first point is concerned, a true one, and the comparatively slight incidence of gout in women as compared with men, who lead much more active lives, points in the same direction—viz, that want of exercise is not such an important feature in the etiology of gout as has been imagined.

As to climate, I am convinced that a climate that is warm, dry, and equable is most advantageous to the subjects of this diathesis, and that climatic conditions which interfere with the free action of the skin are most prejudicial. It is a matter of common observation with patients themselves that if the action of the skin gets disturbed by the onset of a cold east wind they soon begin to feel "gouty."

Water.—I am also convinced that no remedy is more valuable and important in the treatment of this diathesis than the regular consumption of a considerable quantity of pure water, and preferably hot water.

As a diluent and solvent of renal excrementitious substances, it is most important, while in its rapid passage through the system, it must tend to dissolve and carry away waste matters from the blood and tissues. When drunk at a higher temperature than that of the blood the effect of this hot water flowing through the hepatic portal circulation must be to stimulate the functions of the liver cells and promote biliary excretion.

(To be continued.)

CLINICAL MEMORANDA.

HORN ON THE HEAD OF A WOMAN.

THERE is (or was) a horn, similar to that described by Dr. V. Bejan as occurring on the head of a Roumanian woman, in the Pathological Museum of St. George's Hospital, which I removed from the face of an old woman in Yorkshire some years ago. I forget its dimensions, but I think it was somewhat smaller than the one referred to in your note, and its shape was twisted in the form of an antelope's horn. It appeared to be developed from a mole, and there were two or three rudimentary horns on other parts of the face of similar origin. The wound healed well, and the patient lived several years after the operation, but I do not know whether the smaller growths increased in size.

C. ROBERTS, F.R.C.S.

Curzon Street, W.

NATAL SORE.

I HAVE recently seen cases of "Natal sore" from Maritzburg, and I have no hesitation in stating that their appearances and histories correspond with the disease known in India as "Delhi boil." The "Natal sore" has been long ago mentioned by African travellers, including Livingstone, as very common amongst the native tribes; and, quite recently, the medical officer of one of the Castle mail packets, trading between Mauritius, Natal, and the Cape, informed me that he is often called on to treat passengers suffering from this troublesome skin disease.

The late Dr. Tilbury Fox proposed that the name "Oriental sore" should be applied to this disease, as it was then thought to be confined to the East; but it is now known to have a very wide distribution. I saw, many years ago, a case from Jamaica.

J. FLEMING, M.D., F.R.C.S.E., Surgeon-Major M.S.

Mauritius.

UNUSUAL CAUSE OF URETHRAL HÆMORRHAGE.

A., aged 34, sent for me complaining of somewhat severe hæmorrhage from the urethra. On examination the entire left half of the scrotum and penis, and the whole of the perineum to within two inches of the anus were seen to present one mass of varicose veins. There was an enormously dilated venous pouch where the vein passed out of sight

near the anus. The condition was congenital, and had remained apparently unchanged ever since he could remember. There was no other vessel lesion to be made out. The hæmorrhage was arrested by passing a catheter into the bladder, and bandaging the penis on to it, the hæmorrhage coming apparently from a ruptured vein about three inches up the penile urethra.

79, Queen's Crescent, Haverstock Hill, N.W.

THERAPEUTIC MEMORANDA.

OLEATE OF ZINC AND IODOFORM IN GYNÆCOLOGY.

I SHOULD be glad to record my experience of the value of iodoform and oleate of zinc when mixed together, either in equal portions or with two parts of iodoform to one of the oleate, according to the effect desired.

The dry treatment in gynecology having attained such success, I particularly wish to notify the beneficial effect of this powder on ulcerated surfaces of the uterus, or to aid granulation after the application of strong caustics. It may be applied by insufflation, or on the tampon, according to the nature of the case. It is especially useful in cancerous ulceration, in which the pain and discharge may be greatly reduced by its use, the fœtor corrected, and a clean granulating surface often left. It diminishes hyperæmia and exudation, and may be used with advantage to the inflamed endometrium as a dusting powder; it will heal up most ulcerations with great rapidity.

The oleate of zinc seems to me to be preferable to bismuth alum of the oxide of zinc, and when used in combination with iodoform, it will be found to be soothing, astringent, antiseptic, and healing.

W. D. HASLAM, M.D., M.R.C.S.

19, Mecklenburg Square.

A PLEASANT ANÆSTHETIC MIXTURE.

MUCH discussion has lately appeared in the JOURNAL on the subject of anæsthetics. The A.C.E. mixture appears to hold great favour with many practitioners, and undoubtedly very justly so, it being apparently a much safer anæsthetic than either chloroform or ether.

I should like to place before your readers another mixture, which I think will be found to give even greater satisfaction, especially for all minor operations—namely, a mixture of equal parts of alcohol and chloroform. Its anæsthetic effects do not come on quite so rapidly, but it is much less unpleasant to the patient, and I believe even safer than the usual mixture of A.C.E. I have administered it (using a Skinner's inhaler) in minor surgical operations and in dental cases, and have found no unpleasant after-effects whatever, except in one case in which there was slight excitement, which very soon passed off.

A more pleasant mixture can be made with equal parts of the best eau de Cologne and chloroform, and in addition the inhaler should first be sprinkled with a few drops of pure eau de Cologne, so as to render the first two or three inhalations still more pleasant and comforting to the patient. In dental operations I have found this plan most satisfactory for nervous ladies, who are prejudiced against any form of anæsthetic other than gas.

WILLIAM J. STEPHENS,

Anæsthetist to the Brighton Dental Hospital.

OPHTHALMOLOGICAL MEMORANDA.

SPASMODIC ENTROPION TREATED BY STRETCHING THE ORBICULARIS.

Mrs. W., aged 69, consulted me at the Bolton Eye Hospital, on November 9th, last. She had been ill nearly three months; there was mucopurulent conjunctivitis of both eyes, ulceration of both corneæ, very extensive in one eye, double iritis with numerous posterior synechiæ, and spasmodic entropion of the lower lids. Here I am concerned merely with the entropion, for which I stretched the orbicularis by an extreme separation (maintained for about a minute of the eyelids, using for this purpose the eyelid retractor. This single manipulation accomplished its object. When the lids were, before its performance, placed in their normal, they immediately resumed their morbid position, notwithstanding the utmost efforts of the patient. She reports that at no time since the stretching (now six weeks ago) have the lids been turned in except momentarily at the time of making local applications.

The treatment by suture, to which I called attention in the JOURNAL of May 28th last, and of the efficacy of which I have since had additional evidence was contra-indicated by the discharge.

DAVID McKEOWN, M.D.

HOSPITAL FOR WOMEN, SOHO SQUARE.

ENUCLEATION BY ELECTROLYSIS OF A LARGE UTERINE FIBROID.

(Under the care of E. HOLLAND, M.D., M.R.C.P., F.R.C.S.)

Mrs. C. aged 38, having seven children, was admitted on July 4th, severely blanched and flooding. The uterus was involved in a hard, multiform, fibroid enlargement, whose measurements were as follows: upper limit level with the middle of umbilicus; right lateral limit, 5 inches to right of middle line; left limit, $3\frac{1}{2}$ inches from middle line; transit of sound, 6 $\frac{1}{2}$ to 7 inches. The hæmorrhage resisted all ordinary resources; and, as there was no cervix available for a stump, electrolysis was considered a legitimate procedure, and was accordingly begun on July 22nd, as follows. The negative electrode, insulated to $4\frac{1}{2}$ inches from its extremity, was placed in the uterine cavity; whilst the positive electrode was connected with the zinc and potter's clay distributor of Apostoli, and applied externally over the tumour. A current of 50 milliamperes was gradually induced and allowed to play for ten minutes. On the 25th the application was intensified to 80 milliamperes; on the 29th, to 150 milliamperes. After this there was pain for an hour, and the tumour was perceptibly diminished in area. On August 2nd there was again free hæmorrhage, and clots passed for several days. On August 9th, the hæmorrhage still continuing, positive galvano-cauterisation to 250 milliamperes was maintained for twelve minutes, with the result that the hæmorrhage was arrested and never recurred. August 12th. Electrolysis to 250 milliamperes, the negative electrode being in the uterus.

On this and subsequent occasions the patient appeared less tolerant. August 15th, to 250 milliamperes. August 18th, to 300 milliamperes. August 22nd, to 235 milliamperes. After the application on the 22nd, the patient suffered from chilly feelings, thought she had taken cold, and had raised temperature, and vaginal discharge which became more and more fetid. August 27th, much pelvic pain was noted. August 29th, fever increasing; cavity of uterus well douched, after which the temperature shot up to 103°. Between the last date and September 4th, a large sloughing mass was bloodlessly enucleated and extruded into the vagina. September 5th. Mass removed by two applications of the *érascur*, and other small enucleations by fingers and scissors, from a base which was found to be the left lateral wall of the uterus inverted. After the operation the inverted left lateral wall was manually replaced. Between the date of this operation and the 8th, a second bloodless enucleation and extrusion was accomplished, and of a much larger mass, which tightly distended the vagina, and was removed by three applications of the *érascur*, and one or two twisting processes. On the second evening after this operation the temperature rose to 104°, but this was quickly subdued by quinine, judiciously administered by the watchful and accomplished house-physician, Dr. Burford. The douches were most thoroughly used every three or four hours, chlorine water being the usual one, whilst quinine was freely given at each rise of temperature.

On September 15th the patient was quite convalescent, the discharges scanty and without fetor, the sound passing 2 $\frac{1}{2}$ inches, and no tumour being perceptible. From the commencement of the electrolysis to the date of convalescence there were exactly 55 days. It is also well to observe that the tetanoid condition into which the uterus was thrown by the electrical excitement on each occasion led us to anticipate necrosis and enucleation as possible and probable contingencies, and, in doing so, to draw attention to the extreme importance of the galvanic current as a diagnostic agent in all solid tumours of uterine constitution.

ACTION OF HYDROQUINONE.—The action of hydroquinone is prompt and efficacious, and is very marked in typhoid fever, rheumatism, erysipelas. It lowers the temperature, acts upon the pulse, on the respiratory functions, stimulates the elimination of urea, excites diaphoresis, and regulates arterial pressure. Its action is more marked in patients suffering from fever than in healthy persons. It should be given to adults in doses of 30 to 50 centigrammes every hour. Hydroquinone is rapidly eliminated in the urine in the form of quinhydrone, which turns the urine to a dark olive green hue.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

ANNUAL GENERAL MEETING.

TUESDAY, JANUARY 3RD, 1888.

Sir JAMES PAGET, Bart., F.R.S., F.R.C.S., President, in the Chair.

Election of Officers and Council.—The following gentlemen were elected to form the Council and to act as officers of the Society during 1888:—*President:* Sir James Paget, Bart., D.C.L., LL.D., F.R.S. *Vice-Presidents:* Thomas Henry Green, M.D.; *J. Hughlings Jackson, M.D., F.R.S.; *Joseph Frank Payne, M.D.; Richard Douglas Powell, M.D.; William Morratt Baker; *Marcus Beck, M.S.; Sir Joseph Lister, Bart., D.C.L., LL.D., F.R.S.; *Henry Morris, M.B. *Treasurer:* William Cayley, M.D. *Honorary Secretaries:* Sidney Coupland, M.D.; Rickman John Godlee, M.S. *Council:* *Charles Edward Beever, M.D.; Henry Radcliffe Crocker, M.D.; David White Finlay, M.D.; James Kingston Fowler, M.D.; James Frederic Goodhart, M.D.; Walter Baugh Hadden, M.D.; *Edward Emanuel Klein, M.D., F.R.S.; *Stephen Mackenzie, M.D.; Joseph Arderne Ormerod, M.D.; *William Hale White, M.D.; *William Anderson; Anthony Alfred Bowlby; Henry Trentham Butlin; *Victor Horsley, B.S., F.R.S.; John Hammond Morgan; *Bernard Pitts, M.B.; *A. Quarry Silcock, M.D.; John Bland Sutton; Charters James Symonds, M.S.; Frederick Treves. (The gentlemen whose names are marked with an asterisk (*) were not on the Council or did not hold the same office during the preceding year.)

Angiomata of the Mouth and Tongue.—Mr. F. TREVES made some remarks on three cases; two affecting the tongue were arterial angioma, an extremely rare condition. The first patient was a strong, temperate man, aged 57, who belonged to a family of bleeders; he was liable to epistaxis about ten times a year until four years before he came under observation, when the tongue began to bleed; it bled fifty times in the four years. The tongue presented several small, elevated, red growths, two as large as the half of a pea, others mere specks. The largest tumour was quite clearly an arterial angioma. The growths disappeared under the local application of chromic acid; the liability to epistaxis was then again noticed; Baumgarten had noted small, red elevations on the mucous membrane of the nose in cases of recurrent epistaxis. In the second and third cases the bleeding from the mouth relieved an intolerable headache. The second case was a married woman, aged 31; the tumour was first noticed in about the fifth month of pregnancy. Near the edge of the tongue, opposite the molar teeth, was a red, arterial angioma; on several occasions she had bled freely from this tumour, and it was thought advisable to remove it. Hæmorrhage in the wound was arrested by the actual cautery. The third patient was also a woman. The angioma lay behind the two right incisor teeth, and was the size of a cherry; it had appeared in the fourth month of pregnancy; it pulsated freely. Hæmorrhage, at first only on eating, had become considerable. The tumour was easily removed along with the right lateral incisor, the tumour being attached to the dental periosteum. Such cases were not very uncommon.

Congenital Fatty Tumour.—Mr. EVE showed a specimen of congenital fatty tumour in a young child, aged 13. It lay between the layers of the abdominal muscles in the left hypochondrium; it probably sprang from the fascia transversalis. Few cases of tumours between muscular planes had been recorded.—Mr. RICKMAN GODLEE was surprised to hear it said that lipomata between muscular planes were very uncommon. He gave particulars of two, one beneath the gluteus maximus, and the other beneath the deltoid.

Subperitoneal Lipoma.—Mr. J. HUTCHINSON, jun., showed a specimen of double fatty hernia in the linea alba. One tumour was the size of a small apple, and lay in the subcutaneous fat, from which it was perfectly distinct, both in origin and appearance; the aperture in the aponeurosis through which it had passed was quite small. The other tumour was seated at the umbilicus; both had sprung from the subperitoneal fat, and in passing forwards had stretched the peritoneum, and in each case had drawn a process of the latter membrane with them. By a series of specimens shown at the Pathological Society three years ago, Mr. Hutchinson had demonstrated the same tendency of fatty hernia in the femoral and inguinal canals to draw down peritoneal tubes, and hence to lead to the formation of true hernia. Commonly these fatty hernie (derived from the subperitoneal fat, and having no true sac) were mistaken for ommental hernie; as a rule they were irreducible, and they were curiously accompanied in some cases by abdominal pain, nausea, etc. Instances in which the operative removal of the fatty outgrowths had been followed by complete

relief of the symptoms had been recorded by König and Lücke. It was probable that traction on and nipping of small nerves in the peritoneum produced these symptoms.

Bone and Joint Disease.—Mr. BLAND SUTTON exhibited some specimens of bone and joint disease. The first was the tibia and fibula of a horse which, three months before its death, was kicked by a horse on the inner side of the leg over the tibia. There was a skin-wound as the result of the kick, which healed quickly and with trifling suppuration. As soon as the wound was healed the tibia began to enlarge, and continued to do so for three months. The horse suffered considerable pain, and, as the case seemed hopeless, it was killed. The tibia was three times larger than natural, and its exterior was roughened by small bony outgrowths. On section the outline of the original shaft could be defined, and outside this a large mass of new bone had been deposited, and surrounded the slender fibula, though the new formation of bone was strictly limited to the tibia. The second specimen was a greatly enlarged and softened femur of a monkey. In the centre of a longitudinal section, which was easily made with a knife, was the true shaft of the femur, apparently necrosed, but embedded and closely adherent to new bone which surrounded it evenly on all sides. The adventitious bone exceeded the shaft in size three times. The new bone was roughly limited above and below by the epiphysal line; hence, though the shaft was so thick, the condyles and head of the bone preserved their proper proportions. Both femora were affected, and one humerus; the remainder of the skeleton seemed normal. The tibia of the horse and the femur of the monkey were shown, because it seemed possible that they represented early stages of a rare condition, described in man as necrosis without suppuration—quiet necrosis. The third specimen was the elbow-joint of a lion twelve years old, affected with osteo-arthritis. The cartilage had in a great measure disappeared from the articular surfaces of the bone, whilst at the edges of the joint the cartilage was distinctly "lipped." The synovial membrane presented villous fringes of great length, and lodged in the recesses of the joint were those curious cartilaginous bodies so common in this affection in man. All the joints of the fore limbs of this lion were similarly affected. The fourth specimen was a typical example of the condition to which the apt and expressive term "lipoma arborescens" was applied. The specimen came from the shoulder-joint of an old man affected with osteo-arthritis, and all stages, from simple villous processes of the synovial membrane to pedunculated masses of fat, could be clearly recognised.—Dr. NORMAN MOORE said that the separate lemon-seed masses and fringes were the only morbid changes present in rheumatism, but absent in joints containing uric acid.—Mr. RICKMAN GODLEE asked if the epiphysal line in the monkey's bone was healthy.—Mr. W. ADAMS had never seen the fringes in true gout, but he had seen them in the mixed form of rheumatic gout.—Mr. R. W. PARKER had observed a similar condition of the tibia to that shown by Mr. Sutton in children; in all the cases there was central necrosis; the condition was a general chronic osteitis of very long duration.—The PRESIDENT mentioned a case of osteitis following eight years after a severe blow on the tibia; the limb resembled the condition produced by osteitis deformans, but no other bones were affected. The bone bent, indicating that there was a general osteitis. The condition was not uncommon in many animals.—Mr. EVE thought that in animals it was generally due to periostitis, or was associated with arthritis. Mr. Sutton's case was, he considered, an example of dry caries.—Mr. SUTTON said that the epiphysal line was certainly enlarged, but there was no ricketty change in any other bone of the body. The epiphysal line at the head of the bone was not enlarged.

Carcinoma of the Obliterated Hypogastric Arteries and Umbilical Vein.—Dr. HALE WHITE showed specimens from a patient who was in Guy's Hospital for wasting, abdominal pain, vomiting, and constipation, and in whom some nodules could during life be felt in the rectus muscle. The patient gradually sank and died. The necropsy showed primary carcinoma of the pancreas, with numbers of secondary hard masses just under the peritoneum, some of which were the nodules which had been felt during life. But the point of chief interest was that the two obliterated hypogastric arteries and the obliterated hypogastric vein were both converted into cords of hard secondary growth. This was not due to spreading from neighbouring nodules. Dr. Hale White considered that this was a very interesting and rare example of secondary growths particularly affecting degenerate structures.

Tuberculosis of Sheath of Tendon.—Mr. CHARTERS SYMONDS related the case of a young girl who came under treatment with a small growth of the sheath of the flexor tendon of the index finger resembling a ganglion. The tumour was incised, and the girl completely recovered. Similar growths occurred in the palms. He mentioned

two other cases. He showed a microscopical specimen of the growth in the first case which presented a typical tubercular structure.—Mr. F. TREVES referred to the literature of the subject, and said that it would seem that few cases terminated so favourably as Mr. Symonds's.

Syringo-Myelia.—Mr. QUARRY SILCOCK showed a specimen of syringo-myelia, and expressed the opinion that the formation of a tube-like cavity occupying the posterior columns of the cord, and extending through a considerable length, might arise by the formation of a cavity in newly-formed connective tissue, which had developed in that region as a consequence of traumatism. The specimen came from a guardsman aged 23, who had broken his neck by diving into the Thames. The body of the fifth cervical vertebra had been crushed and somewhat displaced backwards, giving rise to a projection in the spinal canal, where the cord was much flattened. Sections of the cord at the level of the second cervical vertebra showed, even to the naked eye, an elongated slit-shaped cavity, lying immediately inside and parallel to the right posterior root. There was a general sclerosis of the cord; the disorganisation was most marked in the right posterior column, that is to say, in the neighbourhood of the cavity. The walls of the cavity were formed of finely reticulate connective tissue with abundant nucleation; there was no lining membrane, and the inner surface was ragged. The central canal had no connection with the cavity; from the connective tissue round the latter, fibrous strands stretched into the posterior root of the central grey matter, and the neighbouring portion of the posterior column. At the level of the sixth vertebra the cavity was considerably smaller in size, but the structure of its walls was essentially the same. The cavity ended below in a mass of felted sclerotic tissue. Mr. Silcock said that a cavity of the nature and in the situation of this had been ascribed to the persistence of a portion of the cavity which in the embryo extended as a fissure between the posterior columns to the periphery of the cord. He thought, however, that this specimen illustrated a different class of cases in which a cavity was formed in sclerotic tissue as a secondary phenomenon.

Pneumothorax in a Child.—Dr. ORMEROD related a case of phthisical cavity leading to pneumothorax in a child six months old. The patient was admitted into St. Bartholomew's Hospital on account of its marasmic condition. Dyspnoea came on suddenly, and the child died. The pneumothorax was connected with a cavity in the middle lobe of the right lobe, the size of a marble. The lung was solidified by grey tubercle; the bronchial glands were enlarged, and contained tubercle bacilli. Dr. Douglas Powell had recorded a case of cavity in the lung in a child aged seven months.—Dr. DOUGLAS POWELL asked whether there was a very well defined tubercular family history, as in his case; the patient in that case died of hæmoptysis. This case was reported to the Society (vol. xxv).—Dr. NORMAN MOORE said that he had reported a case of phthisical cavity in a child, aged 11 months.—Dr. ANGEL MONEY had seen a cavity in the left apex, the size of a walnut, in a child aged three months; the child died of hæmoptysis. This was the only case in five hundred necropsies of children under 10 years.—Dr. ORMEROD said that the mother was said to be phthisical, but there was no other phthisical history.

Living Specimens.—Dr. PENROSE (for Mr. EDMUND OWEN): Lumbar Hernia in the Track of a Lumbar Abscess due to Spinal Caries.—Mr. W. K. SIBLEY: Symmetrical Lipomata.

Card Specimens.—Dr. HALE WHITE: (1) Tubercular Ulceration of Tongue; (2) (for Dr. BEAVAN RAKE, of Trinidad): Intestine and Parasite from a Patient Affected with Ankylostomum Duodenale.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

OBSTETRICAL SECTION.

JOHN RUTHERFORD KIRKPATRICK, F.R.C.S.P., President, in the Chair.

Suppurating Ovarian Cyst.—Dr. ATTHILL showed a specimen of a suppurating ovarian cyst taken from a lady, aged 35, who enjoyed excellent health till about two months previously, when she got cold, and had a sharp attack of peritonitis. During this her medical attendant detected a tumour in her abdomen. The tumour was found to be multilocular; and on the largest of the cysts being tapped, the tumour was pressed out without difficulty through a small opening in the abdomen. He was then surprised to find that it was attached to the uterus by a rather short and thick pedicle. A secondary cyst—the one exhibited—was then discovered, which, on being tapped, was found to contain pus. One interesting point about this cyst was its shape, which was quite different from anything that he had seen. A second remarkable circumstance about the case was that, notwithstand-

ing this suppurating cyst, the lady had apparently nothing whatever wrong with her, having perfectly recovered from the peritonitis.

Placental Cyst.—Dr. A. J. HORNE exhibited a placental cyst from a patient, aged 28, who was in the ninth month of her fourth pregnancy. She complained of intense pain in the abdomen. On external examination he was struck with the irregular appearance of the abdomen, particularly at the left hypochondriac region, where there was a distinct bulging of the uterus. On palpation it was impossible to discover the small parts of the fetus, the uterus felt so tense and firm. On making a vaginal examination he found that he could only reach the presenting head by laying the patient on her back. The membranes were tightly stretched over the head, and there was no appearance of liquor amnii. Thinking that there was internal hæmorrhage, he was very cautious about rupturing membranes; and as the sero-sanguineous discharge was very slight, though it caused her some anxiety, he stopped it by a small antiseptic plug in the vagina. She had no labour pains until the next morning at eleven o'clock, when they came on, and she was delivered of a still-born child. Immediately after the expulsion of the placenta, huge clots the size of the placenta were expelled. She remained in a very anxious state for a couple of hours in consequence of extreme loss of blood, although previous to her labour the loss of blood had been very slight. On examining the placenta he found in the centre of it, close to the insertion of the cord, the huge cyst now exhibited, the weight of which, acting downwards like a suction pump, might, he thought, have been the cause of the hæmorrhage.—Dr. MACAN and Dr. ATHILL took part in the discussion.

Uterine Hæmorrhage of Five Years' Standing, caused by an enlarged and Cystic Ovary: Removal of Ovary: Recovery.—Dr. M'MORDIE exhibited the following case of an enlarged and cystic ovary. L. S., aged twenty-six, single, was admitted to the Samaritan Hospital for Women, Belfast, on July 27th, 1887. A careful examination of the uterus revealed nothing to account for the constant oozing of blood from the os uteri. The right ovary felt enlarged, and there was tenderness upon pressure. Removal of one or both ovaries was recommended as the only means of effecting a cure. The nature of the operation having been fully explained to the girl and her mother, they gave their consent. On August 2nd the right ovary was removed. The hæmorrhage ceased in about ten days after the operation, and the patient was now in the enjoyment of perfect health.—Dr. MACAN said the present case made him more willing to remove such ovaries than he would otherwise have been. The difficulty was to connect pains or hæmorrhage absolutely with an enlarged ovary.—Dr. ATHILL said that, according to his experience, enlarged ovaries and ovarian cysts were not the cause of profuse menstruation, but rather the reverse. Why an ovary in such a condition as that now shown should have given rise to such profuse hæmorrhage was to him a mystery.—Dr. W. J. SMYLY said that, in the majority of cases ovarian tumours did not lead to hæmorrhage. The occurrence of hæmorrhage depended partly on the nature of the tumour and partly on its site. If it developed between the layers of the broad ligament it would give rise to hæmorrhage from congestion. The present tumour was, he thought, an example of dropsy of the Graafian follicles.—The PRESIDENT remarked that if the ovaries in their normal state excited menstruation he did not see why, when diseased and enlarged, they should not set up menorrhagia. The removal of a diseased ovary would divert the menstruation to the healthy ovary, and cause it to become normal.—Dr. M'MORDIE replied.

Pudendal Hæmatocele.—Dr. HORNE read a paper by Dr. PUREFOY (who was unavailably absent) on pudendal hæmatocele, which was cured by the application of cold.—The PRESIDENT, Dr. MASON, Dr. MACAN, Dr. LANE, and Dr. ATHILL, took part in the discussion.

SURGICAL SECTION.

A. H. CORLEY, M.D., President, in the Chair.

The President's Address.—The PRESIDENT delivered an inaugural address outlining the history of surgery for the past fifty years.

Trephining in Brain Disease.—Mr. J. DALLAS PRATT read a paper on a case of mastoid disease with discharge of pus from the middle ear, in which he had successfully trephined. The patient made a good recovery. The discharge from the ear ceased, and the membrane healed up; the deafness also disappeared. Mr. Pratt drew attention to the statistics, 13 cases having been operated on in this manner with only two deaths, or 84 per cent. of recoveries; whereas the operation of gouging, drilling, or otherwise opening the mastoid cells produced a mortality of about 27 per cent. Of eight cases of which he knew, in which no operation was done, not one had recovered. He advocated the performance of this operation in cases of

prolonged otorrhœa, where milder measures had failed, even when no bone disease was present.

Serious Brain Symptoms following Pyæmia.—Mr. MAYNE, of Longford, read a paper on serious brain symptoms following pyæmia. A lady, aged 27, had been dressing a wound; a few days after her finger got sore, the glands in the axilla became inflamed. These symptoms passed off, but after some days the throat got sore and an abscess formed in the tonsil, which was opened, when a quantity of pus escaped. Soon after this the parotid gland inflamed, suppurated, and burst into the external ear, through which pus freely escaped. After sitting at an open window in a draught, paralysis of the left side of the face set in, which was cured by counter-irritation and galvanism. She complained, after some days, of severe pain in the right side of head, and was very irritable. The vision of the right eye became impaired; the pupil was contracted. She had a severe rigor, and paralysis of the right side of the face came on; there was tingling of the left arm, and she dragged the left leg; the right pupil was dilated; she misapplied words. For some days the symptoms became more marked. Mr. Fitzgibbon trephined the left mastoid, but on removal of bone there was no sign of pus. For several days all the bad symptoms appeared aggravated; the paralysis was well marked; the sphincters were paralysed. After some days the paralysis passed away, but was succeeded by noisy delirium, which continued for several weeks. Eventually health was restored. He was unfavourable to the trephining of the mastoid, although the patient had had in early life otorrhœa after scarlatina, but the discharge had not been present for years, and as during that time she had not been troubled with any brain symptoms, he saw no grounds for believing that trephining the left mastoid would benefit the case. All the symptoms pointed to brain trouble on the right side, probably about the fissure of Rolando.—Mr. HENRY FITZGIBBON regretted the want of notice of Mr. Mayne's paper, or he would have consulted his notes of the case, as it was the subject of a paper which he himself read before the Academy last session; but speaking from memory as to the condition of the patient at the time of the operation, he was satisfied the disease had originated from inflammatory action extending from the left mastoid region. It seemed to him that the lady had had otorrhœa more recently than Mr. Mayne mentioned. At any rate, her state appeared to Mr. Wheeler and himself to be perfectly hopeless, except, as the only chance of recovery, by giving relief to some pent-up intracranial matter. Although immediately after the operation her condition became worse, yet within four days he saw matter welling up between the bone and the dura mater. Consequent on the discharge from the wound having ceased, and the patient becoming worse, he went down again, and having scraped away granulations, a fresh gush of matter came from between the dura mater and the bone, with the result that the patient got relief and ultimately recovered.—Mr. BENNETT submitted that diagnosis should be carried forward to a greater degree of certainty than was at present attained before adopting Mr. Pratt's rule, that the trephine should be applied in almost all cases of otorrhœa where the discharge was maintained a considerable time, and did not yield to other means. The cases that could be relieved were those of intracranial suppuration, but these occurred much more rarely than the implication of the sinuses. He had investigated two or three cases in which the path of fatal inflammation proved to be along the auditory nerve to the base of the brain.—Mr. MYLES produced a skull upon which he had marked the points Mr. Wheeler had laid down for trephining the mastoid, with the result that the trephine must hit the anterior edge of the lateral sinus, and if the pus were located, not in the mastoid cells, but in the inner ear, it was beyond the bounds of anatomical possibility that the trephine could reach it.—Mr. ARTHUR BENSON observed that, as regards Mr. Pratt's treatment by injections, all aural specialists had given up the use of injections or washes in chronic otorrhœa, and the dry method was almost entirely adopted—namely, insufflation or the use of dry powders.—Mr. THOMSON said Mr. Mayne's case raised some interesting points. The lady seemed to be suffering from left hemiplegia, and the trephining took place on the left mastoid process, or in that region. He wished to know from Mr. Wheeler, who consented to the operation, why, having regard to the localisation of functions, that particular position was selected; and whether he considered that the removal of a piece of bone from the left mastoid region was calculated to improve hemiplegia occurring on the same side? It appeared from Mr. Henry Fitzgibbon's statement that no pus appeared until the fourth day, when it was manifest. There was nothing remarkable in that. If a piece of bone was removed and the case allowed to go on for four days, unless the wound was strictly a-septic, it was not an unlikely condition that there should be pus. The symptoms produced by pressure were explained by the pus pent up in the wound

for a certain time.—Mr. WHEELER remembered having examined the patient's left ear, and there was an aperture in the upper part of her membrana tympani. Within a short time there had been a discharge from this ear which suddenly ceased, and after this serious symptom supervened. The lady had facial paralysis on the right side, which he attributed to the irritation of the centres of the seventh nerve, carried from the left side, as the centre of both nerves lay close together. He agreed that trephining should not be used indiscriminately for the cure of otorrhœa. There were cases which could be satisfactorily treated by other means. But in cases of prolonged discharge pressing through an opening in the membrane, the operation was indicated; as also in cases associated with bone disease, and where cerebral symptoms supervened from continued or suppressed discharge. In reply to Mr. Myles's criticism he had a skull containing the brain, which he produced, illustrating the operation of trephining on each side. On one side he had pierced the sphenoidal lobe with a probe. On both sides the tympanum and mastoid cells were open. He had made a vertical section through the skull and brain, removing on one side the cerebellum, showing the lateral sinus intact.—Mr. FRANKS said trephining in otorrhœa, unless there were well marked intracranial symptoms, was unsurgical. He had a skull himself which would show that, operating in the same place, the trephine would go into the middle of the lateral sinus.—Mr. PRATT, in reply, said he would undertake to trephine by Mr. Wheeler's method the skulls referred to by Mr. Myles and Mr. Franks without going into the lateral sinus at all. It should be remembered that the lateral sinus was not opened in any of the cases in which that method was adopted.—Mr. MAYNE also replied.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

FRIDAY, DECEMBER 16TH, 1887.

ALFRED HILL, M.D., President, in the Chair.

Contagion of Cancer.—Mr. WYNTER BLYTH read a paper, in which he stated that he had held the belief of the possibility of cancer contagion for many years. The experiments of Langenbeck and Söllin on dogs were detailed, and some remarkable instances of infection of the human subject by accidental inoculation. The author argued that the infection of healthy parts by disease was a proof of contagion, so far, at least, as concerned the grafting of disease from part to part on the same body. The cancerous infection, often started from wounds. In a number of cases the close contact of healthy and cancerous persons had apparently spread the malady. A house, the history of which he was well acquainted with, had three cancerous tenants in succession. A stranger visiting frequently the last tenant contracted cancer, and the niece of this person also developed cancer. The cases of family infection were too numerous to be mere coincidences, whence the necessity of flying to some mysterious and remote influence descending through the generations, remaining latent through the best years of life, transforming the cellular elements into corrosive cankers, when the doctrine of contagion gave a simple and intelligible explanation.—In the discussion which followed, the PRESIDENT, Surgeon-Major BLACK, Mr. MACKAY, Drs. SAUNDERS, SMEE, COLLINS, and SYKES took part, and the further discussion of the paper was adjourned to the next meeting.

Bacteriological-Water Test.—Mr. GUSTAV BISCHOF read a paper on extension of time of culture in Dr. R. Koch's bacteriological water test by partial sterilisation, with special reference to the metropolitan water supply. The following conclusions were drawn: 1. No bacteriological water test can satisfy the demands of hygiene unless it is qualitative, distinguishing between harmless and pathogenic microphytes. No such test is at present known. 2. Merely numerical results without such distinction are entirely unintelligible, unless the time and other conditions of culture of each test be specified. 3. A small portion only of the colonies capable of growing in gelatine peptone is indicated by three days' culture. 4. The ratio of colonies thus indicated by three days' culture to that of the total present appears to differ so widely in different samples that the numbers of colonies obtained from them cannot be compared with each other. 5. Instead of any such comparison, the changes taking place from time to time should be followed up in each sample separately. 6. Extension of culture beyond three days increases the reliability of the results. How far this holds good, and how far culture should be extended, we have at present not sufficient evidence to show. 7. The usefulness of results is probably still further increased by combination of extension of culture with storage in sterilised flasks for a certain time. 8. As regards the control of the working of sand filtration at waterworks, any bacteriological test to be of practical utility should be repeated at intervals certainly not exceeding a fortnight. 9. It is

desirable for the purpose of such control to test the water entering and leaving each filter.—The discussion was opened by the PRESIDENT, who was followed by Dr. PERCY FRANKLAND, and will be continued at the next meeting.

SUNDERLAND AND NORTH DURHAM MEDICAL SOCIETY

FRIDAY, DECEMBER 16TH, 1887.

G. B. MORGAN, L.R.C.S.I., President, in the Chair.

New Member.—Dr. J. Norie, Sunderland, was unanimously elected.

Amputation of Thigh.—Dr. SQUANCE showed this case as interesting from the fact that he had not used the spray at the operation, contenting himself with thoroughly syringing the stump with solution of corrosive sublimate after the completion of the operation. The stump was completely healed on the nineteenth day, having only been dressed twice.

Tracheotomy.—Dr. DRINKWATER exhibited an old woman on whom he had performed this operation nine years ago for obstruction in the larynx. On laryngoscopic examination no obstruction was seen in the glottis, but the moment the woman tried to inspire through the natural air-passages, the glottis closed. She had worn a tube ever since the operation. There was a history of syphilis.—Messrs. WHITEHOUSE and ROBINSON, Dr. BRADY, and the PRESIDENT, made some remarks on this case.

Carcinoma Uteri.—Dr. WELFORD showed a specimen of this disease, in which the morbid process had commenced in the body of the uterus.

Sarcoma of Kidney: Nephrectomy.—The PRESIDENT read notes on this case, and exhibited the specimen. A man, aged 46, was admitted into Sunderland Infirmary on December 6th, 1887. He stated that he had suffered from great pain in the epigastric region for nine weeks, and that eighteen months ago he had, on one occasion, noticed blood in the urine. A large tumour, of the size of a cocoa-nut, could be felt in the right lumbar region, globular, movable, of semi-solid feel, and painful on pressure. The urine was alkaline, and faintly albuminous, specific gravity 1008. Microscopical examination showed blood discs, a few pus corpuscles, and two or three multi-nucleated round cells, with renal epithelium. The tumour was removed by median abdominal section. The patient never rallied from the operation. A section of the growth examined under the microscope showed it to be a lympho-sarcoma. A small nodule of similar structure was found in the left kidney after death.

The Recent Additions to the Materia Medica.—Dr. DRINKWATER read a paper in which he described the action and uses of those drugs introduced within the last five or six years.—A discussion followed, in which the PRESIDENT, Messrs. HOPGOOD and WHITEHOUSE, and Drs. BRADY, LOW, and SQUANCE took part.

Eye Diseases.—Dr. LOW read a paper on the importance of diagnosis in relation to treatment of certain eye diseases, namely, keratitis, iritis, and glaucoma.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

PATHOLOGICAL AND CLINICAL SECTION.

FRIDAY, NOVEMBER 25TH, 1887.

A. S. UNDERHILL, M.D., in the Chair.

Tubercular Nodules on Iris.—Dr. YOUNG showed, for Mr. EALES, a lad, aged 14 years, in whom, on the iris of each eye, there were several round, yellowish, vascular nodules projecting from the anterior surface, some on the body of the iris and others at the angle of the anterior chamber. They had existed for eight or nine weeks, were unaccompanied by pain, and attended with little or no inflammation, and did not yield to treatment. Mr. Eales considered them to be tubercular in nature.

Cephalic Bruit.—Dr. SIMON showed a girl aged 10 years, who presented a typical example of the cephalic bruit. This was best heard over the mastoid and occipital protuberances, but was audible over the whole cranium. She was in excellent health, neither anæmic nor evidencing chronic hydrocephalus. The bruit was of several years' standing, was systolic in rhythm, and only slightly modified by pressure on the carotid artery.

Embolism of Retinal Artery.—Dr. SUCKLING showed a case of embolism of the central artery of the retina, occurring in a man suffering from mitral stenosis. The sight of the right eye was completely lost, and the usual ophthalmoscopic appearances were present.

Lateral Curvature.—Mr. MORRISON showed a girl, aged 13 years, with extreme rotary-lateral curvature. The case illustrated a fact well known to hospital surgeons in that district, that lateral curvature

was not uncommon in the lower grades of society.—Mr. E. L. FEEER remarked on the frequency with which he met lateral curvature amongst the working classes.—Mr. BARLING also agreed as to the frequency of this condition among the poor.—Mr. MAY and Mr. CLAY also made some remarks.

Suture of Patella.—Mr. HASLAM showed a man, aged 30, whose patella he had sutured for a compound fracture last Christmas. The patient was able to resume his occupation as a porter early in July, since which time he had done from twelve to fourteen hours' work every day.

Tubercular Tumour of Breast.—Dr. HOGGEN exhibited microscopical sections of a tumour removed from the breast of a middle-aged woman. In structure it was found to be distinctly tubercular. The patient otherwise enjoyed good health. The case was admitted as scirrhus, and considered as such at the time of operation.

Preparations of Extra-uterine Pregnancies.—Mr. LAWSON TAIT exhibited a series of specimens of extra-uterine pregnancy in all stages of its development from the earliest known case of tubal rupture, which apparently had occurred between the third and fourth week, up to a section of a cadaver at full term. The interest of these cases lay chiefly in the fact that they completely established the view as to the pathology of extra-uterine pregnancy which Mr. Tait had first published in 1873; that all extra-uterine pregnancies were due to the impregnation of the fertilised ovum on the denuded wall of the Fallopian tube; that the tube was distended up to its bursting point, which generally was from the tenth to the thirteenth week. The condition of the subsequent pregnancy depended entirely upon the point at which that rupture took place. If the rupture was into the peritoneal cavity then death took place from hæmorrhage, and twelve of the specimens shown were illustrations of this. If, on the contrary, the hæmorrhage took place into the cavity of the broad ligament, the hæmorrhage was slight, and the pregnancy might go on to full term. Many of these cases, however, did not go to the full term; the fœtus died, and was thrown off by suppuration through the bladder, rectum, or into the vagina, or ended in the formation of a lithopædion. A few well recognised examples of these were found in almost any museum. The minority of cases went on with the child living to full term, and could be operated upon. Mr. Tait had operated seven times under such circumstances. That the danger of rupture into the peritoneum was great was shown by the case of early rupture alluded to, where the patient was well at two o'clock in the afternoon, and was dead from hæmorrhage from a small point of rupture in the tube at nine o'clock at night. In occasional instances, if rupture took place into the abdominal cavity, the placenta was separated from the tube and obtained new attachments. As one example he showed a preparation from a patient in Nottingham—to which town Mr. Tait was suddenly summoned to perform abdominal section on account of the condition of ruptured tubal pregnancy previously recognised by Drs. Hunter, Mackie, and Brookhouse. He opened the abdomen, removed the fœtus, the placenta, and stump of the tube, and tied the latter. As soon as this was done the brisk hæmorrhage ceased, and a part of the placenta which had become implanted on intestine at the back of the uterus was removed, and the sites of it smeared over with solid perchloride of iron. The patient had made a perfect recovery.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

THURSDAY, DECEMBER 8TH, 1887.

M. M. DE BARTOLOMÉ, M.D., President, in the Chair.

Spreading Cancer of the Breast.—Mr. COOMBE showed a specimen of extra-uterine fibroid, and read notes of the case. The patient, a woman, aged 43, was admitted, under the care of Mr. Jackson, to the infirmary on October 11th, suffering from diffused cancer of both breasts, together with the chest wall and part of the back. The total duration of the case was about eleven weeks, and death took place from exhaustion and embarrassed breathing, due to the hardened and hypertrophied condition of the chest walls. The *post-mortem* showed no impaction of any of the internal organs; but a large pedunculated tumour was found attached to the fundus of the uterus, which, had caused no symptoms during life, and was not diagnosed.

Dislocation of the Head of the Femur on to the Pubes.—Mr. PYE-SMITH related this case. The patient was a man, aged 56. Reduction was effected, twenty-two hours after the accident, by traction in the axis of the limb in a slightly over-extended position, combined with rotation inwards.

THURSDAY, DECEMBER 22ND, 1887.

Thoracic Aneurysm.—Dr. DYSON showed a railway spring mak r

aged 33, with thoracic aneurysm. The treatment was absolute rest in bed, and iodide of potassium in increasing doses; he was now taking fifteen grains three times a day. The diet was the ordinary liberal diet of the infirmary, with no special restrictions; great improvement in the size of the tumour had taken place.

Paralysis of the Musculo-Spiral Nerve from Pressure during Sleep.—Dr. SIDNEY ROBERTS introduced this patient, a gardener, aged 30. He went to bed on December 5th in his usual health, but awoke the next morning with paralysis of the extensors of the wrist, the long extensors of the fingers and thumb, and the supinators, and a feeling of "pins and needles" in his left hand; the extensors of the elbow were not paralysed. The paralysis and numbness had continued, and the thickest part of the left forearm was now half an inch less in circumference than the right. Dr. Roberts stated that it was evident lead poisoning was not the cause, and referred to the absence of symptoms of such a condition. There was no history or sign of any traumatic lesion or violent contraction. There was some doubt as to its being rheumatic.

Miners' Nystagmus.—Dr. S. ROBERTS also introduced a patient, aged 25, who had worked in a coal-pit for seventeen years, but only for the last eighteen months had done "holeing," working on his side. He complained of his eyes first about a month ago, but continued to work up to a fortnight ago, when he was compelled to desist. The oscillations were particularly marked in the left eye, and were vertical in direction; in the right the globe rotated round its antero-posterior axis. The fundus of both eyes appeared healthy, except for the presence of a myopic crescent in the left eye, which was also amblyopic.—Remarks were made by Mr. SNELL, Mr. JONES, and Dr. JOHNSON.

Pneumonia occurring in Children.—Dr. GWYNNE read this paper, in which he said that pneumonia at the apex was by no means so common as some writers had asserted. He drew attention to the prominence of head symptoms in these cases, sometimes at an early stage, puzzling the medical man as to whether he had to deal with a case of meningitis or not; cough being by no means a prominent symptom, and often being quite absent for days. He referred to the danger of collapse of lobules due to whooping-cough and measles, and related the history of one of these cases of chronic pneumonia, the result of an attack of whooping-cough a year before.—The following joined in the discussion: Mr. JEFFREYS, Dr. DYSON, Mr. JACKSON, Mr. RECKLESS, Dr. MARTIN, Mr. BANHAM, Dr. S. ROBERTS, and the PRESIDENT.

PLYMOUTH AND DEVONPORT MEDICAL SOCIETY.

MONDAY, DECEMBER 12TH, 1887.

WILLIAM HENRY PEARSE, M.D., in the Chair.

Radical Cure of Hernia.—Mr. C. BULTEEL read a report on seven successful cases of Spanton's operation for the radical cure of hernia, performed at the Royal Albert Hospital. He compared the operation favourably with Wood's, both as to simplicity and results.

Diagnosis of Tabes Mesenterica from Starvation.—Dr. E. MEERES read a paper on a case of medico-legal interest, involving the differential diagnosis between tabes mesenterica and starvation from neglect.

Abdominal Section in Tubercular Peritonitis.—Mr. W. J. SQUARE referred to a case of tubercular peritonitis that had been benefited by abdominal section, performed through error in diagnosis.—Dr. BAMP- TON related a similar case with equally happy result.

Herpes.—Mr. W. J. SQUARE read a paper on herpes, believing the eruption to occur frequently in persons of the gouty diathesis.—The PRESIDENT had noticed in India that herpes and ague alternated, the ague disappearing as the herpetic eruption developed.—Mr. C. BULTEEL instanced a case of abortive herpes on the forearm, followed by pain, œdema of wrist, and symptoms of peripheral neuritis.

Postponement of Paper.—A paper on alcoholic and rheumatic neuritis, by Dr. BAMP- TON, was postponed for lack of time.

Pseudo-glioma.—Mr. J. E. SQUARE showed a case of pseudo-glioma.

RESORCIN IN CANCER.—Resorcin has been used with excellent results in the treatment of cancerous growths on the face, in the form of an ointment containing equal quantities of resorcin and vaseline. This mixture is applied first; an ointment containing 20 grammes of resorcin and 30 grammes of vaseline is then applied. The ointment forms eschars on the surface of the growth. These eschars fall off when pure or iodoform vaseline is applied; fleshy granulations subsequently appear, and healthy cicatrization rapidly follows.

REVIEWS AND NOTICES.

A SYSTEM OF GYNÆCOLOGY BY AMERICAN AUTHORS. Edited by MATTHEW D. MANN, A.M., M.D., Professor of Obstetrics and Gynæcology in the Medical Department of the University of Buffalo, New York. Volume 1. Illustrated with 3 Coloured Plates and 201 Engravings on Wood. Edinburgh: Young J. Pentland.

(SECOND NOTICE.)

A GENERAL review of the first volume of the *System* will be found in the JOURNAL of December 3rd, page 1219, together with some notice of the anatomical and teratological articles which it contains. A brief criticism will now be given of the remaining papers in the volume.

Dr. Egbert Grandin writes on "Gynæcological Diagnosis," in an article of value to the specialist, but of little service to general surgeons or practitioners, and useless to the student. The copious illustrations of instruments are a commendable feature in this article, for what is mentioned in the text ought to be represented by art, even at the risk of causing a book to assume the appearance of a dealer's catalogue. The advisability of describing a multitude of specula and rensula is quite another question. Dr. E. C. Dudley, of Chicago, contributes "General Considerations of Gynæcological Surgery." His advocacy at pages 328 to 332 of "not aesthetic, but surgical cleanliness," is praiseworthy; we fear that few specialists live up to his idea. The observations on the cleanliness of lubricating substances used in the consulting room and operating theatre may profitably be read by every hospital physician and general practitioner. In the paragraph on materials for sutures, no mention is made of silk-worm gut, now so largely employed. Dr. Alexander Skene's "General Therapeutics" will prove useful to the practitioner. We should have liked to have found more about ergot, especially some discussion of its action in combination with iron, as distinguished from its effects when taken alone: That some iron salts may destroy or neutralise ergotin in solutions, there can be little, if any, doubt.

"Electricity in Gynæcology" is the name of a paper by Dr. Rockwell, who is known as the author, conjointly with Dr. Beard, of a work on *Medical and Surgical Electricity*. He writes temperately on his subject. His summary of the experience of Apostoli and Englemann is honestly expressed; these specialists, Dr. Rockwell states, "have treated a large number of cases, and claim most excellent results. Although the tumour is not made to disappear, in every case growth has been arrested, and, in many instances, the size of the tumour markedly diminished." Dr. Gill Wylie writes on "Menstruation and its Disorders." The paragraphs on amenorrhœa are satisfactory; we are glad to see that no operation for its cure is mentioned. The important subject of vicarious menstruation is insufficiently discussed, without any notice of the sources of fallacy in diagnosis indicated by Dr. Matthews Duncan and others. Dr. Wylie, in speaking of dysmenorrhœa, gives a clear demonstration of his own treatment by dilatation with Sims's instrument, and the application of pure carbolic acid and iodoform to the uterine cavity, the cervix being guarded by a special "protector." Dr. Reeves Jackson's "Sterility" is an excellent article, highly valuable for reference at least; but we deplore his open defence of artificial impregnation, and his quotation of Dr. Eustache's sophisms, expressed in language recalling the worst type of ethical pedantry in vogue ninety years ago. The "morality and religion" which, according to Dr. Eustache, do not condemn the practice in question are the homologues of the religion which advocated inquisitions, and the morality which considered the judicial murder of political enemies as consistent with abstract declarations of liberty.

The editor, Dr. MANN, contributes a sound and readable treatise on "Diseases of the Vulva." Under "lupus," Dr. Matthews Duncan's and Mr. Hutchinson's opinions are duly considered. The term "kraurosis vulvæ," now frequent in gynæcological literature, should have been noted and explained. Dr. Mann carefully distinguishes between abscess of Cowper's duct and abscess of Cowper's gland, and speaks of the gonococcus. He might have further mentioned the researches of Dr. Bumm and others, which seem to show that, when the gonococcus alone invades Cowper's gland, its epithelium is destroyed, and the gland undergoes cystic degeneration; whilst, when a septic germ follows the specific germ, suppuration rapidly occurs. Dr. Thaddeus Reamy writes on "Subinvolution of the Uterus and Vagina." He summarises the opinions of authorities very clearly. The subinvolution of the vagina is, in reality, the same condition described by Hart and Barbour where the increased mobility of the anterior pelvic

viscera, natural during pregnancy, is said to continue after childbirth through well-known reasons, and favours every form of prolapse.

In preparing the three monographs on Inflammation in and around the Uterus and on Pelvic Hæmatocele, the authors have had to contend with great difficulties. Dr. Chauncey Palmer writes on "The Inflammatory Affections of the Uterus." We are glad to find that at page 543, in describing acute endometritis, he does not speak of the cervix being tender. There are very few conditions in which that part of the uterus is highly sensitive to touch. Endometritis remains far too much a literary rather than a clinical or pathological disease. The headaches and hysteria, given by Dr. Palmer as symptoms of chronic general endometritis, would be attributed, by other writers, to tubal disease, and by others to perimetritis. When Dr. Palmer discusses more tangible questions, he writes well, as in his paragraphs on erosion of the cervix.

Dr. Richard Maury, in writing on "Peri-uterine Inflammation," has had to deal with questions a little less vague than those included in Dr. Chauncey Palmer's task. Dr. Maury begins well with general pathological and anatomical observations. Further on, however, we do not find good and distinct summaries of the important doctrines of Courty, Bernutz, Gaillard Thomas, Matthews Duncan, and Guérin. The intricate details of their several doctrines are mixed up in the text, and clinical facts are blended too much with pathology. Guérin's *adéno-phlegmon juncto-pubien* is frequently mentioned in medical literature, yet it is only indirectly indicated, and not named, at page 709—an oversight in a book of reference. Dr. Maury takes care to note the important differences of opinion as to the spreading of parenchymatous inflammation to the peritoneum, and the reverse condition. The concluding paper, "Pelvic Hæmatocele and Hæmatoma," by Dr. Van de Warker, is written well up to date, especially the passages on surgical interference.

The index is so complete that the value of the *System* is thereby greatly increased; and, on the other hand, the critic is enabled to find out omissions in the text.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS, IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

LANOLIN ANHYDRICUM (LIEBREICH): LANOLIN PURISSIMUM (LIEBREICH).

We have received from Messrs. Burroughs, Wellcome and Co., Snow Hill Buildings, two specimens of Liebreich's lanolin, anhydrous, and pure lanolin, which are such an improvement of this basis as first brought out that they are well worthy of report. The lanolin anhydricum (Liebreich) is, we believe, now preferred by dermatologists in the treatment of cutaneous affections, especially for moist surfaces, and is perfectly adapted for the application of medicaments to mucous surfaces, such as those of the nares, mouth, uterus, vagina, or anus. It has also special and unequalled advantages for the purpose of employing liquids in the form of ointments. The anhydrous and pure lanolins of Liebreich now forwarded to us are of a light creamy tint, odourless, and very slightly adhesive, so that certain objections which belonged to the earlier forms of this new and valuable therapeutic agent no longer apply.

In the making of ointments, lanolin should be used with a diluent, and the great miscibility of this keratine fat with all medicaments and the great miscibility of this keratine fat with all medicaments and the great miscibility of this keratine fat with all medicaments and the great miscibility of this keratine fat with all medicaments gives it a unique place as an unguent base. Its peculiar features are its purity, antiseptic quality, and the fact that it does not become rancid or harbour germs. In this new form lanolin comes very near to perfection in those qualities of an unguent basis that are claimed for it.

THE INVALID BED ATTACHMENT (GOODWIN'S PATENT).

THE invalid bed attachment invented by Mr. Goodwin is a contrivance for contributing to the comfort and facilitating the nursing of cases of severe or chronic illness. The patient rests upon a canvas sheet attached to an oblong iron frame, the length and breadth of an ordinary single bedstead. When it is desired to move the patient, this iron frame is attached to ropes depending from a stout horizontal beam which projects across the bed; the beam is attached to a strong vertical support, which rests on a heavy foot placed under the bed at one side. By turning one of four cranks the patient may be placed in any desired position, his head or feet can be raised or

lowered, he can be turned on one side, he can be lifted off the bed in the canvas sheet, which then can be adapted to serve either as a "lounging chair" or a hammock; all these movements the nurse can effect with the greatest ease to herself and without putting the patient to any exertion; all the movements also may be performed so slowly and gradually as to be almost imperceptible. When the patient has been raised from the bed, the apparatus can be rotated so that he can be swung off the bed while it is being made and aired, and can be brought to a window if one be near at hand. When not in use the beam can be removed, and the upright unstopped so that only the foot remains, and as it is mostly under the bed, it does not obtrude upon the eye either of the patient or his attendants. The contrivance is simple in use, and can be worked without difficulty after a few minutes' practice; it is stated that the mechanism is not liable to get out of order. The apparatus, which is sold at a moderate price, may be seen and tested at 66, Ludgate Hill, E.C.¹

MULES'S "ARTIFICIAL VITREOUS INSERTER."

This instrument is used in conjunction with Dr. Mules's evisceration scoop, for the operation of introducing an artificial vitreous; it is designed to facilitate the operation of introducing glass globes into

the cavity of the eviscerated sclerotic. Hitherto the insertion of these globes has been a troublesome feature in the operation, necessitating the use of four pairs of forceps by three people, to hold open the flaccid sclera and introduce the globe. One hand of the operator now suffices, as the end of the instrument passed into the cavity is opened by the downward push of the piston acting on the glass globe, the right-angled points catch and hold the edges, whilst the globe itself dilates the opening *ad maximum*, and drops in; should the aperture be insufficient to admit the globe, it should be enlarged under pressure by nicking its edge. The appearance of the instrument so obviously speaks for itself, that further explanation is unnecessary, except that to introduce the sphere within the cage, the pusher is pressed down until the curved ends of the springs are sufficiently wide apart; they are then placed over the globe, and with a little pressure the sphere jumps into the cage. The instrument is made by Armstrong Brothers, Feansgate, Manchester.

pressure the sphere jumps into the cage. The instrument is made by Armstrong Brothers, Feansgate, Manchester.

PINOL (BURROUGHS).

"PINOL" is the name adopted by Messrs. Burroughs, Wellcome, and Co., of Snow Hill Buildings, for the pure essence or volatile oil obtained by distillation of the needles of *Pinus Pumilio*. The medicinal properties of this oil have been shown to depend in large measure upon the altitude at which the trees containing it grow. The oil derived from trees above the line of perpetual snow in the Alps is much superior to that derived from trees growing at lower altitudes. Messrs. Burroughs and Wellcome certify that their pinol is derived solely from trees growing above the snow line.

Pinol has not as yet been extensively employed in England, but the value of "pine treatment" (that is, the treatment by the products of the *Pinus Pumilio* in some form or other) has long been recognised

¹ The statement in the prospectus that "there are at least 105,000 doctors practising in the United Kingdom" is, fortunately, utterly erroneous; the conclusions drawn from the statement must, therefore, be incorrect.

on the Continent. It is there employed, and with considerable success, in a variety of diseases of the respiratory organs, as well as in rheumatism and gout.

The Ext. *Pinus Pumilio* (Burroughs) consists of the filtered residuum left in the still after the distillation of pinol. This is for external application only. A warm bath containing this extract is stated to be very beneficial in thoroughly cleansing the skin, and greatly to facilitate the absorption of pinol subsequently applied. It may also be made into ointment, liniment, or plaster, directions for making which Messrs. Burroughs and Wellcome send with each package.

GALE'S OBSTETRIC CONES.

SINCE the local anæsthetic properties of cocaine have been discovered, among the many purposes for which it has been applied is that of relieving the earlier labour pains by painting with it the os uteri in primiparæ, or when the os is rigid; but in order to do this adequately the use of a speculum is necessary. The obstetric cones made by Gale and Co., 15, Bouverie Street, do away with this difficulty. They are hollow, made to fit the index finger, and can thus be very readily applied to the part desired. They are made with one, two, or three grains of cocaine, the excipient being oil of theobroma, and they also contain three grains of boric acid. The excipient itself acts as a lubricator to the parts. Therapeutically they fulfil their purpose very well, and from a pharmaceutical point of view they seem to be incapable of further improvement.

"THE LEICESTER" ADHESIVE PLASTER.

This is made by A. de St. Dalmas, of Leicester, and is a strapping of a very serviceable kind. The plaster is spread upon stout holland in rolls of six yards in length, and of the very convenient breadth of about nine inches. If kept in a fairly cool place the layers of the roll do not adhere together. It has great adhesive power, but in spite of this it can be easily removed when required. It contains no resin, and altogether it fulfils all the requirements needed in "strapping" either for hospital or general use.

SACCHARIN.

DR. LESLIE PHILLIPS writes: A sample of this supplied me by a firm of chemists has a strong smell of chlorine, while an alkaline solution of the same sample has a distinct odour of essential oil of almonds, the artificial variety of which flavouring substance is, like saccharin, a coal tar product. A patient for whom I ordered an elixir of saccharin with sodium bicarbonate to sweeten tea invariably vomited after taking tea so sweetened, and she stated that it was the after taste, of an iron-like nature, which seemed to excite the nausea and vomiting.

* * A sample of saccharin now before us has certainly no odour of chlorine. It has an odour suggestive of essential oil of bitter almonds, which practically disappears on the addition of an alkaline solution (for example, of bicarbonate of sodium). A solution of it leaves a persistent after-taste, but this does not resemble iron. We may point out that M. Maumené, in the *Chemical Reporter*, January 23rd, 1887, pointed out that a sample examined by him was not homogeneous. Recent chemical experiments with various specimens have led to somewhat discordant results, and seem to point to variation in the composition of the specimens of saccharin examined. It seems very probable that saccharin as now in the market may vary considerably; but it is to be hoped that this variation may speedily cease, as it should in the case of a substance stated to be of a definite chemical nature.

FÆCAL LODGMENTS.

DR. WARD COUSINS (Senior Surgeon to the Royal Portsmouth Hospital) writes: In the *Journal* of December 24th, Dr. Alexander Duke describes a novel contrivance which he has designed for the treatment of impacted feces in the lower bowel. By the aid of this ingenious instrument the operator can boldly penetrate the hardened mass, and then inject into the rectum above it a continuous stream of fluid, so that, after a soaking and softening process, the accumulation can be readily broken up and finally washed away.

I quite agree with Dr. Alexander Duke that any operation of this kind must always prove a very unpleasant surgical necessity, but I cannot see how any method of tunnelling the fecal plug can save the patient a "vast amount of pain," or render the removal of the lodgment less disagreeable to the surgeon.

In any case of fecal accumulation—after the failure of the usual oil injections and large enemata—it is my practice to administer an anæsthetic to the patient, and, with the fingers well protected with soap, to dilate the anal orifice just as in ordinary rectal operations. The manipulation soon stimulates contraction, and leads to the expulsion of the impacted mass. Sometimes the escape of the lodgment may be hastened by the use of a spoon. In this way I removed not long since a three-ounce glass bottle from the lower bowel.

NEW VAGINAL SPECULUM.

MESSRS. EVANS and WORMMULL, with reference to Messrs. Arnold's statement in the *Journal* of December 24th, deny that the speculum described by Dr. Floyer in the *Journal* of November 19th in any way resembles Messrs. Arnold's. Dr. Floyer designed his speculum with a view to its being easily and quickly taken apart, so that it can be thoroughly cleaned; and his idea is well carried out, the speculum only consists of two blades worked by a side screw, on the removal of which the whole falls apart; while the one referred to is regulated by a screw at the bottom, and is so constructed that only a mechanic can take it apart or put it together again.

BRITISH MEDICAL ASSOCIATION.
SUBSCRIPTIONS FOR 1888.

SUBSCRIPTIONS to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches [are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the West Central District Office, High Holborn.

The British Medical Journal.

SATURDAY, JANUARY 7th, 1888.

TREATMENT OF PSORIASIS BY IODIDE OF POTASSIUM.

THE Norwegian physicians, Dr. Greve and Dr. C. Boeck, have recommended large doses of iodide of potassium for the cure of psoriasis. Dr. Haslund has given this treatment an exhaustive trial in the Commune Hospital in Copenhagen, and in an article in the *Viertelj. f. Derm. u. Syphilis*, 1887, 3 Heft, confirms the statements of these physicians. A very remarkable fact established by Dr. Haslund's experiments is that iodide of potassium can be tolerated in much larger doses than had been previously imagined. He gave the drug in many cases in doses that must be considered enormous. In the case of one man he went so far as to give 50 grammes in a day, and in a number of cases he gave 30 and even 40 grammes a day.

It would appear from a tabulated statement in the paper that in forty cases a complete cure of the psoriasis was attained, whilst in four others there was considerable improvement. In six cases no benefit followed. No reason could be detected for failure in these six cases. Of the forty cases which were cured, twenty-four were men, three women, and thirteen children under 15. Most of the cases were chronic, but five of them were acute and recent. The duration of treatment varied from seventeen days to eleven weeks. In the cases of the men the average time was five weeks; in the cases of the three women six, ten, and eleven weeks respectively. In the cases of the children the time was from five weeks to fifteen, the average being nine to ten weeks. Taking no account of six cases in which the average of treatment was only seventeen to twenty-five days, the average of all the other cured cases was slightly over seven weeks. In all the six cases in which a cure was so quickly attained, the eruption was chronic and almost universal.

The disease began to subside in some patients when the daily dose had reached from 7 to 8 grammes, in some 10 grammes, but in most of them in larger doses; in others, only when 20 or 30 grammes daily were given, and in one patient a cure did not begin to show itself until the daily dose was 35 grammes. The total quantity required for a cure varied in men from 160 to 1,390 grammes, in women from 520 to 1,328 grammes; and in the children from 277 to 1,520 grammes. In most of the cases, after the disease once began to disappear, only a short time elapsed until the skin became quite smooth.

Dr. Haslund begins treatment with comparatively moderate doses, but rapidly increases them. It is remarkable that in all the cases slight signs of iodism were observed only in ten, but in none of these was it necessary to suspend the cure, although the doses were in consequence increased more slowly. With the larger doses there was, in seven cases, disturbance of the digestion, which ceased on the dose

being diminished to one-half for a few days, it being very seldom necessary to suspend the iodide altogether. In two cases patients suffered from headache and giddiness; in one patient the pulse was for one day irregular; in two cases there was slight albuminuria, which continued eight days in one, and in the other only for a single day, but it was not found necessary to suspend the iodide.

In one case the symptoms of iodism were severe, indications of paralysis of the heart having become threatening without being actually dangerous. In most of the cases there was not a trace of iodism observed, in spite of the extraordinary doses which were given. Extraordinary indeed the dose must be considered when a girl of 14 years of age took 40 grammes a day, and a girl of 9 years of age had 35 grammes. In two cases it was impossible to continue the iodide on account of idiosyncrasy. A woman, 30 years of age, after one dose presented an appearance resembling that of erysipelas of the whole face, and in her case toleration could not be established. One man, even with very small doses, was so violently affected with headache, sickness, salivation, lachrymation, angina, sinking, and diarrhoea, that the treatment had to be given up.

In three cases the blood was examined during the treatment, and it was found that the number, size, and form of the blood corpuscles were not altered.

Dr. Haslund considers himself justified, after these experiments, in considering that we possess in iodide of potassium, given in large doses, a remedy which can with considerable certainty be relied on to cure an attack of psoriasis, and further that at the present time we know of no remedy which, taken inwardly, can cure it in so short a time. He does not believe that it will prevent relapses, but recommends that iodide should be given for some time after a cure has been obtained.

The most striking apparent effect of the large doses was the quickening of the pulse, which, after ten to fourteen days of treatment, usually reached 100, and then went slowly up to 130 per minute.

The urine was systematically examined in the cases of four persons in order to determine whether the iodide of potassium increased or diminished the quantity of urea. From these examinations it appears that iodide of potassium, even when given in very large doses, has no effect on the excretion of urea. The amount of urine quickly increased or diminished in proportion as the dose was raised or lessened.

The alleged power of iodide of potassium to diminish fat and lead to shrinking of the glandular tissues was not confirmed. In those persons who suffered, not only from psoriasis, but from chronic swellings of the glands, the glandular swellings remained at the end of the cure unchanged. With reference to the supposed atrophic effect which the drug is thought to have on the testes, ovaries, and mammae, Dr. Haslund states that in the female patients to whom large doses were given no diminution in the size of the mammae was observed; on the contrary, in those of them who increased in weight during the cure the mammae became larger. In regard to the ovaries, no examination was made, but he assured himself that in the male patients the testes underwent no change.

Cases of catarrh of the respiratory organs and of the conjunctivæ were few, and in these so slight that no regard was paid to them; when they were present it was usually at the beginning of the cure. Bronchitis was never produced. The perspiration was either not increased, or so little that the increase was not observed. In only a

few patients was the saliva increased, and that only temporarily. In one, however, there was decided salivation.

Those members of the profession whose studies and duties lead them to be specially interested in the action of drugs, will do well to give careful attention to Dr. Haslund's paper. Perhaps it is not out of place to remind those who might be led to repeat Dr. Haslund's experiments that his patients were under close observation in hospital during the whole period of treatment, and that it is only where constant watchfulness and care can be secured that it can be desirable in the meanwhile to imitate Dr. Haslund's treatment by these heroic doses.

CREMATION.

SIR HENRY THOMPSON may be justly regarded as the pioneer of the movement in this country in favour of cremation as a means of disposing of the dead without subsequent injury to the living. The famous paper in which he discussed the subject in 1874 in the *Contemporary Review* awoke active discussion, and created a considerable force of public opinion in favour of urn-burial. This ancient procedure, old enough to be a novelty in our civilisation, has had to encounter many prejudices, and all that opposition which arose from centuries of habitual use of inhumation. The controversy which arose out of Sir Henry Thompson's paper did not, however, end in mere words. Simultaneously with the practical efforts to bring cremation to experimental test in other countries, a small Society was established here, of which Sir Henry Thompson, Sir T. Spencer Wells, and Mr. Ernest Hart, were the medical members of Council. This Society, known as the Cremation Society of England, took the necessary steps for erecting a crematorium at Woking, under the direction of Mr. Eassie, C.E. It has its offices at 11, Argyll Street, W. It has ever since quietly pursued its way without attempting to force the growth of public opinion, and contents itself with offering to those who desire it the means of cremation, conducted under strict precautions and in an effective and innoxious manner. Writing in the *Nineteenth Century*, which is now edited by the gentleman who originally conducted the *Contemporary Review*, Sir Henry Thompson reviews the progress made, and combats some of the objections which have been urged to cremation, while urging anew the arguments in its favour. He explains the state of the law, which, as laid down by Sir Fitzjames Stephen, permits cremation, and contrasts it with the earlier dicta of Sir Richard Cross when Secretary of State, who formally announced to the Cremation Society that he would oppose their proceedings. Sir Henry Thompson points out that the existing state of the law in respect to cremation does not sufficiently provide for the public safety, and he describes the careful provisions by which his Society fences round the performance of urn-burial with a view to obviate the medico-legal objections which have more than once been urged against cremation as a possible means of concealing crime.

Sir Spencer Wells and Mr. Frederic Harrison have so recently preceded Sir Henry Thompson in their reiteration of the arguments in favour of cremation from the point of view of public health and social convenience, that we need not here recapitulate Sir Henry Thompson's logical, vigorous, and effective pleading under these heads. His paper should be read from beginning to end by everyone who wishes to know all that can be said in favour of cremation and how the objections sometimes urged against it can be adequately met.

The crematorium at Woking is in effective operation, and during the past year sixteen cremations have taken place there. Cremation

is effected at a small cost, and under rigorous restrictions as to certificates and *post-mortem* examinations, far more effective than those which are at present applied to ordinary interment. It would be premature to attempt to predict what the future of this mode of disposal of the dead may be in this country; but it is certain that the theological and juridical objections which have been urged against it have to a large extent melted away in face of the practical and carefully measured proceedings of the Cremation Society.

It has, within a short space of time, established itself as a reasonable, practical, and healthy method of disposal of the dead which is compatible with the deepest religious sentiment, and which is capable of being brought within all the requirements of public safety. It is a great thing to have effected so much in so brief a space of time in favour of a procedure which at the outset was met by a violent storm of opposition, and which was alleged to outrage public sentiment. Bishops and archbishops, statesmen, philosophers, and sanitarians representative of most influential bodies, have pronounced in favour of it. The energy and public spirit of a small number of persons have placed at the disposal of the public the means of giving effect to any opinion which exists in favour of cremation, and there can be no doubt that the present essay by Sir Henry Thompson will do much to forward the further growth of a movement which has already made great progress.

THE REGISTRATION OF PLUMBERS.

THE Plumbers' Company has done and continues to do most excellent service to the public, to the cause of public health and sanitary science, as well as to the trade which they represent, by the judicious and well-conceived liberality of spirit in which they have made provision for the education, examination, and registration of qualified plumbers. The scheme which they have adopted has been thought out at the instance of a great conference with the leading members of the plumbing trade, held at the International Health Exhibition, South Kensington, over which Mr. Shaw, the then Master of the Plumbers' Company, ably presided. This scheme in its main features is based on the well-known precedents by which medical men, pharmaceutical chemists, dentists, and veterinary surgeons have organised their respective bodies; so as, on the one hand, to exclude incompetence and false pretence; and, on the other, to provide for a reasonable system of examination and registration, with scientific assistance, guided and controlled by a full representation of all interests. The scheme of the Plumbers' Company, after being thoroughly discussed in the trade itself, and in a number of great towns, and after being submitted to the leading medical and sanitary authorities, has met with what may be fairly described as unanimous approval; and, in the interests of public health, we are pleased to see that, in the large towns where it has been submitted to criticism, it has been heartily accepted.

One of its great merits is that it allows of a remarkable freedom of local development. Its system of local boards and local examinations, acting in unison with the central body, permits local activity, while it provides an adequate uniform method. It excludes those elements of confusion, deception, and jobbery, to which any merely local effort may easily lead; the standing of the company, its representative character, and the sanction given by the presence of men of the highest scientific standing and integrity, furnish the element of security and confidence which the public, the medical profession, and the trade alike, know to be essential to success.

We see, with some regret, that a distinct society has been started in Edinburgh which, while adopting many forms and regulations of the Plumbers' Company, appears altogether to have missed the spirit in which these regulations are devised, and to have been framed under conditions which not only do not afford the necessary guarantees of success to the trade, but which contain many elements having a very undesirable suggestion. It is obvious that any self-appointed council limiting its nominees by its own will, unconnected with the central body, which has the sanction of great public authorities, and of important scientific co-operation, may easily become the means of abuse, and cannot expect to deserve or to retain the confidence either of the plumbers or of the medical profession or to succeed with the public.

The object is not and should not be to afford to any small number of gentlemen, creating themselves as a Council, a monopoly by which outsiders could be excluded and a select few favoured. What is needed is to provide adequate means of examination and registration, and then to leave to the medical profession, to architects, and to the public the right to select their own plumbers from among those who have shown that they are capable of satisfying the necessary tests of efficiency. Any narrow creation of independent local councils, which shall frame their own lists, and select their own members, would totally fail in the object in view. What is wanted is unity throughout the whole kingdom, just representation, the creation of a register for the three kingdoms, and the formation of a class of registered plumbers who shall have fulfilled the necessary minimum tests, of which the trade and the medical profession approve. This is amply provided for in the scheme of the Plumbers' Company, while on the other hand, the scheme proposed by the local association to which we refer appears to us at once inadequate and invidious.

We earnestly hope that the favorable indications of unanimous and conjoint action of the plumbing trade in support of the excellent movement of the Plumbers' Company will continue to meet with uninterrupted success, and that no local attempts to create imperfect local monopolies will meet with countenance.

A MEETING of Convocation of the University of London will be held on Tuesday, January 17th.

THE programme of the annual meeting of the British Medical Association, to be held at Glasgow on August 7th, 8th, 9th, and 10th, is now complete, and will be found at page 38.

DR. C. J. CULLINGWORTH, Professor of Obstetrics and Gynaecology in Owens College, and Physician to St. Mary's Hospital, Manchester, has been appointed Obstetric Physician to St. Thomas's Hospital.

THE Countess of Dufferin's Jubilee Fund, for the supply of Female Medical Aid to the Women of India, has received from the Duke of Westminster a donation of £200.

SOME energetic members of the Medical Staff Corps connected with St. Thomas's Hospital are exerting themselves to raise funds to procure suitable new headquarters for their staff.

A PROPOSAL has been brought before the Municipal Council of St. Petersburg to impose a poll tax of one rouble, in order to provide additional funds for hospital administration. The tax is estimated to produce about one million roubles (£120,000); but the suggestion has not met with a favourable reception, and its adoption is doubtful.

At the last meeting of the Academy of Medicine and Surgery of Naples, Dr. Di Vestra read a report of the inquiries instituted by himself and Professor Cantani into the results of antirabic inoculations. A resolution was unanimously passed, calling upon the Government to subsidise the Italian Antirabic Institution, which is threatened with closure for want of proper pecuniary support.

HER MAJESTY THE QUEEN.

WE understand that Mr. Boehm has consented to undertake the commission for the erection of a statue to Her Majesty the Queen, in commemoration of the Jubilee, in the Hall of the University of London. The funds collected amount at present to £700.

THE BRITISH MEDICAL JOURNAL.

THE volume of the BRITISH MEDICAL JOURNAL just published (July to December, 1887) contains 1,460 pages. This is the largest semi-annual volume of any medical periodical ever published. The volume for the corresponding half-year 1886 contained 1,316 pages. The demands on our space, however, have far more than kept pace with this extension. The pressure on every department is so considerable and so continuous that the plea for brevity, which is now a standing notice in this JOURNAL, is one of ever-increasing urgency. We would earnestly request our contributors, whether of original articles, letters, or other communications, to bear in mind this ever-present difficulty.

SIR TINDAL ROBERTSON, M.D., M.P.

HER MAJESTY has been pleased to signify her intention of conferring the honour of knighthood upon Dr. Tindal Robertson, M.P. for Brighton. Dr. Robertson is the eldest son of the late Mr. F. F. Robertson, of Bath, by his marriage with Anne, daughter of Mr. J. Tindal. He was born in the year 1825, and was educated at University College, London, and at the University of Edinburgh. He became a member of the Royal College of Surgeons in 1850. He was for some years physician to the General Hospital at Nottingham. Of late years, since he became blind, he has resided at Brighton, where he acts as local magistrate, and as chairman of the Brighton Conservative Association. He has been one of the members for Brighton since November, 1886, when he was chosen on a chance vacancy caused by the death of Mr. David Smith. Dr. Tindal Robertson married Elizabeth Anne, daughter of Mr. J. Leavers.

SMALL-POX IN THE NORTH.

THE reports as to the amount of small-pox at Rotherham, imported in the first instance from Sheffield, appear to have been much exaggerated. Mr. J. Hardwicke, medical officer of health of that borough, states that, "owing to the active measures at once taken by the corporation and officials upon its appearance, it is now about stamped out, there being now only five cases in the borough: three in the fever hospital, and two outside, all convalescent." At a meeting of the Leeds Sanitary Committee on Wednesday, applications were received from several places near Leeds for hospital accommodation for small-pox patients. The committee, however, agreed to receive only patients from Morley, which has no small-pox hospital. Another death from small-pox was reported in Leeds on Wednesday.

THE LADY STRANGFORD HOSPITAL.

ADMIRAL INGLEFIELD, reporting on the Lady Strangford Hospital, which has now been in working order for some months, and has been of great service to many sufferers landed from steamers passing through the Suez Canal, points out that, judging from the number already received, more than 200 patients may be expected in a year; and of these, many are likely to be serious cases, chiefly sailors. Last month, 60.8 per cent. of the beds were filled. There have been seven deaths, and fifty-three patients have been discharged cured. Not only from the ordinary steamers, but also from Her Majesty's Indian troopships and other vessels of the Royal Navy, have sick been sent to the

hospital. The committee have still to make up a deficiency of £1,700, and £500 more will be needed to build a separate ward for isolated cases. So many persons are interested, directly or indirectly, in those who pass through the Canal, or many have friends in India, China, or Australia and New Zealand, and not a few are concerned in Egypt, the Canal, or in ships that pass through, that the committee do not hesitate to make this appeal, in hopes that the £2,200 still required for the building fund will be supplied speedily and willingly.

ROYAL MEDICAL BENEVOLENT COLLEGE.

It gives us much pleasure to direct the attention of our readers to the announcement that at the request of an influential deputation from the Council of the Royal Medical Benevolent College at Epsom, the Lord Mayor has consented to take the chair at the biennial dinner on April 17th. This will be the first occasion on which the head of the Corporation has presided since 1856, when Sir David Solomons took the chair. Several members of the House of Lords and the present leader of the House of Commons have also presided. It is a matter of congratulation that the claims of the profession upon the public should be so cordially recognised, and we hope that practitioners of all classes will do their best to make this festival a financial and a social success. The work carried on by the Council of Epsom College is good and deserving of all support. There is perhaps another claim on the Association to co-operate. Dr. Holman, the Treasurer of the British Medical Association, is also the Treasurer of Epsom College. This conjunction of offices and labours will give perhaps to many an additional impulse to aid him in his efforts to provide for the aged, helpless pensioners, and to clothe, educate, and feed the Foundation scholars of the College free of all charge to relatives and friends.

"A WARM SITE."

An interesting point, resulting from an examination of the Meteorological Journals of the late Mr. J. H. Belville and those of the Royal Observatory, Greenwich, was contained in a communication made by Mr. H. S. Eaton to the Meteorological Society at its last meeting. On the eminence on which the Royal Observatory stands the average temperature at night, or rather in the early morning, was in all cases higher than over the low grounds; as this is deduced from the examination of registers which extend over forty-four years, it probably expresses a general truth applicable to similar sites in river valleys and on alluvial soils, and shows perhaps one of the grounds of the growing preference for elevated sites for houses in preference to the low and sheltered situations which used formerly to be so much preferred. Mr. Eaton's statistics do not afford any evidence in support of the suggestion that the climate of the country has changed in the last century; the registers he examined extend, as has been said, over forty-four years (1812-55), but no appreciable change in the mean annual temperature of the air could be detected.

A MODEL ACT.

THE Margarine Act, for preventing the sale of butterine or any compound of butter under any other name than that of "margarine," comes into force this week, and active steps are being taken by the local authorities to carry out its provisions. The provisions of this Act, on which we have already reported, are very severe, and might in many respects be taken as a model for the improvement of the Adulteration Acts generally. The many loopholes which the Adulteration Acts offer to offenders are carefully stopped in this Act; thus the onus of proof that he was in any way deceived as to the nature of the article which he is selling is thrown upon the vendor. The inspector is not compelled to make a purchase of the article and to divide samples; and it is not sufficient that the article shall be colourably what it pretends to be, or that ignorance of its source or origin shall be pleaded. The whole responsibility is put on the vendor instead of, as heretofore, largely on the purchaser,

and the old rule of law, *caveat emptor*, is efficiently abolished. If the Adulteration Acts generally were amended on a similar model, the material well-being of our population, especially of the poorer classes, would be improved. Milk ought certainly to be protected in the same way and to the same extent as butter. It is, however, notorious that skimming and adulteration are still habitually practised with impunity to the extent of at least 15 or 20 per cent., and such is the weakness of the Adulteration Acts that analysts and sanitary inspectors are powerless to stop it. So also as to the numerous mixtures sold as coffee. By the use of various additional titles, and the many other little devices which the Adulteration Acts favour, it is well known that a large part of the coffee and tea sold is fraudulently adulterated to an enormous extent; and, indeed, very few articles of food escape deterioration by fraudulent admixture in some form or other. Were the penal clauses of the Adulteration Acts generally brought into accord with those of the Margarine Act, all this would very soon be put an end to.

BRISTOL EYE INFIRMARY.

AFTER occupying its old home for three-quarters of a century, the Bristol Eye Infirmary has had to respond to the imperative demand for increased accommodation. In the summer of 1886 it was determined to purchase two adjoining houses and a yard, and take prompt steps for the enlargement, and these have now been turned into a capital block of premises, with free internal communication on the various floors, and fitted with appliances for the more convenient and successful carrying on of hospital work. When the furnishing is completed the out-patient department will be adequate for the daily attendance of 150 persons, and accommodation for 18 in-patients. The total expense has been between £3,000 and £4,000, the funds for which are forthcoming.

THE HOUR OF DELIVERY.

AN industrious statistician has recently contributed to a medical journal at Lille, the results of an analysis of one thousand labours, with the precise hour at which delivery took place. He reports that 45 per cent. of the labours terminated between 8 A.M. and 8 P.M., and 56 per cent. between 8 P.M. and 8 A.M. Pushing the inquiry a step further, he found that 23 per cent. terminated between 6 A.M. and midday; 22 per cent. between midday and 6 P.M.; 27 per cent. between 6 P.M. and midnight, and 54.1 per cent. during the night—that is to say, between midnight and 6 A.M. These figures only apply to normal labours, in which nothing interfered with the physiological course, so that they go far to confirm the popular notion which admits the greatest frequency of delivery at night, "conception generally taking place at about that time."

REGISTRATION OF COLONIAL DEGREES.

AN Order in Council has been published extending the provisions of the second part of the Medical Act, 1886, to Ceylon. That Act provided that the *Medical Register* shall contain a separate list of the names and addresses of the colonial practitioners, and also a separate list of the names and addresses of the foreign practitioners registered under the Act. No such lists are yet in existence, but the Order is the first step to the formation of a colonial list. The matter will now have to come before the General Medical Council, which is required to determine whether the diplomas granted in a colony mentioned in such an Order furnish a sufficient guarantee of the possession of the requisite knowledge and skill for the efficient practice of medicine, surgery, and midwifery. In this particular matter of the registration of colonial and foreign degrees, the Act certainly contains some anomalies. At the present time colonial degrees cannot be registered under any circumstances. Clause 16, owing, it is said, to an oversight, only applies to foreign degrees, and not to colonial degrees. It is under this clause that the degrees from the Brussels and other foreign universities have been recently put on the *Register* by registered practitioners who had obtained such degrees before the passing

of the Act. The registration of practitioners holding colonial diplomas and degrees will be governed by Clause 11; it will be necessary to show that the diploma, which must have been recognised by the Council, was not granted while he was domiciled in the United Kingdom, or was granted in course of a period of not less than five years during which he was resident out of the kingdom, or that he was practising in the United Kingdom on the prescribed day, and had been practising there or elsewhere for not less than ten years immediately preceding. As with Ceylon an Order in Council must be in every case issued, and this can only be done if the colony itself affords such privileges of practising as may seem just. Put shortly, the provisions of the Act may be said to be on this head that the Privy Council is charged with the duty of ascertaining that the colony grants reciprocal privileges; the General Medical Council examines into the professional value of the diploma, while the Registrar must satisfy himself of the personal respectability of the candidate.

CULTIVATED IPECACUANHA.

It is satisfactory to learn that a sample of the cultivated ipecacuanha, recently referred to in this JOURNAL as probably imported from Singapore, has, in the hands of Mr. Hare, F.R.C.S.E., yielded results indicating its therapeutic equality with the Brazilian drug. He reports that on comparing a powder of the Indian drug with the ordinary powdered root of the *Pharmacopœia*, he found that in equal doses the action was absolutely identical. In the case of a child, aged seven months, suffering from severe capillary bronchitis, the usual dose of ten grains produced satisfactory emesis and gave relief. When minute doses were subsequently administered, the customary expectorant action was manifested; and, upon alternating the use of the ordinary root with that of the Indian drug, day by day, in expectorant doses, and also, when occasion demanded, in nauseant doses, it was found impossible to distinguish between the two as regards their therapeutic effects.

THE ILLNESS OF THE CROWN PRINCE.

It is with profound satisfaction that we learn, on the highest authority, that the symptoms which caused so much alarm at the beginning of November have almost entirely disappeared. The growth in the subglottic region, which was then looked upon with such suspicion, has now shrunk to a fourth of its former size; the ulcer on its surface has completely healed, and the submaxillary glands, which were enlarged and hardened, are now in a perfectly normal state. The little growth which recently showed itself on the left ventricular band (false vocal cord) sloughed away very soon after its formation, and the ulcerated surface left behind was nearly cicatrised when Sir Morell Mackenzie left San Remo. The Prince is now quite free from the slight but constant feeling of discomfort about the larynx, from which he had suffered since the beginning of last year, and his face has lost the somewhat waxen pallor, which struck so many observers when His Imperial Highness was in England. We are able to state that in the opinion of Sir Morell Mackenzie the appearances in the Crown Prince's throat are now quite compatible with the more severe form of chronic laryngitis. In illustration of this, it may be interesting to quote some remarks from his work on *Diseases of the Throat*, Vol. i, p. 288, where it is stated that "in addition to congestive swelling of the mucosa and sub-mucosa, there occurs in some rare cases an organic thickening or hypertrophy of the soft structures." It is also said there that "nodular excrescences the result of chronic inflammation are often met with," presumably in the rare cases just alluded to. These words were written eight years ago, and the case of the Crown Prince would seem to be a perfect example of the morbid condition which they describe. In addition to the chronic inflammatory process, there is no doubt that perichondritis is also present. In speaking of this affection, Sir Morell Mackenzie (*op. cit.* p. 391) has called attention to the frequency of "impaired

action of one or both of the vocal cords;" and it may be remembered that in the case of the Crown Prince the action of the left cord has been defective for many months past. Whilst, however, there is now good ground for hoping that the disease may be of the comparatively favourable character here indicated, it would be foolish to allow ourselves to take too optimistic a view of the situation. The possibility of the affection being after all malignant, in spite of present appearances to the contrary, must not be too hastily dismissed; and, on the other hand, it should not be forgotten that even the milder complaint, towards which the symptoms seem now more or less definitely to point, is a serious one both in itself and in its possible consequences.

LORD GRIMTHORPE AND THE MEDICAL PROFESSION.

LORD GRIMTHORPE'S facts and arguments appear to be alike influenced in this matter by passion and imagination rather than by sober or accurate inquiring reason. He sets out the number of homœopathic practitioners in Great Britain at 10,000. Is he sure that it is as much as, say, 300? That is the last record which we have at hand, and the list for the last ten years does not appear to be a growing one. Lord Grimthorpe, like Shelley, declares himself in very vigorous language the avowed enemy of intolerance. Shelley's oath was "May infinity and eternity blast me if ever I forgive intolerance." When the froth is blown off the somewhat paradoxical and foaming declarations of Lord Grimthorpe, it will be seen that they are themselves a form of very aggressive intolerance. If Lord Grimthorpe could add a little psychological study to that of the logic of Whately, of which he so comically considers himself to be a monopolist, he would have to admit that the compulsory tolerance for which he clamours conceals only a thirst for a new form of petty despotism. What he really asks for in the name of tolerance is a despotic power over the intelligence and the conscience of the medical profession. He would compel them, if he could, to enter into alliance with those whose dogmas and practice they consider a nullity or a fraud. He may be left to enjoy his opinion "that not a man in this country is foolish enough to believe" that medical men generally are actuated by any other than knavish or cowardly motives in declining to act as allies or accomplices in homœopathic experiments either in or out of hospitals. There is little room for argument with a gentleman who seriously puts forward such a proposition. It is evident, however, that if homœopathic practitioners' shops and patients swarm as numerous as he wildly alleges, his complaint of the lack of opportunity for carrying out their experiments is, at least, exaggerated. The one or two anecdotes which he relates as to the toleration by the Bar, in eminent persons under exceptional circumstances, of practices which are universally reprobated within the Bar, will deceive no one into the belief that ostracism as it used to be called, or boycotting as he prefers to call it, is not a time-honoured means in the Bar, as in other professions, of self-defence against complicity in objectionable proceedings. We do not need to argue with Lord Grimthorpe whether homœopathy be or be not either a nullity or a fraud. Our case is, that such is the conclusion at which the medical profession generally, including without exception all its most eminent men, and all its recognised leaders, have long since arrived. They have had ample opportunities, during the last forty years, of revising that opinion, and of altering it if they had seen any reason to do so, but the simple fact is that they have not. That being so, it will require quite other methods than those which Lord Grimthorpe pursues to persuade them or any other reasonable beings that it is their duty so long as they continue to hold those opinions, either to meet in consultation or to act in concert with those who profess opinions and practise methods of treatment for which they entertain either contempt or disgust, and which they believe, on grounds which are overwhelmingly conclusive, to be either valueless or deceptive. Any attempt to force them into such an alliance is obviously foredoomed to failure. The mere proposal is an effort to establish a silly form of tyranny which reposes on no solid basis either of morality or of social duty.

THE CURE OF HYDATIDS.

AN instructive discussion took place at the Clinical Society recently on three papers dealing with the treatment for the cure or removal of hydatid cysts of the liver and other parts. Opinions differed very much as to the ultimate value of aspirating these cysts, but the explanation of this extraordinary divergence of opinion is probably to be found in Dr. Broadbent's suggestion that the prognosis depended largely upon the nature of the fluid. When this is clear and does not contain, as is often the case, numerous daughter cysts, Dr. Broadbent's experience leads him to anticipate that recurrence will not take place. When, however, the contents consist largely of minor cysts and *debris*, suppuration or recurrence is probable. In any case aspiration ought probably always to be performed, for a certain proportion of cases recover after this simple operation alone, and it must obviously be to the interest of the patient to avoid the risks incidental to a more radical operation. In some cases aspiration fails to afford more than a temporary relief, and surgeons are agreed that in that case the only thing to be done is to cut down upon and extirpate the sac and its contents. The experience of most European surgeons goes to prove that this is most safely done by allowing adhesions to set up, uniting the sac to the margins of the abdominal wound, before proceeding to empty the cyst. Statistics leave no room for doubt on this point. Even a few hours will often be sufficient to prevent any danger of the fluid finding its way into the abdominal cavity, by glueing the sac to the wound. The latter can then be tapped and its removal effected. The most troublesome part of the whole proceeding would appear to be an early and reliable diagnosis. The best way of meeting this difficulty is an exploratory laparotomy, and this few present day surgeons would hesitate to perform in the face of obscure and menacing symptoms.

FOREIGN OPINIONS OF ANTIPYRIN.

M. GERMAIN SÉE was the first to call attention to the very marked influence of antipyrin over pain, whether administered by the mouth or hypodermically. Since he published his series of cases the drug has been employed tentatively in most civilised countries, and the reports are now coming in. With very few exceptions the experiments have been successful. Fränkel, of Berlin, in order to test its anodyne properties, substituted antipyrin for morphine injections in all the cases under his care. In not a single case did he fail to give relief. He employed it in five-grain doses, repeating the injection in an adjacent spot if necessary. He proved that the local action of five grains of antipyrin was about the equivalent of a thirtieth of a grain of morphine. The influence of the drug was manifested in about fifteen seconds, and lasted from six to eight hours. He expresses the conviction that antipyrin may be used with advantage in many cases in which morphine is at present employed. It produces no disagreeable after-results apart from the slight pain of the injection itself. Hirsch, of Hanover, is not less affirmative after a trial of the drug in seven cases of severe rheumatic and neuralgic pain. In the United States, Dr. Waugh, of Philadelphia, has employed it successfully in a series of cases of neuralgia, muscular rheumatism, sciatica, etc. In the treatment of sciatica the relief was more prompt and at least as marked as could have been obtained from the use of morphine. He used it in doses of from two to five grains. Dr. Arca, Professor of Medicine at Buenos Ayres, himself a sufferer from chronic rheumatism, was treated by M. Sée by means of a hypodermic injection of fifteen grains of antipyrin, together with from thirty to sixty grains by the mouth, daily. The result was marked relief, though the pain returned directly he discontinued the treatment. There seems no reason to doubt that in antipyrin we possess a powerful anodyne for pain of nervous or rheumatic origin. Dispensed in the form of tablets, it is easily dosed, and may be administered either hypodermically or by the mouth. Beyond the smarting which follows the injection, no after-effects of moment are produced, and it has rarely been known to give rise to inconvenient, much less toxic, symptoms.

AMBULANCE MOVEMENT AT HAWARDEN.

AN interesting meeting was held last week at Hawarden in connection with the ambulance teaching and nursing class carried on there, Dr. Waters presiding. The results were stated by the Rev. H. Drow, and they appear to be excellent. Dr. Waters, in a speech marked by eloquence, pathos, and humour, referred to the recent history of medical education and of the Medical Act of 1856, which rendered it obligatory that medical men should be qualified in all branches of their profession. He was proud to be able, there in Hawarden, to recall that that Act was passed when Mr. Gladstone was Prime Minister. As a proof of the necessity of good and reliable nursing, he referred to his own experience. When he was resident in Edinburgh Infirmary it was his lot to take fever. In his room he had three physicians attending him. As far as numbers went he was tolerably safe; but it so happened that every night his nurse wrapped herself up in blankets, put a pillow under her head, and fell asleep before the fire. In the morning the doctors came and asked him what sort of a night he had had, and he said he had not slept; but, turning to the nurse, said that she had slept. And so it went on for nine days. He told the doctors what was happening, but all his efforts to convince them that the nurse slept and he was awake were in vain, and he began to reconcile himself to the position. The doctors came in and asked him what sort of a night he had had, and he replied that *she* had had a beautiful night. Then the nurse, before his very eyes, significantly tapped her forehead to let them know that he was wandering. The doctors passed out of the room, and the very first question was, "Has he been raving much to-day?" He himself shouted, "I am not raving, but she is." The nurse was a very distinguished woman, but she wanted her rest. At last one of his doctors came in later at night than usual, and, coming to see him, found his nurse asleep and himself wide awake. His friend was extremely penitent, and he shall never forget the luxury of that one night. The nurse was changed, and in the hands of the new one, who ministered to all his wants, he made a very swift recovery. Nurses of the Mrs. Gamp class were now passing away, owing to the extension of nurses' training institutions. He had tried to establish a nurses' institution in connection with the Chester Infirmary, but the attempt fell through. In these days of over-crowding and crushing mechanical force the spread of the knowledge of nursing and ambulance work must prove of the greatest benefit in diminishing suffering. A demonstration of medical aid in accidents was given by the members of the Sandycroft Corps.

PREGNANCY AFTER REMOVAL OF CANCER OF THE VAGINA.

DR. RÜTER, of Hamburg, describes the following case of this rare disease in the *Centralblatt für Gynäkologie*, No. 33, 1887. The patient was aged 36, married twelve years, and had borne three children; menstruation was regular, and there was no evidence of syphilis. Defecation had been painful for months, and had been attended during the few weeks before she was first seen, on July 1st, 1884, by hæmorrhage from the vagina. The patient was bony and muscular, and not anemic in spite of the frequent bleeding. On rectal examination a hard substance could be felt in the posterior vaginal wall, over which the mucous membrane of the bowel was not adherent. The finger introduced into the vagina encountered at a distance of a little over one inch from the vulvar orifice a hard elevation, which formed the border of the substance detected by rectal exploration, an area of infiltration, tough, with an uneven surface two inches by one-and-a-fifth in diameter. This area occupied the posterior vaginal wall, and reached to within a few millimètres of the reflection of the vagina on to the cervix. The cervix and uterus were entirely free from disease, nor was there any evidence of extension of the new growth into other parts. Touching the brittle tissues of the surface of the growth set up hæmorrhage. There was no fever. The microscope confirmed the diagnosis of epithelioma of the vulva.

On July 23rd, 1884, the growth was removed. The mucous membrane was first set free above and around the upper part of the margin of the growth, so that the vagina was separated posteriorly from its uterine attachment. The bluish, transparent peritonæum was thus exposed; it was accidentally cut through, in fact Douglas's pouch was laid open, and a few drachms of clear, greenish, watery fluid escaped. The aperture was guarded by a refractor. Lower down the growth was detached from the muscular coat of the rectum, which appeared healthy. The entire growth was in this manner quickly detached, scissors being employed; there was but little hæmorrhage. The rent in the peritonæum was closed with catgut sutures. Then the cervix was drawn down and made to cover the hole in the posterior vaginal wall; the raw surface on the cervix whence the vagina had been dissected away was united by deep and superficial silk sutures to the edge of the wound in the vagina. The os externum thus lay almost as low as the vulvar aperture. Sublimate and iodoform were the antiseptics employed in this case. By August 7th the wound had thoroughly united by first intention. On May 15th, 1885, Dr. Riiter saw the patient again. The catamenia had been suppressed since the operation till eleven weeks before this consultation; the right thigh had repeatedly become swollen; the veins did not appear to have undergone distension. The os uteri still lay close to the vulva, and there was no pouch between the cervix and the remains of the posterior vaginal wall, nor any trace of recurrence of the new growth. After May, 1885, the period remained regular till the patient became pregnant at the end of that year. On September 5th, 1886, she gave birth to a child at term, and was able to suckle it. When last examined, on August 1st, 1887, there was no sign of recurrence. The posterior vaginal wall had become lengthened through changes during and after gestation, measuring two inches and a half. Dr. Riiter believes that the swelling of the thigh and the amenorrhœa were due to the dragging down and temporary obstruction of large pelvic vessels caused by the displacement and fixation of the cervix. The influences of pregnancy overcame all traces of obstruction, so that the nutrition of the parts once more became normal.

NATIVE FEMALE EDUCATION IN CALCUTTA.

We all know, and are glad to know, that an effort is being made in India to extend medical aid to native women in India who are cut off by the iron barriers of caste and custom from receiving it at the hands of male practitioners, native or foreign. An attempt is now being made to educate a class of native "women doctors" to meet this want. We have before us a copy of the scheme as promulgated in the *Government Gazette* of Calcutta, published in the *Overland Englishman* of November 29th, 1887. The details of the scheme submitted by the Director of Public Instruction are simply astounding. It is difficult to believe that anyone in the present day can have such an inadequate conception of modern medicine as to lay down such rules as are here authoritatively published by a gentleman holding the responsible position of Director of Public Instruction. According to this enlightened instructor of the public on medical education, all the preliminary knowledge required before entering on the study of medicine is the following:—"Reading and explaining a Bengali book of the standard of difficulty of Raj Krishna Mookirjra's History of Bengal; writing from dictation an easy Bengali book, and arithmetic to easy fractions and simple rule of three." With this amount of mental furniture, Bengali girls, aged 16, are deemed, in the opinion of this public instructor, to be capable of entering on the study of modern medicine, and after three years of study to be turned loose, so far as we can see from the scheme before us, without examination to exercise their skill on their unfortunate fellow-creatures. Here is Sir Alfred Croft's opinion on this extraordinary scheme:—"I am fully aware that it is by no means certain to succeed, owing to the want of education among women in Bengal and to the obstacles which social conditions impose. Material benefits would follow if, happily, it should be success-

ful. If it fails, little or no cost is incurred and no harm done." No harm done! The scheme is cheap, "little or no cost is incurred!" That in the opinion of this educational authority is enough. The Lieutenant Governor of Bengal, not without some misgivings, has given his sanction to this dangerous experiment, not being perhaps better "instructed" than its author. But what are we to say of the medical officers, Dr. Mackenzie, Surgeon-Major Chन्द्रu, and Surgeon-Major Coates, "who are in favour of trying the system." The least we can say is that in giving even a qualified assent to this scheme, they are as much misled as its author and the high official who has sanctioned it. They may plead Dr. Johnson's frank excuse when he fell into error on some literary matter, "Ignorance, Sir, sheer ignorance," but if they are ashamed to offer such a poor plea, as well they may be, then any other excuse they can offer for their weakness in giving assent to such a scheme must be inadequate. We are glad to see that other members of the profession, although their names are not given, had sense and courage enough to withhold their consent from the vain attempt to graft on the education of a school board monitor of a child's class even the simplest elements of the healing art.

SO-CALLED TINCTURA IODI DECOLORATA.

THE alcoholic solution of iodine and ammonia, first introduced by Sir J. Y. Simpson about twenty-five years ago, has, notwithstanding several modifications, remained in general use, and, under the name of "tinctura iodi decolorata," is represented in the Unofficial Formulary recently adopted by the British Pharmaceutical Conference. Various statements have been made at different times as to the actual composition of this preparation, and in a paper recently read before the Pharmaceutical Society at an evening meeting in Edinburgh, Mr. J. Rutherford Hill stated that an examination of four preparations, made according to different formulæ, showed that the iodine in each case existed as iodide of ammonium, together with free ammonia and a slight trace of iodoform. Owing to the solution usually containing about the same percentage of combined iodine as the official tincture does of free iodine, it is frequently spoken of as being of the same strength, and an impression has no doubt thus obtained with some medical practitioners who prescribe the preparation, that in doing so they are ordering a solution which will produce the specific counter-irritant action of free iodine. This impression is probably confirmed by such a misnomer as "tinctura iodi decolorata." Mr. Hill, therefore, suggested that a "liquor ammonii iodidi ammoniata" might be prepared, which would be of the same therapeutic value as the so-called decolorised tincture of iodine, and prevent the occurrence of mistakes. It is further worthy of note that an attempt has been made to attain the object sought by some who order the decolorised tincture, without altogether losing the specific effect of free iodine. It was stated that a certain medical man prescribes tincture of iodine and aromatic spirit of ammonia in separate bottles, and instructs his patient to paint on the iodine at night and to sponge it off with the aromatic spirit of ammonia before going out next day.

VEGETARIAN DINNERS FOR SCHOOL CHILDREN.

COLD weather and Christmas cheer are invigorating to most of us at this time of year, but it is a sad time for underfed children. The committee for supplying vegetarian dinners to school children in London have been actively prosecuting their good work this winter. We are glad to hear that their dinners have proved palatable and acceptable to the children. Their experiment is a fair one; but we should like to know whether the vegetarian dinners aided growth in the children as much as the mixed diets supplied, at equally low rates, to the school children in Birmingham. It does not appear that vegetarian dinners are more economical as to prime cost; it may also be doubted whether they are more economical physiologically. No doubt the ingredients necessary for the nutrition of the body are to be found in vegetarian food; but evidence is not forthcoming that the digestive

organs are able to extract and assimilate nitrogenous matters as well from a purely vegetable diet as from a mixed one. Plants get their supplies of nitrogen from compounds in the soil, not from the atmosphere. The feeding of children is at least as necessary to their development as teaching, and the cost is trifling in comparison to some of the results obtained: 19,673 dinners were supplied at £68 12s., or a little over three farthings per head. We may safely say that this admirable movement will do good, and that it is economically worked; still, in any plan for distributing food to the poor, there remains the necessity of avoiding pauperisation. The independence of the poor is best respected by enabling them to help themselves; and we are glad to see the suggestion made that senior girls in the school should be employed in cooking and serving the food. Teachers in poor schools are worked hard enough, and must not be expected to do much beyond their paid duties. It is to be hoped that well cooked and comfortably served dinners are served in the middle of the day for the teachers in the schools.

SCOTLAND.

DEATH OF PROFESSOR DICKSON.

DR. DICKSON, Professor of Botany in the University of Edinburgh, and Regius Keeper of the Botanical Gardens, died suddenly on December 30th.

EPIDEMIC OF FEVER AT PAISLEY.

DURING the past fortnight there has been a serious outbreak of fever, mostly enteric, in Paisley; it is hoped, however, that the worst is now over. Last week there were fifteen deaths from the disease, and there were sixty-four patients suffering from it in the hospital.

MEASLES AND WHOOPING-COUGH AT ALYTH.

AT Alyth, in Perthshire, measles and whooping-cough prevailed to such an extent that the propriety of closing the schools has been considered. As far as the infant department is concerned, the diseases have nearly done that themselves, as, out of 127 on the register, no fewer than 100 were absent.

CHILDREN'S BAZAAR.

FOUR young ladies in Edinburgh, all under 12 years of age, being greatly interested in the Sick Children's Hospital, organised a private bazaar on its behalf, and realised a sum of £17 10s. 9d., which was paid over to the institution and gratefully acknowledged by the managers.

IMPORTANT MOVEMENT AS TO INFECTIOUS DISEASE.

AT a meeting of Edinburgh Town Council Public Health Committee, a resolution of an almost revolutionary nature was agreed to. The Dean of Guild Court made a representation to the Committee on the subject of the occurrence of infectious diseases in relation to the houses in which they occurred. The Committee agreed to the following motion: "That in cases of infectious disease, such as typhus, diphtheria, and scarlatina, the Medical Officer shall supply to the Burgh Engineer a note of the address of the same, so that he may make a complete examination of the sanitary condition of the house in which the outbreak takes place."

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

THE third meeting of the current session was held in the Faculty Hall on December 28th; Dr. Wallace, President, in the Chair. Mr. A. R. Gunn, M.B., C.M.; Mr. Campbell Syme, L.R.C.P.E., Kilmalcolm; and Mr. William Cullen, M.B., C.M., were duly admitted Fellows. Dr. Robert Park exhibited a uterine cast of dysmenorrhœal origin almost entire. The cast was handed to the pathologist, on the

bringing up of whose report an account of the case will be given. Dr. J. Stuart Nairne then read a paper on two successful cases of cholecystotomy, in one of which obstruction had been due to gall-stones, and in another to catarrhal products.

ROYAL ASYLUM, MORNINGSIDE.

THE spread of the southern suburbs of Edinburgh, in the Morningside district, has so interfered with the comfort and amenity of the East House Royal Edinburgh Asylum, that the managers have resolved, at a cost of, it is supposed, of about £60,000, to erect a new asylum building in the grounds of Craig House, which are already in their possession. The East House has for many years been used exclusively for patients who were able to pay a good rate of board; and, some years ago, Craig House was added for their accommodation also. Dr. Clouston's views are to be consulted on every point, and Mr. Sydney Mitchell is the architect, but the plans are not yet prepared.

IRELAND.

THE Local Government Board have sanctioned the appointment of Dr. Kerwan, as medical officer of the Oranmore dispensary district.

THE Local Government Board for Ireland have refused their sanction to the election of Dr. Magner as medical officer to Timoleague dispensary.

THE MEASLES EPIDEMIC AT CAPE CLEAR.

A SPECIAL meeting of the Skibbereen Board of Guardians was held last week in reference to the epidemic of measles in Cape Clear, Hare Island, and the district. A report was received from Dr. John Jennings from Cape Clear, to the effect that, although the contagion continued to spread, yet there was only one death there for the week. One hundred persons are affected. Dr. W. Jennings reported that the epidemic had broken out in the townland of Coolanuller, near Skibbereen, with one death, that of a boy, aged 15; and that it has crossed the water to the mainland in Aughada, where a number of persons are now attacked, and some deaths have already taken place in adults and children. In the whole of Hare Island, where about forty families live, only three have escaped the disease. Quite a panic exists on the mainland, where the contagion has spread, and it was rumoured that a case had occurred in Skibbereen workhouse, which, however, has turned out to have been chicken-pox.

GLASGOW UNIVERSITY COUNCIL ASSOCIATION.

A MEETING of this Association was held on December 13th, in Glasgow, under the presidency of Mr. COCHRAN-PATRICK, LL.D.

In introducing the business, the CHAIRMAN made some remarks on the Universities Bill of last year. He pointed out the recognition it contained of the need of extra-academical representation in the University Court in the person of an assessor from the Town Council. He was also glad to see that last year's Bill contained a special grant to Glasgow University of £500 a year for maintenance of buildings. He objected to the system of cumulative voting proposed in the Bill, and he thought the Court should consist of thirteen rather than twelve members. The number in the Bill was thirteen, but for voting purposes it was really only twelve, as the Rector's assessor could vote only in the absence of the Rector. He thought also the General Council should have five assessors, one of whom should retire annually, instead of four all retiring together. He emphasised the views of the Association that the financial administration of the University should be removed from the Senate, and that powers of affiliation should be given to the University Courts. He suggested that since the Government had accepted the proposal to have extra-academical representatives in the Court, the Association should not specify in detail who these representatives should be, but leave that to the Commissioners, the various public bodies being entitled to urge their respective claims.

Professor EDWARD CAIRD moved :

That, in prospect of another Universities Bill, the executive be instructed to press upon Her Majesty's Government the reforms held essential by the Association, and the vital objections taken to the Bill of last session

and in speaking to the motion, acknowledged the conciliatory speech of the Chairman. He had no objection to the financial administration being transferred to the Court, provided the Senate were properly represented in it, nor did he object to powers of affiliation, so long as it was only the general principle that in the meantime was being considered.

Mr. GRAHAM, of Aulhouse, moved the second resolution, namely :

That a Universities Bill, in order to command the support of the Association must (1) give the General Council and the Senatus an equal number of representatives in the University Court, and the extra-academical public not fewer representatives than either; (2) vest in the University Court the whole financial administration of the University; (3) provide for the affiliation of new colleges; (4) empower the Commissioners to remove, as they may see fit, any other present restrictions on university teaching.

Both resolutions were duly seconded and carried unanimously.

DR. GÄRTNER ON THE THERAPEUTIC UTILISATION OF MUSCULAR WORK, AND A NEW APPARATUS FOR ITS DOSAGE.

For the following particulars we are indebted to our Vienna Correspondent :—

It is admitted by all physicians that the want of bodily exercise causes various diseases, and obesity is probably in all cases the result of the muscles not being properly exercised. Men and animals work with the expenditure of fat and hydrocarbons, and a certain amount of consumption of fat must, therefore, correspond to a certain amount of work. It is evident from these facts that the value of a certain form of movement as a therapeutic agent must depend on the quantity of work (expressed in kilogramme-mètres) which it involves. The physician is often at a loss when he has to prescribe the necessary work for the patient, as in many cases none of the common forms of exercise are suitable. Dr. Gärtner has tried to meet this want, and has devised an apparatus, which he calls "ergostat" (*έργον* and *στάσις*). The ergostat is a small machine, scarcely larger than a sewing machine, and consists of an iron plate, around which there is a band. The latter is supplied

with wooden blocks, and is fixed at its ends to a lever, and can be bent to a greater or less extent by means of a weight which can be moved to and fro on the lever. A scale on the lever indicates how many kilogramme mètres are equivalent to one revolution of the iron plate. At the axis of the iron plate there is an arrangement by which the number of revolutions of the plate can be controlled, and 10,000 revolutions can thus be registered. The plate is turned by the patient by means of a winch provided with a suitable handle. The winch is made of such a length that the patient has to stoop at each turning. Dr. Gärtner chose the winch-work because it was known as the result of experiment that this was the most rational form of work. A man may with the winch perform great quantities of work much more easily than in any other way without excessive fatigue.

All machines which are moved by human hands and which require much force are supplied with winches; by this arrangement almost all

the muscles of the body, and especially those of the vertebral column and of the hip are exerted. Another advantage of this form of movement, as compared with several others, consists in the fact that the conditions of respiration are very favourably influenced. At each turning the chest is expanded and narrowed, hence a sort of artificial respiration is produced. The work of the respiratory muscles themselves is much facilitated, and they do not become easily fatigued. It is difficulty of breathing which, in most cases, renders the continuation of heavy work impossible, and it was proved by experiments with the ergostat that persons who had not previously been able to perform any work whatever, could, when working with it, raise considerable quantities of kilogramme-mètres without any dyspnoea supervening. The work with the winch has, furthermore, the advantage that the abdomen becomes compressed at each turning, and a kind of massage of its walls is thus produced, which must obviously have a good effect on the peristalsis of the intestine and on the secretion of bile. In addition to all this, the ergostat presents the following advantages:—1. It is at the disposal of the patient at any time of the day; every spare minute can thus be used in healthy exercise. 2. The amount of work is regulated by kilogramme-mètres, in proportion to the patient's strength, just in the same way as the dose of drugs is adapted to the individuality of the patient. 3. It does not require any skill or practice. 4. The physician can judge for himself as to the patient's diligence by the position of the dial which registers the revolutions. 5. The use of the apparatus need make no noise or disturbance in the house.

Dr. Gärtner has employed the apparatus in a case of excessive obesity. The patient, who had become almost breathless on the slightest movement, was able to do a considerable amount of work with the ergostat on the very first day without being attacked with dyspnoea. She has now been working with the machine for nineteen days, and performs 2,000 revolutions, each of which is equal to twelve kilogramme-mètres, in about a hundred minutes. She has not changed her diet or her mode of living in any way, and yet she has lost, since the beginning of the treatment, about four kilogrammes in weight. Similar good results have been obtained in another case of obesity.

The ergostat can also be employed in some forms of nerve-disease, and in disorders of the portal circulation, in chronic constipation, in biliary calculus, gout, and opaluria.

In using the ergostat, the following rules should be observed:—1. The revolutions must be executed very slowly, not more than from twenty to twenty-five in the minute. 2. Speaking is not allowed during work. 3. The work is performed during winter in an unheated room, and the windows must always be opened. 4. The patient's dress must be easy and convenient. 5. No work should be done immediately after a meal.

THE CASE OF DR. CROSS.

The friends of Dr. Cross are working to obtain a respite of the death sentence, and the following is a copy of a requisition to the Lord-Lieutenant:—

To His Excellency the Most Noble Charles, Marquis of Londonderry, Lord-Lieutenant of Ireland.

The memorial of the undersigned humbly sheweth,

That Philip H. E. Cross, a retired surgeon-major in Her Majesty's service, was on the 17th day of December, 1887, found guilty of the murder of his wife, Mary Laura Cross, and sentenced to be hanged on the 10th day of January, 1888.

1. That grave doubts are entertained of the justice of the conviction, arising from the fact that the analyst had not previously examined the body of a person supposed to have died from arsenical poisoning.

2. There is no direct evidence to connect the accused with the alleged crime.

3. That the evidence was entirely circumstantial.

4. That a most important piece of evidence has turned up since the trial, as embodied in the statutory declaration annexed herewith, made on 25th December inst., by Mr. John Charles Westropp Butterfield, of the city of Cork, dental surgeon, to the effect that the late Mary Laura Cross had on two occasions alluded to poison in his study, asked him if he could procure it for her, and inquired if he had heard that arsenic was good for the complexion, and any one of which occasions was as recent as the 6th day of April last.

5. That the said P. H. E. Cross was very unpopular with the masses of the people of Cork and its neighbourhood, had been boycotted, and subjected to many signs of popular indignation.

6. That he is a man of advanced years.

7. That he has served Her Majesty for many years in Europe, Asia, Africa, and America, amongst others was engaged in the Indian Mutiny, at the Crimea, the China campaign, etc., and received three medals.

Your petitioners therefore humbly implore your Excellency to mitigate the capital sentence passed on the said Philip H. E. Cross, and your petitioners will, as in duty bound, ever pray.

[Here follow the columns for signature.]

The petition has been forwarded to Mr. Justice Murphy (who delivered the sentence) for his comments, but the prevalent opinion is that His Excellency will not interfere with the carrying out of the sentence.

MEDICAL LEGISLATION IN BOMBAY.

THERE does not exist in India generally the means of distinguishing between qualified and unqualified ignorant practitioners of medicine, such as was provided by the Medical Act of 1858 for the public in Great Britain and Ireland, and, subsequently, in several of the colonies. It appears from a memorial recently presented to the Government and Council of Bombay by the Bombay Medical Union that in the year 1881 the Medical Society of the Grant Medical College brought under the notice of the Governor and Council of Bombay the necessity of passing an Act in Council in many respects similar to the Medical Act of 1858 of this country. The proposals submitted to the Government were as follows:—

1. That medical men be publicly registered in the city after a sufficient scrutiny of their diplomas or degrees, rendering it illegal for anyone to assume a title which is not so registered.
2. That none but persons so registered be entitled to demand and recover charges in any court of law for professional aid, advice and visits, and the cost of any medicines, or other medical or surgical appliances, rendered or supplied by him to his patients.
3. That none but persons so registered be eligible for employment as a physician or surgeon in emigrant or other vessels, or in any hospital, infirmary, dispensary, or lying-in hospital (not supported entirely by voluntary contributions), or in any lunatic asylum, gaol, penitentiary, house of correction, house of industry, or other public establishment, body, or institution, or as a medical officer of health.
4. That no certificate required by any Act now in force, or that may hereafter be passed, from any physician, surgeon, licentiate of medicine or surgery, or other medical practitioner, be considered valid unless the person signing the same be registered under the proposed Act.

Arguments in favour of these proposals for legislation were at the time (1881) submitted to the Government of Bombay with such good effect, that a Medical Registration Act, founded on these principles, was strongly recommended by that Government to the Government of India. But the Government of Bombay went beyond this. They proceeded farther than the expressed wishes of the Medical Society of Grant College, and suggested that such a measure, if introduced, should not be confined in its operation to the town and island of Bombay alone, or even to one presidency, but should have application to the whole of India. This recommendation of a widespread registration Act was fatal to the proposal emanating from Bombay. It was felt to be impossible to apply a measure of this character to the whole of such a country as India, and the recommendation of the Bombay Government was not accepted.

The Bombay Medical Union, at a meeting held on November 12th, 1887, have unanimously agreed to recommend the Governor and Council of Bombay to return to the original recommendation of the Medical Society of Grant College, which had received the decided approval of the Government of Bombay of that date, and which is to the effect that a Medical Registration Act should be now framed, founded on the principles approved by the Government in 1881, and should apply to the city and island of Bombay, with power on the part of the Government to extend the operation of the Act to the minor cities of the presidency.

Without entering into the question how far such an Act could be adopted throughout India generally, we have no hesitation in saying that it is an absolute necessity that such an Act should be made available for the principal cities of India. Take, for example, the city of Bombay, the population of which is 800,000. The members of the Medical Union having taken some pains and undergone some expense to ascertain the facts, find that the total number of unqualified persons practising in the city of Bombay is about 640, out of which eighty pass themselves off under the title of "Doctor." Surely without reference to any special interests or privileges of medical men, it is the imperative duty of a Government which regards the welfare of the communities committed to its charge, to take means to protect them and their most vital interests from being imposed upon by ignorant and fraudulent practitioners. We have every confidence that the Governor of Bombay, Lord Reay, who is alike distinguished for his high scientific attainments and his wisely-tempered liberal feelings, will adopt a course on this subject which will be conducive to the welfare and the interests of the people committed to his charge; and that he and his advisers will not be reluctant to adopt the principles so highly approved by his predecessor in 1881.

HOSPITAL TELEPHONE.—The authorities of the Hospital for Consumption, at Ventnor, have decided to establish telephonic communication between the different wards of the hospital, the resident medical officer, and the porter's lodge. The installation is being carried out by the Equitable Telephone Association Limited, on their "Swinton" system.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN extraordinary meeting of the Council was held, at the College, on Thursday afternoon, January the 5th. The minutes of the ordinary Council, held on December 8th last, were read and confirmed. The Council then proceeded to the special business for which it had been convened, namely, to read and consider the report of the President and Vice-Presidents on a letter from the Lords of the Council, forwarding a copy of the statement relating to the supplementary charter prepared by the Association of Fellows, and requesting to be favoured with any remarks thereon which the Council may have to offer. A further letter from the Privy Council, forwarding for the information of the College a printed document, purporting to be a report of the statement made by Mr. Ernest Hart as spokesman of the deputation of the Association of the Members of the College to the Lord President on the subject of the application for a supplementary charter, was not read, but was deferred till the next meeting of the Council.

The Council, after a considerable deal of discussion, agreed to a statement to be sent to the Lords of the Council in reply to the objections raised by Fellows and Members to the application which has been lodged for a supplementary charter, subject, of course, to confirmation by the Council at its quarterly meeting on Thursday next.

VACCINATION GRANT.—Dr. White, Belmont, Wadhurst, public vaccinator of the Wadhurst District of the Ticehurst Union, has again received the grant from the Local Government Board for successful vaccination in the district.

CARBONATE OF SODA AND MILK.—At a recent meeting of the Conseil d'Hygiène M. Pronst presented a report on the system of preserving milk with carbonate of soda. He considers that this method should be prohibited. Carbonate of soda prevents the milk from turning sour, but produces a sodium lactate, which is a purgative, and causes diarrhoea in infants.

The friends and pupils of M. Péan a few days ago celebrated his nomination as Member of the Academy of Medicine by a banquet given at the Hôtel Continental. More than two hundred persons were present. Toasts were proposed and speeches were delivered by M. Peyron, director of the Assistance Publique, M. Guibout, M. de Pietra, Santa, and others.

PERMANGANATE OF POTASSIUM IN AMENORRHOEA.—The treatment of amenorrhœa, according to the method suggested by Professor Sydney Ringer and Dr. Murrell, has found a new supporter in Dr. J. D. Korotkevitch, of Turiask, in West Siberia (*Russkaja Medicina*, No. 15, 1887, p. 262). In five successive cases of obstinate amenorrhœa of obscure origin, he administered permanganate of potassium in the following form: R Potass. permangan. one drachm; argill. pur. q. s. M. f. pil. No. 60. Consperg. argill. pur. D. S. Two pills at dinner and supper time. The results were quite satisfactory in all the cases. After treatment lasting for a month or six weeks, the catamenia became regular, and remained so.

PERMANGANATE OF POTASSIUM IN TOOTHACHE.—In the *Russkaja Medicina*, No. 19, 1887, p. 330, Dr. Prokopy Popoff, of Minusinsk, in "Siberian Switzerland," writes that he has most successfully treated upwards of three hundred cases of toothache from dental caries by administering one-twentieth per cent. solution of permanganate of potassium in the form of a month-wash. The following is the formula: R Potass. permang., 3 grains; aq. destil. or fontanæ, 1 (Russ.) fl. pound, Misc. One tablespoonful to be taken in the month, every half-hour, and to be held therein on the affected side for several minutes. The most agonising pain is said gradually to disappear in a few hours. The wash acts, besides, as an excellent deodoriser.

DINITROKRÉSSOL.—M. Th. Weyl has ascertained the following facts concerning dinitrokréssol, a colouring matter which is sold as a substitute for saffron for colouring butter, macaroni, etc. He states that this substance causes death in rabbits in doses of 0.25 gramme to a kilogramme of the weight of the animal. When this quantity is administered, the animal is seized with dyspnoea and convulsions in the extensor muscles, and finally dies of asphyxia. Dinitrokréssol is chemically allied to picric acid or trinitrophenol. The symptoms of intoxication produced by these substances are very similar. Martins yellow, or dinitro-alpha-naphthol, is sometimes used to colour food stuffs, but it is not toxic.

ASSOCIATION INTELLIGENCE.

COUNCIL.

NOTICE OF MEETING.

A MEETING of the Council will be held at the Offices of the Association, No. 429, Strand (corner of Agar Street), London, on Wednesday, the 18th day of January next, at 2 o'clock in the afternoon.

FRANCIS FOWKE, *General Secretary*.

December 24th, 1887.

ELECTION OF MEMBERS.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No member can be elected by a Branch Council unless his name has been inserted in the circular summoning the meeting at which he seeks election.

FRANCIS FOWKE, *General Secretary*.

BRANCH MEETINGS TO BE HELD.

METROPOLITAN COUNTIES BRANCH: EAST LONDON AND SOUTH ESSEX DISTRICT.—The next meeting will be held, by the kind invitation of Dr. Adams, at Brooke House, Upper Clapton, on Thursday, January 19th, at 8.30 P.M. A demonstration of interesting cases of eye disease will be given by A. Q. Slocck, Esq. Visitors will be welcomed.—J. W. HUNT, *Honorary Secretary*, 101, Queen's Road, Dalston.

NORTH OF IRELAND BRANCH.—A general meeting of the North of Ireland Branch will be held in the Royal Hospital on Thursday, January 26th, 1887, at 12 o'clock noon. Gentlemen desirous of reading papers exhibiting cases, specimens, etc., will kindly communicate as early as convenient with the Secretary, JOHN W. BYERS, M.D., Lower Crescent, Belfast.

OXFORD AND DISTRICT BRANCH.—The next meeting will be held at the Radcliffe Infirmary, Oxford, at 3 o'clock on Friday, January 27th. Notice of papers to be read and cases to be shown must be given to either of the Honorary Secretaries on or before Monday, January 23rd. Members are requested to send their annual subscriptions to the Association and the Branch, due January 1st, to Dr. Darbishire, 37, Holywell, Oxford.—S. D. DARBISHIRE, W. LEWIS MORGAN, 42, Broad Street, Oxford, *Honorary Secretaries*.

SOUTH-WESTERN BRANCH.

An intermediate meeting of the Branch was held on Thursday, December 15th, 1887, at Newton Abbot, the President, Mr. PAUL SWAIN, F.R.C.S., of Plymouth, in the chair. About twenty-four members were present, including Dr. JOHN WOODMAN, of Exeter, *President-elect*.

New Members.—Several new members were elected.

President's Address.—The President then delivered an address on College Politics, which was devoted to a discussion of the line which the Council of the Royal College of Surgeons of England had taken in regard to important matters affecting the medical profession, especially in regard to medical education, and advocated the necessity for alterations in the constitution of the Council, and the mode of election of its members, with special reference to the proposed new charter for the College.

Vote of Thanks and Resolution.—A cordial vote of thanks was awarded to Mr. Swain for his address, and the following resolution was passed, on the motion of Mr. E. J. DOMVILLE, seconded by Dr. DEAS:

"That this meeting desires to endorse the opinions expressed by the President of the Branch in the paper read by him, and requests him to publish it, with a view to a copy being forwarded to the Lord President of the Council."

Papers.—The following papers were then read: Case of Pleurisy and Empyema: Tapping: Drainage Tube: Recovery, by Dr. JOHN WOODMAN, Exeter.—On the Importance of Early Diagnosis in Glaucoma, by Dr. L. H. TOSSWILL, Exeter.—Case of Alcoholic Paralysis, by Dr. A. H. BAMPTON, Plymouth.—Dr. ARTHUR KEMPE, Exeter, showed and explained a New Surgical Needle.

Luncheon.—After the meeting the members were hospitably entertained to a luncheon by the local members, Dr. Scott and Mr. Davies, Newton; Mr. Symons, Kingskerswell; and Mr. Goodwyn, Bovey.

METROPOLITAN COUNTIES BRANCH: HERTFORDSHIRE DISTRICT.

A MEETING of the above District was held at the Town Hall, St. Albans, on Wednesday, December 21st, 1887. The chair was taken by ARTHUR DURHAM, Esq.

Hysteric and Neurotic Dyspepsia.—A paper was read by Dr. HALE WHITE on the Treatment of Cases of Severe Hysteric and Neurotic Dyspepsia. Notes of two cases were given, in the first of which the patient had uncontrollable vomiting, in the second the chief symptom was diarrhoea. Each of them was completely cured by isolation, overfeeding, and massage. Hysteria in all its forms may be cured in the same way.—Discussion followed, and a vote of thanks was passed to Dr. Hale White for his paper.

New Rules.—The new rules on the agenda paper were discussed and adopted.

Vote of Thanks.—A vote of thanks was passed to Mr. Arthur Durham in recognition of his goodness in presiding for the occasion. The business of the meeting over, members were entertained at the house of Dr. Lipscomb, of St. Albans.

NEW SOUTH WALES BRANCH: SIXTY-EIGHTH GENERAL MEETING.

THE sixty-eighth general meeting of this Branch was held in the Royal Society's Rooms, Sydney, on Friday, November 4th, 1887. The following members were present: the Hon. Dr. CREED, M.L.C., President, in the chair; Drs. Chambers, Chisholm, Sydney Jones, Pockley, Knaggs, Wright, E. Fairfax Ross, Steel, Worrall, Hankins, McCormick, McDonagh, Bowker, West, Crago. Dr. A. E. Barcroft attended as a visitor.

The minutes of the previous meeting were read and confirmed.

Axillary Aneurysm.—Mr. G. F. HANKINS read notes of a case of axillary aneurysm, with ligature of the subclavian artery.—Dr. SYDNEY JONES said Mr. Hankins was to be congratulated on the success of the operation. The statistics upon which all calculations were based were collected before antiseptics were used. If the result of the operations of the last eight or ten years were collected, a great difference would, no doubt, be found.—Drs. WORRALL, E. F. ROSS, and the PRESIDENT also made some remarks.

Removal of Genitals.—Mr. G. F. HANKINS read notes on a case of total ablation of the genital organs in a man aged 50, and showed the patient.

Diabetic Coma.—Dr. CRAGO read some notes on a case of diabetic coma.

Revision of By-laws.—Dr. JONES proposed, and Dr. CRAGS seconded, "That the consideration of the by-laws be postponed until next meeting night, and that it be the first business of the evening." Carried.

New Member.—Dr. Leacock, of Camden, was elected a member of the Association.

STAFFORDSHIRE BRANCH: GENERAL MEETING.

THE first general meeting of this Branch was held at the Railway Hotel, Stoke-upon-Trent, on Thursday, November 24th, 1887. Mr. W. D. SPANTON, President in the chair.

New Members.—The following gentlemen were elected members of the Branch: Mr. J. Ruskin Hancock, Hanley; Dr. Armitage, Wolverhampton; Mr. F. Matthews, Nantwich.

Raynaud's Disease.—Dr. MCALDOWIE showed a case of Raynaud's disease occurring in a female epileptic, aged 18.

Phosphatic Calculus with Hairpin as a Nucleus.—Mr. WEST showed a specimen weighing half an ounce, which he had removed from a young woman *per urethram*.

Villous Growths in the Bladder.—Dr. W. G. LOWE exhibited two villous growths from the bladder, of papillomatous nature, situated close to the orifice of the urethra. They were taken from a woman aged 73, who had been the subject of occasional hæmaturia for several years, though without pain or difficulty in micturition, and who ultimately died after a sudden profuse hæmorrhage from the bladder.

Wound and Skin after a Dog-Bite.—Dr. W. HIND exhibited the wound and a portion of the surrounding skin after the bite of a dog, supposed to be rabid, and which was excised from a boy on the third day after infliction, on account of pain and a low form of inflammation.

Fibro-sarcoma of Breast.—Mr. SPANTON exhibited a fibro-sarcoma of the left breast weighing three pounds and a half, removed from a young woman last July. In February, 1884, a much smaller tumour of similar character had been removed by Mr. Spanton. The wound healed in five days, and the patient had since been quite well.—Mr. VINCENT JACKSON showed the photograph of a female patient exhibiting an enormously enlarged right mamma, due to a fibro-sarcomatous tumour, which, when removed, weighed more than six pounds. Microscopic specimens of the tumour, prepared by Dr. Heneage

Gibbes, were also shown. The recovery of the patient was rapid and easy.

Specimens.—Mr. STANTON showed: 1. Fibrous Tumour removed from Sheath of Biceps Femoris of a man aged 20, potter's turner, October 8th, 1887, coming slowly, causing inability to move the limb freely; good recovery, but slow. 2. Tubercular Testis, from man aged 46. Three years had pain in left testis, which came on rather suddenly. At times inflamed; never suppurated. Under care of Dr. Eddowes. Operation November 18th.

Papers.—The following papers were read: 1. Dr. McALDOWIE: Notes of a Case of Sensory Aphasia. 2. Mr. FOLKER: Villous Tumour of the Rectum. 3. Mr. FOLKER: Malignant Disease of Upper Jaw, and Operation. 4. Dr. WHELTON HIND: Notes of a Case of Reduction, *en masse*. 5. Mr. VINCENT JACKSON: Radical Treatment of Severe Hemorrhoids.

BORDER COUNTIES BRANCH.

THE winter meeting was held at Melrose on December 23rd, 1887, Dr. McLEOD, President, in the chair, and afterwards Dr. ROBERTSON, President-elect. Sixteen members and one visitor, Dr. William Russell, of Edinburgh, were present.

New Members.—The following new members were elected members of the Branch: Charles Henry Bedford, M.B., C.M., Rowrah, Cumberland (proposed by J. R. Irwin and G. Calderwood); John Ross, M.B., C.M., Wetheral (proposed by S. Lockie and H. A. Lediard); William Rushton Parker, M.D., Kendal (proposed by T. B. Green and B. R. A. Taylor); William Jordan Fairlie, M.B., C.M., Carlisle (proposed by S. Lockie and G. Murphy); William Laing Cullen, M.B., C.M., St. Boswells (proposed by J. R. Hamilton and P. M. Penman).

Proposed Meeting.—It was agreed to hold an evening meeting in Carlisle towards the end of February, to take the place of the Moffat meeting, which fell through for want of papers, and to invite an eminent medical man to introduce a discussion on the occasion.

Auditors for the Year.—Drs. MacLaren and Lockie were appointed to audit the accounts for the year.

Puerperal Mania.—Dr. SOMERVILLE (Galashiels) read Notes of some cases of Puerperal Mania. The cases were three in number, the patients all being multiparæ; two of the cases were fatal, terminating one on the twenty-sixth and the other on the thirtieth day; one recovered after an illness of ten or twelve weeks. Although in all the cases there was more or less abdominal pain and uterine tenderness, there was no peritonitis, no diarrhoea, no tympanitic distension of the abdomen. Dr. Keith's recent observation as to the frequency of mania after the operation of hysterectomy had an interesting relation to puerperal mania.—In the discussion which followed the PRESIDENT, Dr. JOHNSTONE, Dr. BARNES, Dr. HADDON, Dr. HAMILTON, Dr. MACLAREN, and Dr. RUTHERFORD took part.

Umbilical Hernia.—Dr. RUTHERFORD (Kelso) read Notes of a Case of Umbilical Hernia treated successfully by Elastic Pressure.

Ligature of Femoral Artery for Aneurysm.—Dr. ROBERTSON (Penrith) read a paper on Ligature of the Femoral Artery in Hunter's Canal for Traumatic Aneurysm.

Idiopathic Peritonitis.—Dr. HAMILTON (Hawick) read a paper on the Treatment of Idiopathic Peritonitis.—In the discussion which followed Drs. ROBERTSON, HADDON, RUSSELL, RUTHERFORD, and MACLAREN took part.

Leprosy.—Dr. BARNES showed some drawings of Norwegian leprosy.

Casts of Cases.—Dr. MACLAREN showed casts before and operation of (1) a Large Ventral Hernia, and (2) Talipes Equino-Varus.

Dinner.—The members and several guests afterwards dined together in the George and Abbotsford Hotel.

GLOUCESTERSHIRE BRANCH.

AN ordinary meeting was held at Gloucester Infirmary, on Tuesday, December 13th, 1887, at 7.30 p.m., under the presidency of Dr. BATTEN.

Priestley Smith's Perimeter.—Mr. BOWER gave a full demonstration of Priestley Smith's perimeter.

Cases.—He also showed the following cases: 1. Chancra on the Outer Canthus of Eye in a Girl; 2. A Case of Glioma in a Child 3½ years old, and pointed out the difference between true glioma and pseudo-glioma.

Insanitary Houses.—A paper was read by Mr. CARDEW on Insanitary Houses and their Results.

Varicose Aneurysm of Aorta.—Mr. KNAGGS, house-surgeon of the Gloucester Infirmary, showed a pathological specimen of Varicose

Aneurysm of the Aorta Opening into the Pulmonary Artery, from a patient lately under Dr. Batten. The history of the opening into the pulmonary artery was very short, only three weeks.

Vote of Thanks.—A vote of thanks was passed, proposed by Dr. NEEDHAM, and seconded by Mr. BOURN, to the outgoing President, Dr. Batten, for his conduct and zeal in the chair during the past year.

NOVA SCOTIA BRANCH.

THE first ordinary meeting of this Branch was held in Halifax on December 6th, 1887, the President, Deputy Surgeon-General McDOWELL, A.M.S., in the chair; and the other members present were Hon. Dr. Parker, Drs. Hayter, Black, Wickwire, Surgeon-Major Bolster A.M.S., Surgeons Deeble and Browne, Drs. Farrell, Milsom, Cowie, Chisholm, Morrow, Currie, Somers, and Tobin (Honorary Secretary).

Letter from General Secretary of Association.—The letter from the General Secretary of the Association, forwarding a copy of the resolution passed at a Council meeting held in Trinity College, Dublin, on Tuesday, August 2nd, recognising the Nova Scotia Branch of the Association, and thanking those who had been instrumental in founding said Branch, was first read; and it was moved by Dr. MILSOM, and seconded by Dr. PARKER, "That a copy of said resolution should be placed on the minutes."

Tetany.—Dr. MILSOM (Dartmouth) then read notes of a case of tetany at present under his care, in the treatment of which he had been assisted by Dr. Parker. The patient was a man who had been subjected to malarial poisoning in Panama, and was successfully treated by quinine when other remedies had failed.—A discussion ensued, in which Hon. Dr. PARKER, Drs. SLAYTER, SOMERS, and DEEBLE, A.M.S., took part, Dr. Deeble instancing a similar affection in a lady who had suffered from malaria in India, and whose larynx and pharynx were principally affected by the recurrent spasms.

Intubation of Larynx.—Dr. BLACK next exhibited the instruments used in intubation of the larynx, and gave an account of the method as seen in the *clinique* of Dr. O'Dwyer of New York. Intubation versus tracheotomy in diphtheritic croup formed the subject of a discussion in which the PRESIDENT, Drs. FARRELL and BLACK, amongst others, took part.

Lithotrity.—Dr. FARRELL exhibited stones and detritus washed from the bladder in a late case of lithotrity, in which caucine was injected into the urethra and bladder.

Abscess of Lung.—Dr. FARRELL also gave the history of a case of abscess of the lung supposed to be due to impaction of a cherry-stone in the bronchi several years before.—Drs. SLAYTER and CHISHOLM gave similar cases.

Hypodermic Injections of Mercury in Syphilis.—Dr. SLAYTER brought forward a case of secondary syphilis successfully treated by hypodermic injections of mercury. An abscess, however, had formed at the sites of the punctures.—Dr. MORROW had seen successful treatment of syphilitic skin affections in Dr. Lesser's *clinique* in Leipzig.—Drs. SOMERS and CHISHOLM made some remarks, and Dr. SLAYTER briefly replied.

Future Meetings.—It was unanimously agreed to hold meetings monthly throughout the winter, and the meeting adjourned, leaving the Council to fix time and place of such meetings.

BRITISH MEDICAL ASSOCIATION.

FIFTY-SIXTH ANNUAL MEETING.

THE fifty-sixth Annual Meeting of the British Medical Association will be held at Glasgow, on Tuesday, Wednesday, Thursday, and Friday, August, 7th, 8th, 9th, and 10th, 1888.

President: John T. Banks, M.D., D.Sc. (Hon.), F.R.C.S.P., Regius Professor of Physic in the University of Dublin.

President-Elect: Professor W. T. Gairdner, M.D., LL.D., Professor of Medicine in the University of Glasgow.

President of the Council: Thomas Bridgwater, M.B., J.P., Harrow-on-the-Hill.

Treasurer: Constantine Holman, M.D., J.P., Reigate.

An Address in Medicine will be delivered by Thomas Clifford Allbutt, M.D., Consulting Physician, Leeds General Infirmary.

An Address in Surgery will be delivered by Sir George H. B. Macleod, M.D., Surgeon in Ordinary to Her Majesty in Scotland.

A Special Address on his "Recent Investigations in Surgery" will be given by William Macewen, M.D., Lecturer on Clinical Surgery, Glasgow Royal Infirmary.

An Address in Physiology will be delivered by John Gray McKendrick, M.D., LL.D., F.R.S., Professor of Institutes of Medicine, University of Glasgow.

A. MEDICINE.—*President*, T. McCall Anderson, M.D. *Vice-Presidents*, W. L. Bowles, M.D.; George F. Duffey, M.D. *Honorary Secretaries*, J. McGrigor Robertson, M.D., 400, Great Western Road, Glasgow; Robert M. Simon, M.B., 27, Newhall Street, Birmingham.

B. SURGERY.—*President*, George Buchanan, M.D. *Vice-Presidents*, James Dunlop, M.D.; Charles Robert Bell Keetley, F.R.C.S. *Honorary Secretaries*, David Neilson Knox, M.B., 8, India Street, Glasgow; Walter Pye, F.R.C.S., 4, Sackville Street, Piccadilly, London, W.

C. OBSTETRIC MEDICINE.—*President*, Thomas More Madden, M.D. *Vice-Presidents*, William Leishman, M.D.; J. Halliday Croom, M.D. *Honorary Secretaries*, William Walter, M.D., 20, St. John's Street, Manchester; W. L. Reid, M.D., 7, Royal Crescent, Glasgow.

D. PUBLIC MEDICINE.—*President*, Henry Duncan Littlejohn, M.D. *Vice-Presidents*, James Christie, M.D.; D. Page, M.D. *Honorary Secretaries*, Ebenezer Duncan, M.D., 4, Royal Crescent, Crosshill, Glasgow; John C. McVail, M.D., Holmhead, Kilmarnock.

E. PSYCHOLOGY.—*President*, James C. Howden, M.D. *Vice-Presidents*, James Rutherford, M.D.; Julius Mickle, M.D. *Honorary Secretaries*, A. R. Urquhart, M.D., Murray House, Perth; Alex. Newington, M.D., Ticehurst, Sussex.

F. ANATOMY AND PHYSIOLOGY.—*President*, John Cleland, M.D., LL.D., F.R.S. *Vice-Presidents*, R. J. Anderson, M.D.; Henry Edward Clark, F.F.P.S.G. *Honorary Secretaries*, John Barlow, M.D., 27, Elmbank Crescent, Glasgow; Charles Barrett Lockwood, F.R.C.S., 19, Upper Berkeley Street, Portman Square, W.

G. PATHOLOGY.—*President*, Sir William Aitken, M.D., F.R.S., K.C.B. *Vice-Presidents*, Alexander Davidson, M.D.; Joseph Coats, M.D.; Charles Roy, M.D., F.R.S. *Honorary Secretaries*, G. Sims Woodhead, M.D., 6, Marchhall Crescent, Edinburgh; J. Lindsay Steven, M.D., 34, Berkeley Terrace, Glasgow.

H. OPHTHALMOLOGY.—*President*, Thomas Reid, M.D. *Vice-Presidents*, J. R. Wolfe, M.D.; C. E. Glascott, M.D. *Honorary Secretaries*, Henry Bendelack Hewetson, M.R.C.S., 11, Hanover Square, Leeds; A. Friesland Fergus, M.B., 41, Elmbank Street, Glasgow.

I. OTOLOGY.—*President*, Thomas Barr, M.D. *Vice-Presidents*, John Astley Bloxam, F.R.C.S.; J. J. K. Duncanson, M.D. *Honorary Secretaries*, Johnstone Macfie, M.D., 23, Ashton Terrace, Glasgow; H. J. Hardwicke, M.D., 33, Holly Street, Sheffield.

J. DISEASES OF CHILDREN.—*President*, Walter Butler Cheadle, M.D. *Vice-Presidents*, James Finlayson, M.D.; Henry Ashby, M.D. *Honorary Secretaries*, George S. Middleton, M.D., 23, Sandyford Place, Glasgow; W. Arbuthnot Lane, M.S., F.R.C.S., 14, St. Thomas's Street, S.E.

K. PHARMACOLOGY AND THERAPEUTICS.—*President*, James Morton, M.D. *Vice-Presidents*, John Dougall, M.D.; Theodore Cash, M.D., F.R.S. *Honorary Secretaries*, Alexander Napier, M.D., 3, Royal Terrace, Crosshill, Glasgow; Sidney Harris Cox Martin, M.D., 60, Gower Street, London, W.C.

L. LARYNOLOGY AND RHINOLOGY.—*President*, Felix Semon, M.D. *Vice-Presidents*, George Hunter Mackenzie, M.D.; Peter McBride, M.D. *Honorary Secretaries*, D. Newman, M.D., 13, Woodside Place, Glasgow; A. E. Garrod, M.D., 9, Chandos Street, Cavendish Square.

Honorary Local Secretaries, John G. McKendrick, M.D., F.R.S., 45, Westbourne Gardens, Glasgow; James Christie, M.D., Hillhead, Glasgow; John Glaister, M.D., 4, Grafton Place, Glasgow.

PROGRAMME OF PROCEEDINGS.

TUESDAY, AUGUST 7TH, 1888.

9.30 A.M.—Meeting of 1887-88 Council.

11.30 A.M.—First General Meeting. Report of Council. Reports of Committees. Service in the Cathedral.

8.30 P.M.—Adjourned General Meeting from 11.30 A.M. President's Address.

WEDNESDAY, AUGUST 8TH, 1888.

9.30 A.M.—Meeting of 1888-89 Council.

10.30 A.M. to 2 P.M.—Sectional Meetings.

3 P.M.—Second General Meeting. Address in Medicine by Thomas Clifford Allbutt, M.D., F.R.S.

THURSDAY, AUGUST 9TH, 1888.

9.30 A.M.—Meeting of Council.

10.30 A.M. to 2 P.M.—Sectional Meetings.

3 P.M.—Third General Meeting. Address in Surgery by Sir George H. B. Macleod, M.D.

7 P.M.—Public Dinner.

FRIDAY, AUGUST 10TH, 1888.

9.30 A.M.—Address on his Recent Surgical Investigations by William Maccewen, M.D.

10.30 A.M. to 1.30 P.M.—Sectional Meetings.

3 P.M.—Concluding General Meeting. Address in Physiology by John G. McKendrick, M.D., F.R.S.

SATURDAY, AUGUST 11TH, 1888.

Excursions.

SPECIAL CORRESPONDENCE.

SPRAY FROM THE CARLSBAD SPRUDEL.

III.

The Real Secret of the Carlsbad "Cure."—*A Municipality of Sweetness and Light.*—*What it all Costs.*—*The Budget.*—*Cure Tax.*—*Music Tax.*—*Bands.*—*Hints for Home Use.*

WHAT a vast addition it would be to the attractions of our health resorts such as Brighton, Bath, Cheltenham, Buxton, and Droitwich, if they offered to invalids, pleasure seekers, and searchers after that kind of repose which is itself medicine to the mind and body, parks, woods, music of the first order, which could at all rival the attractions which the minusculous town of Carlsbad puts freely at the disposal of its 30,000 annual visitors.

The Real Secret of the Carlsbad "Cure."—At Carlsbad, as I have said, the "cure-guest" drinks his matutinal tumblers of saline water at wells, one of which is covered with a vast winter garden of glass, and to the strains of one of the best bands in Europe, which plays from half-past six till half-past eight—the hours consecrated to these morning devotions at the shrine of the Sprudel; or he walks beneath the splendid colonnade of the Mühlbrunn, where another division of the same band is playing, and around the Stadtpark, which is prettily cultivated and gay with flowers and fountains, and where the grandiose and conveniently arranged restaurant with its orchestral saloons for bad weather and for evening amusement, provide that agreeably suggestive hotel decoration of a landscape, which Dr. Johnson found always to add charms to the view.

A Municipality of Sweetness and Light.—An elaborate, extensive, and varied range of baths are provided by the municipality. The visitor breakfasts beneath the trees or in the various series of garden restaurants of which the sites are furnished by the municipality, and jealously guarded by them; and for his subsequent exercise during the day he has a range of 30,000 acres of pine wood, laid out with mile upon mile of well kept and carefully graded paths. The whole of this fir forest is watched by thirty civil and vigilant keepers and ten foresters, and there are fifty English miles of walk. Seats are provided at every 200 or 300 yards, and the distances are carefully marked for the benefit of the devotees of the strict "exercise cure." The foresting is carried out scientifically and with a view to artistic effect; at a dozen different localities, selected with a serious view to convenience as to distance and picturesqueness, there are little restaurants or coffee houses, of a small but sufficient accommodation, and picturesquely constructed.

What it all Costs.—To supply the visitor with these manifold attractions and conveniences there has been a large outlay by the municipality. The colonnade of the Mühlbrunn cost the town 700,000 gulden; the winter garden of the Sprudel, 300,000 gulden; that of the Markbrunn, 25,000 gulden; 300,000 gulden were expended on the Stadtpark; and as much as 250,000 gulden have been expended on the building of the Kurhaus, which contains suites of baths below, and above an admirable reading room, richly provided with periodicals of all countries, as well as hall room and restaurant, with the inevitable orchestra and music room attached to it; 600,000 gulden have been expended in the erection of a commodious and beautifully decorated theatre, which is provided with electric light, and where the performances are so arranged as to terminate always soon after nine o'clock. This theatre is kept by its lessee practically rent free, so as to enable him to provide for a small fee performances of adequate merit. The bathhouse at the Neubad has been erected at a cost of 150,000 gulden. Sool-baths (of glairy peat) and other specialities in medicated baths are liberally provided.

The Budget.—Now all this is done in a little town of 12,000 inhabitants, in a remote region, which has little to depend upon in the way of industrial production or other sources of wealth. How are the funds provided? The answer is to be found in the annual municipal budget, and it is a very simple one. The average number of visitors to Carlsbad is annually about 27,000, of whom 900 are English and 1,000 Americans. The chief sources of income are a small cure tax and music tax paid by all visitors who remain for more than five days in Carlsbad.

Cure Tax.—The cure tax varies according to the class in which the visitor inscribes himself. Noblemen, officers, landowners, independent gentlemen, professional men, bankers, manufacturers, and well-to-do people generally belong to the first class, and pay 10 florins; the second class, people of moderate means, pay 6 florins; the third class, that of the working class and small shopkeepers and people of small

means, pay 4 florins; the fourth class, children under 14 and servants, pay 1 florin.

Music Tax.—The music tax in the first class amounts to 5 florins for one person, 3 florins for two persons, and for a party of five or more 17 florins; in the second class, one person pays 3 florins; in the third class, one person pays 2 florins. Medical men and their families are exempt from these taxes. For the reading and smoking rooms in the Kurhaus the tickets are 2 florins a month. Each visitor, after his arrival, is supplied with a form of assessment to fill up according to the class in which he intends to rank himself, which is returned a few days afterwards for payment. In 1885 the cure tax yielded, I find from municipal accounts, 166,000 gulden; and the music tax yielded 63,000 gulden; the reading rooms 1,090 gulden; and the payments for baths taken by the visitors amounted to 129,000 gulden.

Bands.—The Kurkapello or official band consists of forty-eight members during the season, which lasts for five months; and throughout the winter it is maintained at a strength of twenty-four. It is conducted by Herr Labitzky, one of the best conductors in Europe, and no mean composer. This band has few rivals in any great city, whether for classical performance of symphonic music or for lighter pieces. In addition to this, there is an admirable band conducted by Herr Pleyer, which is paid by the hotel-keepers. The result is that you have music twice a day by the official band, and as often by the unofficial band. The selection of music was so good, and the performance so thoroughly delightful, that I collected the programmes, and have brought them away with me, and found them of much interest and use to some of our English band-masters.

Hints for Home Use.—I do not know how far these details may be of value to the administrators of our English health resorts, but it occurs to me that, by suitable bye-laws, they need have no difficulty in collecting a large revenue from the visitors, it being always thoroughly understood that these revenues should be expended, as at Carlsbad, for the benefit of the visitors. The torturing strains of the perambulating musicians who now make life more or less unendurable at our English watering places would be replaced by music such as really delights the ear and rests the mind. The incessant growth of smoke-producing houses, which swallow up year after year the green fields, the woods, and the country walks in which every watering place should abound, would be checked. Parks could be laid out, pleasure grounds provided, restaurants (which are the property of the municipality, and are administered under conditions free from extortion, and suitable to the needs of visitors) would abound. Instead of the visitor finding himself in a wilderness of brick, surrounded by competing extortioners whose activity knows no check but that of self-interest, he would find himself in a community where his feelings, his physical necessities, his mental repose, his recreation, and his facilities for healthy exercise are under the care of the municipality. I do not attribute to the Carlsbad municipality any large philanthropy or generous self-sacrifice for the benefit of their visitors, but they have had the wisdom to see that their true interest consists in consulting on a great scale the needs of their visitors as a community, and in providing by common municipal action, out of the resources which the visitors themselves supply, such extensive facilities for health and recreation as combine to make their place one of the playgrounds as well as one of the health resorts of Europe. It ought not to be beyond the resources or outside the sphere of the combined intelligence of the members of our local municipalities who seek to make their towns resorts for pleasure-seeking and health-seeking communities to adopt a similar scheme. What Carlsbad, nesting in the far off mountains of Bohemia, with a poor and scanty population surrounding it, and with only one line of railway communication, can achieve, ought not to be beyond the attainment of our English baths, situated near the centres of enormous wealth and limitless enterprise. Individual enterprise has worked wonders in England, so that too little thought has been given to the special spheres in which municipal combination is necessary to work out results which no individual can compass. It is, of course, easy to say that Englishmen would not submit to a cure tax or music tax at a British health resort. If not, why not? Has the experiment ever been made? My object in giving the above details is to furnish my reasons for believing that such an experiment, intelligently carried out in this country, is capable of producing results which would give the place that adopts it a new era of prosperity, and would confer no small boon on those who do not desire to be necessarily expatriated as they are at present because they cannot get a glass of hot saline water to drink in our English health resorts under the same conditions of convenient and pleasurable surroundings as are supplied at Carlsbad and other similar resorts on the Continent.

Antipyrin in Hay Fever.—*Antipyrin in Nervous Drowsiness.*—*Surgical Erythema from Iodoform Dressings.*—*Ventilation by Perforated Glass.*—*Epidemic of Small-pox.*—*Seaside Hospitals.*—*New Work on School Hygiene.*

DR. ADOLPHE BLOCH, formerly physician to the Havre Hospital, has used antipyrin with excellent results in a case of spasmodic rhinitis (hay fever). The patient was a man aged 33, who complained of cold in the head, from which he had suffered for two years. The affection manifested itself, in the morning on rising, and in the afternoon when the window was opened, by painful attacks of sneezing, with a copious discharge of watery mucus. There was severe itching and pricking in the eyes, which watered incessantly; and pain in the head over the frontal sinuses. These symptoms completely disappeared during the interval between the attacks. The throat and the nasal fossæ were normal. On July 6th, 1887, two grammes of bromide of potassium were prescribed; these were administered daily, morning and night, in syrup of orange-peel. From July 18th one pill, containing five centigrammes of extract of belladonna, was given every morning. The interior of the nose was constantly painted with a solution of hydrochlorate of cocaine (one gramme to thirty grammes of water). This treatment was continued for a week. The affection disappeared for two days, but subsequently reappeared. The dose of extract of belladonna was then administered twice daily. Ten days later, finding this treatment did not produce satisfactory results, M. Bloch ordered two grammes of antipyrin daily at the hours at which the attacks usually came on. After the first dose the affection ceased. During eight days only two slight attacks occurred. The treatment was discontinued for six days; during which there were no attacks; it was then resumed. During twenty days only two slight attacks occurred; one gramme of antipyrin was then administered daily before breakfast. The treatment was discontinued from September 20th to October 3rd. On November 8th the patient stated that the hay fever had disappeared since the early part of October, although he had ceased to take antipyrin. M. Bloch considers that the anæsthetic action of this substance was not confined to the sensory and secreting nerves of the nasal fossæ; it is highly probable that the special action of the antipyrin on the encephalic nerve centres caused the hyperæsthesia of the Schneiderian mucous membrane to disappear.

M. Bloch also obtained good results with antipyrin in a case of nervous drowsiness. The patient, a man aged 21, with a neurotic family history, complained of an irresistible inclination to fall asleep every day after lunch. The complaint showed itself after he recovered from typhoid fever two years previously. His digestion was impaired; he was subject to nightmare. The three last cervical and the three first lumbar vertebrae were painful when touched. The patient complained of weakness in the legs and itching in different parts of the body. Tincture of nuxvomica was prescribed in doses of six to eight drops before meals during six months. The digestion improved; the drowsiness diminished. Eight months later the patient again complained of persistent sleepiness, accompanied by headache and debility. Two grammes of antipyrin in the form of wafers were administered daily—one when the patient woke in the morning, the other at 11 o'clock. Four days afterwards the drowsiness and headache disappeared. The dose was reduced to one gramme, which was administered at 10 o'clock every morning. The treatment was alternately discontinued and resumed during ten or eleven weeks. On January 10th the patient stated that the drowsiness had entirely disappeared. He had not taken antipyrin for three weeks. The action of antipyrin manifested itself from the first day it was administered. A dose of two grammes, and subsequently one of one gramme, produced the effects required. M. Bloch believes that strong doses of this substance (four, six, and eight grammes, as prescribed by Caravias) should not be given. In this case of nervous drowsiness, antipyrin acted as a stimulant; it has the same effect as black coffee, but is more active, and the effect is more complete. M. Bloch considers that the constipation frequently caused by antipyrin powder may be attributed to the form in which this substance is administered. If it were given in water or syrup, this result would not ensue; but the unpleasant taste of antipyrin is best disguised in the wafers employed by Dr. Bloch.

Dr. A. Trousson records a case of erythema, following the application of iodoform dressings. The patient was a child aged 11, suffering from an ulcer, of hereditary syphilitic nature, on the left upper eyelid. Suture was performed in order to prevent contraction caused by cicatrix.

sation; dressings with finely powdered iodoform were applied to the ulcerated parts, which were then covered with hydrophile cotton and a muslin bandage, saturated with a 4 per cent. solution of boric acid. The following morning the patient's condition was very serious. He had been unable to sleep, owing to incessant pain, since the ulcer was dressed. The dressing was removed; it was stained with viscid serum. The left side of the face, from the edge of the eye to the edge of the lower maxillary bone, and from the nose to the eye, was red and inflamed. The nose was of a violet hue, tightly drawn, and covered in parts with phlyctenulæ: several of these had burst and discharged a thick, gummy serum. The inflamed region was bounded by a prominent edge; one of the submaxillary glands was enlarged. The wound itself had a healthy appearance; the suture of the eyelids remained firm. The inflamed parts were carefully washed with a solution of boric acid; dressings of borated lint and hydrophile cotton, thoroughly disinfected, were applied to the ulcer. The next day, the inflammatory phenomena had entirely disappeared. Dressings with boric acid, corrosive sublimate, or carbolic acid solutions were henceforth applied; the ulcer healed rapidly. Three weeks later, cicatrization was temporarily arrested; the ulcer was reduced to half its size. Iodoform was again applied; four hours afterwards, there were serious inflammatory symptoms. The treatment with iodoform was then discontinued, and the patient recovered.

M. Wallon has tried the experiment of ventilating schoolrooms by means of perforated glass. In rooms ventilated by this method, the quantity of carbonic acid was $\frac{1}{10000}$; in rooms ventilated by means of air-pipes, it was $\frac{1}{10000}$; and in unventilated rooms, it was $\frac{1}{10000}$. In rooms ventilated by means of perforated glass and air-pipes, the proportion of carbonic acid was $\frac{1}{10000}$. M. Wallon considers that the system of ventilation by means of air-pipes is superior to that of ventilation by perforated glass, which is only efficacious when there is little wind, violent currents of air interfering with the escape of the carbonic acid. These systems may be employed together with advantage.

At a recent meeting of the Conseil d'Hygiène, M. Dujardin-Beaumetz delivered his report upon the recent small-pox epidemic at Aubervilliers de Pantin and St. Denis. According to him, this epidemic was erroneously attributed to the presence of a temporary small-pox hospital, at the Porte d'Aubervilliers. M. Dujardin-Beaumetz believes that the atmosphere does not carry the germs beyond a hundred metres. Cases of small-pox were observed before the establishment of this hospital. He attributes the propagation of the germs to persons accompanying the patients to the hospital, and to patients who, on leaving it, retain a contagious influence which they carry about with them. He recommended the following prophylactic measures:—The patients should be isolated; all bedding and clothing belonging to persons attacked with small-pox should be disinfected by means of movable disinfecting stoves. The places inhabited by such persons should be disinfected by burning quantities of sulphur. Vaccination and re-vaccination should be made compulsory. Dr. Broussard agreed with M. Dujardin-Beaumetz as to the epidemic at Aubervilliers, and the prophylactic measures he prescribed. M. Léon Collin stated that when chief physician at the Bicêtre Hospital during the siege of Paris, he received into his wards 8,000 small-pox patients from the French army. During six months the average number of cases of small-pox was 1,500. During this period the disease was not more prevalent amongst the soldiers who occupied the Bicêtre fortress (100 metres distant from the hospital) than amongst those inhabiting other Paris fortresses or barracks. M. Proust insisted on the necessity of vaccination and re-vaccination with animal vaccine. He proposed that a calf or heifer should be daily led round each of the quarters where small-pox existed, in order that the entire population might be vaccinated and re-vaccinated. At the end of a week the epidemic would disappear.

At the Société de Médecine Publique et d'Hygiène Professionnelle, Dr. Armaingaud recently read a note on the seaside hospitals at Arcachon and Banyuls. The only seaside hospital for scrofulous children in France is at Berck. Dr. Armaingaud has given numerous lectures on hygienic questions, and distributed pamphlets gratuitously on the same subject at Bordeaux and in other towns in the South of France. With the money he received for inserting advertisements in these pamphlets, Dr. Armaingaud founded a hospital, with 20 beds, at Banyuls.

MM. F. Dubrisay and P. Yvon have just produced a work under the title of *Manuel d'Hygiène Scolaire*, in which all necessary information is given on the situation and arrangement of schools, the personal hygiene of school children; the prophylactic treatment of contagious or other diseases; the organisation of dispensaries.

MANCHESTER.

[FROM OUR OWN CORRESPONDENT.]

Students' Union Conversazione.—The Chairs of Surgery and Obstetrics at Owens College.—Royal Eye Hospital.—St. Mary's Hospital.

At the close of the Michaelmas term, the students of Owens College held the annual *conversazione* of the Union. All the debating and other societies were represented, and there was a large attendance of visitors. Many of the exhibits were very interesting; in particular, there was a fine display of physical apparatus, and experiments were carried out by the students themselves. The medical sciences were also well represented by exhibits of various kinds and numerous experiments. There was a very beautiful series of anatomical, botanical, and pathological exhibits; while the physiological exhibits were not only numerous, but such as to interest the general public. One of the most noteworthy features was the "Darwin Room," which contained copies of Darwin's works, various likenesses of the great naturalist, and several autograph letters.

The Chairs of Surgery and Obstetrics in Owens College will be advertised as vacant within a few days. It cannot be too clearly understood that the electors will endeavour to secure the best men they can; and it does not necessarily follow that local men will be elected, provided suitable and superior candidates from elsewhere apply.

At the out-patient department of the Royal Eye Hospital, in St. John Street, Manchester, over 10,000 patients have been treated during the year; while at the other branch of this hospital, in Oxford Road, about 6,000 cases were attended to in the corresponding period.

The directors of St. Mary's Hospital contemplate making great improvement in their premises, and already several thousands of pounds have been subscribed. Lord Derby, the President, has just announced a subscription of £1,000.

LIVERPOOL.

[FROM OUR OWN CORRESPONDENT.]

The New Royal Infirmary.—The Epidemic of Diarrhœa in the Summer.—Typhus Fever in Liverpool.—Report of Hospital Sunday Committee.—Donations to Hospitals.—University College and Vivisection.

FOR the past five or six years the necessity of having a new infirmary has been agitating the minds of all those interested, and much satisfaction is naturally felt now that the enterprise is fairly under weigh. The question of site caused much controversy. Very wisely, however, the committee determined to build on the old site, which is not only good from a sanitary point of view, but has the University College adjacent. It was hoped that more ground could be obtained so as to have the front of the hospital facing Pembroke Place. This was found to be impossible, a portion only of the already occupied land being purchased. The new infirmary will, however, have a frontage of 184 feet to Pembroke Place; and the architect, Mr. Waterhouse, has cleverly so arranged his plan as to have the administrative block erected here. The wards will be in six blocks, three to the north and three to the south of a main corridor running east and west. In addition, there are to be some wards built on the circular principle. The building is to cost £100,000, the greater part of which has already been subscribed.

The report of the medical officer of health on the recent epidemic of diarrhœa has been brought before the Health Committee. In it, Dr. Taylor recommends that, having regard to our dense population, the present ash-pit system should be abolished. He mentions that more than one half of the deaths were of infants under the age of 12 months, and states that he considers the disease to have arisen from some specific cause originating in, or propagated by, decaying organic matter pervading the atmosphere and polluting both water and food. The report concludes by pointing out how the rapid fall of temperature, with heavy rains and high winds, at the commencement of September, had a very beneficial influence on the public health.

At the last meeting of the Health Committee, a report was given in by Dr. Hope, the Assistant Medical Officer of Health, with reference to the spread of typhus fever, in which he emphasised the necessity of such cases being immediately reported to the health authorities. The spread was mainly in the neighbourhood of Menai Street and Slade Street, and was due to healthy persons visiting the houses of people suffering from fever. Not many weeks ago a young priest succumbed to an attack of typhus, caught in the infected districts.

This year's report of the Committee of the Hospital Sunday and Saturday fund is not very encouraging. The falling off in the sub-

scriptions, which has been noticeable for some time past, continues. Hospital Sunday yielded a little over £3,000, as against £3,200 last year. The decrease in the Saturday collections is £284, and in the donations £150. The cages placed in the public streets produced a better result by £5 than last year. The boxes left in workshops have been very poorly supported, 105 boxes producing only £11. The amount divided among the charities was £3,750.

Several of our hospitals have recently benefited to the extent of £500 each from the executors of the late Mr. Lyon-Jones.

Some days ago the London correspondent of the *Daily Post* referred to a speech by Mr. McLaren, M.P., at the Anti-Vivisection Conference, in which our University College was charged with an aggravated breach of the Vivisection Act. The Dean of the Medical Faculty, in a letter appearing in the *Post* of December 22nd, draws the attention of the public to Mr. McLaren's letter in the *Globe* of the 19th, in which he states that he conveyed a wrong impression to his audience, and desired to withdraw the statement.

SHEFFIELD.

[FROM OUR OWN CORRESPONDENT.]

The Small-pox Epidemic and the New Hospital.—Appointment of Medical Officer of Health.—The late Mr. John Carr.

At the Local Government inquiry into the subject of the Sheffield Town Council's application to borrow £12,500, for the purchase of land as a site for a hospital, and for providing hospital accommodation thereon, at Lodge Moor, for small-pox cases, Dr. Sinclair White made some observations on the present epidemic. It began in March. During the months of April and May the cases were very few, but in June the disease began to increase, and had gone on increasing ever since. In March there were 3, in April 4, in May 21, in June 43, in July 91, in August 146, in September 275, in October 498, in November 604, and, up to December 19th, 585. Notwithstanding the considerable hospital accommodation, not more than one-third of the cases they would have liked to have taken could be admitted. All the cases are not reported, but they had learnt of 2,270. The disease has also broken out at Rawmarsh, and Leeds, and at Wath, Worsborough, Ardsley, Hoyland, and Wombwell. A special conference of sanitary authorities was held at Barnsley, to concert means between the urban and the rural authorities for dealing with the epidemic, should it continue to spread. The new hospital at Sheffield is being pushed on with as rapidly as possible. The hospital, when complete, will be for 100 beds, and this is in addition to the large accommodation already existing.

Dr. Theodore Thomson has been appointed Medical Officer of Health, vice Dr. Sinclair White, resigned, at a salary of £500 per annum.

Sheffield has recently lost, in Mr. John Carr, probably the senior member of the medical profession there. He died on December 8th, and was within about three months of being eighty-six years old. Besides being actively engaged in practice, he had filled many honourable offices in the town. He was a member of the Town Council at its formation in 1843. He had filled the office of Mayor, and had been Chairman of the Health Committee. He relinquished public duties and practice some years ago.

CORRESPONDENCE.

ISOLATION AND SCARLET FEVER.

SIR,—May I ask for a little space to reply to some of the criticisms which my letter of November 5th on the above subject has called forth in the *JOURNAL* since that date. Some of your correspondents have sided with me, some against me; I am equally obliged to all alike. Not one, however, has really traversed my main contention, namely, that strict isolation will gradually increase the number of persons unprotected by a previous attack, and therefore the number of persons liable to be attacked during any given epidemic. The mere statements that adults are less liable to scarlet fever than children are unreliable and misleading, and the experience of physicians, no matter how eminent, of ten or fifteen years ago, is of little value under the newly developing circumstances of to-day. Least of all should I place value on statistics concerning adult patients made in the fever hospitals of the Asylums Board; the majority of adults decline to be moved there; many go through attacks of fever at home, hardly conscious that they have the fever, and only come under observation when kidney disease incapacitates them for work.

In saying that the exanthemata run a severer course in adults than in children, I believed I was stating a general experience—certainly

it is my own experience and that of many of my personal friends; but neither they nor I gauge the severity of a disease solely by its mortality. In the case of children, disease of all kinds is quite uncomplicated by conditions which, without exactly aggravating the type, in adults tend to render its incidence very much more oppressive.

Speaking again from my own experience, I am quite sure that a greater number of adults are attacked both with measles and with scarlet fever now than formerly. When writing my first letter (November 5th), I was thinking over the number of resident officers and of nurses who had succumbed with scarlet fever in the Shadwell Children's Hospital within the last eight or ten years. I ought to state that, although we do not treat such cases, a good many come under our observation in one shape or another in the course of a year (strangely enough, the present year has been an exception to this statement). I think it is exceptional for residents and nurses who have not had the disease not to contract it, if directly and continuously exposed to the poison. It would be interesting to have some precise details from the fever hospitals and from nursing establishments of the numbers of adults who, serving in one or another capacity closely upon fever cases, escape the infection—not being previously protected by a former attack. Do the authorities of these fever hospitals make any point of not engaging officers and servants unless protected by a former attack? What is the experience also of houses of business where large numbers of young men and women are housed together, during such seasons as the one that is just past (although the effects of strict isolation are only now beginning to act)? Would the authorities of the great schools argue that, as 95 per cent. of all cases of scarlet fever occur before the fifteenth year of life, therefore all boys over that age might remain in an infected neighbourhood without danger? I feel sure, from my own observation, that the apparent relative receptivity of young adults and of children depends far more largely on being, or not being, exposed to the poison than on mere age.

I presume one of the objects in view in isolating infected persons is to try and exterminate the *matrices morbi*. Such an end will never be accomplished in this manner, although, as Dr. Thorne has shown, no direct evils from aggregating patients in hospitals (such as occurred in the case of small-pox hospitals) can be urged in connection with scarlet fever. As at present carried out, and under existing laws, isolation only concerns the infected person; in a great many—in the majority, probably—of cases, the locality from which the patient is removed remains untouched. Hence my assertion that efficient treatment on the spot rather than purely isolation measures will, in the long run, prove of greater service alike to the individual and to the public at large.

As regards some individual criticisms, I would say to Dr. Whitelegge that nowhere in my letter did I argue "that mild cases of scarlet fever should rather be encouraged than otherwise." I referred, of course, to cases of fever occurring in houses where the infected can have ordinary treatment. The practice, which is a very common one, of sending the remaining part of the family off to the house of a friend or of some relation is a reprehensible one, and ought to be entirely discouraged. We must not forget that the Asylums Board provide only for the pauper classes, and that scarlet fever by no means restricts its attention to these classes. To Mr. Sweeting's criticism that "the spectacle of a well known surgeon at the end of the nineteenth century gravely propounding that cases of fever should be dosed with drugs at home, is one for gods and men," I would simply reply that there yet remain some twelve years of the nineteenth century, a period of time long enough to bring about changes in medical thought and practice as great and as radical as have been effected during the twelve years which expired at Christmas, and that I, for one, shall be much astonished if the present state of things as applied to infectious disease continues to be held quite as perfect and satisfactory as Mr. Sweeting evidently considers it to be. It is, perhaps, not very wonderful that this difference of opinion on the advantages of purely isolation treatment exists between him and me, considering from what different standpoints we have respectively gained our experience. I am not deprecating honest criticism, nor astonished that the views I tentatively put forward in my letter of November 5th should have met with criticism. On the contrary, I am rather surprised that so little has been found to urge against me. On the other hand, it is possible that some who think with me are, perhaps, induced to remain silent in fear of the cheap ridicule with which, for want of sound arguments, Mr. Sweeting meets my "forecast and suggestion."

On the general question, the arguments, I fear, are not wholly in favour of the *status quo*. The Asylums Board is doing good work from its especial point of view—providing accommodation for infected persons who cannot be properly treated at home. I would

further add, I think the Board are doing this work so well, that in each succeeding year during the "prevalence" of the fever—on numerical grounds we are no longer correct, I believe, in speaking of an "epidemic"—more and more persons will be glad to avail themselves of the facilities they provide; thus a larger and larger provision will have to be made by the Board. But will this suffice? Is not the Board doing part of the work of the local sanitary authorities, and are not the latter only too pleased to let matters rest?

It will have struck many, I doubt not, that notwithstanding all the Asylums Board could do, the fever continued to spread until the cold weather came and put a stop to it. If my suggestion could be carried out of isolating houses when infection breaks out, keeping it there until the infection has exhausted itself—the life of all these disease germs is a very limited one—and adopting every known precaution in the way of disinfection afterwards, on the spot where the fever showed itself, there would be a better chance of eradicating the evil. Mere removal of a patient will never do much good to the community, though the individual may gain. I consider it thoroughly essential to the successful working of any scheme that the homes where infection breaks out should be visited by local sanitary officers fearless in the discharge of their duties. Such visits from such officers would bring to light facts that would astonish those who interest themselves in the physical welfare of the artisan classes. I am sure that thousands of rooms which at present serve as homes for the poor would be pronounced absolutely unfit for human habitation.

Most of us have heard of "mysterious outbreaks" of scarlet fever or other infectious disease. I have myself ceased to attach mystery to such occurrences since one day, when anxious to learn something about an interesting hospital case, I sought out the child's parents in their home somewhere in the heart of East London; during my search, for these people had changed about from room to room, I chanced to come upon three women "sweating" over some slop-work. The proprietor of the room had invited her two fellow-workers to co-operate in fire and lights, on the principle that the three could be served just as cheaply as one; she was sitting on the side of a bed, and was alternately tending a crippled child, ill with measles, and plying her needle.

While such things are, the isolation of a few cases of fever, though highly beneficial to the individuals themselves, will do little to benefit the public health, however much money the Metropolitan Asylums Board may spend, and however much it may elaborate its (almost perfect) hospital arrangements.—I am, etc.,

ROBERT WILLIAM PARKER,
Surgeon to the East London Hospital for Children.

HOW SHOOTING ACCIDENTS OCCUR.

SIR,—Although shooting casualties can hardly be regarded as a medical subject, still the prevention of accidents might not unnaturally be as much within our province as the prevention of disease; so I venture to offer the following brief remarks upon the subject, which was referred to in the JOURNAL of October 29th, 1887, and in which it is stated that, "as a rule, the fact of an accident having happened is *prima facie* evidence of want of care." I think many sportsmen will agree with me in attributing most shooting casualties rather to ignorance than to want of care, in the strict sense of the term. All shooting accidents that have come within my knowledge so long as I can remember appear to have been due to one of three causes, each of which is in a great measure preventable: (1) Ignorance of how to handle and use a gun on the part of the shooter; (2) ignorance in the loader, when two guns are used; (3) ignorance of the manner in which birds should be killed when they are driven to the guns. To the last cause may be attributed the loss of nearly all the eyes which are shot, of which there is a considerable number during every shooting season. In regard, however, to cause No. 1, no one should be permitted to shoot game in company with others until he has as a boy been frequently taken out alone, and carefully taught how to carry and handle a gun. He would then have learned never to point it loaded or unloaded in a direction where anyone is or might be standing; never to get over a fence or ditch without taking out his cartridges; never to shoot at birds flying low except when he is walking them up, and then only when they rise, clear of the line, in front or behind him. He would also learn many other precautions which are so well known to sportsmen as to have become habitual with them; in short, it will be found that men who have been so trained are never the culprits in gun accidents which are included in causes of the first order. As to the second cause of accidents, it is sufficient to say that the directions for training loaders are so carefully and well given in the Shooting Number of the *Badminton Library*, that anyone accustomed to shoot with two guns will at once recognise how, if they are attended to, it is impossible for

his loader to shoot him, or he the loader, provided that he knows how to change guns, and never hands a gun at full cock, with either barrel, to the loader, who under no circumstances is allowed to touch a trigger. The third cause is the most interesting, as whenever an eye is lost in shooting (except those that are destroyed by the unpardonable sin of shooting low-flying birds in cover) it is at grouse or partridge driving.

A great deal might be said, and often is said, on this subject, for the accident is very frequent, but it is enough to say here that it always happens in the same way, that is, by following a bird, or traversing, as it is now called. To those who see driven birds for the first time—or, indeed, till they are accustomed to it—this habit, if they are not strictly warned against it, is almost irresistible; and it happens as follows:

In grouse driving, the batteries being in line, the bird is seen to be coming between the shooter and the next battery, say to the left of the gun in question. He raises his gun to the shoulder, and having covered the bird and not instantly shooting, follows the bird with the gun till he thinks it has well passed the next battery, and fires. The bird not having gone far enough behind the next battery at the moment the trigger is pulled, some (or one, perhaps) of the shot hit the man in the battery. The fact being that, if a man follows a bird in this way, his eyes being kept on the bird, he cannot estimate how far it is from the next battery when he fires. Besides, it must be remembered that if this is done, at some moment of time whilst the bird is followed the gun is pointed straight at the next battery, and, the finger being on the trigger, it might on that instant, from want of nerve or excitability, go off unintentionally. What should, of course, be always done if a bird is passing between two batteries, and is not shot at once well in front, is that the gun should be taken from the shoulder, and not put again to the shoulder till the bird has well passed the line of batteries. Precisely the same cause of accident and its avoidance apply to partridge driving, when guns are placed in line in a field and birds driven over a fence towards them.

It may be asked very naturally, Why is this form of accident so frequent, if its cause and the way to avoid it are so well known? Frequent it is, for I am sure there are not many men who have had much grouse driving who have not sometimes felt and heard shot rattle into their battery. I think the explanation will be found to be as follows:

When a man is shooting rising birds, if a bird is flushed in front of him and comes backward, he either kills it in front of him, or waits till it has well passed the line, then turns round, raises his gun quietly, and kills it. Thus there is no following the bird, for in this case he has plenty of time to see the bird, and there is no haste in the manner in which he kills it. But when birds are driven to him, they come on him suddenly; he misjudges their pace, which is three or four times as fast as rising birds, for they have been on the wing much longer, and when he raises his gun to the shoulder they are past him before he has time to fire, so that he follows the bird and fires after it has passed him. In fact, he finds that shooting the driven is altogether a different business to the rising bird, the whole proceeding being so rapid that he hastily loses his head, and does what he would be incapable of doing if walking up birds in line, that is, following a bird that is flying past a man.

Of course, a man who shoots really well does not follow his bird under any circumstances, but fires almost instantly the gun is to his shoulder; but amongst the large proportion of those who get health and amusement from shooting in their holidays there are many who are liable to dwell on birds and follow them before pulling on them, so, when not accustomed to driving, they should be especially warned against the insidious practice referred to. It may then, I think, be fairly said that it is not so much to want of care as to want of experience that shooting accidents may generally be attributed.—I am, etc.,

WILLIAM B. DALBY.

18, Savile Row, W., December 30th, 1887.

SWISS ALPINE HEALTH RESORTS.

SIR,—The letter of "Teax" gives excellent information about the hotels at Davos and St. Moritz and the journey out, though, in regard to the hotels, several important changes have taken place with the lapse of time.

The journey from London to Davos can be made in two days. Leaving Charing Cross in the morning by the 11 o'clock train, and travelling by the Bâle and Calais route, one reaches Davos about 9 o'clock in the evening of the following day. In the case of invalids, however, it is undesirable to make the journey in one stretch. If only one break be decided upon, Leodquart is the most suitable place

fer stopping at. One can get very comfortably put up there at the Hotel zur Post, and next morning take the diligence for Davos. If a second break in the journey be desired, Bûle is the best place to stop at. Should the intention be to look at all the winter resorts of the high Alps, Davos will be found the most suitable one to begin with. Wiesen can be most easily reached from here, and one can get over to St. Moritz in a day. From that point the Maloja is a pleasant drive.

It is always a great pleasure to me to see a professional brother out here; and, if "M.B., C.M." will write to me, I shall be happy to give him further information.—I am, etc.,

WILLIAM R. HUGGARD.

Davos-Platz, Switzerland, December 30th, 1887.

COMMUNICABILITY OF SYPHILIS THROUGH THE SALIVA.

SIR,—In the case reported under this heading in the *JOURNAL* of December 24th, by Dr. Carleton, M.S., it is stated that the tattooer had "well-marked tertiary symptoms." Now, as tertiary syphilis is generally considered not to be contagious, it would be very interesting to learn from Dr. Carleton (1) how long this soldier had had syphilis; (2) the character of whatever lesions he had about him, especially in or near his mouth, at the time of the operation; (3) the further manifestations of disease in the "victim."—I am, etc.,

ARTHUR COOPER.

20, Old Burlington Street, W., December 27th, 1887.

METROPOLITAN MEDICAL PROVIDENT ASSOCIATION.

SIR,—In answer to the letter from Mr. Piper, which appears in the *JOURNAL* of December 31st, allow me to say that I did not refuse to read Dr. R. H. S. Carpenter's letter. It will be in the recollection of Sir S. Wells that I turned to him and said, "I will read Dr. Carpenter's letter if you, Sir, direct me to do so;" and Sir S. Wells, as Chairman, decided that it would be the more convenient course for Dr. Carpenter to read his own letter when he replied to me. My speech, in fact, had very little reference to Dr. Carpenter's letter, and the question whether I had interpreted, rightly or wrongly, the clauses in it referring to private (so called) provident dispensaries seemed to me of little importance.

Equally incorrect is Mr. Piper's assertion that "those on the platform led off an opposition and an endeavour to drown by noise what Dr. Carpenter said in his reply." So long as Dr. Carpenter confined himself to his undoubted right of arguing the question before the meeting, he was heard with all patience; but, when he persisted in wasting the time of the meeting in irrelevant declamation about some institution with which he asserted that Sir A. Olark and myself were connected, and which he believed to be in some way connected with the Provident Medical Association, and when he either would not hear or would not listen to my assurance that I had never heard of the institution in question, and that the Association had nothing whatever to do with it; when he would not submit to the directions of the Chairman, and exceeded beyond all reason the limits of time prescribed both by the regulations of the meeting and the convenience of those present, an attempt was certainly made to stop him, in which I believe the whole meeting (and not those on the platform more than those in the body of the hall) joined, with the exception of a very small but very persistent minority. It would have conducted much to the proper discussion of the real question, if that attempt had been more quickly successful.

I repudiate entirely any responsibility for the disorder which occurred at the meeting. It was caused by Dr. Carpenter and his friends.—I am, etc.,

T. HOLMES.

18, Great Cumberland Place, W., December 31st, 1887.

SIR,—In the *JOURNAL* of December 31st, I observe a letter from a gentleman who states that he was present at the late meeting at the Society of Arts, at which the subject of provident dispensaries was discussed. Your correspondent there states "that the scene which took place began by Mr. Holmes and others of the Committee on the platform refusing to read a letter they had received from Dr. R. H. S. Carpenter upon which they were commenting."

This conveys a wrong impression. I was in the body of the hall, and have a very clear recollection of the facts, which were as follows: Mr. Holmes was moving the first resolution, and in dealing with the objections to the scheme of the Metropolitan Provident Medical Association he said that he had received a letter from a gentleman which, in his opinion, showed that the writer had entirely failed to grasp the bearings and intentions of the project. Hereupon Dr. Carpenter rose and, in an excited tone, cried: "Read the whole of the letter,

Sir." Mr. Holmes expressed his willingness to do so if the Chairman (Sir Spencer Wells) desired him. Sir Spencer being thus appealed to ruled as follows: "It will be better for Dr. Carpenter to read his own letter after Mr. Holmes has finished his speech."

Most of the noise subsequently was due to the opposition of the majority in the hall to the puerile and irrelevant remarks of two later speakers, an opposition, in my opinion, richly merited.

I left before the end, but can vouch for the above as a correct description of what transpired as far as it goes.—I am, etc.,

EVAN H. HARE, F.R.C.S.

46, Weston Park, Crouch End, N., December 31st, 1887.

FALLACIES IN FROZEN SECTIONS.

SIR,—In your very favourable notice of my work on *The Topographical Anatomy of the Child*, the following sentence occurs: "No reader should forget, however, that there are sources of fallacy in frozen sections." This raises too large a question to be discussed here, but I hope to deal fully with it in a paper I have on hand. Still there is one point in connection with this subject to which I should like to refer. In describing the method adopted in order to ascertain the position of the uterine appendages, I stated that after a vertical mesial section of the body of a girl 13 years of age had been embedded in plaster and hardened in spirit, the coils of the small intestines lying above the bladder and uterus were carefully turned aside, and the ovary exposed. I expressed an opinion to the effect that in doing this the position of the ovary was not disturbed. The reviewer does not share in this opinion, but believes that embedding in plaster-of-Paris and hardening in spirit implies a good deal of disturbance. He, however, very kindly suggests that my opinion may be based upon reasons not expressed in print. This is probably the case, for I ought to have explained that the parts were embedded in plaster while frozen, and allowed to thaw under spirit. I believe that a combination of the methods of frozen section and dissections is sometimes a very useful one, and not so fallacious as some suppose.—I am, etc.,

Edinburgh, 27th December, 1887.

J. SYMINGTON.

OPHTHALMIC OPERATIONS.

SIR,—In reply to Mr. Doyne's interesting queries, permit me to remark that hypermetropes who do not squint manage to see, but their vision is imperfect, much the same as myopes who have never worn glasses; such individuals suffer from a high degree of the affection, too high to be overcome by the accommodative effort which involves a squint. No doubt many hypermetropes exert their maximum of accommodation for distant vision; it must be so, for some of them more than neutralise the defect, becoming slightly short-sighted, and in these cases distant vision is improved by a concave glass. Some hypermetropes bring the type, when reading, very close to the eyes; no doubt this interferes with definition, but the enlarged retinal images thus obtained more than compensate for the loss of definition. The hypermetrope who is obliged to accommodate for distant objects the rays from which are parallel, must accommodate still more in order to focus near objects, the rays from which are divergent, and this effort involves a squint, because the power of accommodation is greatly increased by convergence of the optic axes.

If the hypermetropia can be overcome by convergence it means squint; if, however, it is too high to be so overcome, the patient does not squint. Concomitant squint means diplopia so long as the patient sees with both eyes at once; but the brain has a horror of double images and suppresses one, hence the squinting eye gets weak, and, not being used, is not so much converged, and the patient is said to have grown out of the defect, which means simply that one eye is nearly blind from disuse. Spectacles sometimes suffice for cure, but I do not think such cases are frequently met with.

It will be seen from the above that it is quite possible to mistake a case of hypermetropia for one of hypometropia or myopia, as it is constantly called. Such errors are, however, rendered impossible by the free use of atropine in doubtful cases. With regard to Mr. Snell's ingenious operation, the one advantage that he insists upon is that the operator can stand behind the patient during the whole process. I may, therefore, mention that this is the position which I always assume when performing the operation, which I have illustrated in your columns, and which was described in the *Medical Times and Gazette* of March 17th, 1877.—I am, your obedient servant,

CHARLES BELL TAYLOR, Surgeon to the Nottingham and Midland Eye Infirmary.

MEDICAL MAGISTRATE.—The name of Mr. John H. Wraith, M.R.C.S., L.S.A., of Darwen, has been placed on the Commission of the Peace for that borough.

NAVAL AND MILITARY MEDICAL SERVICES.

ARMY SURGEONS AND THEIR RECORD.

SIR,—At a time when the merits and demerits of army surgeons are being freely discussed, possibly with advantage to public interests, will you allow me to adduce certain historical facts of importance bearing on this subject, which go to prove that the British and Indian Medical Services have traditions of which they may well be proud? Sir James McGrigor, in his autobiography, writes as follows: "It was said with much truth by an eminent individual that he thought the extraordinary exertions of the medical officers of the army might be said to have decided the day at Vittoria, for their exertions had undoubtedly added a full division to the strength of Lord Wellington's army; and without these 4,000 or 5,000 men, it is more than doubtful if his lordship, with all his unrivalled talents, could have carried the day." The eminent individual here alluded to is Napier, the historian of the Peninsular war.

During the retreat from Bruges the Duke of Wellington forcibly remarked: "The medical department is the only one that will obey orders; on them I can rely for doing their duty" (vide *Army Surgeons and their Works*, by Surgeon-General C. A. Gordon, C.B., pp. 69 and 70). Kaye, the historian, in the Preface to his *Lives of Indian Officers*, writes: "I must express my regret that the volumes contain no example drawn from the Medical Service of the East India Company—a service which was never wanting in men equally eminent for their professional attainments, which are exercised so unstintingly in the cause of our suffering humanity, and for those heroic qualities which are exemplified by deeds of gallantry in the field, and by lives of daring adventure."

After the battles of Chillianwalla and Goojerat, Lord Gough wrote as follows: "Camp, Goojerat, 26th February, 1849. I feel I cannot too prominently bring to notice the valuable exertions of Dr. McRae, Field-Surgeon, and of the medical officers of the army generally; they have been most unwearied and praiseworthy."

The following is an extract from the same great commander's evidence before the Select Committee of the House of Lords in 1852-53:

It was my fortune to serve during the whole almost of the Peninsula war, and I have served through several campaigns in India, but in the Punjab campaign I do not think that at any one period there was a wounded man without his dooly, nor wanting any comfort it was possible to give him. The attention and assiduity of Dr. Frauklin, of Dr. Renny, and of Dr. McRae, the indefatigable Field-Surgeon, and of the whole of the medical staff of that army, was the most perfect machinery I ever witnessed.

The following is an extract of a letter from His Excellency the Right Honourable the Commander-in-Chief, Lord Clyde, dated Lucknow, February 21st, 1859:

The military operations in the Presidency of Bengal, which ensued on the great Mutiny of 1857, having been happily brought to a close, I have the greatest satisfaction in recommending warmly to your Excellency's protection two great departments of the military administration, to which the troops and the officers who have commanded them in their long campaigns are under real and great obligations. I allude to the Medical and Commissariat Departments. The former, being composed of officers belonging to the two services, has shown equally in the matters of general organisation and of regimental arrangements. The Director-General, Dr. Forsyth, and the Inspector-General of Her Majesty's Forces, Dr. Linton, C.B., in Calcutta, have worked successfully to meet the great requirements made on them; and the staff and regimental medical officers have well maintained the credit of their noble profession, and the reputation for self-sacrifice which belongs to the surgeons of Her Majesty's armies, a reputation which is maintained in the field on all occasions, as well as in the most trying circumstances of the hospitals.

It should be noted that such splendid double testimony as the above came, on the one hand, at a time when the fate of Lord Gough's army trembled before the indomitable courage of the Sikhs; and again, in 1859, immediately after a period of danger, such as has never, before or since, threatened British power in India. In referring to a list of the medical officers of the Bengal Establishment who fell during the Mutiny, I find that thirty-five surgeons and assistant-surgeons perished, of whom twenty-one were cruelly massacred by the mutineers; the rest succumbed to wounds received in action, cholera, etc.

In a Minute on the Indian Medical Service, dated February, 1856, written by India's greatest proconsul, the Most Noble the Marquis of Dalhousie, the following passage occurs:—

The absurdity of regarding a medical officer as a non-combatant is, I believe, abandoned. The medical officer comes constantly under fire like other men. Every campaign which is fought exhibits the names of medical officers in the lists of killed and wounded; and the returns invariably show that they still more often fall victims to their own exertions on behalf of their suffering comrades. Proof can hardly be required of such well-known facts. If it be, the fatal record of the service which our countrymen have been performing during the last year and a half in Turkey and the south of Russia will more than bear out the statement I have made.

In moving the vote of thanks to the army in the Crimea, the Duke of Newcastle made the following remarks in the Upper House:—

The other body of men to whom I allude are the medical officers of the army. [Hear, hear!] I speak not now, of course, of the medical organisation, upon which so much was said the other night; but I must state, in justice to an honourable profession, that never were greater exertions made, never was more humanity evinced than by the doctors of the British army in the Crimea. [Cheers.] I will only ask your lordships to consider for one moment the services performed by such a man as Dr. Thomson. He was left, under circumstances of the most painful nature, upon the field of battle, not to attend to the wounded of his own army, all of whom had been removed, but to a large body of Russians, many of whom, persuaded that an Englishman was little less than a devil, were prepared to murder any individual who might seek to render them succour and assistance. Among such men was Dr. Thomson left alone; he bound the wounds of some hundreds of these poor Russian soldiers, at the great danger of his life, but, nevertheless, he escaped. He returned to his duties in his own army, but it pleased Providence to remove him from his sphere of usefulness two or three days subsequently. His death was occasioned by the immense exertions he had made, and a disease which he had thereby contracted. [Hear, hear!] I must say, my lords, that if it has not been usual for Parliament to thank men such as these, I consider that it is not wrong for a Minister of the Crown in this House to acknowledge their services.

The following facts have reference to the conduct and losses of the Army Medical Service in more recent campaigns:—

Three surgeons—Conolly, Stace, and Hewson—died during 1885 from illness contracted on active service in Egypt and the Soudan. Surgeon-Major Porter died at Cabul on January 7th, 1880, deeply lamented. In March, 1881, Surgeon-Major Cornish died at Mount Prospect, Transvaal, from wounds received at Majuba Hill. At the same time Surgeon Landon was killed in action at Majuba Hill. In August, 1882, Surgeon-Major Shaw was killed in action in Egypt. Surgeon-General O. Barnett, C.I.E., died in July, 1885, from illness contracted on service at Suakim, loved by all who knew him. In March, 1886, Surgeon Lane died of wounds received in action in the Eastern Soudan. And on January 9th, 1886, Surgeon Joseph Heath was killed in Upper Burma while endeavouring to rescue a wounded officer.

This list of casualties amply proves how strongly actuated the Army Medical Service is by a sense of duty, loyalty, and courage. Those whose names I have mentioned were all faithful unto death, and the youngest of them was not afraid to perish in the cause of his country and in defence of his friend. Such feats as those above quoted (which are, I believe, quite in keeping with the present general tone of the British and Indian Medical Services) certainly do not point to "peacocking," or inefficiency. That no contemptible, despicable sluggard, or hopeless "bad bargain" was ever to be found in the Army Medical Department probably no one would for a moment maintain; but to assert that characters of this description prevail to such an extent as in the slightest degree to justify Mr. Labouchere's sweeping indictment will, I feel sure, be found, on fair inquiry, to be quite contrary to fact.

With regard to the sin of "cartridge-filling" as affecting public interests, and as detracting from the reputation of the Medical Department, no doubt many have been guilty of this terrible offence. Is it not possible, however, that an army surgeon may be not the less a gentleman and a good officer because he is a sportsman? I am inclined to think that sporting proclivities have saved many a young officer, both in England and on foreign service, from the hateful quadrivium of "beer, brandy, billiards, and betting." If Mr. Labouchere can find time to give impartial consideration to both sides of the question now at issue, it is possible—although I cannot say I am young enough to expect it—that he will, "before vote No. 4 comes on for discussion," see reason "willingly to qualify his former remarks." It is hard to believe that certain leaders of public opinion can desire to dismantle a service such as that above referred to. Are we to go back to the old prototype barber-surgeon of bygone times? Can it be, as I have heard it humorously expressed, that "more soap is wanted, and less science?"—I am, etc., D. BOYES SMITH.

Netley, December 19th, 1887.

RANK FOR ARMY MEDICAL OFFICERS.

SURGEON-MAJOR SIMMONDS writes from Laurencepore: An order has lately been published, rendering medical officers incapable of the presidency of not only courts-martial, but all other mixed committees and boards. It is ridiculous that medical officers who have been specially trained to sift important evidence, and on whose judgment the supreme issues of life and death often hang, should thus be less capable of petty judicial functions than the average army subaltern. It is all very well for the authorities, when the medical service is well filled up, to begin degrading it, but the old Nemesis of supply and demand will sooner or later overtake them. Little is to be gained by consulting the unworthy prejudices of a certain section of so-called combatants, right and justice must be done in spite of them.

The Indian medical officer has, as, say, superintendent of a gaol, often absolute control over the prisoners, and the entire equipment of the establishment; and surely, if fit for this, is qualified to preside over an ordinary board of survey on

blankets or brooches. He would prefer a hybrid title embracing the term surgeon, but whatever the title, the rank must be real and not delusive, and thoroughly safeguarded from after subterfuge and positive breaches of faith. If the medical officer is worthy of precedence at all, then he is worthy of real rank, if he is unworthy of the latter, then he has no business to have the former.

DEPUTY SURGEON-GENERAL.—We would state that the designation Army Hospital Corps was displaced by that of Medical Staff Corps about four years ago. The old officers of the former corps became quartermasters Medical Staff, and as such have now both honorary rank and titles. The officers of the Medical Staff are declared by Warrant to be the officers of and to command the Medical Staff Corps. An exactly analogous relationship exists between the Commissariat and Transport Staff and the Commissariat and Transport Corps; there is no regimental union in either case.

We regret that want of space prevents the publication of his letter, but he will find the question of hybrid titles alluded to in the analysis of the voting under the proposals submitted to medical officers. Substantially, his arguments against these titles are those set forth under B. and C. of that analysis.

M.B., M.S. writes: With a view to relieving the minds of any of my brother officers who may be under the impression that the grant of proper titles and rank would be incongruous in the Medical Staff, and would lead to our being mistaken, I enclose for their perusal an extract from a recent *Gazette* of the United States Army, which shows how the case stands in that service. I would merely, as comment on this, refer to the well known opinion of the Surgeon-General of the United States Army as to the gain in efficiency which followed the introduction of this system in his service. Had we, like our more fortunate American brethren, our proper position in the army, I think it goes without saying that we would not be subjected to such stupid attacks as have recently been made on us in the pages of a certain society journal.

Extract from the United States Army "Gazette," January 20th, 1887.

Leave for six months is granted to Major Samuel M. Horton, Surgeon.
Leave for two months, to take effect from December 1st, is granted to 1st Lieutenant Jefferson R. Keane, Assistant Surgeon.
Leave for two months, with permission for an extension, is granted Captain W. H. Arthur, Assistant-Surgeon, to take effect on the arrival at Fort Niagara of Captain Paul R. Brown, Assistant-Surgeon.
Lieutenant-Colonel Andrew K. Smith is assigned the duty of Attending Surgeon in New York City, to relieve Colonel Joseph R. Smith, Surgeon, who will repair to St. Paul for duty as Medical Director.

Justice writes from India: It is high time the crying injustice and sorrowful humiliation to which surgeons-major of long service, in charge of hospitals in this country, have to put up with from the heads of their own department. Orders to bring them into contempt are constantly issued; their superiors are required to "mark and notify" every mistake and correction required in returns sent in, that such lapses may be embodied in confidential reports against them. Even petty breakages of hospital crockery are scored against the medical officers, as if they were so many "slaves" of all work. How long is such pettifogging administration to be endured without organised protest?

A CONTRAST.

FORTUNA FAVET FORTUNIS writes: In a *Gazette* some time past, referred to at the time in your columns, in which Surgeon-General Manby, V.C., and a Quartermaster, Medical Staff Corps, were gazetted out, the anomalous rank of army medical officers was pointed out.

I would refer to a similar instance in the last *Gazette*, in which Surgeon-General Reade, V.C., and a Quartermaster are placed on the retired list. What will be the status and how will they be received in civilian society? The one as Dr. Reade, a retired army doctor, the other as Major —, a retired officer of the army, and as such of superior official and social status to his late commanding officer.

In spite, however, of the indifference with which a grateful country rewards her army surgeons, the name of Surgeon Reade, Gist, will live in the historic memoirs of the Indian Mutiny, as a brilliant example of initiative and gallantry, when, on September 14th, 1857, he led a storming party of his regiment against overwhelming odds; and again, later in the siege, was one of the first to mount the breach of the magazine, which was stormed by his regiment. And yet we are told we have no grievance when men who have made history, and whom we look up to as heroes in our corps, are rewarded with such stint.

THE NAVY.

Surgeon A. W. McLeon has been placed on the retired list of his rank. His commission bears date September 20th, 1877.

Staff-Surgeon VALENTINE DUKE, B.A., M.B., has been promoted to the rank of Fleet-Surgeon. He entered the service as Surgeon September 7th, 1858, and became Staff-Surgeon December 20th, 1878.

Fleet-Surgeon E. J. BUTLER, B.A., M.D., has been placed on the retired list of his rank. He entered the service as Surgeon October 20th, 1859, became Staff-Surgeon August 2nd, 1871, and Fleet-Surgeon January 30th, 1882.

Mr. M. W. COLAHAN has been appointed Surgeon and Agent at Galway and Barra.

THE MEDICAL STAFF.

DEPUTY SURGEON-GENERAL A. F. BRADSHAW is brought on the administrative medical staff of the Bengal army, vice Deputy Surgeon-General J. Ferguson, whose tour of service in India has expired.

Surgeon G. F. H. MARCS is placed on general duty in the Poona Division, Bombay command.

Surgeon R. S. F. HENDERSON, M.B., serving in the Bengal command, has been posted to the station hospital at Mandalay, for duty.

Brigade-Surgeon H. C. HENNETT, M.D., F.R.C.S.I., is granted retired pay with the honorary rank of Deputy Surgeon-General (ranking as Colonel). His commissions are dated:—Assistant Surgeon, September 15th, 1857; Surgeon, May 8th, 1872; Surgeon-Major, March 1st, 1873; and Brigade-Surgeon, December 9th, 1882. He has no war record.

Surgeons W. T. SWAN, M.B.; J. H. DALY; B. L. MILLS, M.D.; C. A. RENN, M.B.; J. G. BLACK, M.D.; and F. W. G. HALL, M.B., all of whom are serving in the Bengal command, have passed the examination in Hindustani by the lower standard.

Surgeon A. DODD, serving in the Bombay command, has leave of absence for six months on private affairs.

The undermentioned gentlemen, who have arrived from England for service in the Madras command, are posted as follows:—Surgeon-Major F. A. DAVY, M.D., to be Senior Medical Officer at the Rangoon Station Hospital; Surgeon F. H. M. BONNAS, M.B., to do general duty in the Bangalore Division and Belgaum and Coond Districts; Surgeon A. L. H. DIXON to do general duty in the Eastern District.

THE INDIAN MEDICAL SERVICE.

SURGEON-MAJOR C. F. OLDHAM, Bengal Establishment, is promoted to be Brigade-Surgeon, vice J. C. Morice, promoted. Brigade-Surgeon Oldham entered the service as Assistant Surgeon July 27th, 1859, and became Surgeon-Major July 31st, 1873. He served with the 1st Goorkhas in the operations in the Malay Peninsula in 1875-76 (medal with clasp), and with the same regiment in the Afghan war in 1878-79 (medal).

The retirement of Brigade-Surgeon E. BONAVIA, M.D., Bengal Establishment, is cancelled.

Surgeon-Major A. J. WILLCOCKS, M.D., Bengal Establishment, Officiating Civil Surgeon, first-class, on return from privilege leave, is appointed to the civil medical charge of the Agra District.

The services of Brigade-Surgeon A. H. HILSON, M.D., Bengal Establishment, Civil Surgeon, First Class, Agra, are placed at the disposal of the Government of India in the Home Department.

The services of Surgeon A. D. EVANS, Madras Establishment, Acting Civil Surgeon, Moulmein, are placed at the disposal of the Major-General commanding the Upper Burmah Field Force from the date on which he may be relieved by Surgeon-Major G. T. THOMAS.

Surgeon C. J. BANDER, Bengal Establishment, Civil Surgeon, is transferred from Pyniaulin, and appointed to the medical charge of the Indian Marine Establishment at the Shore, Mandalay, in addition to his military duties.

Surgeons F. J. CHAWFORD, M.D., and A. H. JACOB are admitted to the Madras Establishment from November 16th, the date of their arrival at Bombay.

Surgeon W. H. QUICKE, Bombay Establishment, is appointed to officiate in medical charge of the 2nd Native Lancers.

The following postings have been ordered in Burmah: Surgeon-Major J. P. McDERMOTT, Madras Establishment, to Yewan, to assume medical charge of the 15th Madras Infantry; Surgeon W. CONRY, Bengal Establishment; proceeds with the section of his field hospital to Mandalay; Surgeon D. P. WABLIKER, Madras Establishment, to the General Hospital for native troops, Mandalay; Brigade-Surgeon G. D. RIDDELL, Madras Establishment, to the medical charge of the Native General Hospital, Mandalay.

Surgeon H. W. PILGRIM, Bengal Establishment, is appointed Officiating Medical Officer to the 9th Native Infantry, vice Surgeon-Major A. H. Williams, M.D., granted leave out of India.

Surgeon F. S. PECK, Bengal Establishment, is appointed Civil Surgeon of Mymensingh, but will continue to act as Civil Surgeon of Sarun.

The services of Surgeon-Major M. ROBINSON, Madras Establishment, are replaced at the disposal of the Commander-in-Chief.

Surgeon A. H. JACOB, Madras Establishment, who has arrived from England, is directed to report himself to the Deputy Surgeon-General, Her Majesty's Forces, Eastern District, for duty.

Surgeons C. R. M. GREEN, E. C. HARE, F. C. CLARKSON, J. D. M. SWINBURNS, and J. MORWOOD, M.D., all of the Bengal Establishment, have passed the examination in Hindustani by the lower standard.

Surgeon G. H. D. GIMLETTE, M.D., Bengal Establishment, Residency Surgeon, Nepal, is appointed to officiate as Medical Officer 1st Central India Horse, and of the Goona Political Agency, from the date of joining, vice Surgeon C. G. W. Lowdell, who has been granted furlough, and whose services are replaced at the disposal of the Military Department.

Surgeon D. SIMPSON is admitted to the Madras Establishment from November 2nd, the date of his arrival at Bombay.

Surgeon-Major G. E. E. BURROUGHS, Bombay Establishment, in medical charge 3rd Light Cavalry, has been granted leave out of India, on urgent private affairs, for six months, from date of being struck off duty.

Deputy Surgeon-General A. M. GARDEN, Bengal Establishment, retired, died at Marrow, near Guildford, on December 17th, at the age of 55. He entered the service as Assistant-Surgeon, January 11th, 1855, and attained the rank of Brigade-Surgeon, November 27th, 1879; he retired with the honorary rank of Deputy Surgeon-General, January 26th, 1881. He does not appear to have seen war service.

THE VOLUNTEERS.

Surgeon T. E. UNDERHILL, from the 1st Volunteer Battalion South Staffordshire Regiment (late the 1st Stafford), is appointed Surgeon to the 2nd Volunteer Battalion Worcester Regiment (late the 2nd Worcester); and Surgeon H. H. SMITH, from the 1st Volunteer Battalion, Worcester Regiment, takes Surgeon Underhill's place in the 1st South Stafford.

The undermentioned gentlemen are appointed Acting Surgeons to the corps specified: R. B. GRAHAM, 1st File; E. W. WHITE, M.B., 2nd Volunteer Battalion West Kent Regiment (late the 3rd Kent); J. M. HAAPER, 1st Volunteer Battalion Somerset Light Infantry (late the 1st Somerset).

Acting Surgeon A. HAY, M.D., 1st Dumfriesshire, has resigned his commission, which bore date January 24th, 1877; he is permitted to retain his rank and uniform.

Acting Surgeon G. A. RAVRATY, 18th Lancashire (Liverpool Irish), has also resigned his appointment, which dated from April 16th, 1884.

Acting Surgeon T. W. C. JONES, 14th Middlesex (Inns of Court), is promoted to be Surgeon to the same corps. Surgeon Jones joined the Inns of Court February 8th, 1882.

SURGEON-GENERAL, writes: I think the recommendation of "A Correspondent," in the *JOURNAL*, of December 17th, an excellent one—that a subscription be started for the purpose of defraying the cost of forwarding a copy of the analysis to every member of both Houses of the Legislature, and to meet any other expenses that may arise in this and the probable struggle arising out of vote 4 in the House of Commons. Should a subscription be started for the above object, at your office, I, too, shall be happy to contribute £1 as my mite.

MEDICO-LEGAL AND MEDICO-ETHICAL.

A SATISFACTORY DECISION.

A CASE which was recently tried in the Sheriff's Court, at Dumfries, should serve as a warning to those who are disposed to pin their faith on bone-setters. A medical man brought an action against a farmer to recover his charges for professional services rendered. The farmer had met with an accident to his knee, causing damage of a more or less permanent nature. When he received the medical man's account, he wrote saying that his injuries had not been properly treated, and that in consequence his knee had been ruined, and that he purposed raising an action of damages for £500 in the Court of Session for maltreatment, on the authority of a north country bone-setter. The medical man immediately brought his action, and when it came on the farmer withdrew his allegations and threat of an action for damages, and craved to be allowed to make payment of the account by instalments. The sheriff, however, held that he was deserving of no sort of consideration, and gave a decree for payment of the full sum, with expenses.

ANOTHER DRAWBACK TO THE EMPLOYMENT OF UNQUALIFIED ASSISTANTS.

MR. CHARLES HENRY HARRAL, L.R.C.P. Ed., M.R.C.S. Eng., L.S.A. (52, Kirkgate, Leeds), referring to the reply to Mr. Nevitt, published in the JOURNAL of December 10th, page 1307, writes: What we wish to know is this. Supposing a claim is made for, say, twelve visits, of which perhaps four are made by an unqualified man, is the principal entitled to charge for such visits with those made by himself? As I understand it, the registrar of this court refuses to allow for any work except that done by the qualified man; and should he keep an unqualified assistant, although he has not seen the case in question, and the debt is admitted, he still requires the personal attendance of the principal at court. This means the loss of much valuable time.

Of course, we all know that the attendance by an unqualified man solely cannot be claimed; but surely he may be permitted to make occasional visits, under the direction and supervision of his employer, who can charge for such services. I believe the same ruling was given in a case of midwifery; so that practically it amounts to this: that one must either have done all the attendance and personally make the medicine, or be non-suited. Surely this is unfair to the employer, and also to the unqualified assistant, who is generally compelled to work for his living until he can obtain his diploma, and who cannot in any other way learn the real practical part of his profession.

The questions to be answered are: First, is a medical man entitled to charge for the partial attendance on a case by an unqualified man, under his direction and supervision? Secondly, can he claim for attendance on midwifery cases by such assistants, the after attendance being made by himself? Thirdly, is the Registrar right in law in requiring the personal attendance of the principal at court when the debt is admitted?

The first question is best answered in the words used by Lord Coleridge in giving judgment in the case of *Howarth v. Beverley*, to which we have already referred: "If the qualified man had given advice, and the unqualified man had been merely the ministering hand under the directing brain of the qualified man . . . the services were those of the qualified man." In such cases the registered practitioner can recover. Where some visits are made by himself, he is undoubtedly entitled to his charges for them; but as regards visits made by an assistant, he must satisfy the court that he did in fact direct and supervise what the assistant did. If he can prove this, he may be entitled to recover charges for the assistant's visits, but not otherwise. County courts are not mere debt-collecting agencies, and are not bound to give judgment for the plaintiff merely because the defendant fails to appear to dispute the claim.

The Leeds registrar apparently considered that he had good grounds for supposing that some practitioners have brought actions to recover payment for services for which they were not legally entitled to charge, and if so, he is perfectly right in insisting on strict proof in all cases which he thinks suspicious. This may be a hardship on some perfectly honourable practitioners, but they have no real ground of complaint unless they are refused judgment when they prove their cases.

2. Midwifery cases stand on the same footing as others. They seem to come within the words of the statute, "medical or surgical advice, attendance, or the performance of any operation."

A MEAN FRIEND.

X. Y. Z. writes: A short time since an accident occurred near my house to Mr. A., on whom I attended. Mr. B. immediately afterwards called at my house, and requested to know at once how much I was going to charge for my attendance, etc., which I could not then possibly tell. Mr. B. requested me to attend his friend properly. Next morning he brought another medical man to meet me in consultation; he ordered a nurse in my name; and later in the day requested me to have a further consultation. An appointment was made by letter, and the consultation took place on the third day, Mr. B. being present, and he paid the consultant's fee.

After my attendance was over I received a letter from Mr. A., saying that his friend B. requested my account, which was duly sent and acknowledged by B. six days afterwards. B., however, stated that the amount was in excess of what he thought proper, and that he could not pay it; however, under the circumstances, he wished to be fairly liberal, and he thought this would be done by his paying £—, which he accordingly enclosed. I complained at once, and asked for the balance of account by a second letter, my charge not being more than my usual fee (which is not more than the usual scale), the amount having

been previously submitted to one of my old tutors. 1. Mr. B. pleads that he did not request me and direct me to attend Mr. A. 2. That the Statute of Frauds has not been complied with, 29 Charles II, chap. 3. 3. That I accepted £— in accord and satisfaction.

* * * On the circumstances stated it is clear that B. requested the attendance and made himself liable to pay the ordinary and proper charges; also that the cheque sent was not accepted in satisfaction of the whole claim. The Statute of Frauds does not seem to apply to such a case as this.

LOW FEES.

SUPPLY AND DEMAND writes: I am surprised to see in a note in the JOURNAL of December 17th, on "a business card," that you consider it unprofessional to charge such fees as "1s. for advice and medicine at the surgery," "1s. 6d. for visit and medicine, and 12s. 6d. for midwifery." What then, I would ask, are the lowest prices that can be considered professional in the above instances?

* * * Our correspondent's conception of what is due, not merely to himself, but to the profession at large, in relation to professional charges, is certainly not in accord with that of the great body of his brother practitioners. Need we remark that the fees in question for medicine and advice, although in excess of those usually specified on such self-advertising cards, are nevertheless lower than the ordinary charge of a chemist for medicine only. But even were it otherwise, the simple fact that the professionally objectionable cards were extensively and indiscriminately circulated of itself constituted a regrettable proceeding. Our correspondent may, we think, peruse with advantage the latter part of the fourth rule, page 53, of the *Code of Medical Ethics*, in reference to "sham" dispensaries.

FEES FROM THE CLERGY.

GRAFTON writes: I have been requested by a vicar, who lives at a distance of five miles, to attend his curate, who resides with him. Am I justified in making any charge for my visits; and, if so, to whom, the vicar or the curate?

* * * If our correspondent had been an observant reader of the JOURNAL he may have noted that the question of professional charges to the clergy has been repeatedly answered therein. Nevertheless, we have pleasure in assuring him that he will be fully "justified in making a charge to the curate," in accordance with the rule laid down in the second edition of the *Code of Medical Ethics*, page 79. His statement of charges should, in our opinion, be made out in the name of the curate, not the vicar, unless so desired.

THE SALE OF FOOD AND DRUGS ACT IN YORKSHIRE.

A CORRESPONDENT writes: At the Leeds West Riding Police Court a milk-seller was charged with obstructing the inspector of weights and measures by refusing to sell a sample of milk for the purpose of analysis, an offence punishable under Section 17 of the Sale of Food Act. It appears that the defendant was driving a milk cart, when the inspector asked him for a sample out of a particular can. The defendant refused to sell; and on the officer insisting, upset the contents of the can into the road. The bench of magistrates dismissed the case, holding that the prosecution had failed to prove that the milk was in course of delivery.

The case forcibly illustrates previous comments on the working of the Sale of Food Act which have from time to time been made in the JOURNAL. An excellent Act is mismanaged, and but too often rendered worse than useless by the action of the magistrates charged with administering it. If there could have been a shadow of a doubt whether the milk in question was in course of delivery the action of the milkman clearly showed his guilty conscience. A declaration on his part that the milk was not in course of delivery, but was intended for purposes other than human food, say, for that of pigs or other animals, an assertion which if true could have been substantiated in evidence, would have fully exonerated the milkman. But to knock down a churn for the purpose of destroying the *corpus delicti* is surely as conclusive evidence of guilt as the dropping of a watch by a pickpocket or a jemmy by a burglar.

* * * The magistrates were not wrong in the course they took. It is no offence merely to be in possession of adulterated milk, and some evidence must be given that it is (1) on sale or (2) in course of delivery to a purchaser in order to support a conviction for refusing to sell. The illustration of the burglar and the jemmy is unfortunate. Parliament has deemed it necessary to make the mere possession of house-breaking tools an offence, without proof of any attempt to break into premises. If a man was found under suspicious circumstances near premises where a burglary had been attempted or committed, the fact that he dropped a jemmy would be strong evidence that he was the burglar; but if he dropped the jemmy in the street, no premises having been attempted in the neighbourhood, he must be punished for possessing house-breaking tools, if at all. On the facts stated, a conviction might have been supported; but if a case were taken for the opinion of the High Court, the judges would not order the magistrates to convict.

LUNACY CERTIFICATES: ACTIONS FOR DAMAGES.

INFELIX writes: A brother practitioner and myself are to be made defendants in an action for damages, brought by a person who was put into confinement under our certificates some three or four years ago. Would you give me a reference to any such case, that has been tried of recent years, in which the grounds of action have mainly been that the statements in the certificates of the certifying medical men are insufficient, or considered so, to prove insanity?

* * * The subjoined list will furnish some of the information for which "Infelix" asks, although, in some of them, the chief or sole ground of action was scarcely the alleged insufficiency of medical certificates to prove insanity. The list does not pretend to be complete.

Smith (complainant), Lattey (defendant), at Southam Petty Sessions. *Midland Times*, December 3rd, 1887; BRITISH MEDICAL JOURNAL, December 17th,

1887, p. 1361. *Tanfan v. Sporgin*; tried in London November, 1886, before Mr. Justice Dean. Daily press, and JOURNAL, November 27th, 1886, p. 1043. *Hughes v. Langmore and Armstrong*; tried in London November, 1886, before Mr. Justice Manly. Daily press, and JOURNAL, November 27th, 1886, p. 1044. *Hasker v. several medical men*. Several actions tried in London in 1884 and 1885. Case from Lewes; tried in London 1885. Female plaintiff v. Whittle and others of Liverpool, and Mondil, of Cheadle, Manchester, about 1884. *Weldon v. Rutherford*. *Weldon v. Semple*.

M.D.—In referring to our correspondent's letter (without the slightest wish to traverse the statements therein) to the assessor—which, *ex necessitate*, came under our notice—we think it well to remark that, in our opinion, he has acted wisely in "unreservedly withdrawing the complaint or accusation as being intended to apply personally to the individual attended to any more than they would to any other practitioner similarly circumstanced." Be that as it may, we deemed it expedient, in consequence of the assumed personality, to investigate the matter more fully, with the result that, under the circumstances disclosed, we feel that the opinion expressed in our reply to "X. Y. Z." was more than justified.

G. J. W. F.—"In the interest of peace," (and of the profession also, it may be well to add), to quote the language of our correspondent, we would suggest that "the matter be now allowed to drop." Nevertheless, if, in assumed justice to himself, he deems further investigation of the alleged facts essential to a due vindication of his professional conduct in the cases, we shall be glad to receive, with as little delay as may be, the proffered correspondence, and especially that which relates to the alleged "dismissal" of Dr. A. prior to Mr. T.'s obstetric engagement by Mrs. W.; in reference to which we note the fact that, although the copy of her exculpating note is dated November 2nd, it was not transmitted to us until December 13th.

MIDWIFERY FEES.

W. F. writes: I was engaged by a clergyman on October 6th to attend his wife in her confinement about the middle of this month. I was sent for to see her about a fortnight ago for some trifling ailment. I have since received a letter to cancel the engagement for the following reasons: 1. That the distance was too great. The distance is not more than a mile, and neither of us has changed our residences. 2. That I had neglected to call on her unasked—a proceeding which I should deem unprofessional. 3. That I declined to administer chloroform as a matter of course during her labour, except if, in my judgment, I thought it necessary to do so.

I need not say that I refused to cancel the engagement, and solicited the fee that was agreed upon. I write to ask if my professional conduct has been correct; and whether, if in the event of a refusal to pay the fee (which the patient seems inclined to do), I can recover it in the county court.

* * W. F. has been perfectly correct in his conduct in the case, and we believe could recover in the county court. It depends, however, on the view taken by the particular judge; they differ on such questions.

A TESTIMONIAL TO A SECRET REMEDY.

MEMBER OF THE B.M.A.—So gross a departure from the ordinary collegiate disciplinary rules, as the "medical opinion" paraded in Messrs. D. and Co.'s placard advertisement, should, in our opinion, for the honour and dignity of the profession, be at once referred to the respective Councils of the University of Dublin and of the Royal College of Surgeons of England, of which the giver of the testimonial is a reputed graduate and member. A simple note from our correspondent, enclosing therewith the illustrated handbill, can scarcely fail to induce them to take action in the matter.

MEDICAL ETIQUETTE.

A. and B. are the two practitioners in a country town. A. is junior, and has been in practice only a few months. A. informed B. that he should have to make any practice he might get out of B.'s. B. sees no objection, provided it is done in a legitimate manner. B. is called to a case, but is out, and will not be home till 12 o'clock. The husband cannot wait, and goes to A., who attends, prescribes, and finds the patient within a fortnight of her confinement. B. has always attended her, and is engaged to attend again as usual. A. is informed of this by the husband, but goes on attending, and also attends the confinement, which is hastened by the present attack. B. asks: Should not A. have informed B. that he had gone to a case of his in an emergency, and declined to attend the confinement? B. only hears of the circumstances a fortnight after, when the husband calls, explains, and apologises.

* * The line of conduct which should have been pursued by A. in the case related by B. is clearly laid down in the following rule (7) extracted from the second edition of the *Code of Medical Ethics*, page 69: "When a practitioner is called to an urgent case, either of sudden or other illness, accident, or injury, in a family usually attended by another, he should (unless his further attendance in consultation be desired), when the emergency is provided for, or on the arrival of the attendant in ordinary, resign the case to the latter, but he is entitled to charge the family for his services."

CONSULTANTS AND GENERAL PRACTITIONERS.

M.D., F.R.C.S.Ed., writes: I am in general practice a few miles from one of our largest provincial towns. Cases sometimes occur when I wish for the opinion of either a specialist or general consultant. He appoints a time to see my patient at his own rooms, and, if I am unable to be present, he writes to me afterwards his opinion of the case, and suggestions as to treatment. So far so good. Instead of now leaving the case still in my hands, I find in a large number of instances that the consultant makes an appointment with my patient to return on a certain day. He goes, and then he is given a prescription, and told to come back again *ad lib.*, resulting in many cases in my losing sight of my patient altogether.

* * In giving the desired publicity to "M.D.'s" temperate communication

relative to the alleged [line of] conduct pursued by certain specialists and consultants, we note with regret that such disloyal action towards a professional brother is calculated to engender a more or less general distrust, and very naturally to induce general practitioners to rely on their own unaided skill in cases of doubt and difficulty. A policy so suicidal on the part of consultants ought, in our opinion, to be severely condemned.

PRINTED TESTIMONIALS.

W. K. asks for advice on the following point: A. gives goodwill of his practice to B., who has just come to the town. Is it a transgression of medical etiquette for A. to leave a copy of B.'s testimonials with his patients as he is introducing B. or taking his leave of them? B. had his testimonials printed in the form of a small pamphlet, as he was competing for an appointment in the town.

* * Although it is customary for the several candidates, in the case of a contested appointment, to transmit to the elective body a copy of their respective testimonials, it would be contrary to professional etiquette, and in bad taste, for A., on personally introducing B., to leave a copy with the patients. If, from some exceptional cause, such a presentation be deemed important, it should be effected by A. alone (in simple confirmation of his individual opinion of his intended successor), either prior or subsequent to B.'s introduction, and should, moreover, be strictly limited to A.'s *de facto* patients.

INDIA AND THE COLONIES.

INDIA.

A PRINCE OF PHILANTHROPISTS.—The Maharajah of Darbhanga, in Bengal, has established a hospital and dispensary for female patients near his ancestral seat in the district of Darbhanga, Behar, and is erecting new quarters for its accommodation at a cost of 55,000 rupees, in connection with Lady Dufferin's Medical Aid for Women Fund. This is one of the least considerable of the long series of philanthropic acts on the part of this distinguished Hindoo on a scale of magnificence hardly ever equalled.

SOUTH AFRICA.

HYDROPHOBIA.—Dr. W. C. Scholtz has sent to the *South African Medical Journal* the following account of a case of hydrophobia published in the *South African Chronicle and Mercantile Advertiser* in August, 1825. The special interest of the quotation is that it is generally stated that the South African colonies were free from the infection of rabies:—

HYDROPHOBIA.

STELLENBOSCH.—A very melancholy and distressing case of this horrible and incurable disease has occurred within these few days at the place of Mr. M. Beyers, at Clapmuts, John Edwards, formerly a farrier in Her Majesty's 21st Light Dragoons, a long resident on the place of Mr. Watney, and well known in the neighbourhood of this district, was suddenly attacked with its characteristic symptoms on the morning of the 15th instant, namely, inability to drink; a kind of convulsive horror on the approach of liquids to his mouth; with a severe shooting pain, extending itself to the bottom of his breast bone; these symptoms continued with more or less severity until the last; his sufferings happily were not so great, unless in forcing himself to drink—thirst being excessive; he suddenly and unexpectedly expired in the afternoon of the 17th, in full possession of his senses, about ninety-two days intervening from the infliction of the bite to the development of the disease. He was visited by professional gentlemen of Stellenbosch, and, when first seen on the second day of the attack, he positively refused to take anything in the shape of medicine from his horror and aversion to anything fluid, his inability to swallow, and a conviction on his mind that he was now going to die. His reluctance, however, was overcome, and attempts were made to relieve, but without the smallest success beyond alleviation, thus adding another melancholy instance of a disease that has hitherto baffled all the efforts of the medical profession.

* * Dr. S. F. Wernich, District Surgeon of Boshof, Orange Free State, has recently recorded in the above-mentioned medical journal a case in which he had made the diagnosis of hydrophobia. The patient, a young farmer of nervous temperament, died after an illness of five days, characterised by extreme excitement, inability to swallow, dread of liquids, the expectoration of white frothy mucus, and the absence of any signs of organic disease. There was no history of a bite from a rabid animal, nor had he been bitten by any animal, so far as could be ascertained, for at least eight years. The symptoms were certainly strongly suggestive of hydrophobia, but it is not possible to say more than this. Dr. Wernich states that rabies is well known in the neighbourhood of Boshof, especially among the older inhabitants. "When it occurs in the dog it is known," he says, "as 'Dol Hond,' and when a person is bitten by a 'Dol Hond' he is said to become 'dol' (mad)."

It would be interesting to learn whether the files of the *South African Chronicle* for 1825 contain any reports of any other case of hydrophobia, or of rabies in the dog.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

DISTRICT MEDICAL OFFICERS AND "CLUB DOCTORS."

As regards the questions submitted by "Retlaw," we will reply to them in the order sent:

1. We doubt if a board of guardians would allow an extra fee where the fracture had been put up by another medical gentleman, and had remained under his care for fifteen days after the accident happened, that is, if the Board was put in possession of the facts of the case. The Central Department would assuredly disallow such payment.

2. The conduct of the district medical officer, on seeing the case above, taking off the splints, etc., of another medical gentleman, and putting on his own, was highly objectionable. This procedure should be reported to the Board of Guardians or to the Local Government Board, or to both.

3. To establish any claim to a fee, he should have taken entire charge of the case.

4. Here again we give the answer as above: lay the fact of the refusal to attend and send medicines before the Local Board and the Central Authority also.

5. The district medical officer has no power to refuse necessary medicines and attendance on any poor person whom he has been called to visit by an order in the handwriting of the relieving officer on the plea that the pauper he is directed to attend is a member of a club which is under the professional charge of some other medical gentleman.

Finally, we advise that pending the decision of the Board of Guardians or the Local Government Board on the points raised by our correspondent, he should continue his professional attendance on his club patients just the same as if no such objectionable district medical officer was in existence.

TO OBTAIN A DIPLOMA IN PUBLIC HEALTH.

DOUBLY QUALIFIED.—You could not do better than procure the certificate in sanitary science of the Cambridge University. The list of books recommended by the University is so long, that we would advise you to purchase, for one shilling, the last published examination papers, which also give this information. They are to be had at the Cambridge Warehouse, 17, Paternoster Row, London.

FEE FOR FORCEPS CASE.

DR. G. H. FITZGERALD (Ponteland, Northumberland), asks if an instrumental midwifery case (forceps) is included in those cases for which an extra fee can be claimed from the guardians for a workhouse case. He adds that the use of the forceps was urgently required.

. Our correspondent cannot claim as of right, any fee beyond £1 for assistance rendered to a case of midwifery occurring in a workhouse, but although such is the law, a board of guardians may grant a larger fee, if a representation was made to them that it was a case accompanied with difficulty and danger, which compelled instrumental aid to bring about delivery. If the Board granted such fee, it would have to be reported to the Local Government Board, to obtain their sanction, or the auditor would surcharge the board of guardians for giving an exceptional fee.

The writer of this reply once had a case of instrumental midwifery, where he called to his assistance the late Dr. Hall Davis and his own assistant. On appeal to the board of guardians, they voted Dr. Hall Davis £5 5s.; the medical officer, £2 2s.; his assistant, £1 1s.; the midwife an extra fee of 10s. 6d., and the paid nurse, 5s. Total, £9 3s. 6d., for a pauper girl. The facts having been laid before the Local Government Board, such grant was at once confirmed. The entire attendance extended over seventy-eight hours.

COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES.

DR. JOHN HADDON (Melrose) writes: I observe from the JOURNAL of December 17th that the Local Government Board is taking up the question of compulsory notification of infectious diseases, and asking answers to six questions from those local authorities where that system has been in use. The fifth question reads thus:—"What is believed to be the general result as regards the limitation of the spread of infectious disease?"

Replies to such a question will no doubt vary according to the experience of particular localities, but it is doubtful whether any authority is capable of forming a true estimate of the value of the notification of infectious diseases, even when supplemented by ample provision for the isolation of such cases in hospitals. Any local authorities which have had notification, with ample hospital accommodation, in use for fifteen years, and have kept a careful record of the prevalence of the several epidemic diseases during that time, may no doubt furnish valuable information, but unless the Local Government Board at the same time is informed of the general sanitary state of the various districts from which answers to their six questions are received, no reply can be of any practical value with a view to future legislation on the subject.

If we took a general survey of the most formidable infectious diseases, and endeavoured to answer the question—How can this disease be stamped out? for each individually it is evident that the measures we might suggest to such an end would depend on our knowledge of (1) the cause of the disease, and (2) the way in which it propagated itself when it had once originated. Thus, as to typhus, how would we proceed to stamp it out?

We are pretty certain that typhus is originated by the overcrowding of human beings, and that it will break out wherever sufficient overcrowding takes place; once originated it is, perhaps, our most infectious disease. With such knowledge, then, shall we rest satisfied with advising notification and isolation in a hospital so as to prevent its spread? Should we not rather advise that a careful inspection should be made of all the property under the dominion of the sanitary authority, and that wherever the conditions likely to give rise to typhus were found the necessary improvements should be effected? We should

not wait for the outbreak of the disease and then merely try to prevent its spread, but rather, acting upon our knowledge as to the conditions under which it originates, endeavour to remove them, and make an outbreak an impossibility. We may thus conclude (1) that notification of typhus with any number of hospitals to isolate the cases as they occur will be powerless to stamp out the disease, though such means may no doubt assist in preventing its spread; and (2) that by the improvement of the houses of the poor this disease may be entirely stamped out, so that neither notification nor the hospital would be needed.

It is a curious fact that in Edinburgh, where typhus used to rage, claiming its victims annually from among the students and physicians, that disease is now seldom met with, owing no doubt to improvements which have been effected in the slums of the old town.

Again, with regard to such a disease as scarlet fever, how would we proceed to stamp it out? We do not know how it originates, but we have a very strong suspicion that defective sanitary arrangements have to do with its inception. Once originated it is capable of spreading to the healthy who are exposed to its infection; but no one can have practised his profession with moderate powers of observation without being inclined to believe that those living under insanitary conditions are most liable to its infection. How, then, shall we proceed to stamp out such a disease? Shall we advise notification and isolation of all cases that occur, and pretend that we are doing our duty to ourselves and the public? If we did, and if we could ensure perfection in both particulars, we could not stamp out the disease.

So far as our present knowledge goes, then, ought we not to advise that the drainage throughout the whole country should be made perfect, according to present ideas, and that a pure water supply should be provided for every town, hamlet, and house wherever placed? To prevent its spread (if it should even then originate), not only might notification and hospitals for isolation be had recourse to, but those supplying any article of food to the people should be under intelligent and regular supervision. Dairies, no doubt, are much to blame but is it not possible that a butcher, a baker, or even a grocer may spread such a disease? If it be possible that Government intends to bring forward any measure calculated to free this country from those preventable diseases which are so destructive to the happiness and prosperity of the nation, it behoves this Association to urge upon the Legislature that the measure must be radical, beginning at the root and not at the fruit of the infectious tree.

QUARANTINE IN MALTA.

DR. L. MANCÉ, Surgeon-Major, R.M.F.A., writes: It was with great pleasure that I read the few remarks on quarantine made by Surgeon-Major Welch, of Netley, in your issue of December 3rd, as they awakened in me a desire of perusing the admirable and complete account of the several epidemics of cholera in Malta, published by that gentleman and Surgeon Leith Adams, in the Blue Book of 1864. After perusing the same I became the more convinced that "there is a clear mass of evidence showing that the disease is communicable by intercourse with the affected, and so precise and incontrovertible as to leave no doubt of the capability of its propagation in this way, independently of all atmospheric conditions whatever. Indeed it may be questioned if the disease ever found its entrance into Malta by any other means" (p. 311). In fact, the great care devoted by the authors to the gathering of data, in order to show that, during the several epidemics occurring between 1837 and 1865, the progress of cholera, not only from one country to another, but also from town to town, from street to street, from house to house, and even from one individual to another of one and the same family, and in the same regiment, deserves the highest praise, and is quite sufficient to lead to the conclusion arrived at by them at page 319 of their report, namely: "It is clear that the disease radiated from Alexandria to the seaport towns of the Mediterranean in the exact ratio of the frequency of their communication with it, and that these towns became new foci for its propagation to others, and into the interior by means of maritime and land communication. . . . These facts are incontrovertible, and, while they furnish indubitable proofs of the communication of cholera by human intercourse, strongly militate against the existence of a general epidemic constitution in the Mediterranean basin." Further on, at page 332, it is stated that "some of the worst streets escaped altogether, others remained exempt for a long time, but on the introduction of the disease clearly showed that the previous immunity was in nowise due to the absence of localising causes. The inference to be drawn was this, that whether dirty or clean, well situated or not, a first case was necessary as a starting point, the subsequent progress depending upon the presence or not of favouring conditions, and the sanitary measures had recourse to."

The inference to be drawn from the above statements, with which I perfectly agree, is that immunity from cholera can only be attained (1) by preventing importation of its virus, and (2) by improving the sanitary conditions of the island, so as to lessen its propagation when it has once been introduced. Though I am a staunch supporter of strict *sfratto* as the only means for attaining the first object, I am as strong an advocate for sanitary measures to obtain the second.

I am sure both you and Surgeon-Major Welch will be pleased to learn that the opinion universally entertained here is that both these preventive measures should go hand in hand, and I defy anyone to prove that in our case "the imposition of quarantine induces a sense of false security, which militates against the adoption of those beneficial sanitary measures on shore, whereby the spread of cholera, if the disease were introduced, could be prevented." In fact, considerable sums of money have been, and still continue to be, annually spent towards the improvement of sanitation in this island.

I still, however, maintain that, up to the time when the sanitary condition of every country will have attained perfection, and when all Governments, from one pole to the other, will, by international agreement, decide to do away with quarantine completely, so that free intercourse may exist between one port and another, whether they be infected with disease or not, up to that time, I say when such ties of affection will bind all nations, *sfratto* alone will be able to save us from the importation of cholera.

It will not be lost sight of that, under present circumstances, the very appearance of cholera in Malta, irrespective of all our preventive measures against its spreading, is considered by other Governments sufficient reason for interrupting all communication with this island.

As to the possibility of adopting *sfratto* when "what was intended as a safeguard becomes at best a useless measure," I may state that if British representatives abroad were as careful to report to this Government the appearance of the very first suspicious case of cholera as foreign Consuls in Malta are in bringing similar cases before the Governments they represent, with the present

easy telegraphic communications available, there would not be the least probability of imposing *scritto* when already too late, as past experience of the last twenty-two years has fully demonstrated.

POOR LAW MEDICAL OFFICERS' ASSOCIATION.

THE annual report of the Poor Law Medical Officers' Association having been issued, showing the continued prosperity of the Association, the Council strongly advises all district medical officers who are not members to enrol themselves, as certain important questions, seriously affecting their interests, are likely to engage the attention of Parliament at an early date.

HEALTH OF ENGLISH TOWNS.

DURING the week ending Saturday, December 24th, 5,989 births and 3,679 deaths were registered in the twenty-eight large English towns, including London, dealt with in the Registrar-General's Weekly Return, which have an estimated population of 9,244,099 persons. The annual rate of mortality, which had been 21.1 and 22.1 per 1,000 in the two preceding weeks, declined again to 20.8 during the week under notice. The rates in the several towns, ranged in order from the lowest, were as follow: Derby, 15.5; London, 18.6; Bradford, 19.1; Norwich, 19.1; Hull, 19.3; Nottingham, 19.3; Leeds, 19.5; Oldham, 20.2; Liverpool, 20.3; Brighton, 20.3; Birkenhead, 20.8; Huddersfield, 20.3; Cardiff, 21.0; Wolverhampton, 21.3; Birmingham, 21.6; Bristol, 22.4; Halifax, 22.4; Newcastle-upon-Tyne, 23.3; Sunderland, 23.3; Sheffield, 23.9; Portsmouth, 24.2; Salford, 24.8; Bolton, 25.5; Preston, 26.5; Manchester, 28.9; Plymouth, 30.4; Leicester, 31.3; and the highest rate during the week, 31.7 in Blackburn. The death-rate in the twenty-seven provincial towns averaged 22.6 per 1,000, and exceeded by 4.0 the rate recorded in London, which, as before stated, was only 18.6 per 1,000. The 3,679 deaths registered in the twenty-eight towns during the week under notice included 455 which were referred to the principal zymotic diseases, against 443, 448, and 500 in the three preceding weeks; of these, 146 resulted from whooping-cough, 91 from scarlet fever, 79 from measles, 47 from fever (principally enteric), 47 from diphtheria, 23 from small-pox, and 23 from diarrhoea. These 455 deaths were equal to an annual rate of 2.6 per 1,000. The zymotic death-rate in London during the week under notice was equal to 2.7 per 1,000, while it averaged 2.4 in the twenty-seven provincial towns, among which it ranged from 0.0 in Brighton and in Portsmouth, and 0.6 in Huddersfield, to 4.4 in Derby, 4.5 in Wolverhampton, 4.6 in Bolton, and 5.9 in Sheffield. The fatal cases of whooping-cough, which increased in the three preceding weeks from 96 to 157, declined again during the week under notice to 45, and caused the highest death-rates in Salford, London, Wolverhampton, and Leicester. The deaths referred to scarlet fever, which had been 91 and 103 in the two previous weeks, declined again during the week under notice to 91; this disease showed the highest proportional fatality in Bristol, Oldham, Wolverhampton, Plymouth, and Birkenhead. The number of scarlet fever patients under treatment in the Metropolitan Asylums hospitals, which had declined from 2,602 to 2,347 during the three preceding weeks, had further fallen to 2,171 on Saturday, December 24th; the admissions, which had fallen from 209 to 162 in the four previous weeks, further declined to 129 during the week under notice. The fatal cases of measles, which had risen in the three preceding weeks, from 69 to 80, were 79 during the week under notice, and caused the highest death-rates in Bradford, Birmingham, Bolton, and Derby. The deaths referred to different forms of "fever" (including typhus, typhoid, and ill-defined forms of fever), which had been 77 and 64 in the two preceding weeks, further declined to 47 during the week under notice; this disease showed the highest proportional fatality in Wolverhampton. The fatal cases of diphtheria in the twenty-eight towns, which had been 44 and 47 in the two previous weeks, were again 47 during the week under notice, and included 24 in London, 5 in Manchester, 2 in Birmingham, 2 in Sheffield, 2 in Liverpool, 2 in Hull, and 2 in Carlisle. The 23 deaths from diarrhoea showed a marked decline from the numbers returned in recent weeks. The fatal cases of small-pox in these towns, which had been 26, 20, and 19 in the three previous weeks, rose again to 23 during the week under notice, of which 21 were recorded in Sheffield, and 2 in Bristol. The number of small-pox patients in the Metropolitan Asylums hospitals, which had been 9 and 10 at the end of the two preceding weeks, had declined to 5 on Saturday, December 24th; no new cases were admitted into these hospitals during the week. The deaths from diseases of the respiratory organs in London, which had been 405 and 413 in the two previous weeks, declined during the week under notice to 357; they were as many as 185 below the average, and were equal to an annual rate of 4.4 per 1,000. The causes of 80, or 2.2 per cent. of the 3,697 deaths registered during the week under notice in the twenty-eight towns were not certified, either by registered medical practitioners or by coroners.

In the twenty-eight large English towns, including London, dealt with in the Registrar-General's Weekly Return, which have an estimated population of 9,244,099 persons, 5,333 births and 4,402 deaths were registered during the week ending Saturday, December 31st. The annual rate of mortality, which had been 22.1 and 20.8 per 1,000 in the two preceding weeks, rose again during the week under notice to 24.8. The rates in the several towns, ranged in order from the lowest, were as follow:—Brighton, 18.5; Huddersfield, 19.7; Norwich, 20.3; Derby, 21.1; Sunderland, 21.3; Hull, 22.0; Bradford, 23.0; Liverpool, 23.2; London, 23.3; Birmingham, 24.4; Cardiff, 24.5; Leeds, 25.1; Bristol, 25.7; Salford, 26.2; Portsmouth, 26.5; Sheffield, 27.7; Leicester, 27.7; Wolverhampton, 27.8; Newcastle-upon-Tyne, 27.9; Plymouth, 28.4; Nottingham, 28.9; Blackburn, 29.0; Birkenhead, 29.9; Halifax, 31.0; Oldham, 31.1; Manchester, 32.5; Preston, 33.7; and the highest rate during the week, 33.9 in Bolton. In the twenty-seven provincial towns the death-rate averaged 23.2 per 1,000, and exceeded by 2.9 the rate recorded in London, which, as before stated, was 23.3 per 1,000. The 4,402 deaths registered during the week under notice in the twenty-eight towns included 153 which were referred to whooping-cough, 80 to measles, 84 to scarlet fever, 52 to "fever" (principally enteric), 38 to diphtheria, 32 to diarrhoea, and 23 to small-pox; in all, 503 deaths resulted from these principal zymotic diseases, against 500 and 455 in the two preceding weeks. The zymotic rate was equal to 2.8 per 1,000. In London the zymotic death-rate was 3.1, while it averaged 2.6 per 1,000 in the twenty-seven provincial towns, among which it ranged from 0.0 and 0.4 in Halifax and Brighton, to 4.6 in Bolton, 5.1 in Preston, 5.4 in Nottingham, and 6.1 in Sheffield. The fatal cases of whooping-cough, which had been 137 and 115 in the two previous weeks, rose again during the week under notice to 153, and caused the highest death-rates in Salford, Oldham, London, Derby, and Leicester. The deaths referred to measles, which had been 80 and 79 in the

two previous weeks, rose again to 86 during the week under notice: this disease was proportionally most fatal in Newcastle-upon-Tyne, Birmingham, Plymouth, Nottingham, and Bolton. The fatal cases of scarlet fever, which had been 108 and 91 in the two preceding weeks, further declined during the week under notice to 84, and caused the highest rates in Norwich, Birkenhead, Oldham, Huddersfield, Blackburn, and Preston. The number of scarlet fever patients in the Metropolitan Asylums hospitals, which had declined in the three preceding weeks from 2,557 to 2,171, had further fallen to 2,046 on Saturday, December 31st; 120 new cases were admitted into these hospitals during the week, against numbers steadily declining from 184 to 129 in the four previous weeks. The deaths referred to different forms of "fever" (including typhus, enteric, and ill-defined forms of fever), which had been 77, 54, and 47 in the three preceding weeks, rose again during the week under notice to 52; the greatest proportional fatality of fever during the week was recorded in Portsmouth, Nottingham, and Preston. The fatal cases of diphtheria in the twenty-eight towns, which had been 47 in each of the two preceding weeks, declined during the week under notice to 38, and included 21 in London, 5 in Newcastle-upon-Tyne, 2 in Liverpool, 2 in Oldham, and 2 in Hull. The 32 deaths from diarrhoea exceeded by 9 those recorded in the previous week. Small-pox caused 24 deaths in Sheffield (against 17 and 21 in the two preceding weeks), 2 in Bristol, 1 in Leeds, and 1 in Hull, but not one in London or in any of the twenty-three other large provincial towns. The number of small-pox patients in the Metropolitan Asylums hospitals, which had been 10 and 5 at the end of the two preceding weeks, were 7 on Saturday, December 31st; 2 cases of small-pox were admitted into these hospitals during the week. The deaths referred to diseases of the respiratory organs in London, which had been 413 and 357 in the two previous weeks, rose again during the week under notice to 442, but were as many as 119 below the average. The causes of 137, or 3.1 per cent., of the 4,402 deaths registered during the week under notice in the twenty-eight towns were not certified, either by registered medical practitioners or by coroners.

HEALTH OF SCOTCH TOWNS.

IN the eight principal Scotch towns, having an estimated population of 1,299,000 persons, 789 births and 559 deaths were registered during the week ending Saturday, December 24th. The annual rate of mortality, which had been 22.7 and 23.0 in the two preceding weeks, declined again during the week under notice to 22.4, but exceeded by 1.6 the mean rate during the same period in the twenty-eight large English towns. Among these Scotch towns, the rate was equal to 11.3 in Perth, 17.8 in Greenock, 20.4 in Aberdeen, 20.7 in Dundee, 20.9 in Leith, 21.1 in Edinburgh, 23.4 in Glasgow, and 40.2 in Paisley. The 559 deaths registered during the week under notice in these Scotch towns included 25 which were referred to whooping-cough, 17 to "fever" (principally enteric), 17 to measles, 13 to scarlet fever, 4 to diphtheria, 4 to diarrhoea, and not one to small-pox; in all, 80 deaths resulted from these principal zymotic diseases, against 79 and 75 in the two preceding weeks. These 80 deaths were equal to an annual rate of 3.2 per 1,000, which exceeded by 0.6 the mean zymotic death-rate during the same week in the twenty-eight large English towns. The highest zymotic rates in the Scotch towns during the week under notice were recorded in Dundee, Leith, and Paisley. The deaths referred to whooping-cough, which had been 29 and 26 in the two preceding weeks, were 25 during the week under notice, of which 13 occurred in Glasgow, 3 in Edinburgh, and 3 in Leith. The fatal cases of measles, which had steadily increased from 12 to 15 in the three previous weeks, further rose to 17 during the week under notice, and included 11 in Edinburgh and 5 in Dundee. The deaths referred to different forms of "fever" (typhus, enteric, and simple fever), which had been 5 and 9 in the two preceding weeks, further rose to 17 during the week under notice, of which 14 occurred in Paisley and 3 in Glasgow. The fatal cases of scarlet fever, which had been 14 and 9 in the two previous weeks, rose again to 13 during the week under notice, and included 8 in Glasgow and 3 in Dundee. The 4 deaths from diphtheria showed a decline of 3 from the number in the preceding week, and were all recorded in Glasgow. The 4 fatal cases of diarrhoea were considerably below those returned in any recent week. The 134 deaths referred to acute diseases of the respiratory organs in these Scotch towns during the week under notice were as many as 65 below the number recorded in the corresponding week of last year. The causes of 68, or more than 12.0 per cent., of the 559 deaths registered during the week under notice in these Scotch towns were uncertified.

During the week ending Saturday, December 31st, 850 births and 607 deaths were registered in eight of the principal Scotch towns, having an estimated population of 1,299,000 persons. The annual rate of mortality, which had been 23.0 and 22.4 per 1,000 in the two preceding weeks, rose again to 24.3 during the week under notice, and was slightly below the mean rate during the same period in the twenty-eight large English towns. Among these Scotch towns, the rate was equal to 14.6 in Perth, 15.8 in Leith, 21.5 in Edinburgh, 23.3 in Greenock, 24.5 in Glasgow, 25.3 in Aberdeen, 29.3 in Dundee, and 35.9 in Paisley. The 607 deaths registered during the week under notice included 73 which were referred to the principal zymotic diseases, against 75 and 80 in the two preceding weeks; of these, 24 resulted from whooping-cough, 14 from measles, 13 from diphtheria, 10 from diarrhoea, 7 from scarlet fever, 5 from "fever" (principally enteric), and not one from small-pox. These 73 deaths were equal to an annual rate of 3.0 per 1,000, which slightly exceeded the mean zymotic death-rate during the same period in the twenty-eight large English towns. The highest zymotic rates in the Scotch towns during the week under notice were recorded in Leith, Greenock, and Dundee. The fatal cases of whooping-cough, which had declined from 29 to 25 in the three preceding weeks, were 24 during the week under notice, of which 10 occurred in Glasgow, 4 in Dundee, 4 in Greenock, and 3 in Leith. The deaths referred to measles, which had steadily increased in the four previous weeks from 12 to 17, declined again during the week under notice to 14, and included 8 in Dundee and 5 in Edinburgh. The fatal cases of diphtheria, which had been 7 and 4 in the two preceding weeks, rose again during the week to 13, of which 8 occurred in Glasgow, 2 in Edinburgh, and 2 in Greenock. The 10 deaths from diarrhoea exceeded those recorded in recent weeks, and included 5 in Glasgow and 4 in Edinburgh. The fatal cases of scarlet fever, which had been 9 and 13 in the two previous weeks, declined during the week under notice to 7, of which 4 occurred in Glasgow. The deaths referred to different forms of "fever" which had risen in the three previous weeks from 5 to 17, declined again to 5, and included 2 in Dundee. The 193 deaths referred to acute diseases of the respiratory organs in these Scotch towns during the week exceeded by 14 the number recorded in the corresponding week of last year. The causes of 61, or 10.0 per cent., of the 607 deaths registered during the week under notice in these Scotch towns were uncertified.

HEALTH OF IRISH TOWNS.

In the week ending Saturday, December 24th, 520 deaths occurred in the sixteen principal town districts of Ireland. The average annual death-rate represented by the deaths registered was 51.2 per 1,000 of the population. The deaths registered in the several towns, alphabetically arranged, corresponded to the following annual rates per 1,000: Arinagh, 20.7; Belfast, 41.4; Cork, 24.7; Drogheda, 38.1; Dublin, 28.8; Dundalk, 17.5; Galway, 16.8; Kilkenny, 16.9; Limerick, 33.7; Lisburn, 10.8; Londonderry, 17.8; Lurgan, 35.9; Newry, 59.7; Sligo, 14.4; Waterford, 30.1; Wexford, 17.1. The deaths from the principal zymotic diseases in the sixteen districts were equal to an annual rate of 5.3 per 1,000. Measles caused 5 deaths in Newry, 13 in Belfast, 3 in Cork, 1 in Limerick, and 2 in Kilkenny. Whooping-cough caused 10 deaths in Belfast. In the Dublin Registration District, the births registered during the week amounted to 132, and the deaths to 199. The deaths represent an annual rate of mortality of 29.4 in every 1,000 of the estimated population; omitting the deaths of persons admitted into public institutions from localities outside the district, the rate was 28.3 per 1,000. Thirty-three deaths from zymotic diseases were registered, being 3 over the average for the corresponding week of the last ten years, and 4 over the number for the week ended December 17th; they include 3 from measles, 4 from scarlet fever, 2 from typhus, 8 from whooping-cough, and 4 from diphtheria.

In the week ending Saturday, December 31st, 565 deaths occurred in the sixteen principal town districts of Ireland. The average annual death-rate was 39.9 per 1,000 of the population. The deaths registered in the several towns, alphabetically arranged, corresponded to the following annual rates per 1,000: Arinagh, 15.5; Belfast, 41.4; Cork, 38.3; Drogheda, 16.9; Dublin, 34.7; Dundalk, 13.1; Galway, 23.5; Kilkenny, 16.9; Limerick, 22.9; Lisburn, 33.8; Londonderry, 12.5; Lurgan, 10.3; Newry, 35.1; Sligo, 43.3; Waterford, 37.0; Wexford, 17.1. The deaths from the principal zymotic diseases in the sixteen districts were equal to an annual rate of 5.0 per 1,000. Measles caused 5 deaths in Newry, 13 in Belfast, 10 in Cork, and 8 in Limerick; whooping-cough caused 18 deaths in Belfast, and 1 each in Cork and Waterford. In the Dublin Registration District the births registered during the week amounted to 188, and the deaths to 245. The deaths represent an annual rate of mortality of 36.2 in every 1,000 of the estimated population; omitting the deaths of persons admitted into public institutions from localities outside the district, the rate was 34.7 per 1,000. Twenty-six deaths from zymotic diseases were registered, being 7 under the number for the preceding week, and 5 below the average for the fifty-second week of the ten years 1877-86; they included 1 from measles, 6 scarlet fever, 3 from whooping-cough, 2 from diphtheria, and 2 from simple continued and ill-defined fever.

HEALTH OF FOREIGN CITIES.

It appears, from statistics published in the Registrar-General's return for the week ending Saturday, December 24th, that the annual death-rate recently averaged 80.3 per 1,000 in the three principal Indian cities; it was 25.6 in Bombay, 28.3 in Calcutta, and 41.0 in Madras; cholera caused 7 deaths in Calcutta, 5 in Bombay, and 36 in Madras; a death from small-pox was recorded in Bombay, and "fever" was fatally prevalent in each of these Indian cities. According to the most recently received weekly returns, the annual death-rate averaged 23.7 per 1,000 persons estimated to be living in twenty-one of the largest European cities, and exceeded by 2.9 the mean rate during the week in the twenty-eight large English towns. The death-rate in St. Petersburg was 26.3 per 1,000, (against 26.5 and 25.8 in the two preceding weeks); the 468 deaths included 10 from measles, 10 from typhoid fever, and 70 from diarrhoeal diseases. In three other northern cities—Copenhagen, Stockholm, and Christiania—the death-rate averaged 27.9 per 1,000, and ranged from 21.8 in Stockholm to 40.8 in Christiania; as many as 30 deaths were referred to measles in Christiania, and 11 in Copenhagen; 6 deaths resulted from scarlet fever in Stockholm, 9 in Copenhagen, and 9 in Christiania; and 6 fatal cases of diphtheria were recorded in Stockholm and 8 in Christiania. In Paris the death-rate was equal to 22.1 per 1,000 (against 22.0 and 21.0 in the two preceding weeks), and exceeded by 3.5 per 1,000 the rate recorded in the corresponding week in London; the deaths included 49 from typhoid fever, 83 from diphtheria and croup, 5 from small-pox, and 13 from measles. The 159 deaths in Brussels, of which 3 resulted from diphtheria, 2 from typhoid fever, and 1 from small-pox, gave a rate of 18.3 per 1,000. In the three principal Dutch cities—Amsterdam, Rotterdam, and the Hague—the mean death-rate was 20.4 per 1,000, the several rates being 17.0 in Rotterdam, 19.9 in the Hague, and 22.3 in Amsterdam; 4 deaths resulted from diphtheria and 2 from whooping-cough in Amsterdam; and 3 fatal cases of measles were recorded in Rotterdam, while no zymotic disease appears to be fatally prevalent in the Hague. The Registrar-General's table includes nine German and Austrian cities, in which the death-rate averaged 24.4 per 1,000, and ranged from 16.4 and 18.4 in Dresden and Berlin, to 27.8 and 32.0 in Hamburg and Buda-Pesth. Small-pox caused 18 deaths in Trieste and 10 in Prague; 38 fatal cases of diphtheria occurred in Berlin, and 18 in Breslau; typhus and typhoid fever caused 18 deaths in Hamburg, and 5 in Buda-Pesth, while measles was somewhat fatally prevalent in Dresden, Breslau, and Buda-Pesth. The death-rate in three of the principal Italian cities averaged 23.7 per 1,000, the several rates being 21.3 in Turin, 24.4 in Venice, and 26.3 in Rome; 16 deaths resulted from small-pox, and 9 from malarial fever, in Rome; 8 fatal cases of diphtheria and 4 of typhoid fever were recorded in Turin; and diarrhoeal diseases caused 4 deaths in Venice. In Cairo the death-rate was 52.1 per 1,000, and in Alexandria 39.7; typhoid fever caused 15 deaths in Cairo; a fatal case of small-pox occurred both in Cairo and in Alexandria; and 114 deaths were referred to diarrhoeal diseases in Cairo and in Alexandria. In four of the largest American cities the recorded death-rates averaged 21.3 per 1,000, and ranged from 16.7 in Philadelphia to 24.0 in New York. Diphtheria caused 55 deaths in New York, 20 in Brooklyn, and 12 in Philadelphia; 17 fatal cases of scarlet fever were recorded in New York, and 5 in Philadelphia; and 11 deaths resulted from typhoid fever in Philadelphia, and 4 in Baltimore.

It appears, from statistics published in the Registrar-General's return for the week ending Saturday, December 31st, that the annual death-rate was recently equal to 20.5 per 1,000 in Bombay, and to 47.6 in Madras. Cholera caused 47 deaths in Madras, and 2 deaths resulted from small-pox in Bombay; while the mortality from different forms of "fever," and from diarrhoeal disease, was excessive in both these cities. The usual return from Calcutta does not appear to have been received. According to the most recently received weekly returns, the annual death-rate averaged 23.9 per 1,000 persons estimated to be living in twenty-one of the largest European cities, and was 0.9 below the mean rate during the week under notice in the twenty-eight large English towns. The death-rate in St.

Petersburg was equal to 25.2 per 1,000, and was slightly below the rates recorded in recent weeks; the 449 deaths included 10 from typhus and typhoid fever, 19 from scarlet fever, 11 from diphtheria, and 72 from diarrhoeal diseases. In three other northern cities—Copenhagen, Stockholm, and Christiania—the death-rate averaged 25.9 per 1,000, and ranged from 18.5 in Stockholm to 35.3 in Christiania; measles caused 28 deaths in Christiania and 7 in Copenhagen; 3 deaths resulted from scarlet fever in Copenhagen, 4 in Stockholm, and 3 in Christiania; and 7 fatal cases of diphtheria were recorded in Copenhagen. In Paris the death-rate was equal to 22.1 per 1,000 (against 21.0 and 22.1 in the two preceding weeks), and was 1.2 per 1,000 below the rate in the corresponding week in London; the deaths included 6 from small-pox, 32 from typhoid fever, and 39 from diphtheria and croup. The 166 deaths in Brussels, of which 16 resulted from diarrhoeal diseases and 3 from diphtheria, gave a rate of 19.2 per 1,000. In the three principal Dutch cities—Amsterdam, Rotterdam, and the Hague—the mean death-rate was 21.3 per 1,000, the several rates being 19.7 in Amsterdam, 21.7 in the Hague, and 23.7 in Rotterdam; 4 deaths were referred to diphtheria, and 3 to measles, in Amsterdam; 2 fatal cases of measles and 2 of whooping-cough in Rotterdam; while no zymotic disease appears to be prevalent in the Hague. The Registrar-General's table includes nine German and Austrian cities, in which the death-rate averaged 25.2 per 1,000, and ranged from 18.3 and 22.7 in Berlin and Dresden, to 32.1 and 32.8 in Prague and Buda-Pesth. Small-pox caused 8 deaths in Trieste and 16 in Prague; 40 fatal cases of diphtheria were recorded in Berlin, 10 in Breslau, and 7 in Vienna; and 19 deaths resulted from typhus and typhoid fever in Hamburg. The death-rate in three of the principal Italian cities averaged 24.5 per 1,000, being equal to 21.1 in Turin, 24.8 in Venice, and 28.1 in Rome; 6 deaths resulted from small-pox and 7 from typhoid fever in Rome; 4 fatal cases of diphtheria and 3 of scarlet fever occurred in Turin; and diarrhoeal diseases were prevalent in Venice. In Cairo the death-rate was 54.8 per 1,000, and in Alexandria 36.5; 17 deaths were referred to typhoid fever and 10 to whooping-cough in Cairo; "fever" caused 10 deaths in Alexandria; while diarrhoeal diseases were fatally prevalent in each of these cities. In four of the largest American cities the recorded death-rate averaged 21.4 per 1,000, and ranged from 17.4 in Baltimore to 24.4 in New York. Diphtheria caused 49 deaths in New York, 32 in Brooklyn, 13 in Philadelphia, and 5 in Baltimore; 24 deaths resulted from scarlet fever in New York; and 8 fatal cases of typhoid fever occurred in Philadelphia, and 5 in Baltimore.

OBITUARY.

GUSTAVE BERNUTZ, M.D.

This distinguished French gynecologist died at Sedan early in December from chronic cardiac disease, the result of rheumatism. M. Féréol read a full obituary of the deceased at a meeting of the Académie de Médecine on December 20th.

Dr. Bernutz was born at Sedan in 1819. His family came from Bouillon in Belgium. His grandfather, Laurent Bernutz, was senior surgeon to the military hospital at Bouillon; his uncle, V. H. P. Bernutz, was attached to the civil hospital in that town; whilst his father, François Richard Bernutz, practised at Sedan. Gustave Bernutz, who has just died, studied in Paris, and was *interne des hôpitaux* in 1843. In 1850 he was selected for the Bureau Central; in 1854 he was attached to the Lourcine, and at once commenced those researches in gynecology which were to make him famous. He would spend three or four hours daily in the wards, and the time which he passed outside the hospital walls was devoted to the consideration of what he had seen within. He was assisted in his labours by a junior physician to the Bureau Central, M. Ernest Goupil. They produced a world-famed book on the diseases of women, which was translated into English for the New Sydenham Society by Dr. Meadows. The chapters on peri-uterine hæmatocele and pelvic peritonitis are masterpieces of scientific gynecology.

Dr. Bernutz was appointed to the Pitié in 1856, and transferred, according to the custom in France, to another hospital, the Charité, in 1869. He resigned hospital duties in 1884. His promising colleague, M. Goupil, died young.

Dr. Bernutz worked hard long after practice had become impossible through the ravages of his malady. Until recently he continued to deliver clinical lectures, and on his death bed he corrected the proofs of those which he intended to publish. Thanks to a colleague who is acting as editor, these valuable lectures are preserved, and will soon be issued to the public.

Dr. Bernutz was one of the compilers of the *Dictionnaire de Médecine et de Chirurgie Pratiques*, writing the articles "Abdomen," "Amenorrhœa," etc., and he was the author of essays on "Uterine Erysipelas" and "Phlegmon of the Broad Ligaments" in *Depaul's Archives de Tocologie*. In 1855 he read before the Société Médicale des Hôpitaux a valuable monograph on syphilitic affections of the cervix uteri. In 1882 he was made an officer of the Legion of Honour.

Dr. Bernutz has left to the hospital of Sedan a sum of 100,000 francs, the interest devolving on his widow till her death. This legacy is left on the express condition that the hospital is to be managed by a religious sisterhood. The deceased was one of the foremost medical men in France to protest against the sudden and arbitrary attempt to secularise the hospitals a few years since. He was

a brilliant example of some of the finest elements of French character, and a practical philanthropist who effected the relief of individual suffering, and hated that school of theoretical fraternity whose principles have been summed up in Chamfort's motto, "Be my brother or else I shall kill you."

JAMES BRIDEOAKE, M.R.C.S.

WE have received intelligence of the death of one of the oldest members of the British Medical Association, Mr. James Brideoake, which recently took place at his residence, Southport. The deceased gentleman was born in July, 1811, and educated at the Leigh Grammar School; he was early apprenticed to a medical practitioner near Huddersfield, and afterwards studied at London and Dublin, taking the diploma of M.R.C.S. in 1836. He commenced practice at Leigh, where he resided for over thirty-eight years, for thirty years of which period he was medical officer to the Leigh Union Workhouse. Mr. Brideoake enjoyed for many years an extensive practice, and it was often remarked by him that he never travelled less than forty miles a day. He was highly esteemed and respected by patients and friends. He retired from active practice about six years ago, and took up his residence in Southport for the benefit of his health. For many years he was a member of the West Leigh Local Board, and took an active interest in other provincial matters. He was a staunch Conservative and churchman. He leaves five daughters to mourn his loss.

GEORGE SYLVESTER, M.R.C.S. ENG.

WE regret to announce the death of Mr. G. Sylvester, surgeon, of Trowbridge, Wiltshire, which took place on December 26th. The deceased was born on March 16th, 1788, and consequently would, had he lived, have completed his hundredth year in March next. Mr. Sylvester became a Member of the Royal College of Surgeons in 1810. He studied at Guy's and St. Thomas's Hospital, London, and became assistant-surgeon in the Royal Navy. He was on board the *Lion*, commanded by Sir Gore Onseley at the taking of Java, for which he received a medal, dated 1848. The deceased gentleman filled for thirty-four years the post of coroner for one of the divisions of Wiltshire, which office he resigned about fifteen years since, when he was succeeded by his son, Mr. F. F. Sylvester. He leaves three sons and one daughter.

JOSEPH WILLIAMS, F.R.C.S.

THE sudden death of Mr. Joseph Williams has caused a deep feeling of regret to a wide circle of friends, by whom he was highly respected. Leaving his residence at Brentford in the morning in apparently good health and spirits for the purpose of visiting a patient at Hammersmith, he was, on the train reaching Gunnersbury, found to be very ill, and shortly after expired. Mr. Williams was born at Westerleigh, near Bristol, in 1832, and had practised at Brentford for upwards of twenty-seven years. His medical education was obtained at St. Thomas's Hospital, where, in his last year, he was gold medallist, and was subsequently house surgeon. In 1865 he gained the Fellowship of the Royal College of Surgeons of England, and in 1880 took the Sanitary Science Diploma. He was surgeon to St. Mary's Orphanage, North Hyde, and district medical officer to the Brentford Local Board, a post which he held from its foundation. The deceased gentleman took a warm and active interest in parochial matters bearing on health and hygiene. He leaves a widow, three daughters, and one son.

MEDICAL NEWS.

THE PLUMBERS' COMPANY.—At the Guildhall on Saturday last thirty-three journeymen and seven master plumbers received certificates of registration by the Plumbers' Company, having attended for the purpose from the following places:—Nottingham, Folkestone, Clacton-on-Sea, Hertford, Manchester, Chippenham, Southsea, Bristol, Maidstone, Norwich, Wells, Trowbridge, Wantage, Exeter, Cambridge, Romsey, and Bath.

SAUSAGE MEAT.—A man named Johnson, of Nottingham, who was found to have been engaged in making and disposing, for public sale, sausages made from horseflesh and putrid meat, has received a well merited punishment of three months' hard labour.

AN international exhibition of hygiene and life-saving apparatus will be organised next year at Ostend, under the direction of the Communal Council.

FRENCH HOSPITAL AND DISPENSARY.—M. Waddington, the French Ambassador, has informed the committee of the French Hospital that the Government of the Republic has made a donation of £2,000 towards the building fund of that institution. M. Waddington has added a personal donation of £100.

THE HUNTERIAN SOCIETY.—On Wednesday, January 25th, Mr. De Berdt Hovell will read a paper before the Hunterian Society, on the Therapeutic Indications of Neurasthenia contrasted with those of Hysteria. Having given much time and attention to the subject, especially with reference to treatment, which has hitherto been so unsatisfactory, Mr. Hovell is desirous of bringing his views before the profession, who are invited to attend.

THE MISSING JOURNALIST.—Nothing has been heard so far of Mr. McNeill, who mysteriously disappeared on his way from Boulogne to London. As he had been somewhat feverish and excited on his way down, it was supposed that he may have been taken ill and gravitated into some hospital. The missing man is about forty years of age, medium height, full dark beard, long moustache. He was the representative of the *Sportsman*. Information respecting his whereabouts is urgently sought by Mr. Christie Murray and other friends.

TWO cases of small-pox have occurred in one of the poorest parts of Nottingham; both persons had only recently arrived from Aldershot; neither are said to have been protected by vaccination, and they have been immediately conveyed to the temporary infectious hospital, where they are now under medical treatment.

A CENTENARIAN CRIMINAL.—According to the *Vratch*, No. 49, 1887, p. 959, about the end of last October an old man, aged 115, residing at Zadonsk, in the Voronej Government, was tried for arson, and sentenced to transportation to Siberia.

MEDICAL MAGISTRATES.—The names of John M. H. Martin, M.D., and John H. Wraith, Esq., M.R.C.S. and L.S.A., have been placed on the commission of the peace, the former for Blackburn, and the latter for Darwen, Lancashire.—Dr. Edward C. A. Ramsay, of Fleetwood, has been placed on the Commission of the Peace for Lancashire.

DR. THOMAS CASSIDY, of Hunmanby, recently died in Edinburgh, where he had gone to recruit his health a little more than a year ago. Dr. Cassidy was highly esteemed, and so long as his health permitted took an active interest in local movements.

WE regret to record the death of Mr. Idris Nannton Davies, surgeon of Llysygraig Ystrad Rhondda, after a severe illness extending over six months. Mr. Idris Davies, who was a cousin of Dr. Davies, Llantrisant, leaves a widow and five children. The deceased gentleman was 56 years of age.

THE Norwich Hospital Sunday Fund has reached the total of £941 15s. 6d. The Birmingham Sunday Hospital Collection for the past year amounts to £4,284, an increase on the previous year's collection of about £50.

IT is proposed to establish a cottage hospital for infectious cases at Brecon, and a site has been generously offered by the Rev. Garnons Williams, of Abercamlais.

DEATHS FROM TRICHINOSIS.—The *Frankfort Gazette* states that at Unterhausdorf, near Reichenbach, in Thuringia, 150 persons became dangerously ill after eating trichinous meat; 33 of them have died.

PRESENTATION.—Dr. H. R. Joel, on the occasion of his leaving Killingworth, has been presented by his numerous friends with an illuminated address and a purse of gold.

THE Paris Municipal Council have resolved on voting 12,000 francs per annum for a Professorship of Evolution or Biological Philosophy, at the Sorbonne, but on condition of having a veto on the appointment of the professor.

SUCCESSFUL VACCINATION.—Mr. H. G. Monk, of East Bridgford, has received the extra award for successful vaccination in his district.

CREMATION IN PARIS.—At the crematory which the Municipal Council has established at Père la Chaise, four hundred kilos of wood are required to consume the body, which is reduced to ashes in the space of two hours.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—Fellowship Examination. The following gentleman has been admitted to the Fellowship of the College.

George Augustus Waite, M.B., B.Ch., Dip. State Med., Dublin, Army Medical Staff, Dublin.

SOCIETY OF APOTHECARIES OF LONDON.—December, 1887.—The following gentlemen, having passed the Qualifying Examination in Medicine, Surgery, and Midwifery, have received certificates entitling them to practise in the same, and have been admitted as Licentiates of the Society.

Coulton, John James, Pentney, Swaffham, Norfolk
 Hearnden, Ernest Morgan, Down House, Sutton, Surrey
 Hicks, John Sydney, 37, Church Street, Falmouth
 Jenkinson, Joseph Arthur, 3, St. Mary's Road, Crumpnell, Manchester
 Lakeman, Thomas, 24, Claylands Road, Clapham, S.W.
 Levy, Harry, 73, Gregory Boulevard, Nottingham
 Norris, Oliver, Sherburn, York, E.R.
 Randall, Philip Nicholas, Hawthornden, South Wimbledon
 Spear, George, 23, St. Mary's Terrace, Paddington, W.
 Tunncliffe, Edwin Thomas Mosse, Riverslea, Woodside Park, N.
 Warry, John Klug, Elizabeth Cottage, Shooter's Hill, Woolwich

The following gentlemen passed the Surgical portion of the Examination.

C. A. Docket, of University College; F. P. Moles, of Owens College, Manchester; C. B. Pym, of St. Bartholomew's Hospital; H. S. Cooper, of Westminster Hospital; R. F. Hiley, of St. Thomas's Hospital; W. Hurst, of Owens College, Manchester.

The following gentlemen passed the Medical portion of the Examination.

J. Bamfylde, of Guy's Hospital; N. Hildyard, of University College; R. R. Slemann, of St. Mary's Hospital.

MEDICAL VACANCIES.

The following vacancies are announced:

BOARD OF WORKS (LEWISHAM DISTRICT) HOSPITAL FOR INFECTIOUS DISEASES, Hither Green.—Medical Officer. Applications by January 10th, to T. L. Down, Esq., Clerk to the Board, Catford, S.E.

BRIGHTON, HOVE, AND PRESTON DISPENSARY.—Two House-Surgeons. Salary, £140 per annum, with apartments, etc. Applications by January 31st to the Assistant Secretary.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn Road, W.C.—Three Clinical Assistants. Applications to the Secretary.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—Resident Medical Officer. Salary, £100 per annum, with board, etc. Applications by January 14th, to the Secretary, 24, Finsbury Circus, E.C.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—Resident Clinical Assistant. Applications by January 12th, to the Secretary, 24, Finsbury Circus, E.C.

CLOUGH UNION.—Medical Officer, Aghnacloy Dispensary. Salary, £115 per annum, and fees. Applications to Mr. M. J. Fiddes, Honorary Secretary. Election on January 12th.

ESSEX AND COLCHESTER HOSPITAL.—Physician. Salary, £200 per annum. Applications by January 16th, to the Secretary.

FARINGDON UNION.—Medical Officer and Public Vaccinator. Salary, £60 per annum, with fees. Applications by January 10th, to G. J. Haines, Esq., Clerk, Faringdon.

GLAMORGAN AND MONMOUTHSHIRE INFIRMARY AND DISPENSARY, Cardiff.—House-Surgeon. Salary, £100 per annum, with board, etc. Applications by January 10th, to the Secretary.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.—Clinical Assistant. Applications to Dr. M. Lubbock.

MANCHESTER ROYAL INFIRMARY (Mossall Fever Hospital).—Assistant Medical Officer. Salary, £100 per annum, with board, etc. Applications by January 7th, to the Chairman of the Board.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART AND PARALYSIS.—Honorary Anaesthetist. Applications to the Secretary, 32, Soho Square, W.

NATIONAL LYING-IN HOSPITAL, Holles Street, Dublin.—Assistant to the Master. Applications to the Master.

OWENS COLLEGE, MANCHESTER.—Lecturer on Dental Surgery. Applications by January 9th, to the Registrar.

PLYMOUTH PUBLIC DISPENSARY.—Physician's Assistant. Salary, £50 per annum. Applications by January 10th to W. H. France, Esq., Honorary Secretary, 7, Athenaeum Terrace, Plymouth.

RADCLIFFE INFIRMARY, Oxford.—House-Surgeon. Salary, £80 per annum. Applications by January 15th to the Secretary.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road, E. C.—Senior House-Physician. Salary, £80 per annum, with board, etc. Applications by January 14th, to the Secretary.

ROYAL SURREY COUNTY HOSPITAL, Guildford.—House-Surgeon. Salary, £80 per annum, with board, etc. Applications by February 15th, to the Assistant Secretary.

SEAMEN'S HOSPITAL SOCIETY, Greenwich, S.E.—House-Physician. Salary, £75 per annum, with board and residence. Applications by January 7th, to the Secretary.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, Leicester Square, W.C.—Two Assistant Physicians. Applications to the Secretary.

SUSSEX COUNTY LUNATIC ASYLUM, Hayward's Heath.—Junior Assistant Medical Officer. Salary, £100 per annum, with board, lodging, and washing. Applications by January 14th, to the Superintendent.

SUSSEX COUNTY LUNATIC ASYLUM, Hayward's Heath.—Medical Superintendent. Salary, £600 per annum, with furnished house, etc. Applications by January 20th, to J. H. Sclater, Esq., Chairman of the Committee of Visitors.

UNIVERSITY OF EDINBURGH.—Examiner in Anatomy. Salary, £75 per annum. Applications by January 16th, to the Secretary.

UNIVERSITY OF EDINBURGH.—Examiner in Chemistry. Salary, £75 per annum. Applications by January 16th, to the Secretary.

UNIVERSITY OF EDINBURGH.—Examiner in Midwifery. Salary, £75 per annum. Applications by January 16th to the Secretary.

UNIVERSITY OF EDINBURGH.—Examiner in Practice of Physic. Salary, £75 per annum. Applications by January 16th to the Secretary.

MEDICAL APPOINTMENTS.

COLVER, James F., L.D.S. Eng., appointed House-Surgeon to the Dental Hospital of London.

DICKSON, George, M.D., appointed Dispensary Physician in the Western Infirmary, Glasgow.

HAMTHORNE, Charles O. M.B., C.M., appointed Dispensary Physician in the Western Infirmary, Glasgow.

LEACH, Alfred, L.R.C.S., L.S.A., appointed Honorary Medical Officer to the St. Gabriel's Hospital for Infants, Grosvenor Road, S.W.

RICHARDSON, G. C., L.F.P.S. Glasg., appointed Medical Officer to the Manchester and Salford Provident Dispensaries' Association, vice J. Sutherland, M.D., resigned.

ROBINSON, Montague G., L.R.C.P., L.R.C.S., L.M., appointed Medical Officer and Public Vaccinator to the No. 2 District of the Daventry Union, vice W. H. Masson, L.R.C.P., L.R.C.S.

ROWNTREE, W. G., M.R.C.S., L.R.C.P. Edin., appointed Medical Officer for the Sixth District of the Parish of St. Mary, Islington.

SMITH, S. O., M.R.C.S., L.S.A., appointed Medical Officer for the Seventh District of the Parish of St. Mary, Islington.

TALENT, J. M., M.B., C.M., appointed House-Surgeon to the Ashton-under-Lyne District Infirmary, vice A. H. Gault, L.R.C.P., M.R.C.S. Eng., resigned.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.

MEDICAL SOCIETY OF LONDON, 8.30 P.M.—Mr. E. Hurry Fenwick: On the Reflex Inhibitory Action of Cocaine as a Diagnostic Factor. Mr. F. Treves: On the Treatment of Carotid Hemorrhage. Mr. Bowreman Jessett: A Case of Gastro-entostomy and a Case of Duodenostomy for Carcinoma of Pylorus.

ODONTOLOGICAL SOCIETY, 8 P.M.—Annual meeting. Election of officers for ensuing year. Mr. A. P. Underwood: Erosion in connection with some points in the Minute Anatomy of Enamel. Mr. S. J. Hutchinson: A Note on Erosion. The President's Valedictory Address.

TUESDAY.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—Dr. W. B. Cheadle, and Mr. Thomas Smith: Case of Occlusion of the Left Bronchus by a Metal Cap, and its Removal by Tracheotomy. Mr. Alexander Haig: Influence of Salicylic Acid and its Salts on the Excretion of Uric Acid.

WEDNESDAY.

BRITISH GYNÆCOLOGICAL SOCIETY, 8.30 P.M.—Annual meeting. President's address. Specimens will be shown by Dr. R. T. Smith, Dr. Bedford Fenwick, Dr. G. Granville Bantock, and others. Mr. Bland Sutton: On the Nature of the Hymen; Supplementary remarks. Council 8 o'clock.

EPIDEMIOLOGICAL SOCIETY OF LONDON, 8 P.M.—Discussion of Dr. Klein's paper on Some of the Infectious Diseases Common to Man and the Lower Animals.

HUNTERIAN SOCIETY, 8 P.M.—Dr. Fletcher Beach: Some of the Uncommon Causes of Imbecility.

FRIDAY.

CLINICAL SOCIETY OF LONDON.—Annual Meeting. Report of Council. Election of Officers. Dr. MacLagan: Cases of Obstruction of the Bowels by Large Gall-Stones. Mr. Clutton: Laparotomy for Obstruction from Gall-Stone: Recovery. Mr. Pearce Gould: A Case of Gall-Stones; illustrating their Spontaneous Fracture; subsequent Suppuration and Operation; Recovery. Living specimens: Dr. Stephen Mackenzie: Case of Sporadic Cretinism.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the announcement.

BIRTHS.

CRESWELL.—December 28th last, at Barnsley House, Billericay, Essex, the wife of John C. Creswell, L.R.C.P., M.R.C.S., L.S.A., of a daughter.

GREVES.—December 30th, at Rodney House, Bournemouth, the wife of Hyla Greves, M.D., of a daughter.

MARRIAGE.

PAUL—GREG.—On January 3rd, at All Saints, Knightsbridge, London, Frank Thomas Paul, F.R.C.S., 33, Rodney Street, Liverpool, to Lucy Geraldine, second daughter of Eustace Greg, Esq., of 21, Kensington Gore, London.

DEATHS.

ELLIS.—On November 3rd, at the Manor House, Crowle, Doncaster, Henry William Thomas Ellis, M.R.C.S., L.R.C.P., aged 76 years.

SCOOAL.—On December 31st, 1887, suddenly, at the age of 34 years, Clara, wife of Edward Fowler Scootal, M.B., Huddersfield.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY	10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's (Ophthalmic Department); and Royal Westminster Ophthalmic.—2 P.M.: Metropolitan Free; St. Mark's; Central London Ophthalmic; Royal Orthopedic; and Hospital for Women.—2.30 P.M.: Chelsea Hospital for Women.
TUESDAY	9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's; St. Bartholomew's (Ophthalmic Department); St. Mary's; Royal Westminster Ophthalmic.—2 P.M.: Westminster; St. Mark's; Central London Ophthalmic.—2.30 P.M.: West London; Cancer Hospital, Brompton.—4 P.M.: St. Thomas's (Ophthalmic Department).
WEDNESDAY	10 A.M.: National Orthopedic.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: Middlesex.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: London; University College; Westminster; Great Northern Central; Central London Ophthalmic.—2.30 P.M.: Samaritan Free Hospital for Women and Children; St. Peter's.—3 to 4 P.M.: King's College.
THURSDAY	10.30 A.M.: Royal London Ophthalmic.—1 P.M.: St. George's.—1.30 P.M.: St. Bartholomew's (Ophthalmic Department); Guy's (Ophthalmic Department); Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Central London Ophthalmic; Hospital for Diseases of the Throat; Hospital for Women.—2.30 P.M.: North-west London; Chelsea Hospital for Women.
FRIDAY	9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.15 P.M.: St. George's (Ophthalmic Department).—1.30 P.M.: Guy's; Royal Westminster Ophthalmic.—2 P.M.: King's College; St. Thomas's (Ophthalmic Department); Central London Ophthalmic; Royal South London Ophthalmic; East London Hospital for Children.—2.30 P.M.: West London.
SATURDAY	9 A.M.: Royal Free.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: King's College.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Middlesex; Royal Free; Central London Ophthalmic.—2.30 P.M.: Cancer Hospital, Brompton.

HOURS OF ATTENDANCE AT THE LONDON HOSPITALS.

CHARING CROSS. —Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; Skin, M. Th., 1.30; Dental, M. W. F., 9.
GUY'S. —Medical and Surgical, daily, 1.30; Obstetric, M. Tu. F., 1.30; Eye, M. Tu. Th. F., 1.30; Ear, Tu. F., 12.30; Skin, Tu., 12.30; Dental, Tu. Th. F., 12.
KING'S COLLEGE. —Medical, daily, 2; Surgical, daily, 1.30; Obstetric, Tu. Th. F., 2; o.p., M. W. F., 12.30; Eye, M. Th., 1; Ophthalmic Department, W., 1; Ear, Th., 2; Skin, Th., 2; Throat, Th., 3; Dental, Tu. F., 10.
LONDON. —Medical, daily, exc. S., 2; Surgical, daily, 1.30 and 2; Obstetric, M. Th., 1.30; o.p. W. S., 1.30; Eye, W. S., 9; Ear, S., 9.30; Skin, Th., 9; Dental, Tu. F., 9.
MIDDLESEX. —Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; o.p. W. S., 1.30; Eye, W. S., 8.30; Ear and Throat, Tu., 9; Skin, Tu., 4; Dental, daily, 9.
ST. BARTHOLOMEW'S. —Medical and Surgical, daily, 1.30; Obstetric, Tu. Th. S., 2; o.p., W. S., 9; Eye, Tu. Th. S., 2.30; Ear, Tu. F., 2; Skin, F., 1.30; Larynx, F., 2.30; Orthopedic, M., 2.30; Dental, Tu. F., 9.
ST. GEORGE'S. —Medical and Surgical, M. Tu. F. S., 1; Obstetric, Tu. S., 1; o.p., Th., 2; Eye, W. S., 2; Ear, Tu., 2; Skin, W., 2; Throat, Th., 2; Orthopedic, W., 2; Dental, Tu. S., 9; Th., 1.
ST. MARY'S. —Medical and Surgical, daily, 1.45; Obstetric, Tu. F., 1.45; o.p., M. Th., 1.30; Eye, Tu. F. S., 9; Ear, M. Th., 8; Throat, Tu. F., 1.30; Skin, M. Th., 9.30; Electrician, Tu. F., 2; Dental, W. S., 9.30; Consultations, M., 2.30; Operations, Tu., 1.30; Ophthalmic Operations, F., 9.
ST. THOMAS'S. —Medical and Surgical, daily, except Sat., 2; Obstetric, M. Th., 2; o.p., W., 1.30; Eye, M. Th., 2; o.p., daily, except Sat., 1.30; Ear, M., 12.30; Skin, W., 12.30; Throat, Tu. F., 1.30; Children, S., 12.30; Dental, Tu. F., 10.
UNIVERSITY COLLEGE. —Medical and Surgical, daily, 1 to 2; Obstetric, M. Tu. Th., F., 1.30; Eye, M. Tu. Th. F., 2; Ear, S., 1.30; Skin, W., 1.45; S., 9.15; Throat, Th., 2.30; Dental, W., 10.30.
WESTMINSTER. —Medical and Surgical, daily, 1.30; Obstetric, Tu. F., 8; Eye, M. Th., 2.30; Ear, M., 9; Skin, Th., 1; Dental, W. S., 9.15.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

Communications respecting editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the Journal, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

In order to avoid delay, it is particularly requested that all letters on the editorial business of the Journal be addressed to the Editor at the office of the Journal, and not to his private house.

Authors desiring reprints of their articles published in the British Medical Journal, are requested to communicate beforehand with the Manager, 429, Strand, W.C.

Correspondents who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication. Correspondents not answered are requested to look to the Notices to Correspondents of the following week.

Manuscripts forwarded to the Office of this Journal cannot under any circumstances be returned.

Public Health Department.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

QUERIES.

F.R.C.S. EDIN.

A MEMBER asks for information as to the nature and extent of examinations for the Fellowship of the College of Surgeons of Edinburgh.

MEDICAL PRACTICE IN ALGIERS.

JUSTITIA asks: What are the restrictions, if any, to an Englishman practising in Algiers with English qualifications?

CONVALESCENT HOME FOR PAINING PATIENT.

MR. RICHARD DAURY (Birmingham) asks to be informed of some sanatorium in the North of England, or convalescent home, where a female adult patient of slender means, and who is suffering from cough, could be sent. The lady belongs to the middle class, and can contribute something towards her maintenance. Her stay at a seaside place must be a prolonged one, if any good is to come of it; and, if so, she must be economical, as she is one of a very large family.

TREATMENT OF SYPHILIS.

M.D. writes: A patient of mine states that about twelve years ago he contracted syphilis from a coloured woman. Primary and secondary symptoms appeared, but after some time he became apparently quite well. About a month or six weeks since sores made their appearance on the fauces and soft palate; and when I saw him the entire buccal surfaces, hard and soft palates, and angles of mouth were a mass of deep ragged sloughing ulcers. He was pale and anæmic, and almost unable to take food. I ordered the following "pill": R Hyd. perch. gr. i; quinine sulph. gr. i; ext. bellad. gr. i, with a chlorate of potash wash, lotions of iodoform and glycerine, and a topical application consisting of iodoform, borax, honey, and muriatic acid.

Will any member suggest a mode of treatment more likely to yield satisfactory results?

IS HOMŒOPATHY INCREASING?

DEPUTY SURGEON-GENERAL CHAS. T. PARKH (West Kensington) writes: In a paper which I have written on homœopathy I stated my belief that there are not so many practitioners of it now as forty years ago in proportion to population. Could you, or your readers, help me to prove or disprove my assertion by reliable statistics?—I want to know: 1. The number of homœopathic practitioners as well as "orthodox" ones in the year 1848, say, in London, and population of that year. 2. The same for the year 1857-58.

My reasons for taking forty years as an illustration are twofold: first, it is the period I have been connected with the profession; and, secondly, because in 1848 a revival of homœopathy took place, or, at any rate, created a great stir both in and outside the profession.

The British Homœopathic Medical and Pharmaceutical Directory, for 1875 (London: Homœopathic Publishing Company), contains in a "List of Qualified Physicians and Surgeons Practising Homœopathy in England, Scotland, and Ireland," 299 names, and in a supplementary "List of Practitioners Holding Degrees from Foreign Universities and Colleges whose Diplomas cannot be Registered under the Medical Acts," 9 names, making a total of 278 names. The British Homœopathic Medical Directory, for the year 1887 (editors and publishers, Thompson and Capper, homœopathic chemists, Liverpool, etc.), contains in a "List of Qualified Physicians and Surgeons Practising Homœopathy in England, Scotland, and Ireland," 238 names; there is no supplementary list. The preface contains the following paragraph: "Many inquiries having been received relative to the omission of well known names, it is necessary to state that in almost all cases such names have been omitted at the individual's own request."

DELIRIUM TREMENS IN HOSPITALS.

G. asks whether there are any general hospitals, metropolitan or provincial, where cases of delirium tremens are not admitted; and, if so, about what proportion they bear to those where they are admitted. It is proposed by the Committee of the hospital with which G. is connected to refuse for the future admission to these cases, hitherto always admissible into it. The plea is a financial one, namely, that special attendants are apt to be required; but, inasmuch as delirium tremens is liable to arise in cases already admitted for other disease, for example, pneumonia, potatorum, or in surgical cases, as compound fractures in intemperate subjects, some provision must always be made for the same. The cases of delirium tremens or acute alcoholism do not average more than three or four per annum at this hospital; and not being admissible into a lunatic asylum, the Committee propose henceforth to send them to the workhouse, two miles off. The physicians of the hospital are unanimously opposed to this change, mainly on the ground of its diminishing the chances of recovery of the patients.

ANSWERS.

W. E. W. (Abertillery).—The Medical Alliance Association (Honorary Secretary, Dr. R. H. S. Carpenter), 130, Stockwell Road, London, S.W.

PUBLICATION OF PASS LISTS OF THE ROYAL COLLEGE OF SURGEONS. MR. E. MANSELL SYMPSON (House-Surgeon, St. Bartholomew's Hospital).—All diplomas are now (and have been for the last nine months) granted by the Council on the recommendation of the examiners, and not as heretofore by the examiners themselves. This often delays the publication of the names of successful candidates for two or three weeks, as the Council only meet on the second Thursday in each month.

CERTIFICATE FROM COLLEGE OF PRECEPTORS. MR. LIEUT. COLONEL J. E. BAINE (Pamphill Manor, Wimborne) asks whether a second-class certificate from the College of Preceptors passes for medical examinations.

Our correspondent ought to consult the Educational Number of this Journal (September 10th, 1887). Among the examinations there, enumerated as fulfilling the conditions of the General Medical Council, is: "College of Preceptors.—Examination for a first-class certificate, or second-class certificate of first or second divisions; algebra, geometry, Latin, and a modern language having been chosen."

BALANITIS.

C. J. R. M. writes: The surfaces in this affection require to be kept separate. Lotions do not do much good unless this is done. What I usually recommend is to tease out some of the down from the ordinary boracic lint, and insert a thin piece, and then drawing the prepucé forward to retain it. Sometimes dusting with calomel or iodoform does good.

OBSTINATE ALOPECIA.

G. H. J. DUNSMORE, M.B. (Coldstream) writes: In reply to "Alopecia" in his query in *JOURNAL* of December 24th, as to treatment of obstinate alopecia areata, I have found the application of a strong solution of hydrarg. bichlor., 2 to 4 grains to the ounce, frequently used, until soreness of the skin results, followed by the use of an ointment of lanolin (Liebreich) and ordinary paraffin oil when the irritation has subsided, very effective; tonics to be given concurrently containing strychnine.

INCONTINENCE OF URINE.

DR. H. M. DUNCAN (South Hampstead) writes: "M. W." (*vide* Queries in the *JOURNAL* for December 3rd) should try (1) one-drachm doses of liq. potassæ in small tumblers of milk or ale *bis die*. If in the space of a week no improvement show itself, add to the treatment three grains of hydrate of bromal at bedtime. (2) Should these remedies fail, try the addition of tr. belladonnæ internally, and apply the extract, softened with glycerine, to the urethra by means of a flexible bougie, say, for a minute night and morning. The patient ought not to take a larger draught of fluid nearer than four hours to bedtime. (3) As a last resource, solution of nitrate of silver (gr. x to \frac{ij}) may be applied to the prostatic part of the urethra, by means of a small injection apparatus. In offering the results of my experience I am assuming that masturbation, constipation, urethral and preputial disease, and abnormal conditions of the urine form no part of the complaint. Finally, if the foregoing methods fail to cure the distressing malady from which "M. W.'s" patient is suffering, I would strongly recommend "M. W." to consult the authorities quoted in that wonderful *anurium* of medicine and surgery, Neale's *Digest*.

STAMMERING.

R. P. writes: The cure of stammering has been known for centuries. A stammerer can sing as well as a fluent speaker, and can repeat "do, re, mi, fa," etc., in the gamut. It is only needed to commence the expiration before pronouncing a consonant. I met Jaeky Broster, of Chester, in the year 1832 or 1833, and his secret was simply teaching his pupils to say "er" the "r" soft before each word. He was an auctioneer, and did not understand the theory of his practice. He was invariably successful, and charged a fee of three hundred guineas, and exacted a bond of secrecy.

NOTES, LETTERS, ETC.

ANTIPIRYN.

DR. C. R. ILLINGWORTH (Clayton-le-Moors) writes: The effects of a solution of antipyrin on fresh blood are the following: The red corpuscles become smaller and lose their colour, and their contents shrink with the cell wall; they lose their tendency to form rouleaux, each corpuscle standing distinctly apart from the others; and they become absolutely destitute of the slightest viscosity. The effect on blood clot is to clarify it so as to give it the appearance of gelatine, and to make it less firm.

It would seem, therefore, that antipyrin relieves pain by preventing congestion in virtue of its solvent action on the constituents of fibrin, and more particularly upon that which exists in the red corpuscles. It should therefore prove of service in all congestions of blood, whether of an active or passive nature; but it should not be prescribed in diseases which are known to be associated with diminished fibrin-forming power, such as septicæmia and typhoid fever.

VACCINATION INSPECTORS.

LINDUM writes: Since I have been in practice (twenty-nine years) I have held the office of public vaccinator and my vaccination has been examined by nearly all the medical inspectors of the Local Government Board. The first time I did not receive the extra grant; but since then I have always had it, and in fairness to inspectors I must say I have received from all of them the most courteous and gentlemanly treatment.

MEDICAL DEFENCE UNION.

MR. R. M. CRAVEN (Southport) writes: Referring to your reply to "A Member," in the *JOURNAL* of December 10th, it may be useful to refer to the fact that the above "Union" is a limited liability company, limited by guarantee under the "Companies Acts, 1862 to 1884," and its management is therefore regulated by its "articles of association," a copy of which the secretary must supply to any member of the company on receipt of 1s., with stamped and directed envelope. As your correspondent appears to be anxious to terminate his connection with the company, I would advise him to carefully peruse the articles of association numbered 8, 14, and 60, as well as the fifth clause of the memorandum of Joint Stock Companies as the secretary to the company has recently retired from his lucrative position at £250 per annum.

DISLOCATION OF THE SHOULDER IN A HORSE; THE ULTIMATE RESULT.

MR. NOBLE SMITH writes: In the *JOURNAL* of April 9th, 1887, page 810, was published my description of the reduction of the dislocated shoulder of a horse in the hunting field last March. The great interest expressed at the time in various ways has led me to think that the subsequent history of the case may be valuable to the readers of this *JOURNAL*.

The mare was put to work seventeen days after the accident. Five weeks subsequently I rode her over a few small jumps. Up to the present time she has gone perfectly sound, and has had almost daily work in harness or with saddle; and, what is of more importance, and without any harm resulting, days' hunting with her over a severe country, and has taken some big fences with several drops. In landing after a deep drop, the shoulders must bear a great strain, and I think we may assume that in this case the animal has perfectly recovered from the effects of the dislocation. This is considered a remarkable result by many eminent veterinary surgeons, and I attribute it to the observance of three principles, which I think should generally be applied in

the treatment of human dislocations. They are: 1. Allowing as short a time as possible to elapse before the reduction of the dislocation is attempted; 2. Avoidance, as a rule, of making such attempts until the patient is under chloroform (or ether); and, chiefly, 3. Daily movements of the joint, commencing soon (twenty-four hours, perhaps) after reduction.

The dislocation in this case was a very complete one, the head of the humerus being displaced upon the outer part of the neck of the shoulder-blade, and the nature of the considerable deformity produced, being very evident. The mare was not moved from the place of accident until I had given chloroform and replaced the bone. Before reduction she could barely hobble a few paces; directly after, she walked into the neighbouring town without difficulty.

CIGARETTE SMOKING—WITH OR WITHOUT A HOLDER?

MR. E. S. MCKAY (Dublin) writes: I have often noticed that the constant smoking of cigarettes without a holder has a great tendency to make the teeth yellow, whereas if a holder be used this is not the case, at any rate to a much less extent. Further, I maintain in pipe smoking the teeth do not become nearly so yellow as in smoking cigarettes the first way I have mentioned. The explanation, I think, of this is due to the fact that a cigarette is held between the lips, a holder or pipe between the teeth, so that in the former case, during inspiration the smoke comes in direct contact with the front of the teeth before entering the mouth, while in the two latter cases it is received at once into the mouth, and can only come in contact with the front of the teeth indirectly during expiration. A knowledge of this will perhaps prove useful to some of your readers, who, while they may be indifferent as to whether they do or do not use a holder, may not be at all so indifferent as to the appearance of their teeth.

MEDICAL PRACTITIONERS AND THE LAY PRESS.

MR. ERNEST G. ARCHER (Thetford, Norfolk) writes: With regard to your censure of Dr. Harris in the *JOURNAL* of December 24th, p. 1411, for allowing an account of an operation performed by him to appear in the *Ipswich Daily Journal*, will you permit me to bring the facts of the case before you? I assisted Dr. Harris at the operation in question, the removal of a large tumour of upwards of ten pounds (not ounces). Naturally, from its magnitude, a great deal of talk was occasioned in this quiet neighbourhood; and a mutual friend of ours, I need hardly say without communicating his intentions to us in any way, sent an account of the case to a local paper, whence it was doubtless copied, or sent by a reporter to the paper where it was seen by "A Member, Ipswich." It is unnecessary to say no one could be more indignant than Dr. Harris or myself at the unfortunate publicity given to this case, but I venture to hope my explanation will show how helpless we were to prevent the unfortunate affair.

* * * Dr. Harris writes to us from Thetford that no one could have felt more annoyed than himself at the paragraph which appeared; that he never sees the paper in question, and does not know how it was published; that he agrees that such notices are unseemly and damaging to the profession. In this instance, at any rate, the medical men concerned seem to have had no intention, that any such notice should be printed.

ENDEMIC DIPHTHERIA.

MR. HENRY GODDICH (Long Ditton) writes: As I notice in your Paris letter the suggestion that the endemic origin of croup and diphtheria lies possibly in the manure and refuse of stables and farmyards, I would call your attention to the fact that I have held that theory for many years.

THE CONSUMPTION OF TEINS.

DR. GEORGE R. YOUNG (Birmingham) writes: With regard to this subject, I should, with your kind permission, like to chronicle a new experience. I was about to give up taking tea; in fact, I had ceased to take it, when I saw in a grocer's widow a little apparatus for infusing tea, called "The Anti-tannic Infuser," which I have tried with the very best results, not only on myself, but also on patients who would not forego the pleasant beverage although doing them harm. It is made on the principle of the well-known infusion jug, as invented by the late Mr. Peter Squire. It can be fitted easily into an ordinary breakfast cup or into a teapot; and, after three minutes' infusion has taken place, can be removed, and with it the tea-leaves which it has contained. I find that the tea made in this way is both pleasant and suitable for anyone, and personally I much prefer it.

METROPOLITAN PROVIDENT MEDICAL ASSOCIATION.

MR. C. J. C. PRIDHAM (1, Old Serjeant's Inn) writes: Provident dispensaries at the present time are "farmed" medical practices, sometimes carried on in the name of a practitioner, but more frequently in no name at all, and under the guise of a provident institution for the benefit of the poorer classes.

A medical practitioner employing, or being employed by, unqualified assistants and adopting this system, can therefore carry on practice, say, in every district of London or other large city, and yet be resident miles away from any one of them.

In some cases, two or three such dispensaries have been owned by a medical man; in another, a practitioner has had one or more, and a joint proprietorship with an unqualified practitioner; in a third, and in a worse type of case, the entire dispensary—house, fittings, drugs, etc.—have belonged to the unqualified man, and the practitioner has been the recipient of a weekly salary or a commission on the profits for carrying it on. The foregoing is by no means an uncommon or unusual state of facts, and it is the fruitful cause of all the irregular or illegal customs which disgrace the medical profession, and constitute grounds for actions and prosecutions under the various statutes.

There are certain directions in these statutes which cannot be surmounted by unqualified practitioners, except by actual fraud. How often, therefore, do we find the proprietors of "branch practices" or "provident dispensaries" "covering" the delinquencies of their unqualified assistants by signing a quantity of vaccination or death certificates in blank for them to fill up at their discretion, or personally filling up such certificates and making false declarations in cases not seen by them, or allowing their assistant to assume their own name and medical rank in order the better to personate them?

It may be contended that these remarks only apply to establishments set up by medical men or unqualified practitioners, and have no bearing upon those large incorporated societies founded by laymen and employing medical officers

A LECTURE ON TUMOURS OF THE BLADDER.

Delivered at University College Hospital, November 21st, 1887.

By SIR HENRY THOMPSON, M.B., F.R.C.S.,

Consulting Surgeon and Professor of Clinical Surgery to the Hospital, etc.

PART II.

SUPPOSING that your investigation of a case of vesical hæmaturia results in the discovery of papillomatous *débris* in the urine, identified by you as such under the microscope; what is to be done? I cannot advise you to pursue any system of local applications to the interior of the bladder by way of injecting or otherwise. The question of operation is the only one a surgeon can entertain. I assume that there is no sign of the presence of cancerous growth of any kind, because if there is I shall advise you on no account to touch it with the knife—we may perhaps occasionally have to open the bladder in such a condition to afford relief, although I confess it has never fallen to my lot to see a case presenting any indication for such a proceeding, still that the need might arise is quite conceivable.

Thus for practical consideration, I may say that two distinct classes of cases are met with—the larger class consists of those patients in whose urine the *débris* of papillomatous growth are found, and which can be identified as such by the microscope. About these cases there is no doubt as to the presence of the growth, the only question is how are they best dealt with?

The second class consists of those cases in which the history and the symptoms, especially the nature and extent of the bleeding, render the presence of tumour highly probable. Nevertheless, after several examinations, no papillomatous or suspicious cell growth has been discovered. For these, with rare exceptions, digital exploration, though a small opening in the perineum, should be performed. This done, the operator ascertains if a growth be absent or present; and if the latter, whether it be a single polypoid growth, which may be easily removed by the forceps through the existing opening, or whether the extent and physical characters of the tumour indicate that a better chance of removal will be obtained by performing a suprapubic operation. Or the inquiry may lead to the decision that the growth implicates the coats of the bladder chiefly, that it is not developed in the form of prominent masses admitting of removal, and therefore that no further operative procedure is desirable. I may add here that when the existing conditions have been determined by exploration, and the surgeon believes that his best course is to attempt removal above the pubes, there should be no delay, but he should at once proceed with that operation. The perineal incision does not in the least degree interfere with the subsequent line of action; the rectum is to be distended in the usual way, and the bladder will retain the necessary injection, which is the next step of the process, notwithstanding the opening which has just been made.

Should the management of the cases constituting the first-class differ from that just sketched? I refer to the cases in which there is microscopic evidence that tumour is present. Is an exploratory incision necessary or desirable also for them?

In the majority of cases I think it is not. It is quite true that when there is only a small polypus with a narrow neck it can be easily removed by a simple perineal incision; and I am bound to state that my most successful cases have been thus treated, and have been permanently cured in that manner. But they would have been successfully treated also by the suprapubic method, which, moreover, offers an additional advantage in the fact that, especially when the patient is not stout, the operation affords an opportunity of removing other minor growths, if such exist, more easily and effectually than the perineal opening does. When I first began to remove vesical tumours the value of the new suprapubic procedure, in regard of simplicity, safety, and efficiency, had not been established; but an enlarged experience of it, in my own hands, has convinced me that it offers advantages when the tumours are multiple or considerable, not to be obtained by the perineal route. I cannot recommend that it should be performed when you merely entertain a suspicion, however strong, that tumour is present in any given case. As long as the absolute proof arising from fragments passed in the urine is absent the perineal exploration is the only legitimate proceeding, unless it is deemed better to wait and make further research for indubitable evidence.

Next, as regards the performance of these operations, I have nothing to add to the details which I thought it right to enter upon very fully in my last lecture, when dealing with the exploratory operation, relative to the mode of removing any foreign bodies, or detaching any morbid products when found by its means.

Again, when the suprapubic operation is to be undertaken for the treatment of vesical tumour, no different mode of performing it, from that required for the extraction of calculus, has to be adopted. Hence the operation is to be performed in the manner already described, in every particular as far as to the opening of the bladder itself. But at this point of the procedure I now give you some further instructions for completing it.

I request you to imagine then, that there is a patient here before us whose bladder I have just opened above the pubes, and that my right index finger has entered the small opening I have just made with the scalpel. You might observe that the water which was injected into the bladder before commencing has been flowing out in a full stream, but that it is now checked by the finger *in situ*. My left hand is still holding the handle of the hook with which I firmly fixed the vesical coats before making the incision, is now in the act of being removed. Of course my finger is engaged in carefully surveying the form, the dimensions, the consistence of the tumour, and especially the nature of its attachment to the walls of the bladder, whether by a narrow or by a broad base. Then the whole of the inner surface of the cavity, usually smooth and polished, is traversed in the search for other growths only exceptionally present. And when the work to be done, and the space required for action have been thus determined, the opening, at present small, may be enlarged either by distending with the finger, or by cutting to the size required, and also, if necessary, for light to see. It is usual, often convenient, to pass a long loop of stout silk, one on each side of the upper margins of the opening of the bladder, through its coats, that an assistant may by drawing them apart display the cavity, and at all events preserve the opening in its place. The operator then applies a pair of forceps of appropriate form, blunt or sharp according to the nature of the tissue to be removed, using the latter only whenever it is not possible to remove them with the blunt instruments. By careful management all the free growth is removed; and if a thick or hardened base is encountered it must be left; there can be no attempt to separate this from the coats of the bladder, with which indeed it is incorporated.

When the growth has a narrow, more or less pedunculated connection with the vesical walls, it is cut off pretty close to the adjacent surface. At last, when nothing remains to be dealt with, the fluid should be allowed to run out of the rectal bag, for the bleeding is usually rather free during the process of detaching the growth, and removal of pressure on the veins caused by the distended rectal bag, materially checks it. There is no occasion to close the bladder, indeed it is better not to do so. Its muscular tissues soon contract and narrow the opening, which may moreover continue to give exit to a quantity of small tumour *débris* which remains, some of the bruised surface of the base remaining will slowly slough and separate. The wound is then treated precisely as after the suprapubic operation for calculus, the directions for which were given in detail in the lecture on that subject.

I shall now briefly give you my view of the general results of my experience of removing vesical tumour to the present date.

I have operated altogether on thirty-eight patients,¹ male and female. In at least five patients, excluding, of course, the recent cases, say the last twelve, since the lapse of a considerable period of time is necessary to determine the question of permanent results, the cure has been complete, no return has taken place, and the patients, with one exception of a man since killed by accident, are as well at this moment as they ever were, and are perfectly free from any urinary symptoms. The victim of the accident had passed nearly two years after the operation, without return of symptoms. An necropsy was made by Mr. J. L. Crisp, of South Shields, who sent him to me and was interested in the result. He was good enough to send the bladder for my inspection, in order to demonstrate that there was no sign of reappearance, indeed a careful scrutiny was necessary in order to discover the very slight remaining cicatrix. The growth is in the museum at University College.²

A large proportion obtained relief from severe symptoms for different periods varying between two and four years, and then reappearance of the growth has led to a second operation. In two cases, one that of a medical man who fully understood the pathology of his terrible disease, I have operated three times; in both of these at the desire of

¹ My last public report was one of twenty cases, since which I have operated on eighteen other patients.

² This case is given in my work on Tumours, in which it is the last, or No. 20

the patient from experience of relief and reprieve, attained by their preceding experience.

Four patients died within a few days of the operation, partly from exhaustion, two from cystitis and peritonitis, all among the very early cases, probably from too great an anxiety on my part to remove the whole of the growth, and the want of safer and more efficient instruments, which experience has led me now to employ. Two died from blood poisoning, each on the twelfth day after operation, one after the perineal incision, and the other after the removal of a large tumour by the suprapubic route. Several are living with threatening return: the great majority gaining relief from severe symptoms and some extension of life, varying considerably in different instances.

We have to remember that every patient with bleeding vesical tumour inevitably succumbs sooner or later to his fate, unless surgical aid is afforded. Every case therefore of permanent cure is a life absolutely saved by our art, while prolongation of life, whatever it may amount to, is equally so. Hence these results, although necessarily showing many failures to remove the disease, certainly manifest a considerable aggregate of clear gain in the matter of human life, and must be so regarded in relation to the sum total of those who are afflicted.

Under these circumstances it is impossible to predict for any individual case the result of operation, even in an approximate degree. Until incision has been made and actual contact with the finger, sufficing to ascertain the physical characters of the tumour, has been completed, no one can say whether it be possible to remove it completely. If separation is not complete there is not much hope of a permanent cure; nevertheless, I am disposed, after observing the issue of one of my cases which suggested the idea, to think that even when not quite removed there are two processes, almost necessarily following, which tend to favour a successful issue. The first is, sloughing of a thin layer of the surface left, due to the crushing action of the blunt forceps; secondly, the cicatricial action and contracting of the surface, which probably suffices to strangle and destroy any very slight remains of the papillomatous tissue there.

HARVEIAN LECTURES ON LUPUS.

Delivered before the Harveian Society, December, 1887.

By JONATHAN HUTCHINSON, F.R.C.S., F.R.S., LL.D.,
Emeritus Professor of Surgery at the London Hospital.

LECTURE II.—THE VARIETIES OF COMMON LUPUS.

The Histology of Lupus Vulgaris.—Of Lupus Erythematosus.—Dr. Thin's Records.—Dr. Jamieson's Case.—Lupus not always the same.—Explanation of the Causes of Variability.—The Bacillus.—Reference to the Schedule.—Definition of Lupus.—Distinctions between Vulgaris and Erythematosus.—Meaning of Symmetry and Non-Symmetry.—Strumous-Lupus.—Necrogenic Lupus.—Lupus Mutilans.—Lupus of Mucous Membranes.—Eczema-Lupus.

I SAID in my last lecture that it was my wish to submit the question of the real nature of lupus to the test of clinical rather than of purely histological evidence. I have, in truth, no faith that it is possible to solve it by the latter. We must not, however, pass it by without availing ourselves of its aid, so far as it can at present help us. I wish, therefore, to somewhat amplify what I then said on this matter. "It is now generally believed" (I quote the words of Dr. Sangster, a much better authority than myself) "that the earliest changes of lupus are to be sought for as an independent cell growth in the corium, either affecting it as a whole (as held by Neumann, Anspitz), superficially (as held by Virchow, Billroth), or beneath the vascular layer (as held by Kaposi)."

The differences in opinion of different observers as to the precise part first attacked are to be explained by reference to the different stages of the disease which they had under their inspection. The most vascular parts of the corium, the immediate neighbourhood of the sebaceous and sudoriferous glands, and the peri-vascular spaces of the blood-vessels themselves, are the parts where the cell growth is first seen. It is usually noticed first in the most superficial parts of the corium, in close connection with the Malpighian layer; so that many observers have believed that it originates in a germination from the under surface of this structure. In the end the deep layers of the corium and even the uppermost of the adipose structures become in-

olved; and at this period the glands and hair-sheaths are for the most part destroyed by pressure. Unless ulceration has taken place, the layers of the epidermis and the rete Malpighii, although somewhat altered, remain intact. A very important observation has been made by several, and is confirmed by Dr. Sangster, that the Malpighian layer is apt to grow downwards in processes much resembling those of epithelial carcinoma.

The cells which constitute lupus tissue are at first not easily distinguished from white blood-corpuses, but at various stages and in different parts they present certain differences, becoming larger and lighter-coloured, with less granular contents. There are also seen oval bodies conspicuous for their shape and faint colour, which resemble the nuclei of the deep Malpighian cells, many of them having a point-like nucleus.

The presence of "giant cells" has been asserted by several observers, Langhans, Friedländer, etc. But the exact nature of the appearances so named has been disputed by others. Professor Lang supposed them to be only degenerated sweat tubes. Sangster is of opinion that "true giant cells are sometimes met with." As to the real origin of true giant cells there is, however, much discrepancy of opinion still existing amongst histologists.

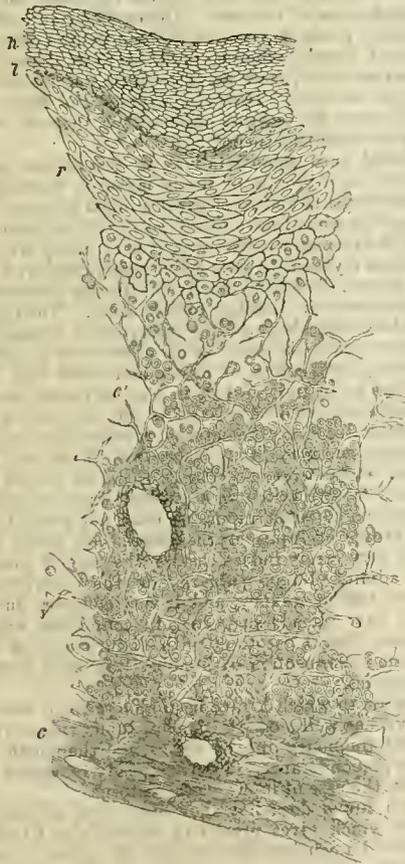

These descriptions apply to lupus vulgaris only; and let us always bear in mind to well developed examples of it only. The microscopist always selects for his purpose a position where the apple-jelly growth is well displayed, and it is this growth which he describes. His observations upon such cases scarcely touch the question as to whether there are not antecedent conditions which cannot be distinguished from common inflammation, nor that as to whether in other states the peculiar features of lupus growth be not wholly concealed by super-added inflammatory products. Respecting these, I suspect that the microscopist would not unfrequently allege that there was no proof that the disease was lupus at all, and the assessor would have to fall back on the clinical evidence. We may take it as certain that whenever the naked eye can recognise apple-jelly, the microscope can always find a definite and characteristic cell-growth in the corium, whilst respecting the other less marked conditions different verdicts will be given. The inflamed form which lupus almost always presents on the hands and feet, for example, will probably but rarely present for the microscopist appearances which are conclusive, and we have to prove that it is lupus by its laws of extension and persistence, and by the presence of better characterised patches on other parts in the same patient. I am anxious to impress this point because it is of great importance in reference to the admission of various allied diseases into the lupus family. My assertion is that lupus is by no means definitely *sui generis*; that it is only a specialised type of chronic inflammatory action, and that the degree of its specialisation may vary much in different cases, being in some so slight as almost to defy recognition.

If from lupus vulgaris we now turn to the histology of lupus erythematosus, we shall find almost all observers unanimous that there are important differences between the two. Some have even thought these differences so great as to wholly detach the maladies from relationship. Such, I need hardly say, is not my view. If we take the examples of common lupus in which cell growth is most marked and those of erythematosus in which the condition approaches nearest to mere erythema (as when it becomes generalised), then assuredly we shall have no difficulty in demonstrating by the microscope most conspicuous differences. The conditions delineated, for instance, by Dr. Thin in his able paper in the *Medico-Chirurgical Transactions*, show little more than dilatation of the capillaries. For Dr. Thin lupus erythematosus is in the main a disease of blood vessels. There are, however, other forms of the malady which present other appearances, and just as it is, I assert, often by the unassisted eye impossible to say conclusively whether any given case should be assigned to vulgaris or to erythematosus, so it is equally difficult when we examine a microscopic section. I shall prove my assertion as to this difficulty—impossibility, if you will permit the word—in the living patient by producing before you a number of portraits published by different authors on lupus, and I have no fear as to your verdict. In reference to the inspection of sections I will ask those who are skilled to examine the drawing which I produce and to tell me whether it shows the conditions of vulgaris or erythematosus. There is, as you will see, abundant cell growth in the superficial layers of the corium, and I quite expect that most will declare the appearances those of common lupus. I have, however, borrowed the woodcut from a paper by Dr. Jamieson, of Edinburgh, and it is taken from a case the whole history of which proves it to have been an example of the erythema form.

¹ I have to express my thanks to Dr. Jamieson for his kindness in lending the woodblock which I here use.

Respecting erythema lupus, indeed, the opinions of microscopists have been not a little various. Some have held that it begins around blood vessels; others (Geddings) that it is a disease principally of the sebaceous glands, whilst others locate it in the corium, or even think that the sudoriparous glands are its special sites. These discrepancies ought not to surprise us, and they reflect no discredit whatever on the observers or their modes of work. The fact is that lupus inflammation in the erythematosus as well as the vulgaris type presents great differences, and that the structures chiefly affected are by no means always the same. Neither it nor vulgaris are diseases of any special structure in the skin, whether gland or vessel, but beginning rather in the areolar spaces they implicate secondarily one or other of the cutaneous viscera or vessels. It may be the sudoriparous glands or the sebaceous ones, it may be the hair follicles, it may be the perivascular spaces, or, lastly, it may chance to be the lymphatics (lupus lymphaticus). Hence some of the differences which the lupus process assumes, and some of the various names which have been given to it. We must not look for sameness where Nature has made variety.

It may perhaps help to simplify our conceptions on the subject if we make bold to deny that there is any such pathological entity as lupus, and to assert that it is simply a name which for convenience sake we give to certain types of the inflammatory process, endlessly varying in detail, but having certain features in common.

With the preliminary statement that all varieties of the lupus when once well established keep to their type, it may next be well that I should state categorically the circumstances under which these varieties take their rise.

1. *The Kind of Local Irritation.*—Whether, for instance, a sting or bite, a wound, a sunblain, a chilblain, or a dissection prick.
2. *The Peculiarities of the Part to which the Irritation is applied.*—Thus the tip of the nose, its ala, its bridge, the clefts of the toes, the scalp, the various mucous membranes, etc., each have their one more or less peculiar form of lupus.
3. *The Vital Endowments of the Individual.*—Whether of vigorous

circulation or easily liable to chill, whether thin or of abundant cellular tissue, whether liable to chilblains or otherwise.

4. *The Age of the Patient.*—Thus the younger the patient the more certain it is that the lupus will be of the vulgaris type, and the more probable that it will become multiple. Lupus erythematosus scarcely ever begins before the disturbances in circulation incident to puberty have occurred.

5. *The Sex of the Patient.*—The female sex is more liable than the male to lupus vulgaris, but in lupus erythematosus the difference in proportions is very marked indeed. The influence of menstruation in disturbing the circulation is probably here at work.

6. *The Inherited Tendencies of the Patient.*—There can be little doubt that those who inherit a state of constitution liable to the easy growth of the tubercle bacillus are liable, also, to all the forms of lupus. They are just as prone, perhaps more so, to be attacked by erythematosus as by common lupus. The mucous membranes are, perhaps, seldom attacked, excepting in those who are tuberculous. An inheritance of a tendency to cancer gives, perhaps, a tendency to common lupus.

I have as yet spoken but very briefly of the tubercle bacillus in its relation to lupus. Many observers have succeeded in finding in the cell-growth of common lupus a bacillus, which all agree in regarding as identical with that of tubercle. It is, however, but sparingly found, not without much patience of search, and in many, or perhaps most, cases, it is not to be found at all. I am not aware that anyone has as yet recognised it in a well marked case of lupus erythematosus, but this, no doubt, is only a question of time, for tuberculous antecedents in the subjects of lupus erythematosus are, I think, more frequently met with than in those who present the vulgaris form. It is premature to venture upon any opinion as to the relation of this bacillus to the lupus process. The cases in which it is found do not differ so far as I am aware from those in which it is not. I must leave you to form your own conclusions as to whether it is likely that a bacillus is the cause of lupus, when I have developed in more detail the clinical history of the varieties of the malady.

We will now, if you please, turn to the schedule of the Lupus Family which has been placed in your hands (see page 7 of the JOURNAL for January 7th).

The general definition of lupus which I have given, as a *serpiginous, infective, scar-leaving inflammation of skin and mucous membranes*, will, I believe, include all varieties of the disease, and, with two exceptions, nothing else. Nothing is lupus which does not spread slowly by infection at its edge, and which does not leave the affected part more or less disorganised; and every form of inflammation of which these are necessary and invariable qualities is lupus, unless it be either syphilis or cancer. I need not trouble you with much as to the distinctions between cancer and lupus, because they are usually very obvious. It is only by exception that malignant action shows any tendency to permit of cicatrization in the parts which it has disorganised. A few rare forms of superficial rodent ulcer are the only conditions in which malignant action produces appearances which clash with my definition of lupus. It is, however, wholly different in the case of syphilis. Probably there is not a single variety of the lupus type of inflammation which may not be simulated, and that too with the utmost closeness, by syphilis. The diagnosis depends upon certain minor features of peculiarity, upon the history of the case, and upon the effects of specific treatment. Thus, then, the truth seems to be that the syphilitic poison can produce lupus inflammations. In doing this, however, it stamps them all with its own nature, and we are concerned, not with the true disease, but with an imitation of it. I cannot too strongly insist that the imitation is most accurate, and the diagnosis often most difficult. So far as the definition is concerned, I should be prepared, whenever a syphilitic skin disease spreads at its edge and leaves a scar where it has been, to say of such a disease, "it is a syphilitic lupus." It may be an eczema-lupus, a rupia-lupus, a lupus vulgaris, or lupus erythematosus."

The next point which stands for our consideration is the distinction between lupus vulgaris and the erythematosus form. I have enumerated in order on the schedule the chief features of difference; but part of my argument is that the two run into each other, and that there are connecting links. No single one of the features of difference is invariably such. Although apple-jelly growth characterises the most marked cases of common lupus, it is very often not to be found, and in some cases of erythematosus form the discs of the disease are somewhat thickened, and present this growth in a minor degree (see one of Hebra's portraits). A more trustworthy feature of difference is to be found in the strong tendency to symmetrical development in the erythematosus form, and the invariable absence of any definite

tendency in this direction in lupus vulgaris. The bat's-wing form assumed by erythematous lupus on the face is well known. We know also that it is not uncommon for the bat's-wings (on the cheeks) to have no continuity with the body (on the nose), and as further illustration of the law of symmetry, we know exactly where to expect the next manifestations of the disease. They will come in the ears, and in both ears, and again without continuity with the cheek patches. Next to the ears, we shall probably see the hands attacked, and it will be both hands. So constantly is this observed, that I have, as just observed, ventured to place the fact that lupus erythematous tends to develop symmetrically and lupus vulgaris not, foremost amongst the clinical features which distinguish them. It is certainly a very remarkable fact.

Whilst, however, insisting upon its importance, we must not exaggerate it. There are many cases of erythematous lupus which show no symmetry, but they are, I think, all of its sub-class, the sebaceous form. The more purely the disease keeps to the erythema type, the more certain it is to be symmetrical. Thus, I never saw one hand affected and the other free. On the contrary, I never in any single case saw lupus vulgaris, however numerous its patches might be, and however widely diffused, with any definite symmetrical arrangement. A tendency to symmetry is shown in the portrait of multiple lupus of children which I showed at our last lecture; but still, the exceptions to it are conspicuous, and far greater than we ever witness in psoriasis, pemphigus or any other skin disease which is really symmetrical in its outbreaks.

I cannot but think that we have a very interesting problem before us in this non-symmetry of the one lupus and symmetry of the other. Let us ask what symmetry implies. It means, in the first place, that there are on the two halves of the face and body and on the two sets of limbs corresponding parts, that is, parts which, by mutual sameness of structure and function, are liable in exactly similar ways to the attacks of disease. Let a poison circulate freely in the blood, and it will be likely to attack these corresponding parts, and produce symmetry of manifestation. The phenomenon in question may, however, imply more than this: it may mean that, wholly apart from any blood infection the tissues originated for themselves, whether with or without the help of external irritants, similar processes of disease. Thus, when chilblains occur on both feet or on both hands or on both ears, we explain the fact by assuming that the corresponding members were alike in structure, and have suffered alike from exposure to cold.

We do not think it necessary to seek for any blood contamination to account for the symmetry. Now by which mode of explanation shall we account for the symmetry of lupus erythematous. You will see that the one presupposes a higher degree of constitutional or inherited peculiarity than the other. A person in whom but little of hereditary peculiarity of tissues existed might easily, if his blood were rich in germs, become the subject of symmetrical manifestations. On the other hand, it would require great pre-existing peculiarity to bring about a symmetrical yielding to disease under the ordinary kinds of exposure to external irritation. It may be that in lupus erythematous we have to reckon with both classes of causative influence. It may be also that in some cases congenital peculiarity of structural proclivity takes a far larger share than it does in others. In the more severe forms—those for instance in which the patches on the face are very large, and the condition almost purely erythematous, those in which the hands also suffer (see for an example the New Sydenham Society's portrait), I think we must presuppose peculiarity of structure. The vital endowments as regards vigour of circulation and cell-growth are probably very similar to what we meet with in those who are exceptionally liable to chilblains. This hypothesis, probable as it is, however, by no means puts wholly aside the possibility that there may be also blood contamination from the original patch.

Our discussion of this question is not wholly a matter of curiosity, or, as some might say, of transcendental pathology. A moment's reflection will show that if we credit the original patch with being the parent of the others, it becomes of the utmost importance that it should be cured promptly on its first appearance. Now I have really very little doubt that it does in some sense, and that too in many cases a very strong sense, stand in the position of parent. We will make every allowance for constitutional peculiarity of tissues, but there yet remain many facts which suggest blood contamination as a very important aid. I am thinking now of the many cases which are exceptions to the law of symmetry, and in which the proximity of the secondary patches to the primary one suggests infection by contiguity. Remember also that there is often, indeed usually, a long interval between the local beginning of the disease and its becoming multiple or general, and, further, that not infrequently the general

outbreak is sudden, and apparently independent of any local exciting causes as regards the parts newly attacked. Whenever there is a considerable interval between the first patch and the secondary ones, we are entitled to suspect infection, and this is almost always the case when lupus erythematous becomes generalised. A few cases there are undoubtedly in which the diffusion is rapid, and which may, perhaps, be placed almost as varieties of Kaposi's disease, for they begin in youth and are very severe and peculiar, implying strongly marked peculiarity of organisation; of these, the boy who sat for the New Sydenham portrait may be quoted as an example. In making this remark, however, I am bound to remind you of the law asserted in our last lecture that the younger the patient the greater the risk of blood infection and multiplicity of lesion. If this be so in common lupus, a disease of but low infective power, we cannot be surprised to see it yet more emphatically marked in lupus erythematous. It is even possible that in Kaposi's disease itself—efficient as local influences combined with family proclivity appear to be—that there is a share taken by blood infection from the parts first affected.

Leaving, however, for a while the further consideration of cases in which lupus erythematous tends to become symmetrical, or even diffused and general, I will ask attention to exceptional facts.

A lady whom I have chanced to see this very morning well illustrates this argument. She is an example of erythematous lupus in its non-symmetrical form. She has three separate patches—one in front of the ear, one on the temple, and one on the nose, and they are all three on the right side of the face. The explanation of this I take to be that the parent patch was not in the middle line, but over the ear. The others are, I should suspect, satellites to it, that is, they result from the infection of adjacent parts by germinal material which has travelled from it to them. How else explain the fact of their proximity? Yet I must beg you to observe that there are wide belts of quite healthy skin between them.²

I have entered into some detail as to this feature of distinction between the two chief groups of lupus maladies because it presents considerable difficulties, and is of great clinical interest. I must be much more brief in what I have to say on the other points.

Respecting the tendency to ulcerate, it is certainly true in a general way that in lupus erythematous it is but rarely displayed, and only to a very slight extent. The more closely the disease keeps to the erythematous type the less is its liability to ulceration. The epidermis may peel, and the discs may show a dirty epidermis or sebaceous crust, but there will be no pus scab, such as is often seen in common lupus. There is, however, destruction of tissue, and a scar will be left when the disease comes to an end, so that, in a certain sense, we must admit that an ulcerative process does exist. As you may see by reference to Hebra's portrait of lupus erythematous, it sometimes notches the alae nasi. Respecting common lupus, moreover, it is not true that it always inflames and ulcerates. Whilst, then, we accept the liability to ulcerate as a feature which in a general way distinguishes lupus erythematous from common lupus, we must not push it too far.

That typical cases of lupus erythematous are never seen in early childhood, and very rarely indeed before the age of puberty, all authorities will admit. Lupus vulgaris, on the contrary, may begin during the first stage of infancy, and is very common during the first decennium. I have already suggested, in connection with this noteworthy difference, that it has to do with disturbances of the circulation which ensue in connection with puberty in both sexes, but more especially in females.

All the statistics to which I have been able to refer, those published by other observers as well as my own, show lupus vulgaris as occurring in almost equal frequency in the two sexes, the female sex always having a slight preponderance. I have already remarked that this is very different in the case of lupus erythematous.

That common lupus does not show any close alliance with that state of health which gives proclivity to chilblains I feel quite sure, for I have collected a considerable amount of clinical evidence on the point. We must distinguish carefully between any liability to feeble circulation and the liability to inflammatory action under the influence of cold, which is the cause of chilblains. Persons especially liable to cold extremities are often quite exempt from chilblains, and the reverse is also often true. Common lupus goes usually with feeble circulation and a retarded venous current, whilst lupus erythematous is so frequently in association with the liability to chilblains

² The further facts as to this case. The lady was 46 years of age. The lupus had begun over the right ear three years ago, and, after extending rather widely had left that part, and travelled in front of the ear. The patch on the temple came a year later, and that on the nose a year later still. All were of the mixed erythematous and sebaceous type, being rough and dirty in the middle, and having congested borders. In the middle a thin scar was left. There was a strong history of phthisis in her mother's family, but not in either parent.

that it is often difficult to tell where one ends and the other begins. In close alliance with chilblains you must allow me to place what we may call the sunblain, a much less common condition of inflammation, which is excited by exposure of the part—tip of nose, ears, or cheek, or possibly even the hands—to the direct influence of a scorching sun. Whatever ensues from influences of this kind, should it become chronic, is almost sure to take the form of lupus erythematosus. I by no means, however, wish to imply that a tendency to chilblains is not frequently met with in association with common lupus. The last feature of difference between the two which occurs in my schedule is that common lupus is scarcely ever fatal, whilst lupus erythematosus, if we except its very minor forms, is a condition which should give rise to serious anxiety. Much might be written on this point. I had long been aware that severe forms of lupus erythematosus were liable to end fatally by attacks of erysipelas, intercurrent pneumonia, or some form of acute catarrhal malady; and, in looking up my notes of cases in preparation for these lectures, I have been increasingly impressed with the importance of the disease as a revealing symptom indicative of a state of constitution very likely to prove incompatible with long life. On trying to seek up patients of whose cases I have preserved notes some years ago, I find that in not a few instances they are dead. The cause of death seems to have varied, and in some I have been unable to ascertain it; in some it is said to have been an attack of fever, but in most I believe it has been either pneumonia or erysipelas. In lupus vulgaris we also not infrequently witness attacks of erysipelas, and now and then it is to be admitted they end fatally; but I am sure there is far less danger in this than in the erythematous form of the disease. In some cases of the latter, when it is very extensive, a state of debility and emaciation is induced, which, apart from the liability to attacks of inflammation, itself threatens to end fatally. In very few cases indeed have I ever known lupus vulgaris so extensive as to cause serious interference with health. The liability to end in pulmonary phthisis is, I think, alike in the two, and is a very slight one.

In now concluding what I have to say as to the features which distinguish these two diseases, I am anxious, even at risk of repetition, to say that they are useful rather for the purposes of clinical diagnosis and arrangement than as implying essential differences. I can entertain no doubt that the two are closely allied, and that they are in a general way induced by a similar kind of causative influences. If such an expression be not too fanciful, I would say that, in the lupus family, vulgaris and erythematosus stand as brother and sister, having many essential resemblances and many strongly marked but superficial differences.

In the preceding lecture enough has been said as to the general characters of lupus vulgaris. I have arranged its principal varieties in a number of clinical groups, which may be found convenient, not only for purposes simply of classification, but as facilitating the formation of rules of treatment. It is to be understood that these groups derive their peculiar features, not from any real difference in the disease (which is in all common lupus), but from the part attacked or the age of the patient.

I will now turn to the second part of the Schedule, and briefly describe the several diseases which I have there placed as the principal forms of common lupus.

Under the name struma-lupus we may place cases in which the conditions of cutaneous struma and lupus are mixed. By cutaneous struma I mean an affection which begins usually immediately beneath the skin and affects the latter secondarily. The skin becomes livid, and ulcerates, and ragged sores with undermined borders are formed. This state of things occurs usually without any combination of true lupus. Sometimes, however, we meet with the apple-jelly growth in one part and a characteristic lupus condition, whilst at another subcutaneous abscesses are formed. I am attending at present a case of this mixed kind. The patient is a woman aged 40, with a somewhat tuberculous history. On her right cheek and side of neck are large patches of lupus, whilst lower down in the neck and over the front of the sternum a succession of abscesses have occurred and the skin has ulcerated in the manner described. These cases are not common, and we know that in most cases of lupus there is no tendency to abscesses and but little to gland disease. My notes would, I think, supply almost a dozen cases in which this complication was present, and to them the term struma-lupus seems applicable. In them the lupus patches always tend to inflame and ulcerate early, and there is, I think, almost always a strong history of strumous antecedents. As the disease is a mixed one, so must the treatment be.

Single-patch lupus may be considered as at the opposite end of the chain to that which we have just spoken of. Under that term I group those cases in which from first to last there has never been more than

one single patch of the disease. In such cases the tendency to inflammation is at its minimum, and usually there has been no ulceration whatever. If a lupus patch inflames, the risk of infection and of the production of satellites is vastly increased. In these cases the disease is simply one of quiet growth and slow and painless extension at the edge. The patient is usually in sound health, and it is almost as likely that there will be a family history of cancer as of tubercle. The part affected is almost always the cheek a little in front of the ear. If lupus begins in a part where the circulation is at a disadvantage and the tendency to chill great, as, for instance, the tip of the nose, or the middle of the blush-patch on the cheek, it is almost certain to inflame and prove infective.

In some of these cases of single-patch lupus the disease has been present twenty years or more; as they cause but little inconvenience the patient often declines treatment, and allows the disease to slowly advance. The advance is usually very slow, but the thickness of the jelly-like growth is often unusually great. There is, of course, not the slightest real difference or distinction between single-patch lupus and the multiple forms, the apparent difference resulting merely from the state of the patient's health and the part attached.

The term multiple, or many-patched, lupus is applicable to cases in which numerous separate patches are produced. I have already explained how this multiplicity is brought about by infection from a primary one. Lupus is always single-patched in the first instance, and sometimes remains so for long, but the risk of multiple infection is always greatest in the early stages. It is greatest also in those who are young. In a large majority of cases lupus is not confined to a single patch, but it is only exceptionally that the patches become very numerous. Now and then a patient may present fifty to a hundred different patches (see the portrait published by the New Sydenham Society). To cases in which the multiplicity is very great the term psoriasis-lupus may seem appropriate, but it is to be remembered that the symmetry of arrangement assumed in psoriasis is rarely present in lupus. The multiplicity may in some instances be so great as almost to defy local treatment.

I may suitably take together the three groups of lupus of hands and feet, necrogenic lupus, and lupus mutilans, for very similar explanations will apply to all three. Common lupus, when it occurs in the hands and feet, assumes, in virtue of the peculiarities in the circulation and the liability to chill, a remarkable tendency to inflame. [A numerous series of drawings taken from various authors were exhibited to illustrate this statement, all showing heaped scabs and extensive ulceration in connection with lupus of the hands.] In most cases in which these parts are affected, an injury has been the starting point. The apple-jelly growth is seldom seen, being always concealed or destroyed by the products of inflammatory action.

The disease would appear to obtain some minor peculiarities in connection with the special kind of irritation which sets it going. The pricks and scratches which those who have to do with dead bodies in *post-mortem* examinations or in dissections are liable to, not infrequently end in a kind of lupus. I believe that Dr. Wilks was one of the first to call attention to this disease, which he described under the name of necrogenic warts. Excepting that nothing of the nature of apple-jelly growth is ever seen, the disease in all respects conforms to the type of lupus. A thickened mass of granulation tissue developed into papillary masses is produced which may heal or ulcerate according to the exposure to cold, season of year, and state of health. Sometimes in the early stages the lymphatic glands may be irritated, but not in the later. The disease is to be cured, as we cure lupus, by liberal scraping or by cauterisation, and it has the same tendency which lupus has, to end, if long neglected, in epithelioma. It spreads at its edge with greater or less rapidity, just as other forms of lupus do.

I have treated many cases of this disease on the hands of my professional friends. It is well known on the Continent, and one of my friends told me that Professor Frerichs, when in London, chancing to see his hands with these leupoid patches on them, took them for an evidence of diligence, and exclaimed: "Ah, Monsieur! vous avez fait beaucoup des autopsies." A man in the garb of a baker once presented himself at the Blackfriars Hospital with this kind of lupus. I remarked to those present that I had seldom seen such hands, excepting in medical men, and he at once said: "Well, I was a medical student once."

I mention these facts in order to make it seem probable that certain minor features of peculiarity distinguish this form of lupus from others, and thus permit its recognition. My argument is that, within certain limits, lupus does derive peculiarity from the special cause which excites it, and that thus necrogenic lupus takes peculiarity from the fact that it originates from scratches or pricks from spiculae of bone or poisoned needles. Yet it certainly is lupus.

Before leaving this topic, I may just say that I have watched one case in a medical friend in which the lupus has been present nearly forty years. Two or three patches were cured long ago by canterisation, but one has persisted during the long period mentioned. It is as thick as ever, and just as liable to inflame in cold weather, but it has extended very little at its edge. The case is parallel with those of single-patch lupus on the cheeks.³

The term lupus mutilans might seem appropriate to cases in which the nose has been extensively destroyed and the patient's features much damaged. It has, however, I believe, been restricted to the rare examples of mutilation of the hand which we now and then witness, and of which I now show you a good portrait. (See lithograph, to be given next week.) I have only seen four or five good examples of lupus mutilans. For its production it is necessary that lupus should attack the hand of a young child, and this is not common. When it happens and, the disease being extensive, the fingers are surrounded and universally involved, a sort of arrest of growth takes place, and the most extraordinary deformity results. The fingers may all be lost, or may be dwarfed until only their tips remain. I have never watched such a case from the beginning, nor probably will any good surgeon ever have the opportunity. I am obliged, therefore, to take the histories given by the patients' friends, and, if they may be trusted, these deformities are sometimes produced without any exfoliation of bone.

That lupus mutilans is really lupus is proved by the usual coincidence of patches of ordinary lupus on other parts of the patient's limbs. In a case which was recently shown to me by my friend Mr. Sibley, a young lady had one hand almost in the condition shown in the sketch, and she had also common lupus on the face and lupus of the soft palate. Lupus mutilans is a result of lupus under peculiar conditions, and by no means a variety of it. The remark just made applies also to elephantoid lupus. It is seen occasionally on the lower extremity, and yet more rarely in the upper. The whole limb having been inflamed in connection with lupus and probably with intercurrent attacks of erysipelas, permanent œdema with thickening and overgrowth results. The diagnosis of lupus is made by the discovery of spots of lupus growth (apple-jelly) at the margins of the diseased part of the limb or on other parts, and it is confirmed by noticing that the surface of the diseased part is in a state of scar. I recently saw a good example of lupus with elephantiasis in a lad who was under Sir W. Mac Cormac's care in St. Thomas's Hospital. They are not common.

The subject of lupus of mucous membranes is a large and very important topic, but I must deal with it very briefly. It is almost always in association with lupus vulgaris, and not with erythematosis, that we find the mucous membranes affected. Almost always the skin is first attacked, but this is not invariable. I have seen lupus begin on the gums or the palate or in the cheek several times without any like disease of skin. We also see cases occasionally in which disease in the lachrymal sac appears to be the beginning of lupus of the cheek. When lupus affects mucous structures there is usually a very definite history of tuberculous tendencies in the family. It would be impossible to identify the changes which attend it as being lupus, did we not constantly find it in association with lupus of the skin. The mucous membrane becomes thickened, papillary, and ulcerated. There is never anything to be found like the apple-jelly growth. In the mouth the gums may be destroyed and the teeth fangs exposed; the soft palate may also be destroyed and the disease may spread to the larynx. The changes may usually be distinguished from syphilis by noting that the bones are never involved, and that no perforations of the palate occur. It is always a creeping, superficial process. How far the disease may pass down the throat I do not know, nor whether it ever invades the stomach. As a suggestion in that direction, I may remark that several of my lupus patients have died of hæmatemesia. The conjunctiva is sometimes primarily affected.

I have several times diagnosed lupus of the mucous membrane just within the anus, but never, perhaps, under conditions which placed the diagnosis beyond dispute. A syphilitic simulation of it is not uncommon in this part, and often leads to stricture. The exemption of the genitals from attacks of lupus is a very remarkable and well established circumstance. I have no doubt that it illustrates the

influence of temperature in causing lupus. The further the part from the centres of circulation, and the more frequent its risk of being chilled, the greater is the danger that it may be attacked by lupus. Warmth is inimical to the disease. On the female genitals I have scarcely ever seen well marked lupus, and very few have been the instances of it on the penis. The glans penis is not infrequently attacked in tertiary syphilis by a disease which spreads just like lupus. Although, as I have said, lupus erythematosis very seldom affects mucous membranes, yet it does so occasionally.

Lupus of the septum nasi is only a form of lupus of mucous membranes made peculiar by the part affected. It is, however, a rather special affection, and as it is almost constantly mistaken for syphilis, it is desirable to say a few words about it. It usually begins just within the nostril, and a small ulcer forms, which soon perforates the septum. The edge of the ulcer may heal, leaving only a comparatively small hole, or it may extend up to the edge of the vomer. Here, again, we observe the distinction from syphilis, that lupus never produces disease of the bone. These perforating lupus ulcers of the septum may occur without any skin-lupus whatever, but the proof that they are of the lupus nature is found in the frequency with which they occur in association with it. I have shown you a portrait of unusually extensive destruction of the lips and face by lupus, and remarked in connection with it that the young lady was one of the very few cases which I have known in which a lupus patient died of phthisis. Now a sister of this young lady, who had herself no skin-lupus, became the subject of a chronic ulcer on the septum nasi, which was only saved from perforation by free canterisation. In a lecture devoted to this special subject, I endeavoured to prove that perforating ulcers of the septum, when occurring as the sole lesion, are by no means necessarily syphilitic, being often examples of lupus.

I here conclude what I have to say as to the clinical groups of common lupus. It is obvious that other groups might easily be made, but I believe that these will be found sufficient for practical classification. I now proceed to diseases which depart from the type of common lupus so much as to constitute sub-species, or special forms of the disease. I will take first what I have been bold enough to name *eczema-lupus*.

For clinical convenience I give the name of *eczema-lupus* to cases which look like eczema, but which really are lupus. In some cases an eczematous process seems to have preceded that of lupus, but in others the lupus disease appears to have produced eczematous inflammation. More or less of eczematous or impetiginous inflammation around patches of lupus is not at all uncommon, but it is not these cases which I would claim for the present category. The name proposed should be restricted to cases which in all parts, and through their whole course, have the features of eczema but the tendencies of lupus. This eczematous development may occur alike in common lupus and in the erythematous form, and it may be either dry or moist. The very prolonged duration of the patches, their incurability, their slow extension by infection at their borders, and, above all, the fact that when cured they leave scars, sufficiently prove them to be lupus. Yet it is part of my assertion that the two diseases conjoined in the name are really mixed in the hybrid malady. Now and then the patient has patches of eczema on other parts which do not assume lupus characters.

One of the first cases which I remember as inducing me to employ this name was that of a lad of about 15, who was under care at the London Hospital. His whole neck was involved in a red patch, from which the serous discharge was profuse; it was, in fact, raw over the whole surface. It had been diagnosed and for long treated as eczema. When it was looked at critically I believe that everyone present was convinced that the right name was lupus. It had been present several years, and was steadily aggressive at its edge, which latter was everywhere abrupt. It was causing scar where it was getting well, and a slight degree of contraction was present everywhere.

Another very marked example of *eczema lupus* occurred in the person of an elderly lady from Durham, whom I saw with Dr. Barron. In this instance almost the whole of one breast was involved in a weeping, abruptly margined patch, which no ordinary remedies could get to heal. Nothing excepting cauterisation did any good, and the patient remained long under treatment and was still not cured when I last saw her.

In another case a rather delicate lady, aged 45, presented dry eczema-looking patches on the left side of the neck and behind the left ear. They extended very slowly indeed, but they never showed any tendency to get well, although they healed in places. No one seeing these patches for the first time would have doubted that they were dry eczema; I can only say that I have seen Miss — once or twice a year for at least eight years on account of these patches, and that

³ Riehl and Peltan (Vierteljahrsschrift für Dermatologie und Syphilis, Bd. xiii, p. 19) describe the typical cases, and state that in incised portions there are the following changes: (1) enlargement of papillæ and thickening of the epidermis; (2) production of small sub-cutaneous abscesses; (3) extensive cell-infiltration into the cutis, resembling that met with in tuberculosis (including giant cells); (4) the presence of tubercle-bacilli, which are more easily found than in ordinary lupus, but not so readily as in miliary tubercle. As regards treatment, they advise scraping, with application of iodoform.

they have never once been quite well. This is not the history of eczema. Cauterisation with the acid nitrate of mercury is the only measure which does real good. Under it the patch on the neck has for some years been quite well, but that behind the ear still persists.

I cannot show you any good portraits of eczema-lupus, for the reason that it is impossible for the artist to portray anything distinctive. Everyone seeing the portrait would call it eczema. It is the history and the clinical course which alone make the diagnosis. I show you, however, three portraits which may be of some slight help. At any rate, they go to prove that the morbid action took on exactly the same characters in three different positions. The patient was a woman named Laura J., thirty-three years of age. She was of healthy family, except that her father suffered from "a breaking out on the skin." She had never had any symptoms of phthisis. As a child she had erysipelas of the leg. Her sister had scrofula badly in the neck, and possibly intestinal tuberculosis. The lupus disease commenced by a patch behind the ear; then followed patches on the left side of the bridge of the nose, and then in the left ear. About two months before I saw her she had a patch form on the right arm, which, after lasting a few weeks, almost wholly disappeared. In the right ear the whole of the concha was affected by a condition which it was impossible to distinguish in any way from eczema. It was ill-defined, slightly congested, and covered with thin scales, and showing several cracks. Behind the ears on both sides there were red weeping patches, which were tolerably well defined, and in that feature differed from the more common forms of eczema. There was also a very slight degree of thickening in the skin which was involved. The disease had been present for several years, and Mrs. J. had been under excellent specialist care in Liverpool. She believed that the word lupus had been mentioned. A cousin of hers was under treatment for lupus. The portraits are not very satisfactory, because the disease partakes more of lupus features than is usual in the pure eczema-lupus, and some may think that they resemble simply superficial and rather indefinite lupus. I believe that I saw the patient only once, and I cannot report anything as to the success of my treatment by cauterisation. It will be seen that the unsymmetrical arrangement of the patches in this case, all on one side of the head, suggested infection by contiguity, and the order and dates of their appearance confirmed it.

The last narrative which I shall trouble you with, is that of a remarkable series of three cases in one family.

A young lady, named S—, has been recently under my observation. Her case is an example of eczema-lupus, of an eruption which weeps like an eczema, but which persists and leaves scars like a lupus. It also shows the lupus process occurring symmetrically on the backs of the hands and nowhere else, and in companionship with a pustular and vesicular eruption on the fingers, repeatedly recurrent and probably allied to chilblains. Further, Miss S.'s case is an instance of lupus occurring as a family disease, for a brother and sister have it also. In her sister it is seen only on the hands, and keeps to the pustular form, but her brother has suffered rather severely from an acne-lupus on his face, and from lupus ulceration of his palate. I have already described his case, and it is one of the best examples of acne-lupus which I have seen. This tendency in three members of the same family to suffer from scar-leaving pustular eruptions on the face and hands, associates the disease, I think, with Hebra's xeroderma (Kaposi's disease). There is this difference, however, that whilst in the latter the disease shows itself in infancy or early childhood, it has not occurred till a much later age in any one of the family now in question.

The S. family are all delicate in the direction of stroma, they are tall, well-made, and most of them of a clear thin skin. Miss S., the eldest, is now 22 years of age, of rather florid complexion, with brown hair and eyes. She considers herself in good health, her only trouble being the patches on her hands. She never had common chilblains on her hands, and never with any unusual severity on her feet. About the age of 6 she had scarlet fever, and after it became liable to have pustules and watery blisters form on her fingers. These would come and go without, so far as she remembers, any close relation to season or weather. On one occasion little blisters formed round her nails, and two of the nails subsequently came off. They were reproduced and are now perfect. Her fingers are long and taper, usually warm, and show no trace of capillary torpidity.

Four or five years ago, the patch which now gives her most trouble began to form on the back of the right hand. It varied much at different times, and would often get almost well, and then relapse again; its chief character being a weeping surface, with pustules at its margin. There is now a conspicuous scar, covering a considerable

area of the knuckles and back of the hand, and at its margin are some little dusky ill-developed pustules. Anyone looking at this scar and not knowing the history, would probably declare it to be lupus. During the last four months, Miss S. has had a patch form on the corresponding part of the back of the other hand; this patch is now of about the size of a shilling, it is red, slightly raised and a little scaly. It is abruptly circumscribed, and would be taken for a patch of psoriasis. She asserts, however, that although at present dry, its usual condition is running moisture. It has been steadily increasing at its edge since it first began, and in spite of many applications. There is at present no proof of scar, but I have no doubt that it is destined to run the same course, unless we succeed in curing it, that its fellow on the other hand has done. I claim to regard them both as patches of lupus, assuming the external features of eczema.

ON SOME NEW APPLICATIONS OF THE INDUCED OR FARADIC CURRENT IN GYNÆCOLOGY.

By G. APOSTOLI, M.D., PARIS.

TRANSLATED BY W. WOODHAM WEBB, M.D., M.R.C.P.L.

THE gynæcological employment of the induced or faradic current is of French origin, and I may safely affirm that my friend Dr. A. Tripiet was the first to use it some twenty-five years since.¹

It is to be hoped that the new branch of therapeutics will, from the renewed interest it is exciting, soon reveal all its advantages.

A. Tripiet was the first to show that, owing to its contractile powers, the induced current could not only be used in obstetrics, but could be turned to good account in general gynæcology.

According to the views of A. Tripiet all, or nearly all, inflammatory conditions of the uterus arise from either an interstitial or an intra-vascular inertia of the muscular fibre. This inertia, mostly post-puerperal, deranges the circulation, causes congestion and stagnation, and a consequent arrest of the nutrition of the organ. By artificially exciting and re-establishing the circulation, he proposes to attain the double end of cure and prevention. Such is the rôle of faradisation indicated by A. Tripiet, when, in his teachings and practice, he insists upon it as the means of removing the congestion to which he traces the subsequent affections.

In a recent memoir² I have endeavoured to counteract these exclusive views of A. Tripiet, by pointing out what he had overlooked—the preponderating part played by septic influences in gynæcology. I demonstrated the primordial influence of lesions of the mucous membrane, showing that it was from them, by way of continuity, the parenchyma became implicated. I also showed that although the faradic current was all powerful in relieving the early and purely mechanical forms of congestion, as in cases of simple subinvolution, it was, on the other hand, useless in chronic forms, and in lesions of the mucous membrane, that is to say in endometritis. And this might be easily accounted for, since in inveterate conditions of the disease, the muscular fibre, compressed by the new deposit of connective tissue, partially disappears, and consequently the induced current, which is a direct excitant of muscular fibre, finds no sufficient material upon which to act.

On the other hand, when, as is so frequently the case, the mucous membrane only is at fault, it is still more evident that there is nothing upon which faradisation can work curatively. I, at the same time, directed attention to the powerful resource we have under these circumstances, in the methodical application of the continuous current, and noted the leading place it must take in future practice.

While giving attention to the action of the faradic current, I have done my utmost to extend the limits of its application beyond those which satisfied Tripiet.

I will now specify the contributions of this kind which I claim as exclusively my own.

1. I have modified the mode of application³ to which Tripiet has given his name. He had originated the unipolar excitation of the

¹ Hyperplasies conjonctives des organes contractiles. De l'emploi de la faradisation dans le traitement des engorgements et déviations de l'intern et de l'hypertrophie pro-tataque. (*Comptes rendus de l'Académie des Sciences*, Août 1859.) *Leçons de clinique sur les maladies des femmes*, par le Dr. Tripiet. Paris, Octave Doin, 1883.

³ Sur la faradisation utérine double ou bipolaire. See *Union Médicale* 28 October and 1 November, 1884; also the *American Journal of Obstetrics*, September, 1884.

uterns, called utero-sus-pubic, in which the circuit was always closed upon the abdomen; for that, I substituted the bipolar method. I did this by using a sound, which contained the two poles side by side. It permitted the closing of the circuit within the uterus itself, while at the same time the current radiated sufficiently to act upon the whole muscular substance of the organ. By thus concentrating within the uterus the entire electrical action we secure the following advantages:—

a. There is less pain; the skin is not in any way injured as it may be when the current is closed above the pubes. b. It may be done more easily, as we get rid of the necessity of a cutaneous electrode, which requires holding either by an assistant, or by the patient herself. c. Being less painful the dosage may be increased. d. The effect is greater, as, other things being equal, the therapeutical effect is in proportion to the intensity of the current.

Simple, easy, and less painful, this method enables us, by using additional intensity, to expedite the curative effect.

My method of uterine faradisation is therefore uniform; it must necessarily be bipolar. Pregnancy is one of the rare hindrances to its employment. But, even in that case, as well as in some others I shall mention, vaginal bipolar faradisation may be used instead, and, although less efficacious, will be found of some service.

2. Next to the question of instrumentation, I claim as my second improvement in treatment the methodic and exact application of the faradic current of tension.⁴ This term "current of tension" requires a word of explanation. No apparatus for faradisation is complete without two independent bobbins, which, according to the length and thickness of the wires, give currents differing in qualities and characters. The bobbin with a short and thick wire gives that which is called the current of quantity, because the generating wire is less resistant and lets pass a greater volume of electricity. This current is the direct excitant of muscular contractility, and is the only one employed by Tripier to overcome muscular inertia, to produce a temporary vascular activity, and to carry out his treatment of uterine congestion. The other bobbin, with a longer and finer wire, is called the bobbin of tension. It gives a current which has, I may say, a much more considerable power of expansion. The current flowing from it acts less on the muscular contractility and influences the sensibility. It has therefore been employed especially when pain is the leading symptom, in order, by a contrary reaction, to deaden a too violent nervous vibration. This revulsive application on the skin is no novelty, though not sufficiently resorted to in gynaecology.

Now it is pain which leads most women to seek relief, and, if we examine the sources of this pain, we find that they are either inflammatory or nervous.

On the one side, then, we have to deal with uterine inflammations, and especially that class of peri-uterine inflammations which is usually so embarrassing; and, on the other, with a nervous condition which we recognise as ovarian pain.

It will be admitted that for these pains all the routine treatment is absolutely useless. No one can boast that by medicines he has ever permanently got rid of such ovarian pains, and the same may be said of the suffering from peri-uterine inflammations.

These problems are among the most pressing in gynaecology. Their gravity is made greater when the number of women is taken into account who are castrated on account of pains which we know can be removed by an electrical current. Such ovarian pain, as we meet with it in innumerable hysterical subjects, is nineteen times out of twenty curable, while the inflammatory pains can be often—I will not say always—mitigated in the same way. Now it is of this means of treatment that I consider myself the originator.

It was in 1833 that I first described, in a special memoir, my electrical treatment of perimetritis. I read a second paper on the subject at the Congress of Copenhagen in 1834.⁵

No other sedative, recognised in gynaecology for the purpose we are treating of, equals the faradic current of tension when applied in observance of the following rules:

a. Of these two applications, intra-uterine bipolar and vaginal bipolar, the intra-uterine will always be preferable as more active and efficacious, whereas the vaginal operation is forced upon us by such circumstances as the impossibility of passing a sound into the uterus. This will be our dilemma in pregnancy, in virginity, or in an acute stage of peri-uterine inflammation.

b. The length of the sitting is an essential condition of success. However prolonged, whether five minutes or twenty minutes, it ought

not to end till the pain has diminished or disappeared. This we can be informed of either by the patient's declaration or by direct contact. We should never interrupt an operation till we have clear evidence of this result. The needful duration of an application will vary not only in each patient, but in the same patient, during the course of her treatment. More time is generally required for the first sitting than for subsequent ones, in which we have only to complete the work begun. I insist upon this important fact, that though a case of perimetritis may only find relief from this treatment, the ovarian neuralgic pain may be, and generally is, done away with in a very short time.

c. The sittings should follow each other quickly. Every day, or even twice a day is not too often, so that the effect may be cumulative, and nothing of the benefit gained be allowed to subside.

d. The number of sittings necessary will always be uncertain. The nervous and inflammatory conditions we have to deal with are numerous and changing, while the treatment I advocate is especially directed against one symptom—the pain. The surgeon will be obliged to modify the treatment in every case. In simple neuralgias he will find from two to five sittings generally enough to secure the patient freedom from pain for several months, and even more. In case of relapse the same treatment will give the same results. With inflammations the case is different. Not even an approximate calculation can be made as to what will be required, since we have to encounter the difficulties of uncertainty of effect, and of deviations in the degree in which cases give way to the treatment.

e. As regards the operation itself, the dosage or intensity of the current to be used (as regulated by the sheathing of the bobbin) will vary within the known extreme limits.

First, in a case of perimetritis we must always be assured of the tolerance of the patient, only pass the current gradually and slowly, and above all, in acute cases, be content to use small—even very small—doses, increasing only as the power of endurance is developed and the phlegmasia shows a disposition to give way.

No pain ought to be inflicted on the patient, first, because it is useless, and, secondly, because too strong an application might do harm.

Great caution is always necessary, especially at the beginning of a sitting. First of all the bobbin should be entirely dismounted. Then starting from zero, the advance should be made millimètre by millimètre, while the eye is kept on the countenance of the patient, as the expression is the best indication of her sensations. The gentleness of proceeding must always be redoubled in acute cases of inflammation.

Secondly, on the contrary, in operating for ovarian pain, we may press forward directly and boldly to attain our end, provided the uterine region is healthy, as in that state it is extremely tolerant. A moderate dose will sometimes suffice, but generally it is necessary to go on to the highest point. Though in perimetritis we must avoid causing any suffering, it may here be well, as a slight dose would do no good, sometimes to rouse the uterus by pouring in a massive current of tension. It is clear from all this that the dosage will always be variable, and require delicate adjustment, by a tact which can only be acquired by practice.

Even my experience, with many hundreds of these cases, does not empower me to lay down any directions which will suit all conditions. I can only say that, having to do with a curative agent which is under control, it must be judiciously adapted to the circumstances.

If, however, the dosage of current is a personal affair as regards the patient, there are some general indications which may be useful in guiding the practitioner.

It is a peculiarity of the greater number of hysterical women that they bear easily the faradic currents of tension, even with the fullest dose; so well, in fact, that after a short time they will affirm that they feel nothing. A novice might thus imagine that his apparatus had failed; or that there was an interruption of the current. When such insensibility shows itself there need be no hesitation, and we may after having slowly passed the bobbin home, continue to use the highest intensity.

But, on the other hand, we find a few women in whom there is a complete contrast of sensibility. They are incapable of submitting to the current even in small doses without complaint. Here we should be very cautious in toning down the current to their power of endurance.

I have observed this interesting fact in dealing with the still rarer cases of complete insensibility to the current of tension. They seemed not only to be able to bear it, but to be unconscious of any action. Under such circumstances, as an exceptional proceeding, after having first tried the effect of the current of tension, I have changed it for that of quantity. This generally tells upon patients more and more

⁴ Sur un nouveau traitement de la douleur ovarienne chez les hysteriques. *Bulletin Général de Thérapeutique*, June 15, 1835.

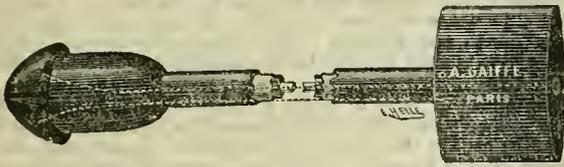

⁵ Sur un nouveau traitement électrique des périmétrites. *Comptes rendus du Congrès de Copenhague, Section d'Obstétrique et de Gynécologie*, page 141.

markedly as the hysterical symptoms are more prominent. The following curious phenomenon then presents itself: immediately the current of quantity is substituted for that of tension, it is found that the intolerance of even the smallest doses is such as to threaten the patient with a nervous paroxysm. This is the point at which to manifest the tact of medication. A state of calm only comes on when we have artificially brought the woman to the verge of a hysterical outburst by an intentional *brusquerie* of faradisation. At this moment there must be a pause, and a gradual cessation of the current. The threatened crisis will be checked, and a condition of tranquil relaxation takes its place. At the same time the ovarian region loses all, or almost all, its previous sensibility, and it is found that even when that sensibility had lasted for years, and been such as to render the slightest touch insupportable, there is, within the space of a few minutes, a transformation so complete, that the woman is indifferent to ordinary pressure.

Nevertheless, it must be borne in mind that, though this pain is called ovarian, its real seat is in the ovarian plexus, which lies above the ovaries, so that the spot where pressure causes most pain is considerably higher than the pubic margin of the pelvis, and away from the median line. This point, which, before the sitting, was exquisitely tender, will, after it, allow of any reasonable pressure. The woman will remain calm and free from any abnormal sensation, provided the source of pain is not irritated, and the corresponding ovary is not compressed by the fingers, used in a bimanual examination, by touch and palpation.

I may, therefore, thus state my opinion that hysterical ovarian pain, not having origin in any structural lesion, may in general be allayed, and that the patients have no further ground for complaint. In this state pressure above the pubes causes no discomfort. But the proof that the cure is not absolute, and that the cause of the suffering has not been removed, is that the calmed pain may be again aroused by pressure between the fingers from within and without, and that, even after a long interval of freedom, there may be a relapse.

3. I now mention my third and last contribution to gynaecological therapeutics.

There are many women who, independently of ovarian neuralgia, have intense and very localised sensibility about the entrance and lower part of the vagina. These are cases of imperfect vaginismus, in which the torment is so unbearable, and the hindrance to connection so complete, that life is rendered miserable. The difficulty of overcoming this trouble is only too well known. I have had to do with a large number of interesting and instructive instances of this affection, and I intend to publish a full account of the most important. For example, in one woman I found a single neuralgic spot, not larger than the tip of the index finger, just at the end of the right nymphæ. Another had the same condition exactly at the posterior commissure. In a third, the excessive sensibility was confined to the orifice of the urethra. The fourth case had a similar neuralgic area on the left side of the vestibule. Besides these single spot cases, I have seen many others in which the localisation was not single, and the extent varied. The remedy of which I have availed myself, and now recommend, for ridding women of these harassing annoyances is the faradic current of tension, well and methodically applied.

Over and above the general rules which I have laid down as to the dosage, duration, and mode of application of the current, which hold good equally in these cases, there is a fourth special indication that must be regarded as obligatory.

Uterine faradisation alone, by reflex action, may possibly effect a cure, without any immediate contact. But such a result is exceptional, and, as a rule, the electrical action must be brought to bear directly on the point concerned. The maximum of effect must be concentrated on the seat of pain under touch. To insure this result, I have designed an instrument, the conical end of which contains the two poles side by side, but separated by an isolating layer of gutta-percha. (See Figure.)

That which I have previously advised should be done to the uterus in certain conditions with my bipolar sound, may be effected here with my bipolar electrode.

If, however, the vaginal neuralgia is deep-seated, and extends over a large segment of the vestibule, this instrument will not answer, and we must replace it by a large bipolar sound, with which a double vaginal faradisation can be made, taking care, when the outer orifice is the part implicated, to rest the exterior pole upon it.

This will serve as a brief exposition of my views as to some applications of faradism in gynaecology. I look upon it as effectual in hysterical neuralgia, useful and variably sedative in the pains of inflammation. It is true that hysteria holds a large place in this medication; and it may be objected that, after all, suggestion has a great deal to do with the effect produced. Cure is admitted, but, in such cases, the question arises: may it not be brought about by the mental impression made by the operator?

This explanation I reject. Among many other proofs that it will not suffice, this is enough: that you may faradise one of these women, without saying a word to her either as to the nature of the treatment, or as to the probable changes that may be the consequence, and the results will be the same as if you had forewarned her.

Moreover, all suggestive influences, however potent they may be in other circumstances, are put out of question by the fact that faradism only relieves when we observe certain fixed and precise rules in its application.

EXTRACTS FROM AN ADDRESS

ON

COLLEGE POLITICS: MATTERS CONCERNING THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Delivered before the South-Western Branch of the British Medical Association, December 15th, 1887.

By PAUL SWAIN, F.R.C.S.,

Fellow of King's College, London; President of the Branch.

GENTLEMEN,—The aim and object of those who desire to reform the present mode of government of the Royal College of Surgeons is that it should no longer be a close corporation, managed well or ill by twenty-four gentlemen wholly irresponsible to the great body of the profession, and whose actions it is impossible effectually to challenge. The College of Surgeons has at its command a very large revenue; last year its total expenditure amounted to no less a sum than £33,629 11s. 7d., leaving a balance in hand of £1,742 14s. 7d. I do not for the moment stop to inquire whether this large sum is spent rightly or wrongly; but I ask you if you think it proper that the expenditure should be committed to twenty-four gentlemen who, however learned they may be in their profession or estimable in their private capacities, are not, that I am aware of, selected on account of any particular business aptitude, and who spend the money in the happy security that their actions cannot possibly be challenged by any single individual of the great profession, out of whose pockets the principal income is derived, and for whose benefit the expenditure is supposed to be made? The Council are apparently becoming afflicted with a distressing mania for building, and I see that the sum of £11,852 11s. 9d. has been spent on the new Examination Hall. They are also embarking on a large building plan for the extension of the College itself, the cost of which is to be eventually £53,700; and furthermore, at an extraordinary meeting of the Council on June 27th, the following resolution was carried, namely, "that for the present this Council do not spend more than £50,000 of the Erasmus Wilson bequest"—also to go in bricks and mortar. Verily let us be thankful for this small mercy for the present.

The Court of Examiners consists of ten members, who are elected by the Council by ballot. They hold the office for five years, and may be re-elected. They must be Fellows of the College; and being members of the Council does not disqualify. Last year the fees paid to the members of the Court of Examiners amounted to £5,219 2s. At a meeting of the Fellows and Members, held at the College in October, 1885, I alluded to the question, and showed that it was not only possible for the members of the Court of Examiners to be in a majority on the Council, but that such had really been the case, and that, too, in the face of a resolution of the Council that not more than one-half

¹ I would call your attention to an able criticism of this expenditure in a leading article in the JOURNAL of October 22nd.

of the members of the Court of Examiners should be on the Council at the same time. Thus the powers of the Council not only to make themselves examiners, but to re-elect themselves indefinitely, has existed in times past, and still exist. The author of a letter in the JOURNAL of October 29th points out the results of this practice.

I have made an abstract of the table he publishes, and find that there are at present ten members of the Council who are also members of the Court of Examiners, and who have shared between them the modest sum of £26,800, one of them having had £4,934, another £3,405, another £3,173, and so on in lesser proportions. Now, what I want to point out to you is this: not that the money spent in examinations is excessive, or that the gentlemen who have received it are, in the present instance, either incompetent or negligent, but that the system renders it possible for all three contingencies to happen, and that the perfectly irresponsible power which now exists, enabling members of the Council to endow themselves indefinitely out of College funds ought to be restrained.

Let me draw your attention to a late action of the Council, by which a serious injury has been inflicted on the profession. If there is one thing about which we have been fairly unanimous it has been the desire to obtain in London one examining body. Now, just when it was on the eve of accomplishment, the Council of the College of Surgeons, in conjunction with the College of Physicians, has excluded the Society of Apothecaries from their examination, the result being that a second examining body has been set up in London. And this has been done with a perfect knowledge of the wishes of the profession on the matter. In November, 1886, a large meeting of Fellows and Members was held at the College of Surgeons, and the following resolution was unanimously carried:

That, with reference to the report from Mr. John Marshall, on page 15 of the Council's Report, this meeting requests the Council of the College to consider the advisability of accepting an arrangement for combination with the Apothecaries' Society, as well as the College of Physicians, for the purposes of conjoint examinations for medical diplomas in England and Wales, under the Medical Act of 1856, and to report thereon at a future meeting of Fellows and Members to be summoned for the purpose at an early date.

On February 25th the President of the General Medical Council addressed a remonstrance to the President of the College of Surgeons.

It is not too much to say that the action of the College has been taken in opposition to what one may fairly say is the unanimous desire of the profession, backed up by the General Medical Council and the whole medical press.

The Council of the College, in the new charter for which they are applying, ask to be enabled "to determine by rules and regulations, instead of, as at present, by by-laws, the conditions of admission to the Fellowship by examination." Now we emphatically protest against any such power as this being vested in the hands of the Council. We know by past experience that it is more than likely that they would use it to lower the standard of examination. Some years ago an attempt was actually made to do this, and was only defeated by the energetic action of three well-known Fellows of the College, one of whom was Mr. Timothy Holmes. As this gentleman pointed out the other day, if the Council had been able to provide "by rules and regulations," instead of by the slower process of altering a by-law, the proposal would have been smuggled through without anyone outside the Council being aware of it.

Of a similar character is another proposition in the new charter, namely, "to empower the Council to elect to the Fellowship Members of twenty years' standing, not exceeding ten [instead of two] in each year." Against this proposal a resolution, proposed and seconded by Members of the College, was carried; but, as usual, the Council has ignored it, and still presses for the insertion of the clause in their new charter. Had I not the authority of Mr. Timothy Holmes for the statement, I could scarcely credit the fact that only last year a prominent member of the Council proposed to admit by vote of the Council fifty members annually to the Fellowship. This proposal was vigorously opposed by the Association of Fellows, and did not pass the Council.

The remedy for this state of affairs consists in taking from the Council this irresponsible power, and endowing the Fellows and Members with at least some of it. The other day I had the honour to form one of a deputation of Fellows to the Lord President of the Council, before whom we laid our objections to the proposed charter. At the termination of that meeting he said: "As I understand, it practically comes to this—that you want an alteration in the constitution of the Royal College of Surgeons, to make it a popular body, to a certain extent, instead of being comparatively a close body." And I think that expression of the Lord President showed that he perfectly grasped the situation.

² One member of the Council has since retired.

Although we have of late met within the College walls and discussed matters at those meetings, yet we do so only on sufferance, and a by-law actually exists which prevents the Fellows and Members meeting within the College walls, or discussing any matter except with the permission of the President and Council. In July, 1869, in conjunction with Dr. Morris, of Spalding, I tested this question. The late Mr. Wakley, many years ago, took a somewhat similar course. My fate was happier than his, for on that occasion he was forcibly removed from the College precincts and conducted to Bow Street. Whatever may have been the result of our action in July, 1869, the fact remains that, *post hoc* or *propter hoc*, in the November of that year Mr. Erichsen, who had been recently elected to the Council, and was then in favour of a more liberal policy, gave notice of a motion affording greater facilities for the meetings of Fellows and Members within the College walls. And on March 22nd, 1870, the first meeting was held, under the presidency of the late Mr. Cock, in the theatre of the College. But, although the Council were apparently compliant in the matter of meetings, they had little trust in the gentlemen whom they had invited to come, for on the eve of the meeting one of the porters of the College was sworn in as a special constable, "to prevent felonies and disorders." This fact was denied by the President, but it was verified by a now prominent member of the Council, who then had a keen scent for College peccadilloes. But, at any rate, a point had been gained; and we are now permitted by the grace of the Council to assemble annually within our own College "to receive as read," as Mr. Tweedy put it the other day, "the Report of the Council, which, as a matter of fact, I believe has been printed and bound up in the College Calendar before our meeting was held." But we demand more than this. We have thrice carried unanimously the following resolutions at meetings held at the College, namely:

That it is desirable that no alteration in the constitution or relations of the College shall be effected without the consent of the Fellows and Members convened to discuss such alterations.

And also

That there shall be an annual meeting of the Fellows and Members, at which the Annual Report of the Council shall be presented, received, and adopted.

Had these two resolutions been accepted by the Council, I believe a substantial justice would have been done, and most of us would have been content to rest satisfied. But, true to the traditions of the past, they have ignored these resolutions, with their usual contemptuous silence.

There is one other point to which I desire to allude before I finish, and that is the claims which the Members of the College have put forward to take part in the election of members of Council, and also to have seats on the Council. With the former of these proposals I concur. It is most desirable that so large a body as the Members constitute should have alike with the Fellows the right of meeting, the right of free speech, and the right of voting at College meetings. I am prepared to support the suggestion that the franchise should be conferred on Members of ten years' standing. With the second proposal, that Members of twenty years' standing should be eligible to sit on the Council, it being understood that not more than one-fourth of the Council shall consist of Members, I do not agree. It would take from the Fellowship the sole remaining privilege which distinguishes it from the Membership, and the position which we have obtained by the expenditure of time and labour would be hardly worth acceptance. But over and above this there is no substantial grievance existing which can justify so radical a change. All the members of the Council are Members of the College as well as Fellows, and in this double capacity represent the whole body. If it be alleged that the Council as at present constituted fails to represent the interests of the general practitioner, which I admit it almost entirely does; then I say the Members, supposing they had the franchise restricted as above indicated, will find plenty of men both in London and the provinces who are Fellows of the College and general practitioners also, and who would fully come up to the standard of representation required by the Members of the College.

THE BEDFORD PROVIDENT DISPENSARY.—The new buildings of the Bedford Provident Dispensary were recently opened by the Marquis of Tavistock. The institution, which was founded twenty-five years ago, is stated to have been of great public benefit, and has always commanded the warm support of the medical men practising in Bedford, the majority of whom are upon the staff. The new building is a handsome and well-planned structure, and most conveniently situated for patients, both in the town and surrounding villages. The cost of the building, furniture, and fittings, exclusive of the site, amounted to about £1,900.

AN ADDRESS ON THE THERAPEUTICS OF THE URIC ACID DIATHESIS.

Delivered at the Opening of a Discussion on the Subject in the Section of Pharmacology and Therapeutics at the Annual Meeting of the British Medical Association, held in Dublin, August, 1887.

By I. BURNEY YEO, M.D., F.R.C.P.,
Professor of Clinical Therapeutics in King's College, London; and Physician
to King's College Hospital.

(Concluded from page 19.)

In the next place, we must pass on to consider the more important medicinal agents which have been proposed for the treatment of this diathesis and its various morbid manifestations, and, first of all:

Colchicum.—I would ask you to consider the use and value of colchicum. This drug has been much discredited of late years, and if one of the results of this discussion is to remove that discredit, it will, in my opinion, have done practical medicine a real service. That the drug may have frequently been misused, I do not doubt; that it may have been administered without a due and discriminating regard to what I have referred to as the "constitutional element" in the therapeutic problem, I am also ready to admit; for I have read criticisms of the use of colchicum by physicians who certainly must either have had very few opportunities of observing its effects in appropriate cases, or they must have made but indifferent use of such opportunities as they have had.

When acute uratic arthritis was a much more common disease than it is now, over-doses of colchicum were probably not infrequently had recourse to, and with ill consequences, but it has never fallen to my lot to observe, or come within hearing of, any of those ill effects which some physicians have asserted to be the common consequences of the use of colchicum. I should hesitate to speak in this way if my individual judgment were at variance with that of other physicians who have had a far greater experience in this matter than I have, but I find that most of those who have had the largest opportunities of forming an opinion of the value of colchicum in gouty affections are advocates of its use. Garrod has given his verdict in its favour after the most searching and careful examination of its action; and so cautious and sound a practical physician as Sir Thomas Watson not only advocated its use as a curative, but also as a preventive, measure. I need hardly say in this city, your great master, Graves, held the same views. Lecorché, in his recent valuable and exhaustive treatise on gout, after relating the details of the numerous experimental investigations he has conducted into the action of colchicum, thus sums up: "In concluding this study of the effects of colchicum, we assert, as the outcome of our physiological researches and our clinical observations, that colchicum constitutes the specific *par excellence* for gout; that it may and ought to be used in the treatment of that affection both in the acute and chronic form."

Professor Bartholow, of Philadelphia, gives one of the best practical accounts of the effects and uses of colchicum that I have met with:

"In small doses," he says, "it increases the mucous and glandular secretion of the stomach and intestines, and probably, also, of the liver, kidneys, and skin. . . . It increases the flow of urine, of the solid constituents, as well as of the water, and promotes the cutaneous transpiration. . . . It is indicated when a prompt elimination of waste is required. . . . It relieves the pain, diminishes the swelling, and shortens the duration of acute gout. In order to accomplish these results, it is not necessary that the more harsh and violent physiological effects of the drug be produced. Sufficient should be given to increase secretion from the skin, the intestinal mucous membrane, and the kidneys, but nausea and vomiting should be avoided. Combination with an alkali increases the therapeutic effect." He gives the very moderate dose of twelve minims of the wine of the seeds, with forty minims of aromatic spirits of ammonia, every three hours, until some physiological effect is produced. He adds: "Combined with saline purgatives, it quickly relieves the constipation, hepatic congestion, and headaches of gouty subjects. It is useful in gouty bronchitis; it often relieves neuralgia occurring in gouty constitutions; it relieves by setting up an eliminative process."

This description so entirely agrees with my own observation, that I find little to add to it. There has existed some difference of opinion,

which experimental tests have failed to settle, as to the action of colchicum on the renal secretion. My own opinion is that it acts somewhat differently in different individuals and under different circumstances. Its most constant action is, I believe, on the hepatic secretion. Again and again when the motions have been hard and clay-coloured from the absence of bile, I have seen a few doses of colchicum restore the natural dark colour due to a proper admixture of that secretion. Then I think I have observed it act sometimes as a diuretic, and sometimes as a diaphoretic, and, when it acts more especially on the skin, the renal secretion may appear to be diminished by it.

Graves thought, and Lecorché supports the view, that it prevents or checks the formation of uric acid in the system, and this it may do by its decided action on the liver. My own view is that it acts more or less on all the excretory organs; that it is a stimulant to excretion; and as I regard the gouty constitution as one whose fault is especially, a sluggish and imperfect retrograde metamorphosis, and delayed excretion generally, not necessarily of uric acid alone—colchicum is in a special sense its remedy by promoting the elimination of waste products. Lecorché's experiments proved that it diminished the acidity of the urine, and decidedly increased the amounts of soda and potash in that secretion.

The prejudice against colchicum has induced Ebstein to make the extraordinary statement that it is preferable to relieve the pain of the gouty paroxysm by hypodermic injections of morphine. He says they act "quicker, more easily, and with less danger." I join issue with him utterly. The internal use of opiates in gout I consider, except under exceptional circumstances, indefensible. In a disease of defective elimination, you would be giving a drug which depresses in a remarkable manner the function of all the excretory organs but the skin. A very small dose of morphine will, especially in the gouty constitution, produce clay-coloured alvine evacuations, sometimes for days.

Colchicum then, I maintain, is one of the most valuable remedies, when judiciously given, for most of the morbid manifestations of this "uric acid diathesis," and so far from being a dangerous vascular depressant, I have shown, in my hospital practice during the session just past, that in a case of chronic gout with subacute exacerbations, moderate doses of colchicum restored regularity and strength to an irregular and feeble pulse. I trust, then, that the absurd prejudice against this most valuable remedy which has been excited in the minds of the public will be removed, for I find many gouty persons who, much to their own disadvantage, positively refuse to take colchicum, because they have been told it is "such a dangerous drug."

I observe in the last number of the JOURNAL of this Association a report by Dr. Taylor, of Brussels, on the action of colchicum on the elimination of urea and uric acid, in which he appears to have shown that the amount of both these substances in the urine is largely increased by the administration of this drug.¹

Next, as to the salicylates.

Salicylates.—We ought in this discussion to be able to determine, more accurately and decisively than has hitherto been done, the real value and applicability of the salicylates in the treatment of uricæmic affections. In the first place, it seems to me impossible to accept the exaggerated estimate of their value advanced by Professor Germain Séé, who has asserted that sodium salicylate is the best remedy for gout in its acute or chronic forms. Ebstein remarks that when he has used this salt in acute uratic arthritis, the inflammation has disappeared very quickly from one joint, to re-appear immediately in another, even when the administration of the salicylate was continued. Lecorché says he has found it useful in acute gout, though altogether inferior to colchicum, it lessens the pain and the violence of the paroxysms, but in no way shortens the attack. In cases of chronic gout with tendency to the production of deformities from deposition of urate of soda (tophi), and to constantly recurring subacute attacks, he considers it valuable. Given, he says, in such cases, from time to time, in the intervals of the attacks, in doses of sixty to eighty grains a day, it increases notably the amount of uric acid excreted in the urine, and so eliminates from the blood the excess of urate of soda. In a great number of cases, he asserts, he has been able by its use to (1) prevent attacks; (2) to prevent the formation of ankyloses and to cause already existing stiffness of joints to disappear; and (3) to facilitate the absorption of uratic deposits. To obtain these good results it was

¹ In a still more recent number of the JOURNAL (August 27th), Dr. J. McG. MacLagan, of Hexham, claims to have demonstrated this in a thesis published in the *Edinburgh Medical Journal* of December, 1881, and January, 1882; and still more recently Dr. MacLagan has shown that the paper alluded to was absolutely and entirely his own, although reproduced without a word of indication as to its original authorship.

necessary "to continue, unperturbably, for months the use of salicylate of soda in doses of sixty to ninety grains daily, only allowing the patient four or five days' interval every twelve to fifteen days, then returning to the medicine with the same regularity." He has found it of "enormous service" in the treatment of gouty asthma, angina pectoris, and cystitis. It should not be employed when there exist evidences of interstitial nephritis. Professor Bouchard (p. 316) considers it a valuable medicine in the treatment of acute gout, relieving pain and sometimes shortening the attack, but he considers its employment dangerous when there is any tendency to cardiac degeneration or when the kidneys are involved. In uric acid deposits, he says, like benzoic acid, it favours the elimination of uric acid, but does not lessen its quantity. He considers its action obscure and its prolonged use attended with great inconvenience, and that it is scarcely applicable to the treatment of uric gravel, and but little employed in chronic gout or in uratic deposits about joints.

Latham thinks salicylic acid often of service in gout, when unaccompanied by renal disease or albuminuria, and he believes it to act by seizing, in the system, either upon glycosin or its antecedent, and so removing an essential constituent of uric acid, and thus preventing its formation in the body. Lecorché, however, states that he has observed an enormous elevation (*hausse enorme*) of the amounts of urea and uric acid in the urine as the result of the administration of salicylate of sodium, that this elevation usually appears within the first twenty-four hours, but may be delayed for 48 or 72 hours, and that it lasts for three or four days, when a progressive diminution sets in. He also states that the amount of phosphoric acid increases, and diminishes in the same manner and at the same rate. It is difficult to reconcile Latham's view of the mode of action of salicylic acid with those observations of Lecorché.

I have little to add, from my own observations, to the testimony of these authorities; I should prefer myself to treat attacks of acute gout with colchicum, and until more fully convinced than I am at present of the value of the salicylate of soda in chronic gout, I should prefer the employment of a less depressing remedy. I believe it is chiefly of value in those cases in which the uric acid and the rheumatic diathesis are combined.

The benzoates, in the next place, require a brief examination.

Benzoates.—The benzoates of sodium and lithium have been largely employed in the treatment of uric acid deposits since their advocacy by Garrod. Latham has stated that benzoic acid acts by combining with glycosin and so preventing the formation of uric acid, and that it passes off in the urine as hippuric acid. The value of the benzoates has, however, been warmly contested, and I am myself, by no means, convinced of their efficacy. It has been stated by Brunton, that if benzoic acid is given it is found unchanged in the blood, that the change into hippuric acid occurs in the kidneys. Senator speaks of the "temporary popularity" of benzoates of soda and benzoic acid as "based on chemical theories, some of which were wholly erroneous," and adds that these "remedies have fallen into just oblivion." I can, however, testify that these benzoates are much used in France and in this country, as remedies for the uric acid formation, and I would ask you to consider whether they are of value or not. Very brief also must be my reference to guaiacum.

Guaiacum.—The high commendation given by Garrod to the use of guaiacum in chronic articular gout has found but few adherents. Ringer, in the ninth edition of his well-known work, does not even mention this drug; and it has received very slight consideration from other authorities. Yet Garrod has spoken of it as having afforded "striking benefit in numerous cases of chronic gout. I could relate," he says, "many hundreds of similar cases in which guaiacum has proved especially valuable; in some its action is almost magical. I have now for twenty years or more employed guaiacum very extensively in the treatment of chronic gout, I believe in some thousands of cases, and there is no remedy of which I can speak so confidently." There is certainly no one in Europe who has so good a right to speak as to the merits of any remedy for gout as Sir A. Garrod, and it is a little remarkable how little attention has been paid to this recommendation. I have certainly found the drug give great relief to the muscular pains of persons who were undoubtedly subjects of this diathesis. A more universally accepted remedy is iodide of potassium.

Iodide of Potassium.—I am satisfied we are but imperfectly acquainted with all the services that can be rendered in the manifestations of the uric acid diathesis by iodide of potassium. Its use in chronic arthritic affection is widespread, but it has its most important applications, I believe, in the less easily recognised degenerative changes dependent on this diathesis. I allude especially to the renal and vascular changes. I believe the iodide of potassium, if long

continued in fairly large doses, has a remarkable influence in retarding the progress of those degenerative vascular changes dependent on the gouty constitution, and which, as I have had occasion to observe, if left untreated, sometimes advance with great rapidity. I am not one of those who, whenever iodide of potassium is found to be of great service in relieving morbid conditions, at once sees a vision of constitutional syphilis. In cases of well-marked vascular and renal changes, with albuminuria, some of which bear signs of former arthritic affections, I have found iodide of potassium, in daily doses of fifteen to thirty grains, continued for a few weeks, and repeated from time to time, of remarkable value in improving the general condition, and I have, not unfrequently, seen the albumen disappear from the urine, or be reduced to a mere trace. How the iodide acts in these cases I am not prepared to say; it certainly promotes the action of certain of the excretory glands, and sometimes acts as a powerful diuretic. Its influence in promoting the elimination of deposits in the tissues is established by its power of removing lead and mercury from the system in cases of chronic intoxication by these metals. Latham has suggested that it prevents the conjugation of glycosin with other substances, and exerts also a solvent action on uric acid. It is necessary to "feel one's way" with regard to dose, some constitutions requiring a much larger one than others. I repeat that iodide of potassium is a valuable remedy, not only in the chronic and subacute arthritic affections of this diathesis, but also in the graver but less apparent arterial and renal changes. I should be glad to hear further evidence for or against this view.

The important group of alkaline remedies must next occupy our attention.

Alkalies.—The use of the various alkalies in the treatment of the uric acid diathesis has received almost universal sanction, and the only difference of opinion that exists, is as to which is the best alkaline salt to employ. They act: 1. By increasing the alkalinity of the blood, and so preventing the deposition in the tissues of acid urates. 2. By their solvent action they further the removal of such uric acid deposits as may have taken place. 3. By their diuretic action they promote elimination by the kidneys.

I have said their use has received "almost" universal sanction, for I believe Latham does not look with favour on the use of alkalies in gout. He considers there is danger of the oxidation of uric acid into oxalic acid, when the alkalinity of the blood is increased; and that so long as glycosin passes unchanged into the blood, oxalic acid will be formed by the action of alkalies.

The employment of the salts of lithium for these purposes has acquired a wide popularity; for my own part, I am disposed to think we are, nowadays, inclined to exaggerate the value of the lithium compounds as compared with those of potash and soda, although the equivalent of lithium is low, and the necessary dose is small, most of its preparations are far less soluble than those of potash and soda, and I fail to see any decided advantage in being able to give 4 grains of carbonate of lithia instead of 8 grains of bicarbonate of potash, supposing they have the same solvent effect on uric acid, and even Garrod does not claim so large a relative superiority as this for the lithia salts.

The diuretic effect of the bicarbonate of potash is, I think, more constant and reliable, especially when given with hot water containing a little milk, which quite conceals its taste. But when we are invited to select a mineral water for the treatment of these affections solely and especially because it contains, say, a tenth of a grain of chloride of lithium in a pint, in preference to another which contains 15 grains of bicarbonate of soda, we are running the risk of becoming the slaves of fashion.

Ebstein maintains that the chloride of lithium has no solvent action on uric acid, and that if a mineral water contains the carbonate in very minute quantities, it becomes wholly converted into chloride in the stomach, and is, therefore, so far as the lithium salt is concerned, quite without efficacy.

Sir William Roberts has also expressed some misgivings as to the superiority of the salts of lithium as solvents of uric acid deposits.

Lecorché, while he admits the powerful solvent effects of the lithium salts on uric acid, states that the results of his observations as to their diuretic and alkalinising properties were not so marked as those of Garrod, and that he had failed to render the urine alkaline by their means. Lecorché has much to say in favour of the use of bicarbonate of soda, which he prefers, as a solvent of acid urates, to either the salts of lithia or potash. He maintains that its prolonged use in large doses is much safer, and is better borne by patients.

"Taken internally, it combines with the uric acid which exists in the blood in the form of an acid binurate, and forms a neutral "nrate of soda," which is much more diffusible, and in this form it is elimi-

nated by the kidneys. He also points out that the bicarbonate of soda, as well as the other alkaline bicarbonates and sulphates, diminish the decomposition of nitrogenised substances in the body, and that these compounds are "*les médicaments par excellence de la diathèse goutteuse.*"

The superiority of the soda compounds in dyspeptic states, in gastric and intestinal catarrhs, and in disturbance of the functions of the liver so common in the subjects of this diathesis, is admitted by Garrod himself. I am convinced from my own observations that a combination of these alkaline salts acts often more efficaciously in removing an acid condition of the fluids than either of them alone. I am fully convinced of the value of the salts of lithium in the treatment of the uric acid formation, but I by no means see the necessity of depending exclusively upon them, as there is a tendency to do; indeed, I am convinced that in many instances of this diathesis a combination of soda and potash salts acts better, and in some even the soda salts alone. It will be interesting to hear what has been the experience of the eminent practitioners here present as to the relative value of these three alkalies.

It has been suggested that we have been to blame in allowing the compounds of lime and magnesia to fall into disuse in the treatment of the gouty constitution. Salts of magnesia are found in many of the mineral springs which enjoy a reputation in the treatment of this diathesis, and many gouty patients have testified to me of the great use they have found in frequently taking a dose of Gregory's powder. The startling effects produced by the Contrexéville springs, the chief constituents of which are sulphate and carbonate of lime, in some of the most serious forms of vesical and renal calculous affections, connected with the uric acid diathesis, should lead us to examine and consider what may be the solvent effects of lime salts generally in these affections.

Closely connected with the use of alkalies in this diathesis is the employment of mineral waters.

Mineral Waters.—The use and efficacy of the several classes of mineral waters which have been advocated for the treatment of the gouty diathesis may well engage a share of our attention. There is one thing which strikes one forcibly in approaching this subject, and it is that nearly every kind of mineral water that exists has been recommended in the treatment of the gouty constitution. The carbonate of soda waters of Vichy, the chloride of sodium springs of Homburg, the sulphate of soda waters of Carlsbad, the lime waters of Contrexéville and Bath, the sulphur waters of Harrogate and Aix, the indifferent thermal waters of Buxton and Gastein, and even the iron waters of St. Moritz: while there are a vast number of other springs, like those of Royat, which base their claim to be considered as remedies for the maladies of this diathesis, upon the salts of lithium they contain.

If each of these springs, so different in composition, is of value in the treatment of the uric acid formation, we should, naturally, look for certain conditions common to them all. What are these?

1. There is the quantity of water, more or less pure, taken into the body under regulated conditions daily. I have already attempted to estimate the value of this remedy.

2. There is, in many of these spas, the altered mode of life; the regular exercise in the open air, the modified diet, the early hours, the absence of business cares.

3. In many foreign spas there is the drier and hotter Continental climate, and

4. The stimulating effect to excretion and "tissue change" which the baths, douches, frictions and manipulations applied, at most of them, induce.

These are conditions, and not unimportant ones, common to most mineral water cures; and in the "indifferent thermal" springs which are chiefly applied to the relief of the chronic joint affections, deposits, deformities and loss of muscular power dependent on uratic inflammations the thermality and modes of application of these hot springs are probably the chief operative agents. I need only, for the purposes of this discussion, refer very briefly to the most typical examples of these resorts.

1. Vichy may be taken as the type of purely alkaline waters, its chief and all-important constituent being bicarbonate of soda (also Vals, Ems, Neuenahr, Apollinaris). We have already considered the importance of dilute alkaline solutions in the treatment of uric acid conditions. Whether the small amount of arsenic contained in the Vichy springs has any curative influence, I will leave with you to determine.

Durand Fardel, after more than forty years' experience at Vichy, satisfied himself that its springs "are extremely efficacious in gout

(regular acute gout), and absolutely curative in uric acid gravel." I gout, he says, it should only be employed in the intervals between the attacks. He appears to consider its good effects to be attributable to the influence of the soda in promoting a normal and regular nutritive metabolism. The water, when drunk and also when taken in the form of a bath, renders the urine alkaline or greatly diminishes its acidity, according to the quantity taken. Durand Fardel denies that it exercises any debilitating influence, as was asserted by Tronseau, and repeated by others, unless it is improperly and injudiciously applied.

The cases best suited to Vichy are gouty dyspeptics, fairly vigorous, with a tendency to pass acid urine, with deposits of urates and uric acid. It is also very efficacious in promoting the evacuation of renal (uric acid) calculi.

2. I will next refer to Carlsbad, as it is one of the special resorts of the gouty. Its waters, as you know, are hot, but of varying temperature, and contain considerable quantities of sulphate of soda, carbonate of soda, and chloride of sodium. It is a common error to regard these waters as powerful and very "lowering" purgative springs. They are no doubt aperient, but when properly administered only gently so, and it is often found necessary at Carlsbad to add a teaspoonful of the Carlsbad salts to the first glass of the water to ensure an action of the bowels. These springs have a remarkable action on the liver, and they have been especially utilised in the treatment of the gouty constitutions when this is associated with hepatic congestion, hæmorrhoids, and "abdominal plethora." Dr. Kraus asserts that he has found its waters "indicated in all cases of gout," and their use "attended with the most remarkable results." He specifies, however, those cases in which vascular and renal degenerations have set in, as well as the weak and debilitated, as requiring very careful supervision. For my own part I should not advise any regular mineral course in such cases; it is exceedingly undesirable to surcharge with water, even for a short time, the vascular system when it is the subject of degenerative changes. Dr. Kraus also states that recent gouty deposits "will generally disappear during or soon after the use of the Carlsbad waters, but that they have no influence over chronic indurations." I regard the Carlsbad course, when accompanied as it is with the employment of the hot mineral or mud baths, as exceedingly valuable in promoting elimination by all the chief excretory organs of the body, akin, kidneys, and intestines, and that in this way it stimulates a complete and normal nutritive metabolism and promotes the discharge of the waste products of imperfect metamorphosis.

3. In the next place we have the large and important group of springs in which the chlorides, and especially the chloride of sodium, are the chief ingredients. Leamington in this country, Homburg and Kissingen on the Continent, may be taken as examples of cold springs of this class; Nauheim and Wiesbaden of hot ones. There exists some difference of opinion amongst physicians as to the precise value in uric acid conditions of these common salt waters. The hot springs of this class are generally admitted to be valuable in chronic rheumatic conditions, but there is some hesitation in admitting their utility in gouty states. In the treatment of gouty articular deposits, Ebstein and others estimate highly the hot springs of Wiesbaden, applied as baths, and also drunk hot. Ebstein quotes the experiments of Pfeiffer to show that the water of Wiesbaden greatly increases the renal excretion and the quantity of urea excreted.

Homburg and Kissingen are especially applicable to chronic dyspepsias, gastric catarrhs in gouty persons, whose gout, however, does not assume a very serious aspect. The waters are diuretic and slightly aperient; they are considered to "promote tissue change," to promote elimination, to check the tendency to obesity, and to "ward off" the more serious gouty affections.

4. The most difficult waters to comprehend are, to my thinking, those earthy waters containing chiefly sulphate and carbonate of lime, like the cold springs of Contrexéville. Those very "hard" waters we should scarcely be disposed to consider, at first sight, as valuable uric acid solvents, yet this is precisely the property that is especially claimed for these springs. I have visited personally most of the important spas of Europe, and have remarked that the springs at nearly all of them are administered by the physicians who practise there in moderate and sometimes in quite small quantities. But it is quite otherwise at Contrexéville; here the first thing that struck me was the very large size of the glasses, each holding about twelve ounces, and the large number of glasses that many patients were ordered to drink. As many as eighteen glasses a day are occasionally ordered by physicians, and over-zealous patients will occasionally add half a dozen more on their own account!

One of the objects of passing this large quantity of fluid through the urinary passages is, no doubt, to mechanically dislodge and carry away

calculous deposits lodged in the kidneys; and it is indeed remarkable the success which frequently attends these efforts. But is it possible that this water exercises any solvent effect on the surface of these calculi, or on uratic deposits in the system? I was assured by the able physicians in practice there that in gouty persons large quantities of uric acid are secreted during, and sometimes for a long time after, the course. Is it a mere "lavage" or washing of the blood? They think not.

Another interesting point about the use of these sulphate of lime waters is the decidedly purging effect they often exercise at Centrexéville. This is at once apparent by the abundant and handy provision made for such accidents. Is this the result of the mere overflow and passage through the intestines of undigested water, as is maintained by practitioners at rival springs; or is it that this large quantity of water carried (when taken, as it is, in the morning fasting) immediately through the hepatic portal circulation stimulates a free secretion of an abundance of thin, very fluid bile, which acts as a quick purge when it reaches the intestine? or is it that both these events happen? Several patients who were trustworthy observers assured me that their alvine evacuations were distinctly "bilious," and not merely "watery."

I am not aware that our own Bath waters have ever been administered cold, for the same purpose and in the same quantity as the somewhat similarly composed springs of Centrexéville. I do not see why they should not be, and as the latter is anything but an attractive resort, I feel sure that all English patients would much prefer passing three weeks at Bath if they could be sure of obtaining the same amount of benefit there.

5. The local treatment of gouty deposits, of gouty deformities, and gouty neuralgias, which is often attended with such marked advantage at such thermal springs as Buxton, Gastein, Wilbad, Bath, and Aix, owes much of its success, no doubt, to the thermality of those springs, and especially to the frictions, douches, and manipulations there employed. And in the case of the indifferent springs, the ingestion of a certain amount of warm water daily acts, no doubt, as a useful solvent and eliminant.

6. The sulphur springs, as those of Aix and Harrogate, find their appropriate application in those numerous instances of the gouty constitution which are accompanied with cutaneous eruptions, as psoriasis and eczema. Uriage, with thermal springs rich both in sulphur and chloride of sodium, and with a hot and dry atmosphere, I have known prove very valuable in such cases. Harrogate, which also has springs of similar composition and a more bracing climate, finds one of its numerous applications in these cases.

The feebly alkaline lithiated waters of Royat, those of Baden-Baden, the arsenical and alkaline springs of La Bourboule, the weaker carbonate of soda waters of Ems and Neuenahr; these and numerous other springs may be doubtless advantageously employed in the treatment of the uric acid diathesis, in some of its various manifestations.

With respect to the use of drugs simply for their purgative effects, I should like to say that purgatives are useful only in so far as they are the means of ensuring the discharge of excrementitious matters from the system; it would be a grave mistake in the treatment of these morbid states to allow the alvine and hepatic excretions to remain locked up in the bowels, or, in cases of abdominal plethora and portal engorgement, not to take steps to relieve that congestion; but it is equally an error to drain away the serum of the blood by drastic purgatives after we know that the bowels have been completely emptied of excrementitious matters.

One of the most complete and satisfactory purgatives in these cases is a pill at night consisting of half a grain of extract of colchicum and 2 grains of watery extract of aloes, followed in the morning by a large tea-spoonful of Carlsbad salts in a tumblerful of hot water.

I am disposed to think if we employ colchicum that we rarely require to use mercurials in the treatment of these affections.

Diuretics and diaphoretics, also, are useful as stimulants of excretion. As a diaphoretic a very hot bath with bran is a most useful agent.

The use of opium should be as much as possible avoided, because of its influence in checking excretions generally.

In the foregoing remarks I have endeavoured to bring before you most imperfectly, I am well aware, some of the chief practical considerations in connection with the treatment of the uric acid diathesis. The subject is itself so wide an one that it has been necessary to avoid, as much as possible, entering upon disputed points in pathology; it has, however, been needful to allude to certain theoretical views, in order to make our therapeutic discussions distinctly intelligible.

I have not attempted to treat exhaustively any of the points upon which I have thought it necessary to touch, my duty being to stimulate discussion by opening and not exhausting the several questions involved in this subject.

I may have (in the opinion of many here present) overlooked or inadequately represented remedial measures which they have found of great value. I can only say we are here to learn of them, and that personally I shall esteem myself indeed fortunate if these few imperfect suggestions, drawn from my own small field of observation, should be the means of opening the rich storehouses of their varied experience and ripe wisdom for the benefit of those who suffer and the enlightenment of those who heal.

Professor LATHAM wished at the outset to draw a sharp line of distinction between gout and the uric acid diathesis. The latter could exist and show itself in various ways without developing gout, as in gravel, calculus, etc. For the development of gout there must be first the uric acid diathesis, and then another diathesis superimposed, so to speak, upon it for the uric acid to act upon. He would leave gout out of the question, and confine his remarks to the treatment of the uric acid diathesis alone. Dr. Burney Yeo had stated that an appeal to the therapeutic effects of remedies was, perhaps, the best mode of settling the theory as to the formation of uric acid, and, if time permitted, he thought he could show that the action and effects of all the remedies to which Dr. Burney Yeo had referred in his most exhaustive and interesting paper would lend support to the view of uric acid formation which he (the speaker) wished to bring forward in order to arrive at proper data for the treatment of the uric acid diathesis, it must in each individual case be determined whether the excessive formation of the acid was due (1) to imperfect metabolism in the muscular tissue, or (2) to imperfect metabolism in the liver, and (3) not the least important, a clear conception must be formed as to the constitution and formation of the acid itself. If we were guided by the "teaching of experience," we found the saying "to live on sixpence a day and earn it" summarised, though in an exaggerated form, the pith of that teaching. The following dogma came very near the truth. There must be moderation in all things. Moderate exercise, moderation in diet, and moderation in nervous expenditure, which last included mental work, worry, grief, or anxiety. These were the first rules to be laid down, and if they could be enforced, then we could turn to certain drugs which would materially help us, if necessary, to lessen the excessive formation of the acid, or to promote its elimination. But he would first ask, would scientific investigation help us to understand why this moderation in all things was so essential? He thought it would; and this led him to say a very few words as to the mode of formation of uric acid in the system. It must be borne in mind that, in the tissues and glandular organs, assimilation and construction were going on simultaneously with disintegration and destruction. His view of uric acid formation was that it resulted not from destructive but from constructive metabolism. Let a man be given a dose of benzoic acid, and on examining his urine some little time afterwards, it will be found to contain hippuric acid; that is to say, the benzoic acid had not been destroyed, but had combined in its passage through the system with glycochin—a normal constituent of the bile, and which, in the ordinary course of things, gave rise to urea—forming thus a more complex substance. Now, let uric acid be analysed, and it may be split up into urea and a number of other substances, and by one mode of disintegration it was split up into glycochin, carbonic acid, and ammonia, the two last being derived from urea. Let the process be reversed: let glycochin and benzoic acid be put into a tube and heated; hippuric acid was formed. Let glycochin and urea be put into a tube and heated; hydantoic acid was first formed, and then uric acid. [Crystals of this substance which Professor Latham had produced in this way were shown under the microscope.] He argued from these data that it was either excessive formation of glycochin in the muscular tissue, due to imperfect metabolism, from insufficient action of that tissue, or it was the inability of the liver to transform all the glycochin that was brought to it either from the tissues or introduced as food into the alimentary canal, that led to the formation of uric acid. For the arguments on these points he must refer them to his lectures in the BRITISH MEDICAL JOURNAL for April, 1886, and since published in a separate form. The treatment of the uric acid diathesis resolved itself into this: to diminish in all ways the amount of glycochin brought to the liver, and to promote the function of the liver, so that the normal assimilation of this substance should not be interfered with. By moderate muscular exercise the glycochin in the tissues underwent its proper metabolism. If horses were kept in the stable, their urine contained hippuric acid; if at work, benzoic acid

only was to be found. In some way or other the glycozin was used up, and so theory confirmed practice in advising moderate exercise. If the patient was unable to move, shampooing or massage might be substituted, and perhaps also the occasional use of warm baths might be useful. If the function of the liver was impaired, then, just as in diabetes as little starchy food as possible should be given, so in the uric acid diathesis as little nitrogenous food as possible should be given, but sufficient for the wants of the system should be given, and especially food rich in glycozin, such as jellies, soups made from bones, etc., should be avoided, and all articles of food or drink which, given in excess, might lead to hepatic congestion, should also be avoided. In addition, such remedies as would promote the digestion and assimilation of the food, such as the vegetable bitters, gentian, etc., should be administered; and it should be borne in mind that the function of the liver might be imperfectly performed, either from exhaustion of the liver-cells by overwork or from exhaustion of the nervous system. Nervous exhaustion, shock, worry, or anxiety would put a stop to the action of the liver, and interfere with the proper metabolism of the substances conveyed to it, and thus moderation in nervous expenditure became a factor in the treatment of the diathesis in question. If, after carrying out these suggestions, the formation of uric acid was still in excess, then its formation might be lessened by an occasional dose of calomel, which, causing bilious evacuations, carried off the glycozin in the bile. Gregory's powder and the mineral waters, to which Dr. Yeo had referred, acted beneficially for the same reason. Further, by the administration of benzoates or salicylates, both of which combined with glycozin and were excreted in the urine, the formation of uric acid was lessened, and, if formed still in excess, its solution and elimination would be promoted by the administration of the alkalies, or their citrates, or carbonates, or iodides. Taking this view of the formation of uric acid, the questions as to the use of alcohol, sugar, or fatty food must be answered according to the special conditions of each individual case.—Dr. MYRTLE (Harrogate) said there could be no doubt that there was a uric acid diathesis, and without attempting to offer any explanation as to its cause, as a practical man he would take it for granted that certain individuals formed this acid in great excess, or were incapable of eliminating the normal quantity, which led to its retention in the system and the development of that class of disease spoken of by Dr. Yeo. He agreed with Dr. Yeo that gout was not merely due to uric acid, but something independent of it. He advocated the use of glycerine instead of sugar in those showing a disposition to acidity. He disagreed with Dr. Yeo, in condemning light clarets, and held that those suffering from uric acid and gout should know how to live without requiring the physician to tell them what they were to eat, drink, or avoid. He pointed out the advantages of a dry climate and abundance of sunshine, condemned the use of colchicum in acute gout, or in fact any active treatment during its early stages. As to the amount of Contrexéville water drunk—ten or twelve ounces daily—that should be able to wash out anything it met with. He referred to the extraordinary fact that natural mineral springs of the most opposite character as to constituents and everything else, were found in similar cases to produce the same good results, and called attention to the fact that if patients went to any of these spas with latent gout, they very soon had acute gout developed, showing that mineral waters were not to be trifled with, and that medical men should be careful how they acted in giving advice to those resorting to such spas. As to Dr. Yeo's statement that women were seldom the subjects of gout, he entirely differed, as in his experience women without any gouty history often were the victims of severe and intractable attacks, brought on by grief, anxiety, and overwhelming sorrow. Without doubt these were cases of a neurotic order, as they most frequently appeared in constitutions known as highly sensitive, and in subjects who led most regular, abstemious, and active lives.—Dr. SPENDER (Bath) urged that in the treatment of the uric acid diathesis there should be a few distinct landmarks for our guidance, such as these: the quantity of excretable uric acid and urea ought to be fully maintained; the excretion should be hastened; and the volume of urine increased as far as possible. Touching upon remedies which had not been alluded to by previous speakers, he eulogised phosphate of ammonia, which had been introduced by the late Dr. Basham in 1872 as a remedy for saccharine diabetes; and he (Dr. Spender) had found it equally valuable for the glycosuric storms which alternated with gout. The chloride of ammonium had a wide range of utility, and must be taken in doses of half a drachm three or four times a day, as Dr. Ringer advised, if we were to treat successfully such neural troubles as gouty lumbago, and sciatica. The value of lithium (though perhaps over-rated) was undoubtedly great, because it increased the

volume of urine, lessened its acidity, and favoured the elimination of the products, which it dissolved in the blood. Lime, as administered in the form of the Bath thermal waters, had a good effect, both in gout and rheumatism, by increasing the alkalinity of the blood, though having no alkalisng effect on the urine. With regard to diet, Dr. Spender insisted on the occasional necessity of entire abstinence from butchers' meat for a few weeks at a time. The action of the skin was best solicited and maintained by daily sponging with very hot water, preferably in the morning. The great therapeutic and hygienic points seemed to be to keep up a regular metabolic action of the system, by supporting the power of the heart and releasing the nervous system from all unfair pressure. In this way we might sometimes abolish the so-called uric acid diathesis by not thinking about it at all, but by thoroughly establishing and strengthening the general health.—Dr. MILNER FOTHERGILL said that, in adopting the term "uric acid diathesis," Dr. Yeo had used a judicious expression. "Gout" and "chronic Bright's disease," the children, often the twin progeny, of that great vaso-renal change which was the outcome of the uric acid formation, were terms rapidly losing their original meaning. The uric acid formation was due to inadequacy in the liver, no matter how brought about, in consequence of which its formation of urea was imperfect, and it reverted to the earlier primitive uric acid formation of the birds and reptiles. This came about in two totally different ways. We were all familiar with the typical gout affecting the hands and feet in robust persons, and due to indulgence in albuminoid food beyond the needs of the system. This was known as "rich man's gout." But there was also "poor man's gout" occurring in spare persons, never guilty of dietetic excess. In such persons the liver was either congenitally feeble, or, as Drs. Budd and Murchison termed it, "insufficient," or was impaired by some disease. In the latter instance, the liver reverted to the early uric acid formation under perfectly ordinary, or even slight, demands, upon it. In dealing with lithiasis, or the uric acid formation, there were several lines of attack, which might be adopted singly; but usually it was well to employ a combination of these measures. The first was to reduce the albuminoid elements of the food to the requirements of the body. These included eggs, the lean of the larger animals, and, to a less degree, cheese and legumes. By this dietetic regimen the labour of the liver in the matter of the metabolism of albuminoids was greatly eased. In other words this was giving the organ physiological rest—that is, such rest as was possible. The dietary should consist of fish, farinaceous matters, fruits, vegetables, and fat in all forms—animal fat, butter, and oil. By so doing the liver was rested as regards albumen metamorphosis. This line of attack could be adopted in all cases with advantage, bearing in mind that it was never well to lower the subjects of the uric acid formation too far. The next line of treatment could also be adopted in all cases. It consisted of an attempt to raise the incompetent liver to a higher platform of functional activity by resort to hepatic stimulants. For prolonged use a compound of strychnine and ipecacuanha as the two bases, with some taraxacum or euonymin, iridin, etc., to which might be added some podophyllin, or other laxative also having an action upon the liver, when some such agent was indicated, which was very commonly. In addition to this medication, some sulphate or phosphate of soda might be taken with advantage. At intervals a mercurial pill at bedtime, with a seidlitz powder next morning, would be found beneficial. These two lines of attack gave good results in all cases. Then followed the resort to the uric acid solvents—lithia and potash. These rendered the insoluble urates of soda and ammonia soluble by taking the place of the latter bases. As urates of lithia or of potash, uric acid was comparatively soluble, and so readily escaped by the urinary channels. The chronic interstitial nephritis (otherwise Bright's disease) found so constantly in connection with lithiasis (the granular, contracted, or gouty kidney) was set up by the irritant presence of excess of uric acid passing through kidneys constructed to cast out a fluid urine. By the conversion of the original urates into the comparatively highly soluble urates of potash and lithia such injury to the kidney was minimised. These uric acid solvents were best borne by stout, florid people of the Norseman type, but were very depressant with spare persons of the Arab or neurotic type, with comparatively large heads and thin flanks. Beyond these, there was a fourth line of attack, namely, plenty of oxygen. Hence Jones held lithiasis to be a disease of sub-oxidation. Certainly uric acid was less highly oxidised than urea. A great deal of the uric acid formation of town life was due to the lack of fresh air and exercise. Of old, after a substantial breakfast, the eater turned out for work or exercise in the open air. His modern descendant, after a substantial meat breakfast, commonly went to his office or counting-house, where he stayed inactive, at a

temperature of 70° F., with a rebreathed air." Could we feel surprised if his liver, under these circumstances, reverted to the uric acid formation of the lethargic Ichthyosaurian in his tropical swamp? In such cases of lithiasis or uric acid formation, horseback exercise in the country was the cure *par excellence*. Frequently a stay at some hydropathic establishment was attended by the best results. There remained one more line of attack, namely, the resort to colchicum. No one who had had personal experience of the pains of gout had any doubt about the analgesic effects of colchicum. The ease it gave was simply magical. At the same time, no sufferer from gout in the possession of his senses would resort rashly or recklessly to this potent pain-killer. Infinitely worse was the resort to colchicum to ward off threatening attacks of gout. When the liver manifested a tendency to revert to the uric acid formation, no matter how brought about or in what form or morbid manifestation, the management of the case involved knowledge, thought, discrimination, and the capacity to adapt concrete measures to the wants and exigencies of the individual. —Dr. BURNEY YEO, in reply, congratulated the Association on having elicited from those who had taken part in the discussion such valuable remarks as they had heard on this practical subject. He thought that the view taken by Dr. Latham that the changes were constructive rather than destructive was negated by the fact that so many sufferers from this diathesis showed no signs of defective nutrition, until degenerative arterial changes had been established. He had found colchicum, in small and careful doses, exceedingly valuable in the treatment of those neurotic affections connected with this diathesis. He protested against the use of opium or morphine in acute gout. He considered it was not good practice or good theory to give a drug which arrested secretion in a malady which was one of defective excretion. He thought it most interesting to learn that uric acid had been detected in the secretion of the skin.

REMARKS ON A CASE OF ACUTE INTESTINAL OBSTRUCTION DUE TO THE PRESENCE OF A MECKEL'S DIVERTICULUM, SUCCESSFULLY TREATED BY LAPAROTOMY.

By A. F. MCGILL, F.R.C.S.,

Professor of Surgery in the Yorkshire College, and Surgeon to the Leeds Infirmary.

ON March 5th, 1887, I saw, in consultation with Dr. Glaister, of Rothwell, a collier, aged 30, who had been suffering from complete intestinal obstruction for nine days. We learnt that while at work on February 25th he was suddenly seized with severe abdominal pain; he walked home, and on taking a glass of water immediately vomited. From that time he passed neither fecal matter nor flatus from the bowel, and vomited everything that he took by the mouth. The symptoms were not of the severest type, as he had long intervals in which he was free from pain and sickness; vomiting was, however, induced by every attempt to take food. His abdomen gradually increased in size, and his general condition much deteriorated. He was treated in the usual manner, chiefly by opium and large injections. When I saw him the abdomen was immensely distended, and numerous coils of intestines were distinctly visible. He was in a feeble and almost moribund condition, extremely wasted, and with a quick thready pulse. The case was apparently one of intestinal obstruction, situated in the small intestine, and due to some mechanical cause. We advised his removal to the Leeds Infirmary, where I operated the same evening. The operation is described as follows in the Infirmary notes:

"The patient being placed under chloroform, the rectum was first examined, with a negative result. The skin of the abdomen having been thoroughly cleansed, an incision was made in the median line, extending from a point one inch above the symphysis pubis upwards for three inches. The peritoneal cavity was opened, and a small amount of clear serum escaped. Through the opening the right hand of the operator was passed into the abdomen, and its cavity was thoroughly explored. As nothing to account for the obstruction was found, the incision was enlarged upwards for an inch or more. The intestines were then allowed to escape; when about three feet had escaped from the peritoneal cavity, the junction of the distended and empty intestine was seen. At this point a Meckel's diverticulum, much dilated and about six inches in length, was seen, passing downwards and forwards, to be attached to the fundus of the bladder. A loop of collapsed intestine passed under the diverticulum, the obstruction being caused by the twisting of the bowel at the point where the diverticulum was attached. The loop slipped from under the diverti-

culum with slight traction, and the distended portion could be seen emptying itself into the part previously empty. The intestines with much difficulty were returned into the abdominal cavity, and the wound closed with silk sutures.

The patient passed a small amount of flatus during the night, and was somewhat relieved the next morning. During the day he became worse, and the vomiting returned. As the passage of flatus had entirely ceased, and the abdomen was very large and distended, a saline purgative (Rochelle salt) was given. A large quantity of flatus was passed, and the patient's condition much improved. He went on perfectly well till the tenth day, when a small amount of fluid fecal material escaped from the upper corner of the wound. This continued for a fortnight, when the discharge ceased, the wound rapidly healed, and he left the hospital perfectly well.

Several points in this case call for remark.

1. The attachment of the diverticulum to the fundus of the bladder has not, so far as I know, been hitherto described.

2. The obstruction was due to the twisting of the bowel at the point of attachment of the diverticulum, and not to compression of the gut under this band. In this case the diverticulum was a cause of volvulus, which in its turn was the cause of the obstruction.

3. The treatment by laparotomy does not now require to be defended, but the mode of operating is not as yet quite determined. According to Mr. Treves the method adopted in this case should be condemned. In his own words, "the practice of allowing the bowels to escape is absolutely bad." It is no doubt, when practicable, preferable to operate without permitting the bowels to escape, the shock of the operation being thus much diminished.

In a case under the care of my colleague, Dr. Churton, I operated in this manner. A middle-aged woman had suffered from acute symptoms of intestinal obstruction for five days. Having opened the abdomen, I was fortunate enough to immediately find a firm fibrous band, which was the cause of the obstruction. This I divided with scissors, and straightway closed the abdomen. The patient had not a bad symptom, and left the hospital in a fortnight well.

But in many cases it is impossible thus easily to discover the cause of the obstruction, and then the surgeon should not hesitate to allow the intestines to leave the abdominal cavity. The danger of the operation is no doubt increased, but we are almost sure not to leave a remediable cause undiscovered. This happened to me about two years ago; I failed during operation to find a Meckel's diverticulum, which had caused obstruction for five days, and the patient, a boy of 15, consequently died. We may occasionally find the cause of obstruction by intra-abdominal examination, but in the majority of cases this method is ineffectual, and the intestines must be allowed to escape.

A second point connected with the operative treatment of this case is the leaving the diverticulum untouched. It might appear at first sight advisable to divide it and sew up the divided end. This would have taken some considerable time, and the prolonged operation might have caused a fatal result. It appears to me to be preferable to leave the diverticulum in position, even though this exposes the patient to the risk of another attack of obstruction.

4. No opium was given, but a saline purge was administered with apparent advantage. The administration of opium as a routine measure after abdominal operations is, in my opinion, much to be deprecated. It seldom does good to the patient, and it lulls the surgeon into a false feeling of security. Unless called for by severe pain, opiates should not be given. In this case the administration of a purgative, which immediately caused the expulsion of a large amount of flatus, did much good, and apparently turned the scale in favour of recovery.

5. This case well exemplifies the great difficulty with which the abdomen is closed in operations for conditions associated with excessive intestinal distension. Though every care was taken to prevent such an accident, it is evident that a small portion of the intestinal wall was caught in the upper angle of the wound. The fistula thus formed soon closed, and, beyond delay in healing, little harm was done. In another case we might not have been so fortunate. It has been suggested that in some of these cases it may be advisable to evacuate a portion of the intestinal contents through a small incision in the intestinal wall. The increased severity of the operation and the risk of septic infection of the peritoneum seem to contra-indicate this procedure. It should only be adopted when all other means of closing the abdomen have failed.

SUPERANNUATION.—Mr. Alexander W. McLeod, late medical officer for No. 1 district of the Fulham Union has obtained a superannuation allowance of £35 per annum.

TREATMENT OF THE PAROXYSM OF MIGRAINE BY ACIDS.

By A. HAIG, M.B. Oxon., M.R.C.P.,

Physician to the Royal Hospital for Women and Children, Waterloo Road;
Assistant Physician to the Metropolitan Hospital.

In a paper read at the Royal Medical and Chirurgical Society in May, 1887, and published in the *Transactions* (vol. lxx), I showed that a certain form of headache was closely connected in time with a large excretion of uric acid; and in a subsequent paper in the *Journal of Physiology*, Vol. viii, Nos. 3 and 4, I showed that within certain limits it was possible to diminish almost at pleasure the excretion of uric acid by giving acids, or to increase it at pleasure by giving alkalies; and further, in a recent paper for the *St. Bartholomew's Hospital Reports*, I have given notes of some cases of the above headache which had come under my notice, calling it "the uric acid headache," with the object of drawing attention to the extremely important part which uric acid plays, as I believe, in its causation; but I may say at once that I have very little doubt, and those who read my cases in the *Reports* will, I think, agree with me that this headache is really a member of the class commonly known as "migraine or sick headache."

My object here is not to discuss the many interesting points in the etiology and pathology of this headache and its related diseases, but to point out as quickly as possible a mode of treatment of the paroxysms, which is the direct outcome of my uric acid investigations, especially those in the *Journal of Physiology*, and which has met with such complete success in my own hands that I am anxious that it should be tried by others on a larger scale.

It will be seen that I have shown in the above papers that, during this headache, uric acid is excreted in excess in the urine, and probably also exists in excess in the blood, and further that it is quite possible to stop this excess in the urine, and also I believe in the blood, by means of acids, and it is to this treatment of the headache paroxysm by acids that I now wish to draw attention.

The acid used is not of much consequence; citric or nitro-hydrochloric are equally good; the only point is that the dose must be sufficiently large, especially if, as is often the case, the headache is going on during the "alkaline tide" of digestion. A dose I commonly find successful is forty to sixty minims of dilute nitro-hydrochloric acid in a tumbler of water, one half to be taken at once, and the rest in thirty or forty minutes; the headache is generally much better within an hour, and quite gone within an hour and a half from the first dose. If the urine is alkaline, or very slightly acid before this treatment is begun, or if the patient has previously been taking alkalies, a third dose of twenty minims of the acid may be necessary; but I rarely have to go beyond one drachm of nitro-hydrochloric acid, and I have given some notes in the *Journal of Physiology* of the effects of such a dose on the uric acid excretion. An equivalent dose of citric acid, taken as strong lemonade, will do as well, or, so far as I know, of any acid that may be preferred, provided it raises the acidity of the urine. It is also possible to reverse the process, and, by giving alkalies, to bring the headache on or increase it.

The above refers entirely to the treatment of the paroxysm; a diet without butcher's meat, beer, wine, etc., is, as I have said in previous papers (*Practitioner*, August, 1884, and March, 1886) the best preventive treatment.

If acids, properly and carefully given as above, completely fail to relieve the headache is not migraine, or at least not migraine due to uric acid; and if the urine be tested in the way I have described, probably no uric acid rise will be found corresponding to the headache.

A large number of drugs reported to be useful in migraine really act as acids, increasing the acidity of the urine and diminishing the excretion of uric acid. Some others probably act like the bromides by quieting the nerve centres, and preventing their reacting to the irritant in the blood; but as compared with bromides, the treatment by acids is more satisfactory in that it removes the irritant from the blood, and leaves the nerve centres intact for other processes.

REQUESTS AND DONATIONS.—Mr. Nathaniel Montefiore has given £1,500 towards the rebuilding of University College Hospital, namely, £1,000 for Mrs. Nathaniel Montefiore, and £500 for Mr. Claude G. Montefiore, Mrs. Alice Lucas, and Mrs. Charles McIver.—The Sussex County Hospital, Brighton, has received £500 under the will of Mrs. Stanford; and 50 guineas from Messrs. Findlater, Mackie, and Co.

SUCCESSFUL CASE OF EXTIRPATION OF THE KIDNEY FOR HYDRONEPHROSIS.

By WALTER FELL, M.B. Oxon., Wellington, New Zealand.

THE patient, Mrs. T., was aged 31. She had had six children, of whom three were living. The catamenia were regular, but she had always been somewhat delicate. I first saw her in June, 1886, when she complained of periodic attacks of intense pain in the right lumbar and hypochondriac regions. On examination a hard, freely movable body, about the size and shape of a kidney, was found in the right flank just below the last rib; it could be pushed forward nearly to the umbilicus. The diagnosis of movable kidney was made, and she was recommended a pad and bandage to keep it in place.

At my second visit, three months afterwards, on September 1st, she told me she had suffered intolerable pain, and that the attacks were becoming much more frequent. She had just gone through two days of intense suffering, with incessant retching and vomiting; the least exertion seemed to bring on an attack. She was thinner, and looked much worn. There was no rise of temperature; the urine was clear and pale, with no albumen. On examining the abdomen, the same movable tumour could be felt as before, but now it was much larger, and came forward as far as the umbilicus, while the anterior part fluctuated. The uterus was pushed forward, and its length was normal, and was unconnected with the tumour, which also appeared to be quite separate from the liver. An operation was recommended, to which she at once consented.

On the next day but one, on seeing the patient again, I found her laughing and free from pain, and on examining the abdomen the tumour had disappeared; the kidney could still be felt a little in front of its usual position, but the fluctuating swelling reaching to the umbilicus was completely gone, and this she told me was always the case: "When the pain was bad the lump was there; when the lump went away she was as well as ever again." The obvious explanation appeared to be that the ureter got blocked for some reason or other, the pelvis of the kidney enormously dilated, pain and vomiting followed, only to be relieved by the obstruction yielding and the tumour emptying itself. I could not get any distinct history of excessive flow of urine at these times, but she thought a good deal was always passed then. There was never any blood in the urine. It seemed to me that, during the paroxysms of pain, she ran considerable risk of rupture of the thinned and dilated pelvis of the kidney; so on September 5th, assisted by Dr. Collins and Dr. Rawson, I proceeded to operate. The spray and full antiseptic precautions were used.

An incision about four inches long was made in the position for right lumbar colotomy, but carried a little more forward than usual. On getting through the abdominal walls, the first thing that came into view was the edge of the liver, and immediately below this the kidney. On passing the hand cautiously forwards towards the umbilicus, a large bag containing fluid was made out; it was evidently a part of the kidney, and pressure on it reduced its bulk somewhat. The cyst being thus partially emptied, a finger could, by invaginating it, get into the centre of the kidney; so that, with the thumb outside, it was possible to make out that the substance of the kidney proper was much reduced. The kidney was, in fact, being slowly converted into a large cyst. After a brief consultation it was decided that the kidney was useless and a source of danger, and had better be removed. Accordingly, as it was bound down tightly by its lower surface, I cut into and stripped off the capsule, which was adherent in parts, and shelled out the kidney; and then, getting my fingers beyond the cystic part, with some difficulty tearing away a lot of loose areolar tissue, I was able to get hold of the large mass of vessels—ureter, connective tissue, and mesentery—which constituted the pedicle, and transfix it and tie it in three portions. After removing the tumour, smart bleeding took place from some unsecured vessel in the upper part of the wound and deep inside. Only a few seconds elapsed before the artery was secured, but the loss of blood was sufficient to cause an alarming condition of collapse. A stout double silk ligature was passed round a mass nearly as large as three fingers, from the centre of which the bleeding came. The whole was tied securely, and the ends of the ligature cut off short. The wound was then sponged and rapidly closed with five deep and three superficial sutures, and dry iodoform gauze dressings were applied. The whole operation, from the time of commencing the administration of the æsthetic, occupied an hour and a half.

The subsequent history is soon told. Recovery was rapid and uninterrupted. The temperature once rose to 100°, but never exceeded this point. On the twenty-second day the patient was sitting up in

a chair, looking stenter and better than she did before the operation. She is now, after an interval of eight months, going about in good health, the one kidney apparently sufficing to do all the work. On examining the kidney that was removed, the ureter appeared, at the spot where it left the pelvis of the kidney, to be intensely inflamed, the mucous membrane being highly congested. Whether this was the cause or the result of the obstruction I am unable to say. The case appears to me to be of interest as being one where a functionally active kidney, capable of and actually engaged in doing a large share of the excretory work, was suddenly removed without in any way apparently affecting the general health, most of the cases I have seen reported having been of the removal of a kidney which, from long suppuration or other cause, had ceased to be anything but a mere *nominis umbra*.

CLINICAL MEMORANDA.

A CASE OF ACUTE TRAUMATIC TETANUS, SUCCESSFULLY TREATED BY LARGE DOSES OF SALICIN AND BROMIDE OF POTASSIUM.

NOTES of the following case have been sent me by my old pupil, Mr. E. Thurlow Prior, of Leddon, Norfolk. I quite agree with him in thinking that the case is one of interest, and that the treatment merits a further trial.

A.M., aged 26, a young man of rather intemperate habits, cut his arm severely on June 30th, 1887, by thrusting his hand through a window. The wound appeared to be making good progress until July 15th, when he complained of pain in the epigastrium. In the course of the day his face began to stiffen, and there were twitches of the muscles of the face and of the back and legs. These grew worse until July 19th, when Mr. Prior was first called to see the patient. At this time the risus sardonicus was well marked, and spasm was elicited by speaking sharply or loudly to him. He was placed in a warm room, which was fitted with carpets and curtains to deaden sound, and full doses of chloral hydrate and bromide of potassium were administered. But he grew worse; the breathing became laboured, the pulse very rapid. On July 22nd he appeared to be actually dying; the respirations and pulse could not be counted, and spasms recurred with extreme rapidity.

At 1 P.M. a draught was given of salicin gr. xx, potassium bromide gr. xx, every two hours. At 5 P.M. the spasms occurred only at intervals of ten minutes, the pulse was stronger and numbered 120, and severe perspirations had set in. On the following morning, July 23rd, the intervals between the spasms had increased to twenty minutes; he breathed easily, and the pulse was still stronger and less rapid. The draught was now ordered to be taken every four hours. The improvement continued during the next two or three days, but several days elapsed before he was free from pain in the epigastrium, and for nearly a fortnight it was necessary to draw off his urine. At the end of six weeks he was convalescent. The only trouble which remains is the stiffness of the muscles of the upper extremity, due to the direct effect of the injury.

The rapidity with which improvement followed the administration of salicin and bromide of potassium leaves scarcely a doubt in the mind that the change in the condition of the patient must be attributed to the action of the medicines. It is, of course, difficult to assign to each drug its actual share in the cure. The improvement was marked by the occurrence of a profuse sweat, and this had probably something (perhaps much) to do with the recovery of the patient. The influence of the salicin was, perhaps, exerted on the vasomotor centre, and its action as a germicide must not be left out of the account. It is to be observed that the case was one of acute tetanus, but not of the most acute variety, for the patient was not in imminent peril until the eighth day of the disease.

HENRY T. BUTLIN.

Harley Street, W.

A CASE OF UNTREATED PSORIASIS OF FOURTEEN YEARS' DURATION, ACCOMPANIED BY CORNS ON THE PALMS OF BOTH HANDS.

In Mr. Hutchinson's paper upon Arsenic Cancer, reported in the JOURNAL for December 10th, several cases of psoriasis are described, in which, after a prolonged course of arsenic, corns appeared on the palms of the hands. In connection with the report of these cases the following instance of psoriasis entirely untreated, but yet accompanied by corns, is of interest.

W. W., aged 52, a butcher by occupation, came under treatment a few weeks ago for vomiting and headache. He is at present the sub-

ject of unmistakable psoriasis, and he has had his present skin affection for about fourteen years. The patches of psoriasis, however, have never troubled him enough to make him take any steps towards its cure, but he is a good deal concerned about a crop of small corns which have lately (he says) made their appearance on both palms. They are scattered indiscriminately over the palms and flexor surfaces of fingers and thumbs. Near the tips of some of the fingers they are sufficiently numerous to thicken the skin and make the fingers feel numb. In many places he has picked the skin, and produced a roughened pitted surface. There are no signs of ulceration on either hand. There is no reddened skin, and there are no cracks or fissures, or warts. The skin on the soles of the feet is natural, except for some large corns, evidently of pressure origin. The skin over the rest of the body is, excepting for psoriasis patches, quite healthy. There is no history of syphilis, and no evidence of it, and no enlarged or hardened glands are anywhere to be felt.

R. J. RYLE, M.B. Oxon.

Barnet, Herts.

RELAPSING COMA DUE TO TUBERCULOSIS.

J. J., a groom, aged 20, was admitted into the Queen's Hospital on December 3rd in a state of coma. The family history was said to be good, there being no account of any hereditary disease. The patient had been steady, and had had no illness except slight bronchitis three months and erysipelas of the head and face six weeks previous to his present illness.

On November 27th, he first complained of great pain in the head, but he had no vomiting. The pain gradually became worse, until in a few days he became unconscious. On admission, the patient was found to be emaciated, the abdomen was retracted, he could not be roused, and he passed his urine and feces involuntarily. The pulse was 72 per minute, and regular; the temperature was subnormal; the plantar reflex and knee-jerk were absent on both sides; the urine contained a cloud of albumen; the patient's head and eyes were turned to the right, and he could not move his left arm; the conjunctival reflex was lost on the left side; the margin of the optic discs was clear, except where the vessels emerged, in which situations it was indistinct; the veins were full and tortuous.

On December 7th, the patient was conscious, could reply to questions, and talked with his friends. The knee-jerk was present on both sides; the grasp of the left hand was much weaker than that of the right. On December 8th, the patient was again comatose; the next day, however, he could be roused, and answered questions sensibly. Towards the evening of December 9th, he again became comatose, the knee-jerk being again lost. He remained thus till December 16th, when he died. He showed a great deal while comatose. On the day of his death coarse rales were heard over the chest but there was never any dyspnoea or important physical signs. The pulse remained regular and the temperature subnormal throughout. At the necropsy the lungs were found to be infiltrated with miliary tubercles, and tubercles with a slight degree of meningitis were found at the base of the brain. The kidneys were healthy.

The interesting features of the case are: 1. The well-marked remittent character of the coma, which was very striking. 2. The absence of fever, the temperature, in fact, being subnormal throughout. 3. The absence of alterations in the pulse or in the breathing, although the lungs were full of miliary tubercle. 4. The loss of the knee-jerk during the stage of coma, with its reappearance during consciousness. The emaciation and the retraction of the abdomen pointed to tuberculosis, but the absence of fever and the sudden onset of the illness prevented the diagnosis being a positive one. In cases of coma without fever tuberculosis must be borne in mind as a possible cause.

C. W. SUCKLING, M.D. Lond., M.R.C.P.

OPHTHALMOLOGICAL MEMORANDA.

CUCAINE IN SQUINT OPERATIONS.

In the JOURNAL for December 10th, Mr. Edgar Browne describes a new strabismus hook, which is also an injection syringe, and which can therefore water its own path with cocaine. In the number for December 24th, Mr. Lloyd Owen points out that it is desirable to anaesthetise the tissues before introducing the hook; he opens the conjunctiva, etc., with the scissors in the usual way, and then, with a pipette, introduces a few minims of cocaine solution beneath them. The tendon is divided two or three minutes later.

I desire to mention another plan which answers extremely well, and

by which the cocaine is retained in contact with the tissues to be divided more effectually, I think, than by the foregoing. The conjunctiva being anaesthetised, and the lids drawn apart by the fingers of the assistant, I pick up the conjunctiva over the insertion of the tendon, and, with an ordinary hypodermic syringe, introduced from before backwards parallel with the tendon, inject two or three minims of the solution. The fluid, unable to escape, forms a bleb just where it is wanted. A few minutes later, the speculum is introduced, and the operation performed in the usual manner, in most cases without pain.

Now that the *British Pharmacopoeia* has ordained that the name of the drug in question shall be cocaine and not caucaine, would it not be well, in spite of some reasons to the contrary, to abide by that decision, especially as cocaine is the name which is known in other countries?

PRIESTLEY SMITH.

Birmingham.

THERAPEUTIC MEMORANDA.

ANTIPIRYN IN MIGRAINE.

SINCE first suggesting, in July last, the extended use of antipyrin in sick headaches, I am glad to see it is gaining ground. I would suggest for convenience and portability the use of Burroughs and Wellcome's dainty little tabloids of the pure drug. I find some cases require larger doses than the eight grains (hourly repeated) which I first recommended, and that double that quantity will then be effectual. It causes in some slight constipation, but it is notable that, if it is taken in conjunction with a usual purgative dose, the latter will act in due course during a seizure, while without it almost any article of food or medicine will only make matters worse. Some light food should always be taken as soon as the headache is dissipated.

For such as are unable to leave home or enjoy travel, to go into crowded rooms, or to venture on certain articles of food and drink, or even medicinal tonics, there is in antipyrin (at no time incompatible) a promise of immunity from the usually dreaded headache which may follow next morning, if not sooner. Its timely exhibition will avert, in most cases effectually, that universal lethargy of function and disturbance of the secretions which are the characteristics of the seizure, and keeps the pylorus relaxed for free communication. Already an established antipyretic in all febrile conditions, it would seem, from some features of its action, to be worthy, also, of extended trial in rheumatic and spasmodic affections, and for the often distressing after-pains of childbed.

J. OGILVEY, M.D., Surgeon-General.

HOSPITAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN, IRELAND, AND THE COLONIES.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

A CASE OF VESICAL CALCULUS, WITH REMARKS ON THE SUPRAPUBIC OPERATION FOR STONE.

Under the care of Mr. EDMUND OWEN.

(From notes by Dr. E. J. LEWIS, late House Surgeon.)

A BOY of 2½ years was admitted 24th October last, who, for three or four months, had been crying on micturition, and who had had, moreover, frequent attacks of hæmaturia. Six weeks previously his doctor had circumcised him; probably he had omitted to sound him, or he might have detected a small stone in the bladder. On 26th October, under chloroform, Mr. Owen incised the meatus and attempted to introduce a small lithotrite (No. 7), but without success. He, therefore, passed a straight staff with a median groove, opened the bladder through the left side of the perineum, and removed a very small stone by a pair of ordinary dressing forceps. There was practically no bleeding; the boy's legs were tied together, and he was put back to bed. In the evening his temperature was 99.8°, but next day it was down again to normal, and during the whole period of his remaining in hospital it never again rose to 99°. The wound promptly healed, and he was taken home on 14th November, in less than three weeks after his admission.

REMARKS BY MR. OWEN.—In a clinical lecture which was given last year by my friend, Dr. Dennis, Professor of Surgery at the Bellevue Hospital, New York, he said, speaking of the high operation: "It is

to be, undoubtedly, the lithotomy of the future." I venture to think that such a statement is, to say the least, premature. That it is at present the "fashionable" operation in surgery is beyond dispute; but it has not yet been sufficiently submitted to the test of time and experience for one to be able to assign to it its exact position amongst surgical procedures. True, on many sides, we hear the operation well spoken of. One is told of quick healing of the wound, of freedom from constitutional and local excitement, and of rapid convalescence, as characterising the procedure. But, on the other hand, one also hears of the bladder-wound giving way though the surface wound had healed, and of, in consequence, urinary infiltration and suppuration. Then, again, sometimes the wound is an extremely long while healing. The operation must be considered as yet on its trial, and in the meanwhile it is a misfortune that it is placed in direct competition with lateral lithotomy. Cheselden's operation has a magnificent history; the high operation may yet have a brilliant future, but this will not be secured by adopting it in the case of every calculous boy.

A few years ago, the question of a choice of operative procedures in the case of a boy with a stone in his bladder was never discussed. Every calculous boy, as a matter of course, was submitted to Cheselden's operation; and at the present day it would appear that, with a less pardonable want of discrimination, boys are being operated on by the suprapubic method. Statistics may shortly be forthcoming which will show that, in its general application, the high operation is not to be preferred to the lateral, though it may be far better in a certain small class of cases. The application of the operative procedures may not improbably be thus resolved:—Lithotripsy, after Bigelow's method, should be tried for all boys with a single, small stone; though, if this prove an oxalate, or too hard for crushing, the boy should be cut. Two very small stones might also be crushed and removed at the single operation. For a hard-ringing stone (oxalate), for a soft though large stone, and for several stones, a cutting operation must be done. For a large stone—of the size of a pigeon's egg and upwards—the suprapubic operation is to be preferred; but for a moderate-sized stone which is, from hardness or dimensions, unsuited for crushing, the lateral operation is, and, I think must continue to be, best suited. Dr. Dennis, who, from the deservedly high position which he holds in the surgical world at New York, as well as from the great practical experience which he enjoys, may well be accepted as the exponent of contemporary surgery on the other side of the Atlantic, said before the American Surgical Association last year: "I would venture to remark that the time is not far distant when there will be but practically two operations for stone in the bladder—suprapubic lithotomy and litholapaxy. If future experience demonstrates that a return of calculus occurs in a fair percentage of the cases after lithotripsy from *détritus* left behind, and that the mortality of the suprapubic is reduced to a figure equal to or less than perineal lithotomy, then suprapubic lithotomy, with its special advantages, will be the recognised operation of the day." This is, indeed, a very bold statement; it may possibly be verified, but in the meanwhile we must be content to record, watch, and wait.

One advantage which is claimed for the high operation is this, that it is "free from the risk of injury to the reproductive organs." But we have yet to learn that the operation of lateral lithotomy is followed by results which are prejudicial to the power of procreation. It has been remarked—I know not by whom, nor with what truth—that the begetting of children enters largely into the religious creed of the ordinary native of India, and that, if lateral lithotomy were frequently followed by sterility, the operation would be persistently declined.

It seems strange that an apologist should be needed for Cheselden's operation; but, as a corollary to the simple case which has been recorded above, and which has suggested these remarks, one may be allowed to say that lateral lithotomy in childhood still possesses its advantages. History tells us that it is comparatively devoid of risk; the time occupied in its performance is a matter of seconds; it drains the bladder in the most advantageous site, urinary extravasation and pelvic cellulitis following it only in the most exceptional cases; the wound requires no tube nor dressing, and it gives the surgeon no cause for anxiety.

THE Tavistock Rural Sanitary Authority, on reappointing Dr. F. M. Williams as medical officer of health, reduced his salary from £160 to £100 per annum; but the Local Government Board refused to sanction it, stating that they could see no sufficient grounds for the reduction. The subject was reconsidered and discussed at the last meeting of the Authority, when it was proposed by Mr. Northey, seconded by Mr. W. Perry, and resolved by a large majority, that the original motion for the reduction of the salary to £100 be reaffirmed, and that the Local Government Board be asked to sanction it.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

A FATAL CASE OF HEMIPLEGIA IN A CHILD WITH NEOROSY.

(Under the care of JOHN ABERCROEBIE, M.D., F.R.C.P.)

A. W., aged 5, was admitted into the hospital under my care on September 17th, and died the same day. For the clinical notes and report of the *post-mortem* examination I am indebted to Dr. F. Penrose, the medical registrar. About a month previously the child had been sent into the country for change of air, and, with the exception of occasional headache, had seemed well until two days before admission, when she was found to be paralysed on the right side; no particulars as to the mode of onset could be obtained. As she steadily got worse she was sent up to the hospital, where she arrived in a partially unconscious condition. The right arm and leg and side of face (?) were paralysed; she could feel on the left side, and could move the left arm and leg. There was no strabismus; the pupils were equal and sluggish to light, the optic discs healthy. No abnormal signs as regards heart or lungs. The right knee-jerk and plantar reflex were absent; they were present on the left side; there was no ankle-clonus. The breathing was slow, and gradually got slower from accumulation of mucus in the trachea and bronchi, and she died asphyxiated about five hours after admission.

The body was examined forty hours after death. It was that of a well nourished child; rigor mortis was well marked; there was no external evidence of violence. The left middle cerebral artery was completely filled by a black, dryish, non laminated, non-adherent clot. The artery seemed perfectly healthy. The left hemisphere, especially in the motor region, was more pink and decidedly softer than the right in the corresponding region, and the change was equally noticeable, both in white and gray matter. The left caudate nucleus showed some fine extravasations on its surface. The pons medulla and cerebellum appeared natural, as also did the fundus of the eyes and the left middle ear; the right showed superficial necrosis of the incus. The sinuses of the brain were healthy. Some adhesions were found over both lungs, and the bronchi were somewhat inflamed, and plugged with mucus. Near the free margin of the large mitral flap were found four minute whitish granulations, which were soft and easily removed, and appeared to be of fibrinous origin; in all other respects the heart was healthy. The urine was found to be albuminous, but no other evidences of disease were discovered, and no infarctions in any of the abdominal viscera.

REMARKS.—Although the clot showed no lamination whatever, and was not at all adherent to the arterial wall; still it must be considered, I think, as undoubtedly of *ante-mortem* origin. The clinical facts would alone quite justify such a conclusion, apart from the fact that there was found in the heart on the mitral valve just such a condition of things as would have been most likely to lead to embolism. The history of the case during life is much too incomplete to justify any opinion as to the cause of these little fibrinous coagula; the fact of the child having been sent into the country is, however, some evidence that she was below par, and the whipping up of a little fibrin from the blood in the cavities of the heart may have been due to her impoverished condition. It is difficult to say why changes had not commenced in the clot, for it must have been sixty hours old at the time of death; but, excepting that it was rather dry, it had all the naked eye characters of a *post-mortem* clot; the softening of the brain, however, in the region supplied by the plugged vessel is sufficient evidence of the time of its formation. On June 17th of this year I published in the JOURNAL a paper on hemiplegia in children, in which I took the view that arterial embolism was by far the most likely cause of the paralysis. This case supports that view very strongly.

REQUESTS AND DONATIONS.—Miss Mary Fothergill, of Hensol Castle, Glamorganshire, bequeathed £500 to the Cardiff Infirmary, £300 to the Cancer Hospital at Brompton, and £300 to the Hospital for the Paralysed and Epileptic.—Mr. W. S. Lewis, of Ketley, Wellington, bequeathed £500 to the Salop Infirmary.—The Queen's Hospital and the General Hospital, both at Birmingham, have each received £250 under the will of Mr. James Horsfall.—The Jervis Street Hospital, Dublin, has received £200 under the will of Mr. Thomas Synnott.—Mr. Solomon Longworth, J.P., of Whalley, has given two hundred guineas to the endowment fund of the Blackburn Infirmary.—The Grocers' Company have given £100, and the Skinners' Company twenty guineas, to the Seamen's Hospital (late *Dreadnought*), Greenwich.—University College Hospital has received £102 10s. from "The People's Contribution Fund."—Mr. George Henry Leather has given £100 to the Bradford Infirmary.—"T. K." has given £100 to the Bristol Royal Infirmary.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JANUARY 10TH, 1888.

GEORGE D. POLLOCK, Esq., F.R.C.S., President, in the Chair.

A Case of Occlusion of the Left Bronchus by a Metal Pencil Cap, and its Removal by Tracheotomy. By W. B. CHADLE, M.D., F.R.C.P., and THOMAS SMITH, F.R.C.S.—The patient was a girl, aged 9. The loose metallic cap covering the end of a pencil, which the child had put in her mouth, became detached, and was drawn into the throat. Urgent choking and dyspnoea followed. This was relieved after the passage of a probang down the oesophagus, and the foreign body was believed to have entered the stomach. There was great pain at the time, and violent cough. Four days later, dullness on percussion and imperfect entry of air were first noted on the left side of the chest. Eleven days after the accident there was marked dullness over the whole of the left side, absence of respiratory murmur except over a limited portion of the upper part in front, displacement of the stomach upwards to the nipple line, and great retraction of that half of the thorax, indicating almost complete collapse of the left lung. The respirations were 30, the pulse 92. The temperature was subnormal—97.8°. There was no dyspnoea, but occasional short cough, aggravated by exertion. The conclusion arrived at was that the pencil cap, which was about one inch long and a quarter of an inch in diameter, had lodged in the extreme end of the left bronchus. After consultation it was decided to attempt the removal of the foreign body by tracheotomy before the supervention of serious inflammatory changes in the lung. Suitable provision was made for dealing with whichever end of the tube should present itself. For the open end a pair of suitably curved forceps, with external grip, were provided; these placed within a facsimile of the pencil cap were found to hold it firmly. The isthmus of the thyroid was divided between two ligatures, the trachea freely opened, and the edges of the tracheal wound attached to the margins of the skin by silk sutures. A long probe passed into the bronchus at once detected the foreign body in the position assigned to it, with the open end uppermost. The forceps were introduced, and the cap was extracted without difficulty. The plan of attaching the tracheal wound to the skin is recommended as serving to keep the trachea widely open; a help to the surgeon, and a source of safety to the patient. With the exception of a short pyrexial attack of short duration on the day after operation, the patient made a rapid and uninterrupted recovery; the lung slowly re-expanded, and a final examination of the chest fourteen days after the operation disclosed as the only abnormal physical signs slight deficiency of respiratory sound, and of expansion on the left side. The entrance of a foreign body into the left bronchus in preference to the right is shown to be by no means so rare an occurrence as commonly believed. Out of thirty-one cases collected in which the position of the foreign body is stated, it entered the left bronchus in eighteen instances, the right in thirteen. The physical signs observed in this case differ materially from those laid down by authority as typical in such conditions, and an explanation of this discrepancy is suggested. The collapse of the whole lung which followed the occlusion of its main bronchus is confirmatory of the accepted theory as to production of collapse of portions of the lung by obstruction of their supplying branches. The entire absence of pulmonary inflammation is opposed, however, to the view that collapse is the leading factor in the production of catarrhal pneumonia. Attention was drawn to the lowered range of temperature during the period of pulmonary collapse, to the inadequate compensatory rise in pulse and respiration-rate, and to the possible causes of the short phase of high pyrexia which occurred the day after operation.—The PRESIDENT complimented the authors on their skill in diagnosis and treatment. In a famous case in which Mr. Brunel had, during an exhibition of conjuring, let a half-sovereign fall into his throat, and Sir Benjamin Brodie had operated on him, the trachea was freely opened, he was turned on his face, his feet elevated, the body shaken, and the coin fell out through his mouth. Experiments subsequently made with sixpences and half-sovereigns showed that they generally went into the right bronchus. In a case of impaction of a piece of pipe in the inflamed walls of the trachea, Mr. Pick had not found any instrument as well adapted to his difficulties as that which Mr. Smith had so skilfully devised.—Mr. F. Sr. GEORGE MIVART had been first called in to this case, three days after the accident, and felt very grateful for the assistance he had received. At first sight the girl seemed to have very little the matter with her, and the case developed very slowly. He was sorry Mr. Smith had found it necessary, after opening the trachea, to stitch the skin to the lips

of the wound, as it left a large persistent scar.—Mr. HULKE congratulated Mr. Smith on a brilliant operation. He had himself published a somewhat similar case in which the end of a tracheotomy tube had broken off and fallen into the right bronchus. It was open at both ends, and so was easier to extract than the pencil-cap which Mr. Smith had had to deal with. He had made a flexible crotchet of silver wire, with which he found no difficulty in hooking it out. It was important that these foreign bodies were metallic and did not swell up and soften, as was the case with such substances as heads of grass, awns, and pieces of bone. Removal was easier in the adult than in a child, for in an adult it was not hard, after a free opening had been made into the trachea, to feel its division with the finger, and make certain of the position of the foreign body.—Mr. BARWELL related a case he had published in the *Clinical Society's Transactions* for 1873, in which a boy aged 17 had let a Punch's whistle slip into his bronchus. He had been quite unable to remove it, and the clinical symptoms were becoming serious when he took a rapid turn to the better and completely recovered. It was probable that he had coughed it up, swallowed it, and passed it unnoticed by the bowel.—Mr. HULKE, *à propos* of this, cited another of his own cases in which a sixpence was visible in the trachea; he could not seize it, but opened the trachea, whereupon it was coughed up and swallowed.—Mr. HOWARD MARSH remarked that he had been much interested with the various physical signs that the physicians found in the chest in these accidents; they seemed to vary quickly, but dulness generally attended collapse, as in Dr. Cheadle's case. He had found it impossible in another case in which a bean had passed into the bronchus to distinguish the foreign body by touch from the surrounding soft tissues, and, when the child died, it was found impacted in the left bronchus. Mr. T. Smith's operation had been so carefully considered that all contingencies had been provided for, and the matter seemed easy.—Dr. HOWARD had been struck with two points in the case before them; first, the good effects of stitching the skin temporarily to the lips of the trachea, for it was most important to be freed from the annoyance of a bleeding wound; and, secondly, the advantage that would be gained by having the tracheal wound higher than any point above it, so that the blood should not drain into the lung. On a question from the PRESIDENT, how this was to be brought about, he acknowledged that he had never done it.—Dr. CHEADLE, confining his few remarks to the medical side of the case, remarked that the difference of physical signs, according to the very varied physical conditions that might be produced in these states, was a complex matter; it was generally true that where the obstruction was incomplete, there was not much dulness, but it was much too sweeping an assertion in some textbooks that there was always resonance after impaction. When there was any it slowly disappeared as collapse set in.—Mr. T. SMITH said he had found no long forceps so well adapted to this case as a pair which opened outwards with a firm grip. With such a pair, duly curved, he had found it easy to grasp the pencil cap in the bronchus. In many previous cases he had seen great difficulty in grasping the foreign body, and the operation had often ended in its being coughed up. He agreed with Dr. Howard that the tracheal wound should be higher than any other part in the trachea. It was widely open; it was thought unnecessary to turn the girl on her face. He quite agreed with Mr. Hulke in the greater danger of soft objects, such as grains of barley, etc. In one of his own children a sugar-plum had obstructed the trachea, and caused very serious symptoms. It was shaken down in the larynx, and, after ten minutes of great anxiety, fortunately dissolved. As regarded the stitching of the edges of the trachea to the skin, he did not think that any serious aggravation of the scar would result.

Influence of Salicylic Acid and its Salts on the Excretion of Uric Acid. Dr. ALEXANDER HAIG, M.B.—After referring to the theory elaborated in the paper published on p. 73 of this week's JOURNAL, the author stated that salicylic acid formed an important exception to the general statement there made, for while it increased urinary acidity it did not in any way diminish the excretion of uric acid. Acids given while salicylates were present in the circulation had no longer the power of diminishing the excretion of uric acid. This action of salicylic acid and salicylates formed the subject of the present paper, and was of importance in explaining the value of these drugs in gout, rheumatism, and other diseases connected with uric acid. Statistics were given to illustrate the excretion of uric acid under salicylates, and were contrasted with others, showing the normal relation to acidity. Excessive excretion of uric acid taking place under salicylates was not accompanied by any headache, and salicylates had previously been found useful in this headache. The action of acids and alkalies on uric acid excretion was probably due to the fact that alkalies increased and acids diminished its solubility, and the same with the

exceptional action of salicylic acid, for salicylic acid, which it was supposed to form, differed from uric acid in being very greatly more soluble in water, and probably also more soluble in dilute acids. Benzooates did not act in the same way as salicylates, probably because hippuric acid, which they formed, was less soluble than salicylic acid. Both uric and salicylic acids were present in the urine passed under the influence of salicylates; this was possibly due to the salicylate acting on the uric acid in the blood, and not on the uric acid which was excreted direct from the kidney. Headache was present with the rush of uric acid which took place under alkali, but not with the rush under salicylates; possibly, therefore, under salicylates, uric acid was present in the blood in a different chemical combination (salicylic acid).—Dr. WARD felt much sympathy with this investigation of the causes of headache, and had confirmed on himself some of Dr. Haig's previous remarks on the connection of them with uric acid. He considered them gouty, and he was surprised that Dr. Haig should find acids a remedy for a gouty state. Similar headaches, or at least attacks of migraine, were found in women and in the French, who had no excess of meat; in his own case he found a high specific gravity of urine was a sign of coming headache. Strychnine and liquor ammoniæ acetatis afforded him the best relief.—Dr. A. E. GARROD did not find much light thrown on the action of salicylic acid in joint diseases, especially in gout, where its effects were trifling, though its slight power as an anodyne made it felt a little in rheumatoid arthritis. Uric acid had nothing to do with the pathology of rheumatic fever, and was not found in such cases in excess in the blood, though it had been very often looked for.—Dr. HAIG considered that he had established one form of headache, a uric acid headache, which he could produce and stop by increasing or decreasing the amount of uric acid. Women, he thought, suffered easily from small quantities of meat; the French from acid wine, for the acid helped the retention of their uric acid, and they did not get rid of it by exercise. A sensitive nervous system reacted to uric acid very easily. In a paroxysm of acute gout, salicylates were too late, for it took them some time to penetrate to the cartilages where the uric acid already was, but taken as a prophylactic they did much good, in his opinion. The relation of uric acid to rheumatism still needed to be worked out.

MEDICAL SOCIETY OF LONDON.

MONDAY, JANUARY 9TH, 1888.

J. HUGHLINGS JACKSON, M.D., F.R.S., President, in the Chair.

The Reflex Inhibitory Action of Cocaine as a Diagnostic Factor.—Mr. HURRY FENWICK read a paper upon a long series of cases in which pain in various parts of the body had been temporarily relieved in 30 to 180 seconds by urethral injection of 20 per cent. solution of cocaine. Cases of its action in neuralgic pain of the cranial, cervical, intercostal, renal, and lumbosacral nerves were mentioned, and the reasons for this power were roughly demonstrated to the Society by means of decapitated frogs. Thus, without a vesico-rectal injection of cocaine, the leg of the decapitated frog was rapidly jerked out of a weak acid solution in some fraction of a second; but after cocaine had been injected into the bladder or rectum, the leg was not withdrawn until after 20 to 30 or more seconds. This remarkable inhibitory power was only observed when weak acid solutions (that is, weak irritations) were used. Cocaine possessed no power of delaying the reflex excitability consequent upon stronger acid solutions. The following propositions were formulated:—1. Slight nerve irritations (as neuralgias) of any part can be relieved by injection into the urethra of a few drops of a 10 or 20 per cent. solution of cocaine. 2. Severe nerve irritation, as in the pain of carcinoma, inflammation, etc., cannot be thus relieved. Mr. Fenwick has used this knowledge largely in the differential diagnosis of urinary disease. Thus, if a renal pain was immediately relieved by cocaine, he judged the neuralgia to be due to a slight irritation, such as that experienced in lithiasis, congestion, or grit. If unrelieved (and cases were given) he diagnosed more serious cases (for example, stone, dilated pelvis, etc.) He then drew attention to the value of cocaine in operations upon the bladder and urethra in preventing damage to an unhealthy kidney. M. Tuffier's experiments upon renal congestion produced by distending the bladder or injuring the walls were mentioned, and it was submitted that this flooding of the kidney—which, if the organ was damaged, led to rigors, suppressions, and suppurations—might be partially or wholly prevented by the inhibitory action of cocaine upon the renal circulation.—Mr. JAMES BLACK asked whether Mr. Fenwick had noticed any serious toxic symptoms after injections of solution of 20 per cent. of

cucaine. He himself had used a 20 per cent. spray to remove growth from the inferior turbinated bone, and the patient became collapsed, livid, cold, and almost pulseless. A second case had exhibited the same alarming symptoms.—Mr. BOWREMAN JESSETT said he had removed an enlarged gland from the neck after the injection of 10 minims of a 20 per cent. solution, but serious symptoms had followed. He added that it was very difficult to obtain relief from pain by means of cucaine in removing polypi from the nose.—Mr. BERNARD PITTS asked Mr. Fenwick whether he had tested remote body sensations in a healthy subject after urethral injection. In a case of his own faintness had supervened, with general numbness and coldness of the surrounding surface.—Mr. WALTER PYE said he had seen many cases of fainting following the use of cucaine. He himself had felt faint after a 5 per cent. solution.

On the Treatment of Carotid Hæmorrhage.—Mr. FREDERICK TREVES read a paper on a method of controlling hæmorrhage from branches of the carotid arteries. He said it was usual to ligature the carotid trunk in hæmorrhage from small vessels, but much might be done by temporarily compressing the main trunk. Temporary pressure, however, could not be applied with success in the neck, and he proposed to isolate the common carotid, and pass a catgut loop around it, which could be pulled upon and so check the passage of blood. He quoted from cases in which he had resorted to this procedure, only one case—that of a child—proving fatal; and in all the lumen of the artery was ultimately restored. He added that no local inflammation or other inconvenience was to be feared as a result of the operation itself.—Mr. BERNARD PITTS asked Mr. Treves what he considered the best plan to adopt in cases of hæmorrhage from the internal carotid artery. In a case under his care, where there was copious hæmorrhage from a tonsillar abscess, he tied the common carotid. The hæmorrhage, however, recurred, and the patient succumbed to the loss of blood. At the *post-mortem* examination a large opening was found into the internal carotid in the vicinity of the abscess. He had made a series of experiments since, and he found that blood escaped much more freely from such an opening when injected into the external carotid. He asked whether there was a prospect of permanent plugging from the temporary ligature.—Mr. HARRISON CRIPPS observed that the mortality in punctured wounds of the carotids was due partly to deficiency of the cerebral blood supply, and partly to recurrence of the hæmorrhage. He thought it was better to ligature the external carotid rather than the common carotid. It most frequently happened that the hæmorrhage came from tonsillar branches of the external carotid.—Mr. TREVES, in reply, said the loop was in no sense a temporary ligature. Even in the child who died the lumen was not obstructed. The suggestion to ligature the artery at the site of the wound would not be possible in a deep punctured wound.

A Case of Gastro-enterostomy and a Case of Duodenostomy for Carcinoma of Pylorus.—Mr. BOWREMAN JESSETT read the notes of two cases in which he had operated for pyloric obstruction due to cancer. The first case was that of a woman who suffered from exceeding pain and persistent vomiting. There was a tumour to the left of the middle line, in the epigastric region, freely movable. The stomach was washed out, and on June 4th he operated. Owing to the patient's failing strength he contented himself with suturing the duodenum to the abdominal parietes, the wound being treated as in gastrostomy. The pain continued for some time, the patient being fed with beef-tea, zymuised beef suppositories, etc. The patient ultimately died on July 3rd, one month after operation. The second case was that of a man who suffered from melancholia. He was extremely emaciated, and only weighed 8 stone 4 lbs. He complained of great pain, relieved by vomiting. There was dulness below the ensiform cartilage; the stomach was not appreciably dilated. He was operated upon, the jejunum being stitched to the anterior wall of the stomach. He died ten days after the operation. At the *post-mortem* examination the cicatrix of an old ulcer was found near the pylorus, the walls of which were thickened. He recommended that duodenostomy should be performed while the patient's condition was still such as to allow of it.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, JANUARY 4TH, 1888.

JOHN WILLIAMS, M.D., President, in the Chair.

Specimens.—Mr. SIDNEY HARVEY showed a specimen of Interstitial Gestation.—Dr. CARTER exhibited Ovaries and Tubes removed for Double Hydrosalpinx.—Dr. W. S. A. GRIFFITH showed (1) a specimen in which there was a Tubo-ovarian Cyst of the Right, and Hydrosalpinx of the Left, Tube; (2) a case of Cystic Adenoma of the Anterior Lip of the Cervix; (3) a Parametric Abscess.

Post-mortem Appearances of Phlegmon of Broad Ligament.—Dr. LEWERS read a note on this subject. The patient was admitted into the London Hospital a few days after her confinement suffering from mania and parametritis, and died of bronchitis. On *post-mortem* examination, the layers of peritoneum forming the right broad ligament were found separated by exudation, measuring from before backwards one inch and a half, and bounded above by the Fallopian tube stretched over the convex surface of the swelling. The external surface of the peritoneum was somewhat granular, with here and there flakes of recent lymph about 1-16 inch thick. On cutting into the swelling the cut surfaces had a coarse, sponge-like appearance, the largest holes being the size of a No. 16 catheter, and all the cavities were filled with a sero-sanguinolent fluid, but none of them contained pus. The right ovary measured 2½ inches long, 1½ deep, and ¾ thick. It was adherent to the adjacent surface of the broad ligament by recent lymph, and on section an abscess containing half a drachm of pus was found. The author said that the specimen illustrated a phase of parametritis rarely met with, and was interesting as bearing on the pathology of ovaritis. He thought it was difficult to conceive of ovaritis occurring as a primary affection, while it was easy to see how it might be secondary. Periovaritis was produced by extension of inflammation along the Fallopian tube to the pelvic peritoneum, producing pelvic peritonitis involving the ovary. Interstitial ovaritis might be produced by extension of inflammation from the connective tissue between the peritoneal layers forming the broad ligament along the connective tissue in the hilum of the ovary, and so to the parenchyma of the ovary—that is, interstitial ovaritis was secondary to parametritis. In the specimen, while the inflammation in the broad ligament was still in the stage of phlegmon, the inflammation in the substance of the ovary had gone a stage further and caused a small abscess.—Dr. MATTHEWS DUNCAN regarded the dissection as of great interest. Dr. T. Keith had mentioned a case of an allied kind observed during ovariectomy. So great was the swelling that he could not pass a sponge into the pelvic cavity. In Dr. Lewers's, as well as Dr. Griffith's case of parametric abscess, there was room for believing that septicæmia was present, and this might be the explanation of the situation of the disease between the folds of the broad ligament, a situation not common, even if it occurred at all, in simple traumatic parametritis. In puerperal septicæmia or pyæmia phlegmonous masses, as distinguished from abscesses, were not rare. They were generally situated on the limbs, and often multiple. They might or might not be superficially red and more or less tender. He had lately seen a case with redness, and with two small, deep, punched-out ulcers the size of a split pea. He had seen also two such cases of phlegmon where eminent surgeons had diagnosed abscess, and operated, finding no matter. Such cases, even when accompanied by bad symptoms, did not all end fatally.—Dr. GRALY HEWITT thought Dr. Lewers's contribution was very valuable, as the opportunity rarely offered of substantiating the actual locality of effusions in this situation. He had frequently met with cases similar to Dr. Lewers's. He was of opinion that presence of effusion indicated a localised septicæmia. The septic material entered by way of the lymphatics or by the blood vessels, and the effusion in the broad ligament was the result.—Dr. CARTER had been present at a necropsy of a patient who died of septic parametritis. The broad ligament of one side was enlarged, and appeared as though some plastic matter had been injected between and separated the parts. The veins were distended, and the lymphatics were embedded in plastic material and kept fixed and patent.—Dr. LEWERS replied.

Scarlatina during Pregnancy and in the Puerperal State.—Dr. BOXALL read a series of papers on this subject. He briefly referred to some of the anomalies which existed in ordinary scarlatina, and suggested that further deviations from the usual type might be expected under the special conditions which appertained to pregnancy and to the puerperal state. He mentioned some of the more recent literature on the subject as containing the varied and frequently diametrically opposed opinions expressed by different observers, and, in passing, drew attention to the confusion which had arisen through the loose application of the terms "puerperal fever" and "puerperal scarlatina." He then described a series of sixteen cases of undoubted scarlatina occurring during pregnancy and in the puerperal state, with special reference to the facts of exposure as far as they could be ascertained in each case. The clinical history of the same cases was presented in a tabular form for further consideration. 1. As regards the liability of pregnant and parturient women to scarlatinal infection, and the duration of the incubation period, Dr. Boxall referred to the rare occurrence of scarlatina during pregnancy, and its almost invariable appearance during the first few days of the puerperium. Bearing in mind the alteration in the existing conditions which took place

at delivery, he insisted that the two classes of cases must be kept separate, and that a distinction must be drawn (a) between those cases which received infection prior to delivery, and those which received infection during or after labour; (b) between those cases which failed before delivery, and those in which the disease did not make its appearance till after the onset of labour. He further pointed out that the duration of pregnancy had an important bearing on the question of incubation. The following inferences were drawn: (1) As regards the time, with reference to labour, at which the disease showed itself: (a) that scarlatina almost invariably occurred within the first week of the puerperium, and its occurrence at a later period was extremely rare; and (b) that in exceptional instances scarlatina might show itself during pregnancy, shortly before the onset of labour. (2) As regards the liability of pregnant and parturient women to scarlatinal infection, and the reciprocal influence existing between the latter and parturition: (a) that a woman exposed to the disease might become infected with scarlatina during pregnancy, during or after labour; (b) that the liability to infection was especially marked shortly before, and during the first few days after, delivery, but did not extend far into the puerperium; (c) that, if infection occurred during pregnancy, the onset of labour might be thereby precipitated; (d) that when infection took place during or shortly after labour, the incubation period might be shortened; and, finally, (e) that the foregoing considerations were in themselves sufficient to explain the frequent onset of scarlatina during the first week of the puerperium, without the necessity of ascribing to scarlatina in pregnancy an incubation period exceeding that of ordinary scarlatina.

II. With regard to the relation of scarlatina to menstruation, Dr. Boxall pointed out that an apparent analogy with regard to the onset of scarlatina existed between labour and the menstrual periods. Careful observations were made on a separate series of sixteen cases of scarlatina in non-pregnant and non-puerperal women. Upon this evidence it appeared that women usually failed with scarlatina shortly after, during, or just before a menstrual period, as in the case of labour. In conclusion, the author suggested that the following considerations (exactly analogous to those which referred to the intimate connection existing between the time of the onset of scarlatina and delivery) might serve to explain these facts: (1) That the liability to infection was especially marked shortly before, during, and immediately after a menstrual period. (2) That infection occurring shortly before a menstrual period might precipitate the flow. (3) That, when infection took place during or shortly after a menstrual period, the incubation period might be shortened.

III. With regard to the clinical course of scarlatina during pregnancy and in the puerperal state, Dr. Boxall, before entering into a consideration of the clinical features of the disease, reiterated the necessity of dissociating those cases in which the attack began before delivery from those in which it commenced after the onset of labour. The initial symptoms were discussed, and attention was directed to the special character of the throat affection. The following observations were presented: (1) That during pregnancy the throat symptoms were unmodified, but that after delivery angina was rare; (2) That in scarlatina after delivery (a) subjective soreness was usually absent at the outset, and even at a later stage rarely caused much distress; (b) signs of slight inflammation, though generally absent at the outset, might usually be observed on the second or third day of the attack; (c) the cervical glands were usually affected, whether any change had been apparent in the throat or not. The fallacy of adducing from the diminished intensity of the throat affection an argument in favour of direct inoculation of the poison through the parturient passages was pointed out. Attention was also directed to the slight intensity of the tongue affection, and to the marked flushing of the face which preceded the rash. These also appeared to be features of scarlatina developed *post-partum* but not of *ante-partum* scarlatina. From these observations it was concluded that some modifying influence, the nature of which was unknown, was called into play at the time of delivery. The peculiarities of the eruption were discussed, with especial reference to site and intensity. Its modifications were attributed to the altered circumstances of the patient after delivery. The frequent occurrence of sudamina and urticaria was also noted. A summary was given of the various complications which the scarlatinal patients presented. Mention was also made of the influence of a previous attack of scarlatina, and of the lapse of time after delivery in diminishing the severity of the disease.

IV. With reference to the effect of the scarlatinal poison on the course of labour, Dr. Boxall gave an epitome of the course of the labour, both of those patients who were delivered during the incubation period and also of those who were delivered during the actual attack of scarlatina. The following conclusions were adduced: (1) When labour occurred during the incubation period of scarlatina, it ran for

the most part its usual course, but the pains might exert a greater influence than usual on the mental condition of the patient; inertia, if induced, set in late in the course of labour, and a peculiar and almost characteristic odour might be present. (2) When labour occurred during an attack of scarlatina, the pains were apt to be feeble throughout, inertia set in early, and *post-partum* hæmorrhage was liable to occur. The same peculiar odour might be present. V. Respecting the effect of the scarlatinal poison on the puerperium, Dr. Boxall gave two tables, one representing the effect of scarlatina on the uterus and lochia, the other showing its effect on the mammary secretion. The nature of the slight and evanescent tenderness over the uterus, frequently noted quite at the outset of the attack, was briefly discussed. Particular attention was directed to the character of the lochia, and a suggestion was put forward that offensiveness might have occupied a more prominent position if local antiseptic measures had been admitted during the puerperium. In the majority of cases an increased flow was observed at the onset of scarlatina. The cause of this was discussed, and a similar increase of the menstrual flow on the supervention of scarlatina was noted. A brief review of the mammary function was given. The liability of the infant (when the mother was affected) to take infection was discussed with special reference both to the question of suckling (which necessarily implied direct contact with the mother) and also to the stage of the disease at which delivery of the mother took place. The following conclusions were offered: (1) That involution of the uterus was not much, if at all, retarded. (2) That the slight and evanescent tenderness over the fundus, occasionally present at the very outset of the attack, was often due to increased sensibility of the pelvic organs, and was rarely an indication of pelvic inflammation. (3) That, provided antiseptic precautions were taken, lacerations healed without difficulty, and the lochia as a rule did not become offensive. (4) That in some cases a peculiar, unpleasant odour might be observed. (5) That the lochia usually proceeded naturally and ceased about the usual time, but in many cases became red and free at the outset of the attack. (6) That the mammary secretion was frequently diminished and sometimes arrested, as the result of the illness. (7) That infants kept at the breast were especially prone to scarlatina, probably from the mere fact of contact with the affected parent. (8) That when scarlatina showed itself in the mother during pregnancy, the fetus might or might not be affected *in utero*. (9) That when the mother received infection shortly before delivery the infant more generally escaped, though it might be subsequently infected.

[As there was not time to finish the reading of two more sections of this paper, the discussion was deferred till another meeting of the Society.]

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SURGICAL SECTION.

FRIDAY, DECEMBER 9TH, 1887.

A. H. CORLEY, M.D., President, in the Chair.

Penetrating Wounds of Stomach and Transverse Meso-colon successfully treated by Abdominal Section.—Dr. CHARLES BALL brought forward the case of a boy, aged 15, who was admitted into Sir Patrick Dun's Hospital on March 29th, 1887, immediately after having accidentally stabbed himself with a half-inch chisel. The blade perforated his abdomen about half way between the tip of the ensiform cartilage and the umbilicus, and about a quarter of an inch to the right side of the linea alba. Dr. Ball saw him four hours after the injury; he was then profoundly collapsed; he vomited blood at frequent intervals, and at each effort to vomit a stream of blood spurted out from the abdominal wound. The whole abdomen was dull on percussion. An incision about three inches long was made in the middle line, between the ensiform cartilage and the umbilicus, and the chisel wound connected with it. As soon as the peritoneum was opened, a considerable quantity of blood gushed out. The stomach was found to be wounded. A clean cut existed in the great curvature, about half an inch in length; it was not bleeding. The mucous membrane, though perforated, was not prolapsed, and none of the contents of the stomach were found extravasated. The wound was sutured by passing a fine catgut suture, after the method of Lembert (but continuous), four times across the wound, only including the serous membrane; the ends were then tightly tied, thus absolutely closing the opening, and at the same time puckering up the serous membrane and bringing a considerable area on each side of the wound into apposition. The omentum was reflected upwards and search made for other wounds, as copious bleeding

continued. An opening in the transverse meso-colon, near its spinal attachment, could be felt with the finger; and, upon sponging away the blood, it was found that a large vein was wounded, to which, with some little difficulty, a catgut ligature was applied. The patient vomited shortly after the operation, but the vomit was free from blood. He was allowed nothing by the mouth, except small pieces of ice, for six days, and was fed by nutrient enemata of artificially-digested food. From the sixth to the fourteenth day, he was allowed gradually-increasing quantities of beef-tea and milk, and he then was allowed solid food. On the third day, he vomited some pieces of onion, quite unchanged, which he stated he had eaten the morning of the accident. Four weeks after the operation, he was discharged from hospital quite well.—The PRESIDENT pointed out that Professor Otis, writing on the surgery of the great American war, had emphasised the necessity of opening the abdomen in cases of gunshot wounds, while he disparaged the old method as oestrich surgery. Dr. Ball deserved praise for having the intelligence to conceive and the courage to carry out the operation.—Mr. HEVSTON and Dr. ARTHILL took part in the discussion; and Dr. BALL replied.

Foreign Body in the Œsophagus.—Mr. W. THOMSON read a paper on two cases of foreign body in the Œsophagus. In one, the patient tried to swallow a quarter of a pound of beef, and was brought in dead. In the second, the patient felt a piece of beef stick in the Œsophagus, when he went to a hospital and had a tube introduced. He went home; suffered much pain; the neck and face became emphysematous. He was admitted to the Richmond Hospital, suffering from dyspnoea and dysphagia. An attempt to explore brought on such a spasm that it was necessary to desist. Later in the day, tracheotomy was done with great relief. It was determined to explore the Œsophagus subsequently, but next morning the patient said the lump had passed down, and that he was able to swallow freely. He died that night. Opposite the cricoid cartilage the Œsophagus was transfixed by a bone, which passed forwards at the left of the trachea for a quarter of an inch. The posterior end also transfixed the Œsophagus, making a rent through which fluids passed freely into the posterior mediastinum. A piece of beef, two inches long, hung from the bone, like a morbid preparation in a jar.—Mr. TOBIN had had a similar case under his care in St. Vincent's Hospital. A woman, aged 57, was admitted, having a few days before swallowed a piece of meat and bone. She could not swallow fluids. Œsophagotomy was performed on the fourth day after the accident, and a large triangular bit of bone was removed. On the sixth day after the operation the patient died, partly from exhaustion and want of food, and partly from dyspnoea, due to the extravasation of pus and fluids, and perhaps from septicæmia, which the pus and fluids set up.—Dr. WHEELER, Mr. MYLES, Sir WILLIAM STOKES, Dr. GUNN, Dr. LENTAIGNE, Dr. P. MOLONEY, and Mr. W. THORNLEY SROKER took part in the discussion; and Mr. THOMSON replied.

MANCHESTER MEDICAL SOCIETY.

WEDNESDAY, DECEMBER 21ST, 1887.

JAMES HARDIE, F.R.C.S., President, in the Chair.

Congenital Heart Disease.—Dr. HUTTON showed a boy, aged 8 years, the subject of congenital heart disease, and described the hearts of two sisters of this boy, both of whom had congenital heart disease. One of the hearts was also exhibited. The main malformation was in both cases due to arrest of development of the interventricular septum, leaving an opening between the ventricles just below the points of attachment of the aortic valves and the tricuspid valves. In the case of the boy there was seen to be great hypertrophy of the heart, and a loud systolic murmur was heard most plainly over the third left costal cartilage.

Epilepsy after Injury.—Dr. MOROAN showed a patient at present under his care in the Manchester Infirmary, in whom an epileptic attack immediately followed an injury of the ulnar nerve. About eight months ago the man was struck by a stick on the left "funny bone." He fell down unconscious, and remained in that state for some hours. Since that time similar attacks had occurred periodically, sometimes as often as eight times in a week. These seizures commenced with a feeling of coldness in the left arm, followed by clonic spasms; next, the little and ring fingers became flexed, while the wrist was bent on the forearm, and the latter on the arm; the left corner of the mouth and the left toe were then successively "drawn up;" unconsciousness followed, and conjugate deviation of the eyes towards the right side. As there had been partial left hemiplegia ever since the first attack, as likewise the tendon reflex on the left

side was exaggerated, and the deviation of the eyes during the attacks was towards the right side, Dr. Morgan looked upon the case as one of Jacksonian epilepsy, due to some gross cortical lesion (probably syphilitic) in the Rolandic area of the right side, and not as one of mere reflex epilepsy.

Suture of Tendons.—Some cases of suture of tendons were related by Mr. T. JONES. They will be published in full in the JOURNAL.

CLINICAL SOCIETY OF MANCHESTER.

TUESDAY, DECEMBER 20TH, 1887.

S. WOODCOCK, M.D., President, in the Chair.

Œdema of Larynx.—Dr. G. H. DARWIN related the history of a case of Œdema of the larynx, etc., produced by the action of raw spirit (brandy), which had accidentally entered the glottis during syncope. The patient was a widow, aged 45, who, while suffering from an attack of diarrhoea, fainted at stool, and her sister, who was attending, poured some raw brandy into her mouth, where it remained for a few seconds, and was drawn by the next inspiration into the larynx and bronchi. Here it caused immediate and alarming dyspnoea, followed by spasmodic cough and great pain in the ears. The throat was seen to be intensely red, and the voice was reduced to a whisper. There was found great congestion and swelling of the ventricular bands, which partly hid the vocal cords; and the whole of the lining membrane, so far as could be seen, was intensely red and swollen. Bronchial rales were heard all over the chest and back, and fremitus was distinctly perceptible over a large area. There was much pain behind the sternum increased on inspiration, and incessant coughing, with expectoration of frothy mucus tinged with blood. The treatment consisted of ice to suck, hot fomentations to neck and chest, and nutritive suppositories. On examination twelve hours afterwards the whole throat and larynx were covered with straw-coloured blisters, and there was great uneasiness, to relieve which steam inhalations were used. The following morning the Œdema was much increased and the breathing very difficult, with gasping and crowing inspiration. The patient gradually recovered.

Reflex Paralysis.—Mr. HERBERT LUND read notes of two cases of so-called reflex paralysis, occurring in two women, aged respectively 28 and 27 years. The exciting cause in both was carious molar teeth in the lower jaw, producing sudden weakness in the right arm, the weakness increasing gradually to a maximum, so that the arm could only by a great effort be abducted and raised, and disappearing abruptly on removal of the teeth. In the second of the two cases the weakness had existed for three months, and disappeared in a few hours after extraction of the teeth. Similar cases had been published by Mr. Salter (*Guy's Hospital Reports*, 1868). Mr. Lund then mentioned the theories as to the pathology of these cases: 1. Dr. Brown-Séquard's, that peripheral irritation of a sensory nerve produced anæmia of the cord and impairment of nutrition and function. In the *Guy's Hospital Reports*, 1861, Sir W. Gull refutes this opinion. 2. Lewisson's "inhibitory theory," demonstrated by his experiments upon rabbits; squeezing the kidney, uterus, or intestines of a rabbit producing paraplegia, the paralysis disappearing at once when the pressure was relieved. The three classes of "urinary paraplegias" of Professor Charcot were next enumerated: (1) Paraplegia in which the spinal cord is the seat of an inflammation. (2) Paraplegia, invasion rapid, cessation sudden, spinal cord unaffected. (3) Paraplegia depending upon direct propagation of morbid process from bladder, along nerves, to the cord. The second class Professor Charcot calls "reflex paraplegia," and under this heading Mr. Lund submitted that his two cases might be included.

Enchondroma of Finger.—Mr. E. S. BISHOP showed a case of single enchondroma of a finger. The patient was aged 29, and the growth had lasted twenty-five years. He pointed out that chondromata of the hand were usually multiple, and sprang from the medulla; this, on the contrary, was single, and arose from the deeper layers of the periosteum, thus resembling the tumours of this class springing from near the articular ends of long bones.—Mr. JONES doubted the peripheral origin of the chondroma; but Dr. HARRIS confirmed Mr. Bishop's observation that the phalanx from which the tumour had sprung was intact, except as to its periosteal covering.

Alopecia.—Dr. EAMES showed a collier, aged 21, affected with complete alopecia. The patient's hair began to fall off about four years before. A wash of hyposulphite of soda was used, and the disease appeared to be cured. Twelve months ago the affection returned, and by April last all hair had disappeared from the body, except in the axillæ. It remained in this state until last September, but hair was now again appearing.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.

WEDNESDAY, DECEMBER 21ST, 1887.

CHARLES SMITH, M.A., M.R.C.S., President, in the Chair.

Ophthalmoplegia Externa.—Dr. MCKENZIE DAVIDSON showed a case of bilateral ophthalmoplegia externa. The patient was a healthy woman, aged 26, of good family history. Eight years previously she began to complain of pain in the eyes, and discomfort, as if there were sand in them, with slight watering. At the present time the patient had double ptosis. On lifting the eyelids both eyes were seen to look outwards. The right eye could follow the finger inwards to a certain extent, but the left had no power of movement inwards at all. Otherwise the condition of the eyes was normal, nor did the discs show any trace of previous neuritis. These symptoms—almost complete paralysis of both third nerves—pointed to a central lesion located at the lower part of the third nerve nucleus. Dr. Davidson could not discover any obvious cause. Though her appearance was suggestive of syphilis, no history of that disease could be elicited. The treatment consisted in the exhibition of iodide of potash gradually increased.

Retention of Urine.—Dr. URQUHART read notes of some cases of retention of urine.

Cancerous Uterus.—Professor OGSTON showed a specimen of cancerous uterus which he had removed through the vagina. The cervix showed a distinct rim of healthy mucous membrane surrounding the "cauliflower" vegetations. The patient got up eighteen days after the operation, and left the hospital in three weeks.

Intra-alveolar Fracture of Central Incisor.—Dr. W. H. WILLIAMSON showed a specimen of intra-alveolar fracture of a right central incisor. There was a double fracture of the dentine at one point and of the cementum at another. The cementum had evidently united after the first fracture, and long after had been fractured at a different point. The pulp had been completely calcified.

REVIEWS AND NOTICES.

ON THE ANIMAL ALKALOIDS, THE PTOMAINES, LEUCOMAINES, AND EXTRACTIVES IN THEIR PATHOLOGICAL RELATIONS, being a Short Summary of Recent Researches as to the Origin of Some Diseases by or through the Physiological Processes going on during Life. By Sir WILLIAM AITKEN, M.D., F.R.S. London: H. K. Lewis.

WE have given in full the title of this little book, as it states exactly what the contents really are. Its pages, the Professor states, owe their existence to a lecture delivered by him introductory to the course of instruction at the Army Medical School at Netley.

The investigations underlying the most important practical work of the military medical officer relate, we understand, especially to the causation of diseases, with a view to their prevention. There is no disease which apparently acknowledges a single cause; but rather there are many and ever varying factors or conditions which, as antecedents, combine to produce disease. Many physiological agents undoubtedly aid and abet these factors; but we must regard the physiological agencies themselves as competent, under certain abnormal conditions, of generating many forms of disease.

The author deals first with the elaboration of toxic alkaloids and of azotised uncrystallisable extractives from proteid substances, and shows how they are the necessary products of vital physiological processes. He next deals with the pathology and symptoms of poisoning by these bodies, poisoning as the result of an accumulation of normally elaborated but toxic products; and he thus accounts, after a careful study of the physiology and pathology of fatigue fever, for the origin of certain constitutional diseases, such as the typhus of armies and of camps. What is true of fatigue fever and of typhus fever, Sir W. AITKEN says is equally true as regards typhoid, and he is convinced of its occasional spontaneous origin.

The researches of Professor Gautier and others have now abundantly proved that not only after death, but even during life, the animal organism, by virtue of its physiological powers, is able to elaborate the alkaloids to which the name of leucomaines has been applied, bodies which are, many of them, essentially toxic in their properties, and which resemble so closely the poisonous cadaveric alkaloids to which Selmi first called attention. This subject receives due attention at the author's hands, who treats the whole question from its clinical aspect in a most creditable manner. The book, indeed, is well worthy of perusal, not only by the army surgeon, but also by

every physician who is interested in such an important problem in medicine.

The work that has been done and the discoveries that have been made in connection with these animal alkaloids are very extensive, but we cannot yet comprehend their full significance, far less forecast the numerous and important results to which we have every reason to believe they will lead. Therefore it is that, filled with hope and assurance, we look confidently forward, with Sir William Aitken, for more of the same thoughtful work, so as to accelerate those discoveries which promise such a great and glorious future for pathology and practical medicine.

THE NATURAL HISTORY OF COW-POX AND VACCINAL SYPHILIS.

By CHARLES CREIGHTON, M.D. London: Cassell and Co., Limited.

IT is important for the candid reader of this work to bear in mind the elementary and well ascertained facts as to the formation of matter. However much the cosmogony or creation of the world had puzzled philosophers of former ages, a fresh departure, made in 1797, placed the question in so clear a light that it makes a fit preface to the arguments of Dr. CREIGHTON. At that date we learnt for certain that a primeval point, or *punctum saliens*, of the universe, evolving itself by its own energies, moved forward in a right line, *ad infinitum*, till it grew tired. After which, the right line which it had generated began to put itself in motion in a lateral direction, describing an area of infinite extent; and, further, that this area, as soon as it became conscious of its existence, succeeded in forming a solid space, filled with vacuum—a suitable nidus for the generation of chaotic matter; from the accumulation or deposit of which, as a centre, suns were projected, and from them planets, resulting eventually in organisation. And as with the creation of other matter, so it has been, we now learn, with the creation of vaccine lymph; it had its own origin, and has since demonstrated its own inherent powers. Though discovered about the same time that the cosmogony was explained, we have hitherto been in the position of a Sanchoniathon, Berosus, or Ocellus Lucanus about its nature. And now Dr. Creighton has removed the veil which, for many years, had obscured its origin.

Thanks to an inspired evolution from Professor Hirsch, Dr. Creighton was able, some years ago, to assure us that small-pox was the linear descendant of an originally innocent eruption, occurring in prehistoric times, among dirty Indians and Africans; and had acquired its specific and communicable ability by powers, nowise originally possessed by it, but yet inherent in it, and depending upon circumstances for their development. To this luminous doctrine the present work is a sequel. Vaccinia, however, differs from small-pox in not having yet attained the ability to disseminate itself atmospherically; it is, indeed, within measurable distance of its origin, and cannot be supposed at present to possess its final powers. It has grown, however, from an antecedent ulcerative process in the cow—not, indeed, prehistoric, but in our times. Harmless pimples (harmless, but potential for harm) forming on a cow's teats become ulcers by the merciless manipulations of milkers; those pimples, instead of dying away as pimples should, obtain in their ulceration a specific, transmissible quality; and go on to become inoculable from cow to cow, from cow to man—in man commonly being vesicular, but always having a tendency to revert to the original ulcerative process of the cow. It is that reversion that constitutes "vaccinal syphilis." This "syphilis" has no concern with venereal syphilis. The ulcerated arms of individual children, and the groups of syphilitic inoculations that we read of, are alike manifestations of this reversion to type. As with "vaccinal syphilis" so, we know (on Dr. Creighton's authority), with venereal syphilis; it has originated at some time in a simple scratch or sore, and by degrees, as time and opportunity have been given it, it has become a transmissible disease.

All this is very conclusive and satisfactory; of evidence we have none; nor do such theses stand in need of evidence. In its place Dr. Creighton bases his claim to the verdict of the profession and the public largely upon abuse of the plaintiff's attorney. He shows up with much detail what he characterises as Jenner's sophistries and falsehoods. Readers who have not got at hand a library of early vaccination literature have scant means of learning the facts of that period for themselves; but we may observe in passing that they will do wisely to verify each statement of our author before accepting him. His chief claim to be heard, however, is based on his own certain and infallible knowledge; and he kindly warns the "apologists of a contrary doctrine that he appeals to facts that are as well authenticated as any facts can be;" and such people

must beware how they attempt to wrap themselves in any "mantle of orthodoxy." He does not attempt to add to our knowledge of the protective powers of vaccination; and he gives us no assistance towards reducing whatever of risk there may be in the operation as nowadays practised.

We could have wished that it had fallen within the scope of Dr. Creighton's essay to notice a hypothesis of Dr. Birdwood, of the ship hospitals, another recent contributor to the literature of small-pox. This disease, being primarily a skin affection, and caused by germs that reach the susceptible individual through the atmosphere, is confluent or discrete, severe or slight, according as more or less of the germinating matter happens to fall upon the skin of the individual. This is, of course, why a person living near a small-pox hospital is more liable to attack than a more distant person; this is no doubt the reason why the face gets most pustules; and this (though we never heard of the fact) is why persons of large superficial area obtain more numerous small-pox pustules than smaller persons. As the constitutional effect of small-pox results from the local complaint, a certain security against death as well as against attack should be possessed by persons having small dimensions. Dr. Birdwood's evidence on this point is not yet forthcoming, but for the present we may commend Dr. Creighton's book to his study, and bid him beware of holes, exposing needless skin, in the mantle of his orthodoxy.

A MANUAL OF BANDAGING, ADAPTED FOR SELF-INSTRUCTION. By C. HENRI LEONARD, A.M., M.D., Michigan. Second Edition. Baillière, Tindall, and Cox.

A HANDBOOK OF ROLLER BANDAGING. By FANNY E. FULLAGER. Griffith Farran. 1887.

AMBULANCE LECTURES. By J. M. MARTIN, M.D. J. and A. Churchill. 1887.

ACCIDENTAL INJURIES, THEIR RELIEF AND IMMEDIATE TREATMENT. By JAMES CANTLIE, M.A., M.B., F.R.C.S. William Clowes and Sons. 1887.

THE first of the above-mentioned works by Dr. LEONARD, of Michigan, is one of the clearest and best manuals of the kind we have seen. Certainly the preface tarnishes, to our minds, the brightness of the work itself, for it is truly, as he allows, a chapter of preliminary egotism to which we are unused in our sober ways. But the material contained in the book is so practically laid before the reader and so clearly given that we cannot help being more than pleased with the work. We do not know any manual on the subject so well illustrated, and the author has adopted a method which we recognise as extremely valuable and original. All his diagrams—and they number 139—are done in white lines on a black ground, with the result of making them far clearer than the usual diagrams. But not only are the diagrams clear, they are correctly drawn, and explain themselves in a way we rarely see.

Moreover, the explanations and directions for use are particularly good—concise, clear, and practical—and are evidently the outcome of a large experience in the manipulative work of bandaging. They are expressed with the downrightness for which our American brethren are proverbially famous, and we have here many common-sense remarks which will be useful to learners and to practitioners alike. In a small manual of 150 pages it would be difficult to find practical information so clearly and fully given.

It would be unreasonable to expect the work to give everything that could be given in a subject which allows of so many little fads and references according to such manipulator's fancies and dexterity; but the author has tried to include many other applications of minor surgery, and the first twenty-five pages are devoted to poultices, the use of charpie or cotton wool, and the different kinds of compress, while the last fifty pages include chapters on immovable dressings, strappings, and the different kinds of knots. But we would recommend the author to give the plan described in Hoath's *Minor Surgery* as by far the best direction for tying a reef knot, and one which every dresser ought to be aware of.

The work has deservedly reached a second edition, and we feel it can be cordially recommended as a sound and useful guide for English students and for nurses, and those wishing to learn more of bandaging than is usually learned in ambulance classes.

The second is a small sixpenny pamphlet of twenty pages, meant for pupils attending ambulance classes. It has a large number of illustrations, which certainly do not reflect credit on the draughtsman for their beauty, clearness, or correctness. We do not expect a

little book of this kind to contrast favourably with such a work as has been noticed above, but we feel that a simple work for beginners should be written clearly and illustrated well. Pupils of the ambulance classes will be wiser to get a better, if rather more expensive, handbook. There is one piece of advice the authoress gives, which is good if pupils will give themselves time to practise it, and which few refer to on teaching handaging, and that is to be able to use the right and the left hand in applying the bandage to opposite limbs.

In the ambulance lectures of Dr. MARTIN will be found very sound advice clearly given, and well illustrated. We have here six lectures which will serve as an excellent guide to those giving such a course, and at the same time they will be acceptable to pupils as a reference book of immediate aid to the injured. The language used is clear, and the advice full of common sense, which will be found useful, while the illustrations, which number fifty-three, are many of them very practical, as showing how to utilise simple means at hand. The lectures include (1) An Outline of the Human Body, with a description of the simplest or most necessary appliances; (2) Hæmorrhage and its Treatment; (3) Fractures; (4) Shock, Choking, and Suffocation; (5) Methods of Lifting and Carrying the Sick and Injured; (6) Nursing, and an Appendix on Roller Bandaging. The work can be strongly recommended.

In the small manual of Mr. CANTLIE, on Accidental Injuries, we have a fuller work than the last; and the fact that this is the twelfth edition is an evidence of its popularity. The name given to the subject is a rather faulty one; for whether the injuries are accidental or intentional can make no difference in the treatment to be adopted. It is not often that a work runs to twelve editions in four years, and we must congratulate the author upon his well-deserved success. In the present edition he has added a chapter on the systematised forms of loading, carrying, and unloading stretchers as adapted to civil life, and recommended by the St. John Ambulance Association, and as many as forty-two new woodcuts appear in the work. The style is clear, and the directions for the different kinds of bandaging, carrying, lifting, and improvising surgical appliances, are just what will prove useful to those wishing to profit by ambulance classes. It is, however, more a work of reference for beginners than the lectures previously noticed, and has evidently been extensively used by those who have had to prepare such lectures, as well as by the classes attending them.

UEBER DEN EINFLUSS DES KOCHSALZ UND GLAUBERSALZHALTIGEN MINERALWASSERS AUF EINIGE FACTOREN DES STOFFWECHSELS. Von Dr. B. LONDON, Carlsbad.

THE action of mineral waters containing chloride and sulphate of soda upon the nitrogenous exchanges in the body, as well as on the excretion in the urine of the sodic chloride of the food, has received much attention of late years; but the results obtained by different observers cannot be said to agree very closely. Seegen, for example, in some papers of his we reviewed some time ago, maintained that the ingestion of sodic sulphate diminished the nitrogenous waste of the tissues, the body thus becoming richer in nitrogenous compounds, but poorer in the non-nitrogenous, particularly the fats. In the excrements, however, he found no diminution in the amount of nitrogenous substances, but the water of the feces was increased, and the amount of urine either unaltered or diminished in quantity. Other observers, on the contrary, such as Bischoff, Voit, and Pettenkofer, etc., have obtained different results. Bischoff, for instance, found that a large addition of sodic chloride to the food increased the urea excreted; the quantity rising in proportion to the volume of water poured out; the ingestion of much water also causing a similar increase. And according to Voit, an augmented nitrogenous tissue-waste occurs in consequence of the ingestion of sodic chloride, a decided diuretic action also manifesting itself. The endosmotic equivalent of the sulphate he further found to be greater than that of the chloride.

The results of a great many other observers are given as to the increased consumption of albumen in the tissue cells when water is imbibed in considerable quantities; and reference is made to Professor Hay's conclusions that a very slight increase in the urea excretion occurs when sodic chloride and sulphate are largely taken, and that after some hours diuresis sets in with consequent concentration of the blood.

Although the author, as the result of a series of carefully conducted and laborious experiments with Carlsbad mineral waters, was unable to arrive at any positive conclusions as to the excretion of nitrogen and the albumen exchanges in the organism, yet he uniformly found that the ingestion of these waters increases the excretion of the urine, the increase following very rapidly on the ingestion.

He likewise observed that where the body is methodically flooded by the mineral water, the circulation of the lymph in the tissues is quickened, the organic activity is increased, and in the more copious amounts of fluid poured out at the kidneys, concretions of different kinds may be eliminated. Further, the peristaltic activity of the intestines is heightened in a painless fashion, leading to more copious motions without diarrhoea.

IGNAZ PHILIPP SEMMELWEIS: EINE GESCHICHTLICH-MEDICINISCHE STUDIE. Von Dr. JACOB BRUCK. Wien: Karl Prochaska.

In the first chapter of this monograph a sketch is given of the early history of puerperal fever as it occurred in some of the chief lying-in hospitals in Europe, so far as any reliable records are available; and we learn that the mortality from this cause varied greatly, sometimes being as low as $1\frac{1}{2}$ per cent., and sometimes as high as 26 per cent. Till Semmelweis's time the theories held as to this disease were of the vaguest and most varied kind. He appears, however, to have been really the first to regard it as the result of a wound infection, and as a process identical with pyæmia. Indeed, he laid it down as a fever produced by the absorption from the inner surface of the uterus of decomposed animal matter, generated in the patient herself, or conveyed to her by unwashed hands or instruments.

Semmelweis's life was really a short one, for, born in 1818, he died in 1865, at the early age of 47; but short as his life was, his energy and genius enabled him to accomplish much.

The evil effects produced by the contact of dead animal matter with the genitals of pregnant or lying-in women, conveyed on the fingers of students or medical men from the dead house or dissecting room, were clearly recognised by him, and we find him in 1847 recommending the hands of all who had to do with the lying-in room to be thoroughly washed in chlorine water. By this means he was able greatly to reduce the mortality in his wards. Not only did he recognise the poisonous character of putrid animal matter, but he likewise regarded the living secretions as being capable, under certain conditions, of producing puerperal fever; and he pointed out the dangerous qualities of the lying-in chamber, if tainted with animal exhalations. We notice further that he brought his views forward in London in 1848, and a paper of his is to be found in the *Medico-Chirurgical Transactions* (vol. xxxiii) "On the Causes of the Endemic Puerperal Fever in Vienna." But little attention, we are sorry to say, appears to have been paid to his theories, although their truth we are now bound to acknowledge. Semmelweis was certainly, in some respects, in advance of his time, and this led ultimately to his withdrawal from Vienna to his native Pesth. During his six years' superintendence of the St. Rochus's Hospital in that city only eight deaths occurred from puerperal fever in 938 deliveries. In 1855 he was appointed professor of midwifery at the high school. His prophylactic measures against the occurrence of puerperal fever consisted, as far as possible by the means at his command, in hindering the entrance of decomposing materials from without, in preventing internal decompositions, and in removing at once any products of these decompositions. He further tried to introduce these antiseptic measures into operative gynaecology. In some measure we may therefore say, without detracting in the least from the honours so deservedly due to Lister, that Semmelweis anticipated some of the antiseptic methods of that distinguished surgeon.

The whole monograph must prove most interesting to all obstetric physicians, and the author deserves every credit for the able manner in which he has advanced the claims of Semmelweis, a physician who certainly deserves to have his name held in thankful remembrance by his fellow citizens.

MATERNITY, INFANCY, AND CHILDHOOD: Adapted especially to the Use of Mothers, etc. By JOHN M. KEETING, M.D., Visiting Obstetrician, and Lecturer on the Diseases of Women and Children, Philadelphia Hospital, etc. Edinburgh: Young J. Pentland. 1887.

The supply of works, large and small, on the hygiene of pregnancy and the care of infants is certainly, so far as number goes, in excess of the demand, and an addition to the number is only justifiable if the work is one of decided merit. The author really appears to have complied with this condition; the numerous practical suggestions distributed throughout the book testify to his experience of the subjects he treats, and his style is pleasing as well as clear. It is obviously difficult to say anything new with respect to the precautions to be taken during pregnancy, or the management of the new-born infant; but there is scope for observation and improve-

ment when we come to the question of rearing infants by any other than the maternal supply.

Mothers and nurses can never be too strongly impressed with the necessity for caution in the preparation and administration of the artificial food to which recourse must be had. A number of useful formulae are given for making cow's milk resemble the human secretion; but they all contain milk-sugar, a substance which, as the author himself informs us, is peculiarly liable to turn acid. We may note that the author prefers the "average" mixed milk to that obtained from one cow, except in the country. The directions for peptonising milk are quoted from a lecture by Mr. Fairchild, and cover the whole ground; but the author abstains from offering any opinion as to the value of this method of feeding—an unfortunate omission, even if intentional, for it is a department which is just now to the front.

The lists of different foods comprise many not known in this country. With reference to weaning the child, Dr. Keeting is of opinion that, after four or six months' nursing, the gradual addition to the dietary of a bottle is of advantage, and he gives some useful hints as to the choice of season. Dr. Keeting sets his face against the indiscriminate use of perambulators, the evil results of which "any mother can see for herself by going to one of the city parks," and mothers would do well to bear his remarks in mind.

The author disclaims any intention of countenancing the administration of drugs, except when ordered by medical men; but he is too liberal in his allusions to the effects of this or that drug, items of information which directly conduce to that undesirable result. It seems extraordinary that he should find it necessary to warn parents that "it is a very great mistake" to procure sleep for their children by means of "bromide, valerianate of ammonia, brandy, or gin." Is it not rather an exaggeration to ascribe rickets in the children of the well-to-do to "high pressure and nervous exhaustion," etc.? High pressure is the fashionable bogey just now, but it can scarcely operate at an age when rickets is to be feared.

Chapter xii, on Diseases of the Ear and Eye, is written by Dr. Turnbull. Both Dr. Keeting and his colleagues attach great importance to children being taught to blow the nose properly, and allude to this very frequently. Dr. Turnbull relies on Valvalva's method for the relief of many aural symptoms, but he omits to convey the necessary caution as to its use. He trespasses a good deal on what should be the exclusive domain of the medical man, but in other respects this chapter is very recommendable. The chapter on Nasal Affections, by Dr. MacCoy, of Philadelphia, is rather too technical for the ordinary reader. The chapter on Throat Diseases is not equal to those which precede it, and the author's classification is obscure indeed. Nevertheless, the book as a whole undeniably attains a high standard of excellence, and may safely be recommended as a reliable and comprehensive guide to the management of childhood.

NOTES ON BOOKS.

Sprains, their Consequences and Treatment. By C. W. MANSELL MOULLIN, M.A., M.D., F.R.C.S. 1887. (H. K. Lewis: London).—We have in this volume a carefully written essay on the subject, rather dealing with it from a philosophical point of view than from the practical view of the lecturer to popular ambulance classes, or even as adapted to the wants of the busy practitioner. The general principles of treatment are very carefully and fully considered, but it would be difficult for student or practitioner to learn what the author would recommend as the most appropriate treatment in sprain of any particular joint. It should rather be read by the student before he begins to see the practice of surgery, and much as we recognise the soundness of the views held by the author, we do not think the work so likely to be popular as the more practical ones which are now issued. And yet there is very much that is practical, rather hidden away in the masses of this volume, for the chapters on treatment by heat, cold, pressure, rest, forcible manipulation, and massage, are very complete, and make up a large proportion of the book. The whole is carefully written, and will repay thoughtful perusal, for the author, though strongly in favour of active measures of manipulation when joints have become fixed, is inclined to the simpler forms of treatment in ordinary cases, and the bolder methods of some modern writers are looked upon with only partial favour. The chapter on massage is particularly good, though it assumes more knowledge of the process than is often possessed, and its mode of application to different limbs is not sufficiently described. There is, however, much

in this book that does not readily appear, and we would recommend a much fuller index than at present exists, for the reader loses much that would prove useful to him for reference.

The Asclepiad. No. 16, Vol. iv.—This number begins with a lengthy article on the Clinical History of Scarlet Fever, in which Dr. RICHARDSON discusses several questions of special interest at the present time, when the recent epidemic of the disease in the metropolis seems to be on the wane. As to the occurrence of scarlet fever at different periods of life, he shows that it attacks most frequently in the third and fourth years of life. In London the chief incidence of the disease is in the four months from September to December, inclusive, whilst in New York, during the months from July to November, inclusive, the death-rate from the disease is below the average. As to the recurrence of scarlet fever in the same individual, the author states that he can discover, neither in literature nor in general experience, a case in which a second attack of scarlet fever has proved fatal. The mortality from the disease, its types, idiopathic and rheumatic scarlet fever, the pathology and poison of the disease, and its treatment, are headings of sections of this useful article. The Physiology of Good and Evil, forms the subject of an article, which is closed with the following dictum, that "Emphatically, science re-echoes the saying in all its solemn import; 'The wages of sin is death.'" A biographical sketch of John Brown, M.D., and the Brunonian system follows, in which the traits of character and person of that physician are well portrayed; whilst a portrait of him occupies the place of honour at the beginning of the book. A few other short articles go to make up the substance of this number, which, with the index and table of contents thereto appended, completes the fourth volume of a work which, whatever else may be thought of it, still maintains the character for industry and speculation of its author.

Dermatitis Venenata: An Account of the Action of External Irritants upon the Skin. By JAMES C. WHITE, M.D. (Boston, Mass.: Cupples and Hurd. 1887).—Under the title *Dermatitis Venenata* Dr. White has given the profession a book which, as a work of reference, will be useful to all those engaged in the practice of medicine, and will be indispensable to all those who are more specially interested in materia medica. He has discussed in a clear, concise, and systematic form the action of all substances belonging to the vegetable, animal, and mineral kingdoms which are known to produce dermatitis when applied to the human skin. Dermatitis of this kind is common among dyers, printers, chemists, silk-weavers, manufacturers of coloured papers and cloths, soap-makers, etc., and amongst a different class of persons, those, namely, who not infrequently irritate their skin by the use of cosmetics. The list of substances whose action is discussed by Dr. White is very large. The work is entirely systematic, and is written in a scientific spirit. As a solid contribution to practical medicine, we cordially recommend it to our readers.

The Diagnosis and Treatment of Eczema. By TOM ROBINSON, M.D. (London: J. and A. Churchill. 1887).—Dr. Robinson has had considerable experience in observing and treating eczema, and has assimilated with more or less success the ideas of Professor Laycock, Sir James Paget, and Mr. Hutchinson; we fear not always with complete success. Dr. Robinson believes that eczema is due to a physical peculiarity in the structures of epiblastic origin, and that persons who have the eczematous diathesis have certain peculiarities, namely, "a tendency to become bald or grey early in life; their teeth degenerate early, sometimes the incisors are pitted or marked transversely, they wear down and fall out in some instances in the most unexpected way. The nails are also of great interest in those patients, and present many forms of malformation; in some instances they are marked by white spots or white transverse lines, they are pitted with small circular depressions, or they are marked by transverse furrows; the longitudinal flutings are exaggerated in others. The shape of the nail is also of importance. It is often flat, sometimes even concave in its upper surface, and is frequently shaped like a shield; and they are often the subject of fatty degeneration of the cornea, constituting the state which is called *arcus senilis*." The chapters on the diagnosis and treatment of eczema contain nothing that calls for remark.

Letts's Medical Ledger. (London: Cassell and Co., Limited).—This handy volume has been arranged with the object of facilitating book-keeping, and lessening the trouble which the practitioner incurs in keeping his ledger. It is arranged for use in conjunction with *Letts's Medical Diary*, and is calculated to render the keeping of accurate accounts, without unnecessary detail, a matter of easy attainment. When the diary has been used as a journal, the data

are then posted to their respective accounts in the ledger. The use of abbreviations in these books materially lessens the amount of writing which is required when ordinary daybooks and ledgers are used. The publishers of the *Medical Ledger* state that they will be glad to receive suggestions for the improvement of the work, which, we may remark, is published in foolscap size, with 400 or 500 pages; also in quarto, with 200 or 400 pages.

The Climatic Treatment of Phthisis in the State of Colorado. By M. CHARTERIS, M.D.—In this little pamphlet Dr. Charteris gives the results of an autumn visit to Colorado, with some remarks on the climate of that picturesque State and its adaptability to the case of the consumptive. He claims for Colorado that it possesses all the advantages which have made Davos famous, with the additional recommendation that it is suitable for continuous residence throughout the year, and offers the prospect of remunerative employment to those who are sufficiently recovered to resume their avocations. These are solid advantages, and in view of them, and in the growing popularity of high altitudes in phthisis, it is not surprising that our American brethren unhesitatingly give the palm to Colorado among the multitude of competing sanatoria for phthisis. Dr. Charteris advises that the consumptive should pass the winter at one of the health resorts in Colorado, of which Colorado Springs seems the most desirable, and then proceed to a ranche in the spring. By this means the essential point of continuous open-air life may be secured, and well-paid though rather rough work may be obtained by those who desire it. We are somewhat surprised that Dr. Charteris should include Denver, a town with 80,000 inhabitants, among the desirable places for the consumptive, as the noxious influence upon phthisis of the air of large towns is now well understood; and his own figures show that in 1886, of 991 deaths in Denver, no fewer than 186 were due to phthisis—a proportion higher than that of some English cities. He shows, however, that of this number only twenty contracted the disease in Colorado, which confirms the growing impression that the air of high altitudes is infinitely more efficacious for prophylaxis than for cure. It seems not improbable that in the case of persons with hereditary consumptive tendency, or who are otherwise threatened with the disease, the routine treatment will one day include resort to one of the high-altitude stations. Dr. Charteris gives a few cases in illustration of his views, but the clinical details might have been more fully given. His views generally on climate are up to date, but some questionable statements are made, such as the remark that a sea-voyage tends to produce hæmoptysis. It would be a misfortune if the idea should prevail that hæmorrhage was any decided contraindication to allowing the consumptive the excellent chance of recovery which a prolonged residence on shipboard in some cases affords. There is really no evidence to prove that this opinion is correct.

Outlines for the Management of Diet in Health and Disease. By EDWARD TUNIS BRUEN, Physician to the Philadelphia and University Hospitals. (Edinburgh: Young J. Pentland. 1887).—This book is one of the "practical lessons in nursing" series, and its substance was originally delivered to the nurses of the training schools of the Philadelphia, University of Pennsylvania, and women's hospitals. The first chapter takes up the elementary physiology of digestion; but, bearing in mind that the work is presumably destined to educate and instruct non-medical persons, the author has failed to place himself on a level with his readers. He talks of "metabolism" and "assimilation," "succus entericus" and "arterial tension," without reflecting that such terms must be difficult of comprehension to persons outside the pale of the profession. The same fault pervades the subsequent chapters. The information, for example, that nitrogenous principles undergo resolution into urea and a "complementary hydrocarbonaceous product" is of doubtful value. There is an extensive tabulated list of food substances arranged in the order of their digestibility, in which black tea is classed as "easy of digestion," and apples rank with cooked fruits. With due allowance for individual peculiarities, however, such lists may doubtless serve a useful purpose. The author very properly objects to the habitual use of alcoholic beverages, except when prescribed by the physician as medicine, but it is open to doubt whether the cocoa milk substitute will become popular in lieu thereof. His advice to elderly people to partake of brandy, whisky, or gin "just before or with the meals" savours of physiological heresy, as does the permission given subsequently that tea may be used "without detriment if taken without food," but, in justice to the author, it must be remarked that he inculcates the greatest caution and reserve in the use of stimulants, whether alcoholic or otherwise. Water is evidently the author's favourite beverage.

and "should be freely used between meals." We cannot subscribe, moreover, to the assertion that "inorganic substances in drinking water, unless they carry with them sewage matter, are unpleasant rather than harmful." It is hardly correct either that charcoal is the only depravative substance which can be safely and yet effectively mingled with water without communicating taste or hurtful properties. Random statements of this kind do not add materially to the value of the book. Allusion is made to the "popular fallacy" of supposing that better milk can be obtained from one cow, and the mixed supply is preferred, but it is a most dangerous fallacy on the author's part to assert that placing milk on ice "obviates any probability of the transmission of poisonous microbes into the system." The addition of two ounces of lime water to half an ounce of milk is certainly excessive, though this mixture is credited to Meigs. Perhaps two ounces is a misprint for teaspoonfuls, which is ample. On the whole the book is not up to the usual mark, although it contains much information of a practical kind.

THE *Diary* for 1888 of the *Sanitary Record and London Medical Record* goes far towards attaining the object which has been held in view in its preparation, namely, to provide a handy and compendious *vade mecum* for the professional man and sanitary official—a book in which he may not only record his appointments and doings of each day, and be reminded of duties which the recurrence of particular dates imposes upon him, but to which he can turn with confidence for facts, figures, statistics, suggestions, instructions, references, addresses of societies, and manifold other hints and helps for which he must otherwise have recourse to a whole library of books. Besides the *Diary* proper the volume contains a full and careful review of the Acts on sanitary matters passed during last session; an account of the various diplomas in public health which exist, and how to obtain them; an article on the duties of householders; instructions as to vaccination, both with human and with animal lymph; abstracts of the statute law as to various sanitary subjects; an interesting article by Mr. Geschen on the reform of local government; and a quantity of other generally useful information such as is continually wanted. Such a book is of constant value to persons engaged in sanitary work.

Medical Diagnosis: A Manual of Clinical Methods. By J. GRAHAM BROWN, M.D. (London: Simpkin, Marshall and Co. 1887).—Dr. Graham Brown's work has reached a third edition in a very short time, and the present issue fully justifies the favourable notice we gave of its predecessors. The book is admirable, full of valuable information, which is given in the most concise and yet intelligible manner. It is primarily, of course, a student's handbook, but the student's teacher also will find it a useful book of reference to remind him of methods not in every day use, and to refer him to authorities where fuller details may be obtained if desired. The style is so condensed as to be by no means easy reading. This however is, in our opinion, a recommendation, for the book should be in the student's hands at the bedside and in the clinical laboratory, where the facts themselves may be studied with its assistance. It were ungracious to find fault where nearly everything is excellent, yet we may be allowed to point out that in estimating the high tension of the pulse, no warning is given of recurrent pulsation. This is a matter of importance, but almost invariably omitted from clinical handbooks. A little fuller account of Ehrlich's method of staining the tubercle bacilli is desirable; in our hands this has proved by far the most reliable method, but it will certainly not be found satisfactory if employed exactly as described by Dr. Brown. We would suggest, too, that Sir William Roberts's simple and essentially clinical methods of estimating albumen and sugar in the urine might find place in the book. Dr. Graham Brown is to be congratulated upon the success of his book, and we recommend it strongly.

DONATIONS AND BEQUESTS.—The Earl of Derby has given £1,000 to St. Mary's Hospital, Manchester.—Mr. Anna Maria Hargreaves bequeathed £500 to the Halifax Infirmary.—"A. F. F." has given £300 to the Hospital for Sick Children.—The Misses Fairfax have given 100 guineas to the Great Northern Central Hospital, to name a bed.—The executors of the late Mr. John Henry Smith have given £100 to the London Hospital.—The Hereford General Infirmary has received £100 under the will of Mrs. Ann Powell, of Whitecross Lodge.—The Royal Hospital for Diseases of the Chest has received £100 under the will of Mrs. E. Chambers.—"M. T." has given £100 as a Jubilee Donation to the British Home for Incurables.—"A Friend to the Hospital" has given 50 guineas to the Dental Hospital of London.—The Goldsmiths' Company have given £50 to the Metropolitan Convalescent Institution.

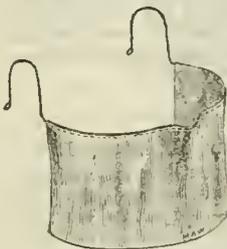

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS, IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

ORO-NASAL VEIL ESPECIALLY ADAPTED FOR OPHTHALMIC PRACTICE.¹

By JOHN WARD COUSINS, M.D. LOND., F.R.C.S.,

Senior Surgeon to the Royal Portsmouth Hospital, and to the Portsmouth and South Hants Eye and Ear Infirmary.

THE veil represented in the engraving will be found very serviceable and convenient by many practitioners engaged in ophthalmic work. During the examination of the fundus of the eye, especially by the direct method, the faces of the surgeon and the patient are separated by an interval of only a few inches, and the respiratory exhalations of many patients under such close adjustment are often very unpleasant and disturbing. The veil is suggested as a simple protection against the expiratory interchanges which occur during close examination; and, from personal experience, I can recommend its use to any of my professional brethren who possess a sensitive

olfactory organisation, and who are called upon to labour frequently in the out-patient department of an ophthalmic hospital. It consists of a silk curtain, suspended from a frame of silver wire, which is shaped to rest upon the nose and over the ears in the same way as a pair of spectacles. The nasal loop is curved downwards for the purpose of carrying the veil over the nose, and keeping it from coming into direct contact with the respiratory orifices of the wearer. The frame is made of flexible wire, and can be bent to fit the face accurately so as to exclude the direct passage of air. Many of my friends have already used this simple contrivance in their practice, and they have found it to be a surgical comfort of great utility. Sometimes I use it during laryngoscopic examination. The veil can be obtained, very neatly made, from Messrs. Maw, Son and Thompson, at a trifling cost.

VAN ABBOTT'S GLUTEN PREPARATIONS.

We have received from Messrs. Van Abbott, 5, Princes Street, Cavendish Square, the well-known manufacturers of gluten bread for diabetic patients, samples of gluten butter biscuits, gluten buns, and almond cakes, sweetened with saccharin.

The butter biscuits and buns contain only as small a percentage of starch as is absolutely requisite to hold the gluten together—namely, 1.6 and 1.9 respectively. The almond cakes have 3.8 per cent. of starch, with 4.1 per cent. of sugary matter.

The preparations are flavoured with saccharin, the new sweetening principle, which thus finds its most legitimate application. Unfortunately, its taste is so persistent as to outlast for hours that of the articles of food flavoured with it, even if the quantities used are exceedingly minute. Nevertheless, we doubt not that these new sweetened gluten preparations will find favour.

G. AND G. STERN'S "PUMILINE."

THE *Pinus Pumilio* is a species of pine growing at various altitudes among the Alps. It is a fairly large tree on the lower levels, but above the line of perpetual snow it never reaches a condition beyond that of a small tree or shrub. It has long been observed that patients suffering from diseases of the throat and lungs, or from rheumatic and similar affections, derive benefit by residing near or amidst pine forests, and it is claimed for the *Pinus Pumilio* that it has more medicinal activity than other pines. The use of the products of this tree, apart from residence near pine woods, has been shown to be of very considerable value in the treatment of the diseases above-mentioned. The volatile oil obtained from *Pinus Pumilio* certainly differs in its peculiar fragrance and in other physical properties from oils yielded by most other coniferous plants. That obtained from the trees growing above the snow line is stated to be superior in medicinal activity to that obtained from trees growing in the valleys.

¹ Exhibited in the Ophthalmic Section, at the Annual Meeting of the Association Dublin, 1887.

Specimens of pumilino essence, pumilino extract, and pumilino jujubes have been submitted to us by Messrs. G. and C. Stern, of 11, Billiter Square. The essence is the volatile oil obtained only from trees growing above the snow line. It is very fragrant and agreeable, and can be employed in a great variety of ways, either internally or externally.

The extract is obtained from the needles and young shoots, and is of the consistence of thick treacle. It is used for baths, and as an external application in gout, rheumatic, and neuralgic affections. The jujubes are very palatable, and possess a most agreeable aromatic flavour.

MACKESSON AND ROBBINS'S CAPSULED PILLS.

We have received from Messrs. Mackesson and Robbins, of New York, a sample of their capsuled pills containing one-sixtieth of a grain of strychnine. They are recommended as being useful in the cure of dipsomania. They are, like all the pills made by the firm, ovoid in shape, and hence can be more readily swallowed by many patients than those of the ordinary round shape. They are elegant in appearance, and the covering is tasteless and perfectly soluble.

DAHL'S DYSPEPSIA CAKES.

DYSPEPSIA CAKE MANUFACTURING COMPANY, BROOKLYN, N.Y.

THESE biscuits are prepared from the outer layers of cereal grains, in which a considerable proportion of albuminoids, fat, and phosphoric acid are contained, and which, in larger or less proportion, enter into the composition of brown or whole meal bread.

In spite of the somewhat unprepossessing and woody appearance of the dyspepsia cakes, we found the percentage of indigestible fibra (cellulose) to be only 4.4, whilst there are no less than 13.5 per cent. of albuminoids, with upwards of 4 per cent. of fat. The cakes are, therefore, highly nourishing.

LIQ. CAULOPHYLLIN ET PULSATILLÆ CO. (OPPENHEIMER).

THIS preparation is recommended by the makers (Messrs. Oppenheimer, of Sun Street, Finsbury Square), as well as by independent medical testimony, as being a good uterine tonic, and useful in the treatment of painful, suppressed, and excessive menstruation. It is also stated to restore tone to the whole genito-urinary system. It is a well-made preparation.

THE ICTHYOL COMPANY'S PREPARATIONS.

ICTHYOL is a substance obtained by processes of distillation from peculiar fossil deposits, consisting largely of fish. It has an odour not wholly unlike that of cabbage, and contains a considerable proportion of sulphur, much of which is unoxidised. A few years ago Dr. P. G. Unna, of Hamburg, called attention to the therapeutic properties of ichthyol. Since then its effects have been tried by many medical men, chiefly in Germany. We believe that it has not been extensively employed in this country, but the Ichthyol Company (Cordes, Hermann and Co.), of Hamburg, now offer several of its preparations both for internal and external use. It has been advanced with great weight that ichthyol is curative in many skin diseases, for example, eczema, psoriasis, ichthyosis, etc., and that it is of great value in rheumatism, lumbago, and similar affections. Ichthyol can exist in combination with many bases, but the ammonium sulph-ichthyolate is generally recommended. This, however, has a somewhat unpleasant taste, and is therefore best taken internally in the form of pills and capsules. It is also put up in the form of ointment for external use, as well as of a soap for rough skin and chapped hands.

An alcohol-ethereal solution can be used as a spray in headache, neuralgia, and an ichthyol plaster and wadding are also employed. The various preparations forwarded to us by Cordes, Hermann, and Co. form a most excellent and convenient series.

CASCARA SAGRADA FRUIT LOZENGES (SACKER'S).

ONE disadvantage in prescribing liquid preparations of cascara sagrada is that they impart to mixtures containing them a very bitter and unpleasant taste. The lozenges made by Mr. W. E. Sacker, of 79, Fenchurch Street, contain the active matter of the bark of rhamnus purshiana (cascara sagrada), mixed in such a manner with a fruit paste that the bitterness of the drug is very well disguised. We have found by experiment that they are effectual as an aperient, and at the same time they are fairly palatable. The dose for an adult is from one to three lozenges.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1888.

SUBSCRIPTIONS to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the West Central District Office, High Holborn.

The British Medical Journal.

SATURDAY, JANUARY 14th, 1888.

THE UNIVERSITY OF LONDON AND DEGREES FOR LONDON STUDENTS.

THE Senate of the University of London had under consideration, on Wednesday last, the question of opposing the granting of a charter to the Royal Colleges of Physicians and Surgeons of London, for the purpose of conferring degrees of medicine and surgery. The Senate discussed this question in a large spirit, concerning itself only with its position as an University of London, and whether the principle of granting degrees in medicine and surgery by a body other than itself should, as such, be opposed or accepted without opposition. It resolved that neither its own interests nor the public interests required that it should offer such opposition, seeing that there was a general opinion in the profession that increased facilities for graduating in medicine and surgery in London should be secured for the students of the metropolitan medical schools. The resolution to this effect (which was carried only by the casting vote of the chairman) was accompanied by the expression of an opinion that the degree should not be granted except upon satisfactory evidence that the preliminary education was not inferior to that required by the Universities generally, and that the charter should not confer retrospective powers of granting degrees. These, of course, are only pious opinions; and inasmuch as the Universities of Durham and Aberdeen, as was pointed out, confer their degrees, the one after a very moderate amount of evidence of preliminary education, and the other on the production of the ordinary certificate of registration as a medical student, this recommendation has no very stringent or deterrent character, and does not involve even any hypothetical difficulties. Thus far the way has been cleared in a very satisfactory and encouraging manner for the acceptance by the Privy Council of the principle of granting increased facilities for the obtaining of higher medical titles by the students of the great metropolitan and other schools in England. The University of London is the body most directly concerned in the application, in so far as its privileges and monopolies might have been supposed to be attacked by the new proposals. In the general interests of the profession they have waived any such claims, and have not stood upon their special or selfish interests. On the other hand, it is to be feared that the creation of a teaching university will be very prejudicially affected unless those who are more immediately concerned in the creation of the new degree-creating power combine to give that attention to the details of the new scheme for which the way is now cleared. The Senate of the University of London is quite outside the discussion of the question of the constitution or scheme of the newly proposed graduating body of the Colleges, and

they have merely signified that they do not consider that their interests call upon them to interfere with any such scheme. Obviously, however, the profession must now look after itself. The crudities and injustices of the scheme of the two Colleges remain untouched. With the principle of the creation of such a body we are all agreed; and the manner of its constitution and government are the points at issue. The University of London has behaved with striking magnanimity and wisdom. The rest must be done by the profession itself. The Privy Council will meet on January 16th formally for the purpose of taking cognisance of such petitions and opposing clauses as may have been lodged; but we understand that no active steps will be taken in the matter till after the meeting of Parliament.

COLLEGIATE GOVERNMENT.

THE recent address of the President of the South-Western Branch of the Association deals usefully with the pending questions relating to the constitution and government of the Royal College of Surgeons of England. Such addresses and discussions enable the Branches of the Association to fulfil one of their most valuable functions—the discussion of principles and details affecting the duties and privileges of the profession in their relations to the State, to the great corporate bodies, and to the public. Mr. Swain is one of those public spirited and able provincial practitioners who turn occasionally from personal cares and local occupations to the contemplation of the larger professional interests and relations of the body to which he belongs; the practitioners, removed from the immediate personal influence of the metropolitan circles which are constantly engaged in the conduct and government of the corporations seated in London, are able to bring to the discussion minds uninfluenced by the peculiar assumptions which naturally pass current in official circles and among their junior surroundings, of the divine right of hospital surgeons and physicians, belonging to the “great hospitals,” to govern the whole profession. In earlier times, this excessive preponderance was gained by the isolation of provincial towns and districts, the difficulties of transit, the absence of opportunities for literary intercommunication by means of widely-read journals, the force of old central and narrow monopolies, the relatively low level of medical education amongst all but a very limited number, and the absence of any efficient organisation or representation of the great mass of the profession. The growth of higher education, the rapid and easy communications of modern times, the creation and organisation of the British Medical Association and its Branches, the part of modern journalism, and the universal acceptance of the principles of fair representation as the only true basis of government have altered all this. But, not unnaturally, those in possession are slow to recognise and loth to accept the inevitable reforms which such changes bring. Without any charge of abuse or nepotism, it is plain that the distribution of the large annual income divided by the Council among its members in their other capacity of examiners self-appointed, so to speak, in itself gives an insensible bias to regard with complacency a state of things which brings about not unpleasant results. The rich prizes which are thus dangled before the eyes of the younger members and those able outsiders who are on their probation are not without their legitimate and necessary influence. The atmosphere of the Council chamber and its vicinity have a placating influence which not all can resist. All this is not specially and

peculiarly applicable to the existing circumstances of the College of Surgeons; it is the universal experience of history, and applies to the best of men in the best of worlds. The somniferous content of the possessors and incumbents of power and place is historical, and belongs to human nature, of which it often nourishes, assimilates and digests some of the best qualities. Mr. Swain assigns their due part to these influences and characteristics of humanity, abstaining, as is meet and just, from making any personal imputations. He summarises generally the facts, figures, and arguments which we have recently submitted to the profession as the bases of the demand for collegiate reform; and we are glad to see that he and his audience are, like the rest of the profession, generally in accord with them. As a Fellow of the College he fails in sympathy with the Members. It is a not uncommon weakness—in fact it is that which he protests against in others—that he does not feel the pinch of the shoe on any other corns than his own. He is fully conscious of the public mischiefs and peculiar injustices of the inadequate powers of the Fellows in the government of the College; but, although the Fellows are in a very small minority, and the Members are the overwhelming majority, and furnish the great bulk of the revenue, he, as a Fellow, thinks the Members may be very well left without any representation at all, or that the Fellows should be asked to represent them. He repeats the old fallacy, that the man who passes a higher examination in surgery, gets his certificate accordingly, and his passport to whatever professional distinction and public and private employment it may secure him, not for these purposes, not for that which the certificate and title represents to the public and profession, but for a political purpose—“the sole remaining privilege,” whatever that may mean, of sitting on the Council. In other words, the certificate of a further and final examination in surgery has, in this absurd hypothesis, its value more as representing a possible political monopoly. Even if this extraordinary contention were acceptable to reason and experience, as a judicious suggestion of motive, it would have neither logical nor political validity in the case. It is of course a far less disputable or imaginative proposition that the freemen of the old limited boroughs paid their fees and took up their freedom with the view of obtaining the “sole privilege,” as it actually was, of having a very influential and profitable vote for a member of Parliament, a privilege for which some of them obtained much emolument and received many benefits. That was not held to be a valid reason against a great extension of the franchise to its natural constituency. Mr. Swain may be sure that the Fellows will not succeed in their own claims by depreciating the far larger and more obvious constitutional claims of the Members. The two causes are really one, and by endeavouring to separate them he is only weakening that in which he is more particularly interested.

A NEW HYPNOTIC.

A new hypnotic, which appears to possess certain advantages, has been recently introduced by Professor v. Mehring; it is said to occupy in its physiological effects an intermediate position between chloral and paraldehyde. It has been called amylen hydrate, and is sold under that name, but chemically it appears to be tertisry amylic alcohol; it was originally discovered by Wurtz, and in constitution it is said to be dimethylethyl carbinol $\left. \begin{array}{l} (\text{CH}_3)_2 \\ \text{C}_2\text{H}_5 \end{array} \right\} \text{C.OH}$. It is a clear,

colourless, slightly oily liquid, which floats upon water, having a sp. gr. of 0.81; it boils at a little above the boiling point of water, 102.5 C. It has an odour resembling paraldehyde, with a faint suggestion of camphor; it is warm in the mouth, and has a hot aromatic taste, with a slight pungent after-taste. It is only slightly soluble in water, though freely in alcohol, and v. Mehring recommended it to be given with extract of liquorice, but Dr. Scharschmidt, who has recently reported on an extensive trial of the drug in Professor Jolly's wards, states that a satisfactory mixture is made by adding it to a little red wine, sweetened with sugar.

Experiments on dogs showed that the first effects of the drug were on the cerebrum, the animals falling in ten minutes or half an hour into a deep sleep; as the dose was increased the medulla oblongata became affected, respiration became slower, death being brought about by arrest of the heart, reflex action having previously disappeared. In doses sufficiently large to procure deep and prolonged sleep, however, these effects on the heart and respiration were not produced. In the dog,

the respiratory movements fell from twenty to sixteen, a fall which is not greater than that which occurs in normal sleep; the differences in the pulse rate and blood pressure were hardly perceptible. v. Mehring gave the drug to sixty patients in doses varying from 46 to 77 grains, he observed no unpleasant after-effects, no nausea, headache, or digestive disturbance. Scharschmidt found that so large a dose was not necessary, although he corroborates v. Mehring's statement that even then there was no appreciable disturbance of the respiration or pulse-rate. In 80 per cent. of the cases sound sleep of from five to seven hours' duration was procured by doses which did not exceed 45 grains, and were in some instances as low as 20 grains; by repeating the dose, or giving a larger one, sleep was, in all the cases where failure was at first noted, subsequently obtained. In 24 of Scharschmidt's cases there was much excitement, and by producing sleep under such conditions as mania, delirium tremens, and epilepsy or hysteria with delirium, amylene hydrate appears to have proved itself superior to urethran. Too large a proportion of pharmacological discoveries have ended in disappointment, and it would be rash, in the face of recent experience, to express a confident opinion that the new hypnotic will prove as useful and as harmless in the hands of other observers as it has done in those of v. Mehring and of Scharschmidt, but, as our contemporary the *Therapeutic Gazette*, which has published an excellent epitome of the papers in the *Therapeutische Monatshefte*, observes, its prospects as yet appear very promising.

THE QUEEN'S JUBILEE GIFT.

THE Queen has often shown her keen sympathy with the poorer citizens of this country when some great calamity has checked the public mind; and in the manner in which she has decided to dispose of the surplus of the Women's Jubilee Offering she gives evidence of her helpful sympathy with the industrial classes in those domestic calamities, less extensive indeed, but in their incidence on the individual not less severe, which are the common lot of every household. Such calamities, while they do not spare, as the Queen has so often sadly experienced, the most elevated social situations, bear with peculiar hardness on the classes in which health and the power to work are their only wealth.

The Queen has taken counsel of experienced counsellors, and has been wisely advised. She has approved the recommendation of the Duke of Westminster, Sir James Paget, and Sir Rutherford Alcock

that the surplus of the Women's Jubilee Offering, which was a personal present to the Queen herself, should be devoted to the foundation of an institution for promoting the education and maintenance of nurses for the sick poor in their own homes. Guarded by reasonable safeguards against abuse, such a system of home nursing is calculated to confer enormous and as yet inestimable benefits upon the artisan class. The scheme is merely sketched in the letter which we publish in another column, but its general scope may be well perceived. It is none the less likely to be popular and useful because it does not betray a disposition to seek novelty for novelty's sake. The plan has been tried on a fairly extensive scale in several districts of London, and in certain provincial towns, and has been found to work on the whole most satisfactorily.

The value of good nursing in the treatment of serious illness is now universally recognised, and some special organisation is needed to place it within the reach of the artisan, whose weekly wage, even when he is in good work, does not enable him to defray the expenses of a trained nurse. Sickness in such a family brings in its train many discomforts to the other members, and increased danger to the sufferer; when the father or mother of the family is prostrated by illness, the condition of the household is truly pitiable; it is not merely or chiefly a want of appliances, but a lack of knowledge to appreciate the needs of the invalid, and to make the best use of existing material. Under such circumstances a nurse trained to her duties as a sick-tender, and possessed of the special tact which teaches people to help themselves, may work a marvellous change, not only in the surroundings of the invalid, but in the general comfort of the home. That this is no exaggerated statement will be freely admitted by those who have seen what has been done, what is being done day by day, by the agencies which, with limited means, are already at work.

We pointed out, in an article on the work of the Metropolitan and National Nursing Association published some years ago, that a thoroughly well-organised system of nursing the sick in their own homes might go far towards relieving the hospitals from some of the strain now put upon them. The artisan has been really educated to look upon the hospital as his only resource in serious illness; no alternative has been offered between the skilled nursing and comfortable surroundings of a hospital, and the untrained attentions of well-meaning relatives, generally sufficiently taxed already to meet the ordinary daily round of household duties. Thus it is that, in spite of the separation from friends and relatives which removal to a hospital entails, patients who have once experienced the advantages of skilful nursing are generally anxious again to enjoy them when again suffering from disease. Hospitals are thus often morally forced to admit a large proportion of patients, because it is felt that they cannot be nursed in their own homes, owing to there being no one to organise the willing services of anxious but untrained friends.

The hospital of St. Katharine was founded and richly endowed by Queen Matilda in the year 1148, and was originally served by the Augustine monks of the neighbouring monastery of the Holy Trinity. The hospital was dedicated by this Queen to St. Katharine, in pure and perpetual alms, for the repose of the souls of her son Baldwin and her daughter Matilda. Queen Eleanor, widow of Henry III, after a long struggle with the monks, succeeded in regaining control of the hospital for the Crown, and in 1273 founded the hospital afresh for a master, three brother-chaplains, and three sisters, ten poor women called bedeswomen, and six poor scholars; the right to nominate the

master, chaplains, and sisters was reserved to herself and the Queens of England, her successors; among subsequent benefactors of the hospital, which appears to have hitherto been a purely religious and charitable institution, we find Edward III and Philippa, his wife, who granted certain lands in Kent and Hertfordshire, and a new charter which specially prescribed visitation of the sick as one of the duties of the community. Richard II, Henry V, Henry VI, Edward IV, and Henry VIII and Queen Katharine, were benefactors of the hospital, which escaped extinction when the other religious houses were suppressed, owing, it is said, to the personal intercession of Anne Boleyn. However this may be, her daughter Queen Elizabeth took some interest in the hospital, and preserved it from destruction. In consequence, we are told,¹ of "many heavy complaints made against the Master," Lord Chancellor Somers visited the hospital in 1698, reformed many abuses, and prepared the way for the establishment of a charity school in 1705. When St. Katharine's Docks were built, the hospital was removed to Regent's Park. The revenues of the hospital, it is provided, may be applied to such good and charitable purposes as may be directed by the royal patroness for the time being.

"The Royal Hospital of St. Katharine in the Regent's Park, in the County of Middlesex," is at present governed by rules made in July, 1878; the community consists of a Master, three resident brothers, three resident sisters, three extern sisters, ten nurses, ten bedswomen, and ten bedsmen. There is also a school in which twenty-four girls and thirty-six boys are clothed and taught, and afterwards apprenticed. The only persons directly charged with the duty of tending the sick are the nurses; they are called "the St. Katharine's nurses," and must be connected with societies of bodies for training, superintending, or employing nurses; the stipend paid to each nurse is £50. There is also a Chapter Clerk, the present incumbent of the office being Sir Arnold White. The Queen is patron and visitor, and the rules appear to provide that almost every question which is likely to arise shall be referred to her; for instance, it is provided that the extern sisters and nurses shall only be appointed to the full number "when the income of the hospital, not otherwise appropriated, in the judgment of the Patron admits." It would not be difficult to graft upon this scheme the new features which would be required to give effect to the Queen's wishes. The buildings for a central office exist in St. Katharine's Hospital, a grey stone edifice well known to persons who traverse the eastern side of Regent's Park; there are resident and non-resident sisters, to whom salaries are paid out of the funds of the hospital, and who may, in process of time, all be required to have had special training in the nursing of the sick.

THE Leeds Workpeople's Hospital Fund for 1887 amounts to £3,555 ss against £2,000 in 1886.

BOTH at Doncaster and at Thetford steps are being taken to provide temporary hospitals for the reception of cases of infectious disease.

THE Turin Academy of Sciences has awarded the Pressa prize of 12,000 francs to M. Pasteur.

THE death is announced of Mr. Peter Henry Maclaren, L.R.C.P., of Bedlington, from a fatal dose of chloral, taken to procure sleep.

¹ Dr. Ducarel's *History and Antiquities of the Hospital of St. Katharine, near the Tower*. Bib. Top. Brit., vol. ii, part 1.

LEAD-POISONING IN SHEFFIELD.

THE Sheffield Corporation, which has just taken over the water supply of the town, is called upon to deal with an epidemic of lead-poisoning that is very prevalent in some of the high-lying districts of the borough. Sheffield is supplied with water from two sources, and it has been proved with regard to one of them that there are certain vegetable acids in the water which take up lead, and render the water to some extent poisonous.

THE MORNING BATH.

THE Englishman's love of his "cold tub" appears to be a standing puzzler to persons not to the manner born. Professor Dujardin-Beaumont, the eminent Paris physician, in a learned lecture on hydrotherapy, published in the *Therapeutic Gazette*, makes the following observations, which show that he labours under a slight misapprehension: "Lotions of cold water and sponge baths have passed from the domain of medicine to that of hygiene, and the people of the North practise them constantly, especially the English, who, in their fondness for their bath-tubs, are in the habit every morning of taking thorough rub down with a sponge dipped in cold water."

REVACCINATION.

THE Local Government Board are about to issue an order reducing the minimum age at which revaccination may be performed at the public expense from fifteen years to twelve years, in ordinary circumstances, and from twelve years to ten years in the case of "any immediate danger from small-pox." This is a step that might with advantage have been taken long ago, as much of the so-called successful primary vaccination is not sufficient to protect beyond infancy, and moreover, the period between 10 and 15 years of age is the one during which revaccination is most likely to be sought. If the operation is delayed until after the ordinary school age, it is likely to be deferred altogether, or until a small-pox panic arises.

REGISTRATION OF NURSES.

A MEETING was held this week, at the residence of Mrs. Bedford Fenwick, Mr. Savory in the chair, at which Her Royal Highness Princess Christian, Sir Joseph Fayrer, Dr. Quain, and some other members of the medical profession were present, as well as leading members of the nursing profession. Resolutions were passed approving the formation of an association for the registration of nurses, and a series of rules proposed for the constitution of the association were presented, discussed, and approved with slight modifications.

MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE SOCIETY.

THE monthly meeting of the Executive Committee of the above Society, and the quarterly meeting of the General Committee will be held on Wednesday next (January 18th), at 38, Wimpole Street, W., the former at 4.30 and the latter at 5.0 P.M. The report for the quarter and accounts for the half year to December 31st, 1887, will be presented.

THE HEALTH OF NEWCASTLE.

THE high death-rates that have recently been visible in the mortality returns of Newcastle-on-Tyne have drawn special public attention to the sanitary arrangements of the town, with the result that room for considerable improvement has been disclosed. The Sanitary Committee of the Town Council have been exceptionally active of late, and their personal inspections in various localities have led them to pass a severe vote of censure on the Chief Sanitary Inspector. This is certainly not altogether surprising if the statements recently published in the *Newcastle Daily Leader* be accurate. It would appear that the tenement dwellings of the poor were found, on personal inspection, to be in a disgraceful and filthy condition; that many of the courts and yards were covered with human

excreta and refuse, one street "presenting the appearance of one common ashpit;" that ashpits have been allowed to become filled to overflowing with putrefying garbage; and altogether, that cleanliness and filth-removal have been greatly disregarded. The reports of the medical officer of health have not given quite such a gloomy account of the city's condition, but scattered through them are to be found continual condemnations of the open privy system, and complaints of defective closet accommodation, of foul privies, of unpaved and dirty yards, etc. It is to be hoped that the increased vigour which seems to have been imported into the work of suppressing filth nuisances will have a good effect upon the general health of the town. The authorities might well consider whether a system of "trough" water-closets could not be advantageously encouraged in the districts inhabited by the poorer and more careless sort of people.

NULLIFYING THE ADULTERATION ACT.

Dr. SEDGWICK SAUNDERS, the medical officer of health for the City, has complained in his report of the glaring inadequacy of the penalties inflicted in the City for offences under the Sale of Food and Drugs Act, as compared with those imposed elsewhere; he doubted the wisdom of trying to protect the public from systematic adulteration if prosecutions only resulted in the infliction of insignificant and merely nominal penalties. In one case of milk adulteration 33 per cent. of water had been added, and in another 30 per cent., and the alderman imposed in the former a fine of 20s. and costs, and in the latter 10s. and costs.

ROYAL VICTORIA HOSPITAL, MONTREAL.

WE are informed that Mr. H. Saxon Snell, F.R.I.B.A., of London, has been commissioned by the Board of Governors of the Royal Victoria Hospital, Montreal, which was constituted by a charter obtained during the last session of the Dominion Parliament, to prepare plans for the building, and to direct its construction. It will be remembered that two distinguished citizens of Montreal—Sir George Stephen, Bart., President of the Canadian Pacific Railway, and Sir Donald Smith, K.C.M.G., of the Hudson's Bay Company—gave one million dollars for the foundation, and that the Corporation of the City have granted a plot of land, about twelve acres in extent, situated at the north-east angle of Mount Royal Park, at an elevation of 300 feet above the St. Lawrence river, as a site. The hospital is to be designed to receive 300 in-patients, and, in addition to a commodious out-patient department, is to be provided with accommodation for the medical school, and for a training school for nurses.

STRYCHNINE IN ALCOHOLISM.

THE good results obtained from strychnine in dipsomania by N. M. Popoff, V. A. Manassein, Partzevsky, Tolvinsky, and Zivadsky, have induced Dr. S. Jaroshevsky (*Meditsinskoié Obozrenié*, No. 4, 1887, p. 332) to undertake an experimental inquiry into the antagonism between the alkaloid and alcohol. From experiments made on dogs Dr. Jaroshevsky feels justified in drawing the following conclusions: 1. Strychnine undoubtedly neutralises the intoxicating and narcotic effects of alcohol. 2. It enables large quantities of alcohol to be taken for a considerable stretch of time without causing the usual organic lesions which follow the use of alcohol alone. 3. There are, however, limits beyond which the alkaloid itself becomes injurious to the organism. 4. Therapeutically, strychnine should be used in all forms of alcoholism. 5. It may be regarded as a powerful prophylactic against alcoholism.

BENZOATE OF SODA IN URÆMIA.

STARTING from Cohnheim's theory of uræmia and from the fact that benzoate of soda inhibits the formation of urea within the system, Dr. A. S. Partzevsky, of the Basmanais Infirmary for Labourers, in Moscow, administered benzoate of soda (*Meditsinskoié Obozrenié*, No. 5, 1887, p. 508) in ten cases of uræmia, in seven of which the patients

were suffering from parenchymatous, and in three from interstitial, nephritis. The drug was given every hour, in daily doses varying between one and two drachms. It was given either in a solution or in wafers, in capsules, and, where the internal administration was impossible, in enemata. Nine patients recovered, one died. Analysis of the cases has led Dr. Partzevsky to the conclusion that benzoate of soda cuts short uræmic attacks, the convulsive phenomena gradually disappearing and giving place to a deep sleep. The latter, in "a majority of cases, terminates by passing into full consciousness." Given on the first appearance of symptoms (headache, sickness, dilatation of pupils), the salt may prevent any further development of the fit. Albuminuria mostly disappears altogether.

THE ILLNESS OF THE CROWN PRINCE.

WE are pleased to be able to state that Sir Morell Mackenzie continues to receive highly satisfactory reports concerning the Crown Prince from the physicians in attendance. The condition of the illustrious patient is still better than it was last week. Further absorption of the small vegetation which recently appeared has taken place, and the slight general thickening of the left ventricular band has diminished. There is much less secretion from the larynx, showing that the catarrhal condition of the left side, which has from time to time caused a good deal of trouble, is also greatly improved. The Prince's voice, though rather hoarse, is fairly strong when he makes an effort, but in obedience to the advice of his physicians His Imperial Highness speaks as little as possible. Whilst, therefore, reiterating the warning we have already several times given as to the imprudence of placing too much reliance on the present favourable aspect of the case, it is, we think, fairly permissible to hope for the best. We have already called attention to the peculiarly anomalous and perplexing nature of the case, which will, no doubt, apart from all points of extra-medical interest, remain as a *cause célèbre* in laryngological literature. As showing the extreme difficulty frequently met with in the diagnosis of tumours of the larynx, we may refer to a case related by Dr. Eugen Hahn—whose authority in questions of this kind no one will deny—before the Berlin Medical Society last month. A young man, aged 23, was suddenly seized with acute spasm of the glottis, apparently without any previous symptoms whatever. The presence of a tumour being suspected, tracheotomy was performed, and the larynx was afterwards extirpated. On admission an abscess associated with perichondritis of the cricoid cartilage was found, but no malignant tumour was discovered. This case, so frankly reported by Dr. Hahn, affords further justification, if such were needed, for the caution which has led the Crown Prince's present advisers to discountenance severe operative procedures, for which there was no decisive indication, while the danger directly attending them was only too obvious.

JAPANESE ART EXHIBITION AND MEDICAL COLLECTORS.

THE Fine Art Society open on Monday to the public, at 148, Bond Street, what is claimed to be the finest loan collection of the works of the ancient masters of Japanese art which has ever been brought together. Among the finest specimens of old lacquer are a series of the miniature medicine cases, in compartments, formerly carried by every gentleman in Japan at his girdle; the doctors' (shan) swords, worn to assert their position as belonging to the noble classes, are also of interest. The well-known collections of Mr. Anderson, of St. Thomas's Hospital, of Mr. Ernest Hart, and of Sir Trevor Lawrence, are largely drawn upon for this remarkably beautiful and interesting display, as well as those of H. R. H. the Duke of Edinburgh, Mr. Gilbertson, Mr. Salting, and some thirty others. The catalogue, with introductions by Mr. Katsoka, is a valuable art document, worth preservation as the work of a clever native expert, who has had the advantage of a European education. It is not uninteresting to note that while the earliest authorities on Japanese arts and products were medical men, Dr.

Kaempfer and Dr. Siebold, so at this moment the chief literary authorities and the possessors of the most illustrative collections of the works of the old masters of Japan in this country are also medical men; Mr. Anderson's splendid work on *The Pictorial and Glyptic Arts of Japan*, and his catalogue *raisonné* of the picture collections of the British Museum, and Mr. Ernest Hart's lectures on Japanese Art, published by the Society of Arts, with a historical index of Japanese artists and the glossary of their seals and signatures, being the standards of existing knowledge; while in America the collection of Dr. Bigelow, of Boston, is of vast extent and unsurpassed beauty.

POISONOUS FOOD.

In December some paragraphs appeared in the JOURNAL on cases of poisoning by unwholesome mackerel. The two patients, who had severe peritonitis, fecal vomiting, and violent delirium, are both convalescent, yet remain very weak. In both these cases peritonitis and delirium, almost maniacal, were the most marked symptoms. This fact is noteworthy, for in the great majority of instances of poisoning by unwholesome food, the patient is seized with symptoms of enteritis, cholera, or collapse, or at least one or two of these three symptoms predominate. It will be remembered that, in the case of the young gentleman at Bayswater, the two other members of his family who partook of the same mackerel had severe choleraic diarrhoea within a few hours, and felt perfectly well next day. Dr. George Johnson, F.R.S., has collected some interesting cases of collapse from poisonous food, which are published in his *Medical Lectures and Essays*. A woman had collapse and other choleraic symptoms twice in three months—first, after eating pungent decayed cheese; and on the second occasion, after eating tinned lobster. A case of the poisoning of a mother and three children by decayed American cheese is recorded; there were symptoms of gastro-enteritis, and the mother had several fits, to which she had never previously been subject; she and one child died. Some Irish peasants, in 1826, made a stew of the flesh of a dead calf which they found on the sea-shore; choleraic symptoms, followed by coma, as in opium-poisoning, occurred and proved fatal. Still, the occurrence of collapse, choleraic symptoms, and even coma, after poisonous food, is well known even to the non-medical public. The recent cases of mackerel poisoning show what is not known to all medical men, and is certainly not taught in the schools—namely, that poisonous fish may cause acute peritonitis, with symptoms suggesting strangulated hernia or rupture of intestine, and acute delirium after the peritonitis has abated.

THE FUTURE OF GREAT CITIES.

MR. FREDERIC HARRISON'S address at Toynbee Hall on the sanitary shortcomings of London is suggestive, eloquent, and forcible. Every year 70,000 souls are added by immigration and births, the excess of births and of immigration being chiefly among the poorest classes, and those who swell the number of the unemployed. The rich fly from its vast dreariness and its atmosphere of soot, and largely console themselves with frequent or general residence in purer air. Its municipal arrangements are sadly dislocated and chaotic. The mortality of the poorer neighbourhoods is fearfully in excess of normal rates. Its house-room grows largely by the malign and imperfectly supervised activity of the jerry builder. The supervision of drainage and plumbing ceases at the street-kerb, so that a large proportion even of its best houses, and even of those most recently built, are mere receptacles of sewer-gas and traps for fatal disease-germs. Of this some melancholy examples, showing unusual carelessness of architects and neglect by vestry officers of even the nominal precautions which they might enforce, have recently been brought to our notice. The water supply of London is, next to the purity of air and soil—if, indeed, second to it—of the highest importance to health. Of this Mr. Harrison speaks with just horror and indignation. "It is meagre in quantity, inconvenient in supply, very various in quality and exposed to one or two

immense risks of pollution. We are actually drinking water that is minutely, but sensibly, infected with poison and excrement." So that London stands always on the verge of a catastrophe. The rich are able to secure themselves from danger by specially providing themselves with potable waters above suspicion; so that no wonder the Apollinaris Company now boast of an authentic record of an annual sale of twelve millions of their pure table-water imported from Germany, and to this has to be added the sales of other natural and artificial waters employed by the caution of the well-to-do, classes for the same purposes of health and luxury. But pure table-water should also be the heritage of the poor. London, we fear, will never cease to be the city of soot, and of the unsolved problems of adequate prevention of fire, provision of open spaces, sanitation of houses, and disposal of the dead, until a really earnest generation of sanitarians shall arise, who will insist upon improved municipal government, and attention, above all things, to the physical needs of health and happiness for the four millions of Londoners.

FATAL AFTER-RESULTS OF CHLOROFORM INHALATION.

DR. UNGAR has recently published in the *Vierteljahrsschrift für gerichtliche Medicin* an account of some researches which he has made in order to determine precisely the effects of chloroform on the tissues. He kept a large number of rabbits and dogs under chloroform for many hours, with intervals of suspension of the anaesthesia. After death, marked changes were discovered in the tissues. The muscular tissue of the heart was very fatty, and numerous points of fatty degeneration were found in the endocardium. Similar fatty changes were found in the epithelium of the larynx, trachea, bronchi, pulmonary alveoli, and gastro-intestinal tract. The epithelium of the convoluted tubules of the kidneys was either full of fatty granules or was in process of breaking down. The liver cells and the epithelium of the smaller biliary ducts were affected in a similar manner. Fatty changes were also detected in the striated fibres of the diaphragm, and, though less marked, in the rectus abdominis and the extensors of the thigh. In nearly every case these appearances were most marked the longer the animal had been kept under chloroform. Dr. Ungar observes that the animals were healthy, whilst in the case of patients fatty changes due to illness, cachexia, alcoholism, etc., often exist before the narcotic is given. In such a case the chloroform may do much harm even when the patient recovers. Some of the animals died more than twenty-four hours after coming to from the final dose of chloroform. Dr. Ungar is therefore induced to believe that death shortly after operations may be more often due to the narcotic than is generally supposed. His researches do not confirm Nothnagel's theory that the fatal action of chloroform consists in the disintegration of the coloured corpuscles of the blood. He believes that the anaesthetic acts directly on the chlorine and chlorine salts diffused through the tissues. The successful administration of chloroform during labour, to which Dr. Ungar refers, appears to prove that the anaesthetic acts less seriously in our species than in animals, yet his paper contains important suggestions which should not be overlooked.

A CASE OF HERMAPHRODITISM.

In the *Russkaja Meditsina*, November 27th, 1887, p. 710, Dr. Lukomsky, of Priluki, in the Poltava (South Russian) Government, describes a case of true hermaphroditism, which is specially interesting from the fact that the subject of the anomaly has been known to the writer from its childhood. In 1857, at the village Kraslopy, near Priluki, a Cossack's wife, was delivered of a child, which, about a week later, was baptised, and christened "Melania." The child grew up, remaining always healthy and strong, and doing female rustic work. On her deathbed Melania's mother adjured her husband never to allow their daughter to marry. In 1887, however, Melania married

a peasant residing in the same village. Shortly afterwards both Melania and her husband came to Dr. Lukomsky, urgently beseeching him to examine her, and to tell them whether she was a woman or a man. Dr. Lukomsky's report was as follows:—"Melania is a tall, powerfully built, and well made person, aged about 30, the general outline of the body not presenting the usual rounded contour seen in women. The head is furnished with long flaxen hair, while the upper lip and chin are covered with scanty, short, bristle-like hairs. The voice is rough and deep, the neck long, the 'Adam's apple' fairly prominent. The breasts are ill-developed; the pelvis has rather the male configuration; the pubes is covered with thick curly hair. Just below the pubic arch there is a penis as thick as a man's thumb; it measures about $4\frac{1}{2}$ centimetres in length when flaccid, and has neither prepuce nor urethral orifice. Under sexual excitement complete erection takes place. Just below the penis there is a normally developed scrotum containing two testicles, freely movable, both somewhat larger than a pigeon's egg. Below the scrotum there is a slit measuring about 7 centimetres in length, with major and minor labia on each side, with a small clitoris and urethral orifice beneath it, as well as with caruncule myrtiformes, at the site of a hymen, which has been ruptured after Melania's recent marriage. The vagina is fairly spacious. On examining with a speculum a uterine cervix is seen, somewhat smaller than the average. Melania has never menstruated. 'She' hates the male sex, but is highly voluptuous in regard to women. In coition with women a whitish fluid is ejaculated from the vaginal slit. The hermaphrodite dresses like a woman, but is fond only of male occupations." A divorce was obtained from the Holy Synod on the medical evidence. It will be noticed that nothing is said as to the uterus and the ovaries. In the interests of science Dr. Lukomsky should furnish some details on those points, and should give a more detailed description of the vagina and breasts.

THE ETIOLOGY OF INEBRIETY.

THE first of a course of three lectures on Inebriety was delivered by Dr. Norman Kerr, President of the Society for the Study and Cure of Inebriety, on January 11th. Inebriety, as distinguished from the act of drunkenness, was defined as a disease of the higher nerve centres, characterised by a very strong craving for intoxication. Under the head of predisposing causes, sex, age, religion, race, climate, education, pecuniary circumstances, occupation, marriage relations, hereditary (the insane), temperament, associated habits, head and other injuries, diet, and intoxicating agents were considered. The male sex predominated, but the proportion of females was increasing rapidly in England, where it was much larger than elsewhere. The greatest liability was between 30 and 40 years of age, but juvenile inebriety was extending fast, both on the Continent and at home. The Jews showed less liability than other religious communities. Religious hysterical excitement had an influence. The Italians and the Spaniards exhibited a much smaller tendency to inebriety than other people, and cold climates predisposed more than hot climates. Refinement and culture were serious predisposing causes. In males, marriages made little difference; but in females, married inebriates were five times as numerous as the unmarried. In 703 cases at the Dalrymple and other homes, 308 had a family history of inebriety. The phlegmatic was the temperament least liable. Though the alcohol and tobacco habits were frequently associated, Dr. Kerr held that tobacco did not, to any great extent, predispose to inebriety. Syphilis, cerebral, chest, and other diseases markedly predisposed thereto. So did head injuries, bad feeding, and bad hygienic conditions. The chief exciting causes were nerve-shock, head and other injuries, sex, pregnancy and maternity, occupation, idleness, climate, overstrain, sociability, and intoxicating agents. Domestic worry, financial troubles, bereavement, unexpected good fortune were all varieties of shock which had operated considerably. Traumatic inebriety was a common phase.

Inebriety was often excited by gout, dyspepsia, and epilepsy. Sexual physiological crises were a prolific cause. Among the predisposing occupations were those of commercial travellers, horse-keepers, daily newspaper work, and liquor traffickers. A marine climate excited some; Italians, sober in Italy, became drunkards in England. About one half of the cases at the Dalrymple and other Homes had been excited to inebriety by association. In other cases the excitant had been an inebriant. If these and other exciting causes were the occasion of inebriety in some individually, why not all? Because, unless there was an inebriate diathesis, there was no response in inebriate manifestation, and the storm of excitement passed harmlessly by, after having exhausted itself.

SCOTLAND.

PERTH SICK NURSING SOCIETY.

ATTENTION being directed at present to the nursing of the sick poor through the proposed scheme in connection with Her Majesty's Jubilee offering, it is interesting to notice that the Perth Sick Nursing Society has, by means of its nurses, been able to make 4,500 visits to the sick poor in 1887, its total income having been £144, and total expenditure only £135.

THE CHAIR OF BOTANY, EDINBURGH.

NOTWITHSTANDING the ludicrous article in the *Standard* on the subject, the Chair of Botany in Edinburgh University has tempted a number of eminent botanists south of the Border to become anxious inquirers on the subject. It is not possible yet to name all the prospective candidates, still less those most likely to be seriously thought of; but a sufficient number will be at the command of the patrons to enable them to fill up worthily so valuable a chair.

COTTAGE HOSPITAL, KIRKCALDY.

THE want of a cottage hospital in Kirkcaldy has been long felt, and more especially since the multiplication of large waxcloth and linoleum manufactories has rendered the occurrence of serious accidents and injuries more frequent. This want is likely to be satisfactorily supplied by the establishment of a cottage hospital, and last week Mr. Michael B. Nairne, of Rankellour, offered, through the magistrates and Town Council of Kirkcaldy, a sum of £3,000 for the erection of a hospital for non-infectious diseases.

ABERDEEN AND INFECTIOUS DISEASES.

IN Aberdeen, last week, a man who had wilfully exposed himself so as to be a source of danger to others, while he was suffering from scarlet fever, was charged with a contravention of the Public Health Act, having pleaded guilty, he was fined a guinea, with costs, or in default imprisonment for ten days. It was reported, at a meeting of the Aberdeen Town Council Health Committee, that the entire cost of the new pavilion, which has been erected for receiving patients suffering from infectious diseases, was £1,062. At the same meeting a communication was received from the Trades Council, referring to alleged carelessness on the part of officials in the transference from the hospital to their homes of convalescent patients.

NORTH BERWICK DEATH-RATE.

THE following statement regarding the mortality of North Berwick (which has been termed the Biarritz of Scotland, and which is so largely favoured by members of the profession from England), will be of some interest; it is taken from the registrar's return. "There has not been a death in the district since September 24th. The town has been quite free from epidemic disease, and has been exceptionally healthy. Only thirty deaths have been registered during the year, being 11.1 per 1,000." These statistics refer entirely to the resident

population, and not to the host of visitors during summer and autumn; among whom five deaths occurred, of which two were sudden deaths and one suicidal.

DEATHS FROM INFECTIOUS DISEASES.

At a meeting of Edinburgh Town Council, held on Tuesday, the convenor of the Public Health Committee, Bailie Russell (M.B. and B.Sc.) made an interesting statement with regard to the mortality in Edinburgh during 1887. The general death-rate had been 18.65 per 1,000, which was slightly greater than in the two previous years. The chief item to be considered in this mortality was that due to infectious diseases, from which there had been 599 deaths, equal to 12.4 per cent. of the entire mortality. Of these 599 deaths, 275 were registered as due to whooping-cough; 145 were due to scarlet fever, of which 2,587 cases had been reported, and 42 were due to measles, of which 2,369 had been reported. During the year there had been two marked outbreaks of typhus fever, but these they had been able to deal with effectively and promptly, and although they had been able in recent years to keep typhus under control by improved sanitary conditions, these outbreaks showed the disease had lost none of its former power when it had made a little headway. Bailie Russell also gave some statistics regarding the work done for infectious diseases in the city hospital. At the end of 1886 there were 128 inmates of the institution, at the end of 1887 there were 181, while during the year 1,500 patients had been treated in it. He also made a statement as to the seizure of material intended to be used as food, but which the authorities had condemned as unfit for such a purpose, no less than seventy tons of meat having been seized and condemned as unfit, and £102 10s. obtained as fines from those who had tried to pass such food on the public. At the same meeting the Dean of Guild gave notice of a motion of some interest and importance to the effect that the Health Committee consider the expediency of the medical officer of health reporting the death-rate in the several wards of the city separately, and also stating the death-rate according to the rental.

IRELAND.

SEVERAL parties in Newtownards, last week, who all partook of a cheap fruit bread, were taken seriously ill with vomiting and diarrhoea. A portion of the bread has been sent for analysis.

DR. HUMPHREY J. BROOMFIELD, F.R.C.S.I., Lecturer on Anatomy in the Carmichael School, has been appointed Assistant Visiting Physician to the City of Dublin Hospital.

PORTRAIT OF DR. BANKS.

At the conclusion of the business of the annual meeting of the Dublin Branch of the British Medical Association on January 25th, the portrait of Dr. J. T. Banks, the President of the Association, will be presented to the President and Fellows of the King and Queen's College of Physicians by the President of the Branch, Dr. Mapother, on behalf of the subscribers to the reception fund of the annual meeting in Dublin. The annual dinner of the Branch will be held in the Hall of the College of Physicians on the same evening, and it is understood that many distinguished guests will be present.

BOYLE UNION: MEDICINE EXPENSES.

A SPECIAL meeting of the Boyle Dispensary Committee was held recently, on the subject of the great increase in the medicines used, as compared with former periods. The committee came to the conclusion that this increase was due to the great abuse in the issuing of red (or visiting) tickets, to parties who, to say the least, are not entitled to medical relief under the poor law. One of the Boyle guardians has suggested that whoever issued a visiting ticket to anyone not eligible for it should be made to pay for the visit himself, and

also for the medicine supplied from the dispensary. If this could be carried out, it would at once put a stop to a crying evil, and be a great boon to all dispensary medical officers. The expenses for medicines for the past half year, for Boyle, with a population of 41,215, were £245 5s. 6d., and of Castlereagh only £149 11s. 7d., with a population of 43,442. It is the practice in Boyle Dispensary, once a patient gets a visiting ticket, to be attended for twelve months without a second being issued; a strange arrangement; and one which must necessarily give greater trouble to the dispensary medical officer, than if the ordinary procedure was adopted.

BELFAST NATURAL HISTORY AND PHILOSOPHICAL SOCIETY.

A VERY successful lecture in connection with this Society was given in the Ulster Minor Hall, on January 2nd, by Dr. A. W. Hare, of Edinburgh. The subject was "Facial Expression," and it was handled with a force and lucidity that held the attention of a large and distinguished audience. The lecturer illustrated his remarks by a series of excellent lime-light views, many of which were drawn from the works of Sir Charles Bell and Duchenne. Dr. Hare will have a hearty welcome should he return to Belfast in the capacity of lecturer.

A STRANGE STORY.

AN evening paper published on Monday a "romantic story," which has since been copied into other journals, and which has, of course, excited a good deal of notice. It relates that in a certain family, well known in a suburban district, one of them, who had always been regarded as a woman, one day appeared dressed as a man, and was introduced to the friends as a man. The story is true, and it was consequent on the discovery of the real sex by a medical man in the city. But the fact might have been allowed to rest there. Now, for the sake of an attractive "mystery" paragraph, the whole town—and particularly the female portion of it—is set talking over a matter which must involve sexual topics that ought not to be so discussed.

ULSTER HOSPITAL FOR CHILDREN AND WOMEN, BELFAST.

A "Fairy Tea and Christmas Tree" was given in connection with this institution on January 4th. The hospital was tastefully decorated, and numerous presents were provided for the youthful patients. A large concourse of visitors assembled at 4 o'clock, and refreshments were served in the operating theatre. The chief feature in the entertainment was the apparition of Father Time, laden with gifts for the children. The success of the afternoon was mainly due to the active exertions of the lady superintendent, Miss Moore, to whom the hospital owes so much of its efficiency. It is now in a very satisfactory financial condition.

FALSE CHARGES AGAINST MEDICAL MEN.

DR. DAVY, of Terenure, may be congratulated on the triumphant issue of the action brought against him, involving charges to which medical men, however innocent, are peculiarly liable. His character, it will be seen, was completely vindicated, and the Recorder described the case as an atrocious one, and ordered criminal prosecution for perjury against the prosecutor. The risks of medical practice are seriously enhanced by the perils disclosed by such a report, and Dr. Davy must be condoled with for his misfortune in having to incur this unfortunate attack as heartily as he must be congratulated on the triumphant issue from this unmerited ordeal.

HEALTH OF BELFAST.

FOR the past two weeks the death-rate in Belfast has reached the abnormally high figure of 41 per 1,000, almost twice the average. It is singular that with this heavy death-rate there should not be associated some special epidemic, but such is the case. The deaths are fairly distributed among the various diseases usually prevalent in

winter, and the specific fevers do not claim more than their share of the mortality. Scarlatina, measles, typhoid, and whooping-cough are all well represented in the death returns, but without a remarkable preponderance on the part of any of these diseases. Another sign which indicates the present unhealthy state of Belfast is the wide prevalence of epidemic and contagious sore-throat. The cases have been unusually severe, and have often closely simulated scarlatina, but in no instance coming under our notice has there been any subsequent desquamation. The high mortality in Belfast is currently attributed to the scarcity of water, which still to some extent prevails. The year 1887 was one of the driest years ever recorded in the north of Ireland. In estimating the gravity of the Belfast death-rate, it is well to remember that during the autumn the town was exceptionally healthy, the death-rate for some time being as low as 19 per 1,000. On the mere principle of averages, it is always probable that a period of exceptionally low mortality will be followed by one of somewhat high mortality, as during the former period many persons, especially the aged, live on who in the ordinary course would have died. At the same time, the high death-rate should be a warning voice to the corporation to expedite the drainage schemes which they have in hand. The urgent necessity is universally admitted.

CORK DISTRICT LUNATIC ASYLUM.

At a meeting of the governors last week Alderman Dale said he wished to take the opportunity of saying that the present satisfactory condition of the asylum was due to the management of Dr. Dwyer, the resident medical superintendent. At the same meeting the refusal of the Cork Guardians to pay for patients sent to the asylum was under consideration. It appears that the former had agreed to pay for the maintenance of the lunatic paupers admitted to the asylum, and they further passed a vote of thanks to the asylum board for relieving the lunatic ward of the union at a time when it was overcrowded. By the asylum rules it is in the power of the governors to seek for payment at any time for any patients transmitted to the asylum, if the medical officers certify such patients as not dangerous, at the cost of the guardians. After a long discussion it was determined to make another application for the amount due, and if not paid to take proceedings for the recovery of the same.

THE EXECUTION OF SURGEON-MAJOR CROSS.

SURGEON-MAJOR PHILIP EUSTACE CROSS was hanged at Cork on Tuesday last, for the murder of his wife. We have already given a summary of the evidence produced by the prosecution. There could be no doubt that the cause of his wife's death was arsenic; and when it was put to the jury by the judge that if they believed Mrs. Cross died of poisoning by arsenic they should find the prisoner guilty, there was little difficulty in determining what the verdict would be. Since the date of the conviction an increasing number of persons had formed the opinion that the extreme penalty ought not to be carried out, the cause of that belief being that there were some elements of uncertainty in the case, and that the prisoner did not seem to have got much of the "benefit of a doubt" recognised in criminal cases. We commented, at the time, on the character of the judge's charge, and in the same day's issue of the *Saturday Review* a severe article on the subject appeared. It said: "The manner in which Mr. Justice Murphy addressed the jury was a manner very much to be avoided by judges, and might very well have led to the conviction of an innocent man..... A judge having to deal with a capital charge against such a man was bound to put away all indirect considerations, to abstain from anything like the language of passion or emotion, to content himself with a close analysis of the facts before him. It is not too much to say that Mr. Justice Murphy did exactly the contrary." The memorial to the Lord-Lieutenant, which we published in the *JOURNAL* of January 7th, was influentially signed, and various reasons were adduced in favour of a mitigation of the capital sentence. But it did not seem from the first that such an appeal was likely to

result in success. In these cases the judge is always consulted, and his opinion was already settled. Then the extreme journals protested against any leniency. It was asked: "Is the suggestion this, that Mrs. Cross was poisoned by her neighbours, or by those who had boycotted her husband, or is it that a man who is boycotted and a member of the Property Defence Association may poison his wife with impunity?..... How strange that these advocates of justice undefiled have found a tongue to condemn judicial speeches for the Crown, only when a wife-poisoning emergency man has been sentenced to hang? A great public question, of vital moment to every person in Ireland, has been raised by this Cross memorial. It is whether the administration of the law, the machinery of Crown prosecution, the partisanship, and all the rest of it, shall grind to powder all the accused of one class, marked for destruction, and leave unharmed all of another class claiming immunity as 'loyalists,' and so forth." Thus the bitterness of political strife was also brought into the question, and Dr. Cross was between the hammer and the anvil. Reprieve would have been read as a yielding to the clamour of "loyalists," no matter what new facts might have been brought forward. The wretched man protested his innocence of the crime. He left no "confession," but went to the scaffold with absolute fearlessness. Dr. Moriarty, the prison surgeon, is represented as saying, "I have seen many executions, but never such bravery as exhibited by Dr. Cross. He was a grand old man. He walked erect and without faltering." Still the question, Was Dr. Cross guilty of murder? remains unsolved. Whatever his moral failings in regard to the unhappy woman he has left a widow, there was no necessary outcome of murder from them. They were useful in his trial only as supplying a motive. Yet motive may be discerned where it has really no active force at all. Lawyers have the knack of building up a case from facts which have no cohesion except that which is provided by their own imagination. Therein lies their art. So far as the present case is concerned, the question has passed beyond the region of dispute. Whether Dr. Cross was a callous murderer or not, we have the verdict of a jury as answer; but beyond that we have the dying man's solemn declaration that he did not kill his wife.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY meeting of the Council was held at the College on the afternoon of Thursday, the 12th instant. The minutes of the Extraordinary Council, held on the 5th instant, were read and confirmed. Reports were received from the various Committees.

The Secretary reported that four dissertations had been received on The Pathology, Diagnosis, and Treatment of Tumours of the Bladder, the subject of the Jacksonian prize for the past year, bearing the respective mottoes or devices, "Veritas," "Thorough," "Totis Viribus," and "FALSTAFF: What says the Doctor to my water? PAGE: The water itself was a good healthy water, but for the party that owned it, he might have more diseases than he know of."

The President reported to the Council that Mr. Henry Power had consented to deliver the next Hunterian Oration, and accordingly declared Mr. Power appointed Hunterian Orator for February, 1889.

The Council resumed the consideration of the proposed reply, prepared by the President and Vice-Presidents, to the letter from the Privy Council and the statement presented to the Lord President on behalf of the Association of Fellows on the subject of the supplemental College charter.

After a long discussion on suggestions and additions, it was resolved to hold another extraordinary meeting of Council on Thursday next for the further consideration of the letter to be sent to the Lord President of the Council.

A letter of December 13th from the Lords of the Council forwarding, for the information of the College, a printed document purporting to be a report of the statement made by Mr. Ernest Hart, as spokesman of the deputation of the Association of Members of the College, to the Lord President on the subject of the application for a supplemental charter was read, but its consideration was again postponed.

The Council, in pursuance of the resolution of the Council of December 8th, elected, as a Committee to consider and report to the Council on the regulations relating to the election of members of the Court of Examiners, Sir James Paget, Mr. Marshall, and Mr. Hutchinson, together with the President and Vice-Presidents.

THE BRITISH PHARMACOPEIA OF 1885.

By WILLIAM CRAIG, M.D., F.R.C.S. Ed., F.R.S.E.,

Lecturer on Materia Medica and Therapeutics, Edinburgh School of Medicine.

THE first edition of the *British Pharmacopœia* was published in 1864, the second edition in 1867, to which an "Addendum" was added in 1874, and in 1885 the third edition was published. This book, for several years to come, must be of the deepest interest to every member of the profession, and, therefore, a few remarks regarding its merits and demerits may not be altogether devoid of interest.

It is now fully two years since this edition was published, and teachers and others have had time to estimate its true worth.

I frankly admit at the outset that this edition is, in many respects, superior to all previous ones, but notwithstanding many excellencies, it is not without very serious defects, some of which I will endeavour to point out.

Foremost amongst these I place its great size. The volume consists of 564 pages, whereas its predecessor, including the "Addendum," extended only to 488 pages. We have thus an increase of 76 pages in this third edition. This great increase in the size of the volume has been caused mainly by the introduction of many new substances and a corresponding number of new preparations, but partly also by the reintroduction of old remedies that had been at one time official.

It is a matter of great regret that the British Medical Council should have increased the size of the volume so much. Whether the responsibility for this rests with the Medical Council, the Pharmacopœia Committee, or the editors, I am not in a position to say, but undoubtedly it is to be regretted that all the three editors were connected with the Pharmaceutical Society, and none with the teaching of materia medica in any of the medical schools of this country. It is hardly possible to conceive that any teacher of materia medica in any of our medical schools could have sanctioned the retention in our *Pharmacopœia* of the numerous official drugs and preparations which are seldom if ever used in the treatment of disease. Be that as it may, all must admit that the book is too large, and the important practical question is, How could it have been made less? That question I will now endeavour to answer.

I have not much to say against the introduction of new medicines into the present edition. Many of these medicines were already official in America and other countries, and deservedly so, because they had proved themselves worthy of a permanent place in all *Pharmacopœias*. On the other hand, it may be fairly questioned if there was much need for such medicines being made official as cupri nitras, potassii cyanidum, sodium, etc.

It is only, however, to a small extent that the size of the volume could have been lessened by this method. There was ample room for the insertion of all needed new medicines without increasing the size of the volume. Nay, more; had the pruning knife been judiciously applied, this volume might have been the best and yet the smallest of all the editions of the *British Pharmacopœia*. There are many medicines and preparations in this edition which are seldom if ever prescribed in the treatment of disease, and certainly there is no beneficial effect to be obtained by their employment which would not be more readily obtained by other and more useful drugs.

We have far too many official medicines, and also too many preparations of even most useful drugs. Surely we could do with less than thirty-two preparations of iron or twenty-nine preparations of mercury!

The *Pharmacopœia* could be reduced in size by at least one-third, and yet no patient would suffer in consequence. Nay, more, were the volume greatly reduced in size, students would be enabled to master their materia medica much more efficiently, and consequently the members of our profession would possess a better knowledge of the actions and uses of remedies.

I shall now mention a few of the medicines which might have been excluded.

Scammonium has no virtues not possessed by scammonie resina, and is three or four times dearer. I am aware that it is stated in the *Pharmacopœia* as a source of the resin, but this is not done on account of the price.

Cambogia is another medicine which can well be dispensed with. It is apt to irritate, and possesses no properties not possessed by elaterium. Cerevisie fermentum might have been omitted without any loss to our patients; so, too, with mezerei cortex, rheados petala, and sambuci flores. Laricis cortex possesses no properties not possessed by oleum terebinthinae. Papsavoris capsulae have no properties not possessed by opium. Laurocerasi folia are only useful for the hydrocyanic acid contained in them. Hemidesmi radix is not of suf-

ficient importance to be still official in this country. Moschus might have been consigned to the same position as castor. Elemi, mastiche, and manna are not worthy to be retained; so, too, with saasafra radix, serpentariae rhizoma, sumbul radix, and many others which could easily be named. The omission of these and such like medicines—and, of course, the preparations derived from them—would have materially lessened the size of the volume.

The real question is not—Has the drug any virtue? but—Has it any virtue not already possessed by other and more useful medicines? The size of the volume might have been still further lessened by the exclusion of many needless preparations of several useful and highly important drugs. To this class belong os nstum, zincum, zincum granulatam, bismuthum, bismuthum purificatum. We have far too many preparations of iron, mercury, lead, antimony, etc. Ferrum redactum possesses no properties not possessed by other and more important salts of iron. Ferri sulphas granulata is twice the price of ferri sulphas; but that is no good reason for its retention in the *Pharmacopœia*, seeing it possesses no medicinal properties not possessed by the cheaper salt. Vinum ferri is a favourite with many, but it is a useless preparation; it possesses only traces of iron, and the sherry it contains is not necessarily the best. In like manner, the preparations of mercury are far too numerous. It is to be hoped that in the next edition of the *Pharmacopœia* the bulk of the volume will be greatly reduced.

Another defect is in regard to the nomenclature of drugs. This might be greatly improved. The present edition is much better in this respect than its predecessor, but even yet there is room for improvement. To call acidum phosphoricum *concentratum* is very misleading, especially when omitted in connection with other strong acids. Acidum aceticum glaciale, acidum sulphuricum, acidum lacticum, acidum nitricum, have each a higher percentage of acid than *concentratum* phosphoric acid.

Ergotinum should be *extractum ergotae*. Extractum filicis liquidum is a misnomer, for it is not a *liquid extract* in the true sense of that term. As well call "oleo-resina cubebe" a liquid extract. Gelsemium should be gelsemii rhizoma. Many similar examples might be given. More uniformity in nomenclature would be of much advantage to the student of materia medica.

The doses given in the *Pharmacopœia* might be revised with advantage. Some drugs should have no doses ascribed to them, inasmuch as they should never be given internally: for example, santonica has a dose of 10 to 60 grains. This substance should be used only as a source of santonium, which is tasteless, and has all the medicinal properties, whereas santonica is bitter and disagreeable; so, too, with regard to cusso. Surely it is not expected to swallow a quarter to half an ounce of this substance. I suppose it is meant that the infusion prepared from this quantity is to be taken as a dose. Conii folia is a bad form for internal administration. I suppose few practitioners, if any, give the powder of the dried leaves. Other similar examples might be given.

In some cases there is a want of consistency in the official doses; arsenii iodidum has the dose of $\frac{1}{30}$ th grain, but in the liquor arsenii et hydrargyri iodidi the dose is given as 10 to 30 minims, which is equivalent to $\frac{3}{2}$ to $\frac{9}{2}$ grain, or nearly from three to nine times the dose; and that notwithstanding the fact that this liquor contains an equal quantity of another very powerful substance—the mercuric iodide.

After what I have said about the size of the volume, it may seem out of place for me to complain about the exclusion of drugs from the present edition; and yet I regret to miss such substances as digitalinum and stramonii folia, for the former will still be prescribed in the treatment of disease, and the latter smoked in asthma, notwithstanding their exclusion from the *Pharmacopœia*.

There are other defects in the volume to which I might direct attention, as physostigmatis semen, but I have said enough to direct the attention of the profession and of the General Medical Council to the demerits of the *Pharmacopœia* of 1885; and I have also endeavoured to point out the direction in which amendment is to be looked for in any subsequent edition. Above all, it is to be hoped, for the sake of the already overtaxed medical student, not to speak of the advantage to our patients, that the next edition will be greatly reduced in size.

NOTIFICATION OF INFECTIOUS DISEASE AT BOLTON.—The report sent to the Local Government Board by the medical officer of health for Bolton, approving of the compulsory notification of infectious disease, was discussed at a meeting of the Town Council on Wednesday, and disapproved by twenty-seven to twenty-four.

DR. GARRÉ, whose name is so well known to students of bacteriology, has been appointed professor in the University of Bâle.

HONORARY DEGREES FROM UNIVERSITIES.

A CORRESPONDENT writes to us under the title, M.A. and M.D. : It is interesting to ascertain in how far the universities appreciate and recognise literary and scientific work done by medical men. The two oldest and greatest universities in England have, until very recent years, treated medicine in a most unkind and unbecoming manner, and only now have they seemed to awake to the knowledge of this fact; and they have, by strenuous efforts, begun to attempt to call their medical faculty into life, and to take means to establish a properly equipped medical school, and to attract students. Hitherto their graduates in medicine have been very few, and even these have received, in most instances, much of their instruction at other schools of medicine.

The Oxford University grants four honorary degrees, namely, D.D.; D.C.L.; M.A.; and Mus.D. From 1870 to 1885, it has conferred the following number of honorary degrees: 82 of D.D., 142 of D.C.L., 26 of M.A., and 5 of Mus.D. So far as can be made out of the 142 D.C.L. degrees, 9 only have been awarded to distinguished medical men.

Cambridge, according to its Calendar, has conferred titular degrees on 169 persons; so far as can be ascertained, only 11 have been conferred on medical men. Perhaps the absence of vitality in the medical faculties of their universities is the true reason why they have not shown a keener appreciation of the labours of men who have attained eminence in medicine.

The University of Dublin confers no fewer than ten honorary degrees; the last Calendar shows that, up to this date, it has not been very liberal with its D.D. degrees; 12 only have been conferred. The degree of Doctor of Laws has been conferred on 234; only 4 medical men are to be found in this list, but 37 distinguished medical men figure as honorary Doctors of Medicine, 3 as Masters of Surgery, and 3 as Masters in Obstetric Science. Considering the high repute of her medical faculty, the fulness and excellence of her course of study, the number and eminence of many of her medical alumni, I think this University cannot be accused of lavishly awarding her honours. In Scotland, most of the medical teaching is done at the universities, and a large proportion of those who register as qualified men are graduates in medicine.

The Universities of St. Andrews, Glasgow, Aberdeen, and Edinburgh grant two degrees as honours to persons selected by the Senatus Academicus: the D.D. degree for distinction, the LL.D. degree for literary or scientific eminence. In the Faculty of Divinity the D.D. can now be obtained by B.D.'s of a certain standing, who adopt prescribed forms for proceeding to this degree, but hitherto most, or, in fact, nearly all the degrees of D.D. conferred by the Scotch Universities have been honorary. The Calendars of the Scotch universities are now very complete, and give useful information concerning courses of study and all university matters. Those of St. Andrews, Aberdeen, and Edinburgh have a list of the honorary degrees given each year, and I certainly fail to see why the Calendar of the Glasgow University should not also give this information. The Senatus Academicus of each University wields this great honour-giving power, and doubtless a keen and scrutinising acumen discovers those apparently deserving of such degrees. A wise impartiality weighs in the balance the merits and demerits of those at first glance considered worthy of the honour; and a careful estimate of their work, professional, literary, or scientific, is, of course, made by such competent authorities as for the time sway the councils of their national seats of learning.

Slight variations seem to exist in the different universities that I have record of, as to the ratio in which these two honorary degrees are given. Taking St. Andrews from 1860 to 1885 inclusive, it has conferred 55 D.D. degrees, while it has during the same time given 87 LL.D. degrees. Aberdeen has since 1851 and up to 1885 given 91 D.D. degrees, while in the same time it has given 122 LL.D. degrees. The Edinburgh Calendar states that the list of D.D.'s now includes over 300 names, and the same is said about the degree of LL.D. from 1847 to 1874, a period of twenty-seven years; 107 LL.D. degrees were given, and only 10 fell to the lot of medical men.

At St. Andrews during the twenty years ending 1876, no medical man was deemed worthy of the LL.D. degree; and even though a little more liberality has of late years been shown in according this degree to medical men, only 10 medical men at present find a place among the list of St. Andrews honorary graduates. Aberdeen has since 1860 given its LL.D. to 14 medical men out of a total of 87.

Edinburgh, whose Faculty of Medicine, from its eminence, from the preponderance of its students and its medical graduates, almost overshadows the other faculties in the University, seems in this matter to do them scant justice.

Down to that supreme effort at degree-giving which took place at

the celebration of the tercentenary in 1884, only 29 LL.D. degrees fell to the lot of medical men out of the 191 conferred. That those who have to do with conferring the degree of LL.D. must at times have qualms of conscience and take a fit of seeing merit *evou* in medical men is quite apparent, for in some years medical men figure in a fair proportion.

In the list of 1875 this is seen more markedly than in any other year, for of 14 LL.D. degrees conferred, 8 fell to medical men. At the tercentenary celebration 124 LL.D. degrees were conferred, 42 on distinguished medical men; at such a time medicine was evidently duly recognised, but since that period only 4 medical men have received this honour, though 24 degrees have been awarded. Even in this University the highest honours are given with greater sparingness to medical men than to those of some other professions, and yet her medical sons have done, and are doing, as much to increase the fame of their Alma Mater as any of her children.

Now if honorary degrees are given at all on fair and equivalent grounds, a perusal of the Calendars and the list of honorary degree holders would lead one rather to the belief that the clergy, without any comparison, are the most distinguished of the professions; that they should be the best, and probably are, I admit.

That nearly all professions are distinguished by honorary degrees is legitimate, but that lawyers and medical men should be so unworthy of honour from their university is very sad indeed, and yet we hear of medical graduates of all the Scotch universities doing good work, and some even attain the highest eminence.

In Glasgow in 1886 six D.D.'s were given, thirteen LL.D.'s, three only of the latter were given to medical men. It is very seldom that one notices a medical graduate of Glasgow University receiving further honours from his own university. Yet there are 1,596 medical men among the 5,848 who constitute the members of Council of that University.

Of the twelve professors in the Medical Faculty only four are themselves students of, and graduates in, medicine of that University. It is highly probable, and I offer it as a possible explanation of the facts that a perusal of the University Calendars has forced upon me, that in all seats of learning, old customs, old fashions, and old beliefs linger long. The Church at one time was the learned profession, lawyers and doctors of medicine are of yesterday; the Church gave legal advice, dispensed medicine, and up to a given date even acted as surgeon.

Though matters have changed the belief in the profession still holds good, and D.D.'s are common in Scotland, and though at times and in certain cases those in other professions wonder what their old fellow-student has done to be so graced by his Alma Mater, age, a certain pulpit success, and a lucky avoidance of the pitfalls which beset clergymen, seem often to the uninitiated mind to be the principal ostensible reasons of the decoration of the doctorate. It is very possible that the medical professorate are not so much in touch with the graduates of their University, who live at a distance from their University, and that they are in most cases in a minority at the meetings which select those to be honoured, and that it is owing to this that I see clergy, rectors of schools, and school examiners in a very much higher proportion than lawyers or medical men in the lists of honorary graduates.

THE WOMEN'S JUBILEE OFFERING.

THE Queen has expressed her approval of the scheme contained in the following address from the Committee nominated by Her Majesty to consider and report upon the best means of effecting her wish to benefit nurses as well as the nursed by devoting to this object the surplus of the Women's Jubilee Offering.

"Eaton, December 26th, 1887.

"In obedience to the desire which your Majesty has graciously expressed to us, that we should consider and report on the method by which the surplus of the Women's Jubilee Offering may be best applied for the promotion of nursing, we have the honour to state to your Majesty our belief that the best method, and that which will be most gratifying to those who contributed to the fund, will be by the foundation of an institution for promoting the education and maintenance of nurses for the sick poor in their own homes. We believe that the institution should have its chief centre in London, but that similar central institutions should be in Edinburgh and Dublin, and that with one or all of them should be affiliated any institutions desiring such affiliation, and satisfactorily fulfilling, in any part of the kingdom, the general purpose of the foundation.

"We would recommend that the nurses should all be duly approved women of excellent personal character, and of good education,

similar to that of well-trained nurses in hospitals, and a special training in district nursing and in maternity hospitals, so that they may be fit to attend poor women after childbirth.

"We hope that your Majesty would give to the institution a name indicating the occasion of its foundation, and to the nurses authority to wear an appropriate badge or other decoration. We believe, also, that it would be very useful if, with your Majesty's authority, the nurses were classed in two or more ranks, the higher of which would indicate, by name or decoration, length of service, or remarkable skill, or devotion to duty. Further, we venture to suggest to your Majesty that it would add to the esteem and utility of the proposed institution if its official work could be done in St. Katherine's Hospital, or if it could be in some manner connected with that ancient foundation; for that hospital is one of the oldest benevolent institutions in the kingdom. Ever since its foundation in 1148 the Queens of England have been its patrons; and the charter granted in 1351 by Queen Philippa assigned to it, among its chief purposes, the visitation of the sick and poor. We are prepared, if it be your Majesty's pleasure, to consider, or to take part in considering and reporting in detail, on the means by which the institution which we commend to your Majesty's favour may best conduce to the end proposed.

"WESTMINSTER.

"JAMES PAGET.

"RUTHERFORD ALCOCK."

PSYCHOLOGICAL MEDICINE AT THE NINTH INTERNATIONAL CONGRESS.

A WELL-KNOWN alienist physician has sent us the following observations on the Section of Psychological Medicine and Nervous Disease of the International Medical Congress:—The President of the Section showed in his address how rapidly the urban population are developing insanity, so that very soon the Americans will not only be in advance in progress, but also in the ratio of their insane to their sane population. Their healthiest population is that of the advancing new States; their worst the New York State. With the negroes civilisation increases, but insanity outpaces it. It was shown that the American ideal in asylums is as good as possible, and that the newest plans for the treatment of patients are to be found in the States; even lady doctors and pathological laboratories are being introduced, but it seemed that the former were not appreciated as fully as might have been expected by the superintendents.

Discussions took place on treatment, but, as a rule, this was not from the therapeutical, but from the humane, standpoint. Restraint or non-restraint, that was the question; whether it was the duty of the superintendent to have a non-restraint shibboleth, or not. In the Section it was decided to the satisfaction of all, that a good deal of liberty should be allowed, even to medical officers.

Dr. Mendel, of Berlin, read a paper on the Origin of the Facial Nerve, with some clinical facts supporting his physiological observations. He also read a paper objecting to the use of the term "moral insanity;" in America it may well be believed that feeling is strong as to the use and misuse of the term. Probably no other nation in the world has so many persons who are morally insane, and, at the same time, no nation has so many persons who need to be kept in awe of something—persons who would be only too glad to give up self-control, if assured no punishment would follow. The nation is seething in its development, and with its great possibilities of good are also great possibilities of evil. It was generally felt that the use of the term "moral insanity" must be retained, but its use limited.

As might have been expected, there were one or two papers which were not up to Congress pitch. Either they were crude or they were ill thought-out, being but the outcome of fevered imagination. Such a one was by a superintendent, on Remissions of Insanity, who appeared to hold that a force allied to spiritual force had a good deal to do with the disease. No such thing as complete cure or recovery between attacks seemed possible to him. This, coming from one of the friends of the insane, was too terrible to leave unchallenged.

There are certain moot points in each Section, and one sure to crop up in Psychological Medicine is classification. It would be well if in future Congresses—for the next hundred years, at least—a notice were given that no such papers could be received; for they all come to the same thing; they add one more variety to the list already too long.

A very interesting paper was read by Dr. Spitzka, of New York, on a New Disease, the symptoms resembling very nearly those of insular sclerosis, and the pathological changes being due to multiple aneurysmal dilatation throughout the nervous system. In the case

described there was a history of similar symptoms having occurred in other members of the family, and Dr. Spitzka pointed out the fact of inheritance of special vascular tendencies. Other pathological subjects were considered, and some original work was shown by Dr. Homan, of Helsingfors, who had been for some years working at the effects of early amputation of limbs in the lower animals, not only on the higher nerve centres, but on the peripheral nerves themselves. It seems that too much has been made of the easily-spoken-about but not yet proved conduction of degeneration. Several writers devoted their attention to single symptoms, to the clearing away mystification in the use of terms; but we were astonished that no one took up the word "paranoia," in all its glory, and descanted upon it.

The English Section was honoured by the selection of Dr. Blandford to read a paper before the General Congress, and the large audience spoke well for the appreciation of our countryman, and the attention displayed proved the justice of the selection. The paper being on the Treatment of Recent Cases of Insanity in Asylums and Private Houses, was, of course, of more practical interest to us; but it showed the Americans our methods of dealing with the insane better than a more elaborate essay would have done.

Special papers were read, as we have said, on particular groups of symptoms, but these were not of any great novelty, and were, as a rule, the careful arranging of the author's experience according to his idea of order. Such contributions are good for reference, but not for cursory notice. The best attended meetings of the Section were those devoted to the papers from British contributors on the Relationships of Syphilis to Neuroses, and it will suffice here to say that papers were contributed by Drs. Shuttleworth and Beach on Idiocy and its Specific Relationships; by Dr. Wigglesworth, on Acute Syphilis and its Relations to Mental Disorder; by Dr. Mitchell, of the Royal Asylum, Edinburgh, on the Statistics of Syphilis among the Insane Population of that city; by Dr. Warner, on some of the Epileptic Associations with Syphilis; and by Dr. Savage, who took a general survey of the ground traversed by the former speakers, and also contributed a paper on the Connection between General Paralysis of the Insane and Syphilis. The discussion merits further notice, and we shall hope to give it in more detail.

The Section did much practical work in visiting asylums, and we have no doubt that the meeting of men from distant countries started some friendships and cemented more, which will be for the advancement of psychiatry.

REGISTRATION OF FOREIGN DEGREES.

JUDGING from some of the letters which have been addressed to us, it would appear that there are still considerable doubts as to the right of registered medical practitioners who have recently obtained, or may in the future obtain, foreign degrees, to register those degrees.

Certain questions raised by correspondents have been submitted to a competent legal authority, whose opinion is subjoined. The M.D.Brussels was selected for convenience, and because, after admitting many persons having the degree of M.D.Brussels to register that degree, the General Medical Council will, of course, acknowledge it to be a degree obtained after a proper examination, and therefore will, we presume, recognise it as a diploma "furnishing a sufficient guarantee of the possession of the requisite knowledge and skill for the efficient practice of medicine, surgery, and midwifery," as required by Section 13 of the Medical Act, 1886.

I.—B. C. is a registered medical practitioner who has continuously practised medicine in the United Kingdom or elsewhere for a period exceeding ten years immediately preceding the prescribed day, he was practising medicine in the United Kingdom on the prescribed day, and is a British subject. He obtained the degree of M.D.Brussels after proper examination, on a date after the passing of the Medical Act (1886), but before the prescribed day. If an Order in Council were to be issued declaring that the second part of the Medical Act (1886) applied to Belgium—

1. Could B. C. then register the M.D.Brussels as an additional qualification?

If not—

2. Could he cause his name to be inserted on the separate list of names and addresses of the foreign practitioners? If (2) is answered in the affirmative, would his name be withdrawn from the general list on which it now appears in virtue of the registration of his English diploma?

* (1) When an Order in Council applying the second part of the Act to Belgium is issued, it seems that B. C. will be entitled to be registered under Subsection (3) of Section 12 as a British subject practising medicine in the United Kingdom on the prescribed day and for ten years preceding, who will show that he holds what should be a recognised foreign diploma, assuming that the Brussels M.D. entitles its holder to practice in Belgium.

(2) The separate list does not seem intended to supersede an ordinary British qualification.

II.—D. E. is a registered medical practitioner, a British subject, who has continuously practised medicine in the United Kingdom or elsewhere for a period exceeding ten years immediately preceding the prescribed day. He obtained the M.D. Brussels, after proper examination, on a date subsequent to the prescribed day. If an Order in Council were to be issued declaring that the second part of the Medical Act (1856) applied to Belgium—

1. Could D. E. register the M.D. Brussels as an additional qualification?

If not—

2. Could D. E. cause his name to be inserted on the special list of the names and addresses of the foreign practitioners?

* (1) Yes, it seems so. The prescribed day, by Section 17, is the day on which the Act is declared to apply to the foreign country.

(2) This is already answered in I (2).

THE CRIMINAL RESPONSIBILITY OF THE INSANE.

II.

DR. HARRINGTON TUKE sends us the following comments on the case of the Rev. G. C., in continuation of those published on November 26th, p. 1175.

The summing up of Mr. Justice Field was strongly adverse to the prisoner. I do not impute any blame to the judge, whom I know to be as humane and benevolent as he is just and learned. The fault seems to be in the present test imposed by the law as to the responsibility of an insane criminal. This test, in my opinion, often, as in this case, involves the manifest injustice by procuring the condemnation of an obvious lunatic. The judge, in the discharge of his duty, several times impressed upon the jury that they were to first consider whether the prisoner knew the nature and quality of the act he had committed, and, if so, they must find him guilty of murder. Now, it would seem to me, and I should think it would strike every reader of the evidence adduced in this trial, that the prisoner knew well the "nature and quality" of his act. He got a razor from his case, walked to the door of the vicar's bedroom; when admitted, after a short delay outside the locked door, he walked to that side of the bed in which his right hand would have the most power to use a razor as a weapon, and with the candle still in his left hand fatally wounded his victim in the throat. The question addressed by him to the vicar "What do you mean?" would appear to indicate some latent delusion as to an imaginary wrong, but that only strengthens the hypothesis that he knew the nature of the ghastly deed he was perpetrating.

Twice his victim's wife came to his room; on the second visit he noticed the blood of the murdered man on her dress, and desired her to go and change it. The murder was a mad act, no doubt, but the history I have given from the testimony of an eye-witness shows it was done by a man who possibly well knew the "nature and quality" of the crime he had committed. The unnatural calmness and composure of the prisoner during the whole time is worthy of notice.

The second question, "Did the prisoner at the moment of murder know that he was doing wrong?" a question the careless answer to which has often led to the "miserable spectacle," as Sir Edward Coke calls it, "of the execution of a madman," which, as he goes on to say, is "against law and of extreme inhumanity and cruelty," was frequently and impressively put to the jury, and also dwelt upon by the counsel for the prosecution.

In this extraordinary trial we have materials for a more minute examination of this question than are usually available in cases of murder in which insanity is pleaded for the defence. We have in evidence that at ten o'clock on the night of the murder the prisoner read family prayers in the presence of the lady whose husband he killed before her eyes two hours afterwards. He had probably his own private devotions; unless we presume his prayers to have been merely mechanical, he must, when he uttered the application, "Deliver us from evil," have known right from wrong. He spoke rationally, and, at all events, there then appeared no reason to doubt his mental capacity or his moral responsibility. That the prisoner knew right

from wrong the next morning early is shown by his ready acquiescence in the remark of the policeman who arrested him, "that the murder of the vicar was a bad job," and his unresistingly allowing himself to be arrested. According to the evidence of the next witness, he admitted that the murder was a sad affair.

It is seldom that an eye-witness can describe an act of murder, and is able to do so, by her want of knowledge that a murder had been committed. The prisoner carefully concealed the razor from the wife; the way he held the candle in his left hand seems to have prevented her seeing his act of desperate violence. She did not believe her husband when he says, "He has cut my throat!" and went at once to the prisoner's room. The prisoner had hidden the razor beneath his looking-glass, and to the question whether he had anything in his hands, shows them, and answers, "Nothing."

The wife returned to her husband, whom, in the agonies of death, she found lying on the floor in a pool of blood. She went a second time to the prisoner, and said, "What have you done? Come and help me." Her nightdress was stained with blood. The only reply she obtained is, "I have done nothing. Go and change your dress."

The concealment of the razor in the first instance, the hiding of it afterwards, and the denial of the crime seem to point to at least some feeble knowledge that he had committed an act which was wrong, and which he naturally shrank from admitting.

It must be perfectly understood that I and all the other medical witnesses present at the trial, and probably most of those who may read this account of it, believed, and still believe, that the prisoner's murderous act was that of a madman—that it was a recurrence of the same "homicidal mania" that had suddenly appeared at the same season nine years before, when, as Dr. Wright told the jury, Mr. C. had made an unprovoked attempt to cut the throat of an aged patient, and shortly afterwards had tried to throttle another; and this was the view apparently held by the jury, who refused to trouble themselves more than was absolutely necessary with either of the purely legal questions which had been dwelt upon, in the strict discharge of their duty, by the judge and the Crown counsel.

This and other trials show the disagreement that exists between law and psychological medicine as to the responsibility for crime. The lawyers apparently do not understand that a perfect knowledge of right and wrong is quite consistent with even hopeless and dangerous insanity. I had frequently recognised this difficulty, and in giving evidence before the "Royal Commission on the Abolition of Capital Punishment" I was much struck by the incredulity of Lord Derby, the Chairman, and other members of that distinguished Committee, as to the fact which I stated from my own experience, that I had heard an insane man condemned to death, who was afterwards executed, on the ground that at the moment of the murder he was able to distinguish right from wrong.

At a fully representative meeting of the Medico-Psychological Association held at the College of Physicians in 1864, several foreign alienist physicians being present, I brought forward a resolution as to the point whether the presence of the knowledge of right and wrong is any proof of sanity. The resolution was in these terms:

"That so much of the legal test of the mental condition of an alleged criminal lunatic which renders him a responsible agent, because he knows the difference between right and wrong, is inconsistent with the fact, well known to every member of this meeting, that the power of distinguishing between right and wrong exists frequently among those who are undoubtedly insane, and is often associated with dangerous and uncontrollable delusions."

In the course of the debate that ensued, Dr. Morel, of Rouen, a well-known French psychologist, expressed his surprise that the law of England should make an insane man responsible for his acts because he has a knowledge of what he has done. The best way of ascertaining if the acts of an insane person correspond to a particular trouble or disorder of the mind was to study the nature of the act in relation to the particular malady. The resolution was carried unanimously. It may be taken, then, that an insane man, in the opinion of competent judges, may be irresponsible, although knowing right from wrong; and it appears to me that the verdict of the jury in the case of the Rev. G. C. was consistent with this opinion, and inconsistent with the doctrine that the knowledge of right and wrong renders an insane man liable to capital punishment; but that he should be confined and prevented from further mischief, is consonant with right and justice.

MEDICAL MAGISTRATES.—Messrs. Richard Hingston, L.R.C.P. Lond., William Nettle, M.R.C.S. Eng., and Charles Bainbridge Rendle, M.R.C.S. Eng., have been placed on the Commission of the Peace of the Borough of Liskeard.

Jan. 14, 1888.]

ASSOCIATION INTELLIGENCE.

COUNCIL.

NOTICE OF MEETING.

MEETING of the Council will be held at the Offices of the Association, No. 429, Strand (corner of Agar Street), London, on Wednesday, the 18th day of January next, at 2 o'clock in the afternoon.

The following Committees will also meet:—
Tuesday, January 17th, 1888.—Habitual Drunkards Committee, 8.30 P.M.—Therapeutics Committee, 3 P.M.—Premises and Library Committee, 4 P.M.—Relative Rank Committee, 5 P.M.—Fees to Witnesses Committee, 6 P.M. *Wednesday, January 18th, 1888.*—Arrangement Committee, 10.30 A.M.—Journal and Finance Committee, 11.30 A.M.

FRANCIS FOWKE, *General Secretary.*

December 24th, 1887.

NOTICE OF QUARTERLY MEETINGS FOR 1888.

ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Meetings of the Council will be held on January 18th, April 18th, July 18th, and October 17th, 1888. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before each meeting, namely, March 28th, June 27th, September 26th, and December 28th, 1888.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No member can be elected by a Branch Council unless his name has been inserted in the circular summoning the meeting at which he seeks election.

FRANCIS FOWKE, *General Secretary.*

COLLECTIVE INVESTIGATION OF DISEASE.

THE Report upon the CONNECTION OF DISEASE WITH HABITS OF INTemperance, which was presented to the Section of Medicine in the Annual Meeting of 1887, and a further portion of the Report upon OLD AGE have been completed, and will shortly be published in the JOURNAL.

Reports upon the two remaining inquiries, namely, that into DIPHTHERIA, and that into the GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES, are in preparation, and will be published as soon as ready.

The following inquiry only of the first series remains open, namely, that on THE ETIOLOGY OF PHTHISIS.

A fresh inquiry into the ORIGIN AND MODE OF PROPAGATION OF EPIDEMICS OF DIPHTHERIA has just been issued.

Memoranda upon these subjects, and forms for recording observations may be had on application to the Secretary of the Collective Investigation Committee, 429, Strand, W.C.

BRANCH MEETINGS TO BE HELD.

METROPOLITAN COUNTIES BRANCH: EAST LONDON AND SOUTH ESSEX DISTRICT.—The next meeting will be held, by the kind invitation of Dr. Adams, at Brooke House, Upper Clapton, on Thursday, January 19th, at 8.30 P.M. A demonstration of interesting cases of eye disease will be given by A. Q. Silcock, Esq. Visitors will be welcomed.—J. W. HUNT, Honorary Secretary, 101, Queen's Road, Dalston.

METROPOLITAN COUNTIES BRANCH: WESTERN DISTRICT.—The next meeting will be held on Friday, January 27th, at St. Mary's Hospital, Paddington (by kind permission of the medical staff). The chair will be taken, at 8.30 P.M., by H. Charlton Bastian, Esq., M.D., F.R.S., the Vice-President of the District. Business: 1. Minutes of preceding meeting. 2. Clinical remarks on Chronic Diseases of the Knee-joint in Young People: by Edmund Owen, Esq., M.B., F.R.C.S., Surgeon to St. Mary's Hospital and the Children's Hospital; several illustrative cases of patients will be shown. 3. Demonstration of cases of Chronic Diseases of the Spinal Cord: by D. B. Lees, Esq., M.D., F.R.C.P., Physician to St. Mary's Hospital and the Children's Hospital. 4. Drs. Waller, Silcock, Handfield-Jones, and R. Maguire, will exhibit microscopic specimens, and give short demonstrations, etc.—C. A. PATTEN, Honorary Secretary, Marpool House, Ealing, W.

NORTH OF IRELAND BRANCH.—A general meeting of the North of Ireland Branch will be held in the Royal Hospital on Thursday, January 26th, 1888, at 12 o'clock noon. Gentlemen desirous of reading papers, exhibiting cases, specimens, etc., will kindly communicate as early as convenient with the Secretary, JOHN W. BYERS, M.D., Lower Crescent, Belfast.

DUBLIN BRANCH.—The eleventh annual general meeting of the Dublin Branch of the British Medical Association will, by the kind permission of the President and Fellows, be held on Wednesday, January 25th, at 4 P.M., in the hall of the King and Queen's College of Physicians, Killiare Street. The officers and Council for the ensuing year will be elected by ballot, and any other necessary business transacted. Edward D. Mapother, Esq., M.D., President-elect, will deliver the annual Address. At the conclusion of the business of the annual meeting, the portrait of the President of the Association, Dr. Banks, will be presented to the President and Fellows of the King and Queen's College of Physicians by the President of the Branch, on behalf of the subscribers to the Reception Fund of the late annual meeting of the British Medical Association in Dublin. Subscribers to the Reception Fund, although not members of the Branch, are invited to attend the meeting. Members wishing to bring any subject of professional interest before the meeting, to nominate any member to serve as an officer or on the Council of the Branch, or to propose any gentleman as a member of the Association, or of the Branch, must inform the Honorary Secretary on or before January 13th. The annual dinner of the Branch will be in the College hall, at 7 P.M., on the day of the meeting. The charge for dinner tickets for members who purchase their tickets on or before Tuesday, January 24th, is 17s. 6d.; for members purchasing their tickets after that date, and the guests £1. Applications for tickets and the name and address must be forwarded to the Honorary Secretary. Members' guests are not limited to their professional friends.—L. H. ORMSBY, M.D., Honorary Secretary and Treasurer.

OXFORD AND DISTRICT BRANCH.—The next meeting will be held at the Radcliffe Infirmary, Oxford, at 3 o'clock on Friday, January 27th. Notice of papers to be read and cases to be shown must be given to either of the Honorary Secretaries on or before Monday, January 23rd. Members are requested to send their annual subscriptions to the Association and the Branch, due January 1st, to Dr. Darbishire, 97, Holywell, Oxford.—S. D. DARBISHIRE, W. LEWIS MORGAN, 42, Broad Street, Oxford, Honorary Secretaries.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.

THE December meeting of this Branch was held at 198, Union Street, Aberdeen, on Wednesday, December 21st, at 8 P.M.; the President of the Branch, Dr. SMITH, of Kinnairdy, being in the chair.

Minutes and Ballot.—The minutes of the last meeting were read and approved, and Dr. J. J. Y. Dalgarno, Royal Infirmary, Aberdeen, was ballotted for and admitted a member of the Branch.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

Sweating Fever.—*Treatment of Obesity.*—*Action of Bile.*—*Antipyrin in Epilepsy.*—*Cocaine Poisoning.*—*A Bullet extracted from the Wrist after seventeen Years.*—*The Lungs as Filters for Micro-organisms.*—*Antiseptic Lozenges.*

SWEATING fever appeared in Poitou last summer for the first time since 1845. The opinions concerning the origin and nature of this affection differ greatly. The *Poitou Medical* has published a volume containing the works of different authorities upon the epidemics of 1845 and 1887. Dr. Gaillard, who wrote a complete clinical description of the epidemic of 1845, remarked that it principally attacked persons in easy circumstances. He employed sudorifics and tonics. Dr. Gaillard noted that it was more serious when it appeared during pregnancy or delivery. He regarded sweating fever as non-contagious—an opinion which was shared by most of the medical men of the locality in which it appeared. Drs. Thandière and Litardière reported the epidemic at Sillars in 1887; 244 persons were attacked. Measles was observed at the same time as the sweating fever. Dr. Guillé, who observed both these affections simultaneously at Montmorillon, regarded the epidemic as military measles, or measles accompanied by sweating fever. This opinion was shared by Dr. Brouardel, who was sent by the Academy of Medicine to investigate the nature of the epidemic. Dr. Guillé believes that the affection is not directly contagious, but is transmitted by the air. Dr. Coutancin remarked that in the same district the affection followed the direction of the wind. Dr. Bernard observed that in several patients the number of blood-corpuscles was reduced by one-third; this accounts for the long duration of convalescence and consecutive anæmia. He regards sweating fever as a contagious affection of malarious nature. Dr. Ponteil observed that the affection usually proved fatal in the case of pregnant women. He attributed the disease to infection. M. Parmentier distinguishes two clinical aspects of sweating fever. In the first the number of white and red corpuscles in the

blood is not modified. In the second the number of white corpuscles is doubled, while the number of red corpuscles is reduced by one quarter. The proportion of hæmoglobin is diminished. Dr. Brouardel gave a detailed description of sweating fever in his report to the Academy of Medicine. The first period is marked by nocturnal sweats, fever, suffocation, epigastric constriction, *barre*, palpitations, delirium; and in some cases epistaxis and cough are present. The second period, which begins on the second or third day, is characterised by itching and pricking, followed by the appearance of a miliary eruption, which appears on the surface of an exanthem, which assumes three forms—those of measles, scarlatina, and puerperal fever. This rash appears on the face and extends to the neck, trunk, and limbs. The sweats and nervous disturbances are modified. The third period is constituted by desquamation. Convalescence is exceedingly tedious. Dr. Brouardel distinguishes two forms of sweating fever—1. A serious form, followed by death in forty-eight hours, decomposition taking place rapidly. 2. A mild form, in which relapse often occurs. This rubecolic sweating fever (*suetto rubéolique*) described by Dr. Brouardel is principally observed in children who have had measles. The incubation period is twenty-four hours. Dr. Brouardel has shown that sweating fever is eminently contagious. The nature or pathological anatomy of this affection is at present unknown. He recommends isolation and disinfection.

At a recent meeting of the Biological Society, M. Leven presented a communication on the treatment of obesity. He holds that it is principally due to nervous disturbance, which causes the food to be transformed into fat. Treatment which aims at curing the neuropathic phenomena should be adopted. Irritation of the solar plexus should be guarded against. A diet which is easily assimilated should be employed, such as eggs, soup, and plenty of milk. It is well to avoid intellectual or physical fatigue. M. Grimaux stated that he had employed a diet composed of eggs, potatoes, and milk rice, and found himself benefited by this system.

M. Dastre, who has continued his investigations on the influence of bile on the digestion, described the results of two experiments he had recently performed. He made a fistula between the gall-bladder and the intestine. The animals operated on recovered four months after the establishment of the fistula. A meal composed of meat, fat, and milk was given to them, and, while the digestive functions were in action, M. Dastre ascertained the following facts. The chyliferous vessels were only transparent between the stomach and the fistula, where the pancreatic juice had acted alone. Beyond the fistula, where the bile and pancreatic juice had acted, these vessels were white and milky. M. Dastre concludes that bile aids in the digestion of fatty substances as much as the pancreatic juice, but that bile or pancreatic juice, acting separately, fails to promote the assimilation of fat.

M. A. Robin read a note by M. Lemoine (of Nancy) on the treatment of epilepsy by antipyrin. It appears that this drug relieves the headache and neuralgic pains following epileptic attacks, but does not cure the disease.

M. Lafont, who has been studying the phenomena of cocaine poisoning, states that this affection is characterised by a tendency to sensory hyperæsthesia, and tachycardia which often ends in collapse. M. Déjerine stated that he had observed similar phenomena. In a case which he had seen, the patient seemed to feel the contact between his fingers and an external object, but he appeared to be insensible to pain when his fingers were pinched. Scabs resembling syphilitic rupia were observed at the spots where the injections had been made.

At the Surgical Society M. Poncet lately showed a bullet weighing 22 grammes, which was extracted from the left carpus, where it had remained during seventeen years. Since 1870 the patient remarked that the lower portion of his hand projected, and that he could not use it freely. In 1880 he suffered from severe pain in this limb after a fall. A movable body could be felt inside the carpus, between the pisiform bone and the styloid process. An incision was made; pus escaped, and a cavity was discovered in which the bullet had lodged under the nina. The bones of the carpus were laid bare, and were observed to be necrosed; these were cleaned. Six days later there was no more pus; the cavity had almost disappeared. M. Poncet concludes that large bullets should be immediately extracted. In the present case the patient would have been spared five years of suffering and twelve years of functional disability if surgical interference had been immediately had recourse to. M. Reclus observed that he did not share this opinion. He cited two cases in which bullets had not been removed. The patients experienced no inconvenience; one of the bullets was 11 millimètres in diameter. M. Poncet replied that it was only in the case of rifle bullets that he considered surgical interference necessary.

MM. Straus and Dubreuilh, by their recent experiments, have confirmed the statement that the air expelled from the lungs is free from microbes. They saturated some broth prepared for the purpose with a portion of air expelled from the lungs. On examination the broth was found to be almost free from microbes. This result proves that the lungs act as a filter, and purify the air which passes through them from micro-organisms. The breath of human beings crowded together in a confined space is only deleterious on account of the noxious gases it contains. The microbes found in the air under such conditions are due to the clothes, sputa, dust, etc.

In the *Union Médicale* of December 11th Dr. Durrant describes the effect of Dr. Albin Meunier's antiseptic lozenges in the treatment of pulmonary tuberculosis and other affections of the respiratory organs. The discovery of the pathogenic microbe of these affections suggested that they might be completely cured if an efficient agent could be found to destroy the microbe, or render the organism impervious to its attacks. The antiseptic treatment of affections of the respiratory organs was a method in accordance with the most recent scientific theories; its practical application was, however, rendered almost impossible for the following reason. It would only prove effectual if the antiseptic remedies were administered in large quantities; these in strong doses exercised an injurious and even dangerous action upon the cells of the organism. Dr. Albin Meunier has discovered a means by which antiseptic remedies which destroy the pathogenic microbe of pulmonary phthisis and other broncho-pulmonary affections may be administered in active doses without any danger whatever to the organism. Dr. Meunier's antiseptic lozenges are composed of carbolic acid, eucalyptol, iodoform, creasote, menthol, etc.; one to three lozenges are given at each meal. The beneficial effects of volatile essences in the treatment of broncho-pulmonary affections have been demonstrated by numerous observations. They arrest the evolution of the bacillus, modify the character of the secretions, and diminish the fits of coughing. Dr. Meunier's lozenges are rapidly absorbed, and the organism is quickly and thoroughly impregnated with the antiseptic substances. Their odour is observed in the breath, in the urine and perspiration of the patient shortly after the lozenges have been swallowed. Owing to the purity of the substances employed, this treatment never disturbs the digestion. The action is prompt and effectual; tonics and strengthening medicines may be combined with this treatment. Under it the patients increase in weight, diarrhoea and night-sweats disappear, and the local symptoms are modified.

VIENNA.

[FROM OUR OWN CORRESPONDENT.]

The Carlsbad "Cure."—*Hypodermic Injections of Antipyrin.*—*General News.*

DOCENS DR. JAWORSKI, of Cracow, gives, in the *Przegląd Lekarski*, under the above title, some interesting details respecting the influence of the springs of Carlsbad on diseases of the stomach. The author first emphasises the fact that the majority of gastric disorders are due to an increased activity of digestion, and not, as had long been thought, to impairment of the secreting power of the gastric mucous membrane of the stomach, or to complete destruction of the digestive action. He refers to the publications of Richmann in 1882, in which increased secretion of the gastric juice was said to be the cause of the disease, and also refers to researches on the diseases of the stomach by Jaworski, Gluzinski, and others, which illustrated this statement by several facts. Further investigations had shown that, in ulcerations of the stomach, hydrochloric acid was increased, and that hæmatemesis, as a result of *ulcus ventriculi*, was observed when the secretion of hydrochloric acid had risen to the highest point. The diminution of the secreting power of the stomach greatly lessened the danger of gastric ulcer. The springs of Carlsbad had been said to stimulate the secretion of the stomach, and to quicken the digestion. Dr. Jaworski, however, observed that, although the water and the dried salts of Carlsbad increased the secretion of the gastric mucous membrane when given in small doses, when used in large doses, or when taken for a long time, they lessened the secretion both of acids and pepsine, so that, after prolonged use of these remedies, the secretion was completely arrested without any great disturbances in the mechanism of the stomach. Out of 232 cases which Dr. Jaworski had examined, in 156 he found the cause of the gastric disorder to be increased secretion of hydrochloric acid. The good effect of the springs of Carlsbad in almost all diseases of the stomach was thus explained. With reference to the indications for the use of the waters, Dr. Jaworski, as the result of numerous internal examinations of the

stomach, distinguishes the following stages and forms of gastric diseases. The use of the springs of Carlsbad is indicated: 1. In increased secretion of the gastric acids during the time of digestion only (*hypersecretia digestiva transitoria*). In such cases the use of the Carlsbad waters lessens the sensibility of the mucous membrane of the stomach. 2. In increased secretion of the gastric acids when the stomach is empty (*hypersecretia hyperacida continua simplex*). When the Carlsbad waters are used in such cases in small quantities, not only the normal, but the functional and structural conditions were re-established. 3. (a) In the third stage, which had been called by Jaworski *catarrhus acidus v. gastrorrhœa hyperacida continua*, where the secretion of hydrochloric acid had attained the highest degree, so that the acidity of the non-digesting stomach was scarcely less than it is at the period of active digestion. In these cases, disturbances of the chemisms of digestion and anatomical changes of the glandular apparatus, and even in the muscular layer of the stomach, were already present. The use of the Carlsbad water, in large doses and for a long time, will diminish the acid secretion to a high degree, and produce a considerable improvement in the disease; (b) As, according to all the experimental results which had been hitherto obtained, the round ulcer of the stomach (*ulcus ventriculi rotundum*) was attended with the acid catarrh just mentioned, and was probably produced by it, the favourable effect of Carlsbad water in cases of gastric ulcer was satisfactorily accounted for. 4. Besides the continual increase of the acid secretion, there was still another abnormal and periodic hypersecretion of hydrochloric acid of nervous origin. The difference between these forms consisted in this, that in the former the increased acidity was met with at each internal examination, whereas in the nervous form, the increased acidity was only occasionally observed. In this latter the Carlsbad water might be advantageously employed. 5. In certain neuroses, sensory (*hyperæsthesia, cardialgia*) as well as motory (*vomitus nervosus*), Carlsbad water is not less useful. Dr. Jaworski does not remember any single case in which the water had been vomited, and this was also true of cases in which no other liquids, and even no medication, could be retained in the stomach. In such cases the good result was to be ascribed to the mild effect of the warm and diluted alkaline solution and the free carbonic acid on the mucous membrane of the stomach. The use of the waters of Carlsbad is contra-indicated in:—1. The fourth stage of the secretory debility (*insufficiencia secretionis acidæ*), when the acid secretion was insufficient even during digestion. 2. The last stage, which had been called *catarrhus mucosus*, when hydrochloric acid and sometimes even pepsine was quite absent even during digestion. Even in these cases it was worth trying whether the glandular apparatus could not be irritated to secretion by small quantities of Carlsbad water. Dr. Jaworski further points out that the effect of Carlsbad water was not only a symptomatic one, as was believed by many, that it not only neutralised the hyperacidity of the gastric contents, but that it also produced permanent anatomical and functional changes in the glandular apparatus, by which the power of secreting hydrochloric acid was diminished, and thus a permanent benefit obtained. Whether Carlsbad cure was indicated in a given case should be learned from the internal examination of the stomach. During the time the water was used the progress of the case must be determined from time to time by internal examinations. It had been proved by several experiments that a too protracted use of the Carlsbad water and salt finally led to complete loss of the power of secreting hydrochloric acid. On the other hand, it was a known fact that there was no strict causal connection between the subjective disturbances and the objective changes in the stomach, so that no sure conclusion could be drawn from the former as to the condition of the stomach. It was therefore absolutely necessary to examine the contents of the stomach chemically from time to time in order to obtain a true idea as to its secreting power, so that it might not be completely destroyed. It should also be borne in mind that atrophy of the glandular apparatus predisposed to the development of neoplasms in the stomach. Korczynski and Jaworski had shown (*Klinische Befunde bei Ulcus Carcinoma und Magenblutungen*, Berlin, 1887) by statistics that malignant neoplasms of the stomach coincided with the above-mentioned condition of mucous catarrh, and that there was probably a more or less close causal relation between them.

Subcutaneous injections of antipyrin are now used at the clinic of Professor Drasche in the general hospital with much success; 0.25 gramme (25 centigrammes) in a Pravaz syringe were used with the best results in cases of local pain, where injections with morphine were also indicated. In the same way they were used in cases of ulcerating tumours and cancers with very beneficial effects.

Dr. Edward Albert, ordinary Professor of Surgery in the Vienna

University, has recently had the title of "Hofrath" conferred on him by the Austrian Emperor. Docens Dr. Jarisch, who had hitherto been connected with the Vienna Polyclinic, has been appointed Extraordinary Professor of Dermatology and Syphilis in the University of Innsbruck, in the Tyrol.

SAN REMO.

[FROM OUR OWN CORRESPONDENT.]

The Crown Prince at San Remo.

SAN REMO has fortunately escaped the severe downfall of snow with which Geneva, Nice, and its immediate neighbours have been visited; but the weather has been very cold, and almost, in an English sense, seasonable. The Crown Prince, though debarred from much outdoor exercise, continues to make progress, and has in no way suffered from the change in weather. Sir Morell Mackenzie, on his return from Algiers, expressed himself satisfied with the improvement that had taken place, and confirmed his opinion that the small growth and thickening that had been observed was not of a serious nature. The Royal party at the Villa Zirio have had a happy if not a merry Christmas and New Year, and the Princesses declare it to be one of the happiest they have ever held.

On Christmas Day the Crown Prince himself, with all the family, was at the German church in the morning, much to the delight of his compatriots. In the afternoon, the Crown Princess and four Princesses, with Lady Ponsonby and ladies of the suite, attended a carol service in the English church. Some very pretty German carols with Italian words were also sung at the Villa Zirio by the boys of one of the government schools, the Crown Prince coming out into the garden and inviting the Syndic of the town into the Villa and showing him the innumerable Christmas presents he had received.

The Crown Princess, through Dr. Freeman, sent Christmas congratulations to the ladies of the Home, and intimated her intention of paying them a visit in the course of the week.

Prince Henry is still here, and a tennis-court as well as a small amateur theatre at the Villa have been arranged for the young people.

Dr. Krause gave a luncheon to Sir Morell Mackenzie, at the West End Hotel, before his departure, and invited Drs. Freeman, Heryng, Hovell, and Count Seckendorff to meet him.

Many people have arrived within the past week. Villas are being let and the hotels filling, and there is no doubt that the spring season will be an exceptionally good one.

The Crown Princess attended the monthly ordinary committee meeting of the Ladies' Home, and showed an active interest in the working of the institution.

The last few days, the weather being perfect, the Crown Prince has been out a great deal, on Sunday taking a walk of over two hours in the morning, and again walking in the afternoon, looking, at any rate, in perfect health.

GLASGOW.

[FROM OUR OWN CORRESPONDENT.]

The University Council Register.—*The Medical Charities Committee.*—*Hospital Entertainments.*—*Friendly Societies' Medical Association.*—*The Pathological and Clinical Society.*—*Queen Margaret College.*

THE Register of the General Council of the University for 1888 has been made up, and shows a total of 4,562 names, that of 1887 having been 4,416.

The Medical Charities Committee at a recent meeting decided to make an attempt to arrange a conference with the managers of the various medical charities in the city for the discussion of the whole question of medical charity, and the securing, if possible, of united action. Hitherto the Committee has confined itself chiefly to compiling reports and statistics and collecting information regarding methods used in various institutions for discriminating between the deserving and undeserving. If the subcommittee appointed to memorialise the managers on the proposal of a conference succeeds in its object, a very important forward step will have been achieved.

The various hospitals have held this year, as usual, their seasonal entertainments. At the Royal Infirmary the annual meeting of nurses was addressed by Professor Jack, of the University. It was mentioned that, at the beginning of 1887, patients were present in the institution, 196 on the medical and 305 on the surgical side. During the year 4,789 had been admitted, 1,901 on the medical and 2,888 on the surgical side. At present there were 13 more patients under treatment than at the beginning of last year. The mortality of 1887 had been 8.8, against 9 in 1886, or excluding deaths within 48 hours of admission,

6.3 as against 6.6. At the Western Infirmary an entertainment was provided for children, and also at the Sick Children's Hospital, and the Glasgow Medical Mission. Besides these, a very large number of institutions provided dinner or supper for the poor on one of the first days of the year, 5,000 at least being thus entertained. During the holidays the work of the Ambulance Association was largely increased. This is due not only to the value of the Association becoming more widely appreciated by the public, but also to the skill and celerity with which the officials respond to calls upon them. Their ambulance waggons are constantly ready, and are usually despatched within two minutes of the receipt of a message.

The Committee appointed by the various friendly societies to consider the formation of a Medical Association for Glasgow and district have issued their report. They report in favour of such an association, which would appoint medical officers who should devote themselves exclusively to the work of the association. Upwards of fifty such friendly society medical associations already exist, having a membership of nearly 211,000, and the charges vary from 2s. 6d. to 3s. 6d. per member per annum. A meeting to consider the whole question will be held in February.

Of the recent meetings of the medical societies of Glasgow, probably the most interesting was that of the Pathological and Clinical Society, held towards the end of December. Dr. William Macewen occupied the evening by showing cases of cerebral abscess that had been operated on, and an epileptic, from whose brain a small tumour had been removed, whose presence in the motor area had been the source of irritation. Dr. Macewen also discussed the elicitation of a differential cranial percussion note, and its aid in diagnosis, showing patients in whom the note was abnormal, and sections from a case with dilated ventricles, in which during life a distinctive note was produced. At the January meeting of the Society, specimens of cervical dislocation of the spine, ossification of the choroid, and a diphtheritic cast of trachea, bronchi, and bronchial tubes, obtained from a tracheotomy wound, were shown by Mr. Maylard, Dr. Reid, and Dr. H. C. Cameron respectively. The latter showed, also, a specimen of subperiosteal sarcoma of the humerus.

At Queen Margaret College, a course of evening lectures has been arranged, each of the College lecturers delivering one of the course. The course includes ten lectures, and among them is one on "Metamorphosis and Mimicry," by Mr. J. H. Fullarton, B.Sc., and one on "Disease and Atmospheric Particles," by Dr. McGregor-Robertson. The other subjects belong to literature or art, such as that of Professor Caird on "The Genius of Carlyle," Professor Nicol on "American Poets," Professor Veitch on "Border Song."

CORRESPONDENCE.

ELECTROLYSIS IN THE TREATMENT OF UTERINE FIBROIDS.

SIR,—In your Hospital Reports in the JOURNAL of January 7th is published a case of "enucleation by electrolysis of a large uterine fibroid," occurring at the Soho Hospital. As this case has already been quoted as an example of the risk attending Apostoli's treatment, it seems only fair to point out that the electrical applications were conducted with a frequency and intensity which certainly were in excess of anything recommended by him, and that the sloughing which followed may probably be referred to this, and not to the inherent risk of the method itself. Apostoli's galvanometer is only graduated up to 200 milliamperes; he never exceeds this, and generally works with lower intensities—at least with the negative pole. Moreover, he usually applies the electricity once a week. In this case the applications were much more frequent and severe. Thus, on August 12th, 15th, 18th, and 20th, the negative pole was introduced into the uterine cavity four inches and a half, and currents of 250, 250, 300, and 235 milliamperes were used for ten minutes; and it was after this energetic action that sloughing occurred, happily terminating in the recovery of the patient. In promoting the absorption of fibroids, Apostoli recommends the puncture of the tumour *per vaginam* to the extent of a quarter to half an inch, not the cauterisation of a large surface, as in this instance, in which the negative pole was introduced into the uterine cavity.

This pole is described by Engelmann as "the irritating pole which promises the highest potency of the destructive and denutritive action of the galvanic current." There is probably a considerable difference between the action on a tumour through a puncture, and the application of a long unprotected electrode in the uterine cavity. When I visited Apostoli's *clinique*, I particularly inquired as to the occurrence

of accidents such as that described in this case, which struck me as not improbable; and I was assured that nothing of the kind had been observed, nor does Engelmann refer to any instance of the sort in his many cases he has treated. In a recent case of my own, in which I have made five negative electro-punctures of a large fibroid, rapidly increasing in size, two of them of 200 milliamperes, there has been a tolerably free and somewhat offensive uterine discharge, not provisionally existing, and the tumour has *pari passu* diminished from the size of an adult head to that of an orange; but there has been no sloughing, and no discharge of any substance, the tumour having apparently simply absorbed. The action of the negative galvanic current in electrolysis is probably simply that of a strong stimulus to absorption, not of a cautery, as is proved to be in this case, the lesson to be learnt from which is probably that very high intensities should be avoided, and that its application should be made at longer intervals. The hopefulness of this treatment has always seemed to me to lie in the well-known clinical fact that uterine fibroids often undergo spontaneous absorption—as, for example, during the involution following labour; and it seems not unreasonable to suppose that we may find a means of doing by art what is often done by Nature, under conditions as yet but little understood, but well worthy of further study.—I am, etc.

W. S. PLAYFAIR.

George Street, Hanover Square, January 7th.

HOW SHOOTING ACCIDENTS OCCUR.

SIR,—Sir W. Dalby's paper on this subject is worth reading and considering by everyone who finds exercise and pleasure in shooting. I can homologate all his sentiments, but I would like to point out that here, at any rate, in Scotland, on some moors and covers, some of his precautions are quite impossible; for instance, that of never getting over a fence or ditch without taking out your cartridges. Last week I was one of a party where the ground was so broken with hedges, ditches, fences, and obstructions innumerable, that if we had abstracted our cartridges on each occasion we would have had pretty good exercise and plenty to do. In a case like that it is enough to exercise care, and see that your gun is at half-cock.

Most of the accidents in the field which I have seen have occurred from shooting in line. This is an accident which ought really never to occur, and still it is not always due to ignorance on the part of the sportsman. Some men get so excited that they forget everything but the game and the gun. As a rule they are poor shots, and no amount of experience would ever make them either careful or good shots. A sportsman is born, not made, and I should not like that a law would be passed that nobody be allowed to shoot unless he has as a boy been taken out alone. Most of us as boys have had very little chance of using a gun. The fact is, that nobody should try shooting who, after the first trial or two, finds he has not a "knack" for it. I was myself brought up where there was plenty of fishing and shooting. I could never learn to fish, although I tried hard, and I think that sportsmen should only exercise that sport which they find they are best suited for; nobody certainly ought to lift a gun who knows nothing about it. If anyone wishes to learn let him study his gun first, and the first time he goes out he should let that be known, so that the others may keep out of his range. There ought to be very little danger in shooting, and I think if men of inexperience, and experience too, would be content to "keep cool" in spite of losing a "chance," there would be none at all.—I am, etc.,

Crosshill, Glasgow.

STUART NAIRNE.

THE ERGOSTAT AND LATERAL CURVATURE.

SIR,—I was very much interested in reading the account of the ergostat in the JOURNAL of January 7th, and cannot but think that its usefulness will become recognised, and is sure to extend in the future.

Amongst the various calisthenic exercises I recommend for patients suffering from lateral curvature of the spine is that which has received the appellation of the "top-sawyer movement," from the position of the men when sawing through blocks of wood, etc. The use of the ergostat would cause similar movements, but apparently would throw the shoulders further back at each turn of the handle, and thus induce much fuller respirations; but what is more difficult to acquire, and yet of the utmost importance in the treatment of delicate patients, is to regulate the amount of exercise, and this probably can only be done very accurately by the employment of the machine under consideration.

I have frequently watched chaff-cutters at work, and thought how beneficial some similar exercise would be to scoliotic girls. In performing many exercises, the breath is rather apt to be held for a longer

time than is desirable, and especially is this so in the slow movements with dumb-bells, and no doubt would be so at first with the ergostat. In giving the rules for the employment of this apparatus, it is recommended that speaking should be abstained from. This may be a wise precaution when the patients have become mechanical enough to conduct the revolutions without any special mental effort; but until they have become sufficiently educated to continue the free respiratory movements while their attention is directed elsewhere, I think it a good plan to instruct the patients to count audibly.

I should like, also, to say that it is important to have the handle of a carefully provided length, in order that the hands may be placed a fair distance apart, and so allow the chest to expand fully; while at the same time the arms should be extended as much as possible during the whole time. It would be a valuable addition if (without interfering with its stability) the props or uprights of the machine could be constructed so that the height may be regulated according to that of the patient using it.—I am, etc.,

AUGUSTUS CLAY, Assistant-Surgeon Orthopædic and Spinal Hospital.

Birmingham.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.

SIR,—Macaulay's "every schoolboy" knows that even a breath of suspicion with reference to the financial department of any charity is immediately succeeded by a lamentable dearth of contributions by the public. I need not therefore proffer any additional justification for trespassing upon your valuable space with this communication. When I assert that one of the medical officers present at the meeting recorded in the JOURNAL for December 24th, audibly regretted "that the meeting was not a legal one," it will be seen how far the interests of the hospital were intended to be promoted by the small band of some twenty governors constituting such meeting, out of a roll-call of about 800 subscribers we claim the distinction to muster. But there is a far more serious feature arising out of these proceedings. The persons convening the meeting were informed of the impropriety and illegality alike of their proposed venture, and were entreated to abandon their project. They knew that when the treasurer rejected the date improperly fixed by the requisition, and substituted in lieu thereof January 18th, he was wholly influenced by a desire to place before the governors the official audit up to December 31st, 1887. The board of management, after mature deliberation, regarded the acquisition of this audit as the best guarantee that the accounts were above suspicion. At any rate, the auditors, being wholly unconnected with the management of the institution, but jealous to a degree of their professional status, would be present to deal with all matters provoking either inquiry or investigation. The *reductio ad absurdum* is reached when one reflects that the persons who refuse to await the result of the audit are identical with those who are persuaded that an inquiry into the accounts is an urgent necessity.

The board of management, as may be assumed, took no part whatever in the meeting. They could not well arrive at any other determination, with any regard either for consistency or for the best interests of our hospital. On January 18th the management will be completely vindicated in the eyes of the public, but I should hesitate before predicting how long it will be before the mischievous effect of the meeting held on December 20th will be removed, and confidence in the hospital fully restored.—I am, etc.,

THOS. J. SAVAGE,
Honorary Solicitor to the Hospital.

57 and 59, Ludgate Hill, E.C.

METROPOLITAN PROVIDENT MEDICAL ASSOCIATION.

SIR,—In reply to your two correspondents in your last issue, I shall be glad of your permission to say that I have no alteration to make in my statement to you on December 31st, which was simply a record of fact.

Sir Spencer Wells, who was in the chair, held in his hand two dispensary circulars, which had been enclosed in the letter sent to him by Dr. R. H. S. Carpenter. He commented upon the letter, but did not read it, though requested to do so by that gentleman. Shortly afterwards Sir Spencer left the meeting, and Mr. Bousfield presided instead. It was during this time that the "disorder" took place, and it commenced in this way. Mr. Holmes, who like several others of the committee had received a copy of the letter and two dispensary circulars which accompanied it, followed Sir Spencer's example by commenting upon the letter and declining to read it, although requested to do so by Dr. Carpenter, who accused Mr. Holmes of misrepresenting its contents. Subsequently the letter was read by Mr. Hentsch, on behalf of the Medical Alliance Association, and the dis-

turbance which followed arose, I repeat, from those on the platform and their supporters in the body of the hall, endeavouring to overcome by noise, which included stamping of the feet, what Dr. Carpenter said in reply to Mr. Holmes, and in a denunciation of some of the members of the committee who were present.

The proceeding, which was a lamentable exhibition of unfairness, it is to be hoped will not be valued by thoughtful men of the profession, and the sooner it is forgotten, in my opinion as an outsider, the better it will be for those originating it. For that reason, if for no other, I decline any further correspondence upon the subject.—I am, etc.,

TOWRY PIPER,
Pridham, Piper and Co., Solicitors to the
Medical Alliance Association.

1, Old Serjeant's Inn, Chancery Lane, London, W.C.

SIR,—I was present at the meeting, and am astounded to read Mr. Timothy Holmes's insinuations in the JOURNAL of December 24th, to the effect that the discourtesy arose from general practitioners opposed to the scheme. It is true that the scheme met with determined opposition, and it is likely to do so from general practitioners, whose very living is put in peril. (I may say that a strong association is now in process of formation to oppose it step by step.)

The meeting may not have been packed, in the ordinary acceptance of the word, but it is curious that I and two other practitioners to whom I have spoken received no notification of its being held. I went through the invitation of a friend, and was shocked beyond conception to see the manner in which a gentleman—whose white hairs alone should have been a guarantee for indulgence and reverent respect—was hooted down and interrupted by cries of "Turn him out!" etc., by men who must have been in the nursery at the time when he had had a large experience of general practice.

At the next meeting, should due notice be given, it will be apparent that the main body of general practitioners are convinced that the existing charitable institutions, clubs, etc., are amply sufficient to supply the needs of those who are unable or unwilling to pay small fees to their private medical attendants, and that this long-suffering body are determined to oppose any further attempts to provide certain influential people with cheap philanthropy at the expense of their pockets.—I am, etc.,

F. H. COREY.

18, Abercorn Place, N.W.

SIR,—The letter of "A.S.R.W.," published in the JOURNAL of December 24th, on the above subject, appears to take far too gloomy a view of the consequences resulting from the establishment of local "provident dispensaries." That they may possibly absorb some members who would otherwise be private patients at low fees, is doubtless true, but is not the disadvantage more than counterbalanced by the gain of having on your list a number of "provident members," whose periodical subscriptions fully make up for the occasional loss of a low fee, to say nothing of the chance of making a doubtful debt (if you give credit) amongst a class of patients whom it is both undignified and unprofitable to give to a collector, or to sue in the County Court! I consider also that it is not justifiable to lay the burden of a debt on the wage-earning class, or to do what is now frequently done, demand a ready-money fee, however small, from a family who require every penny they can get for extras and comforts for the patient. To obviate these evident difficulties and disadvantages, the best remedy is undoubtedly a well-conducted provident dispensary. I think the scheme adopted by the Metropolitan Provident Medical Association in starting local dispensaries is worthy of the support of the general practitioners, first, because it invites the co-operation of the local medical men, whom it consults before starting a new dispensary; secondly, the medical officers attached (and all local medical practitioners can be so) have a seat on the governing committee forming the rules for admission and payments, etc., of members; thus comparing most favourably with the old club and one doctor system, which is only the provident system in an inferior degree, and under no control from the profession.—I am, etc.,

E. A. M.

A DISPENSARY DOCTOR SENT TO PRISON.—At the Bandon Quarter Sessions last Tuesday the appeal was heard of Dr. Magner from the decision of a Crimes Act Court at Ballinspittle, Co. Cork, sentencing him to two months' imprisonment for language used at Ballinadee last October. The sentence was confirmed, and an application to have the accused treated as a first-class misdemeanant was refused by the County Court Judge.

NAVAL AND MILITARY MEDICAL SERVICES.

THE NAVY.

The following appointments have been made in the Admiralty:—JOHN C. B. MACLEAN, M.A., M.B., Staff-Surgeon to Plymouth Hospital; GEORGE B. MURRAY, Staff-Surgeon, to the *Agincourt*; ROBERT F. YEO, Surgeon, to the *Hyacinth*; JAMES W. O. UNDERHILL, Surgeon, to the *Durcan*, additional, for temporary service; JOHN J. DENNIS, M.D. Surgeon, to Haslar Hospital; JOHN S. LAMBERT, Surgeon, to the *Wye*; E. C. WARD, M.D., Surgeon, to the *Royal Adelaide*; MURDOCH MACKENZIE to be Surgeon and Agent at Stornoway; J. F. SOMERVILLE to be Surgeon and Agent at Swanage; J. F. BATE, Surgeon to the *Janus*; ROBERT HADDIE, Surgeon to the *Hercules*, additional; JAMES O'CONNELL to be Surgeon and Agent at Crookhaven; G. G. JONES to be Surgeon and Agent at Amlwch.

We understand, the *United Service Gazette* says, that the Medical Director-General of the Navy, Sir John Reid, K.C.B., will be succeeded on February 1st by Inspector-General JAMES N. DICK, C.B., Senior Medical Officer on the Active List.

Staff-Surgeon MICHAEL RONAN, B.A., late of the *Hooper*, and formerly Surgeon at Chatham Dockyard, who has been some time in hospital, is ordered to be discharged and placed on half-pay.

THE MEDICAL STAFF.

BRIGADE-SURGEON W. R. LANE has retired with the honorary rank of Deputy Surgeon-General. He entered the service as Assistant-Surgeon December 29th, 1854; became Surgeon January 4th, 1871; Surgeon-Major March 1st, 1873; Brigade-Surgeon, November 5th, 1887. Beginning his career in the 2nd Grenadier Guards, he continued with this battalion as Assistant-Surgeon, Surgeon, and Surgeon-Major successively till May 25th, 1877, when he was transferred to the 1st Scots Guards as Battalion-Surgeon, and remained with this corps till November 5th last, when he was appointed Brigade-Surgeon to the Brigade of Foot Guards. He served with the 1st Scots Guards in the Egyptian war in 1882, and was at the battle of Tel-el-Kebir; he has the medal and clasp and the Egyptian bronze star for this campaign.

Surgeon-General H. T. READE, V.C., C.B., is granted retired pay. His commissions are dated:—Assistant-Surgeon, November 8th, 1850; Surgeon, November 3rd, 1857; Surgeon-Major, September 7th, 1871; Brigade-Surgeon, November 27th, 1879; Deputy Surgeon-General, March 27th, 1880; and Surgeon-General, November 30th, 1886. We learn from *Hart's Army List* that he served in medical charge of the 61st Regiment at the siege of Delhi from July 1st, 1857, to the final capture of the city on September 20th; he was present at the repulse of the sorties of July 4th, 9th, 18th, and 23rd, accompanied the regiment at the assault of the city on September 14th, and subsequently with a small party of the 61st repulsed an attack of about 300 Sepoys on some wounded men, whose lives were thereby saved; on September 16th he was one of the first up the breach at the storming of the magazine, and with a sergeant spiked a gun—mentioned in despatches, and recommended for promotion for "unwearied exertions and gallant conduct in the field" during the siege and assault of Delhi (medal with clasp, and Victoria Cross); he was awarded the V.C. for the following services: "During the siege of Delhi, on September 14th, 1857, while Surgeon Reade was attending to the wounded at the end of one of the streets of the city, a party of rebels advanced from the direction of the Bank, and having established themselves in the houses in the street, commenced firing from the roofs. The wounded were thus in very great danger, and would have fallen into the hands of the enemy, had not Surgeon Reade drawn his sword, and, calling upon the few soldiers who were near to follow, succeeded, under a very heavy fire, in dislodging the rebels from their position. Surgeon Reade's party consisted of about ten in all, of whom two were killed and five or six wounded. Surgeon Reade also accompanied the regiment at the assault of Delhi, and, on the morning of September 16th, 1857, was one of the first up at the breach in the magazine, which was stormed by the 61st Regiment and Belooch Battalion, upon which occasion he, with a sergeant of the 61st Regiment, spiked one of the enemy's guns." He was nominated Companion of the Order of the Bath on June 21st last. He was Principal Medical Officer at Portsmouth.

Surgeon-Major J. D. CROWE has also been granted retired pay, with a step of honorary rank. His commission as Assistant-Surgeon bears date October 1st, 1867; as Surgeon, March 1st, 1873; and Surgeon-Major, October 1st, 1879. He has no war record.

Quartermaster FREDERICK PHILPOT also has gone on retired pay, with the honorary rank of Major. He entered as Apothecary, September 21st, 1860; was made Captain of Orderlies, June 25th, 1873; granted the honorary rank of Captain, September 21st, 1890; and became Quartermaster Medical Staff from July 1st, 1881. He was in the Crimean war in 1854-56, including the battle of Inkerman and the fall of Sebastopol (Crimean and Turkish medals). He was also engaged in the war in Egypt in 1882, and has the medal and Egyptian bronze star.

The name of Surgeon-Major P. H. E. CROSS has been removed from the list of Retired Departmental officers. He was convicted of the murder of his wife, and was hanged at Cork on January 10th. His service as Assistant-Surgeon in the army dates from April 3rd, 1849; he was promoted to be Surgeon May 15th, 1855, and Surgeon-Major February 27th, 1872; he retired on half-pay April 14th, 1875. He received the medal and clasp and the Turkish medal for the Crimean campaign, including the siege and fall of Sebastopol; and he had also the medal for the Indian Mutiny campaign, in which he served with the 13th Light Infantry.

Deputy Surgeon-General HENRY MARTYN FRASER, M.D., who died at Leamington on December 31st, was the son of the late Rev. Hugh Fraser, M.A., of Ardrichattan, Argyshire. He entered the Army Medical Service as Assistant-Surgeon September 11th, 1849; became Surgeon October 2nd, 1857; and Surgeon-Major June 15th, 1869; he retired on half-pay July 29th, 1874, with the honorary rank of Deputy Surgeon-General. He served in the Indian Mutiny campaign, and was at the siege and capture of Lucknow, where he acted as Sanitary Officer to the forces under the Commander-in-Chief. He was also present at the taking of Sandee in October, 1859, when he was Chief Medical Officer with the force under Brigadier Hale.

Deputy Inspector-General EDWARD BRADFORD, F.R.C.S., F.L.S., died on January 4th, at Harrow, at the advanced age of 86. He entered the Army Medical Service as Hospital Assistant, December 5th, 1826; became Assistant Surgeon March 20th, 1828; Surgeon, September 24th, 1841; Surgeon-Major, April 16th, 1852; and retired on half-pay December 7th, 1858, with the honorary rank of Deputy Inspector-General. He was appointed Honorary Surgeon to the Queen August 16th, 1859. He had no war record, but was in receipt of a reward for distinguished and meritorious service.

INDIAN MEDICAL SERVICE.

BRIGADE-SURGEON A. H. HILSON, M.D., Bengal Establishment, is promoted to be Deputy Surgeon-General with temporary rank, *vice* W. R. Rice, M.D., confirmed. Deputy Surgeon-General Hilson's commission as Assistant-Surgeon bears date January 29th, 1857, and he attained the rank of Brigade-Surgeon September 9th, 1884. He served in the Indian Mutiny campaign in 1857-59, and was present in numerous engagements with the rebels, at one of which he was severely wounded—mentioned in despatches (medal). He was also with the Bhoonath expedition in 1865-66 (medal with clasp). The services of Brigade-Surgeon A. H. Hilson are temporarily placed at the disposal of the Military Department.

Brigade-Surgeon W. R. RICE, M.D., Bengal Establishment, is promoted to be Deputy Surgeon-General, *vice* R. F. Hutchingson, M.D., whose term of service has expired. Deputy Surgeon-General Rice entered the service as Assistant-Surgeon November 20th, 1856, and became Brigade-Surgeon April 10th, 1884. He has the medal for the Indian Mutiny campaign in 1857.

Surgeon J. MACGREGOR, M.D., Bombay Establishment, is appointed to the medical charge of the 20th Native Infantry, *vice* Surgeon H. P. Dimmock, appointed Civil Surgeon of Shikarpore.

The services of Surgeon-Major C. T. PETERS, M.D., and Surgeon D. C. DAVIDSON, both of the Bombay Establishment, are placed at the disposal of Government in the Civil Department.

Surgeon-Major W. GRAY, M.B., Bombay Establishment, is allowed furlough to Europe for one year on medical certificate with the necessary subsidiary leave.

Surgeon G. M. NIXON, Bengal Establishment, on return from deputation in the Gaol Department, is appointed to the civil medical charge of the Furruckabad district from the date of taking charge.

Surgeon W. G. McEVoy is admitted to the Madras Establishment from November 5th, the date of his arrival at Bombay.

Surgeon A. V. ANDERSON, Bombay Establishment, is ordered to officiate in medical charge of the 3rd Light Infantry.

Surgeon C. H. L. MEYER, Bombay Establishment, is directed to officiate in medical charge of the 8th Native Infantry.

Surgeon-Major C. J. W. MEADOWS, Bengal Establishment, officiating civil surgeon of Patna, is appointed to act as civil surgeon of Mozampur, during the absence, on deputation, of Surgeon-Major R. G. Mathew.

Surgeon-Major D. W. D. COMINS, Bengal Establishment, officiating civil surgeon, Burdwan, is appointed to act as civil surgeon of Mymensingh, during the absence, on deputation, of Surgeon F. S. Peek.

Surgeon M. O'DWYER, Bengal Establishment, on return from furlough, is appointed to the civil medical charge of the Goojerat district.

Surgeon G. A. EMERSON, Bengal Establishment, on return from deputation in the Gaol Department, is appointed to the civil medical duties of the Boolandshur district, pending the deputation of Surgeon-Major J. Armstrong.

Deputy Inspector-General J. W. WINCHESTER, Bombay Establishment, retired, died on Christmas Day at Edinburgh.

Surgeon J. C. MARSDEN, Madras Establishment, Medical Officer 29th Native Infantry, is appointed Civil Surgeon of Coorg.

Surgeon B. SNOW, M.D., Bengal Establishment, is appointed to officiate as Residency Surgeon in Nepal.

Surgeon-Major J. McONAGHY, M.D., Bengal Establishment, on return from furlough, is posted to the civil medical duties of the Bari Banki district.

Surgeon D. B. SPENCER, Bengal Establishment, is appointed to the civil medical charge of the district and police of Bhamo, Burmah, in addition to his military duties, *vice* Surgeon-Major F. F. O'Connor, transferred.

Surgeon N. CHATTERJEE, Madras Establishment, is appointed to the civil medical charge of the police and district of Yamethin, Burmah, in addition to his military duties, *vice* Surgeon J. Crimmin, relieved.

The services of Surgeon-Major E. LEVINGE, Madras Establishment, are permanently placed at the disposal of the Commander-in-Chief.

The services of Surgeon J. W. EVANS and H. K. FULLER, M.B., both of the Madras Establishment, are permanently placed at the disposal of the Public Department.

Surgeon-Major D. F. BATEMAN, Madras Establishment, Medical Officer 3rd Light Cavalry, has leave of absence for one year on private affairs.

Surgeon-Major P. MURPHY, M.D., Bombay Establishment, Superintendent of Mahabeshwar, in the district of Sattara, is appointed to be a magistrate of the first class.

Surgeon-Major J. S. WILKINS, Bombay Establishment, is directed to officiate in medical charge of the 21st Native Infantry.

The services of Surgeon-Major J. DAVIDSON, M.B., Bombay Establishment, are replaced at the disposal of His Royal Highness the Commander-in-Chief.

The following is the allotment of annuities for 1888 from the Bombay Medical Retiring Fund; Deputy Surgeon-General J. F. SHEKLETON, M.D., F.R.C.S., £252; Brigade-Surgeon J. P. STRATTON, M.D., £210; Surgeon-General C. G. H. ROSS, £210; Surgeon-General L. S. BRUCE, £168; Brigade-Surgeon H. ATKINS, £168. (*Lapsed to Government, these officers having received a refund of their subscriptions.)

THE VOLUNTEERS.

Mr. HUGH PRYTHECH has been appointed Surgeon to the Liverpool Brigade of the Royal Naval Artillery Volunteers.

The undermentioned Acting-Surgeons are promoted to be Surgeons in their corps specified: J. A. GRAY, 1st Middlethian; W. C. WICKS, M.B., 3rd Volunteer Battalion Northumberland Fusiliers (late the 1st Newcastle); H. R. KEA, 1st Volunteer Battalion Worcester Regiment (late the 1st Worcester).

Acting Surgeon G. R. GRIFFITH, of the 1st Cheshire and Carnarvon Artillery, has resigned his appointment, which bore date September 11th, 1878.

Surgeon J. LEWIS, M.D., 2nd Volunteer Battalion Welsh Regiment (late the 1st Glamorgan) has resigned his commission, which was dated September 28th, 1876; he is granted the honorary rank of Surgeon-Major, and is permitted to retain his uniform.

Surgeon and Honorary Surgeon-Major T. W. TREND, M.D., 2nd Volunteer Battalion Hampshire Regiment (late the 2nd Hampshire), has also resigned his commission, dating from February 15th, 1865; he is allowed to retain his rank and uniform.

It is reported that Professor Kiessman, of Strassburg, will retire at the end of the summer session, and will be succeeded by Professor Naumyn, now of Königsberg.

MEDICO-LEGAL AND MEDICO-ETHICAL.

DISGRACEFUL ACTION AGAINST A MEDICAL MAN: VINDICATION OF CHARACTER.

At the Kilmainham sessions on January 6th, before the Recorder and a jury, the action of George Devlin against Dr. Davy, Terenure, to recover £1,000 damages for alleged *crim. con.* with plaintiff's wife, was heard.

Dr. Smyly, LL.D., appeared for the plaintiff; and Mr. Campbell represented Dr. Davy.

The plaintiff, a gardener, deposed that he was married in the year 1866, and in 1874 went to live at Terenure. Dr. Davy's visits to his wife then commenced, and from the first he suspected that an undue intimacy existed between them. In cross-examination he admitted that he was in prison several times for assaulting his wife, and that she had obtained a divorce from him on the ground of cruelty.

Mr. Campbell read Mrs. Devlin's evidence in the Divorce Court, which detailed the shocking brutality she received at the hands of her husband. He was an habitual drunkard, and kicked her and beat her a number of times. Counsel also read a letter from the plaintiff to his wife when he was in gaol for assaulting his wife a short time after the alleged occurrence in August, 1885. The letter was couched in the most affectionate terms, and asked that she would get Dr. Davy to come to court and give evidence that she was out of danger from the effects of the injuries he (the plaintiff) had inflicted upon her.

To the Recorder—He never, when before the magistrates for assaulting his wife, said he did it because she had misconducted herself.

Mrs. Susan Devlin, daughter-in-law of the plaintiff, was examined for him. She, however, said she never saw the defendant in her life. The plaintiff had offered her money to swear falsely.

Mrs. Mary Anne Purcell, servant to the Devlins for eleven years, stated that there was no truth in the plaintiff's allegations. Mrs. Devlin was always a most respectable woman. The plaintiff had offered her money to swear falsely.

Mrs. Mary Tills, daughter to the plaintiff, gave similar evidence. The plaintiff had also offered her money to swear falsely. She said: My mother has a little shop, and has kept us eight or nine years by her own industry. My father is a villain and a ruffian. He treated us shamefully.

Dr. Davy was called, and denied all the allegations made.

At this stage the jury stopped the case, and returned a verdict for the defendant. The verdict was received with some applause in Court.

The Recorder said not the slightest stain could rest on Dr. Davy. In all his experience on the Bench and at the Bar he never heard a more atrocious or more infamous case, or a more scandalous attempt on the part of a man to destroy the reputation of his wife and obtain money. The Recorder made an order that the Crown Solicitor should institute a criminal prosecution against Devlin for perjury.

ARE MEDICAL PRACTITIONERS "TRADERS"?

In a case of *Hance v. Harding*, which was decided by Baron Huddleston without a jury shortly before Christmas, a point of some interest as regards the status of members of the medical profession was raised and discussed. The validity of a post-nuptial settlement made by Mr. Alfred Peskett, a general practitioner, M.D., and Licentiate of the Apothecaries' Society, in 1882, was in question. He became bankrupt in July, 1883, and the settlement was impeached under Section 91 of the old Bankruptcy Act of 1869, which provides that any settlement made by a trader shall, under certain circumstances, be void if the settlor becomes bankrupt within two years of the date of such settlement. In determining the action it therefore became important to see whether Mr. Peskett was a trader within the meaning of the then Bankruptcy Act. Medical men are generally considered to belong to one of the learned professions, and not to be, strictly speaking, traders. But it appeared that, in an affidavit sworn in the bankruptcy, Mr. Peskett had described himself as a surgeon and apothecary, and, further, that he had on some occasions given his patients receipts for "attendance and medicine," and it was contended that these facts were sufficient to constitute him a trader. It was, however, shown that Mr. Peskett's practice was to charge his patients per visit, supplying them with medicines, but making no separate charge for them. Baron Huddleston held that there was no proof of any trading in drugs, so as to make Mr. Peskett a trader in the ordinary sense; and the question therefore narrowed itself to this, whether the description as an apothecary was sufficient to constitute Mr. Peskett a trader, and this he decided it had failed to do. It is

curious that the law reports are almost silent on the question whether medical practitioners are to be deemed traders. Under the former Bankruptcy Acts, the distinction between traders and non-traders was of importance. The only case cited was *Palmer's*, decided in the year 1856, where the Court of Appeal in the case of Mr. Palmer, of Rugeley, otherwise notorious, decided that a surgeon who practised as an apothecary was a trader who could be made bankrupt. The facts of that case on which the decision was based are not, however, reported, and Baron Huddleston distinguished it from the one before him, where he found, not as a matter of law but as a fact, that Mr. Peskett was not shown to be a trader. As far as legal authority, therefore, goes, it seems that a medical practitioner who dispenses medicines, and makes a charge for so doing, is to be considered as carrying on a trade; but that, if he merely supplies medicines as part of his attendance on his patients, and without charging separately for them, he does not. The question now is one of theoretical rather than of practical interest, because the legal distinction between traders and non-traders has, for most purposes, ceased to exist. It may, however, be a source of gratification to some members of the profession to know that they may dispense the medicines they prescribe without necessarily by so doing constituting themselves tradesmen.

PROSECUTION UNDER THE DENTISTS' ACT: A LEGAL POINT.

AN important case was tried at Wisbech on Tuesday, when Frederick W. Bradley was charged with infringing Section 3 of the Dentists' Act, 1878, which provides that any person calling himself a dentist, or dental practitioner, or any name implying that he is registered under the Act, unless he be so registered, is liable, on summary conviction, to a fine not exceeding £20. Mr. R. E. Melsheimer prosecuted on behalf of the British Dental Association, and Mr. S. D. Waddy, M.P., defended. The prosecuting counsel said defendant had described himself on his cards and plate as "F. W. Bradley, A.P.S. Eng.," and had carefully avoided using the word "dentist." Two clerks were sent from London as patients, and the charge was based on the novel ground that the defendant used the title "dentist" in connection with these patients. These witnesses were examined, and deposed to visiting the defendant, and being advised by him as to their teeth, and to the fact that the defendant said he was a practical dentist. Mr. Waddy, for the defence, submitted that the defendant did not use the title "dentist" or "dental practitioner," and that the Act was not intended to apply to efficient practitioners. The Bench, after consideration, found defendant had infringed the law, and fined him £5 and costs, at the same time consenting to state a case for the Divisional Court.

M.R.C.S.—The right of M.R.C.S. England, legally, is to practise surgery only, and not medicine. The right of M.R.C.S. to practise midwifery does not depend any more than that of L.S.A., on whether a person holds only one qualification, and both are equally entitled to practise it legally.

AGREEMENTS WITH UNQUALIFIED PRACTITIONERS.

ASSISTANT writes: I am in communication with a gentleman whose name appears neither in the *Register* nor *Directory*, about buying a practice from him, or allowing him an annuity out of it. There seems to be a medical practitioner in the same place. What should I do? I want a situation and must keep myself safe.

* * * In reply to the inquiry of "Assistant," the Court of Appeal decided, in the case of "*Davies v. Maknna*," that no valid agreement for disposal of practice can be made except with a duly qualified medical practitioner. Of course the gentleman to whom "Assistant" refers may be such, though he does not appear in the *Register* or *Directory*.

BONDS WITH ASSISTANTS.

A MEMBER asks for information as to the kind of bond to be signed by an indoor assistant in the country. Is there a form to be bought, or must a lawyer be employed?

* * * Forms of bonds may, we believe, be bought, but probably they would not express the intention of the parties. It would be safer to employ a solicitor in such a matter.

THE NATIONAL MEDICAL AID COMPANY.

A CORRESPONDENT sends us a circular of a society calling itself the National Medical Aid Company, Limited.

We consider the scale of remuneration simply disgraceful, and times must be bad indeed when highly educated medical practitioners are offered 3s. per annum for medical aid to sick members over 14 years of age, and 1s. 10d. per annum for similar attendance on those under 14 years, and even these liberal fees are dependent on none of the members being in arrears, as the profession are frankly told that in those cases they will only be "entitled to draw on those weeks" for which payments have been made.

We believe that in the metropolis, at all events, small as are the fees often

paid to the hard worked practitioner of medicine, there are few if any clubs that offer less than 4s. per annum for healthy male adults, and no society up to the present has offered the munificent sum of 1s. 10d. per annum for attendance on sick "infantile members."

We should cordially recommend all members of our profession to have as little as possible to do with the National Medical Aid Company, Limited.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

DISMISSAL OF A PUBLIC VACCINATOR WITHOUT INQUIRY.

THE Board of Guardians for Cardiff have decided to terminate the contract of Dr. Horder, the public vaccinator for the town. This decision of the guardians appears to have been at the least precipitate. In his capacity of public vaccinator Dr. Horder was asked by three medical men to supply them with lymph. Even had he refused to oblige them he would have been perfectly within his legal rights, but, as a matter of fact, he complied with two of the requests, though he was unable to supply lymph to the third, owing to his shortness of stock. At a meeting of the guardians on December 15th a charge was brought against Dr. Horder of refusing to supply lymph to three practitioners, but the guardians neither informed Dr. Horder that he had incurred their displeasure, nor that they intended to discuss his conduct; an amendment "that Dr. Horder be heard in his defence" was negatived; and notwithstanding that Dr. Horder has held the post of public vaccinator for ten years, and has always obtained the Government grant for successful vaccination, the original motion, giving him twenty-eight days' notice of the termination of his contract, was carried. Unless a serious and not a frivolous charge can be brought against Dr. Horder, such action on the part of a board of guardians is unjust, and prejudicial both to their own authority and to the public service.

It is to be hoped, therefore, that, if only in their own interests, the guardians will take the earliest opportunity of reconsidering their determination, and, by instituting a proper inquiry into the whole matter, restore public confidence in their decisions.

HEALTH OF ENGLISH TOWNS.—During the week ending January 7th, 6,238 births and 4,279 deaths were registered in the twenty-eight large English towns, including London, which have an estimated population of 9,398,273 persons. The annual rate of mortality per 1,000 persons living in these towns, which had been 20.8 and 24.8 in the two preceding weeks, was 23.8 during the week ending Saturday, January 7th. The rates in the several towns ranged from 14.8 in Brighton, 17.7 in Bradford, 18.8 in Huddersfield, and 19.5 in Birmingham, to 29.3 in Preston, 31.9 in Wolverhampton, 35.6 in Manchester, and 40.3 in Plymouth. The mean death-rate in the twenty-seven provincial towns was 24.6 per 1,000, and exceeded by 1.8 the rate recorded in London, which was only 22.8 per 1,000. The 4,279 deaths registered during the week under notice in the twenty-eight towns included 493 which were referred to the principal zymotic diseases, against 457 and 503 in the two preceding weeks; of these, 183 resulted from whooping-cough, 90 from scarlet fever, 67 from measles, 53 from "fever" (principally enteric), 42 from diphtheria, 30 from small-pox, and 28 from diarrhoea. These 493 deaths were equal to an annual rate of 2.7 per 1,000; in London the zymotic rate was 3.1, while it averaged 2.4 per 1,000 in the twenty-seven provincial towns, among which it ranged from 0.4 and 0.7 in Portsmouth and Bristol, to 5.1 and 6.2 in Bolton and Sheffield. The highest proportional fatality of measles was recorded in Birmingham, Nottingham, and Bolton; from scarlet fever in Sheffield, Huddersfield, and Blackburn; and from whooping-cough in Salford, Leicester, Norwich, and Wolverhampton. The 42 deaths from diphtheria included 28 in London, 2 in Birmingham, 2 in Derby, 2 in Leeds, and 2 in Cardiff. Of the 30 fatal cases of small-pox recorded in the twenty-eight towns, 27 occurred in Sheffield, 2 in Leeds, and 1 in Bristol. The number of small-pox patients in the Metropolitan Asylums Hospitals was 8 on Saturday, January 7th, and 2 cases were admitted to these hospitals during the week. These hospitals also contained 1,259 scarlet fever patients on Saturday, January 7th, against numbers declining from 2,602 to 2,049 in the five preceding weeks; the admissions were 147 during the week. The death-rate from diseases of the respiratory organs in London was equal to 4.9 per 1,000, and was below the average.

HEALTH OF SCOTCH TOWNS.—In the eight principal Scotch towns, having an estimated aggregate population of 1,314,274 persons, 804 births and 685 deaths were registered during the week ending Saturday, January 7th. The annual rate of mortality, which had been 22.4 and 24.3 per 1,000 in the two preceding weeks, further rose to 27.1 during the week under notice, and exceeded by 3.4 the mean rate for the same period in the twenty-eight large English towns. Among these Scotch towns the rates ranged from 20.3 and 23.1 in Leith and Aberdeen to 29.5 and 30.3 in Paisley and Edinburgh. The 685 deaths registered during the week in these towns included 89 which resulted from the principal zymotic diseases; of these, 30 were referred to whooping-cough, 23 to measles, 13 to diarrhoea, 7 to scarlet fever, 7 to "fever," 4 to diphtheria, and not one to small-pox. These 89 deaths were equal to a rate of 3.5 per 1,000, the highest zymotic rates being recorded in Edinburgh, Dundee, and Leith. Whooping-cough caused the highest proportional fatality in Aberdeen, Greenock, Leith, and Glasgow; measles in Dundee, Edinburgh, and Leith; and "fever" in Dundee and Paisley. Of the 4 deaths from diphtheria, 2 occurred in Edinburgh; and the 7 fatal cases of scarlet fever included 2 in Glasgow, 2 in Dundee, and 2 in Perth. The mortality from diseases of the respiratory organs in these Scotch towns was equal to 6.7 per 1,000, against 4.9 in London.

HEALTH OF IRISH TOWNS.—In the week ending Saturday, January 7th, 469 births and 592 deaths were registered in the sixteen principal town districts, which have an estimated population of 871,128. The average annual death-rate was 35.4 per 1,000. The rates ranged from 5.2 in Armagh to 45.7 in Newry; in the latter town, 7 out of the 13 deaths were due to measles. In Belfast, measles and whooping-cough both showed a decrease. In Cork the deaths from measles rose to 15, and the same disease caused 3 deaths in Limerick and 2 in Kilkenny. The deaths registered in Dublin and suburbs represent an annual rate of mortality of 38.5 in every 1,000 of the estimated population; omitting the deaths of persons admitted into public institutions from localities outside the district, the rate was 37.5 per 1,000. The zymotic deaths rose to 37, and included 2 from measles, 9 from scarlatina, and 9 from whooping-cough.

HEALTH OF FOREIGN CITIES.—It appears from statistics published in the Registrar-General's return for the week ending January 7th, that the death-rate recently averaged 33.0 per 1,000 in the three principal Indian cities; cholera caused 32 deaths in Madras and 15 in Calcutta; and 3 deaths resulted from small-pox in Bombay. According to the most recently received weekly returns, the mean annual death-rate in twenty-one of the largest European cities was 24.4 per 1,000, and slightly exceeded the mean rate in the week under notice in the twenty-eight large English towns. In Paris the death-rate was equal to 24.8, against 22.1 in each of the two preceding weeks, and exceeded by 2.0 the rate in London; the 1,070 deaths included 60 from typhoid fever, 37 from diphtheria and croup, 6 from scarlet fever, and 3 from small-pox. In the three principal Dutch cities—Amsterdam, Rotterdam, and the Hague—the mean death-rate was 21.1 per 1,000. In Berlin the rate of mortality was only 17.6 per 1,000; of the 478 deaths, 24 resulted from diphtheria, 5 from scarlet fever, and 6 from measles. The death-rate in Vienna was equal to 26.0 per 1,000; the 395 deaths included 11 from scarlet fever, 5 from measles, and 5 from diphtheria. In St. Petersburg the 497 deaths gave a rate of 27.9 per 1,000, and included 20 from typhus and typhoid fever, 11 from scarlet fever, and 89 from diarrhoeal diseases. The death-rate in Rome was equal to 27.7 per 1,000; 4 deaths resulted from small-pox and 10 from typhoid fever. In four of the largest American cities the rate of mortality averaged 22.2 per 1,000, varying from 17.6 in Baltimore to 24.7 in New York. The 677 deaths in New York included 51 from diphtheria and 25 from scarlet fever; 32 fatal cases of diphtheria were recorded in Brooklyn; and typhoid fever was somewhat fatally prevalent both in Philadelphia and in Baltimore.

THE new asylum which the managers of the Royal Edinburgh Asylum for the Insane have decided on erecting, and which is to embrace all modern improvements, and intended to form a model institution in every way, will, it is understood, cost £30,000.

COLLEGE POLITICS.—After the address read by Mr. Paul Swain (see page 65) before the South-Western Branch, the following resolution was passed: "That this meeting desires to endorse the opinions expressed by the President of the Branch in the paper read by him, and requests him to publish it with a view to a copy being forwarded to the Lord President of the Council and the President of the Royal College of Surgeons."

OBITUARY.

HUGH MILLER, M.D., F.F.P.S. GLAS., L.M.

WE announce with regret the death of a prominent obstetric physician of Glasgow, which took place on January 6th. Dr. Miller graduated at Glasgow in 1864, where he began practice, devoting himself specially to midwifery. He was for a long time obstetric physician and lecturer on clinical obstetrics to the Glasgow Maternity Hospital, to which, at the time of his death, he was consulting physician. He was also examiner in midwifery to the Glasgow Faculty. His contributions, some of which appeared in this JOURNAL, were all on subjects connected with his speciality. It is only about a year since Dr. Miller returned from a sojourn abroad in search of health, overwork having, for a time, broken him down. His death was the result of pneumonia of a week's duration. He leaves a widow, a son, and four daughters.

UNIVERSITY INTELLIGENCE.

MELBOURNE UNIVERSITY.

It has been decided to erect new biological and physical laboratories for the use of the University of Melbourne, Australia.

OTAGO UNIVERSITY, NEW ZEALAND.

At the last degree day, the degree of Bachelor of Medicine was for the first time conferred on a student of Otago University, Mr. W. Ledingham Christie. Dr. Coughtry, who gave an address on this occasion, urged that the single chair of anatomy and physiology, which he had formerly occupied, should be replaced by two separate professorships of anatomy and physiology respectively.

INDIA AND THE COLONIES.

INDIA.

CEYLON MEDICAL SERVICE.—Dr. J. L. Van Der Straaten has been appointed to act as principal civil medical officer of Ceylon. He is a Fellow of the Medical, Obstetrical, and Chemical Societies of London, and Honorary Treasurer of the Local Branch of the British Medical Association. He has visited Europe twice.

ARSENIC IN BEER.—A number of men belonging to the Manchester Regiment stationed at Agra have narrowly escaped being poisoned by drinking beer from a cask, which has since proved to have been previously used for storing arsenic. The beer drawn from the cask was, it was stated, comparatively pure, but the dregs contained enough arsenic to poison a whole regiment.

BEQUESTS.—Mr. Joseph Nicholson, of Sheffield, bequeathed £525 to the General Infirmary, and £105 to the Hospital for Women.—Mrs. Louisa Webber, of Upper Woburn Place, bequeathed £500 to the Royal Free Hospital, £300 to University College Hospital, and £300 to the St. Pancras and Northern Dispensary.—Mr. James Wishart, of Leith, merchant and shipowner, bequeathed £300 to the Edinburgh Royal Infirmary, and £250 to the Leith Hospital.—Mr. Joseph Aley, of The Hough, Stafford, bequeathed £400 to St. George's Hospital.—The Queen's Hospital, Birmingham, has received £250 under the will of Mr. William Slaney Lewis.—Mr. John Endell Powles, of Newton Court, Monmouth, bequeathed £100 to the Monmouth Hospital and Dispensary.

THE HOSPITALS ASSOCIATION.—Dr. J. S. Bristowe, F.R.C.P. Lond., F.R.S., Senior Physician to St. Thomas's Hospital, has accepted the Presidency of this Association, *vice* Sir Andrew Clark, M.D., resigned. Sir Edmund Hay Currie, Mr. E. H. Lushington, Treasurer of Guy's Hospital and Mr. F. C. Carr Gomm, Chairman of the London Hospital, have also joined the Council of the Hospitals Association.

FATAL FOOTBALL.—During this season the number of fatal injuries at football has been very great. Two deaths from this cause are reported to have occurred in one week.

THE DUCHESS OF ALBANY has consented to act as a Patroness of the Fancy Dress Ball to be held on February 9th, at the Hôtel Métropole, in aid of the funds of the North London, or University College, Hospital.

MEDICAL NEWS.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Second Examination of the Board in Anatomy and Physiology on January 9th.

J. Atcherley, J. A. Abbott, and P. Gross, students of Yorkshire College, Leeds; P. I. Mehta, of Bombay; *T. Ohlmus, *O. R. Lewis, and *T. Lawson, of Edinburgh University; H. G. Barlow, of the Bristol Medical School; O. L. Robinson, of Dublin; R. C. McCullagh, of Belfast; A. E. Davis, of Newcastle-on-Tyne; E. L. Rowse, of Charing Cross Hospital; C. W. Vernon, of St. Bartholomew's Hospital.

Passed in Anatomy only.

C. F. Sutton, R. A. Burdett, and A. H. Aldridge, of Owens College, Manchester; W. Hutchinson, of Michigan; A. F. Gervis, of St. Thomas's Hospital; R. H. Heptinstall, E. T. Hollings, F. P. Shackleton, T. W. Swales, and O. F. Rowley, of Yorkshire College, Leeds; S. Greenwood and J. F. Atkins, of Birmingham; and C. Bernard, of Bristol Medical School.

Passed in Physiology only.

A. Shanks, of Glasgow University; F. T. Jackson, of Liverpool; J. A. Bell, of King's College; *E. J. McCardell, of Kingston, Canada; A. B. S. Stewart, of Yorkshire College, Leeds; A. E. Lathbury, of St. Bartholomew's Hospital; C. I. Blakeman, of St. Thomas's Hospital; J. H. Dempster, of King's College; J. Hall, of London Hospital; and *W. R. Willey, of St. Mary's Hospital.

Passed in Anatomy and Physiology on January 10th.

*W. H. Kershaw and F. J. W. Porter, of London Hospital; *R. E. Weigall and *A. A. Parry, of Melbourne University; *W. F. West, I. F. Nall, F. I. Rawlinson, W. W. Kennedy, J. Moore, and W. B. Curgeoven, of St. Bartholomew's Hospital; H. Fairfax, of Charing Cross Hospital; E. J. C. Tyler, of St. Thomas's Hospital; J. D. S. Nodes, of University College; E. J. T. Crutchley and R. A. Earle, of Middlesex Hospital; and W. F. L. Green, of King's College.

Passed in Anatomy only.

W. White, of Middlesex Hospital; E. G. Boon and F. J. O. Stephenson, of St. Mary's Hospital; T. Prescott, of King's College; H. L. A. Kellar, of St. Thomas's Hospital; J. R. Daly and H. F. Ransome, of Owens College, Manchester; F. Winnett, of Toronto; E. C. Ryall, of Dublin and Mr. Cooke's; J. L. S. Sherlock, of London Hospital; and R. H. B. Dudgeon, of Liverpool Infirmary School of Medicine.

Passed in Physiology only.

J. T. Barrow, of Charing Cross Hospital; M. Jenkins and F. D. Lumley, of Guy's Hospital; F. H. Lewis and A. Addie, of St. Bartholomew's Hospital; C. O'Sullivan, of London Hospital; and G. T. K. Maurice, of St. Mary's Hospital.

Passed in Anatomy and Physiology on January 11th.

E. W. Witham, of Westminster Hospital; S. Shore-Smith, of St. Bartholomew's Hospital; J. Spurr, of St. Mary's Hospital; T. Bamford, of University College; W. W. Wingate and W. E. S. Cobb, of Guy's Hospital.

Passed in Anatomy only.

F. W. Gattey and W. A. Mercer, of King's College; *W. W. Lacey, *W. M. Keal, of St. Bartholomew's Hospital and Mr. Cooke's School; H. H. Brind, of St. Mary's Hospital; A. W. Sturdee, S. R. Strouts, H. E. Burch, and Y. H. Mills, of London Hospital; E. H. Greaves, of Guy's Hospital; A. H. Reinhardt, of Yorkshire College, Leeds; P. T. Lunn, of Middlesex Hospital; *A. M. Ewing, of Toronto and Mr. Cooke's School.

Passed in Physiology only.

A. E. Price and R. H. D. Mahon, of St. Thomas's Hospital; C. S. Bowker, of Middlesex Hospital; H. S. Archdale and W. D. Sparrell, of Guy's Hospital; R. Jackson, G. Lys, A. Greenwood, and W. H. Goodson, of Guy's Hospital; H. C. Powell, of Charing Cross Hospital; B. W. Longhurst and P. L. Webster, of King's College; E. A. Brown, J. H. Mortimer, and W. J. C. Keats, of St. Bartholomew's Hospital; W. L. Deut, of King's College; *G. R. Bickerstaff and J. R. Fidler, of St. Mary's Hospital.

Under Old Regulations of College of Surgeons.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the necessary examination in Surgery for the diploma of Member, and having since obtained a medical qualification, were, at a meeting of the Council on January 12th, granted their diplomas.

O. W. Andrews, M.B. Dur., 11, Addison Terrace, Notting Hill; T. N. Greaves, L.S.A., 53, South Hill Park, Hampstead; and T. Lakeman, L.S.A., 24, Claylands Road, Clapham Road, S.W.

MEDICAL VACANCIES.

The following vacancies are announced:

BELGRAVE HOSPITAL FOR CHILDREN, 79, Gloucester Street, S.W.—House Surgeon. Applications by January 31st, to the Honorary Secretary.

BIRKENHEAD BOROUGH HOSPITAL.—Senior House-Surgeon. Salary, £90 per annum. Applications by January 30th, to the Chairman of the Weekly Board.

BIRMINGHAM GENERAL HOSPITAL.—Two Assistant House-Surgeons. Applications by January 28th, to the House Governor.

BRIGHTON, HOVE, AND PRESTON DISPENSARY.—Two House-Surgeons. Salary, £140 per annum, with apartments, etc. Applications by January 31st to the Assistant Secretary.

- BRISTOL GENERAL HOSPITAL.**—Assistant Physician. Salary, £50 per annum, with board, etc. Applications by January 23rd, to the Secretary.
- BRISTOL HOSPITAL FOR SICK CHILDREN AND WOMEN.**—House-Surgeon. Salary, £100 per annum, with apartments, etc. Applications by January 23rd, to the Treasurer and Committee.
- BROMLEY UNION, Kent.**—Medical Officer for No. 5 District. Salary, £60 per annum, vaccination fees and extras. Applications by January 19th, to R. G. Mullin, Esq., Local Officer, Bromley, Kent.
- ESSEX AND COLCHESTER HOSPITAL.**—Physician. Salary, £200 per annum. Applications by January 16th, to the Secretary.
- HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.**—Medical Registrar and Pathologist. Honorarium, £52 10s. Applications by January 24th, to the Secretary.
- HIDDERSFIELD INFIRMARY.**—Junior House-Surgeon. Salary, £40 per annum, with board, etc. Applications by January 27th, to the Honorary Secretary.
- MACCLESFIELD GENERAL INFIRMARY.**—Junior House-Surgeon. Salary, £70 per annum, with board, etc. Applications by January 21st, to the Chairman of the House Committee.
- NATIONAL HOSPITAL FOR DISEASES OF THE HEART AND PARALYSIS.**—Honorary Anaesthetist. Applications to the Secretary, 32, Soho Square, W.
- RADCLIFFE INFIRMARY, Oxford.**—House-Surgeon. Salary, £80 per annum. Applications by January 18th to the Secretary.
- ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—Assistant in the Pathological Department of the Museum. Applications by January 21st, to the Secretary.
- ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road, E. C.**—Senior House-Physician. Salary, £80 per annum, with board, etc. Applications by January 14th, to the Secretary.
- ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, Ventnor.**—Assistant Resident Medical Officer. Applications to the Secretary, 34, Craven Street, W.C.
- ROYAL SURREY COUNTY HOSPITAL, Guildford.**—House-Surgeon. Salary, £80 per annum, with board, etc. Applications by February 15th, to the Assistant Secretary.
- STOURPORT FRIENDLY SOCIETIES MEDICAL ASSOCIATION.**—Resident Medical Officer. Salary, £170 per annum, and extras. Applications by January 21st, to A. Bouckley, Esq., Arley Kings, Stourport.
- SUSSEX COUNTY LUNATIC ASYLUM, Hayward's Heath.**—Junior Assistant Medical Officer. Salary, £100 per annum, with board, lodging, and washing. Applications by January 14th, to the Superintendent.
- SUSSEX COUNTY LUNATIC ASYLUM, Hayward's Heath.**—Medical Superintendent. Salary, £600 per annum, with furnished house, etc. Applications by January 20th, to J. H. Sclater, Esq., Chairman of the Committee of Visitors.
- UNIVERSITY OF EDINBURGH.**—Examiner in Anatomy. Salary, £75 per annum. Applications by January 16th, to the Secretary.
- UNIVERSITY OF EDINBURGH.**—Examiner in Chemistry. Salary, £75 per annum. Applications by January 16th, to the Secretary.
- UNIVERSITY OF EDINBURGH.**—Examiner in Midwifery. Salary, £75 per annum. Applications by January 16th to the Secretary.
- UNIVERSITY OF EDINBURGH.**—Examiner in Practice of Physic. Salary, £75 per annum. Applications by January 16th to the Secretary.

MEDICAL APPOINTMENTS.

- ANDERSON, James, M.D., F.R.C.P.,** appointed Assistant Physician to the National Hospital for the Paralyzed and Epileptic, *vice* J. A. Ormerod, M.D., resigned.
- BASTIAN, H. Charlton, M.D., F.R.C.P., F.R.S.,** appointed Physician to the National Hospital for the Paralyzed and Epileptic.
- BEVOR, C. E., M.D., M.R.O.P.,** appointed Physician to Out-patients, to the National Hospital for the Paralyzed and Epileptic, *vice* H. C. Bastian, M.D., F.R.C.P., F.R.S., resigned.
- BOXALL, Robert, M.D., M.R.C.P., M.R.C.S.,** appointed Physician to the Samaritan Free Hospital for Women and Children, *vice* W. S. A. Griffith, M.B., F.R.C.S., resigned.
- BUCHAN, W. A. M.B. Edin.,** appointed Assistant Physician to the Plymouth Public Dispensary, *vice* T. E. White, M.R.C.S., resigned.
- GLANVILLE, M., M.R.C.S. Eng., L.S.A.,** appointed House-Surgeon and Secretary to the Dorset County Hospital, Dorchester, *vice* F. J. Malden, M.B., M.R.C.S., resigned.
- Lewis, Lewis, L.R.C.P. Lond., M.R.C.S. Eng.,** appointed one of the Visiting Medical Officers of the South Lambeth, Stockwell, and North Brixton Dispensary.
- MACKENZIE, Arthur C., L.R.C.P. and S.E., L.F.P.S.G.,** appointed House-Surgeon to the General Hospital, Birmingham.
- MARTLAND, T., M.R.C.S., L.R.C.P. Lond.,** appointed Medical Officer and Public Vaccinator to the Wigan Union, *vice* G. G. Tatham, M.D.
- McMURRAY, J., M.D., M.Ch.,** appointed Visiting Medical Officer to the Kirkdale Industrial Schools.
- ORMEROD, J. A., M.D., F.R.C.P.,** appointed Physician to Out-patients, to the National Hospital for the Paralyzed and Epileptic, *vice* Thomas Buzzard, M.D., resigned.
- PROWSE, William Hyess, M.R.C.S., L.S.A.,** appointed Medical Officer of Health to the Acton Local Board, *vice* C. H. Farnival, resigned.
- RUSSELL, W. B., M.B., B.A.,** appointed House-Surgeon to the Scarborough Hospital and Dispensary, *vice* H. O. O. Wharry, M.R.C.S. Eng., L.S.A., resigned.
- TOOTH, Howard, M.D., M.R.C.P.,** appointed Assistant Physician to the National Hospital for the Paralyzed and Epileptic, *vice* C. E. Beever, M.D., resigned.
- WILLIAMS, F. M., M.R.C.S., L.R.C.P.,** appointed Medical Officer to the Tavistock Union (Milton Abbey District) *vice* H. Swale, M.B., M.R.C.S., resigned.

WILLIAMS, W. B., appointed Resident Medical Officer to the Royal National Hospital for Consumption, Ventnor, *vice* D. J. Mason, M.B., C.M., resigned.

REQUESTS AND DONATIONS.—Mrs. Mary Ellis, of Cadogan Place, has bequeathed £100 to the Chelsea Home for Men in Consumption, and one-third of the "residue" of her estate (which is likely to be of very large amount) to be divided in such proportions and in such manner as her trustees shall, in their discretion, think proper, among certain charitable institutions, including the Royal Free Hospital, St. George's Hospital, the Earlwood Asylum for Idiots, the Hospital for Consumption and Diseases of the Chest, the Cancer Hospital, the Chelsea, Brompton, and Belgrave Dispensary, the Chelsea Hospital for Women, the Victoria Hospital for Children, Queen's Road, Chelsea, and the Royal Hospital for Incurables.—The Children's Hospital, Birmingham, has received £250 under the will of Mr. William Slaney Lewis.—The Sheffield Public Hospital and Dispensary and the Sheffield General Infirmary have each received £103 17s. 8d., being legacy and interest under the will of Mrs. E. M. Beaumont, of Kenwood Park.—Mr. H. E. Wright has given 100 guineas to the Chelsea Hospital for Women.—The Duke of Bedford has given £100 to University College Hospital.—"J. T. T." has given £100 to the Paddington Green Children's Hospital.

PASTEURISM IN HAVANA.—The following statistics of the Laboratorio Histo-bacteriologico (Pasteur Institute) in Havana, from April to December, 1887, are published in the *Revista de Ciencias Medicas*: The total number of patients was 181, of whom 75 underwent the treatment. In 14 of these cases the animals which had inflicted the bites were proved to be suffering from rabies, by the result of inoculations made on rabbits in the laboratory. Of the 106 persons who were not treated, 61 are stated to have been bitten by "suspected" animals. In these cases the animals had not been sent to the laboratory, or had arrived there in a state of decomposition. No information is vouchsafed as to the results in the cases treated, nor is it explained why so large a proportion was left untreated, in spite of the "suspicion" attaching to them.

SMALL-POX IN HAVANA.—The *Revista de Ciencias Medicas* for December 20th states that from the beginning of May to December 16th there were 1,436 deaths from small-pox in Havana. From an analysis made by Dr. Vicente de la Guardia of 298 fatal cases registered in the month of November, it appears that 201 occurred among the white and 97 among the black population. Of the whites, 118 were males and 83 females; 67 of the former were under and 51 over ten years of age, the corresponding numbers in the females being 61 and 22. Of the negroes, 51 belonged to the male and 46 to the female sex; among the former 26 were under and 27 over ten, while among the females 27 were under and 19 over that age. Unfortunately, no particulars are given as to the proportion of vaccinated to unvaccinated persons in these lists. The epidemic is at present more widely prevalent than ever, but the mortality appears to be diminishing. An exhaustive official inquiry is about to be made as to the causes which have led to so severe an outbreak.

CLINICAL SOCIETY OF LONDON.—The following are the names of the officers and Council of the Clinical Society of London, proposed for election for the year 1888, who will be balloted for at the meeting to be held this (Friday) evening. The gentlemen whose names are marked with an asterisk (*) were not on the Council, or did not hold the same office during the preceding year. *President*: W. H. Broadbent, M.D. *Vice-Presidents*: *W. H. Dickinson, M.D.; Sir Dyce Duckworth, M.D.; J. Hughlings Jackson, M.D., F.R.S.; *J. Warrington Howard; *Sir William Mac Cormac; Howard Marsh. *Treasurer*: Christopher Heath. *Council*: F. G. D. Drewitt, M.D.; J. K. Fowler, M.D.; *T. Colcott Fox, M.B.; W. B. Hadden, M.D.; *Stephen Mackenzie, M.D.; *Angel Money, M.D.; *Isambard Owen, M.D.; F. C. Turner, M.D.; W. J. Tyson, M.D.; Samuel West, M.D.; W. Hale White, M.D.; W. H. Cripps; H. T. Butlin; Rickman J. Godlee, M.S.; C. H. Golding-Bird, M.B.; W. A. Merdith, M.S.; *C. W. Mansell Moullin; *F. Shirley Murphy; Walter Rivington, C.M.; *C. J. Symonds, M.S. *Honorary Secretaries*: *Thomas Barlow, M.D.; R. W. Parker.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—The following members were elected on January 9th as officers and councillors for the year 1888. *President*: Daniel Corbett, Dublin. *Vice-Presidents (resident)*: S. J. Hutchinson; J. H. Mummary; W. F. Forsyth; (*non-resident*) Richard Rogers, Cheltenham; G. C. McAdam, Hereford; J. Cornelius Wheeler, Southsea. *Treasurer*: Thomas Arnold Rogers. *Librarian*: Felix Weiss. *Curator*: W. C. Storer Bennett. *Editor of the Transactions*: Frederick Canton. *Honorary Secretaries*:

Willoughby Weiss (*Council*); C. J. Boyd Wallis (*Society*); E. G. Betts (*Foreign*). *Councillors (resident)*: J. F. Corbett; J. Smith Turner; Sir Edwin Saunders; John Fairbank; David Hepburn; Ashley W. Barrett; Walter Coffin; Thomas Gaddes; R. H. Woodhouse; (*non-resident*) F. H. Balkwill, Plymouth; George Brunton, Leeds; F. Apperley, Stroud; J. H. Redman, Brighton; W. Bowman Macleod, Edinburgh; R. Wentworth White, Norwich.

LEPROSY.—Dr. N. Pringle (Lewisham), in announcing that he has received the promise of a donation of £100 as a commencement for "The Indian Jubilee Leper Fund," adds that he is so perfectly satisfied that scientific and of course sympathetic voluntary segregation is not only possible, but perfectly feasible, that he will gladly communicate his views to those interested in that line of treatment.

A SINGULAR CASE OF GLANDERS IN MAN.—According to the *Syn Otelchestva* (December 10th, 1887), a man has just died from glanders at one of the St. Petersburg hospitals. The deceased never kept, and never came in contact with, any horses in his life. Symptoms of glanders made their appearance in him shortly after his face and eyes had been profusely bespattered with foam from a passing cab-horse, the patient being in the act of crossing the street at the time.

SEASIDE CONVALESCENT HOME FOR LONDON WORKMEN.—This home, which was established at St. Margaret's Bay in 1883 by the agency of the Hospital Saturday Fund, received during the past year 370 patients, as against 302 of the previous year. Through the generosity of the late Lord Wolverton, the committee were enabled, in August last, to open a new wing, a portion of which is reserved for London postmen.

The Salford Town Council has resolved to purchase a site for the sum of £7,000 on which to erect a hospital for the treatment of infectious diseases. The Wilton Hospital has been bought by the London and North-Western Railway Company for the sum of £21,000, and it is stated that the cost of erecting the hospital will probably be about £14,000.

THE MISSING JOURNALIST.—The fate of Mr. McNeill, who disappeared so mysteriously at Boulogne on his way from Paris to London, has been explained by the finding of his body in the harbour, with wounds on the head clearly pointing to murder.

Miss Oxley, of Guy's Hospital, and Miss Loch, of St. Bartholomew's Hospital, have been appointed by the Secretary of State for India to the charge of the nurses which it is intended to introduce into the military hospitals in India.

A LARGE new pump-room is to be built at Buxton. The iron water hitherto supplied from the well will in future also be supplied in this room.

MEDICAL MAGISTRATE.—Mr. George Arthur Phillips, M.R.C.S. Eng., has been placed on the Commission of the Peace for the Borough of Walsall.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.

MEDICAL SOCIETY OF LONDON, 8.30 P.M.—Lettsomian Lectures, by Mr. Reginald Harrison. *Lectures II*: The Pathology of the Enlarged Prostate viewed in respect to its Causation and Prevention, and the Treatment of some Complications arising out of it.

TUESDAY.

PATHOLOGICAL SOCIETY OF LONDON, 8.30 P.M.—Dr. Norman Moore: Carcinoma of Gall Duct. Mr. W. K. Sibley: Abscess in Lung and Brain and Tumour of Pituitary in an Ewe. Mr. Symonds: Epitheliomatous Cyst in Neck. Mr. H. Fenwick: Etiology of Vesical Growths. Dr. Collier: A Recent Specimen of Charcot's Disease of the Knee-joint. Professor Crookshank: Further Inquiries into the so-called Hendon Cow Disease and its Relation to Scarlatina in Man. Mr. R. W. Parker: Specimens of Bone Disease. Mr. Godlee: Specimens of Ricketty Bones.

WEDNESDAY.

ROYAL METEOROLOGICAL SOCIETY, 8 P.M.—Annual General Meeting. Report of the Council. Election of Officers and Council. Mr. W. Ellis (President) will deliver an Address. 7 P.M., Ordinary Meeting. Mr. G. M. Whipple: The Non-Instrumental Meteorology of England, Wales, and Ireland, 1878-1885.

THURSDAY.

HARVEIAN SOCIETY OF LONDON, 8 P.M.—Address by the President (Mr. Edmund Owen). *Conversations.*

FRIDAY.

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 7.30 P.M.—The Council will present reports on: 1. The Publication of the Society's Transactions. 2.

Proposal of the Manchester and Salford Sanitary Association for the Federation of Sanitary and Kindred Societies. 3. The Disposal of Books belonging to the Society. The discussions will be continued on Mr. Wynter Blyth's paper on the Contagion of Cancer, and on Mr. G. Bischoff's paper on Extension of Time of Culture in Dr. Koch's Bacteriological Water Test by Partial Sterilisation, with special reference to the Metropolitan Water Supply. Dr. Rowland: An Improved Method of Sewer Ventilation.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the announcement.

BIRTHS.

BARRETT.—At 13, Rillbank Terrace, Edinburgh, on the 9th instant, the wife of William H. Barrett, M.B., of a son.

MURPHY.—On January 7th, 1888, at Belmont, Queenstown, County Cork, the wife of F. H. S. Murphy, Esq., M.D., Surgeon, M.S., of a daughter.

DEATH.

LYALL.—At 1, George Square, Edinburgh, on the 10th instant, Andrew Lyall, M.D., late of Leven, aged 41.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY --- 10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's (Ophthalmic Department); and Royal Westminster Ophthalmic.—2 P.M.: Metropolitan Free; St. Mark's; Central London Ophthalmic; Royal Orthopaedic; and Hospital for Women.—2.30 P.M.: Chelsea Hospital for Women.

TUESDAY --- 9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's; St. Bartholomew's (Ophthalmic Department); St. Mary's; Royal Westminster Ophthalmic.—2 P.M.: Westminster; St. Mark's; Central London Ophthalmic.—2.30 P.M.: West London; Cancer Hospital, Brompton.—4 P.M.: St. Thomas's (Ophthalmic Department).

WEDNESDAY --- 10 A.M.: National Orthopaedic.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: Middlesex.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: London; University College; Westminster; Great Northern Central; Central London Ophthalmic.—2.30 P.M.: Samaritan Free Hospital for Women and Children; St. Peter's.—3 to 4 P.M.: King's College.

THURSDAY --- 10.30 A.M.: Royal London Ophthalmic.—1 P.M.: St. George's.—1.30 P.M.: St. Bartholomew's (Ophthalmic Department); Guy's (Ophthalmic Department); Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Central London Ophthalmic; Hospital for Diseases of the Throat; Hospital for Women.—2.30 P.M.: North-west London; Chelsea Hospital for Women.

FRIDAY --- 9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.15 P.M.: St. George's (Ophthalmic Department).—1.30 P.M.: Guy's; Royal Westminster Ophthalmic.—2 P.M.: King's College; St. Thomas's (Ophthalmic Department); Central London Ophthalmic; Royal South London Ophthalmic; East London Hospital for Children.—2.30 P.M.: West London.

SATURDAY --- 9 A.M.: Royal Free.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: King's College.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Middlesex; Royal Free; Central London Ophthalmic.—2.30 P.M.: Cancer Hospital, Brompton.

HOURS OF ATTENDANCE AT THE LONDON HOSPITALS.

CHARING CROSS.—Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; Skin, M. Th., 1.30; Dental, M. W. F., 9.

GUY'S.—Medical and Surgical, daily, 1.30; Obstetric, M. Tu. F., 1.30; Eys, M. Tu. Th. F., 1.30; Ear, Tu. F., 12.30; Skin, Tu., 12.30; Dental, Tu. Th. F., 12.

KING'S COLLEGE.—Medical, daily, 2; Surgical, daily, 1.30; Obstetric, Tu. Th. S., 2; o.p., M. W. F., 12.30; Eye, M. Th., 1; Ophthalmic Department, W., 1; Ear, Th., 2; Skin, Th.; Throat, Th., 3; Dental, Tu. F., 10.

LONDON.—Medical, daily, exc. S., 2; Surgical, daily, 1.30 and 2; Obstetric, M. Th., 1.30; o.p. W. S., 1.30; Eye, W. S., 9; Ear, S., 9.30; Skin, Th., 9; Dental, Tu., 9.

MIDDLESEX.—Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; o.p., W. S., 1.30; Eye, W. S., 8.30; Ear and Throat, Tu., 9; Skin, Tu., 4; Dental, daily, 9.

ST. BARTHOLOMEW'S.—Medical and Surgical, daily, 1.30; Obstetric, Tu. Th. S., 2; o.p., W. S., 9; Eye, Tu. Th. S., 2.30; Ear, Tu. F., 2; Skin, F., 1.30; Larynx, F., 2.30; Orthopaedic, M., 2.30; Dental, Tu. F., 9.

ST. GEORGE'S.—Medical and Surgical, M. Tu. F. S., 1; Obstetric, Tu. S., 1; o.p., Th., 2; Eys, W. S., 2; Ear, Tu., 2; Skin, W., 2; Throat, Th., 2; Orthopaedic, W., 2; Dental, Tu. S., 9; Th., 1.

ST. MARY'S.—Medical and Surgical, daily, 1.45; Obstetric, Tu. F., 1.45; o.p., M. Th., 1.30; Eye, Tu. F. S., 9; Ear, M. Th., 3; Throat, Tu. F., 1.30; Skin, M. Th., 9.30; Electrician, Tu. F., 2; Dental, W. S., 9.30; Consultations, M., 2.30; Operations, Tu., 1.30; Ophthalmic Operations, F., 9.

ST. THOMAS'S.—Medical and Surgical, daily, except Sat., 2; Obstetric, M. Th., 2; o.p., W., 1.30; Eye, M. Th., 2; o.p., daily, except Sat., 1.30; Ear, M., 12.30; Skin, W., 12.30; Throat, Tu. F., 1.30; Children, S., 12.30; Dental, Tu. F., 10.

UNIVERSITY COLLEGE.—Medical and Surgical, daily, 1 to 2; Obstetrics, M. Tu. Th., F., 1.30; Eye, M. Tu. Th. F., 2; Ear, S., 1.30; Skin, W., 1.45 S., 9.15; Throat, Th., 2.30; Dental, W., 10.30.

WESTMINSTER.—Medical and Surgical, daily, 1.30; Obstetric, Tu. F., 8; Eye, M. Th., 2.30; Ear, M., 9; Skin, Th., 1; Dental, W. S., 9.15.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS respecting editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

In order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the office of the JOURNAL, and not to his private house.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL, are requested to communicate beforehand with the Manager, 429, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication. CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, or forwarding their Annual and other Reports, favour us with Duplicate Copies.

TO CORRESPONDENTS.

Our correspondents are reminded that prolixity is a great bar to publication, and, with the constant pressure upon every department of the JOURNAL, brevity of style and conciseness of statement greatly facilitate early insertion. We are compelled to return and hold over a great number of communications, chiefly by reason of their unnecessary length.

QUERIES.

S. K. asks how a large crop tent can be rigged up?

M. S. C. wishes to hear of a good Roman Catholic boarding school in England, where two brothers, aged 13 and 15 years respectively, would be taken for about £10 per annum.

CLIMATE FOR PHTHISIS.

M. S. asks to be informed as to the presumptive relative value of Texas and Florida for a case of phthisis with early hæmoptysis, and the parts generally visited? Are the States equal to New Zealand?

BATHS FOR COUNTRY HOUSES.

BAICE, asks members to give their experience of the different baths advertised. He is in search of a full-sized bath to be heated with oil-lamp beneath; he lives in a house where no water can be laid on.

UNDESCENDED TESTICLES.

PHYSIAN writes: A family medical attendant discovers incidentally in the course of examining a boy, 8 or 10 years old, that the testes are undescended. 1. Is it his duty, twenty years afterwards, when the man may be contemplating marriage, to suggest an excision of the scrotum, in case matters should still be as before, and the patient unaware of any defect; and 2, supposing the scrotum still empty, would it be wrong for the man to marry in view of sterility, both disappointing and perhaps proving injurious to the health of the wife?

ANSWERS.

"ALPHA" should apply to Dr. Corfield, Hygienic Laboratory, University College, Gower Street, London, W.C.; or Dr. W. Blyth, officers of the medical officer of health, St. Marylebone Vestry, Marylebone Lane, W.

A YOUNG APOTHECARY probably refers to varicocele, a condition which he will find fully discussed in all the textbooks of surgery.

ECZEMA.

W. J. C.—The causes of eczema vary so much in different persons, that the treatment and prevention must be decided in each case according to its special characters. The chapter on Eczema, in Dr. McCall Anderson's recently published work on *Diseases of the Skin*, is unusually full and instructive, and we cannot do better than refer "W. J. C." to this book.

"WINTER CLIMATE OF FLORENCE AND GENOA."

DR. ST. CLAIR THOMSON (Florence) writes: Florence has, empirically, a reputation as a climate for cases of asthma, and experience tends to confirm this. I know of several asthmatics who have found out for themselves the suitability of this climate; amongst them being some who have been told by London physicians that they would become confirmed bronchial-asthmatics unless they lived in Algiers, or even further afield. The cold is very sharp in the short winter; and at all times the difference between sun and shade temperature is considerable. Consequently, it is not suited to most phthisical invalids until the spring. The dryness of the climate suits people of a gouty disposition. Although there are several villages near to Florence which would suit "H. A. L.'s" patient, none of them afford sufficiently comfortable accommodation.

I can only speak personally of Genoa from some short visits in the winter. I found it as cold as Florence, bleaker, and with much less sun. I don't know that it has any reputation as a climate for asthma; and most certainly "H. A. L.'s" patient would not find there the conveniences for studying art, which are easily obtained at Florence.

MRS. LAMBERT (Tavistock Place, Sunderland) writes: In reply to the query of "H. A. L.," in the JOURNAL of December 31st, I beg to inform him that a friend of mine, a young lady of 25 (who in this country suffered terribly from asthma and bronchitis, and was nearly constantly confined to her room) has found a

residence in Leghorn most beneficial; indeed, while there or any place round about she is perfectly well. I shall be pleased to forward her address if necessary. She will, I am sure, be glad to give any information.

NOTES, LETTERS, ETC.

ERRATUM.

IN the JOURNAL of December 31st, p. 1420, owing to an accidental transposition, it was erroneously stated that Dr. Archibald Macdonald had made some remarks on the treatment of tubal fœtation by galvano-puncture; his paper dealt with the prevention of puerperal septicæmia.

RECIPROCITY.

MR. THOMAS A. WHITE (L'Abri, Territet, Vaud) writes: I remark in the JOURNAL of December 24th a paragraph relating to the registration of foreign diplomatas, in which a lady M.D. of Zurich wishes for registration in England. I would wish to inform you of what has just happened to me here. I have been in practice at Montreux for the past nineteen years, without Federal diploma, but manifestly with the connivance of the cantonal authorities, and, since January 1st, 1883, have had the sanction of the municipal authorities.

I say with the connivance of the cantonal authorities. Some years ago I attended, at one of the mountain summer resorts, a case of fracture, and one of the medical men there had me summoned for practising; the case was referred to Lausanne, and they ordered the proceedings to cease; and at a Medical Conference held some time ago at Lausanne, a medical man who has not been here so very long was making such a violent tirade against me that the President ordered him to desist. This same medical man, joined by the newest arrival (whom I neither know or have met), has made a public complaint against me as practising medicine here, and the cantonal authorities had to take the matter up, and ordered the Prefect at Vevey to inflict the highest fine they can upon me, namely, 300 francs, but he, under the peculiar circumstances of the case, has reduced the sum to 200 francs. I am at present, through my *avocat*, appealing to the cantonal authorities against this decision. The matter is under due consideration here, but whether the Federal authorities will reject or accede to our Medical Act and establish reciprocity I am not sufficiently advised to inform you.

I give you this letter, as the reciprocity question is before both Governments, and not as a complaint; for if I live in a country and break its laws (though under most peculiar circumstances), I must be judged by its laws. You will see from the foregoing how important it is to members of our profession who are living abroad for various reasons that reciprocity should be established, and that we should not be subjected to the effects of the ill feeling of an individual, even if, as I am, generously treated by the medical men of this place.

POISONING BY NITRE: TREATMENT WITH APOMORPHINE.

DR. H. W. PEARCE (Coole Abbey, Fermoy, Ireland) writes: A farmer's wife, aged 60, took a very large dose of nitre, mistaking it for sulphate of magnesia. This was taken on an empty stomach. When I got to the house I found that she had swallowed some bread and milk, she had also swallowed some warm water, but could not excite vomiting. Her pulse was about 38; she appeared very sallow and pale, and complained of some epigastric pain, but her chief complaint was of cold. "Oh, the cold, the terrible cold is killing me!" Her hands and feet, however, did not feel cold to the touch, and she had a considerable covering of blankets. I at once dissolved one of Messrs. Burroughs and Wellcome's hypodermic tablets of 1-10th grain apomorphine, and injected the same into her arm. In three minutes and a half emesis took place without apparent effort on the patient's part, and over a pint of the contents of the stomach was vomited. I then got her to swallow about half a pint of warm milk, which again was ejected. After this there was a little retching, or rather I might call it a few involuntary contractions of the stomach, and then the action of the drug seemed ended; there was little prostration, though there was some purging with blood in the stools, but no blood, as well as I could ascertain, in the urine. An opiate in some brandy and water, and a little good chicken broth had made her all right by next day, and she went about her household work as usual. When I was leaving her, about two hours and a half after her taking the nitre, the pulse was about 60, and colour had reappeared in face and hands. She had taken about 3ii of nitre, having stirred it in some warm water, and drank it in suspension, before it was half dissolved. I only applied a very rough test to the vomited matter, merely dipping a bit of cotton-wool in it and dried it. When this was lit, it burned in the characteristic way such substances do when impregnated with a strong solution of the salt. This case seems to me to speak well for apomorphine. I must add that I had some experience of the drug, as I hypodermically injected it, with marked success, on a former occasion, when a child had swallowed some spirits of turpentine and on two occasions when I thought my dogs had taken poison.

PALPATION OF THE THORAX.

DR. FREDERICK A. FLOYER, M.B. Camb., writes: A method of diagnosis has recently come under my observation which I believe has not hitherto received the attention it deserves. The value of tactile sensation in the examination of the abdomen is already well known, but that it is possible to diagnose by the fingers various conditions of the lung in disease, has not, so far as I am aware, been dwelt upon. That this is possible, according to scientific laws, is easily demonstrable.

In ascultation the impressions received are those produced by the vibrations originated in the movements of the air along the air-passages, or of the lung, etc.; these movements and impressions being altered according to morbid influences. Great differences in the wave-length of vibrations are capable of being appreciated by any sensitive conductor. The fingers, being extremely sensitive, can readily appreciate vibrations over a large gamut, and the variable sensations are precisely identical with those communicated through the auditory nerve, except that in the one case the expression is tone, and in the other tactile sensation. The high degree of perfection to which this method can be brought has been demonstrated to me by a practitioner whose fingers, by long experience, are far more sensitive than his auditory nerves. His interpretation of various intra-thoracic conditions is quite equal to that arrived at by auscultation. Moreover, his description of what he feels is precisely the same as that of another man with the stethoscope. Dr. W. H. Stone, of St. Thomas's Hospital, in writing to me on the subject, says, "this method is especially good for slow vibrations, less than 10 per second, which to the ear are difficult."

GENERAL BLEEDING IN LOCAL INFLAMMATORY SWELLINGS.

Mr. G. P. ATKINSON (Pöhteract), writes: On April 20th, 1856, I was called in consultation to a confinement case, where I found an arm presentation with the fetal hand protruding beyond the vulva, and the vagina so swollen as to make turning an impossibility. I bled the patient to $\frac{1}{2}$, and gave a soothing draught, and we left her quietly for fifteen minutes; on re-examination, I found all swelling had subsided; turning was readily effected, and delivery completed within ten minutes, and she made a good recovery. Would not bleeding be likely to be followed by similar effects in cases of physical obstruction, with an inflammatory constitution of surrounding walls of other natural passages; for example, the larynx or trachea containing one or more tumours in such difficult cases as that of the Crown Prince of Germany, and would not its effects be likely to prove more thorough and durable; and attended with little risk to the patient compared with a serious operation? I make these remarks with all due respect to others for professional consideration.

"A DOCTOR'S PRESENT."

E. B. writes: I excised the shoulder-joint of a little sailor boy, at the hospital I have the honour of belonging to; all went well, and a good useful arm resulted. One day I told the little man he might go home; he pulled out from under his pillow, a spherical box, elaborately ornamented, and as he told me containing box after box inside, and that in the innermost "was two rubies." Well, I didn't open this before the students, but took it home for the surprise of my little ones; when, lo, behold, the two rubies were there; and I had them set in a gipsy ring for a young puss, who thinks the possession of a ring will put her a stage above her fellows. I offer Walter Besant this story.

ANTI-TANNIC INFUSER.

A MEMBER writes: Like your correspondent of January 7th, I was much taken with the idea of an anti-tannic infuser; I therefore made some tea with one, following strictly the directions. The infusion looked like the ordinary beverage, except that it was weaker; but, on adding a few drops of weak perchloride of iron solution, it unfortunately turned to ink.

SQUINT.

Mr. ROBERT W. DOYNE (Oxford) writes: Dr. Bell Taylor's reply surprises me more than his first letter. The direct deduction from his opening sentence, taken with his previous letter, is that no hypermetrope, unless he squints, ever has vision of normal acuteness, that is, $\frac{20}{20}$. I cannot imagine anyone admitting this which is so easily disproved by observation. The very existence of what is known as relative accommodation disposes of the argument.

With reference to the next point, I do not believe that anyone, except for a few moments, can use his maximum of accommodation, and the proof that he gives to the contrary is certainly startling, for he insinuates that, whenever a hypermetrope overcorrects his error by accommodation, he does so to the extent of his maximum of accommodation.

He next proceeds to contradict his first statement, by demonstrating a hypermetrope who does not correct his hypermetropia for parallel rays without squinting and only squints, as certainly is often the case at first, when looking at near objects. In his explanation here he ignores the assistance to accommodation that is given by the normal convergence for near objects.

His next statement goes further than his first, and he implies that all hypermetropic children squint whose hypermetropia does not exceed 12 D or 14 D. For having claimed that they can by convergence make use of their maximum of accommodation (and this in children is 12 D or 14 D), he in effect says that only those do not squint whose hypermetropia is greater than this. I may incidentally mention the very extreme rarity of such a degree of hypermetropia. In his remarks on diplopia, he appears to maintain that it does always exist at first, notwithstanding that most observers (I would have said all) agree that it is the exception to find it in concomitant squint, and that usually it is only by certain manoeuvres that the impression of a second image can with difficulty be forced upon the mind. In connection with this point his assertions are completely unqualified, and, if true, would prove that in all cases without diplopia squint becomes a monocular affection, and gets well without treatment so far as parallelism of the visual axis is concerned.

As regards the cure by glasses, I believe that, if this mode of treatment is adopted at the very onset of the squint, nearly all cases of alternating periodic, most cases of periodic, and a few cases of recent permanent squint will get well without further treatment, and that the cases that ultimately require strabotomy will be very greatly reduced. No doubt a few get well without any treatment at all. He concludes this subject by drawing attention to the well-known fact that the use of atropine will reveal those cases of hypermetropia that simulate myopia, a condition, however, that can at once be detected by the ophthalmoscope.

TENERIFFE AND ITS SATELLITES.

Mrs. OLIVIA M. STONE (Kensington), author of *Teneriffe and its Six Satellites*, writes: Now that the Canary Islands are rapidly becoming better known as one of the most advantageous health-resorts within easy reach of England, it may be of some interest to mention a few facts concerning diseases in the archipelago. The one pre-eminent fact is that the climate seems to modify the virulence of the worst, the most dangerous diseases. Puerperal fever, which, though rather prevalent, is seldom, I may almost say never, fatal, though I know of cases where the patient has been neglected for several days before medical advice was obtained. Diphtheria is also very prevalent in the large towns, owing to the total absence of the most ordinary sanitary precautions, but it seems always to exist in only a mild form. I know of certain families who apparently have it frequently, but this terrible disease seems to be only fatal where the most elementary knowledge of nursing is absent. Fevers of all kinds are lighter in character. The treatment recommended there by the profession is different to that in vogue in England. For example, it starts by a thorough clearing out of the system by means of somewhat violent purgatives and emetics.

Equable as is the climate by day and night, the natives suffer most from chills, which often end fatally. This, I think, may be in a great measure accounted for by the absence of woollen or silken clothing. Those who visit the Canaries from colder northern latitudes where wool is worn next the skin, and who most wisely continue this habit, do not suffer in this way. It is advisable that every article of clothing worn in the islands be either made of wool or silk. Thus armed one is almost impregnable to the attacks of any disease of a catarrhal nature. Malaria does not exist. Precautions as to hours of recreation, such as keeping in the house at sundown, are in these islands unnecessary,

and one may be out on the hottest day at its hottest hour without any fear of sunstroke.

The only disease which in any way can be said to be peculiar to or prevalent in the Canary Islands is elephantiasis, which, as your readers well know, does not affect well-nourished inhabitants, and is neither contagious or infectious. In Gran Canaria diseases of the stomach and intestines are common among the peasants; such are clearly traceable to the national food, *gofio*, which in this island is made of Indian corn.

For phthisis the Canary Islands have been proved of inestimable value, and therefore on this point nothing more need be said. The temperature throughout the year by day and by night varies exceedingly little. In my recently published work on these islands I have gone so fully into this question that I need not recapitulate it here.

I should not have thus ventured to trouble you had I not been asked by some leading members of the medical profession to summarise facts scattered through the pages of my book, and to add thereto others which I had deemed unsuitable for the general reader.

METROPOLITAN PROVIDENT MEDICAL ASSOCIATION.

A. S. R. W. writes: Mr. Timothy Holmes's remarks on my letter of December 24th prove conclusively the offensive nature of this scheme. He says: "The dispensary and the general practitioner are the same, or are intended to be the same, and that 'the' course open to us will be to join in the movement." Has he considered that if every medical man in a working-class district was to join the newly-established branch every family in the same district would join for the sake of getting their medical attendant for 2s. 6d. a week; also has he calculated that the medical man would have to visit thirty patients daily, some of them two or three times a day, for the handsome sum of £3 10s. per week?

Will Mr. Holmes state how "all possible care" had been taken to get all the general practitioners to attend the meeting? I for one received no invitation, and I could name several more who have never even heard of the scheme.

There will be three courses open to us: 1. To ignore the existence of these dispensaries, and starve; and 2. To co-operate with them, and attend as a slave on hitherto private patients; and 3. To still remain independent and under all the dispensaries, which would require extensive advertising. I am sure all will agree it will be better to accept 2s. per week and remain our own masters, than to take this beggarly 2s. 6d. and be at the beck and call of the capricious club patient.

This is what I mean by a packed meeting: "An assembly of a few men who it is known will give their support to a scheme and who have been informed that a meeting will be held at a certain time and place." Mr. Holmes must admit that those gentlemen who were in favour of the scheme, particularly Dr. Glover and himself, were awarded a patient hearing, whilst those gentlemen who attempted to point out the weak places were treated with ignominy and deriding jeers.

Mr. ALBERT KISCH (Abingdon House, Sutherland Avenue) writes: In reply to a writer in the JOURNAL of December 24th, who criticises the method of the above Association, and points out the difficulties which beset medical men attempting to compete with it, Mr. Holmes suggests that all general practitioners concerned should co-operate in the work of the Association. For the benefit of any hesitating gentlemen, permit me to place before your readers some data by which anyone can readily ascertain what would be the probable effect on his income if he were to accept Mr. Holmes's cordial invitation.

In my interview with Mr. W. G. Bunn, the secretary, whose courtesy and frankness I gladly acknowledge, that gentleman informed me that a dispensary of the Association comprising 900 members, would be likely to yield to the doctor £50 per annum. An energetic man, in a working-class district, might, therefore, by joining one of these dispensaries, earn the magnificent income of £266 18s. 4d., by accepting the entire medical charge of 9,000 persons, or, in other words, that sum represents what he might expect if he cast in his lot with the Association, by joining the branch dispensary of his district, which would naturally absorb all his *clients*.

Has Mr. Holmes any idea of the amount of work involved in the medical charge of 9,000 persons? A personal experience on a smaller scale enables me to say that it would be enormous, and that it would probably sometimes entail as many as 150 visits on a day. The remuneration awarded is so ludicrously insufficient, that comment is superfluous. If Mr. Holmes would but try the work himself for one year, he would certainly appreciate the magnitude of the injury which he and his colleagues are, with the best intentions, inflicting on the hardest worked section of the profession, by foisting this pseudo-philanthropic scheme upon them.

Mr. JOHN H. GRAY (St. James's Road, Upper Tooting) writes: As I was one of those present at the meeting, convened by the Medical Attendance Organisation Committee, on December 6th, I shall be glad if you will allow me to confirm most emphatically the statements of Mr. Holmes and Mr. Hare in their letters which appear in the JOURNAL of January 7th. By those very accurate statements, Mr. Piper's desire that "the responsibility for the irregularity which occurred may be on the proper shoulders," has been fulfilled. I think I am able to speak as an impartial observer, for although sympathising generally with the object of the promoters, I considered that there was need for further discussion of the scheme, and for amendment of some of its provisions, and therefore I was one of the very small minority who voted for an adjournment of the meeting. But, if time is to be wasted (as it undoubtedly was) the other day) by what Mr. Hare justly terms "puerile and irrelevant remarks" on the part of those who are of Dr. Carpenter's way of thinking, there can never be anything like fair and reasonable discussion. If "Mr. Holmes and others of the committee" had been guilty of hatching a scheme for their own special aggrandisement at the expense of the general practitioners, they could hardly have met with a more discourteous opposition.

What your correspondent, "A. S. R. W.," could mean by saying that it was "a packed meeting," I am at a loss to imagine, seeing that it was summoned by printed circular, and that access was perfectly free and unrestricted; but so comparatively small was the attendance, that if anyone had cause to complain of want of support, it must have been those who are anxious to secure the active interest of the general body of metropolitan practitioners in this reformatory movement rather than those represented by "A. S. R. W.," and Dr. R. H. S. Carpenter.

Mr. F. E. COCKELL, Jun. (62, Forest Road, Dalston) writes: Like your correspondent, "J. H.," I have expected a more general outcry against the scheme of universal

HARVEIAN LECTURES ON LUPUS.

Delivered before the Harveian Society, December, 1887.

By JONATHAN HUTCHINSON, F.R.C.S., F.R.S., LL.D.,
Emeritus Professor of Surgery at the London Hospital.

LECTURE III.—ON THE VARIOUS FORMS OF LUPUS VULGARIS AND ERYTHEMATOSUS.—[With Lithograph.]

Difficulties of Classification.—*The Bacillus in Lupus Necrogenicus.*—*Acne-Lupus (Lupus Follicularis Disseminatus of Tilbury Fox).*—*A Mixed Form of Chilblain-Lupus.*—*Lupus-Psoriasis (Dr. Stephen Mackenzie's Case).*—*Lupus in Relation to Port Wine Stains.*—*Lupus Lymphaticus.*—*Rupia-Lupus of Young Children.*—*Navus-Lupus.*—*Alliances of Rhino-Scleroma and Sycosis with Lupus.*—*Kaposi's Disease.*—*Hobra's Xeroderma, a Family Form of Lupus.*—*On the Varieties of Lupus Erythematosus.*—*On Lupus-Cancer.*—*On Syphilitic Imitations of Lupus.*—*Concluding Remarks.*

THE classification of diseases is easy if we permit ourselves to keep aside unusual and ill-marked forms. If, however, we endeavour to comprise all, it becomes sufficiently difficult, and to lookers-on it may appear that needless complexity and useless detail are introduced. There is, however, a great and obvious gain in the conscientious admission of all witnesses, for very frequently we find unexpected testimony borne which proves of great value to the discovery of truth. The rare and the minor forms of disease are precisely the connecting links between the larger groups, and they enable us to see their continuity and to trace their relationships.

In our last lecture I had to bring before you the subjects of strumalupus, eczema-lupus, lupus mutilans, necrogenic lupus, and some others. Most of these are rare, but still very real, sub-species of the disease, and I shall be obliged, on the present occasion, to trouble you with the description of others some of them of even greater rarity in practice, but all of equal importance, to complete the picture of the group of diseases which we are investigating.

Before proceeding to fresh topics, I wish to supplement by a few words what I said last week as to lupus necrogenicus. I omitted to mention that observers have found the tubercle bacillus in great abundance in the granulation growth which attends this malady. I make this statement chiefly on the authority of Riehl and Paltauf, who found the bacillus more easily in it than in sections of common lupus. This is interesting because, in the first place, this is the only form of lupus in which contagion seems at all probable. The others, it is true, often begin from local irritation, but it is usually of a kind not in the least likely to convey infective material (chilblains, insect stings, and the like). We know nothing of lupus as a disease capable of spreading by contagion from one person to another. In the necrogenic form, beginning as it does from dissection pricks, it is easy to suppose the transference of bacilli possible. It is remarkable, however, if that be so, that it is precisely the form of lupus which shows the least tendency to spread. It rarely produces satellites, and I never in a single instance knew it followed by patches on other parts of the body, nor by anything indicating visceral tuberculosis. In our last lecture I instanced a case in which it had been present for forty years without doing any harm. On the other hand, lupus erythematosus, in which, so far as I know, the bacillus has not been found, is very infective, and is very frequently associated with a tuberculous family history:

I give the name *acne-lupus* to a disease which was, I believe, first described by the late Dr. Tilbury Fox under that of lupus follicularis disseminatus.¹ I am sorry to propose a change from that used by a dermatologist so distinguished, but I believe that mine expresses more with greater brevity, and will be more easily remembered. It is obvious that they imply the same thing. The disease is a combination of acne with lupus, or rather, perhaps, it is lupus attacking acne spots. I have seen but very few good examples of it, but it is a very definite variety of the disease. In the case of a young man named S., whose sister's case I have already detailed to you, both cheeks showed acne spots. On the left cheek, however, many of the spots had enlarged, and were obviously of the apple-jelly structure. There could be not the slightest doubt that they were lupus, and equally little that they were

arranged like acne, and occurred in connection with sebaceous follicles. This young man had also lupus of his *alae nasi* and of his palate. As already recorded, two of his sisters had somewhat similar affections, and the family was decidedly strumous. Acne-lupus is a form of common lupus, and not of the erythematosus division. It is, so far as I have seen, never symmetrical, and the apple-jelly is very characteristic. It is of interest to note that it never attacks acne spots on the back, but occurs, I believe, on the face only, illustrating what we have had so frequently to ask attention to, the influence of cold and exposure as causes of lupus. I show you portraits taken from another case, but in it the conditions were not so definite as in the last S.

The group of cases which I have next to describe is one to which I find it extremely difficult to give any concise name which shall, at the same time, be appropriate and descriptive. It is lichen, acne psoriasis, eczema, chilblains, and lupus altogether. Yet it is a definite disease, and one case is like another. It begins in early childhood, and it affects the parts which are exposed. Thus I have no doubt that it has affinities with Kaposi's disease, but I have not as yet seen it in more than one member of a family. If it happened to several brothers and sisters, it would be at once accepted as a modification of Kaposi's disease. In my own notebooks, in default of any name, I have been in the habit of classing its cases as belonging to "the Philip Holmes series." Now "Philip Holmes" was the youth whose condition is depicted in the portraits which I now show. His was not the first case that I had seen, but it is one of the best, and it is the only one of which I have preserved an illustration. Holmes's grandfather had been the subject of psoriasis. The boy in infancy had a rash which was called red-gum, and which never quite left him. I saw him first in 1874, when he was 11 years old, and the portrait before you was taken in 1877, when he was 14. He was florid but rather delicate, and had a cough. You will see that his cheeks (the conditions were quite symmetrical) were covered with acne-like pustules, some of which spread at their bases, and are exactly like acne-lupus. His whole ear was in a condition of eczema-lupus, and on his forearms and hands were ulcerating pustules and patches of various sizes. Everywhere the eruption was leaving scars when it receded, and the largest scars were on his elbows and backs of forearms (the psoriasis positions). A tendency to produce stigmata (a prominent feature in Kaposi's disease) was very marked. There had been bad chilblains on the feet. This eruption was, however, much more than mere chilblains. It had then been persistent for years, and it remained so during the five years more that the youth was under my observation. In some respects it was worse during cold weather, but often, like psoriasis, it relapsed "in spring and fall." It was not a disease of the sebaceous follicles only, for there were scars also in the palms. I find in the older atlases one or two portraits which bear upon this malady, so far as to show ulcerated and lupoid eruptions on the elbows and forearms, arranged like psoriasis, but none of them either delineate or describe the patient's face.

I possess the notes of several cases like that of Philip Holmes, and have seen several others of which I have preserved no notes. The cases constitute very important connecting links. I have no doubt that the eruption results from inherited peculiarities in the organisation of the skin and the general health-status of the patient very similar to those so wonderfully displayed in cases of Kaposi's disease.

Closely allied to the cases just mentioned, but with important differences, are the forms known as psoriasis-lupus, and well illustrated in the full length and excellent portrait which I now display, and which has been lent me by Dr. Stephen Mackenzie. There is no doubt whatever as to this case being one of lupus; probably the case of Dr. Jamieson's, from which we borrowed our microscopic illustration last week, was very like it. The question is whether it should be called vulgaris or erythematosus. You will see that it has notched the nostrils like vulgaris, and that it presents definite thickening of the skin, not easily distinguishable from apple-jelly growth. Still, as it is arranged with symmetry, I prefer to consider it as erythematosus, and as it affects the exposed parts and began in youth, I must again call your attention to its similarity to Kaposi's disease. Indeed, if I place side by side Dr. Mackenzie's portrait of lupus-psoriasis and Dr. Radcliffe Crocker's of Kaposi's malady, you would be puzzled to distinguish them. A sister of the subject of this psoriasis-lupus patient had common psoriasis, a fact of much importance in reference to my assertion as to hybridity. The disease began at the age of 16 all over the face, and subsequently affected the neck, forearms, and arms. Finally, and this is very unusual, it even involved to some extent the trunk, abdomen, and chest. You will see that the eruption is dusky and erythematosus, that it leaves scars, and

¹ I had previously exhibited a portrait of acne-lupus under that name in the Annual Museum of the British Medical Association, but I had not published any account of it.

that, as already noted, it has taken away the *ale nasi*. This case is in some respects a better illustration of *psoriasis-lupus* than the one which I published under that name many years ago in the New Sydenham Society's *Atlas*.

I almost fear that I may incur the charge of audacity in suggesting such a name as *navus-lupus*. My meaning is, not that lupus-sometimes become nevoid, nor that a nevus may sometimes look like lupus, but simply and definitely this, that skin in a nevus condition may become affected by the lupus growth, and I assert that there are certain very rare cases in which the one process does really become engrafted on the other. The combination may occur with different results, the latter varying with the kind of nevus which is attacked. Sometimes it is the thick, mixed nevus so commonly seen in infancy, and sometimes it is the port wine stain; if the former, it is always in very early life; if the latter, it may not be till puberty or after. My attention was first attracted to this subject by a case which my friend Mr. Higgins was kind enough to transfer to my charge at Moorfields many years ago. Its subject was an infant who had been born with a nevus on the side of the head. At the time of birth the nevus was so small that it was not noticed, but it developed as small red spots on the temple at a week old, which spread and ulcerated until a considerable part of the face was covered with scab, and the lips and nose were attacked. Part of the nose and of its septum were destroyed. In this instance satellites were produced near to the edge of the parent nevus. Thus we had serpiginous spreading, infection by contiguity, ulceration, and scarring—the characteristics of the lupus process. It was not without great interest that I discovered, a few days ago, amongst the plates published by Dr. Anthony Todd Thompson, the portrait which I now produce. It shows a nevus of considerable thickness and of very large extent, covering one side of the head and a considerable part of the face. It was still spreading when the child died of meningitis, and Dr. Thompson notes especially that it not only crept on at its edge, but that it showed a tendency to produce little islands of nevus structure in the skin near to it—satellites. We have in this instance proof only of infective tendencies, for I believe there had been no spontaneous ulceration. The important point is that the child at the time of birth had no nevus at all, at least none large enough to attract its mother's attention.

My next case is one for the opportunity of seeing which I was indebted to Sir William Gull. The child had been the subject of careful observation from the time of her birth. She was a young lady of 17 when I saw her. Within a week of her birth, an exceedingly slight port wine-stain was observed on the right arm, a little above the elbow. For some years no change occurred, and then the stain began to spread at its edge, producing abruptly margined rings, near to the edges of which minute satellites would appear. In this way gradually a large part of the back of the arm and forearm became covered, and the condition was produced which is shown in the drawing which I have placed before you. Where the disease had receded there were indications, slight I must admit, but definite, of scarring. Thus the disease proved its affinity to lupus by a steady, slow, infective spreading, and by disorganising the tissue in which it had occurred. If anyone should incline to object that my cases are, after all, only examples of *navi* showing a tendency to spread at their edges, and to leave scars, I have only to reply to him that our difference concerns only words. An infective scar-leaving, ulcerating nevus differs widely from what is usual in common *navus*, and assumes the characteristics of lupus. If we refuse to recognise it as one of the lupus group, we shall lose, I believe, an important link of connection between the latter and certain other maladies, which I am about to describe.

I possess a portrait, dated exactly 50 years ago, and bearing the signature of William Bowman, now Sir William, which formed part of a collection of drawings made by the late Mr. Partridge. I am not in a position to give any facts as to the case, excepting such as the portrait itself puts in evidence. It shows a child with a large tumour under the skin of the chest, in all probability one of the congenital cystic and nevoid forms. On the surface of the tumour are a number of little, apparently vesicular, outgrowths, which show minute tufts of vessels. I dare not lay much stress upon a mere portrait without any cotemporary description, were it not that I have more than once seen an exactly similar state of things in the living subject. At the College of Surgeons, not long ago, Mr. Bryant showed me a patient who had had from birth one of these subcutaneous tumourous, and over it quite recently a small development of minute serous cysts (lymphatic?) had been formed, some of which showed minute capillary tufts. At a meeting of the Pathological Society, now nearly ten years ago, the late Dr. Tilbury Fox, brought for demonstration a young man upon whose thigh a large port wine

stain had been present from birth. Near to this stain, though not actually upon it, there had recently been developed a number of serous cysts, just like those which I have mentioned. With these cysts were minute capillary tufts. Dr. Tilbury Fox, by microscopic examination, proved that the cysts had been developed from lymphatics. The disease was an infective one, and its patches were spreading at their edges and producing satellites. Although in this instance the morbid conditions which had recently occurred were not actually on the port wine stain, still they were so near to it that I have little doubt that it had been the cause of their development, and that the case might be claimed as being closely allied to *navus lupus*. I feel sure that there were only differences of degree between it and Sir William Gull's patient.

The statements which I have just made lead me by a short step to the description of a variety of the lupus process, in which I believe that the lymphatic spaces in the skin are the parts chiefly involved, or at any rate which has for its chief feature the production of little vesicular outgrowths, which contain a lymph fluid. This is the disease to which some years ago I gave the name lupus lymphaticus. It is a very well-characterised malady. One case is exactly like another, and there can be no question as to its individuality. All my dermatological friends admit this, although some—for whose judgment in this matter I have the greatest possible respect—doubt whether it ought to be called lupus. Nearly a dozen good examples of this disease have now been identified. Curiously enough the disease has not as yet, so far as I am aware, been recognised either in America or on the Continent. For the present it is a London disease only. I feel sure that it will not long remain so.

Briefly the characters of this malady are the following: It almost always begins in childhood. I have only once known it originate in an adult. A number of little persistent vesicles arranged in a confluent group are its first stage. By an infective process, which travels probably along the lymphatic walls, it very slowly advances. The original patch grows larger, and numerous satellites are developed near to it. The patches sometimes inflame, and become covered with scab, and now and then attacks of erysipelas occur. I have several times known the patch spread until it was as large as an outspread hand, but I have never as yet seen the patches reproduced on different parts of the body. Scars are left when the process comes to an end, but I have not as yet, excepting under the influence of treatment, witnessed anything very definite in the way of spontaneous cure.

The chin, the nose, the shoulder, and the side of the trunk are the parts on which it has been observed. In the case of Dr. Tilbury Fox, and in that of Mr. Bryant, conditions precisely the same as these which I have now described occurred in connection with congenital *navi*; but in not one of my own cases had anything of the nature of nevus preceded the disease. The latter, indeed, did not begin in any of them until the child was several years old. In one case, which was shown me by Mrs. Garrett Anderson, M.D., the patient was a lady of about 50, and the disease had not been present more than six or eight years. The facts, which seem to me to require that this disease should be placed in the lupus family, are the following: It begins usually in the young; it spreads by infection of continuity and contiguity; it spreads very slowly, but may in the course of time involve large areas; it leaves scars, and it is liable to erysipelas. I have, however, an item of evidence to offer which for some will perhaps be more conclusive. I mean that of the microscope.

Some sections of skin, which were cut for me by my son, showed such a large amount of cell growth in the corium that they were indistinguishable from lupus. There seems to me nothing whatever improbable in the supposition that lupus should, in some instances, infect the lymphatic system chiefly, just as it does, we well know in others, the blood-vessels or the sebaceous glands. I do not believe that in these cases the process is confined to the lymphatic vessels, but simply that they take the chief share. I may ask attention to the fact that the cure of the disease is to be effected by precisely the same remedies as those which we should employ against common lupus.

I now have to invite your attention to a very extraordinary and important case which throws, if I mistake not, a flood of light upon the life-history of lupus in general. I might place by its side several others of a somewhat similar kind, but I think we shall probably get the lesson which I think the case teaches more clearly, if for the present we restrict our attention to it. At the conclusion of the lecture I shall have the pleasure of bringing the patient before you, and may say, in anticipation, that not one of you will have the slightest hesitation in admitting that the disease in its present stage is common lupus. The poor boy is literally covered with large patches of what would formerly have been called lupus exfoliatus. On his cheeks, forehead, limbs, and penis these patches occur. Some of them are as large as the palm

of the hand, many of them show the apple-jelly growth in great perfection, and all of them are still spreading more or less at their edges. The trunk is the only part which is exempt. The case would be of interest were it only as an example of extreme multiplicity and of unusual size of patches. Its chief interest is, however, not in the present condition, but in the history of its origin, and of the mode of progress. The boy, who is four years and a half old, is, as you will see directly, apparently in excellent health. His parents are in good health; there is no history of scrofula, and there is not the slightest reason to suspect the inheritance of syphilis. The disease began by a patch on his forehead, which inflamed and ulcerated. Then in the course of a few months others developed on various parts of the limbs and face. All of these inflamed and became covered with thick scabs. In some instances the scab was heaped up in a conical form, almost amounting to *rupia prominens*. These conditions you will see well shown in the large portraits which I exhibit, and which represent the disease as it was at that stage. There was certainly nothing, then, which would have justified the use of the term *lupus*, and the boy had been under the care, before I saw him, of very skilled observers who had not used it. I ought to have said that in addition to the large patches which I have described, the whole of the back and parts of the belly were covered with an inflamed lichenoid eruption, amounting in some instances almost to small boils. I ought also to have laid especial stress on the fact that the large patches, although very numerous and almost covering the limbs, were nowhere arranged with symmetry. The treatment under which these large *rupial* sores healed and passed into a characteristic condition of *lupus* occupied about a year, and was for the most part of a very mild character. Mercury and arsenic were in the first instance pushed, and seemed to do harm rather than good. We were content afterwards to give bark and use a weak tar lotion and ointment. Under these remedies the patches skinned over, but you will note that they are still spreading serpigginously as a quiet, non-ulcerating form of *lupus*. The chief interest of the case seems to be in its being an example of extreme activity of the infective process in the first instance, and also in its making it probable that the early stages of *lupus* are those of inflammation rather than of new growth. It illustrates, also, what I have repeatedly asserted, that activity of infection-processes is greatest in the young. It is scarcely necessary to remark on the lesson which it teaches as to the paramount necessity of destroying, by the most energetic means, the initial patch when the patient is a young child. We must not wait for the disease to declare itself by unmistakable characters as *lupus*, but, if a young child gets an unhealthy ulceration of unusual character, caustics or escharotics must be used at once with the greatest freedom, the great danger of systemic infection being kept clearly in sight.

A case instructively illustrating these remarks has recently been under the joint care of Dr. Percival, of Northampton, and myself. Only by the most energetic measures have we succeeded in getting the original sore to heal. As in the case just recorded, the patient is a young child and apparently in excellent health. I must not, however, venture to trouble you with details.

I would call the disease which the case just narrated illustrates *rupia-lupus*, for the reason that it begins with all the appearances of a *rupial* eruption and ends by becoming definitely *lupus*. I am particularly anxious to assert and illustrate this transition in the case of common *lupus*, because it is of very frequent occurrence in the syphilitic form. *Rupia* always constitutes round sores, and beyond a certain and very limited extent its patches do not spread at their edges. The patches of *lupus*, on the contrary, are never round, but by spreading at their edges constantly tend to assume irregular forms; and in the case of syphilis crescentic often horse-shoe shapes. Now, it is by no means uncommon in the case of syphilitic *rupia*, beginning in the secondary stage of the disease, and being at first as well characterised as anyone could well wish to see it, for the eruption to undergo a sort of partial cure and to slide gradually from *rupia* into *lupus*. In these cases most of the patches heal, leaving the well-known shilling-like scars; whilst a few of them heal only partially, and take to spreading at their edges after the manner of *lupus*.

Let us next glance at the pathological relationships of the curious disease which Hebra and Kaposi have described under the name of *rhino-scleroma*. This malady affects in the first instance the nostrils and upper lip, and is attended by great thickening of the parts. The nostrils may be plugged by a very firm and remarkably indolent growth, which ulcerates but slowly, and which resents injury but little. If you cut it or scrape it away, it quietly grows again. By slow degrees the disease may extend into the nostril, perforate the septum, and destroy the soft palate. It keeps to skin and mucous membrane, and does not involve muscle or bone. It does not cause

gland disease. Its subjects are young adults. So slow is its progress, that its final stage has, as yet, scarcely been observed. Excepting in Vienna, where a series of examples of it have been recorded, *rhino-scleroma* would appear to be of the most extreme rarity. In this country only a single case of really typical character has been observed. It fortunately fell under the care of Dr. Payne and Dr. Semon, and was by them carefully studied, as it had indeed already been by Professor Cornil in Paris. You will have noticed in my description that this malady resembles *lupus* in many features. It occurs in young adults, it begins in a part liable to irritation, the outlet of the nostrils, and I might have said, it apparently sometimes is excited by the irritation of discharges; it spreads by contagion of continuity and contiguity, it keeps to skin and mucous membrane, and shows none of the more marked characteristics of malignancy. It differs from *lupus* in that it has no apple-jelly growth, that it occurs in one particular part only, and that it but rarely inflames or ulcerates. Finally, we have as yet no proof that it can infect the blood and produce distant growths. To come to its histological features, we have excellent data from several different sources, and the reports are, with some minor exceptions, very unanimous. Kaposi, Geber, Mikulicz, Cornil, and, lastly, Dr. Payne, agree in reporting the presence of cell-growth in the deep skin, not distinguishable from that of granulation tissue. The small round cells making up this tissue are very numerous, and are often collected around blood-vessels. A few large and peculiar cells are to be found, and in some parts the interpapillary prolongations of the Malpighian layer appeared to grow downwards, after the pattern of epithelial cancer. All these features have been observed repeatedly in *lupus*. It remains to be added that Frisch in Vienna, Cornil in Paris, and Dr. Payne in London, have succeeded by staining processes in proving the presence of bacilli in connection with the larger cells of *rhino-scleroma*. They are not those of tubercle or *lupus*, but "short, thick, almost ovoid bodies, often coloured at each end and colourless in the middle" (Payne).

It is very clear that *rhino-scleroma* differs from *lupus*, but by no means so certain that it is not a closely allied malady. Hebra thought it a sarcoma, Geber and Mikulicz a kind of chronic inflammation, Cornil refuses to consider it sarcoma, and Dr. Payne, agreeing with him in the main, appears inclined to class it with *lupus*. That it may conveniently and quite correctly be placed in this association, I cannot myself feel any doubt, and I have great confidence that the future will disclose connecting links even if such are not already on record. I may just remark that should, in certain cases, *rhino-scleroma* manifest more malignant tendencies, it will not on that account dissociate itself from *lupus*, since it is well-known that cancer is occasionally the final result of the latter. Although *rhino-scleroma* probably acquires part of its peculiar character from the part in which it begins, yet it will be very exceptional to what we know of other maladies if it should prove that it is absolutely restricted to the nostril. We shall probably find that similar conditions are occasionally produced on other parts of the face at greater or less distance from the nose. Its peculiar features are slow growth, no tendency to inflame even after partial operations, and the hard, bossy induration which it causes. In a lecture which I published more than ten years ago, with the design of drawing attention to Hebra's observation of this remarkable malady, I recorded three cases more or less resembling it. In two the palate was affected, and I have since been inclined to regard them as forms of adenoma, though by no means certain that they are not like the palate-attacking form of *rhino-scleroma*. The third and most important of my cases was exactly like *rhino-scleroma* in all its features, with the exception that it began on the cheek, and did not involve the nostril. I will here repeat the particulars of this case, for I never saw any other exactly like it, and it is of great value as proof that a chronic inflammation new growth of the kind described may, after a series of years, assume some of the features of *lupus*.

"A young lady, Miss B., from South Wales, was placed under my care by Mr. Dukes, of Canonbury, for a bossy mass of growth in the skin of her left cheek. It did not involve the nose, nor was it quite in the upper lip, but was placed just over and external to the outer angle of the mouth. Thus it was very near to, but not actually in, the *rhino-scleroma* territory. Its characters were almost exactly like those described by Hebra, and its behaviour under treatment also agreed very closely. Miss B. attributed the growth to a wasp-sting some years before. The mass was almost as large as a halfpenny, abnormally defined, a quarter of an inch thick, glossy on the surface, and of reddish-brown tint. There was no ulceration. For want of a better name I called it *lupus*, and treated it, as I always do *lupus*, by free cauterisation. We used both the actual canter and the acid nitrate of

mercury. These did little or no good. The sores we caused healed quickly, and the mass soon resumed its original state as to density, thickness, and smoothness. I next, a year later, applied a paste of chloride of zinc, and took away a thick leathery slough. A very considerable depression resulted from this, for we did it most liberally, as I was determined, if possible, to effect a cure. We were, however, again disappointed. No sooner was the sore healed than it again began to indurate, and a year later Miss B. returned to me again with the mass not so thick as formerly, but still very conspicuous. I now persuaded her to come into the London Hospital. She did so, and I put her under chloroform, and destroyed the growth very freely indeed, with the actual cautery. Her condition was much improved when she left the hospital.

"A year later (in November, 1877), I heard from Miss B. that her face was still uncured. She writes: 'The last operation did a great deal of good, for when healed the mark was quite white, with the exception of the centre, where a small red spot remained, which has since spread to the top and bottom, leaving the sides clear.' Miss B. complained that the part would flush and burn after taking food, and that, on taking the slightest cold, it became much swollen and painful. The tendency to recur is, therefore, very strongly marked.

"Now, although I called this lupus, I certainly never saw any example of lupus exactly like it. Its bossy hardness, its elevation, its freedom from ulceration, and its rapid healing and re-induration after healing, are all points in which it agrees with rhino-scleroma, and does not agree with lupus. Had it been on the nose, it would have agreed in all respects with Hebra's description."

I have quoted the above as I published it in 1879. I am now in a position to give the sequel to the case, and to say that it subsequently approached much more nearly to lupus.

Miss B., now Mrs. L., came to me in July, 1883—that is, about six years after my former treatment. I then found that the result of our deep cauterisation with the actual cautery, as described above, had been a cure so far as the central part of the growth was concerned. A soft white scar remained over the site of the former disease; but, during the last year or two, there had been spreading at the upper angle of the scar. The disease had, however, taken on a new type of growth. It was no longer bossy, thick, and smooth as at first, but presented a rough dry surface, like some varieties of lupus sebaceous. Its edge was abrupt and slightly raised; it had spread in a long irregular patch until it had almost reached the inner angle of the eye. There was no production of lupus elsewhere, with the exception of two or three other small spots, near to the margin of the scar on the lower part of the cheek. The precise form finally taken on in this case is a very exceptional condition of lupus. The patient spoke of being able to pull little roots out of it, by which she meant portions of dry epidermis, which dipped down between equally dry papillae, like granulation growths. With this, however, there was not, and never had been, any moisture or formation of pus scab.

Everyone will recognise this description as being applicable, with the exception of the absolute dryness, to what happens in many forms of lupus on the hands and feet, and now and then on the face. The bleeding of the lupus patch, when its epidermic investment is pulled off, is a feature which has attracted the attention of all observers. Usually, however, the epidermic investment makes the surface of the patch smooth. In this case it did not do so, but left it rough and as if papillary.

There is a not uncommon form of the disease known as sycois which is certainly nearly allied to lupus; it is locally infective, and spreads by contagion of continuity and contiguity. It destroys not only the hair-follicles, but the intervening skin; and it leaves a scar where its action comes to an end. Like lupus, it results in spontaneous cure when the tissues in which it began have been destroyed. It certainly occurs most frequently in association with evidences of struma and feeble circulation, and occasionally it results in conditions which everyone would recognise as common lupus. It is, however, quite correctly named sycois, since it is in the beginning a suppurative inflammation of the hair-follicles, and is always restricted to hair-growing regions. As a rule this form of sycois-lupus affects the whiskers or chin, and develops symmetrically. It is very chronic and very difficult of cure. Not infrequently it is coincident with ophthalmia tarsi, which is in fact the same disease attacking the eyelashes. It has long been recognised that ophthalmia tarsi destroys the skin around the hair-follicles and leaves a scar. In this way it frequently causes disfiguring lippitudo, and displaces the edges of the lids into a minor kind of ectropium. In very exceptional cases the hair of the scalp may be affected as well as that of the parts named. I have known the entire scalp reduced to a condition of tight scar in a patient in whom the eyelashes and whiskers were also destroyed.

Sycois of the eyelashes is common in early life and in both sexes, whilst the same affection in the face usually waits for its development until the sexual hairs have grown.

I have placed the name sycois-lupus in my syllabus of to-day's lecture mainly as a suggestion, and I did not know that it had been previously used. I have since found, however, in a paper on lupus by Mr. J. L. Milton very similar statements to those which I have just made. Mr. Milton goes so far as to place amongst some cases of lupus which he records in detail two which were only sycois. For myself, I do not think that we shall serve any useful clinical purpose by putting sycois in the lupus family. It is a relative only. The features of difference may easily be pointed out. Sycois, although it spreads by continuity and by contiguity of tissue, does not apparently infect the blood, and does not, as a rule, become multiple. It does not spread in the skin surrounding the hairy districts, but restricts itself to the latter. It is a disease of hair-follicles primarily, and of skin only secondarily. It never produces apple-jelly growth, and is seldom attended by common lupus in other parts. Lupus in all its forms is a disease of the deep skin, and not of any one of its structures; and it is capable of spreading in all regions. For these reasons I abandon the term sycois-lupus, and also that of lupoid sycois, given by Mr. Milton, and prefer to keep to the old name, asserting only that scar-leaving sycois is a disease nearly allied to lupus.

I may here add that there is a syphilitic form of sycois which approaches yet more closely to lupus. It travels over the whole beard by a crescentic spreading edge, leaving a scar behind it (the horse-shoe form). It is curable only, so far as I have seen, by liberal cauterisation of the spreading edge, just as in the case of lupus.

In advancing the opinion that Kaposi's disease is a family form of lupus, I have first to say a few words as to the characters of that disease and as to the meaning which is to be attached to the expression "family form." By the latter term, in conformity with the usage of Adams in his work on inherited tendencies, the expression is applicable to any disease which shows itself in several brothers and sisters without having existed in their parents. It is not to be applied, as might at first sight have appeared probable, to diseases such as gout, scrofula, and the like, which pass on in successive generations in the same family. Retinitis pigmentosa and ichthyosis are perhaps our best-known examples of "family" disease. If a single case of either of these be identified it may be assumed as certain, if there are several brothers and sisters, that two or three of them suffer, and that the rest are wholly exempt. Under some law of inheritance, as yet but partially understood, it would seem that part of the offspring of a certain pair derive a very definite peculiarity of structure which destines them to peculiar and remarkably uniform kinds of disease. Another proposition must be made as regards family forms. It is this: that although the disease has not occurred in preceding generations in exactly the same form, yet it would appear to have been led up to, as it were, by some other allied malady. Thus the rare disease known as xanthelasma, which is produced *de novo* in connection with jaundice, and severe liver disease, and is as such never seen excepting in adults, may now and then have its family form. When this happens, three or four brothers and sisters all show multiple xanthelasma in early childhood and without the slightest trace of the disorders of general health which attend it as an acquired disease. Probably almost all diseases have their family forms, receiving more or less of modification in this peculiar kind of transmission.

I have ventured to give the name Kaposi's disease to a malady which was described by Hebra and Kaposi conjointly under the name of xeroderma, and which has subsequently received a more or less modified designation from almost everyone who has written about it. Inasmuch as the names proposed have most of them been very unwieldy, and imply pathological statements which may or may not be quite appropriate, I put in a claim to the thanks of the profession for suggesting that this very peculiar malady should, for the present at least, be known simply by the name of the surgeon who has taken the chief share in bringing it to our knowledge. It is most certainly a family disease, being a very definite type of what we mean by that expression, and the question is as to what are its alliances. In retinitis pigmentosa we have a malady which always affects several children in the same family, and in which the nerve structures of the eye, and perhaps also of the ear, undergo a progressive degeneration, attended with the free deposit of pigment. In Kaposi's disease, making allowance for the difference between skin and retina, we have a very similar course of events. In both, the child at the time of birth appears quite healthy, and in both pigment accumulations are the first symptom of disease. In Kaposi's disease a condition of very inordinate freckles is the first stage. Next the skin shrivels, and becomes dry or even scarred. At this stage ulcerations may occur, and the alæ

nasal may be destroyed, just as they are in lupus. I have the pleasure of being able to show you, through the kindness of Dr. Radcliffe Crocker, an excellent portrait of a patient who was the subject of this malady, and I place beside it another which has been lent me by Dr. Stephen Mackenzie, showing a peculiar case of psoriasis lupus. Dr. Mackenzie's patient was undoubtedly the subject of a modification of lupus erythematosus. I ask you to note how closely similar the conditions in the two portraits are. In Kaposi's disease precisely the same parts are affected as those which suffer in lupus erythematosus. The disease begins on the face, and it next affects the hands and arms, and lastly in a slighter degree the feet and legs. There can scarcely be a doubt that the child is born with a skin so constituted that it will not wear well. In other words, that it cannot bear the ordinary exposure to wind and sun. Under these influences it first becomes pigmented and then inflames. Now this is precisely what occurs in the most severe and typical forms of lupus erythematosus. The portrait published by the New Sydenham Society may suitably remind us of one of these cases. In them the influence of exposure is only less definitely marked than in Kaposi's cases. Another feature of resemblance between the two maladies, or rather I would say an indication of alliance, is that both diseases may end in malignant action. Here, however, we have a feature of resemblance with lupus in general, rather than with lupus erythematosus in particular, for it is lupus vulgaris that is apt to fungate and pass into epithelial cancer. In Kaposi's disease, even in childhood, if the condition be severe, there is great liability to the formation of fungous excrescences, which, although often consisting of granulation tissue only, may in others run a malignant course. Thus I think you will admit that I have established my point that there are close features of resemblance between lupus and this remarkable malady. I by no means assert that they are the same disease, but simply that the one is the family form of the other, receiving, as usual in family forms, conspicuous modifications. My friend Dr. Radcliffe Crocker, in his excellent report on the disease published in the *Medico-Chirurgical Transactions*, remarks that "few will dispute that the disease is *sui generis*." This is precisely what I do dispute. Pathology knows no Melchisedec, and if we would rightly understand the nature and origin of the various and often very peculiar maladies which come under our observation, we shall succeed better by seeking for relationships than for differences. In all probability no malady is really isolated.

I have incidentally said so much as to lupus erythematosus, that it may probably not have been noticed that I have not yet given any description of it and of its varieties. I shall be very brief on this subject, for the time now at my disposal is very short, but I must not wholly omit it. First, let me say that I think it is to be regretted that the old term lupus sebaceus has been lost sight of, and that all cases, whether what used to be called sebaceous, or those purely erythematosus, are now classed under the latter name. This involves a confusion of things which present important features of difference. The earliest observations which we have as to the disease associate it with the sebaceous glands, and subsequently the same conditions were figured by Cazenave under the name of *acne sebacea partielle*. Yet there are forms of lupus erythematosus which are congestive only, and show no tendency to implicate the glandular system. In dealing with the histology of lupus in general, I mentioned that Geddings and Kaposi considered that lupus erythematosus began around the glands. Dr. Thin considered the blood vessels chiefly at fault, and Neumann and Jamieson the upper layers of the corium. These differences of opinion, at first startling, find, I think, a fair explanation in the fact that the disease is not always the same. Nor does it always in the same case present the same conditions at different parts or at different stages. I cannot say that I have found Kaposi's division into two forms, lupus erythematosus discoides and lupus erythematosus discretus et aggregatus, of much assistance in clinical work. The classification I would venture to suggest is the following; but, in making these subdivisions, I am well aware that many cases will have to be placed in more than one.

The first subdivision should, I think, be into lupus sebaceus and lupus erythematosus proper. In the former category I would count all cases in which there is conspicuous implication of the follicles, all in which the well-known dried orange-peel condition is seen. Many of these cases are comparatively slight, and remain for long strictly local. As Kaposi has well remarked, they rarely leave the face and head. Sometimes they, like lupus vulgaris, are non-symmetrical. Their significance as revealing symptoms is far less grave than that of the true erythematosus form. Some of them have little or no erythematosus congestion around the patches, but in others it may be considerable. At the other end of the chain, and in strong contrast, I would place the cases in which erythema is the conspicuous feature, and

almost the sole one. In many of these there is no roughness of the surface, and the orifices of the sebaceous glands are at no stage unduly conspicuous. In these the disease often spreads rapidly, the arrangement is always symmetrical, the hands and feet are often attacked, and outbursts of febrile illness are not infrequent. Between the typically sebaceous and the typically erythematosus, we have many cases which, in varying proportions, combine the peculiarities of both.

For purposes of clinical convenience I would arrange the cases of lupus erythematosus proper into groups; first of those in which the disease was restricted to the face and head; secondly, those in which the hands as well as the face were affected; thirdly, those in which the disease showed a tendency to become general, that is to extend to neck, shoulders, upper arms, and possibly to the trunk; also, fourthly, those in which erysipelas had repeatedly occurred. In our last lecture I spoke of the great danger which attaches to lupus erythematosus in its typical forms, and especially of the risk of a fatal attack of erysipelas. Kaposi's testimony on this point is very strong; indeed, he would appear to have met with erysipelas very frequently, and speaks of an "erysipelas perstans faciei," with which I am not familiar. The circumstance that he drew from the experience of a large hospital in which the patients remained for long periods, whereas my cases have been chiefly observed in private practice, may explain some discrepancies. He would be likely to encounter more serious complications than have fallen to my lot. The best published portrait of a purely erythema lupus with which I am acquainted is that in the New Sydenham Society's *Atlas*; one which I now show you, published at the Hôpital St. Louis in Paris, and designated scrofulide erythematosé, is also excellent, and has the merit of being a photograph. Those given by Hebra show the sebaceous and mixed forms only.

I have yet two topics to which I must advert before I conclude. I refer to the simulations of lupus by syphilis, and the association of lupus with cancer.

A large number of the diseases of the skin in the later periods of syphilis are lupoid in character. By that statement it is meant that they occur without symmetry, that they are infective and serpiginous, and that they leave scars. In these features they differ wholly from the eruptions of the secondary period, which are symmetrical and exanthematous and show no tendency to infective spreading. A syphilitic lupus, like other forms of lupus, may spread indefinitely, and may last for years; indeed, unless cured by treatment, it will as a rule never get well. We occasionally see very severe secondary eruptions, especially those of the rupia class, gradually slide when nearly cured into lupoid peculiarities, that is, some of the patches may take on serpiginous spreading. As a rule, however, syphilitic lupus is decidedly late (that is, tertiary) in its appearance. It may simulate any of the known varieties of lupus, and the closeness of the resemblance may be most deceptive. I cannot see that anything is gained by disuse of the term lupus in connection with syphilis. If instead of it we employ such terms as horse-shoe sores, serpiginous ulceration, and the like, we lose in clearness of meaning and do not gain in anything.

Many observers have recorded cases in which cancer has developed in lupus patches, either whilst the disease was still extant or after cicatrization had taken place. I have shown you a portrait from a case of my own in which this took place in a partially cured lupus, and several others have fallen under my notice. In three or four cases I have seen lupus and cancer in the same patient independently of each other, and on more or less distant parts. Thus it would appear that not only is the scar tissue of lupus prone to be attacked, but probably there is something in the patient's state which gives proclivity to both. The form of cancer is epithelial, but very malignant. It reappears usually very quickly after excision, and advances very rapidly. It is often attended by large fungating granulation masses, exactly such as are seen in the cancer which follows the ulcerations of Kaposi's disease. A very important addition to our knowledge of cancer in this relation has been made since these lectures were commenced. I have only to-day obtained a copy of a very able paper on *Lupus-Carcinoma* by Dr. Bayla, of Tübingen, published in Bruns's *Beiträge*. He has collected no fewer than forty-two cases, and in one of them it began as early as the twenty-sixth year. The paper is accompanied by four portraits, which well illustrate what I have just said as to the noteworthy tendency to fungate. These portraits I now produce for your inspection.

In conclusion, Mr. President and Gentlemen, permit me to recapitulate shortly the main arguments of my lectures. It has been sought to show that there are a large number of maladies, some of them, it is to be admitted very rare, but yet of extreme interest, which are cognate with common lupus, and that between common

lupus and lupus erythematosus there are bonds of essential relationship, whether we regard their clinical features or their histological characters. Next, it has been made probable that all forms of lupus are in occasional relationship with the state of health which gives liability to tuberculosis and to diseases of the scrofulous class; but in limitation of this it has also been proved that many lupus patients are in excellent health, and that there appears to be some proneness to cancer as well as to tubercle. That lupus begins as an inflammation under the influence of various exciting causes and derives its peculiarities from the part affected, and the special structures in that part, as well as from the age and preclivities of the patient, has also been asserted. Thus it has been sought to discredit the supposition that lupus, or any of its peculiar forms, deserves such terms as *sui generis*, the implied creed being that they are closely related amongst themselves, and also to other various pathological processes. The doctrines of infective spreading and system-contagion have been asserted as being explanatory of the phenomena of lupus, and as finding in it some of their best illustrations. The laws of hybridity and those of partnership in disease have also been appealed to, as well as those of modification in hereditary transmission, under which latter it has been attempted to establish the pedigree of the very remarkable malady known as Kaposi's disease.

I much regret that I have not had time to say anything in reference to treatment, since I might have drawn from it very important evidence in support of the conclusions placed before you. This, however, must be reserved for another occasion.

In reference to the introduction of not a few new names, and the alteration of some old ones, I am well aware that I have laid myself open to criticism, and that I have taken on me grave responsibility. My innovations in these matters, however, I willingly leave to the judgment of others. If found useful they will live, if otherwise let them die. I can only assure you that I have done nothing from caprice, but that I have honestly endeavoured, as far as my ability admitted, to make clear a very intricate subject, and to lighten the labours of those who will follow me.

LETTSONIAN LECTURES

ON

SOME POINTS IN THE SURGERY OF THE URINARY ORGANS.

Delivered before the Medical Society of London, January, 1888.

By REGINALD HARRISON, F.R.C.S.,

Surgeon to the Liverpool Royal Infirmary; and Lecturer on Clinical Surgery in the Victoria University.

LECTURE II.

THE PATHOLOGY OF THE ENLARGED PROSTATE VIEWED IN RESPECT TO ITS CAUSATION AND PREVENTION, AND THE TREATMENT OF SOME COMPLICATIONS ARISING OUT OF IT.

MR. PRESIDENT AND FELLOWS,—I purpose this evening speaking of the pathology of the prostate relative to some points in connection with the prevention and treatment of certain disorders arising out of it when it becomes hypertrophied. The causes of hypertrophy of the prostate have formed the subject of much careful observation, and I feel some hesitation in again referring to them. Still, on the other hand, though my views may not prove generally acceptable, I am inclined to think that a narrative of the observations upon which they are to a large extent based may serve a useful purpose in indicating lines of thought which may result, sooner or later, through the investigations of others, in clearing up doubtful passages in the physiology and pathology of this part. In the first place I shall speak of the prostate as forming the retentive apparatus of the male bladder, under whose influence the urine is collected and held, irrespective of any glandular function which, by the nature of other structures it may contain, it is capable of exercising. And I think it will not be difficult to substantiate the proposition that, in the human species at all events, this part may with greater propriety be designated the "prostate muscle," rather than the "prostate gland," for whatever function it may exercise intermittingly, relative to the process of generation in its latter sense, seems to be subservient to the physical part it is continuously playing as a portion of the retentive apparatus. In support of such a view I would draw attention to Mr. Ellis's important paper (*Royal Medical and Chirurgial Transactions*, vol. xxii), On the Muscular Arrangements of the Genito-Urinary Apparatus, wherein it is

remarked, "I would propose the name *orbicularis vel sphincter urethrae* for both the prostate and the prolongation around the membranous urethra, whilst I would confine the old term 'prostate' (without the word gland) to the thickened and more powerful part near the neck of the bladder. This orbicularis may be considered as only an advanced portion of the circular layer of the bladder, though it must have the power of acting independently of the vesical fibres." But if its muscularity is admitted, we must conclude that it for the most part exercises its function in conjunction with the bladder in the form of a hollow muscle, for it would be against the nature of things for it permanently to exist in the shrivelled and contracted state it presents after death. We have been too much accustomed to regard the prostate from its *post-mortem* aspect, that is to say, as a mass of muscle of the size and form of a chestnut, in which is contained some secretory tissue. For concluding that it thus exists during life, I believe there are no substantial grounds, as it seems to me that under no circumstances, save the rare and momentary one when the bladder is absolutely empty, does it present such an appearance. On the contrary, the muscular fibres are spread out like a funnel, with the apex downwards so as to form a strong muscular support for the bladder and its varying amount of contents, the degree of expansion being naturally relative to what the viscus may contain. Hence the action of the prostate may be said to be just as continuous as that of the heart. In reference to this important point it will be necessary that I should furnish some reasons for such a conclusion.

In the first place, the clinical examination of a healthy person with varying amounts of urine in his bladder affords no evidence that the prostate presents the contracted appearance we are accustomed to see; on the contrary, when the finger is introduced into the rectum, in the natural condition, the parts are felt to be disposed in the manner I have indicated, and providing a muscular floor for the bladder and its varying amount of contents.

But the retentive function of the prostate is more strikingly shown when we proceed to what I would speak of as actual demonstration. And for this purpose we have only to observe what follows in connection with certain surgical operations on those parts with which most of us are familiar. Incisions may be made into the male urethra, in any part of its course, as far as that point which we are accustomed to call the apex of the prostate, without any incontinence of urine following. I have seen cases of lithotomy by the median operation retain full control over the bladder during the whole period of their convalescence, in spite of the dilatation to which the prostate has been subjected by the introduction of the finger and the extraction of the stone. And this remark applies equally to cases of external urethrotomy.

When, however, the knife impinges to any appreciable extent upon the prostate, as in the lateral operation for stone and the modified median operation which I have recently drawn attention to, where the prostate is divided, from that moment incontinence takes place; the patient has no command over his urine; he can neither collect nor expel it, and in this condition he remains until the healing process has made considerable advance. We have here, striking evidence, not only as to the habitual function of the prostate relative to the contents of the bladder, but that the action of the part must be unceasing in its character, subject to the circumstances under which it has to distribute its force over the area it supports or brings into action. How completely the prostate forms the lower action of the bladder was demonstrated to me in a striking manner only a few weeks ago, and in a way that I had not previously noted. It was a case of lateral lithotomy in a young man where, ten days after the operation, there was some free hæmorrhage. As the bleeding did not proceed from any part of the perineal wound, I had the patient put under ether on the operating table, and, suspecting where the bleeding came from, I introduced the nozzle of a Higginson's syringe into the orifice of the urethra, expecting that the fluid would run out of the open urethra; this it certainly did, but not until it had first entered the bladder, out of which the fluid escaped, together with some old clots which had evidently collected in the viscus, just as water would do out of the side of a cask in which a hole had been made. This I was able to see, as the wound was held open with retractors under a strong light. In addition, however, to testimony of this kind, I am convinced, from a careful examination of the prostate, both before and after operations on this part, where the introduction of the finger into the bladder formed a detail of the proceeding, that the more usual condition of the healthy prostate is one of relaxation, and not of contraction, as we are accustomed to see when death has taken place.

But further, when there are no such physical functions to perform relative to the contents of the bladder, the prostate, as a muscle, so

far as I have been able to ascertain, only exists in a rudimentary form. I refer to those distressing abnormalities known as extroversion of the bladder, where, from the fissured nature of the structures, there is no receptacle for the urine which escapes from the ureters as it is excreted. Here, though the sexual sense may be normal, there is from the nature of the parts no necessity for any provision being made for the collection and retention of what the kidneys secrete. I have not been able to discover, though I have taken considerable pains to do so, that in these abnormalities hypertrophy of the prostate has ever been noticed. This seems to me to be a point of some significance in connection with what has been already urged. But though in an argument of this kind I would prefer to substantiate my position from positive evidence rather than by a deduction from the negative, I cannot help remarking that, if the office of the prostate was solely in relation to the sexual act, the pathology of the part would tend to indicate this more than I believe it does. It is not very common to meet in practice with cases of acute suppurative commencing in the follicles of this part, where one would think that irreparable damage must have been done, and yet we have evidence to show that the individual has not necessarily been unsexed by this process. Nor can I assert, though the opportunity for doing so has now for some years been abundantly provided me in my operations, involving varying degrees of mutilating the prostate, that I ever extinguished the procreative powers.

In the next place, I would point out that adult man seems to require some special provision such as the prostate affords for the purpose I have just indicated, by reason of the exceptional degree of pressure to which the most dependent portion of his bladder is constantly subjected. And in making use of the words "exceptional degree of pressure," I do so in contradistinction to what is found, so far as I have been able to observe, not only in the animal kingdom, but in other varieties of the human species which are not in exact correspondence with the type I have taken. As demand and supply in the disposition of muscular tissue are apportioned, it seemed to me that we had hitherto failed fully to recognise and appreciate all the circumstances which rendered it necessary that the adult male bladder should, as I have already pointed out, be provided with a muscular apparatus of considerable strength at its most dependent point.

But in what respects, it may fairly be asked, does the adult male bladder differ from other varieties of its own species, and from those animals which in their higher organisation more closely approach it? I maintain that in man the perpendicular axis of what I would speak of as urine-pressure falls directly upon the outlet of the bladder, whereas in the female, not only are there other means of supplying muscular support to the base of the bladder, but in consequence of the difference in the pelvic organs, a considerable portion of the weight of the viscera, especially in its more extreme degrees of distension, is borne by the pubic portion of the pelvis. Further, allowance must be made in the female sex for no provision being necessary for seminal ejaculation, in which function the muscular fibres of the prostate undoubtedly play an important but occasional part.

In the higher mammalia—excepting, perhaps, in the case of dogs—the prostate is not so largely developed as in man. In reference to this point, Mr. Bland Sutton kindly informs me that, although he has conducted many thousand *post-mortems*, yet, excepting in the doubtful case of dogs, he has never seen an enlarged prostate—at all events, such a one as would cause obstruction to the flow of urine. In animals, it will be observed that the perpendicular axis of urine pressure, when the bladder is tolerably full, does not fall, as in man, on the outlet, but on the parts which support the bladder, according to its varying degree of distension. In the dog, it seems to me not improbable that the exceptional degree of prostatic development is related to the somewhat peculiar condition under which, in this animal, micturition is performed.

As my opportunities of examining the urinary apparatus in the lower animals have been few, I feel much hesitation in making reference to any observations I may have rather casually made so far as they related to the point under discussion. It, however, appeared to me that where the habits of the animal, as observed in some apes and marsupials, necessitated the frequent adoption of an erect position, the males had a much greater development of the prostate muscularly than was usually found in other kinds of quadrupeds.

I regret very much that we have not at our disposal more abundant means for referring to dissections illustrative of the comparative anatomy of the body. I am sure they would prove of much assistance in investigations of this kind, having relation to normal and morbid human anatomy. But, apart from this, if time permitted, it

would not be difficult to adduce further evidence to show that in man the collection and storage of urine, if I may make use of such a term, implies a degree of muscular support to the most dependent portion of the viscera, for which no such complete provision has to be made under any other condition of life I am acquainted with. I should not, however, feel at all surprised if, when the "missing link" is discovered, he is found paying the penalty for his assumption of the erect posture by developing in some degree an enlarged prostate.

But to proceed; if the prostate represents the chief means of retention and support for the contents of the male bladder, is it necessary to pursue the argument for the purpose of explaining why it becomes hypertrophied? Does not one follow upon the other? Are not the circumstances of individual life sufficient to explain why it happens to one person and not to another?

Many of the facts connected with the natural history of hypertrophy which have been collected for us, or with which, in our daily practice, we are familiar, seem to me to support the view I have taken relative to the function of the part. In the first place, it is not met with during those periods of life which are most remarkable for muscular activity and development; on the contrary, it is called into existence where, pathologically speaking, quantity seems to supplement deficiencies in quality.

But as with similar changes in other parts of the body, so may prostatic hypertrophy be shown to be exactly compensatory; whilst in others, by an excess of the process, it may be proved to be detrimental. And in reference to this point I would remark that we have been too much accustomed to regard prostatic hypertrophy as necessarily a morbid and hurtful process. To such a conclusion I think exception may be taken on substantial grounds. It is stated by Sir Henry Thompson that actual hypertrophy of the prostate exists in about 34 per cent. of men at and above 60 years of age; that it produces manifest symptoms in about 15 or 16 per cent. From this it would appear that the larger proportion of persons are not injuriously affected by the change, a circumstance which seems to suggest that the majority of persons with large prostates are in some way or other benefited by them; and this deduction is considerably borne out by everyday experience. I am disposed to think, from my own examinations, that the frequency of some degree of prostatic hypertrophy is thus rather under- than over-estimated. Though it is not easy to form an absolutely correct estimate of the size of these parts relative to standard measurements by rectal examination, my conclusion is that a far greater number of males over 60 years of age have some enlargement of the prostate, and are never in any way conscious of the alteration, than we should conclude from the figures I have just referred to. How frequently, for instance, when we are examining elderly persons, say for some disorder of the rectum, we make the discovery that their prostates are enlarged, though they have no reason to be conscious of this change. I can at this moment recall many instances of this in my own practice where the persons are in every sense of the word in the enjoyment of the most perfect health, with an entire absence of any urinary ailment. Quite recently I was asked to examine a gentleman who, in the course of an acute bronchitis, had retention of urine for the first time in his life. This patient had an enormous prostate, which must have been in course of formation for several years. Surely, under these circumstances, in the first instance the hypertrophic change must have been called into existence for a distinctly conservative object, and had been merely disarranged by the violence of the cough from which he was suffering.

But though prostatic hypertrophy is, as I have shown, in the greater number of instances more or less compensatory, it may, as in others, be in excess of what is required, and thus prove detrimental. In the latter category, reference no doubt will occur to us of those examples where the prostatic mass is made up of projections having a somewhat lobulated or nipple-like form, where the degree of irritation and obstruction excited is often very considerable, and apparently out of proportion with the cause. These I would speak of as being the structural upheavings of a frequently-contracting muscular ring. In a muscle or part undergoing hypertrophic growth, and where the process is prompted by circumstances which are obviously liable to some degree of variation, tissue production may be excessive or become unnecessary. Such excess would naturally tend, under the contraction of the part, not only to protrude itself where the resistance was least, but to assume a more lowly-organised form than that which in the first instance was developed. In this way, I believe, these excesses of more or less degenerated prostate tissue are formed, which subsequently cause so much vesical irritation and irritability. And this observation, whether a large prostate still remains almost entirely muscular or has become largely converted into fibrous tissue, has an important bearing in practice in those cases where we have to express

an opinion in reference to the probabilities as to whether the use of the catheter will be a temporary or a permanent expedient; for where there is evidence to the touch that fibrous tissue predominates largely over the muscular, the use of the catheter is generally perpetual; whilst, on the other hand, when the prostate is found soft and yielding to the touch, as when it remains muscular, a complete restoration of function may be anticipated. Thus, then, may the resistance which is constantly going on in the most dependent portion of the bladder against that downward pressure which is exercised by the collection and retention of urine in the bladder, prove the common cause of its hypertrophy.

But this is not the only condition under which hypertrophy involving the lower section of the bladder can be studied. In the examination of the bladder, both after death and in the course of surgical operations, it is impossible not to be struck with the altered relations which frequently exist between the body of the viscus and its neck or outlet. In early adult life the bladder may be regarded as an abdominal rather than a pelvic organ; as years advance it gradually sinks within the pelvis; whilst still later on it will often be found to have become further depressed within the pelvic cavity. In this way I have seen a prominence given to the floor of the prostate, which was really due not to the development of more prostatic tissue, but to the depression or partial prolapse of the posterior wall of the bladder. This artificial condition of obstruction I have endeavoured to show, in some instances, not only precedes prostatic obstruction, but, further, is followed by the development of a strong muscular buttress between the orifice of the ureters, which in many instances leads to the obstruction of what otherwise would prove, by the sinking of the posterior wall of the bladder, an inconvenient pouch. Thus hypertrophy of the prostate and the adjacent part may not only be due to the natural resistance of urine-pressure, but may also be called into existence for the evident purpose of supplementing a structural defect of more or less accidental origin.

It is impossible to observe the function of micturition in the child and the adult without recognising that in the two conditions there are wide differences in the influences that the will exercises upon the merely mechanical act. In the child the process almost approaches the involuntary; the calls of Nature are impulsive, and must be obeyed without hesitation. This may be illustrated in a variety of ways, in health as well as in disease. In adult man this is to a large extent changed, as we find the process becomes much more subservient to the will than perhaps at first sight we should feel disposed to admit. That there is a wide difference in our respective powers of continence in this respect I am willing to admit. In some individuals the function of micturition seems in health but very slightly removed from a purely voluntary act. Let me illustrate what I mean. A medical man, closely approaching 70 years of age, asked me to examine his rectum for some slight ailment. In doing so I found that he had a very large, soft prostate. I mentioned this to him, when he remarked, "I could hardly believe it, as I have always had such excellent waterworks. I have been in the habit of not passing urine for eight or ten hours." Here then is an illustration of a man who submits his bladder to the same degree of urine-pressure at 70 as he did when he was 27. Again, a captain of one of our ocean steamers, in consulting me in reference to some urinary disorder clearly connected with a large prostate, in comparing his present with his past powers of retaining urine, remarked that, in consequence of remaining on the bridge of his steamer for long periods of time, particularly in thick weather, without leaving it to pass water, he had acquired a power of retention which had gradually become constant. Is it remarkable that Nature had thus substituted quantity for quality, and had made provision against the effects of a muscular strain which could not have been inconsiderable? We might from our daily practice multiply examples of this kind where persons, so far as was known, were not deriving anything but good from that excess of muscular tissue which we are accustomed to speak of as the prostate gland. If we admit that the muscular fibres, of which the prostate is so largely composed, exercise the function I have urged relating to the contents of the bladder, I do not think we can be at a loss to understand how they become hypertrophied.

Let me, however, not be understood as implying that in the human species the prostate has no relation with the sexual act. Evidence is not wanting to show that, both as a muscle, as well as by reason of its glandular element, it exercises purely physical functions relative to this important but casual function, independently of the continuous action I have laid stress upon in relation to micturition. The less important function of the glandular portion of the prostate has been, I believe, correctly described by Dr. Handfield Jones (*The London Medical Gazette*, vol. v, 1847), in the following words:—"Its part in

the generative function is probably not to prepare any essential element of the fecundating fluid, but merely an appropriate viscid material, involved in which the seminal animalcules may be more securely transported on their destined route."

Passing to some considerations relative to the prevention of prostatic hypertrophy, and the complications arising out of it, I would observe that more care should be systematically taken to preserve the muscular power of the bladder, and to aid it artificially when the necessity obviously arises. If a man goes on using his bladder as he would a water-bottle, from adolescence to old age, he must not be surprised if Nature prevents it breaking down entirely by the process I have described. The timely use of the catheter has often, I am sure, provided the means for warding off changes which unfortunately do not always cease when they have become precisely compensatory. Nor is there anything exceptional in this, for as age advances we recognise the importance, and make use of artificial assistance in a variety of ways which I need hardly particularise. In the clinical history of most cases of hypertrophy of the prostate, we can generally trace a period when a weakness of the viscus indicated itself by a frequency in action, which was subsequently corrected by an overgrowth in the part. But, unfortunately, the process of hypertrophy, as observed in the prostate, is not infrequently in excess. In by far the larger proportion of these instances the individuals are able not only to keep themselves comfortable by the use of the catheter, but I question very much whether their lives are in any way shortened by the continued inconvenience they have thus to submit to. Many of us could record some remarkable example of longevity under these circumstances. But making due allowance for this class of cases, there are others whose lives, in spite of careful and efficient catheterism, are rendered miserable and useless by what they suffer in this way. For no sooner does urine collect in their bladders to any appreciable extent than they require to get rid of it. Many expedients have been resorted to, both in the way of drugs and operative procedures for the permanent relief of this condition, about which it would be impossible to speak in detail. Let me, however, refer to a case (*JOURNAL*, December 24th, 1881; April 8th, 1882) which I reported some years ago, where I tapped the bladder from the perineum through the enlarged prostate, quite independently of the course of the urethra, and where a cannula was retained in this position for two months with great comfort to the patient. He was a man about 80 years of age, and had suffered much from almost all the complications that an enlarged prostate is capable of giving rise to. But the future of the case was perhaps still more interesting, for he completely recovered and lived for several years, and in this I include the acquisition of the natural and unaided use of his bladder. Further, the explanation of this was found in the fact that during the time the cannula was retained in his bladder his prostate underwent a gradual diminution in size, which was noticed by all who had the opportunity of watching and examining him. His condition prior and subsequent to the operation proved a most remarkable and instructive contrast. I may add that this process has been repeated, not only by myself but by others, with very satisfactory results, and this tends in no slight measure to substantiate the views I have already advanced relative to the pathology of the disorder. And in connection with puncture through the prostate, I would like to say a few words in reference to cases where relief has been afforded under similar circumstances by an incision through the part similar in many respects to what is adopted in lateral lithotomy. There can be no doubt that prostatectomy, which affords a free and incontinent escape for urine from the bladder, has proved of very great temporary and permanent service in this class of cases.

At the meeting of the International Medical Congress at Copenhagen, in 1884, I took the opportunity of illustrating this method of treatment as an alternative in cases where the catheter was of no avail in affording relief. And I will again refer to this operation, as sufficient time has now elapsed to enable me fairly to judge of the results obtained. The kind of cases to which this treatment has been applied are those of difficult micturition, due to the large prostate, which are not adequately relieved by the use of the catheter. This class, therefore, includes instances where there is unusual difficulty in introducing the catheter; where bleeding almost always attends the use of this instrument; where the withdrawal of the urine is followed by no sense of relief; and where the bladder, by the constant presence within it of pus and tenacious mucus, is converted into little else than a chronic abscess through which urine percolates. These, as well as some other forms of prostatic disease which might be included, are practically unrelievable by the catheter, and soon terminate in a painful death. For the relief of such conditions various expedients for establishing a more or less permanent communi-

cation with the bladder, other than the urethra, have been practised, namely, puncture above the pubes, by the rectum, and from the perineum, with the retention of a cannula or tube for the discharge of urine at these several points. Excellent in design as these proceedings are, they appear to me to fall short in one important respect—in not dealing with the cause of the obstruction. Two of these measures are open to objection, on the ground that the artificial canals are inconveniently placed as permanent vents, for it would seem desirable that the urethra should, as far as possible, be utilised and the external opening for the escape of urine be dependent. On considering various plans of treatment which had been applied under the circumstances mentioned to the obstructing prostate, it appeared to me that, by combining Cock's well-known and safe operation for opening the membranous urethra with Mercier's for dividing the prostatic bar from within the urethra, as will be presently noticed, it would be possible to obtain precision with an increased freedom from risk. Such an operation was suggested by the late Mr. Guthrie, but I cannot find that he ever tested it in practice. The want of anaesthetics probably interfered with the progress of this as well as of other departments in surgery. Apart, however, from the operative procedure, it appeared to me, from some experience I have had in lithotomy and other operations on the parts constituting the neck of the adult male bladder, that the means which had been subsequently adopted for rendering the prostatic section thus made permanent were very inadequate. Further, I had been impressed with the advantage that followed the employment of suitable bougies as dilators in cases where the prostate threatened to obstruct micturition (*The Prevention of Prostatic Obstruction*. London: Churchill. 1881). Influenced by observations of this kind, I was led to attach considerable importance to the treatment immediately following section of the enlarged prostate with the view of rendering it more permanent than had hitherto been attempted. The necessity for prostatotomy having been determined by the symptoms presented in each case, as well as by physical examination, I will describe briefly the operation and after-treatment employed.

The former consists in opening the membranous urethra, from the perineum, on a guide, and introducing the finger within the prostatic urethra; the obstructing portion of the prostate is then divided a little to one side of the median line, partly by incision with a curved probe-pointed bistoury from within outwards, and partly by division with the finger when the latter is feasible; a large drainage-tube is then introduced into the bladder. I attach considerable importance to the prolonged use of the drainage apparatus, as the object is to render the section of the prostate not a temporary one as after a lithotomy, when no such provision is made, but permanent. Hence, I am in the habit of retaining these tubes for six, eight, or ten weeks. If, after such periods, on removing the tube, I find that a catheter can be made to enter the bladder easily along the natural route, or if, as it sometimes happens, urine forces its way, in spite of the drainage tube, along the natural passage, I regard these as indications that the object in view has been obtained. The perineal wound is then allowed to close. Let me briefly illustrate this by the narration of one of my earliest cases (*JOURNAL*, June 9th, 1883).

A man, aged 63, came under my care in February, 1883, suffering from a large prostate, which was a constant source of irritation to him. The straining and forcing to urinate were but very slightly relieved by catheterism, and the only way he could get any sleep was by tying the instrument in, and this was generally followed by some cystitis. A fortnight after I saw him, I opened the prostatic urethra by a median perineal incision, and incised the prostate laterally. In doing this I found that, though the prostate was not very large, the orifice of the bladder was much obstructed by one of the nipple-like enlargements, which are sometimes more effectual in rendering micturition difficult and catheterism uncertain than some larger masses. A drainage-tube was introduced and retained for four weeks, when it was removed, and the perineal opening allowed to heal. In this case, so perfect was the drainage that the whole of the urine escaped by the apparatus, and the patient was kept absolutely dry throughout. He remained under treatment for two months after the operation. Three months after he returned to report himself. There was a slight fistulous opening in the perineum at the lower angle of the wound, through which urine sometimes passed in drops during micturition. He could now hold his urine for several hours. Some slight enlargement of the prostate could be felt from the rectum, but this did not appear to have increased. A full-sized catheter was easily introduced without any hitch or obstruction in the prostatic urethra, or at the neck of the bladder, being felt. This patient was seen at intervals for two years after the operation, and remained perfectly well. He has since neglected to report himself. Though I advised him to pass a catheter for himself occasionally, I believe that he did not do so.

Taking the case thus operated on, I have noted the following results: 1. The operation has merely afforded just such a temporary relief as the retention of a catheter or cannula would do as a drain, the condition of the patients, so far as recovery was concerned, being more or less hopeless at the time of operation. 2. The establishment of a permanent vent for the urine through the perineum. In two instances where this occurred the patients exchanged a life of misery for one of comparative comfort. The shorter route here proved most acceptable. 3. The substitution of easy for difficult catheterism. In one patient I thus operated on, though he had to use his catheter afterwards, so long as I heard of him, which was for over two years, he never had any difficulty in passing the instrument, and the bladder continued to be far more tolerant of urine than it had previously been. 4. The complete recovery of the patient, as I have just illustrated.

In discussions relative to the method of operation adopted, it has been pointed out that in some cases of this kind, it must be absolutely impossible to explore the whole length of the prostatic urethra with the finger. This circumstance has never influenced me, or seriously interfered with my carrying out the object in view. I never met with a prostate of such a size or shape as to prevent a staff or guide being passed into the bladder, and where a director will go a knife may safely follow.

But, to proceed, though a more or less permanent vent or opening for the urine, either above or below the pubes, may prove of value in some instances of urethral obstruction due to prostatic hypertrophy, where ordinary catheterism is useless so far as the amount of relief that is afforded, it is not applicable to all cases of this kind. For we must remember that in the former class of cases it is merely a matter of urethral obstruction that we have to deal with, whilst in others the symptoms are for the most part due to the irritation that is provoked in the bladder by the protruding masses of more or less degenerated prostatic tissue. The one is to the other, as well as to the bladder, as urethral stricture is to vesical calculus. The examination of specimens of hypertrophy in connection with their clinical history clearly points in some to the mechanical irritation which protruding masses of more or less prostatic tissue excite in the interior of the bladder. In connection with the treatment of such cases, where the lives of the individuals are not only absolutely useless, but most miserable, I am glad to see there are signs that something now may be systematically done for their relief. Heretofore we have been drawing for any experience we may possess in reference to this point upon what I would speak of as the casualties of lithotomy. There is much, however, in favour of direct surgical interference in these exceptional cases of grave prostatic obstruction and irritation, as the nature of the growth, unlike cancer, renders a return of it improbable. I have now on three occasions deliberately removed by perineal section considerable portions of the hypertrophied prostate, with permanent relief to the patients; and I have no hesitation in recommending the adoption of this course in suitable cases, after, if possible, perineal exploration of the part with the finger. Now, three instances may seem very insufficient data for basing such a recommendation upon; but it must be remembered that this is an exceptional remedy for the purpose of meeting exceptional circumstances. No operation of this or any other kind would in my judgment be warrantable so long as a man can keep himself reasonably comfortable with the use of the catheter, and therefore the percentage of cases where more radical measures would seem to me to be indicated is really extremely small. But we must be provided for these, and though they are oftener met with in the aged and feeble, with reduced powers of repair, whose chances of recovery from any operation are reduced, such means as I am referring to must not be too hastily set aside in these days when the practice of operative surgery, especially in relation to the interior of the body, has been shorn of many of its dangers, and is altogether very different from what it was, even at the commencement of the present century. I am induced to make these observations partly because I think it would be a misfortune if operative procedures were extended to what I would speak of as ordinary forms of prostatic obstruction, and partly because I think the risks attending the removal of protruding portions of the prostate have been somewhat exaggerated, and thus surgeons have been debarred from undertaking operations which, in proper cases, have afforded both immediate and permanent relief. So far, I have been able to do all I desired in the way of removing more or less of the obstructing prostate by proceeding from the perineum, which I have always opened with considerable freedom. In connection with the subject of prostatotomy, or removal of portions of the prostate, under such circumstances as I have indicated, I would take this opportunity of expressing the interest with which I read the paper by Mr. McGill, and the no less instructive discussion which followed it, at a recent

meeting of the Clinical Society. In this paper the author demonstrates by instances how portions of the prostate might be removed by scissors through a suprapubic incision. I am disposed to think that this, on still further trial, will be found the best way to deal with such cases, for it places the operator in view of those projecting masses of degenerated prostatic tissue which invariably protrude towards the cavity of the bladder, and which really are the cause of the distressing symptoms of irritation which accompany them. Care, however, will be necessary, as I have just urged, in the selection of cases for operations of this kind, it being distinctly understood that they are undertaken, not because the prostate is large, but because it has induced symptoms which cannot be alleviated in any other way. You may remove the prostate entirely, but this necessarily renders the individual incontinent for life. Lobulated masses proceeding from an hypertrophied prostate and isolated fibromas in the part, may thus be dealt with with permanent advantage; but this is a very different thing to extirpating the prostate in its entirety, or seriously mutilating the muscular ring, which under all circumstances is essential to the integrity of the bladder as a urine holder.

The following instance, which I will briefly relate, substantiates the proposition with which I opened this lecture; and, as it similarly bears upon the operative point now under consideration, I may consistently close my remarks with it.

In August, 1882, a patient, aged 64, came under my care with symptoms of primary carcinoma of the prostate, which caused bleeding, continuous pain, and irritability of the bladder. As no treatment afforded relief, I did a free median cystotomy, and proceeded with my finger and a blunt gouge to enucleate the prostate and the growth connected with it. In this I succeeded, with the exception of a small portion in front, which I could not get away. There was very little bleeding, and the patient made a good recovery, though he lost power of retaining his urine. Some degree of retentive power eventually returned, but it became necessary to provide him with an apparatus for controlling the incontinent escape of urine from the bladder. He lived for fourteen months after the operation, and was able to return to his work as a stevedore. He eventually died from a recurrence of the disease in the glands of the groin. I showed the specimen of what was removed at a meeting of the Royal Medical and Chirurgical Society, in connection with a discussion bearing upon the subject.

A FURTHER INVESTIGATION

INTO

THE SO-CALLED HENDON COW DISEASE,

AND ITS

RELATION TO SCARLET FEVER IN MAN.

Abstracted from a Report to the Agricultural Department of the Privy Council, read before the Pathological Society, January 17th, 1888.

By PROFESSOR EDGAR CROOKSHANK, M.B.,
Of the Bacteriological Laboratory, King's College, London.

Description of the Streptococcus isolated from the Ulcers of the Teats.—Determination of the Species: Streptococcus Pyogenes.—Acute Abscesses; Distribution of Streptococcus Pyogenes.—Nature of Contagium undetermined in the Exanthemata.—Post-mortem Appearances in the Hendon Cows.—Post-mortem Appearances of Cows from Wiltshire.—Post-mortem Appearances of Inoculated Calves.—Summary.

At a special meeting of this Society I laid before you the results of an investigation which, though admittedly incomplete in some details, enabled me to bring forward evidence to show that the theory that a certain eruptive disease of the teats of cows at Hendon was the very disease which we call scarlet fever in man could not be maintained. That was the object of my communication, while as a side issue—which I, nevertheless, regarded as of greater interest than the overthrow of the above-mentioned theory—I brought forward evidence to show that this disease was in reality cow-pox. I was anxious that these conclusions should be made known without delay, partly to allay the public anxiety, and partly because I wanted to give every opportunity for my statements to be examined. Thus I wished to afford anyone interested in the matter an opportunity for visiting the farms while the details were fresh in the memory of the milkers, and before the disease had totally disappeared from among the cows.

I pointed out that the study of the streptococci which I had isolated was not yet completed. I had yet to study the effects of inoculation, and I was therefore only in a position to say that this streptococcus corresponded morphologically and on cultivation with the so-called scarlatina streptococcus. I inclined to the belief that these organisms were identical, not only with each other, but with certain other organisms which had been regarded originally as distinct species.

I promised further investigation on these points, and I also stated that I thought I should find in a calf at the Royal Veterinary College the *post-mortem* appearances which had been described by Dr. Klein. This animal showed symptoms of septicæmia, and has now been killed and carefully examined. I will therefore proceed to lay before you the details of these and of further inquiries in connection with this subject.

I desire to lay this further evidence before you, so that you may be concerned to-night in discussing the identity of the disease I have investigated with the disease which has been fully described clinically and pathologically by Dr. Cameron and Dr. Klein, and the micro-pathology of which has been so fully illustrated by Dr. Klein in a very extensive series of lithographed plates.

DESCRIPTION OF THE STREPTOCOCCUS ISOLATED FROM THE ULCERS OF THE TEATS.—I will first describe more in detail the chain-forming micrococcus which I found in the discharge from the ulcers.

The individual cocci are small spherical cells with a special tendency after fission, for the resulting elements to remain attached to each other, forming chains or rosaries. There may be a few, three or four, elements linked together, or a number of individuals forming straight or serpentine chains. The size of the individual elements is not always equal, here and there in a chain a larger element appearing.

In plate cultivations the appearances of the colonies are not very striking. They appear to the naked eye, after three or four days, as extremely minute, greyish-white, translucent dots, which, under the microscope, have a slightly yellowish-brown colour. They are finely granular and well-defined. They do not liquefy the gelatine, and after weeks do not exceed the size of a pin's head.

If the surface of nutrient gelatine solidified obliquely is traced over once or twice with a platinum needle, bent at the extremity into a little hook charged with the micrococci, a ribbon-shaped film develops in two or three days at 18° C. This film is composed of minute greyish-white translucent dots or droplets, which can be more easily recognised with the aid of a pocket lens.

According to the number of organisms seen on the jelly, the dots or colonies may be completely isolated or form a more or less continuous film. This film by reflected light has an iridescent appearance like mother-of-pearl, but has a bluish or bluish-grey tint by transmitted light, and with a pocket lens appears distinctly brownish.

The gelatine is not liquefied, and even after several weeks the cultivation is limited to the inoculated area and the individual colonies are not larger than pins' heads. Cultivated on the oblique surface of nutrient agar-agar at 37° C. the growth is very similar, forming a film composed of minute dot-like colonies like grains of sand. But the film appears less transparent, is whiter, and the colonies have a greater tendency to get irregular in form. If inoculated with one tracing of the needle the growth is scanty, but tends to get thicker in the centre than towards the margins, which may have a terraced appearance.

Inoculated in the depth of the gelatine there appears after a day or two, at 18° C., a thread-like growth along the track of the inoculating needle. This delicate thread is found on examination with a pocket lens to consist of a linear series of extremely minute granules. In a few days more the beads or granules become more marked, but even after weeks the cultivation only appears like a string of minute white compact globular masses or grains. In broth at 37° C. the cocci in twenty-four hours create a turbidity, and gradually develop chains varying in length according to the age of the cultivations. Even in forty-eight hours there may be chains of 8, 10 or 20 elements. After a few days the growth settles down at the bottom of the tube in the form of a white deposit, while the supernatant liquid becomes clear again.

Cultivated in milk at 37° C., they convert it in two or three days into a solid mass, while uninoculated control tubes remained liquid. Inoculated subcutaneously in the ear of rabbits, they produce in two days an inflammatory thickening, with erysipelatous redness, and without suppuration.

DETERMINATION OF THE SPECIES: STREPTOCOCCUS PYOGENES.—From its microscopical appearances, its characters on cultivation, and its effect on animals, it is obvious that this organism is iden-

tical in every respect with the streptococcus found in acute abscesses by Ogston, and studied more minutely and named *streptococcus pyogenes* by Rosenbach. For some time my attention has been drawn to the probable identity of the organisms described in puerperal fever, measles, scarlatina, diphtheria, with the chain-forming micrococcus in pus, and I find that, independently, bacteriologists on the Continent have not only considerably extended that idea, but have come to definite conclusions. Formerly, certain differences in the result of inoculation of animals were regarded as establishing a distinction of species; but further researches have shown that often these differences are not constant, and moreover, in the history of the well-known pathogenic organisms we meet with different effects produced by one and the same species. Indeed, we find that the pathogenic effect depends upon several conditions, such as the source of the micro-organism, the dose, the mode and place of infection, and the nature of the inoculated soil. The principal method of attenuation of virus depends upon the fact that by passing organisms through different animals, they assume different properties. Thus, anthrax bacilli from sheep are fatal to sheep, but if passed through mice produce a transitory illness. The microbe of swine-erysipelas passed through pigeons is increased in pathogenic power, but by passing through rabbits is progressively diminished, producing only a mild disease. But not only is the pathogenic effect different, but the organism itself may be altered. Thus, according to Huber, anthrax bacilli from the guinea-pig are thicker than when they are derived from the mouse or sheep, and the latter are thicker than in the rabbit.

Even the *streptococcus erysipelatis* of Fehleisen, which at first was regarded as quite a distinct species, has been identified by many German authorities with the *streptococcus pyogenes*. Similar in their microscopical features and their characters on cultivation, Baumgarten does not consider it beyond the limits of possibility that they might differ in their effects on inoculation, according to the condition with which they had been associated. Thus, when derived from suppuration, there might be a tendency towards the development of an inflammation accompanied with the formation of pus; and when derived from erysipelas, there might be a tendency towards the formation of an erysipelatos inflammation without suppuration; while under other conditions the organisms might lose their pathogenic properties altogether. But apparently there is no longer even this distinction, for these differences after inoculation have been minimised by recent researches. I will give further details of these investigations directly, and I will now proceed to enumerate the various diseases and conditions in which the Continental authorities principally have arrived at the conclusion that we have to do with one and the same micro-organism.

DISTRIBUTION OF STREPTOCOCCUS PYOGENES.—*Acute Abscesses.*—I have already mentioned that a chain-forming micrococcus was first described by Ogston in acute suppuration. It was later studied by the methods of cultivation introduced by Koch, and named by Rosenbach *streptococcus pyogenes*. According to Flugge, after subcutaneous inoculation of mice with a small quantity of a cultivation, there is no result in 80 per cent. of the animals experimented on. Sometimes there is limited pus-formation at the seat of inoculation, sometimes the animals die without any very striking pathological appearances.

Erysipelas.—In erysipelas Fehleisen isolated a streptococcus and described the appearance on cultivation. Fehleisen regarded the organism as quite distinctive, with special characters on cultivation; but Rosenbach pointed out the extremely close resemblance in every respect to the *streptococcus pyogenes*, though he described an apparent difference on cultivation on nutrient agar-agar. Further investigations, however, by other observers showed that these organisms could not be distinguished with certainty, either by their morphological appearances or by their characters on cultivation. Moreover, the marked differences which have been described after inoculation were not obtained by those who repeated the experiments. Passet found that the result of inoculating *streptococcus pyogenes* in the rabbit's ears induced a very similar condition to the result of inoculation of *streptococcus erysipelatis*, and both organisms, by subcutaneous inoculation and by inoculation in the cornea of rabbits and other animals, induced results without any constant difference. Passet showed that the inoculation of the cornea produced the same form of keratitis. Hoffa and Hajek described minute differences at the seat of inoculation, but Biondi and Eiselsberg repeated the experiments, and failed to establish the alleged differences. Baumgarten also investigated this subject, and failed to prove any essential difference, and indeed found much more often than might have been expected from the publications of previous

authors that no marked result at all was obtained on inoculation; and he concluded that *streptococcus pyogenes* and *streptococcus erysipelatis* in their form, cultivation, and their effects on animals were identical. Thus Passet, Biondi, Eiselsberg, Baumgarten, and Fränkel have definitely accepted the identity of the streptococcus associated with suppuration, and the streptococcus associated with erysipelas.

Spreading Gangrene.—From a case of spreading gangrene, which was identical with Ogston's erysipelatosid wound gangrene, and regarded by him as the most intense and dangerous form of erysipelas, Rosenbach obtained pure cultivations of *streptococcus pyogenes* by incising the skin of the limb, and inoculating tubes from the turbid reddish fluid which escaped. That the streptococcus was identical with *streptococcus pyogenes* was ascertained by comparison of the mode of growth, and of the effect on animals with a cultivation derived from pus.

Surgical Fever.—Eiselsberg proved the presence of *streptococcus pyogenes* in the blood of several cases of surgical fever in Billroth's clinic. The organism was identified by cultivation.

Puerperal Fever.—Fränkel isolated from puerperal septicaemia a streptococcus, which he called *streptococcus puerperalis*; he identified it with *streptococcus pyogenes*. Winkel obtained a pure cultivation of a streptococcus from the blood of the heart in a case of puerperal peritonitis. It produced erysipelatos redness when inoculated in the rabbit's ear, and in form and in cultivation was similar to *streptococcus erysipelatis*. Cushing found that *streptococcus pyogenes* was associated with puerperal infection. The cocci were found in endometritis diphtheritica as well as in secondary puerperal inflammation. These observations were confirmed by Baumgarten, and there can be little doubt, from the description, that the streptococcus isolated from puerperal fever by Dr. W. R. Smith, which is regarded by Dr. Klein as a distinct species of streptococcus, is the same organism as the one previously found by the observers just named, and, if so, it is only another manifestation of *streptococcus pyogenes*.

Puerperal Mastitis.—In puerperal mastitis Bumm isolated the *streptococcus pyogenes*.

Diphtheria.—In three cases of typical diphtheria Löffler found a streptococcus. He isolated it by cultivation, found that it was similar in form, characters on cultivation, and effects after inoculation, with Fehleisen's streptococcus of erysipelas. Löffler was not inclined to regard them as identical, because Fehleisen never found his cocci in the blood vessels. Flugge named the organism *streptococcus articularum*, and states that, after subcutaneous inoculation or injection of a cultivation in mice, a large proportion of the animals die, and in the sections of the spleen and other organs the streptococci are again seen. Baumgarten investigated the same subject, and decided that the streptococcus was *streptococcus pyogenes*.

Scarlet Fever.—Croke, in cases of scarlet fever with severely affected throat, found bacilli, cocci, and streptococci in the organs of the throat, and cocci in the internal organs. Croke left it an open question whether these cocci were the specific organisms of scarlet fever, or to be regarded as diphtheritic or septic associates. He inclined on clinical grounds to the latter view. In cases of scarlatinal diphtheria Löffler found the same chain-forming micrococcus which he had found in typical diphtheria. Babes was able constantly to prove in inflammatory products secondary to scarlatina the presence of a streptococcus greatly resembling that in pus. Heubner and Bahrdt, in a fatal case of scarlet fever in a boy, complicated with suppuration of the finger and knee joints and with pericarditis, found a streptococcus identical in form, from the description, with *streptococcus pyogenes*. Cultivations were not made. The secondary affection started from the diphtheritically affected tonsils, which were followed by retro-pharyngeal abscess. Fränkel and Freudenberg examined for micro-organisms three cases of scarlatina with well-marked affection of the throat. In all three cases they obtained cultivations of cocci from the submaxillary lymphatic glands, spleen, liver, and kidney. These cocci could in no way be distinguished from *streptococcus pyogenes* derived from pus; nor from the undoubtedly identical streptococcus which one of them (A. Fränkel) had already repeatedly cultivated in large numbers from puerperal affections. In two of the cases *streptococcus pyogenes* was the only organism present, and in all three cases it was far in excess of other colonies which developed. The organisms were also found in sections of the organs by microscopical examination.

The identity of this streptococcus with *streptococcus pyogenes* and *streptococcus puerperalis* was established by comparison of their macroscopical and microscopical appearances in cultivations on nutrient agar-agar, nutrient gelatine, and in broth, both at the ordinary and at higher temperatures, and also by experiments on animals. They concluded that it could be stated with certainty that the organ-

isms in question did not stand in causal relation to scarlet fever.

They consider that special methods of microscopical and biological research were apparently needed for demonstrating the true scarlet fever contagium, which probably was especially present in the skin.

They consider that the presence of the streptococcus was due to a secondary infection to which the door was opened by the lesions of the throat, a view which was supported by the fact that the organisms were found in the submaxillary lymphatic glands.

They preferred to use the term "secondary" to "complicated" or "combined" infection, because this expresses the fact that by the effect of the scarlatinal virus the soil is rendered suitable for this ubiquitous microbe, when it has once gained an entrance.

From the blood and desquamation of scarlet fever, Dr. Edington cultivated a streptococcus, which he named provisionally *streptococcus rubiginosus*.

Dr. Klein examined eleven cases of scarlet fever. In ten of them the tonsils were ulcerated, and in many severely. From five cases, from four during life, and from one after death, with ulcerated throat, a streptococcus was isolated—in one case in company with staphylococcus aureus. Dr. Klein regarded this chain-forming micrococcus as the contagium of scarlet fever, and named it the *micrococcus scarlatinae*. The Edinburgh commission regarded Dr. Klein's streptococcus as identical morphologically with the streptococcus rubiginosus, and Dr. Woodhead suggested that it was identical with the *streptococcus pyogenes*. In a specimen of tinned milk which had been suspected of containing the contagium of scarlet fever, Dr. Klein isolated a streptococcus, which he regarded as identical with the streptococcus from the scarlet fever cases. If the organism is identical with the streptococcus of scarlatina, it is obvious that improperly preserved milk is another source of the *streptococcus pyogenes*. From the blood of a monkey, which Dr. Klein received two days after death, a streptococcus was isolated, which corresponded with the streptococcus from the Hendon cow disease, from the scarlet fever cases, and from the tinned milk. This monkey died in a house where scarlet fever had occurred.

From the presence of this streptococcus and from the anatomical condition of the viscera, Dr. Klein regarded as without doubt the unity of this disease with acuta scarlatina. The *post mortem* appearances, however, were from description the *post-mortem* appearances of septicæmia, which are common to many diseases besides scarlet fever, and the streptococcus, which can only be regarded as the *streptococcus pyogenes*, may have been either the result of septic infection secondary to some undetermined disease, or it may possibly be accounted for by the animal not being examined earlier than two days after death.

So-called Hendon Cow Disease.—In the disease which Dr. Klein calls the Hendon cow disease a streptococcus was isolated which is identical with the streptococcus from scarlet fever. The Hendon cow disease was regarded as scarlatina in the cow, and the streptococcus as the micrococcus scarlatinae. From the ulcers of the Wiltshire disease I have isolated an organism identical with the description of Dr. Klein's streptococcus. I regard this disease as cow-pox, and the organism as identical with the *streptococcus pyogenes*.

Vaccinia.—In vaccine lymph, Cohn and others have recognised the presence of micro-organisms. Guttman and Pfeiffer have separated the different species by Koch's methods. Guttman found: (1) micrococcus pyogenes aureus; (2) staphylococcus viridis flavescens; (3) staphylococcus cereus albus. (Syn. micrococcus vaccinæ, Cohn, Voight, Garré). Dr. Klein has isolated a micrococcus which he calls streptococcus vaccinæ, and which he states is identical with one of Guttman's cocci. But the *streptococcus pyogenes* may occur in vaccine lymph, and Pfeiffer regards it as the result of contamination. Hence it is suggested that before calf lymph is employed for vaccination it should be tested on a rabbit's ear. If in two days no rash has been produced, the possibility of the presence in the lymph of *streptococcus pyogenes* or *erysipelatis* is excluded. The nature of the contagium in vaccinæ as in scarlet fever is unknown.

Variola.—In the pustules of variola Hlava has established the presence of *streptococcus pyogenes*, and Garré found streptococci in the internal organs in a case of variola hemorrhagica.

Variola and Pemphigus.—In a fatal case of variola complicated with pemphigus, Garré found a streptococcus in the pemphigous vesicles. Whether it was identical with *streptococcus erysipelatis* Garré left an open question.

Foot-and-Mouth Disease.—In 1868 Professor Brown figured a streptococcus in the milk of cows affected with foot-and-mouth disease. From the vesicles of this disease in sheep Dr. Klein isolated a streptococcus which he regarded as the contagium of the disease. From Dr.

Klein's description of its morphological features and characters on cultivation it closely corresponds with *streptococcus pyogenes*. Mr. Watson Cheyne investigated the same disease, and informs me that he also isolated a streptococcus, which he concluded was *streptococcus pyogenes*. Baumgarten also regards Dr. Klein's alleged contagium as most probably the *streptococcus pyogenes*. Against the fact of this organism being the virus of this disease, and in favour of its being *streptococcus pyogenes* we have the results of inoculation experiments. A great number of subcutaneous inoculations in sheep were without any result. One of several guinea-pigs fed with the organism had an abscess, another an ulcer. In sheep fed with the organism two out of nine, after a number of repeated administrations, developed a disease regarded by Dr. Klein as foot-and-mouth disease. There is the possibility of two fallacies: one that the disease, if really foot-and-mouth disease, may have occurred spontaneously; the other that the result which occurred may have been a spurious form of foot-and-mouth disease. The control experiment of exposing a number of sheep with these two sheep to see if the disease spread was wanting.

Cattle Plague.—Semmer cultivated streptococci from the blood and lymphatic glands of a sheep with this disease. A calf inoculated with a cultivation was stated to have died in seven days from cattle plague. The cocci were stated to lose their virulence by successive cultivation, and the weakened cultivations to protect against the virulent disease. I think it extremely likely this was another manifestation of *streptococcus pyogenes*, and that the animal died very probably of septic infection. Dr. Klein is also of opinion, in spite of Semmer's statements, that the specific nature of these micro-organisms cannot be considered to be established.

Swine Fever.—In a severe case of this disease with well-marked intestinal ulceration I have obtained from the blood of the spleen a mixed cultivation of streptococci and other organisms. Isolation and cultivation in the pure state are not yet completed. It was very probably mixed infection with *streptococcus pyogenes*.

Yellow Fever.—Babès observed the presence of streptococci in the vessels of the kidney and liver in yellow fever. Cultivation experiments are wanting. It was probably secondary infection with *streptococcus pyogenes*.

Fièvre Bilieuse Typhoïde.—Babès, in a case of this disease, found masses of streptococci filling the vessels of the liver, kidney, and spleen; probably another instance of secondary infection with *streptococcus pyogenes*.

Measles.—From the blood and from inflammatory post-products in measles Babès isolated a streptococcus, which he describes as closely resembling the *streptococcus pyogenes*.

Endocarditis.—Wysokowitsch found cocci in the internal organs in ulcerative endocarditis, and produced the disease in animals by injection of *streptococcus pyogenes* and other organisms after injury to the valves. Wechselbaum, by microscopical research and by cultivation experiments, proved the presence of *streptococcus pyogenes* in acute verrucous endocarditis. Baumgarten confirmed this. He found *streptococcus pyogenes* alone in one case, and accompanied by *staphylococcus aureus* in another.

Typhoid Fever.—Senger found a streptococcus in a case of typhoid with secondary infection. This was probably *streptococcus pyogenes*, for Dunin found in post-typhoid suppuration the well-known pyogenic organisms, mostly as staphylococci, but sometimes streptococci.

Pneumonia.—Wechselbaum found the *streptococcus pneumoniae*, which resembled *streptococcus pyogenes* and *erysipelatis* morphologically and on cultivation. It was found in twenty-one cases by microscopical research, and cultivated in nineteen. It had no effects on the rabbit's ear. Baumgarten nevertheless regards this as *streptococcus pyogenes*, and is of opinion that it is only a matter of further research to establish that view. In pneumonia after typhoid, Neumann found streptococci by microscopical research in the lungs, and by cultivation isolated a streptococcus. It corresponds with Wechselbaum's streptococcus in not affecting the rabbit's ear.

Empyema.—Rosenbach obtained a pure cultivation of *streptococcus pyogenes* in a case of empyema. Wechselbaum in two cases also established its presence.

Broncho-pneumonia.—Thaon found chain cocci in the lungs of children in fatal cases of broncho-pneumonia, complicating measles, diphtheria, and whooping-cough. They were regarded as identical with the streptococcus isolated by Löffler from diphtheria. Fränkel discovered a streptococcus in the lungs of a case of true croup complicated with broncho-pneumonia, and by cultivation established its identity with *streptococcus pyogenes*.

Progressive Tissue Necrosis in Mice.—Koch produced a disease in mice by subcutaneous injection of putrid blood. In tissue sections a chain coccus was found, and Baumgarten is of opinion that it is very pro-

bably identical with the *streptococcus pyogenes*, but cultivations are still wanting.

Septicæmia Consecutive to Anthrax.—Charrin found cocci in rabbits, examined some hours after death from anthrax. These when isolated produced death in rabbits from septicæmia without suppuration. Chains composed of fifteen to twenty elements were found in all the organs. This was probably another instance of *streptococcus pyogenes*.

Pyæmia and Septicæmia.—Rosenbach examined six cases of pyæmia. From Case No. 1 cultivations of *streptococcus pyogenes* were obtained from the blood of the patient during life. The blood was stroked over the surface of the culture medium, and in two tubes the *staphylococcus pyogenes aureus* was also present. In Case 2, with suppurative pleuritis, the pleura was tapped during life, and cultivations of *streptococcus pyogenes* were obtained. In Case 3, streptococci were found in the metastases in the kidneys, and in the other suppurations that were examined.

In Case 4 the pleura was opened during life, and *streptococcus pyogenes*, associated with *staphylococcus pyogenes aureus*, was cultivated from the fluid which escaped. In Case 5 pure cultivations of *streptococcus pyogenes* were obtained from pus from the knee, which was punctured during life. This case was one of erysipelas and pyæmia after removal of carcinoma of the breast. In Case 6, a case of whitlow, with metastatic abscesses, the patient recovered, and no streptococci were found. Thus in six cases of metastatic pyæmia *streptococcus pyogenes* was found five times, partly in the blood and partly in the metastatic deposits, and twice in company with *staphylococcus pyogenes aureus*. Baumgarten also found the *streptococcus pyogenes* in the internal organs in pyæmic cases, and Eiselsberg found *streptococcus pyogenes* in company with *staphylococcus pyogenes aureus* in the blood of cases of septicæmia.

Congenital Syphilis.—Kassowitz and Hochsinger found the presence of a streptococcus in the tissues and internal organs, and especially in the blood vessels, in fatal cases of congenital syphilis. These observers regarded their discovery as having an important bearing on the etiology of syphilis, but Kolisko pointed out that it was only the result of septic infection with presence of *streptococcus pyogenes*, as had already been established in scarlet fever.

Idiopathic Cerebro-Meningitis.—From the meningeal exudation of a case of apparently idiopathic cerebro-meningitis Banti found by Koch's methods the presence of *streptococcus pyogenes*, *staphylococcus aureus*, and *albus*. The cocci probably entered through an abscess of the jejunum.

Blepharadenitis and Phlegmonous Dacryocystis.—Widmark isolated by cultivation, *streptococcus pyogenes*, and other organisms from these diseases. In phlegmonous dacryocystis Widmark found *streptococcus pyogenes* almost exclusively.

Fatal Case of Leukæmia.—Flugge cultivated a streptococcus from necrotic patches in the spleen of a fatal case of leukæmia. Cultures corresponded very closely with *streptococcus pyogenes*. Inoculation in two rabbits' ears produced similar results to *streptococcus pyogenes*, or *erysipelatis*. Flugge called it *streptococcus pyogenes malignus*, but concludes that it is probably identical with the streptococcus from pns.

Earth.—Nicolai, and later Guarneri, isolated a streptococcus from soil. Microscopically it could not be distinguished from other streptococci. Baumgarten is of opinion that it is neither in form nor in cultivation to be distinguished with certainty from *streptococcus pyogenes*.

Air.—Emmerich succeeded in proving the presence of chain cocci in the air of a hospital where erysipelas had broken out. These cocci in their form, their characters on cultivation, and in inoculation results, were identified with the *streptococcus erysipelatis*.

Various Rotting Substances.—Baumgarten states that in the most various substances undergoing putrefaction streptococci are always found, which morphologically are exactly similar to the *streptococcus erysipelatis*. Baumgarten, therefore, regards it as quite possible that the *streptococcus erysipelatis*, or *pyogenes*, is essentially a saprophytic organism, that is to say, an organism which may be found wherever there is decaying organic matter, and that its parasitism is only incidental.

NATURE OF CONTAGIUM UNDETERMINED IN THE EXANTHEMATA.—I think, therefore, that the results of these numerous investigations constitute a mass of evidence in support of my opinion that in a disease which is accompanied with a lesion of the skin or mucous membrane, and in which the blood and tissues are profoundly affected by the virus of that disease, micro-organisms may gain an entrance into the circulation and escape destruction.

The occurrence, therefore, of *streptococcus pyogenes* in diphtheria, scarlet fever, vaccinia, variola, measles, typhoid, etc., must be re-

garded as a secondary result, and associated with septic or pyæmic complication—and I am forced to the conclusion that, excepting negative evidence, bacteriology has not assisted us in the least in the determination of the real nature of the morbid agent or actual contagium of the exanthemata.

That there are certain diseases which are due to micro-organisms is, I am sure, accepted by all modern pathologists, but we are far from having solved the nature of the contagium of all communicable diseases. In many cases, as in hydrophobia, where bacteria have been brought forward as the specific agents, they have been gradually substituted by the less definable term *virus*. Misapplied bacteriology will be both misleading and mischievous, and this criticism is applicable if a micro-organism is maintained to be the actual contagium of a disease, such as scarlatina, in the face of obvious fallacies and without affording the evidence which is usually regarded as necessary for admitting a causal connection.

POST-MORTEM APPEARANCES IN THE HENDON COWS.—A great deal of importance appears to have been attached to the *post-mortem* appearances which were found by Dr. Klein in the original Hendon disease. This is all the more surprising inasmuch as it was presumably not only a non-fatal form of scarlatina, but of such a very mild type that, according to Dr. Klein, neither feeding capacity nor milking power was affected, nor was the body temperature abnormal. Putting aside the danger of coming to conclusions from two *post-mortem* examinations, I will pass on to quote fully what the *post-mortem* examination of these two cows revealed.

In cow 4, killed January 9th, we read as follows:—

Naked Eye Appearances of Cow 4.—“On opening the chest, it was found that both lungs exhibited on the upper posterior lobes numerous petechiæ under the pulmonary pleura, the peripheral lobules of these parts being much congested. There were numerous adhesions by recent soft lymph between the lower lobes of the lung and the costal pleura, particularly laterally. In the liver there were several reddish streaks and patches reaching from the surface of the organ to a depth of about a quarter of an inch. In these patches the liver tissue was much softened. The spleen and kidneys, with exception of slight congestion, appeared normal. In the placenta there were numerous petechiæ.”

Microscopical Examination of Internal Organs of Cow 4.—“Lung.—Sections made through the portions above mentioned as containing much congested lobules show not only great congestion of the blood vessels, large and small, but a large amount of hæmorrhage; blood in substance being present in the air vesicles and infundibula, in the lymph spaces of the interlobular septa, and in the tissue and lymphatics of the pleura.

“Liver.—Under the capsule, as well as in the substance of the liver, there occur in connection with the interlobular branches of the portal vein, larger and smaller foci of inflammation, consisting in the presence of numerous round cells. Some of these foci are several millimetres in diameter, others are very small. From the interlobular tissue the inflammation extends into the lobules between the liver cells. The liver cells of these lobules involved in the inflammatory process are swollen up, and many of them are undergoing disintegration. In some of these foci, particularly those situated in the vicinity of the capsule, the round cells are so much crowded that given foci look almost like miliary abscesses. The blood vessels are much distended and filled with blood.

“Kidney.—Sections showed well-marked glomerulo-nephritis, infiltration of the sheath of the cortical arterioles, with numerous round cells; the epithelium of the convoluted tubules swollen, opaque, and, in many places, disintegrating.”

Naked-Eye Appearances of Cow 3.—“In the lungs there were numerous lobules, especially in the peripheral parts, which showed great congestion; there were, in addition, pleural adhesions; the cortex of the kidney was congested, but its medulla was pale.”

Microscopical Appearances.—“The lungs and kidneys showed, on microscopic examination, the same appearances as in Cow 3; in addition, there was a good deal of round cell infiltration in the wall of the infundibula and bronchi in the lung and around the arterioles in the kidney.”

Such *post-mortem* appearances can hardly be regarded as of primary importance. At most they are suggestive of some coincident affection. In both the description of the naked-eye appearances suggests pleurisy, or possibly some pleuro-pneumonia. The microscopical appearances in both are suggestive of septic poisoning.

POST-MORTEM APPEARANCES OF COWS FROM WILTSHIRE.—I have already mentioned that a cow from the outbreak which I investigated in Wiltshire was sent to the Brown Institution. Having duly received

notice of the *post-mortem* examination, I accompanied Professor Brown; and inasmuch as there was no suspicion of any disease complicating the eruptive disease of the teats, it was not surprising to find that naked eye appearances at the *post-mortem* examination were practically negative. All that could be noted of the viscera was as follows: petechiæ on the spleen; liver, a few whitish irregular spots; fatty patches on surface of the cortex of the kidney.

I have already mentioned that there was an unusual condition of ulceration in this cow, and milking had become a matter of great difficulty to inexperienced hands. The result was that after the cow had been at the Royal Veterinary College, the udder became enlarged, and the teats red and swollen. At the *post-mortem* examination an incision into the udder revealed an enormous abscess.

At the *post-mortem* of Cow 2, which was also sent to Dr. Klein, there was a somewhat similar condition, and the visceral changes were negative.

I shall refer to the examination of the ulcers of these two cows later, but it is interesting to observe that microscopical sections of the kidney of the Wiltshire cow No. 1 revealed a similar condition to that found in the kidney of Dr. Klein's Hendon cow.

Microscopical Examination of Kidney of Wiltshire Cow 1.—Sections showed glomerulo-nephritis; infiltrations round Bowman's capsule with round cells; infiltration of the sheaths of the vessels with round cells, especially of the cortex; blood-vessels in the boundary zone of the medulla engorged; arterioles of the glomeruli engorged, and slight hæmorrhages into the capsule; epithelium of the convoluted tubules granular, opaque, and in some parts breaking down.

Inasmuch as sections of the kidney of cow No. 1 (Wiltshire) show similar appearance to those in sections of Dr. Klein's Hendon cow No. 4, the appearances in the latter can hardly be regarded as a necessary indication of the disease being scarlatina in the cow.

Microscopical Appearances of the Ulcers of (Wiltshire) Cows 1 and 2.—Cow 1: Sections of a portion of the spreading ulceration of the teat, showed only a superficial ulceration, not extending far into the depth of the tissue. There were marked hæmorrhages in the corium. These appearances were somewhat different from the appearances in sections of a circumscribed ulcer from a teat of (Wiltshire) cow 2.

Sections of this ulcer also show infiltration of the corium with round cells, but the ulceration extends deeply into the tissue. There are spaces or cavities in the stratum Malpighii, especially in the superficial layers. These spaces are empty or filled with granular matter and round cells, and are separated from one other by trabeculae. In short, it may be said that the appearances under the microscope compared side by side with Dr. Klein's illustration of an ulcer from a Hendon cow (Plate x, fig. 12) are so strikingly similar, that Dr. Klein's illustration looks as if it might have been drawn from a section from (Wiltshire) cow 2.

It is interesting also to note that Dr. Klein states that appearances of microscopical sections of ulcers of the Hendon cows "recalled vividly the condition observed in the vesicles of cow-pox."

POST-MORTEM APPEARANCES OF INOCULATED CALVES.—Though the *post-mortem* appearances in the Hendon cows cannot be regarded as throwing much light upon the question, this is not the case when we come to examine the *post-mortem* appearances of calves inoculated with the scraping of an ulcer or with cultivation of the streptococcus from cases of scarlatina. These *post-mortem* appearances are very striking, but they cannot be regarded as characteristic of scarlatina; they are in reality the *post-mortem* appearances of septic infection, and common, therefore, to many diseases. For example, let us take the case of Calf No. 1, which was inoculated in the skin of the groin and the belly with a subculture of streptococci from the blood of a scarlatinal patient. This calf was killed, and the *post-mortem* appearances were as follows:—

The lymphatic glands of the groin much congested and swollen, some of them dark red, almost black. Similar appearances were found in some lymph glands in the subcutaneous tissues of the throat, and in the pelvis; in some, also, of those along the aorta and vena cava, in the bronchi, and in the anterior mediastinum, along the trachea, and along the stomach and mesentery. Many of these glands were either partially or wholly of a dark red colour, when cut into bloody fluid easily oozed out. Those that were not dark red were soft and juicy, and clear fluid oozed from them when cut into. Some of the dark red, almost black glands—for example, some in the bronchi, the glands along the aorta and vena cava, and in the pelvis—were not larger than a pea, others as large as a bean, and up to the size of a walnut. Sections examined under the microscope showed a large amount of blood effused *en masse* into the cortical and medullary

lymph sources, and into the tissue of the lymph follicles of the cortex, by which the adenoid tissue of these latter had become to a great extent destroyed.

"Both lungs were congested in the upper and middle portions, groups of lobules in the latter being dark red and hepatized and not floating in water. The pericardial cavity was filled with several ounces of clear liquid; patches of soft pseudo-membranes were found on the root of the aorta and pulmonary artery, on the wall of both anfringes, and particularly along the free margin of the latter. The liver was congested, and showed dark red patches of softened liver tissue. The spleen was enlarged, dark in its substance, with numerous petechiæ in and underneath the capsule. Both kidneys showed much congestion."

The result of microscopical examination of the organs of this and other calves Dr. Klein sums up by saying that the appearances "closely resembled those found in the viscera of cases of fatal human scarlatina."

I will now give for comparison with this account the *post-mortem* appearances of the calf, which was killed at the Royal Veterinary College. This calf had been inoculated in the groin with a scraping from an ulcer of (Wiltshire) cow 1. During the second week after inoculation it was very dull, and did not feed well. It had diarrhœa for several days, and passed bloody urine. It was noticed that it had a slight cough, which got worse. The place of inoculation was suppurating freely, and there was considerable inflammatory thickening around the seat of inoculation. The animal was killed thirty-six days after inoculation.

The *post-mortem* examination of the viscera was made under the supervision of Professor Brown and Professor Axe. I have submitted the microscopical specimens to Professor Brown. I will now give a detail account.

Naked Eye Appearances: Lungs.—Upper and middle lobes of each lung adherent to the walls of the chest; patchy congestion, especially of middle lobe, and patches of recent adherent lymph. Posterior parts of the upper lobes of both lungs were completely consolidated, and on section varied in colour from brick-red to greyish-white. The interlobular tissue was infiltrated with inflammatory products, which mapped out the tissue of the lung in small indurated areas, in which the tissue was granular looking and friable. These appearances in the upper lobes were due to pleuro-pneumonia. Scattered through the other lobes of both lungs were white, mostly firm, nodules raised above the level of the surface of the lung. They were surrounded by a zone of congestion, and in some cases sections were composed of indurated, in others of friable, lung tissue. In the posterior part of the right upper lobe there was a recent infarct. *Bronchial Glands.*—The bronchial glands at the roots of each lung were enlarged to two or three times their natural size, and were hard and firm in section. *Pericardium.*—The parietal surface of the pericardium was covered with recent adherent lymph. The visceral surface of the pericardium was normal. *Aorta.*—Along the external surface of the aorta were chains of enlarged lymphatic glands connected by dilated lymphatic vessels. These glands were dark red or purplish in colour, from hæmorrhage into their substance. *Heart.*—The heart was normal and the endocardium not stained. *Esophagus.*—There were chains of red glands on the œsophagus similar to those along the aorta. *Mesenteric Glands.*—The appearance of the mesenteric glands was very striking. The mesentery was dotted along the lymphatic vessels with glands, varying in size from a large shot to a pea, which were deep red or prune coloured. In addition there were here and there enlarged glands, without hæmorrhage into their substance, and greyish in colour. *Spleen.*—There were scattered petechiæ on the spleen. *Kidneys.*—The kidneys were firm on section, and there was marked congestion in both, while it was more pronounced in one kidney than the other. *Liver.*—The liver was congested, the congestion being more marked in patches.

Microscopical Examination.—Lung.—Sections from the consolidated upper lobes showed thickening of the pleura and infiltration with round cells. The exudation filled the alveoli, and was breaking down in some cases in the centre. The vessels were injected, and there were hæmorrhages into the alveoli. The periphery of the lobules was infiltrated with round cells. *Kidney.*—Slight infiltration around glomeruli and arterioles; epithelium of convoluted tubes, granular and disintegrating, hæmorrhage in straight tubes, and engorgement of vessels. *Liver.*—Inter- and intra-lobular vessels engorged; intratubular collections of round cells displacing the liver cells; interlobular connective tissue infiltrated with round cells; liver cells granular and cloudy.

There can be no doubt from the symptoms and *post-mortem* appearances that this calf suffered from septicæmia, as the result of introducing septic matter subcutaneously in the groin; and the *post-mortem*

appearances, excluding the consolidation of the apices due to the coincident pleuro-pneumonia, almost reproduce the *post-mortem* appearances observed by Dr. Klein. That the micrococcus from scarlet fever cases should fail to produce in calves fever, ulceration of the tonsils, or scarlatina rash, or any condition resembling clinically the disease in man, and yet that the result should be regarded as scarlatina in the calf, is quite untenable; but I am quite ready to agree with Dr. Klein that similar lesions may be produced in calves, whether inoculated with scrapings from ulcers, or with the streptococcus from the Hendon cows, or with the streptococcus from cases of scarlet fever. The micro-organism is a septic organism (*streptococcus pyogenes*); and its inoculation or the inoculation of septic lymph may produce septicæmia.

SUMMARY.—From the evidence I have adduced, and from the facts that I have described, I am led to the belief that:

1. The nature of the contagium of scarlet fever is unknown.
 2. The micro-organism regarded by Dr. Klein as the contagium is the *streptococcus pyogenes*.
 3. *Streptococcus pyogenes* is found, sometimes in company with *staphylococcus pyogenes aureus*, as a secondary result in scarlet fever and many other diseases.
 4. A streptococcus was first observed in scarlet fever by Crooke, later by Löffler, Henbner, and Bahrdt; but its exact relation to scarlatina, and its undoubted identity with the streptococcus from pus and puerperal fever, was definitely established in 1885 by Fränkel and Freudenberg.
- To these I would add the following statements:
5. Both the Wiltshire and Hendon cow diseases were called cow-pox by people on the farms.
 6. Both diseases correspond in their clinical history.
 7. The ulcers on the teats correspond in naked eye and in microscopical appearances, and the latter "vividly recall the appearances of cowpox."
 8. Calves inoculated from the discharges of the ulcers are similarly affected.
 9. *Post-mortem* examination of such calves, or of calves inoculated with streptococci isolated from scarlet fever cases, show similar appearances.
 10. The *post-mortem* appearances in such inoculated calves are the result of septicæmia.
 11. There are no specific visceral changes in cow-pox apart from complications or coincident affections.
- I propose to publish shortly the history of the lad shown at the Society, the full details of the calves inoculated from the boy, and of calves inoculated from those calves, the results of revaccination of those calves, and further details from Wiltshire and Gloucestershire.

RUPTURE OF THE SAC IN THE EARLIER STAGES OF TUBAL PREGNANCY, WITH NOTES OF TWO CASES.

By WILLIAM JAPP SINCLAIR, M.A., M.D.,
Honorary Physician to the Southern Hospital for Women and Children,
Manchester.

CASE I. *Tubal Pregnancy: Sudden Death: Necropsy.*—During the greater part of 1880 a patient, nullipara, was under treatment for an enlargement of the uterus, with retroversion. In November she did not menstruate, and in December she had symptoms which suggested pregnancy, but they were very slight, and from the history and circumstances it seemed an improbable event. On January 1st, 1881, she was taken suddenly ill, with faintness and pain in the bowels. The medical man who was sent for in the emergency found the chief symptom diarrhœa with tenesmus. The patient sank rapidly, and when I arrived in the evening, in response to a telegram, she was dead.

From my previous knowledge of the case, on learning the details of the fatal illness, I concluded that the patient had died of hæmorrhage from the bursting of the sac of a tubal pregnancy. We were permitted to make an examination of the abdomen, and we found it full of blood. There was a tubal pregnancy apparently of about six weeks' duration; the sac was near the middle of the left Fallopian tube, and the orifice, from which blood oozed on disturbing the parts, was on the posterior surface, so that there was a free opening into the pelvis. The uterus contained several fibroid tumours projecting on the serous surface, the largest of them about the size of a walnut. In cutting through the abdominal walls, which was done carefully as if in the performance of an operation on the living, we were struck with the

appearance of the blood through the peritoneum before it was cut. As soon as the peritoneum was reached we knew there was blood in the abdomen, because of the black colour apparently given to the peritoneum by the blood behind it.

It will be noted in the history of this case that the pregnancy was not capable of definite diagnosis. It was too early for certainty in almost any case; but in this case there were the previous symptoms of diseased uterus and disturbed menstruation, the uterus was always enlarged to the touch, owing, as was found after death, to the presence of small fibroids. The sound was not used after the menstrual period had been missed, and there was no sort of examination to excite unusual movements of the uterus or tubes for nearly a month before the rupture of the sac.

When the rupture took place, it will be observed that the disturbance set up in the bowels became the most prominent feature in the case, and so obscured the diagnosis that the experienced practitioner who was called in on the emergency concluded that some unusual bowel complication had occurred.

This case made a deep impression on my mind, and I resolved that if ever the opportunity occurred to me, I would operate at once, and endeavour to stop the hæmorrhage by surgical means. It seemed a simple operation, and the only question was how far the bathing of the whole abdominal cavity in blood, which could not possibly be completely removed, might militate against a successful result. Very few cases of operation in the early stage had been published at that time, and the proceeding did not seem so common-place then as it may appear now.

CASE II. *Tubal Pregnancy: Rupture of Sac: Laparotomy: Recovery.*—The next case is that of a patient of Mr. Priestley, of Fallowfield, at whose suggestion I had the opportunity of helping in the treatment. She was residing at a distance from home at the time of the rupture of the sac. Mr. Priestley's notes of the case prior to operation are as follows:

"The patient, Mrs. —, between 30 and 35 years of age, vii-para, after menstruating regularly for more than twelve months from the birth of the last child, missed two menstrual periods, and was, when the present symptoms commenced, a week past the second. A week after the first missed period there was a slight brownish discharge, which subsided after a two days' rest on the couch.

"On February 13th, 1887, the patient 'believes she caught cold.' On February 15th, after a hasty tea, she hurried to catch a train. Hardly was she seated in the carriage when she was seized with a 'sudden terrible pain, paleness, vomiting, and faintness.' She was carried out of the train on its next stoppage, in a few minutes, and conveyed home, when her abdomen was found to be 'distended like a drum.' The temperature was normal. On February 16th the pain and faintness continued, and the temperature was found to be 101°. She also complained of muscular pain in the limbs. The pain diminished towards evening, under the influence of sedative medicine. On February 17th the intense abdominal pain returned quite suddenly at 3 A.M., and at 5 A.M. a clot of blood passed by the vagina. More morphine was administered, and the pain abated towards evening. On February 19th, at 3 A.M., four days after the first attack of pain in the abdomen, the patient was once more seized with intense abdominal pain, and immediately became collapsed and pulseless. During the day she was seen by Mr. Priestley, and subsequently by Dr. Sinclair. She had then rallied. The abdomen was much distended and tympanitic; it was very tender all over, but extremely so beneath the ribs on both sides; there was dulness in both flanks, and in a zone one inch above the pubes (horizontal position of the body). The uterus was high up, and its movements were slightly impeded; the left broad ligament was somewhat full and stiff. The cervix was soft, the os externum patulous, and a trickling discharge of blood still continued. The pulse was over 120, and very soft; the temperature was somewhat above the normal. Diagnosis: rupture of a tubal pregnancy.

"It was determined to open the abdomen at once, and, if the diagnosis proved correct, to proceed to check hæmorrhage by surgical means, and remove the ovary and tube, and, if possible, the ovum."

The operation was performed with as much attention to antiseptic precautions as the circumstances of the emergency would permit. It seemed tolerably certain that hæmorrhage had repeatedly occurred when, in the process of rallying, the blood-pressure had reached a certain point, and there was every reason to fear a recurrence, which might be fatal, if we delayed till morning. The operation was, therefore, proceeded with immediately after our consultation, which was held late on the night of February 19th. The incision was carried as quickly as possible down to the peritoneum, and when this was reached any possible shade of doubt as to the nature of the case which might

have lingered in the mind of anyone present was removed. Although the light was not all that could be desired, the presence of a black liquid behind the peritoneum was most evident. As soon as the peritoneum was cut, the black blood spurted out like the fluid from a tense monocystic ovarian tumour when it is wounded. The amount of blood which flowed out was enormous. It could not be measured, merely estimated, and it would be easy to exaggerate; but it seemed to my colleagues and myself as if the quantity was about as great as would be the whole amount of blood in the body of a healthy woman of the patient's size. When we remember that the blood had been re-making, and bursting out to an almost fatal extent for four days, this estimate may be considered fairly accurate. When the blood, which was quickly pressed out by manipulating the abdominal walls, ceased to flow freely, the distension had disappeared; the belly was quite flat. Several handfuls of clots were now cleared out of the pelvis, and bright arterial blood could then be seen welling up rapidly through the black fluid which remained. Fresh hæmorrhage had evidently already begun. The ruptured sac was found at the extreme end of the right Fallopian tube, with very active hæmorrhage going on from its interior. The tube and ovary were ligatured in the ordinary way, and removed. No embryo was ever seen.

There could be no possibility of washing away all the extravasated blood, as it had been evidently bathing every abdominal organ up to the diaphragm. The pelvis was emptied with the help of sponges, and all the blood within reach was washed out by means of a warm saline solution—common salt in boiled water, $\frac{1}{2}$ per cent. This was poured from a jug, while the intestines within reach were gently moved about by two fingers of the left hand introduced through the wound. A considerable quantity of the fluid was left in the pelvis, a large Koerberlé's tube was put in position, and the abdominal wound was closed in the usual way. As it was anticipated that a large quantity of blood and sanguineous fluid would be discharged from the tube, the dressing applied consisted only of cotton wool and lint wrung out of corrosive sublimate solution, and packed round and above the orifice of the tube. This was kept in position by means of a flannel binder gently applied.

A large quantity of fluid was discharged into the dressings, and a large quantity was also drawn through the tube by means of an ordinary two-ounce glass syringe, with a piece of india-rubber tubing attached, of such a calibre as to enable it to be easily passed through the glass tube to the pelvic floor. The syringe was also frequently used to inject warm saline solution in the hope of breaking down the blood-clots and encouraging the discharge of the disintegrated blood within reach. The result was highly satisfactory. The bloody fluid continued to flow freely for several days, and the intestines and omentum seemed to be longer than usual in closing in round the tube and obstructing the free gravitation of the fluid to the pelvis.

The patient bore the operation well, and soon showed signs of improvement. The pulse, which was very quick and soft before the operation, fell to 100 within twelve hours; in two days it fell to 90, and never again rose appreciably higher. The temperature varied between 99° and 100°, for three days. During this time vomiting was severe, and though continuous since the administration of the anæsthetic, it began to cause us uneasiness. The pulse, however, continued satisfactory. From February 24th to March 8th, the temperature rose and fell from 99° to 102°. There was considerable hardening of the pelvic floor on the right side, with partial fixation of the uterus. Hardening could also be felt along the course of Poupart's ligament on the right side.

The hæmorrhage from the uterus, which had been almost continuous, though slight, before the operation, completely disappeared until March 1st. It came on then with a molimen like menstruation; the day before its appearance, the temperature rose for the first time to 102°. The glass tube was removed on February 28th; it had been kept in an unusually long time, owing to the continued flow of disintegrated blood, and precautions were taken to prevent it doing harm by pressure. A rubber tube was substituted for the glass one, and this was gradually shortened, and finally removed on March 3rd. The rest of the history has no event worth noting; the patient gradually recovered, and the last report of her, in June, was to the effect that she was quite well. Keeping to the experience of myself and of the gentlemen with whom I was associated in the treatment of the two cases outlined here, I should like to call attention to a few points.

1. There was an entire absence of symptoms pointing to abnormal pregnancy in both cases. Neither of them could exceed two months, and in both the Fallopian tube was distended to the bursting point without giving rise to such uneasiness as to evoke any complaint from the patient.

2. When the rupture occurred there were produced, in addition to

the signs of internal hæmorrhage, symptoms having no apparent relation to the pelvic viscera, and sufficiently prominent to obscure the diagnosis. This is a striking fact in the history of the first case, and, though Mr Priestley had diagnosed the second case, it was with considerable doubt as to the value to be assigned to the apparently irrelevant symptoms.

3. In making a vaginal examination in the second case it was found that the uterus seemed to be impeded in its movements, not fixed, and not free. During the operation the uterus was found to be surrounded with blood-clots, which explained the peculiar impression that had been conveyed in the examination. This fact must be of some diagnostic value in any similar case in which the hæmorrhage has not proved rapidly fatal, so that blood-clots have had time to form.

4. A minor point, to which attention has already been called, was the appearance of the black blood through the uninjured peritoneum. This is obviously of some importance where any doubt exists as to the diagnosis. The aspirator needle, if used to clear up a doubtful case, might fail to give reliable information if its point happened to be inserted into a blood-clot.

5. The use of the saline solution seems to me to be specially suitable for cases of this kind. Owing to its solvent effect on the blood, it probably aided greatly in carrying away all the fluid, which might have been subjected to the risk of infection by exposure or manipulation during the operation. To the viscera with which it came in contact it would be as irritating as non-sterilised blood-serum.

6. A physiological point of some interest may be noted. Mr Priestley and I examined the urine, with the object of ascertaining whether it contained an unusual amount of colouring matter, or any abnormal constituents resulting from the presence of such a large amount of blood in contact, under pressure, with the peritoneum; but the results were entirely negative.

THREE UNUSUAL CASES OF ABDOMINAL SECTION IN PRIVATE PRACTICE,

UNDER THE CARE OF HERBERT W. WHITE, L.R.C.P. ED., L.F.P.S. GLAS.,
Bradford.

By STUART NAIRNE, F.F.P.S.G.,

Surgeon to the Glasgow Samaritan Hospital for Women.

THE three following cases are unusual, in so far as their occurrence so soon one after another in the practice of one man is concerned, in the condition of the patients that preceded the operations, in the various guesses as to the diagnosis, in the apparent gravity of the cases, and in the very pronounced benefit resulting from the use of antipyrin. The whole after-treatment of the cases was conducted by Mr. White, to whom I am indebted for the histories, and by whose active and judicious management the cases were undoubtedly saved.

CASE I.—Mrs. G. came under the care of Mr. White on June 4th, 1886. She was suffering from latent peritonitis, with symptoms of septicæmia. She was grey, collapsed, dull, and semi-delirious; there was albumen in her urine; her pulse was 140, and her temperature 104° F. She was vomiting frequently, and had wasted considerably away. A large tumour protruded from the abdomen, filling the pelvis, and extending to the umbilicus. The case looked so hopeless that operation was delayed, and the patient put on tonic and antifibrile treatment. She had been allowed to get into this state for fear of falling into the hands of an operator, when, she was told, her death would be assured. She hung on for several days, and at length the operation was performed, June 29th, under an attack of peritonitis, her temperature being 102° and her pulse 120. Adhesions were universal, to the abdominal walls, the bowels, and the pelvic viscera. The pedicle was broad and thin. It was tied with the Staffordshire knot. A considerable number of ligatures were left inside the peritoneal cavity. The abdomen was carefully sponged out, not washed, and the incision in the abdominal walls entirely stitched up. She had a bad night, with vomiting, and her temperature rose to 104.6°. The operation was performed at 2.30 p.m., and at 8 p.m. her temperature was 104.6°. She was then given a powder of 20 grains of antipyrin, and the improvement was so marked and immediate as to establish the value of the drug in this instance. The temperature oscillated between 99.4° and 100.4° for some time, but never rose beyond the latter after the first powder of antipyrin. Troublesome diarrhoea commenced on the third day after the operation, and continued till July 9th, when her temperature became normal, and she made uninterrupted progress towards convalescence. In the first week in August she was well enough to go to Morecambe,

and on her return, September 5th, she expressed herself as feeling well, and had walked four miles the day before her return. The cyst was multilocular, filled with pus and grumous blood, which emitted a most fetid odour. After the operation I should also note she passed large quantities of fetid pus *per vaginam*.

CASE II.—Mrs. H. had suffered a long time from headache, pain in the groins, back, arms, and sides. She complained of a "catching in her breath." She had also bearing-down pain, pain on defecation, and dyspareunia. She was quite unable to follow her occupation. On examination the os was found indurated, patulous, and the womb enlarged one inch. A small, movable tumour, exquisitely painful to touch, was found in Douglas's pouch, and diagnosed as a prolapsed ovary. It was the right ovary. She had never been treated for uterine complaint. The "headache" and the "catches in her breath," and the other subjective phenomena, had been treated with no benefit. Operation for removal of the ovary was performed on June 30th, 1886. She vomited exceedingly after the operation, but did not become collapsed. After the first three days recovery was uninterrupted, and she was able to leave home for Bridlington in the first week of August. On September 6th Mr. White reports: "She has returned from Bridlington stronger in every way. She has resumed her household duties, all the symptoms are abated, dyspareunia is gone." This last statement is particularly interesting and important.

CASE III.—Mrs. P. had fallen downstairs a year ago, and afterwards complained of severe pain in her back. There was a history of another fall, two months after this, with a renewal of the pain, and finally, three months later, whilst lifting a weight, she became "dead sick" with a return of the old pain. From this time the pain persisted, and gradually became worse. When seen by Mr. White on July 19th, 1887, she was very much exhausted, sweating, cachectic, and suffering great pain. Her pulse was 120, and temperature 102° F. She had been totally confined to bed since April. Her complaint had been variously diagnosed as hæmatocele, blood-clot, and general treatment had been adopted which did her no good. Examination *per vaginam* revealed a hard, ovoid tumour in Douglas's pouch, painful to touch, and about the size of a hen's egg. Abdominal section was performed under these unfavourable conditions on July 22nd. The tumour was found attached to the right corner of the uterus, and the ligature had to embrace part of the muscular tissue of the uterus for its complete removal. It was a scirrhous tumour, and weighed within a few grains of two ounces. She passed a very bad night after the operation, vomiting; was collapsed, and altogether very hopeless looking. On the third day, however, she began to mend, and thereafter made good progress towards recovery, she was able to leave for Morecambe on August 23th. Mr. White's report on September 6th says: "She is not entirely free from pain, but is greatly improved and able to get about."

These cases have been put on record as being an encouragement not to abandon any case, however bad, where there is a reasonable prospect of completing an operation. In all these cases the wound healed by first intention, and the stitches were removed about the eighth day. The second case had no trained nurse; the nursing in the first and third cases, provided by the Bradford Nursing Institution, was excellent; and the happy result of all three cannot but be a recommendation to the performance of such operations in patients' own homes.

RUPTURED EXTRA-UTERINE GESTATION SUCCESSFULLY TREATED BY ABDOMINAL SECTION.

By JAMES McNAUGHT, M.D., M.R.C.S.,
Newchurch-in-Rossendale.

As the treatment of ruptured Fallopian pregnancy by abdominal section is still *sub judice*, the following case successfully treated in that way is worth recording.

The patient was 34 years of age, and had been married for ten years. She had never been pregnant before, and had menstruated quite regularly up to two months previously. Menstruation had been always painful and rather scanty. During the last few days she had had pain at the lower part of the belly, and the bowels had been a little relaxed. At 3 P.M. on July 21st she went to the closet to pass water, was suddenly seized with severe pain at the lower part of the belly, and fainted. She managed after recovery to struggle into the house, and knock for her next door neighbour. She had again fainted several times before my arrival at 6 P.M. She was then pale and blanched, and had evanescent attacks of syncope and pulselessness, but in the intervals was able to tell me by degrees what had taken

place. She suspected she was pregnant; the breasts had been tender and enlarged, and she had had morning vomiting for two or three weeks. She complained of great tenderness at the lower part of the abdomen, chiefly on the left side, but also a little on the right. On examination the uterus was found pushed down generally and fixed; and as she lay on the left side a distinct bulging was felt on the left side of the pelvis pushing down the vagina. Simulants were given freely; and Dr. Green, of Rawtenstall, was sent for at my request.

The following day she had somewhat recovered; the pulse was perceptible, but thready; much pain in abdomen; objective signs unaltered. The diagnosis of ruptured extra-uterine gestation was made, and after much pressing she consented to abdominal section. Her circumstances, she stated, entirely precluded the summoning of an operator from Manchester, and I was therefore somewhat reluctantly compelled to undertake the operation myself, with the kind assistance of Dr. Green, of Rawtenstall. An incision about four inches long was made and carried down to the peritoneum by careful dissection. The peritoneum, which seemed unusually thickened, bulged up slightly, and when incised by the point of the knife, venous blood escaped freely, which at first took me somewhat aback. As, however, I felt on examination that there was nothing but fluid behind the membrane, the intestines being far enough away, I freely slit it up to the length of the incision. A quantity of dark, venous, fluid blood then gushed out of the abdominal cavity. The rest was mopped out, and a few clots taken away from the bottom of Douglas's pouch. In the right Fallopian tube, half an inch from its junction with the uterus, was found a swelling the size of the yolk of an egg, and at the back facing Douglas's pouch there was an opening into it partially filled with blood-clot, admitting the tip of the little finger. Shreds of membrane hung out of this, and after tying a double ligature on each side, it was excised. Nothing was seen of a fetus. The belly was washed out with hot water, sponged dry, and the edges of the wound brought together with wire and silkworm gut sutures. No drainage-tube was inserted, as I had not a suitable one by me. Before the hot water was used the pulse was very feeble and the aspect sunken, but immediately afterwards there was a welcome revival. Hot bottles, etc., were applied in bed; one-sixth of a grain of morphia injection was given, and enemata of beef-tea and brandy every two hours. The wound was dressed with Gamgee's tissue, retained by broad strips of adhesive plaster.

For the next two days retching was very troublesome, nothing being retained. She had scarcely any sleep during the first two nights, and the belly was tender and painful. Morphine was given subcutaneously in small doses, and enemata of beef-tea and brandy continued.

July 26th. Restless night, retching, and feeling of nausea continued. Much pain in the belly, and some tympanites. The lowest stitch was removed; the edges of the wound, which were adherent, were drawn apart, and the peritoneum, which had united, scratched through. A good deal of perfectly odourless bloody serum escaped, and the belly was washed out, siphonwise, with hot weak, perchloride solution, and a large drainage-tube inserted to the bottom of the pelvis.

Next day the retching had ceased, but she had passed a restless night. Tube aspirated, and a little serum withdrawn. She was now able to retain a little champagne.

The temperature so far had remained normal, or rather subnormal, but on the 23th it rose to 100°, the highest recorded during the progress of the case. The tube was withdrawn on the 29th, as nothing seemed to escape from it. The stitches were removed on August 3rd, the wound having all united by first intention, except where reopened. This was left to granulate, and it closed in about ten days. She was sitting up for a short time a fortnight after the operation, and was able to leave for her native place on August 27th.

This case resembles others recorded in one remarkable particular, namely, that the patient had been married for some years without pregnancy, and had never previously conceived. She gave a history of painful and scanty menstruation, and stated that connection had always been very painful to her, pointing, probably, to some mischief in the uterus or appendages. The fact that bulging was felt particularly in the left side of the vagina whilst the rupture was in the right tube is accounted for by the blood remaining fluid and gravitating to that side of the pelvis as she lay in the usual position for examination. The symptoms unmistakably pointed to internal hæmorrhage, and the fact of suspected pregnancy, and the fixing and pushing down of the uterus, left little doubt as to the nature of the case. The successful result may, perhaps, encourage others, who practise in country districts away from the reach of specialists, to undertake abdominal section, rather than wait the otherwise almost certainly unfavourable issue.

A CASE OF CHOLECYSTOTOMY FOR GALL-STONES, WITH REMARKS ON THE TREATMENT OF THE IMPACTED CALCULUS.¹

By JOHN W. TAYLOR, F.R.C.S.,

Surgeon to the Birmingham and Midland Hospital for Women.

EVERYONE who has any practical knowledge of the operation of cholecystotomy, or is *au courant* with its literature, must have recognised the fact that the one occasional important difficulty of the operation is the removal of the obstructing calculus from the cystic or common duct. Sometimes this difficulty is almost insurmountable, and under such circumstances, as is well known, Mr. Tait has practised crushing the stone from outside the duct, either at the time of the original, or at a subsequent, operation. When the stone is very hard, this proceeding may be risky, or, at all events, may appear to the operator to be specially dangerous. Some alternative method is a desideratum.

Perhaps the narration of the following case may help to point out the direction in which we may seek for such an alternative treatment with the greatest probability of success.

Mrs. K., aged 42, was sent to me by my old friend and colleague, Dr. Woollett, of Monmouth, on March 21st, 1887, with the following history. For four or five years she had noticed a swelling on the right side of the abdomen. This grew suddenly larger about eight months previous to the date already given, and although unattended with special pain or tenderness, showed no signs of any subsidence or diminution, and caused her considerable uneasiness and anxiety. She had had eleven children, nine of whom were living; her last confinement occurred about twenty months before her visit. Menstruation was regular. There had not been at any time the slightest history of jaundice or even of acute colic.

On examination a large, rounded tumour was found in the right hypochondriac and umbilical regions, extending some distance below and to the left of the umbilicus. It was very freely movable, and careful palpation elicited a vibratory thrill. There was no true fluctuation. I diagnosed the case to be one of distension of the gall-bladder, and this diagnosis was subsequently confirmed by the opinion of my colleagues, Dr. Savage and Mr. Tait; Dr. Savage noticing the fact, which had at first escaped my observation, that the edge of the liver was to be felt overlapping and covering the tumour, except at its most extreme limit.

The patient was admitted into the Birmingham and Midland Hospital for Women at Spark Hill, and on April 2nd I opened the abdomen on the outer side of the right rectus muscle immediately over the most prominent part of the tumour. On dividing the peritoneum, liver substance was seen lying immediately underneath the incision. This appeared to have been dragged down by the enlarging tumour, and formed a thin covering to it. By pressing the tumour from the opposite or left side of the abdomen upwards and towards the right, a small portion of the tumour was found uncovered by the liver, and seen to be the rounded end of a largely distended gall-bladder. This was tapped, and fully a pint of clear, somewhat glutinous fluid evacuated. The puncture was then enlarged with a tenotomy knife, and the index finger introduced within the gall-bladder. Several large stones were felt lying loosely in its cavity, and these, four in number, were removed with scoop and forceps. One remained, wedged into the cystic duct, which it seemed impossible to move. There was no space for the application of any of the forceps at my command, and after repeated attempts to extract the stone I could only succeed in breaking off some portions of its upper surface.

As all the gall-stones were hard, and very considerable force was necessary in order to break them, I was afraid to attempt the crushing of the stone from outside the duct, and therefore determined to complete the operation in such a manner as to afford the best means for any subsequent treatment of the impacted calculus that might be necessary. I sewed the incision in the gall-bladder to the abdominal wound by several stitches, so as to leave a large external opening, and placed within this a short piece of large-sized rubber tubing. The nurse was directed to syringe out the gall-bladder with warm water every night and morning through the drainage-tube. No disturbance followed the operation, and by the fourth day it was noticed that the water returning from the gall-bladder on the use of the syringe was tinged with bile, indicating that the passage of the duct was becoming free. No alteration was made in this regular treatment of the case for more than two weeks after the operation. The large drainage-

tube was kept within the external opening, being only removed temporarily for cleaning, and the gall-bladder well syringed out twice each day.

On April 18th, sixteen days after the cholecystotomy, I examined the gall-bladder for the impacted stone with Lister's sinuss-forceps. I found that the stone was loose, and that it was soft. It broke into pieces on being grasped by the forceps, and the fragments were extracted without any difficulty from the opening in the gall-bladder. The latter was syringed out a few times after this to ensure its being thoroughly cleaned out from any *débris* of the broken calculus. The tube was removed, and the abdominal opening allowed to contract and close. The patient left the hospital for her house on April 26th, quite convalescent, and with gall-bladder and ducts patent and free from any calculus.

REMARKS.—1. The power possessed by a current of water, when wisely and patiently employed, for the dislodgment of foreign bodies or wax from the auditory meatus suggested its use in the present case. It appears to have been largely responsible for the successful result. 2. There is probably, in addition to this, some time in the history of a biliary calculus retained after operation, when a considerable amount of softening occurs due to the inflammatory changes and discharge set up by the operation. If so, it is of some importance that the best time for any secondary interference should be ascertained. 3. In difficult cases, whether at the time of the cholecystotomy or afterwards, it is probable that an impacted calculus may be divided by delicate forceps similar to those utilised in the present case, when no other forceps could be employed with advantage from within the gall-bladder.

These three points—the regular daily use of the syringe after operation, the taking advantage of a time when the stone becomes softer, and the use of proper forceps, will, I believe, be of use in bringing difficult cases of cholecystotomy for gall-stone to a successful termination.

A NOTE ON THE TREATMENT OF SPINAL ABSCESS.

By THOMAS LAFFAN, M.K.Q.C.P.I., Cashel.

I HAVE, in common, I suppose, with most surgeons, met with a good many of these melancholy cases of abscess dependent on diseased spine, most of which at least have but one end—death. I have witnessed several of these where death ensued notwithstanding the cure of the spinal affection. In these the fatal end was brought about by the discharge from an extensive fistula, which was without the reach of surgical art. It is not possible to bring pressure to bear on the walls of such fistulae; still less is it possible to slit them open and allow them to granulate from the bottom. We are told that spinal abscesses should not be opened hastily, inasmuch as they may become absorbed, and on the other hand we are directed not to allow them to enlarge to any considerable extent without opening them, as the constitutional disturbance that would follow on their being opened would be attended by risk proportioned to their size. These two rules will be found in practice to be more or less contradictory. If we act on the advice not to open them hastily, we too often give time for very considerable though not always apparent enlargement. If, on the other hand, we do open them early, we, in my experience, all but invariably ensure the death of the patient, and we also deprive him of the chance that the abscess might become absorbed. This seldom happens, but that it does sometimes happen is evident from a careful collation of writers on the subject. I have had myself one such, but only one, out of all my cases; it occurred in a girl aged 30; she was the daughter of a farmer, of healthy appearance, and with a family history which was good, though not wholly free from some suspicion of scrofula. About May, 1875, she strained her back whilst jumping off a ditch, and after more or less medical treatment she came under my care in the following November. At that time she had an abscess in the left iliac fossa, which was about the size of the two hands clenched. She had disease of the tenth and at least two adjacent dorsal vertebrae. The spine of the tenth was very prominent, and those of the two adjacent ones were also prominent, but very much less so. She had had several rigors; the pulse, appetite, perspiration, and the menses were what obtain in a hectic case. She was placed in the horizontal position, and such remedies as suggested themselves, the enumeration of which would but occupy time without communicating any fresh information, employed. She was kept for four months

¹ Read in the Section of Surgery at the Annual Meeting of the British Medical Association held in Dublin, August, 1887.

¹ Read in the Section of Surgery at the annual meeting of the British Medical Association held at Dublin, August, 1887.

in bed, and for three months after that a Sayer's jacket was kept on; she went on favourably in every way, and not only was the Potts' spine cured, with, of course, deformity, but the abscess became eventually absorbed. I examined her with the greatest care on June 21st last, and the following state of things was observed: Her appearance was healthy, though not entirely free from wear and tear; her pulse, temperature, and respiration were natural; a fulness, which when first seen had existed in the left iliac fossa, had entirely disappeared. No trace whatever of the abscess could be found on palpation, or otherwise. A severe pain in the spine, from which she had also on the occasion of my first seeing her suffered, had likewise disappeared. There was some little pain across the hips after sitting, and the left leg was weaker than the right; the bowels were moved every second day. The appetite, urine, and sleep were natural; there was neither perspiration nor vomiting. She could stoop, work, and get jolted in a vehicle without pain or uneasiness. A prominent spine, the slight pain and weakness I have referred to, and menses which were almost *nil* from the start of the disease, comprised the total of the obverse side of the pleasing picture. Though it is quite possible that in this case the remains of a partially absorbed abscess, which might recrudescere hereafter, might still be pent up in parts inaccessible to the sight and touch, yet all the probabilities go the other way, and the case may, I think, be fairly cited as one of those exceptional ones in which spinal abscess gets cured, and the rule of not allowing spinal abscesses to get very large comes in for inconvenient question. Some similar cases have, of course, been reported, but unhappily they are *rari nantes in gurgite vasto*. No one ought, I think, to propose to sacrifice the overwhelming majority for a few chance cases, and therefore these abscesses should be opened, if only a way could be found to obviate the terrible danger arising out of the existence of a long and tortuous line of inaccessible fistulae. I often asked myself, Was it possible that nothing could be done for those sad cases? and it was therefore with no ordinary pleasure that I read Mr. Treves's proposal for dealing with some of them.

Mr. Treves proposed to cut down direct on the bodies of carious vertebrae associated with abscess. He proposed to attain by such an operation four objects:

1. He would come into direct contact with the diseased areas.
2. He would open the suppurative collections at their points of origin, and evacuate their contents by the shortest possible route.
3. He would be enabled thereby to remove pieces of diseased bone.
4. He would be enabled to apply treatment direct to the local tissues.

Mr. Treves, however, proposed to confine it to the lumbar and last dorsal, and he does not state at what period of the abscess he would cut down on the spine. Now, it appears to me that, if the surgeon should wait until the abscess becomes apparent at one of the usual sites, the mere tapping of it at the proximal end, while furnishing an exit for detritus—which, no doubt, now helps to keep the sinus discharging—would not of itself prove sufficient to agglutinate the walls, and therefore dry up such sinuses.

We every day witness the continued patency of long fistulous tracts long after the disease at the proximal end has been cured. I do not see, therefore, how cutting down on the vertebrae, where a large abscess has been allowed to form, can, in the majority of cases, at all events, effect all the good we desire. I do not see either why this operation should be confined, as Mr. Treves proposes to confine it, to the lumbar and last dorsal. Such a restriction seems to me calculated to limit within too narrow a field its sphere of usefulness. I would extend it to the dorsal vertebrae, where it is we find the great bulk of the disease.

I am not blind to the anatomical difficulties which would beset cutting down on the vertebrae here. I do not, however, think that they are either insuperable or indeed at all comparable to those which have been successfully mastered in other regions of surgery. We might expect, for instance, that the pleura would occasionally be perforated, and that pneumothorax would ensue; but we have now a sufficient number of cases of this to prove that it is a very much less formidable affection than it was once supposed to be. It is not to be denied that it is much less formidable than interminable fistulae, whose existence affords a too certain presage of the patient's destruction.

Now for my second point. It will not, I maintain, do to cut down on vertebrae where an abscess can be seen and felt. The diagnosis of spinal caries having been once made, I would anticipate the external appearance of the abscess by cutting down upon the vertebrae at once, and maintain a direct opening with the diseased bodies. If disease should be really present, we might count on the presence of a considerable effusion around the bodies of the vertebrae; and this thicken-

ing might be counted on as a sufficient protection against the premature admission of air to the carious mass. The case of Potts' disease without abscess, if there be any such, would present a difficulty; but the thickening already referred to might here, as in the last case, afford sufficient protection against atmospheric action. On the other hand, if the diagnosis should be incorrect, and no spinal caries should be found to exist, no possible mischief could accrue to the healthy vertebrae themselves.

In conclusion I submit the above note to the Section with a profound conviction that for a disease which is but too often indeed the opprobrium of our art bold remedies offer the only resource.

Dr. ILLINGWORTH deprecated in the strongest possible terms the procedure recommended. The formation of any wound meant the incurring of new dangers. Aspiration, when the pus was fully formed, offered the safest means of prevention of septic processes. Spinal support during the process of aspiration was essential.—Mr. WALSHAM said that he considered Dr. Laffan's a very grave proposal. He understood Dr. Laffan to advocate cutting down on the dorsal vertebrae in cases of spinal caries, for the purpose of preventing the formation of an abscess as well as for the early evacuation of the pus, should such form. Such a procedure appeared to Mr. Walsham fraught with danger, as a deep wound would have to be made, probably a portion of a rib or two would have to be excised, and the pleura might easily be opened. On the other hand, if spinal caries was treated early by recumbency combined with some efficient support, the great majority of cases recovered without any suppuration. In the lumbar region cutting down on the vertebrae, as suggested by Mr. Treves, was no doubt, in suitable cases, of service, but Mr. Walsham would hesitate to attempt such an operation for caries in the upper dorsal region, even when pus had been formed.—Mr. EDWARD L. FREER (Birmingham) was in favour of aspiration where possible; when impossible, recourse should be had to free incision, with antiseptic dressings, weak iodine injections, and free drainage. Some disappeared altogether if the spondylitic vertebrae were kept at rest, so he did not advocate early operative interference of any kind.—Dr. GIBNEY (New York) advocated the directing of treatment to the bones diseased, and claimed that, when sufficient mechanical support, long continued, was provided, it was quite unimportant to give any attention to the spinal abscess. The cases thus managed, in New York city at least, gave satisfactory results. He was convinced that orthopaedic surgeons, as a rule, aimed to fix the spine and seldom treated the abscess.—Dr. LAFFAN, in replying, expressed his astonishment at the amazing number of cures which the speakers had had, and he invited them to authenticate them by publishing them. As for him, he had had no such success; and as far as he could gather, and he had inquired in several quarters since the commencement of the meeting, his experience was not unique. If the disease, therefore, was so fatal, he maintained that for it the remedy he advocated was the proper one. Some of the speakers had talked about the antiseptic treatment, but its advocates asked too much from it. He had tried it in these cases, and it had not saved them. He aimed at two objects in bringing that paper before the Section: the first one was to bring once again under public notice a line of treatment which should recommend itself, if for no other reason, because it had been suggested by so able a surgeon as Mr. Treves; and next, because he desired to extend and develop an operation which, he repeated, alone held out any rational prospects to patients.

TWO RARE GROWTHS OF THE SOFT PALATE.

By CLARENCE ELLERMAN, M.D. HEIDELBERG.

THE two cases which are described at length below present a certain amount of interest, on account of their uncommon occurrence, and this reason, I consider, justifies their publication.

CASE I.—Mr. S., aged 29, a student, came to the Heidelberg throat clinic (Professor Jurasz) to seek advice about his throat. On examination, he was found to be suffering from granular pharyngitis. Moreover, during the exploration of the pharynx, a small tumour was noticed lying somewhat to the right of the uvula, and partially concealed by the same; in length it measured about three and a half centimetres, was elongated in shape, and in colour agreed with the surrounding mucous membrane. To obtain a good view of it, it was necessary to seize it and draw it forward. The tumour was mobile, slightly narrowed at the base, of a soft consistency, and quite painless when manipulated. Its general appearance gave one at first the im-

pression of a large papillomatous growth, like those which, as is well known, are frequently observed at the base of the uvula. This view was, however, not confirmed by microscopical examination. The removal was easily performed without any loss of blood by means of a galvano-cautery snare. It was now for the first time observed that the surface of the tumour was not smooth and continuous, but partially divided into several portions by lateral fissures. It should also be mentioned, as it has its importance, that on the right side of the soft palate, the space between the anterior and posterior arches of the same was unusually large and deep; this appearance was found to be caused by the total absence of any trace whatsoever of the tonsil at its usual resting place. On the left side no such anomaly was apparent. The young man declared that he had never felt any inconvenience from the presence of the tumour, and that he had, in fact, been quite unaware up till now of its existence. The microscopical examination gave the following interesting results: The tumour failed to show any analogy to the characteristic texture of a papilloma, but presented a histological structure unmistakably like that of tonsillar tissue. A careful study soon left no doubt that such was the case. Tonsillar crypts, coated with a fine layer of stratified epithelium, were plainly discernible. The walls of the lacunæ were studded with numerous compact nodules of lymphatic tissue, the so-called lymph-follicles. These follicles presented the well-known reticulated structure, containing in its meshes innumerable leucocytes. The epithelium rested on a fine, almost invisible, basal membrane, which separated it from the mass of adenoid tissue which lay below. Towards the centre the connective tissue of the stroma had taken the place of the adenoid tissue, and was concentrated into a dense fibrous structure very poor in cells. Several large, greatly dilated blood vessels (arteries and veins) traversed it, ramifying towards the periphery. It was, broadly speaking, identical with tonsillar tissue, and there remained no doubt that the removed tumour was an aberrated tonsil.

The case which I have just described may be, I think, accounted a somewhat rare occurrence. However, the fact that similar occurrences seldom are observed is no positive proof that they seldom occur; for it can be readily understood that such tumours, by reason of their unimportant size and the absence of any symptoms of incumbrance, often escape notice, and even when they are now and then removed, they seldom undergo a microscopical examination.

CASE II.—Miss L., aged 28, noticed for some time back that she had a pendulous tumour hanging from the soft palate, which caused all sorts of unpleasant sensations in the mouth, accompanied by a copious flow of saliva. On examination, a long, purplish looking growth was perceived on the right half of the soft palate, lying midway between the tonsil and uvula. It presented a smooth surface, and was of a yielding consistency. It was removed by the galvano-caustic process. On being examined microscopically the growth, which was composed of different papillæ coated with epithelium, presented a peculiarity in respect to the condition of its blood vessels. The first thing that struck one on looking at a section through the microscope was the enormous size and development of the capillary vessels as compared with the size of the tumour itself. (This condition could be easily perceived with the naked eye on holding the section towards the light.) The capillaries were enormously dilated, ran in the centre of the papillæ, and ended in the shape of a bulbous expansion. In some parts the vessels seemed to be unaccompanied by connective tissue. It appeared as though the pavement cells of the epithelium were intimately connected with the endothelium of the dilated capillary vessels. Careful observation, however, showed this view to be a mistaken one; there still existed between the epithelium cells and those of the capillaries a very delicate, almost invisible, partition of connective tissue, which appeared to be in a state of atrophy. At the point where the tumour had been severed, the walls of a large artery were to be seen. Further, in two places, clumps of adenoid tissue were visible, which were evidently to be considered as follicles. The connective tissue matrix was, moreover, in some places very rich as regards cells.

Now this is undoubtedly the picture that would be presented by a plexiform angioma, and this is what I consider it to be. It is, however, not impossible that it originally existed as an ordinary papilloma, and that through the action of the negative pressure, which arises in the pharynx during the motions of swallowing and suction, upon the vessels on the surface of the tumour, the vessels were in a constant state of dilatation, and ectasia was the result. An analogue for this is found in the distension of vessels in granulations which appear at the edges of a tracheotomy wound; in the latter case it is of course the result of the inspiratory dyspnoea.

THERAPEUTIC MEMORANDA.

THE ODOUR OF IODOFORM.

THE odour of iodoform, the *Pharmacopœia* states, is "persistent and disagreeable," and to some these characteristics are so intense that it is avoided in practice, and less efficient agents are used. Various attempts have been made to disguise the odour by oleate of zinc, eucalyptus, coffee, coumarin. The latter substance seems to effect this better than the other agents, but yet it is not perfect.

From a series of comparative trials I beg to offer the following prescription as securing the end in view,—R Iodoform, gr. 60; ol. amygdalæ, ℥jss; ol. theobrom., ℥jss; ol. myristica, ℥xx; moschi, gr. iij; coumarin, gr. vj; sp. tenuior., ℥i. The essential ingredient here is musk. To some people, however, the smell of musk is also disagreeable, and the other substances are added with the view of leaving a pleasant odour, neither of musk nor iodoform. If the iodoform is desired for dusting purposes, as in soft chancres or burns, the combination of 1 grain of musk to 10 or 15 grains of iodoform is satisfactory. These prescriptions have been made up by leading pharmacists here, and they bear willing testimony to the facts mentioned.

MATTHEW CHARTERIS, M.D., Professor of Therapeutics and Materia Medica, Glasgow University.

SMALL DOSES OF MERCURY IN SYPHILIS.

I AM anxious to bring before the profession a plan of treatment which I have tried in cases of primary syphilis for more than ten years, a treatment which has been attended with uniform success, and without any further symptoms after the primary ones have passed away. A modified plan of the same treatment has been most satisfactory in its results in more advanced cases.

The great secret of the treatment consists in the dose, which can be continued an indefinite length of time, enabling the practitioner to sweep out every trace of syphilis; and it will be found that when all the primary symptoms have disappeared no tertiary will follow. Sometimes a slight recurrence of the primary appears, which will quickly yield to a return of the treatment, and I have invariably found that time and patience complete the cure.

My plan has been in cases of hard chancre to give hyd. c. cret. gr. $\frac{1}{4}$ *ter die*, giving any tonic or other medicine with a view to keeping the patient in the best possible state of health, avoiding too much stimulant such as spirits, wine, or beer; this should be followed up for a month or longer at the discretion of the practitioner, when the dose can be given *bis die*, and after three months or longer, once daily for a considerable time. Should the symptoms be rebellious after the third or fourth month, I give in addition liq. hydrarg. perchlor. ℥v—℥x *bis terve*.

I intended to have brought this treatment before the profession several years ago, but was most anxious to be sure of my statements as shown by many typical cases which I have kept in view for many years.

S. C. GRIFFITH.

Finsbury Square, E.C.

STROPHANTHUS IN HEART DISEASE.

DR. SUCKLING'S memorandum on his experience of strophanthus in heart disease comes as a thunderbolt: it certainly is at variance with the general opinion of the profession. I have used Hewlett and Sons' tincture for the last six months with immense advantage in heart affections, more especially in cases where digitalis seemed to be doing more harm than good. I quite agree with Dr. Suckling that digitalis will often do good after strophanthus has been given without relief, but this simply proves that the action of the two drugs is not the same. Strophanthus has, in several of my cases, produced an intermittency in the heart's action, always relieved by increasing the dose, (this symptom I have never seen mentioned by other observers). The salicylates can be given in combination with strophanthus when they cannot be borne alone on account of their depressing action on the heart. In conclusion, I may say strophanthus is of inestimable benefit in inorganic heart affections.

EDWARD G. DUTTON.

THE TREATMENT OF HABITUAL CONSTIPATION.

AN hour after reading the memorandum of Dr. Althaus, p. 1379, on Dr. Oiltmann's method of treating the above affection, I had an opportunity of trying it. Two days before I had performed herniotomy on an old man aged 74, and found that morning very distressing meteorismus, with a rising temperature, which opium had not prevented. The remedy was obviously to empty the colon with the least

amount of irritation, and I at once injected a teaspoonful of glycerine into the rectum. Within five minutes there was a copious dejection and much flatus followed, to the thorough relief of my patient, who is now convalescent.

But the point is this: As soon as I had asked for the glycerine and injected it, the nurse observed: "That was Mr. Warden's favourite plan, he said it was better than all the pills in the world," and this gentleman died in practice here about sixteen years ago. Truly, "*Nihil sub sole novi!*"

G. F. CADOGAN-MASTERMAN.

Stourport, Worcestershire.

A DANGEROUS MIXTURE.

SEVERAL prescriptions have lately come under my notice in which occurs a mixture of chlorate of potash and syrup of iodide of iron. This seems a not unreasonable combination, and its incompatibility does not suggest itself, nor will it be found on reference to ordinary textbooks. As, however, a case has recently been reported from Australia in which death resulted from the administration of such a mixture, I think it desirable that the attention of prescribers and dispensers should be drawn to the fact that chlorate of potash liberates the whole of the iodine from iodide of iron, and, if at all concentrated, the solution soon becomes saturated, and crystals of iodine are deposited after a few hours. The products of the decomposition are shown in the following equation:

Further details of the reaction may be found in the *Pharmaceutical Journal*, vol. x, p. 850, and in the *Journal of the Chemical Society*, 1880, vol. xxxviii.

Heat favours the reaction; and the process, which may be slow in the medicine bottle, would be much more rapid in the stomach, where the development of nascent iodine might produce symptoms of gastric irritation which were neither expected nor desirable.

R. H. PARKER.

OBSTETRIC MEMORANDA.

A CASE OF TRIPLETS: THREE HEAD PRESENTATIONS.

I was sent for at 4 A.M., on December 27th, 1887, by our midwife, to see Mrs. D., as her labour pains had quite ceased. Labour had commenced about 3 P.M. the previous day, but the pains had never been severe. On examination I found the head low down; I gave a dose of ergot, and as it had no effect I repeated the dose in twenty minutes. This had no effect, so about 5.30 A.M. I applied the short forceps, and delivered her of a female child, without any difficulty. On examination of her abdomen I found there was another child; I examined by the vagina, but could not make out any presentation. I waited an hour, and as no pains came on, I determined to leave Mrs. D., as the midwife was perfectly able to take charge. I looked in a couple of times during the day, but things were *in statu quo*; however, at 8 P.M. I could make out a head presentation. At 8.30 A.M. the next morning I was sent for, and found the second child born without any assistance, and the midwife informed me that there was a third to come. I examined, but could not make out the presentation. At 8 P.M. I was sent for, and found the child low down, and as the woman had been over fifty hours in labour, I applied the short forceps and delivered her of the third female child, the largest of the three. With some difficulty I removed two placentae; the first one was very large, and had two umbilical cords attached to it; the third placenta which was a full-sized one, had only one cord, and evidently belonged to the last and largest child. The mother has made an uninterruptedly good recovery, and the three little girls are thriving very well. The woman was a primipara, aged 29.

Tenby.

JOHN GRIFFITH LOCH.

CLINICAL MEMORANDA.

CASE OF CANCER OF THE PANCREAS, WITH ULCERATION AND HÆMORRHAGE INTO THE STOMACH.

Mrs. S., aged 61, was first seen February 26th, 1887. She was said to have been ailing a long time, but had been very ill for the last six months. Her complaints were constipation, flatulence, and aching or colicky pains, chiefly referred to the umbilicus and lower left abdominal region, backache and nausea, with increasing emaciation. There was

a fulness, tenderness on pressure in epigastrium, to the left of the middle line, with abdominal aortic pulsation immediately below. There was no jaundice and no fatty stools.

She had two slight vomitings of dark blood, one on March 15th, when I found her with a thready pulse, collapsed and cold, having brought up a teacupful of blood; the second about two hours before her death on March 20th, when she complained of feeling "something burst in her inside," and vomited to about the same amount. No blood ever appeared in the stools.

Necropsy on March 21st.—Rigor mortis was well developed. The skin was of a waxy colour. The lungs collapsed and pale. The heart small; all its chambers empty. The left ventricle firmly contracted; the other chambers flaccid, and their walls very thin; muscular substance of a dull brown colour. The outside of the organ heavily loaded with fat. On opening the abdomen the liver was found stretched quite across the upper part of that cavity, the left lobe in close contact with the under surface of the diaphragm, extending well into the left hypochondrium, and overlapping the stomach. On removing it the stomach appeared beneath as a large blue tumour, which, when opened, was found to be completely distended with blood, immense black coagula being turned out through the incision. The pancreas was enlarged and nodular, its substance infiltrated with cancer. It was closely adherent to the stomach and duodenum. A large ulcerated cavity occupied its central part, which communicated by a ragged opening with the stomach. At this point a vessel, the size of a goose-quill, apparently a branch of the celiac axis, had been opened, and from it the bleeding had evidently occurred. The spleen was small and friable. The blood vessels generally were empty, and appeared to have been thoroughly drained by the bleeding which had taken place into the stomach.

A. MIDDLEY CASH, M.D.

Torquay.

SURGICAL MEMORANDA.

ACCIDENTAL CURE OF HYDROCELE.

J. H., aged 50, an engine-driver, has had a hydrocele for the last ten years. I have tapped it on three occasions, and drew off (1) 14½ ounces, (2) 16 ounces, and, lastly, 17½ ounces of fluid. He would never sanction the injection of iodine. A fortnight ago, whilst carrying a heavy basket, he rubbed the rim of the basket against the hydrocele, which was about ready for tapping again. The whole sac inflamed, and then subsided, and to-day the scrotum, when examined, appears quite natural, and bears no traces of ever having been distended by about a pint of fluid.

REPORTS

OF

HOSPITAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN, IRELAND, AND THE COLONIES.

MANCHESTER ROYAL INFIRMARY.

SUTURE OF TENDONS.

(Under the care of Mr. T. JONES, F.R.C.S.E.)

CASE I.—F. L., aged 35, was admitted on September 9th, 1887. Three months previously she had cut her right hand severely whilst cleaning a window. The wound healed well. On admission, it was found that she could not flex the middle finger of the right hand. Several scars were visible, one more prominent than the others, running in a transverse direction, half an inch in front of the superficial palmar arch, and situated over the third metacarpal bone. Half an inch above this cicatrix, a small rounded elevation could be felt, which was looked upon as the proximal end of the cut tendon. Under chloroform, an Esmarch's bandage having previously been applied, a vertical incision, an inch and a quarter in length, was made, its centre placed over the rounded projection above referred to. The proximal end of the tendon was readily found, and the distal, after a little difficulty; the latter was closely adherent to the sheath. These adhesions having been separated, an attempt was made to approximate the ends of the severed tendon, but it was found that the tension was very considerable. The following plan had then to be adopted. An incision was made into the proximal end of the tendon, in a transverse direction, and taken as far as its centre; the knife was then carried forwards, so as to split the tendon downwards in the middle, to within

an eighth of an inch from its divided end. The flap of tendon so separated was now turned forwards and stitched to the distal end by means of catgut. There was little or no hemorrhage when the bandage was removed; the wound was well washed with a saturated solution of fluosilicate of sodium, and the edges brought together with silver sutures. The finger was kept flexed for nearly three weeks, when it was found that firm union had taken place, and considerable resistance could now be offered to any attempt at passive extension of the finger. Two months later, she could flex the finger without any difficulty, and was able to follow her ordinary housework; previous to the operation she had been unable to do so.

CASE II.—J. W., aged 31, a Sawyer, was admitted on September 22nd, 1887. A few hours previously, his right hand had been caught by a circular saw. On admission, he was found to be suffering from a lacerated wound of the right hand, on the ulnar side of the dorsum; it was about one inch and a half in length, and extended in a direction upwards and inwards, its centre being situated over the knuckle of the fifth metacarpal bone. The extensor tendons of the ring and little fingers were divided, and the head of the fifth metacarpal bone was splintered.

On the afternoon of the same day, under chloroform, the splintered portions of the head of the injured metacarpal bone were removed, about a quarter of an inch being taken away altogether from the lower end of the bone. The cut tendons were then sutured with catgut, the divided ends being brought into apposition; the wound having been well washed with carbolic lotion (1 in 20), was sutured with silver wire, and dressed with iodoform gauze and a weed-wool pad. The fingers were fixed in an extended position on a straight splint, the anterior part of which was well padded.

The patient got on very well after the operation; the temperature remained normal. The wound healed by granulation, and, when sent to Cheadle thirteen days after the operation, a healthy granulating surface was visible.

December 20th The patient came to show himself about a fortnight ago; he could extend his ring and little fingers quite well, and was able to follow his occupation.

The patient was presented to the meeting of the Manchester Medical Society on December 21st, 1887; the parts were soundly healed, and the power of active extension had been restored in the injured fingers.

CASE III.—T. L., aged 21, a Sawyer, was admitted on September 19th, 1887, suffering from a cut hand. He had caught his left hand in a circular saw, causing a lacerated wound about one inch below the wrist, extending from the dorsum of the fifth metacarpal bone at its inner side, round to the palm of the hand, extending a little forwards, as it went round, as far as a point one inch and three-quarters from the ulnar border of the hand. The tendons on the dorsum were intact; but the flexor tendons of the fourth and fifth fingers were completely divided. Under chloroform, the divided ends of the tendons were found, but with great difficulty, owing to the great laceration of the tissues and the bleeding into the tissues; the divided ends were drawn together, and made to overlap slightly, being fixed by means of catgut sutures. The wound was then well washed in carbolic lotion (1 in 20), several wire sutures being inserted; a horsehair drain was introduced. After dressing it with iodoform gauze and weed-wool, a posterior splint was applied, so as to flex the wrist and fingers, the elbow being kept in a flexed position by means of a bandage round the neck, serving as a sling. The temperature was irregular for the first few days, but soon came down; the wound healed by granulation. For domestic reasons he was allowed to go home on September 24th, 1887, and was made an out-patient.

When seen on December 21st, he was found to possess very good use of his ring and little fingers. There were, however, some adhesions between the cicatrix and the deeper structures; and it is suggested to separate these, in order to render the movements of the fingers still more free.

TRALEE UNION.—The Local Government Board, Ireland, have sanctioned the appointment of Dr. Hayes as medical officer of the Tralee No. 1 dispensary district. When elected, Dr. Hayes's salary was fixed at £100 per annum; but notice of motion has been given to increase it to £120, as unanimously recommended by the dispensary committee.

THE RAMSGATE SHOOTING CASE.—Dr. Savage and Dr. Forbes Winslow, who were officially appointed to visit the prisoner, Richardson, at Canterbury, with a view to forming an opinion as to his mental condition, have expressed the opinion that at the time of the act he was of unsound mind, and that he continues in the same state.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, JANUARY 17TH, 1888.

Sir JAMES PAGER, Bart., F.R.S., F.R.C.S., President, in the Chair.

Vaccinia.—Dr. KLEIN, F.R.S., exhibited and demonstrated the residues of vaccinia in the calf which Professor Crookshank had exhibited to the Society on December 15th. This calf had been inoculated by Professor Crookshank in the second generation from the Wiltshire boy, also shown to the Society on that occasion. This animal had subsequently been inoculated with cow-pox at the National Vaccine Establishment, and when exhibited to the Society on this second occasion the calf presented well-marked vaccinia. Another calf, also inoculated under the same conditions by Professor Crookshank, also took vaccinia when subsequently inoculated at the National Vaccine Establishment. These facts Dr. Klein had expressed in the following table:

WILTSHIRE BOY.

Calf 1, did not take.	Calf 2, did not take.	Calf 3, took.	Calf 4, took.
		Calf 5, took.	Calf 6, did not take.
			Calf 7, took.

Calf 3 was further inoculated with Warlomont's lymph, but did not take.

Calf 4 was further inoculated with human lymph in six places; result doubtful. Calf 5 was further inoculated with cow-pox at Lamb's Conduit Street Animal Vaccination Station; it took well.

Calf 7 was exhibited at the Pathological Society on December 15th. It was further inoculated with cow-pox at Lamb's Conduit Street Animal Vaccination Station; it took well, and was again exhibited to the Society on January 17th.

Dr. Klein considered that the experiments had been spoilt, owing to calf 3 having been inoculated with stored calf lymph, which it was known was not reliable; and to calf 4 having been inoculated with lymph from a child's arm. A calf vaccinated at the National Vaccine Establishment in the ordinary course, was also exhibited for comparison.

Carcinoma of Gall Duct.—Dr. NORMAN MOORE showed specimens of primary carcinoma of the common bile duct. The first case was that of a man aged 44; the microscopic section seemed to show the development of the carcinoma from the large flattened epithelial cells of the common duct, and its extension outwards into the duct wall. The cells lay in the meshes of a well-developed stroma. The liver was only slightly affected at a few isolated points; the lumen of the duct was enlarged, and the surface slightly bile-stained. The ducts in the liver were not dilated, and there was no cirrhosis. Jaundice and emaciation were the most noticeable symptoms. No carcinoma was present in other organs. The second specimens were from the case of a woman aged 63, and had been made through a dense mass of new growth, which occluded the common and the cystic ducts. The gall bladder was adherent to the walls of a small hydatid cyst, containing caseous material; there were no deposits in the liver, the bile ducts in the liver were dilated, and that organ was cirrhotic. No secondary growths were found in other organs. The tumour was an epithelioma. The most prominent symptoms were pain, jaundice, emaciation, and hepatic enlargement; they had existed for two years, but had been severe for only six months. The diagnosis in these cases was difficult, and had not a careful microscopical examination been made, the first case shown might have been set down to catarrh of the bile ducts.

Abscess of Brain and Adenoma of Pituitary Body in a Ewe.—Mr. W. K. SIBLEY showed specimens taken from a ewe, aged 2 years. The animal had been apathetic, ill, blind, and deaf for some time. It was killed, and the *post-mortem* examination revealed pleural adhesions, small nodules in the lungs, and a large abscess in the right cerebral hemisphere; there was general meningitis. The nodules in the lungs were due to nematode worms (*strongylus pilaria*), such as were frequently present in the lungs of sheep. The bronchioles contained vegetable debris. Sections of the pituitary body presented all the appearances of an adenoma. The lungs also contained small abscesses. He discussed the mode of origin of the cerebral abscess, and rejecting the theory of pyæmia, suggested that this was the primary lesion, and that it had been set up by disease of the cranial bones which had been found after death. The morbid condition of the central nervous system might have disturbed the normal correlation of nerve-influence between the brain and the pulmonary tissue, lowering the vitality of the latter; this lowered vitality permitting the breaking down of the consolidation produced by the parasites, which on this theory would be attributable not to pyæmia but to a

trophoneurosis. Mr. Sibley also commented on the rarity of tumour of the pituitary body.—Professor BROWN said that it was rare to meet with an specimen of the lungs of the sheep in which these nematode worms were not present. Vegetable debris frequently found their way into the bronchi in the death struggle.

Cystic Epithelioma of Neck.—Mr. SYMONDS read notes and showed microscopical sections of a case of cystic squamous epithelioma of the neck. The patient, a man aged 56, came to Guy's Hospital in August, 1883, with a tumour in the right side of the neck. It extended from the angle of the jaw to the middle of the thyroid cartilage and from the sterno-mastoid to half an inch across the median line. It was connected with the thyroid cartilage and over the centre the skin was adherent; otherwise the tumour was fairly movable. It was freely circumscribed and gave an indistinct sense of fluctuation. There was no evidence of nerve implication. No ulcer or growth could be found in any part of the mucous membrane of the mouth or pharynx, so that the growth was considered to be a sarcoma, though the brawny condition of the implicated skin, the position to the larynx, and the pain resembled more closely the epithelial growths. The mass was extirpated on September 7th, the vertical elliptical incisions including the infiltrated skin. It proved to be widely and closely adherent, and its removal involved sacrifice of portions of most of the muscles in the submaxillary region and one inch of the internal jugular vein. The pharynx and sterno-hyoid membrane were exposed, as well as most of the chief arteries and nerves. The growth proved to be a large thick-walled cyst filled with sanious fluid containing flakes of epithelial debris. Several enlarged glands were also removed. The wound united without suppuration, but in four weeks recurrence had taken place to an extent rendering all operation useless. The wall of the cyst was five-eighths of an inch thick, white on section, and showed under the microscope a typical epitheliomatous structure.

The Relation of the Hendon Cow Disease to Scarlet Fever.—Professor CROOKSHANK, before reading the paper which is published at p. 122, protested against his calf (7 in above table) having been exhibited without his having been consulted. He did not object to the Society seeing the calf, because he wished to tell them that it was not protected. The three calves 5, 6, and 7 were inoculated from calf 4 on the seventh day of the eruption, when, that is to say, it was in the pustular stage, and Bryce had pointed out that the fluid in the vesicles in the advanced stage was unfit for propagating vaccinia; the attainment of this stage was marked by the fluid becoming puriform. The calf shown by Dr. Klein on the present occasion was inoculated after the lymph had become puriform. Four calves were inoculated direct from the Wiltshire boy; two of these took and two did not.¹ In the two calves which took revaccination, so far, had completely failed. Three calves were inoculated from one of the two first which had taken, but as had been said this inoculation had unfortunately been made rather too late—namely, after the fluid had become puriform. The two calves were therefore not protected, as was known would probably be the case from the writings of Bryce.² It was one of these calves, which had been vaccinated at the National Vaccine Establishment which Dr. Klein had brought to the meeting. He (Professor Crookshank) thought that if this was to have been done, it would have only been fair to have shown one of the first calves that had not taken when revaccinated. He thought that for one observer to publish part of the as yet unpublished researches of another, and to show one of his animals without his having been consulted, and been allowed to give his version of the results, was an event unparalleled in the history of the Pathological Society of London. Professor Crookshank also showed a boy, a milker, from Wiltshire, who had suffered from the spontaneous disease; he presented depressed scars on the back of his hand. He asked the Society to test the accuracy of the drawing he had shown at the special meeting of the Society.—Dr. KLEIN said that Professor Crookshank had given a great many facts about the *micrococcus pyogenes*, but he had not said anything new about the micro-organism which he (Dr. Klein) had observed in scarlet fever, nor given any observations of his own about it. This was the important point, and Dr. Klein said that he maintained that the micro-

organism which he had found in the Hendon cows and in human scarlet fever was not the same as the *micrococcus pyogenes*. Professor Crookshank had, indeed, said that he was under the impression that the two organisms were the same, but in reality he would not be competent to express such an opinion until he had accepted Dr. Klein's offer to present him with the *micrococcus scarlatinae* in order that he might compare them. Professor Crookshank showed microscopical sections of the kidney of one of the Wiltshire cows containing streptococci, but this cow had a large abscess in the udder, and Dr. Klein, who had also examined the kidneys, had proved them to be full of milary abscesses, that is to say, the animal was suffering from pyæmia; such a condition could not be compared with the description he had given of the morbid changes in the Hendon cows. Again, the sections of the ulcers of the skin had been made in the second week of the disease, and could not be compared with his descriptions of ulcers examined in the first week. There were also marked clinical differences. Dr. Klein dwelt especially on one, namely, that in the Hendon cows the ulcers only commenced on the fourth, whereas in the Wiltshire cows they were at their height on the fifth day. In the Edinburgh cows, to which he had referred at the special meeting in December, the ulceration occurred still later. So that they probably had to do with three diseases, and not one. He maintained that the symptoms in these three diseases were different, that the progress of the ulceration were different, and as to the Hendon cows and Wiltshire cows that the *post-mortem* appearances and micro-organisms present were different.—Dr. COLLINS had visited the Wiltshire farms with Dr. Crookshank, and was able to corroborate the local evidence brought forward; the milkers stated that the disease was rare, but was not unknown to the older of them; they named it cow-pox.—Dr. THORNE THORNE concisely summarised the different statements in relation to the whole question, and showed that no conclusion could be drawn from such conflicting evidence. Of the Hendon cow disease Professor AXE had said that it was a well-known and a common disease, he had seen it often, and that, whilst it was prevailing, two boys became inoculated and developed vaccinia, and that, therefore, the Hendon cow disease was exonerated from any participation in the outbreak of the London scarlet fever. Dr. Crookshank stated that it was a well-known and not an uncommon disease, and adduced a case in which a boy was inoculated and developed vaccinia. In contrast with these statements Dr. Thorne remarked that in 1880, when the Local Government Board established a calf vaccine station, Dr. Buchanan spared no pains to find a case of genuine cow-pox wherewith to start the inoculations, and could find none. Lately certain calves and certain boys were inoculated; but the boy shown that evening by Dr. Crookshank as having caught cow-pox from the diseased cows presented old large vaccine marks of the usual kind on the arms; again, the calves which Dr. Crookshank had inoculated had been three or four weeks subsequently inoculated at the calf vaccine station with vaccinia, and had developed the typical disease. The speaker considered that the only precise investigation was that originally undertaken by Drs. Power, Cameron, and Buchanan; and he thought that the evidence adduced by these writers in regard to the Hendon cow disease was reliable.—Professor BROWN concurred with the last speaker in his view that the whole subject was at present in hopeless confusion.—Dr. PRINGLE stated that during thirty years of service in India, he had seen no case of cow-pox in the cow. Small-pox was quite common in the natives, but he had never seen it communicated to the cow. In two cases of apparently true vaccinia in the cow, he had inoculated children and calves from the clear fluid, but had uniformly failed to communicate the disease; and he contended that the possibility of transferring the disease was the sole reliable means of establishing its identity.—Dr. COEY observed that the cicatrices on the hand of the boy shown that evening by Dr. Crookshank were not those of typical vaccinia.—Professor CROOKSHANK, in reply, denied that he had asserted cow-pox to be very common in the cow; it might occur in outbreaks at long intervals; moreover, many outbreaks would be successfully kept back from sight owing to the injury farmers would suffer from their disclosure. As regards the boy exhibited, the disease bore resemblance to that described by Jenner; and with respect to the incommunicability of the disease to the calves which were subsequently successfully inoculated with vaccinia, he pointed out that the lymph with which the calves were first inoculated was taken beyond the proper date, and that this would account for their escape.—The PRESIDENT commented on the singular likeness between the disease on the face of the boy previously shown by Dr. Crookshank and Coely's drawings of vaccinia. He remarked that Professor Klein held that there were three different diseases under discussion; and in face of the more recent differentiation of disease in man, he could not help believing that the same would be found true of disease in animals.

¹ "The above experiments, however, will serve to show the greater difficulty of vaccinating the cow with humanised than with primary lymph, and that when successful a much milder disease is the result." "Vaccine lymph in passing from the cow to man undergoes a change which renders it less energetic on being returned to many individuals of the class producing it." (Coely.)

² "The fluid contained in the vesicle in the advanced stages of cow-pox has undergone a certain stage whereby it is rendered unfit for propagating this affection so as to give security from true small-pox, and this change is said to be marked by the puriform appearances which the fluid then assumes." "The areola is fully formed, and this is said to be a mark that the virus begins to be active, and therefore improper for use." (Bryce.)

CLINICAL SOCIETY OF LONDON.

FRIDAY, JANUARY 13TH, 1888.

W. H. BROADBENT, M.D., F.R.C.P., President, in the Chair.

Obstruction of the Bowels by large Gall Stones.—Dr. MACLAGAN read notes of cases. Case I.—Between the middle of July and April 6th this patient had four different attacks, each lasting from three to six days, all characterised by acute griping pain in the abdomen, sickness, nausea, and temporary obstruction. About a fortnight after the last attack the patient voided at stool first one, then another, then a third, and two days later a fourth gall stone. The stones (which were shown) averaged about an inch in diameter. During the whole illness there existed a tumour about the size of the fist between the umbilicus and the liver, just to the right of the middle line, in the region of the gall bladder. After the stones were voided there was no more severe pain, but constant nausea. The liver increased much in size all over, and very rapidly. The patient gradually sank and died. On *post-mortem* examination, the liver was found to be very much enlarged and fatty. The gall bladder communicated with the duodenum by a free opening. There was much inflammatory thickening all around. A fifth gall stone was found in the remains of the gall bladder. In Case II, there was a swelling of the size of a hen's egg in the region of the gall bladder, tender on pressure. This suddenly decreased in size. Immediately succeeding this diminution there were developed symptoms of acute intestinal catarrh, followed in a few days by those of intestinal obstruction. The obstruction lasted for three weeks, and was then relieved. Treatment was by morphine and nutrient enemata. The patient gradually improved, and continued to do so for six or seven weeks, after which she again had a recurrence of the old symptoms, with renewed obstruction, lasting for a fortnight. A third attack supervened. At the same time the temperature rose, and marked tenderness was developed over the region of the liver, and the patient gradually sank and died. No *post-mortem* examination was obtained. After the first attack was over, there was felt to be something in the right iliac fossa, causing tenderness on firm pressure, and preventing one from getting the hand freely into the fossa. This continued for a fortnight. The tenderness then disappeared, and the hand could be pressed into the fossa. At the same time a hard lump was felt just above the crest of the right ilium. This was believed to be the stone, which had passed from the cæcum into the ascending colon.

Laparotomy for Obstruction from Gall Stone: Recovery.—Mr. CLUTTON described the case, which was that of a woman of 70 years of age, whose abdomen was opened on account of obstruction, which was thought to be due to an impacted gall stone. The calculus, being felt in the lower end of the ileum, was pushed through the ileo-cæcal valve. The patient was relieved of her symptoms, and made a perfect recovery. Mr. Sidney Harvey, under whose care the patient had been for some years, was able to diagnose the probable presence of an impacted gall stone from the fact that, fifteen months before, she had passed a large faceted biliary calculus, and from that time, as long as she remained under treatment, he was unable to find a tumour in the position of the gall bladder. The symptoms of obstruction began about twenty-four hours before the operation was performed, with sudden acute pain in the abdomen, and vomiting. On examination, Mr. Harvey found that the tumour in the position of the gall bladder had disappeared. The operation was undertaken at this early period on account of the age of the patient, the exhaustion that had already been induced, and in the hope that the stone which was believed to be the cause of obstruction could be pushed through the ileo-cæcal valve without opening the intestine. This proved to be the case, for the calculus was found close to the valve, and movable. Some difficulty was experienced in pushing it through the ileo-cæcal valve in the colon; but, this having been overcome, the calculus was left to find its own way along the rest of the large intestine, and was passed naturally in five days after the operation. The calculus was pyramidal in shape, the base measuring 3.3-10 inches in circumference.—THE PRESIDENT said that these cases raised two questions: namely, the value of laparotomy for cases in which large gall stones were in the small intestine, and the time at which the operation should be done. In one of Dr. MacLagan's cases (in which he himself had also been consulted) the gall stone could be felt in the bowel, near the ileo-cæcal valve. It was interesting also to notice that the swelling at the gall bladder disappeared just as the intestinal obstruction commenced. He himself had only seen one case of acute intestinal obstruction by gall stones; that was in a patient aged 90, and was fatal in four or five days. The gall stone was found, on inspection, not to have travelled more than half the length of the small intestine. He asked whether it would be safe to open the bowel and remove the

gall stone on the spot, or whether it would not be better to attempt to pass the stone through the remainder of the small intestine to the colon, as done by Mr. Clutton; whilst Dr. MacLagan's case gave much encouragement to wait, as the stone might eventually pass naturally?—Dr. ORD said he had seen three cases of obstruction of the intestine by gall stone. The first was that of an old lady who had had several attacks of biliary colic, and at last one of extraordinary violence, at the end of which she passed a stone not at all unlike that shown by Dr. MacLagan. In twenty-four hours, however, she had another attack, with vomiting and symptoms of peritonitis and obstruction. She died shortly afterwards, and at the *post-mortem* examination a stone, as large as the top of one's thumb, was found tightly grasped by the wall of the small intestine, not far from the ileo-cæcal valve. It seemed to have entered through the gall duct, the liver end of which was markedly dilated. The stone seemed to have worked its way down the tube, until quite near the end, when it had rent the tissues to get into the intestine. In similar cases he should tend to adopt the principle of waiting, whilst using opium to relieve the spasm; though his next case told the other way. This patient he had seen with Mr. Thomas Smith. She was a lady over 65 years of age, in whom acute signs of obstruction of the bowels had suddenly occurred. There had been no previous history suggestive of gall stones. Mr. Smith opened the abdomen and drew out a gangrenous, or almost gangrenous, piece of intestine, but he could at that time find no obstruction. At the *post-mortem* examination he found, just above the semi-gangrenous portion, a large gall stone measuring $\frac{3}{4}$ inch by 1 inch. The third case was in a woman, who, soon after her confinement, and not having had any signs of biliary colic, had a sudden attack of obstruction of the bowels not far within the sphincter, where a hard substance was felt, which turned out to be an impacted gall stone. This was of so large a size that it must have ulcerated through into the intestine, yet without giving rise to any pain or jaundice.—Dr. GIBBONS quoted a case in which the patient had suffered for some years from biliary calculi, and had been put on a milk diet by her medical attendant, with the view of preventing any further formation. For some weeks previous to her death she had been, for her, in good health, but about ten days before her death she was seized with violent pain in the abdomen, and all the signs of biliary colic. She recovered from this, but for two or three days before her death she felt unwell, and sent for her doctor. In the night she was seized with a fit of vomiting, and fell back dead. The *post-mortem* examination revealed the presence of a large stone, which had passed along the bowel and become arrested near the cæcum, which had been perforated, causing collapse and death.—Mr. BARKER showed a calculus which he had removed from a lady *post-mortem*. It had ulcerated its way into the duodenum, and had passed down to the upper part of the ileum, where it was tightly grasped by the bowel. It could not be moved downwards, though it could be easily pushed upwards. It would, therefore, have been very difficult to press it down through the ileo-cæcal valve, as recommended by Mr. Clutton. The stone measured four inches in circumference. At present he would have operated on the patient, who was under Sir William Jenner, Mr. Erichsen, and others.—Mr. CHRISTOPHER HEATH said he had no experience of operative interference in these cases, but he had certainly obtained good results in renal calculi by rubbing. He thought it was quite possible that, with the patient under chloroform and the abdominal walls quite relaxed, the stone might be pushed on through the ileo-cæcal valve. He said that the results of operative interference were not such as to inspire too great confidence.—Mr. KNOWSLEY THORNTON congratulated Mr. Clutton on his successful operation, which he could not help contrasting with Dr. MacLagan's case, in which the waiting plan was not very successful. He thought it would be better generally if surgical interference in these cases was prompt, and if the stone was pushed down before the intestine became inflamed. He suggested that it was probable that the stone "played" up and down, until it caused irritation and became gripped. In respect of the operation, he alluded to Mr. Lawson Tait's suggestion that the stone should be pushed to a healthy part of the intestine and there crushed with padded forceps; for these stones were generally easily broken with very little force. Or they might be split up by puncture with a fine needle passed into them through the coats of the bowel. The fragments could then be pushed on through the ileo-cæcal valve. Very little risk was caused by such puncture of the intestine.—Mr. GANT mentioned the case of a man in the Royal Free Hospital, who was admitted with acute peritonitis, radiating from the cæcum. The abdomen was opened, and the intestines were examined. No obstruction, however, was found, and, although the operation afforded

some relief, the patient died. At the *post-mortem* examination there was found ulceration near the ileo-caecal valve, and a gall stone was discovered lying behind the bowel outside the peritoncum, on the quadratus lumborum muscle.—Dr. GLOVER remarked on the cases treated simply by the administration of 12 or 16 ounces of olive oil, by which the passage of the stones was said to have been much facilitated.—Dr. MACLAGAN, in reply, said that in Dr. Ord's case the stone was so large that it was probably ulcerated through into the transverse colon, and not into the small intestine. As regarded the question of operative interference, if the mass in the gall bladder consisted of one very large stone, which was so large that it could not pass through the small intestine, one should advise operation; whereas, if the mass consisted of three, four, or more stones, as they could probably each pass along the bowel, one might in that case counsel delay. Both his cases had died of inflammation of the liver, not of inflammation of the small intestine. Mr. Clutton had advised speedy operation, and had said that the stone would generally be found near the ileo-caecal valve. But as it required some time to enable the stone to travel to that point, it probably would not, if the operation were done at an early stage, be found so low down. The rubbing which was resorted to in his case was to relieve the tenseness of the abdominal wall, not to assist the onward progress of the stone. He did not think in his case the administration of oil would have done any good.—Mr. CLUTTON said that his remarks in favour of early operation applied only to cases of urgent obstruction. In Mr. Treves's book were recorded twenty cases of acute intestinal obstruction, due to gall stones; of these, fourteen had died, and only six recovered.

HARVEIAN SOCIETY OF LONDON.

THURSDAY, JANUARY 5TH, 1888.

EDMUND OWEN, M.B., F.R.C.S., President, in the Chair.

Sporadic Cretinism.—The PRESIDENT showed a case of this disease which had been sent to him by Dr. Davson; the child, aged 5½, had been born in the Hampstead district, of healthy parents. She looked about three or four years younger than her actual age. She had been weaned at three years, but was still fed from the bottle. Amongst the chief clinical features were the large mouth and protruding tongue, and the absence of all trace of thyroid gland; the presence of diffuse tumours over the subclavian triangles, and of large and rounded limbs. The child could not walk or stand, neither could she speak. Reference was made to a valuable paper which was contributed nearly forty years ago by Mr. Curling on two similar cases, in which he suggested that the physical and intellectual defects in those children were probably due to absence of the thyroid gland depriving the economy of certain assimilative processes. Mr. Owen then referred to the work of Kocher, Ord, and Horsley upon the subject of cretinism, which he called the myxoedema of childhood. He was of opinion that the characteristic deposits in the neck, as also those which shrouded the muscles of and thickened the limbs, were the result of mucoid infiltration of the subcutaneous tissue, and not of the nature of fat. He concluded by calling attention to the importance of Mr. Horsley's vivisection experiments upon monkeys, by which it had been amply shown that the removal of the entire gland was likely to be followed by progressive myxoedema.—Mr. VICTOR HORSLEY thought the case a striking example of the disease. With reference to the kind allusion of the President to his own work, he wished to mention that Munk of Berlin had challenged his results. As he would take another opportunity of replying to Munk's statements (which could be easily explained), he wished only to remark on what appeared to him to be the most pressing problems connected with the destruction of the thyroid in these cases. There were three forms of the one disease resulting from atrophy of the thyroid. They were: (1) intra-uterine cretinism (child always born dead); (2) sporadic cretinism of childhood, in which there was early extra uterine loss of the gland; (3) adult cretinism, or myxoedema of middle life. Now, we were familiar in the last form with the congestion of the gland, its invasion by leucocytes, and its subsequent atrophy, with destruction of the gland tissue, but we were ignorant of what like destroying changes occurred in the thyroid in the first two forms. The solution of that question he desired to urge upon the attention of pathologists. In conclusion, he agreed with Mr. Owen that the resiliency of the arms seemed more than fat and connective tissue would account for, but he thought we must be very cautious in attributing the whole to mucin, for, as he himself had shown, this element in the case was wanting where the chronicity of the disease was notably increased.

Extensive Tubercular Disease.—Mr. QUARRY SILCOCK showed a case

of a young man, who was admitted to St. Mary's Hospital in June, 1886, suffering from tubercular arthritis of the left ankle-joint, tubercular nephritis, and tubercular abscesses on the front of the sternum. After consultation, he had amputated the leg in the lower third, and scraped the tubercular abscess, the man's general condition greatly improving; the hæmaturia diminished in amount, the abscess on the front of the sternum cicatrised, and the stump had practically healed when the patient left the hospital. Subsequently, however, the stump was damaged by a fall, a tubercular periostitis of the upper third of the fibula resulting therefrom, which, although scraped and otherwise combated, was exceedingly intractable to treatment. Accordingly amputation through the condyles, after the method advocated by Sir Joseph Lister, was done in June, 1887, with excellent results, for although the nephritic symptoms (hæmaturia and lumbar pain) were at that time very marked, the wound healed by first intention, the man being up on the ninth day from the operation. Mr. Silcock pointed out the apparent hopelessness of the case when first under observation, and cited it, as exemplifying the now well recognised doctrine, that where several tubercular lesions co-existed, the removal of one tended to the amelioration of the symptoms attending the others. He remarked that at some time, in future, it might be thought advisable to attack the renal lesion, for the hæmaturia and pain attendant upon it were becoming increasingly severe.

Trephining in Pre-historic Times.—Mr. VICTOR HORSLEY, F.R.S., delivered an address upon this subject. He commenced with three propositions concerning the operation in the neolithic age, which he proceeded to maintain by the help of lime-light reflections upon a screen; he also exhibited specimens of the flint instruments of the period.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, JANUARY 6TH, 1888.

C. B. KEETLEY, F.R.C.S. in the Chair.

Living Specimens.—Mr. WHITMORE exhibited a male patient from whom he had excised a Portion of the Rectum for Malignant Disease.—The Specimen and Microscopic Sections prepared by Dr. P. S. ABRAHAM were presented.—Dr. SPICER showed Three Patients from whom Laryngeal Growths had been removed.

Syphilitic Disease of the Eye.—Mr. J. HUTCHINSON, jun., showed two cases of syphilitic disease of the eyes presenting unusual features. The first, that of a woman who had lately suffered from severe tertiary symptoms, came under care for ulceration of the upper eyelid, with surrounding thickening; a small gumma sloughed out, and on the conjunctival surface a second ulcer appeared. With iodide of potassium internally and iodoform locally the ulcer healed, and at the same time a gummatous ulcer on the palate cicatrised. In the second case, a girl, aged 17, with inherited syphilis and typical teeth, there had been double iritis, and while under treatment interstitial keratitis appeared in both corneæ. Two small gummata developed in the inflamed iris, and had become absorbed under mercurial inunction. Since then iritis and keratitis had relapsed, but were disappearing with specific treatment and tonics. The rarity of gummata of the iris and tertiary ulcers of the conjunctiva was the reason for exhibiting the cases.—Dr. MARSDEN LOW, Mr. WHITMORE, Dr. BENNETT, Mr. LLOYD, and Dr. ALDERSON made remarks, and Mr. HUTCHINSON replied.

Nasal Trephine.—Dr. SPICER exhibited a revolving trephine, worked by an electro-motor, for removing bony growths from the nasal passages.

Epithelioma of Larynx.—Dr. ABRAHAM exhibited microscopic sections of epithelioma of the larynx which had been removed by Mr. Keetley, and remarked upon their characters.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

MEDICAL SECTION.

FRIDAY, DECEMBER 16TH, 1887.

JAMES LITTLE, M.D., President, in the Chair.

Argyriasis.—Dr. A. W. FOOT, *à propos* of the discussion in this JOURNAL, on absorption of silver nitrate applied to the throat, read notes of a case in which the solid caustic had been applied to the throat for eight years, and was followed by silver-staining of the skin and mucous membranes.—Mr. FITZGIBBON mentioned two instances of discoloration of the skin produced by the continued application of nitrate of silver to the throat, but he had no doubt the discoloration was due to the solution having been swallowed. He attributed it to the effect of light upon the white chloride of silver as in photography. Iodide of

potassium had been used, with marked though not complete benefit, in removing the discoloration.—Dr. HEAD said he knew a lady who, suffering from vaginitis, was treated with nitrate of silver by injecting a drachm of 30 gr. solution into the vagina, and in two years she became quite skin-stained.—Dr. DUFFEY pointed out that a case had been recently reported, in which the local application of nitrate of silver to an ulcer on the leg was followed by discoloration of the skin.—Mr. STORY said the local application of nitrate of silver to the conjunctiva, which was a common procedure some years ago, had often produced very deep discoloration, turning the whites of the eyes quite black.—Dr. BALL asked as to silver found in the liver and kidneys; how its deposit there was to be accounted for by the action of light?—The PRESIDENT observed that Dr. Head had disposed of the theory that staining was entirely due to swallowing the fluid.—Dr. FOUR, in reply, said the silver deposited in the liver, kidneys, spleen, and viscera was metallic silver in the oxidised or reduced form, and was indifferent to light.

Cerebral Tumour.—Dr. KENDAL FRANKS read a paper on a case of cerebral tumour. The patient was a married lady, aged 40, who in June, 1887, for the first time was seized with an epileptiform attack. These attacks recurred with diminishing intensity every four or five days until the middle of July, when they were replaced by modified attacks of *petit mal*. After the first attack she exhibited symptoms of amnesic aphasia. At first this was very slight, but after each epileptiform attack became more marked. Headache gradually developed, sometimes becoming very acute, and was always referred to the top of the head about the coronal suture, being most marked a little to the left of the bregma. She came under observation first on September 7th. Cerebral vomiting appeared for the first time on September 9th. On September 13th a paralytic condition of the bladder, necessitating the frequent use of the catheter, appeared; this lasted for five days, then disappeared for ten days, and finally returned on September 23th, and lasted until coma supervened. The only other paralytic symptoms which appeared were, on September 25th, some almost inappreciable paresis of the right external rectus, giving rise to a certain amount of diplopia; secondly, on October 3rd, a partial paralysis of the right orbicularis muscle; and, on October 4th, partial paralysis of the palate. A tumour in the left side of the brain was diagnosed, but its nature and exact position, Dr. Franks maintained, it was impossible to foretell by the symptoms produced. That there was a tumour and not an abscess, as was held by Mr. Wheeler, who saw the case in consultation on October 9th, was proved by the history of the case—the total absence of any predisposing cause, the gradual onset and progress of the disease, without any rigors or pyrexia whatever, until three days before death, and by the total absence of all symptoms of pus formation. Mr. Wheeler, who saw the case the day before death occurred, wished to trephine over Broca's space on account of the aphasia, but Dr. Franks objected on the grounds that none of the symptoms indicated Broca's space as the seat of the lesion. The only localising symptom was the aphasia, which was only partial and was of the amnesic variety; and therefore if it indicated one spot more than another, it pointed to the posterior portion of the parietal bone, the angular gyrus, the posterior part of the infra-marginal convolution, and the posterior portions of the superior and inferior temporo-sphenoidal convolutions, and the central portions of these parts was more than three inches from Broca's space. The *post-mortem* examination showed that the posterior half of the temporo-sphenoidal lobe was occupied by a cavity, extending two inches in antero-posterior diameter, containing perfectly clear serum. The cavity had no true cyst wall, but was bounded by disintegrating brain tissue. The microscope failed to reveal any trace of inflammation, or of any old blood-clot. The nearest part of the cavity to Broca's space measured nearly two inches. Dr. Franks maintained that to have explored the brain by means of a grooved needle through a trephine opening over Broca's space would probably have failed to reach the cyst, and that, even had it been reached, the amount of damage which probably would have been inflicted in the search for a tumour whose situation was so uncertain would have been such that no prudent surgeon would willingly have made the attempt. He strongly objected to Mr. Wheeler's statement that the *post-mortem* examination corroborated his diagnosis.—Mr. WHEELER said: On the 6th of October last a near connection of this patient wrote to me asking me to arrange a consultation with Dr. Franks the next evening. As I was unable to go at the desired time, I was further requested by the same relative on the 8th to see the patient by myself the following day, who stated that it was at Dr. Franks's request. As he would not see the patient until late next evening, I wrote for and received the following history of the case from her husband:—"The patient was in very good health up to the end of June, 1887, when, the weather being very hot, she

felt it much. One morning she was out under hot sun, but walked a mile and a half in the afternoon; was well up to 7.30 p.m. Shortly afterwards she was found lying in her room insensible with face much flushed, extremities cold, pulse feeble. She remained unconscious for several hours, and then awoke perfectly clear in her mind. There was a slight scratch on the forehead, but no appearance of bruise. For some weeks attacks somewhat similar followed, preceded by confusion and a sense of falling. After a short period speech became confused; she always knew what she wished to say, but could not use the right words, nor could she write a letter. Subsequently, violent pain in the head, with vomiting, came on. She fell into a semi-conscious state about three months from the first attack, then perspiration set in, and she lost control over her bowels, and required to have the urine drawn off." I found the patient in a semi-conscious state; saliva dribbled from her mouth, her gums were spongy, and there was a well-marked mercurial odour; pulse 96, but rose to 110; respiration under 24; temperature under 100°; could swallow fluids; no stertor; her pupils responded to light; some urine drawn off; specific gravity 1018, no albumen. I made an ophthalmoscopic examination, but was unable to detect any neuritis. Reflex tests gave no indication except abdominal and mammary. Heart sounds normal. I advised, in writing, even as a last resource, an operation in Broca's region, and stated that, in my opinion, there was a fluid collection, probably an abscess, and that, if a solid tumour existed which had been diagnosed, it would not be impossible to remove it. The *post-mortem* examination showed there was a clear serous collection, separated from the surface by a thin layer of healthy brain tissue, but there was no evidence that pus cells did not exist. I was then requested to meet Dr. Franks at 9.40 p.m. After a few minutes' conversation, he stated that Dr. Head's opinion, with which he agreed, was that the patient suffered from a tumour; and as he dissented from the operation, I proposed that we should see the patient. Her pulse was then over 150, temperature 102.6°, respiration nearly 40. She could not swallow; her pupils did not contract to light. I stated that she was so altered from the time I first saw her that I could not then recommend the operation. There was clear evidence to me that this patient was suffering from aphasia, agraphia, and amnesia, with every indication for operation in the region of Broca; and my opinion is that had she been operated on in time at the site indicated, the cyst could have been emptied, and probably her life saved. For the anterior edge of the cyst would be scarcely three-quarters of an inch from the site of the advised operation; there could be no difficulty in tapping it at even a greater distance, for scarcely two inches and three-quarters of the temporal lobe is posterior to Broca's region; but, supposing it could not have been emptied by the proposed operation, the correct treatment was to trephine a second or third time, and make explorations as often.—Dr. HEAD said that he saw the lady for the first time late on the evening of September 14th, and not being anxious to express a definite opinion without a further examination, he saw her again on the following morning. He had seen several cases in his practice resembling this one in many ways. In two of those cases, the tumours were such as it would have been utterly impossible to remove, even if it were known where they were. Therefore, having regard to his experience, he thought it would be inadvisable to trephine over Broca's space to look for a tumour the locality of which was doubtful, and he advised Dr. Franks not to operate. If the tumour became localised, or evidence of its locality more clearly defined, then the operation might be performed. When he saw the patient again on October 3rd, she was in a comatose condition, and the symptoms had not developed enough to enable him to localise the tumour. She was suffering intense pain, but he did not like to give opium. He suggested cannabis indica. She expressed herself greatly relieved. He suggested a caustic issue, and that the mercury should be given tentatively, but stopped if untoward symptoms arose. It was stopped on September 22nd. On October 3rd he examined her breath and gums, and she had not the smallest sign of mercurialisation. She had bad teeth, but there was no salivation, and there was not the smallest sign of mercurial tætor. Cannabis indica, she herself said, relieved her pain, so he did not see how that treatment could have done her much harm. With all the care he gave the case he could not attempt to localise the position of the tumour, or diagnose whether it was solid or fluid, except the probabilities being that it was on the left side. Under these circumstances he advised Dr. Franks not to operate.—Mr. SWANZY said he was asked to see the lady in order to ascertain whether, by means of the ophthalmoscopic or any other symptoms, a closer diagnosis could be made than had been effected. He examined her with the ophthalmoscope under considerable difficulties, and expressed an opinion that there seemed to be a slight haze over the fundus, which meant an optic retino-neuritis.

At the same time it was so very slight he could not lay much importance upon it. Whatever appearance there was, it was in one eye quite as much as in the other. The lady complained of not being able to see people who stood on the right side of the bed. He further examined to see whether this was due to any blindness in the right eye. So far as could be ascertained by covering one eye and then the other, and by counting the fingers, the sight of one eye seemed to be as good as that of the other. Still she complained of an unpleasant sensation and difficulty of moving the right eye to the right side, indicating a little paresis of the external rectus. He understood there had been a little drooping of the left upper lid, but when he examined her there was nothing of the sort. There was nothing enabling one to localise anything in the brain. If there had been any optic neuritis it would not localise the lesion in the brain; it would confirm the diagnosis already sufficiently made—that of a tumour of the brain.—Mr. BEWLEY, who made the *post-mortem* examination, supplemented his report. Sawing round the skull in the ordinary manner, the saw suddenly passed through the bone behind the left ear, and some clear serous fluid came out from a point above and a little behind the left ear. The membranes of the brain were found perfectly healthy. The cyst was situated in the temporo-sphenoidal lobe, its nearest point one inch and a half from the anterior rim to the fissure of Sylvius. The other parts of the brain, as far as he could make out, were perfectly healthy.—Mr. FITZGIBBON, Mr. FOX, Dr. C. J. NIXON, Mr. A. H. CORLEY, Mr. BROOMFIELD, Mr. MYLES, Mr. M'ARDLE, Mr. HEUSTON, Mr. BARTON, The PRESIDENT, Dr. PRATT, and Dr. COX took part in the discussion.—Mr. KENDAL FRANKS replied.

SOUTH INDIAN BRANCH (MADRAS).

JUNE 3RD, 1887.

The VICE-PRESIDENT in the Chair.

Intra-uterine Fracture.—Surgeon-Major BRANFOOT exhibited a foetus born dead which presented fractures of the shaft of both femurs and of the tibia and fibula of each leg; muscular contraction had occurred in both upper and lower limbs. [The specimens were subsequently examined by a sub-committee consisting of Brigade-Surgeon Sibthorpe and Surgeon-Major Branfoot; the femur, tibia, and fibula of the limb dissected were all bent nearly to right angles; it appeared that after ossification the bone had been fractured, and that new bone had been formed in the angles.] The mother was a primipara, and was under treatment for six weeks before delivery for acute articular rheumatism.

Ovarian Tumours.—Four specimens of ovarian cystic tumour were shown by Surgeon-Major BRANFOOT, namely, a simple cyst and a colloid multilocular cyst from the same patient, a papillomatous cystic growth, and a dermoid cyst; all three patients recovered after ovariectomy.

Dupuytren's Enterotome.—Brigade-Surgeon SIBTHORPE related a case in which Surgeon Maitland, of the General Hospital had cured a case of artificial anus left after herniotomy for strangulation with gangrene of gut by the use of Dupuytren's enterotome; the *éperon* had disappeared in ten days after the instrument was first applied.

Cardiac Thrombosis.—A heart, showing a thrombus extending from the right auricle into the right ventricle and pulmonary artery, was exhibited by Brigade-Surgeon SIBTHORPE. The patient, a Hindu ryot, aged 65, was suddenly seized with dyspnoea nine days after excision of the scrotum had been performed for elephantiasis, which had been followed by much reactionary hæmorrhage. The dyspnoea very rapidly increased, the heart's action became rapid and feeble, the temperature fell to 97° F., and the patient died in fifty-five minutes after the seizure. The necropsy showed that the mitral valve was incompetent. The clot on the right side was red, firm, and adherent to the walls of the heart; it extended to the bifurcation of the pulmonary artery.

Spinal Caries.—Brigade-Surgeon SIBTHORPE also showed a specimen of caries of the dorsal vertebrae in a man aged 25; the twelfth dorsal vertebra had almost disappeared, and the front of nearly all the others was eroded; the twelfth rib and the first lumbar vertebra were also carious. The abscess extended from the first dorsal to the first lumbar vertebra, had obliterated the right pleural cavity, and had reached the manubrium, the posterior surface of which was eroded.

New Stretcher.—A new stretcher, designed as improvement on the new army regulation pattern, was exhibited after the meeting by Brigade-Surgeon SIBTHORPE. Two small bamboo poles carrying the canvas bottom were kept in place by transverse pieces of light wood, which were so made as to serve as feet when the stretcher was placed on the ground; with pillow, strings and straps it weighed 22 lbs. The advantages claimed were—lightness (the regulation patterns weigh 31½ lbs.), cheapness (four rupees), ease of repair in case of accident.

REVIEWS AND NOTICES.

SYPHILIS. By JONATHAN HUTCHINSON, F.R.S., LL.D., Consulting Surgeon to the London Hospital, etc. With eight chromo-lithographs, pp. 532. Cassell and Co. 1887.

THIS is one of Messrs. Cassell's series of "Clinical Manuals for Practitioners and Students of Medicine," and certainly the publishers are to be congratulated in the present instance on their choice of an author; for no one has a better right to speak with authority on syphilis than Mr. Hutchinson, who, moreover, for many years past has been almost constantly writing or lecturing on the subject. This being the case, it was hardly to be expected that the present volume would contain much that had not been said before; and, indeed, it may be considered as to some extent a gathering together of what was previously scattered in many periodicals and other works, but with the important addition of a large number of illustrative cases from the author's own notebooks. The result, we may say at once, is a collection of facts and suggestions which forms a most valuable contribution to the literature of syphilis, and at the same time a storehouse of knowledge from which the practitioner cannot fail to derive profit; for though he will not find a complete or systematic treatise on the subject, nor very extensive reference to the works of foreign writers, he will find what he will probably value more, namely, much information and many practical hints that will be of real assistance to him in the management of his cases.

The book is divided into two parts, the first of which occupies less than 100 pages, and contains a summary of the chief events in the course of syphilis, as well as of its treatment. The remainder of the book consists of 242 pages of commentaries on a great variety of subjects, including remarks on the most important questions connected with the nature, diagnosis, and treatment of the inherited as well as of the acquired form of the disease.

As to the nature of the contagium of syphilis, the author speaks as follows: "The creed which will be found to interfuse not only this work, but almost all that I have ever written on syphilis, is that the disease depends upon a living and specific microbe, and that it is transmittable only so long as that microbe retains its vitality." With regard to the affection commonly known as the soft chancre, Mr. Hutchinson appears still to hold the opinion—an opinion held, we imagine, by few syphilographers at the present day—that that sore is related to syphilis; for under the heading "on soft or non-infecting sores" we find their etiology thus explained: "It would appear that some of the inflammations resulting from syphilis, but not attended by the actual presence of the virus, may produce a peculiarly irritative and very contagious secretion..... Sores form within a day or two of its contact, which are attended by ulceration, and by the secretion pus which is capable in its turn of inoculating other parts."

Respecting the all-important subject of the treatment of syphilis, most authors are now pretty well agreed as to the remedies to be employed, but there is still much difference of opinion as to details, such as the particular preparation of mercury to be used, the mode of its administration, and the length of time treatment should be continued. Mr. Hutchinson, we are glad to find, recommends for ordinary cases one of the simple preparations, namely, grey powder, given by the mouth. We also agree with him entirely that mercury should be begun as soon as the diagnosis of syphilis has been made, without waiting for general symptoms; but it does not accord with our experience that when mercury is given early it is "quite the exception for any secondary symptoms to occur at all." Rather should we be inclined to say that, in carefully watched cases, it is quite exceptional not to be able to detect some form of secondary manifestation. Again, we should not think it wise in any case to trust to a six months' course of treatment as adequate for cure, nor do we consider a period of two years from the time of contagion sufficient for marriage to be safely contracted, though it must be admitted that on this latter point Mr. Hutchinson has considerable evidence on his side when he states that in a very large number of marriages which have taken place after this interval and with his own permission, he has never, with one exception, known of any hurt to either wife or child.

There are certain points which might have been more clearly stated with advantage, as well as others on which it is not easy to find out exactly what the author's opinion really is. For example, the statement that syphilis "can be conveyed from one person to another only by direct contact of surfaces" might mislead an inexperienced reader. Again, with regard to the question of whether a primary venereal sore should be destroyed, we are told in the second part that the author would deem it a neglect of duty not to canterise freely

any sore which came under his treatment within five days of exposure; and in the first part, that "if a patient who has never suffered from syphilis before, and who can give his dates correctly, comes under observation at any period within a fortnight of the contagion, with a single sore, it will certainly be wise to destroy it utterly."

On another interesting point it would be very difficult to reconcile the various statements made with regard to it. We refer to the pathognomonic or non-pathognomonic nature of syphilitic manifestations. On the very first page of the preface it is distinctly laid down that "none of the symptoms of the disease are pathognomonic"; but on page 30 we read, "In the case of the condyloma the diagnosis is usually easy, for nothing resembling it is ever produced excepting in syphilis;" on page 75, "interstitial keratitis, in its typical form, is always a consequence of syphilis, and it is in itself sufficient for the diagnosis;" on page 229, "that the choroiditis was syphilitic no one could doubt, for its features were pathognomonic;" while on page 485 the statement made in the preface is repeated with emphasis: "We have absolutely no malady which is peculiar to syphilis."

From the passages we have quoted, and others which the reader will no doubt find out for himself, it will be seen that the book needs revision, and it must also be remarked that its value as a work of reference would be decidedly increased by a more methodical arrangement of the material in Part II. These, however, are matters of minor importance, considering the many admirable qualities of the book as a whole. We have read it through with great pleasure and profit, and can with confidence recommend it to all practitioners of medicine.

HEALTH MAPS. A Complete Series of Prescribed Exercises of the Body for Daily Use: for maintaining the Health in a State of Integrity, for correcting any tendencies to Functional Irregularity, and for resisting the Encroachments of Disease. By ANNA LEFFLER ARNIM. Groups I, II, III, IV, V. London: Swan Sonnenschein, Lowrey, and Co. 1887.

CALLISTHENICS and deportment used to be a part of the education of every young lady, and in spite of many defects both in method and application, the young ladies benefited by the instruction. Pope, no mean observer of human nature, has said, in a quotation which is now hackneyed, that "they move easiest who have learnt to dance;" and it will be admitted at the present day more readily perhaps than ever before, that vigour of body and grace of movement depend upon a training of the whole muscular apparatus. Dancing did to some extent accomplish this, for the dancing master had devised exercises for the foot, the leg, the thigh, the muscles of the trunk, and even to some extent for the arm and hand. Forms of exercise which make great calls upon limited groups of muscles do not tend to produce good æsthetic results; the increased development of the groups which are much used is accompanied by a wasting of the groups which are less used, and there is a loss of symmetry. The overgrown leg of the professional dancer or the attenuated calf of the horseman are not beautiful, though gaping fools may admire the one, and fashion, aided by the bootmaker, may have rendered the other an object of ambition to young sportsmen who, after an autumn on the moors, may be heard to lament at the beginning of the hunting season their inability to squeeze their new well-grown calves into the "neat" tops that had been their pride in the previous March.

Without denying the health-giving qualities of such exercises as riding or cycling, it will probably be admitted, on theoretical grounds at least, that other forms of exercise which make more universal calls upon the muscles, not only produce better types of manly and womanly beauty, but a better general state of health. Herein probably is to be found an explanation of the extraordinary popularity of cricket, boating, and football in this country and in Australia, and of football and Lacrosse in America. Lawn-tennis is another popular game which calls into play nearly every muscle of the body. But everyone is not in a position to indulge in these pastimes, and for such unfortunates Miss ARNIM'S Health Maps will have distinct value; she has elaborated a series of exercises which bring into use *seriatim* most of the important groups of muscles; each exercise is illustrated by a diagram. For these diagrams we have nothing but praise; they are drawn with spirit, and indicate very clearly the movements which are to be performed. The "maps" are, however, intended to have a wider application, and will be of considerable service in suggesting methods of obviating some of the evil consequences of constrained attitudes assumed during work. Some of the exercises recommended for special purposes, as for instance Fig. 7, Group III, are extremely simple, and are such as the attitudes which they are intended to cor-

rect naturally suggest. The authoress no doubt seeks to magnify her office, and some of the exercises in the series appear so simple as to provoke a smile; the series, however, must be taken as a whole, and simple as many of the individual exercises are, there is much to be learnt, not only as to their sequence, but also as to their performance. "To be a well-favoured man is the gift of fortune," said Dogberry, "but to write and read comes by nature;" and, *pace* Dogberry, we must learn not only to read and write, but also, under many of the circumstances of modern life, to exercise our bodies.

The author's physiology is sometimes in fault; it is, to say the least, doubtful whether the exercises in Groups II and IV would have the special effects on the liver, spleen, and kidneys, or on the digestive organs, which are attributed to them. Groups I, III, and V will be the most generally useful. The diagrams are arranged on a folding screen, which may be made to stand extended upon a table before the pupil. In looking at a group thus extended, the general resemblance to the restless movements of a healthy child is rather striking. Fig. 11, group V, represents a young person who "seats himself upon a bench or table, the edge being just allowed to come under the bend of the knee. He then commences to rotate the lower half of the leg, confining the movement to the knee, and keeping the thigh as motionless as possible. To be performed three times," etc. How many parents have been "fidgetted to distraction" during the recent holidays by the performance of this "exercise" many more than three times by a son or daughter whose exuberant vitality had at the moment found no other outlet!

NOTES ON BOOKS.

Lewis's Pocket Casebook for Practitioners and Students. Designed by A. S. BRAND, M.D. (London: H. K. Lewis).—This small casebook is intended to be used by the general practitioner on his daily round. The book is of the dimensions of an ordinary pocket book, and four pages are given to each case. On the first page there are spaces for date, name, age, and other like facts, and below headings for tabulating symptoms observed under the various systems; this table extends across the second page. On the two following pages the subsequent course of the case can be recorded. The omission of any heading in the table for the previous history of the patient appears to be the only fault which is likely to be found with this well planned and convenient pocket book. It contains space for about fifty patients, and is provided with an index.

Contributions to Clinical and Practical Medicine. By A. T. H. WATERS, M.D. (London: J. and A. Churchill. 1887).—Dr. Waters has collected in book form a number of clinical lectures and papers upon diseases of the lungs, some of which have appeared before at different times. The whole bears the impress of careful work by an accomplished clinical observer, and as a practical guide is of great value. The first chapter gives the results of a large number of observations upon the temperature in phthisis and other diseases. In phthisis Dr. Waters finds that the highest temperature occurs at or near 5 o'clock in the afternoon, and is low in the morning. The tubercle bacillus is not mentioned as of diagnostic importance, probably because of the early date at which many of the lectures appeared; but it is suggested that the exacerbations of acute phthisis and of septicæmia may be due to analogous conditions. In a later chapter Dr. Waters maintains the existence of an acute pneumonic phthisis, not of tubercular origin, and not accompanied by so much prostration as is present in acute tubercular phthisis. For pneumonia quinine is recommended in full doses as a valuable therapeutic agent, especially where the pulse is quick or the temperature is high. The author has not been able to satisfy himself as to the existence of a special "septic pneumonia," but considers that septic poison may modify the symptoms of a pneumonia. The article on bronchitis is a reprint of that in Quain's *Dictionary*. The remaining chapters of the book comprise practical remarks upon pleurisy, cancer of the lung, perihepatic abscess bursting into the lung, and Alpine climates in lung disease, in all of which useful hints will be found.

Bibliotheca Medico-Chirurgica, Pharmacutico-Chemica, et Veterinaria. Herausgegeben von GUSTAV RUPPRECHT. (Göttigen: Vandenhoeck and Rupprecht's Verlag. 1887).—This publication aims at placing before its readers in a systematically arranged summary a list of new works, important treatises and periodicals, published both in Germany and abroad, and embracing the wide domain of general medicine. It appears quarterly, each number containing classifications, under which

the new works are grouped, as well as an alphabetical index. It has now nearly completed its forty-first volume, the second of its new and more complete series, having been first published in 1847. We draw the attention of all medical men, whether interested in the progress of their science generally or of some of its more special points, to this valuable compilation, as giving them means to attain a rapid acquaintance with the progress effected by their foreign contemporaries in the numerous provinces of medical knowledge.

Krause's Monthly International Journal of Anatomy and Physiology.—The first number of this valuable journal for 1888 contains the following articles: "Qu'est ce que l'Homme pour un Anatomiste," by L. Testut; "Recherches sur la Portion Terminale du Canal de l'Ependyme chez les Vertébrés," by Dr. G. Saint Remy; "Sur la Structure des Nerfs Cérébro-rachidiens," by Dr. Louis M. Petrone. They are all articles of solid and valuable research, and the journal is one which well deserves the support of anatomists.

First Aid to the Injured: The Ambulance Pupil. By a Pupil of the St. John Ambulance Association. (Crosby, Lockwood and Co., London).—This is one of the best textbooks which has come under notice for those attending classes of the St. John Ambulance Association. The facts in anatomy and physiology are clearly, tersely, but sufficiently described. The directions for treatment are excellent, and at the same time easily understood, and likely to be put into practice. This small, compact ambulance work is to be highly commended.

Notes on Surgery for Nurses. By JOSEPH BELL, F.R.C.S.Ed., (Edinburgh: Oliver and Boyd. London: Simpkin and Marshall).—This is a charming little book. It contains just the kind of information that a surgical nurse would require, and is written in such a simple and interesting style that it cannot fail to draw attention to the salient features which the writer wishes to describe. These notes, the author tells us in his preface, embrace only the main points of the lectures which he has for twelve years delivered to the nursing staff of the Edinburgh Royal Infirmary, and one can well imagine that by personal explanation and the help of diagrams much that is here briefly described in writing would be more easily understood and remembered. No school of nursing is now considered complete without a systematic course of lectures, and we notice a little inclination to teach the nurses too much in the short time at their disposal. This little book will, we think, give a hint to those who lecture, and be of great service to the nurses themselves in impressing upon them the most important points of their surgical teaching.

REPORTS AND ANALYSES

AND
DESCRIPTIONS OF NEW INVENTIONS,
IN MEDICINE, SURGERY, DIETETICS, AND THE
ALLIED SCIENCES.

PURE COMPRESSED MILK EXTRACT. (W. TULLOCH and Co., Philpot Lane.)

This preparation represents the solid matter of skim milk in a palatable form, capable of being kept for any length of time. It is said to be the highest degree of concentration to which milk can be subjected, and has on that account an advantage over ordinary condensed milk. It must be understood that the preparation is devoid of cream or fat; and whilst it may well be used in ordinary cookery, or as an addition to coffee, tea, or cocoa, we would hesitate to employ it in the nursery. It is, when used with discretion and in the proper place, a good preparation.

"ICHTHYS" FISH SAUSAGES.

NOVELTIES in the shape of everyday articles of food are so uncommon, that an idea, which successfully carried out would materially add to the popular dietary, deserves special notice.

Mr. W. P. Eoglish, of Hull, has brought into the market, at the low price of 3s. 4d. for four pounds, sausages made of the flesh of cod and other fish, separated from skin and bones. They are very palatable when fresh, and peculiarly so when smoked or curried.

They will be found very suitable food for invalids, and will be appreciated in family cookery. Any intelligent cook will be able to prepare a number of tasty dishes from the contents of the "Ichthys" sausage.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1888.

SUBSCRIPTIONS to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the West Central District Office, High Holborn.

The British Medical Journal.

SATURDAY, JANUARY 21st, 1888.

VIRCHOW ON THE DIAGNOSIS AND PROGNOSIS OF CANCER.

THIS subject is discussed, in an article constituting the first "Heft" of Virchow's *Archiv*, Band cxi, from a purely scientific point of view, but it is evidently more or less a vindication by the author of his position in regard to the case of H.I.H. the Crown Prince of Germany. The opening words run thus: "It may seem almost superfluous at the present day to say anything on the diagnosis of cancer to those who have a knowledge of the subject. But an old dispute has quite recently been revived, namely, whether the anatomical or the clinical diagnosis is the more correct." The "constitutional" character of the disease has been regarded as its chief characteristic, that is, as expressed by the word "malignancy," or tendency to generalisation, but the sarcomata are still more malignant than the carcinomata, and even the most "innocent" growths, such as enchondroma and myxoma, occasionally form metastases. Malignancy, then, has ceased to be a diagnostic criterion, apart from the fact that an accurate diagnosis is a desideratum before a growth has begun to form metastases. The diagnosis must rest upon the knowledge of the histological structures of the growth. As early as 1847 the author showed that the alveolar structure belonged to all carcinomata, and not to ordinary cancer alone; further, that the alveoli contained, not a mere "cancer juice," but chiefly cells (Virchow's *Archiv*, 1847, i, p. 105). These cells were then declared to be "identical in kind with epithelial and epidermoidal cells, and especially with the cells of the so-called transitional epithelium." A cancer is thus analogous in arrangement to a gland, without an excretory duct. Attempts have been made, hitherto without success, to discover a cancer bacillus. "It is possible such may exist; indeed, such a discovery would constitute an important advance.....which might explain much that is still obscure as to the metastatic processes which occur in cancer." But gland cells have been shown to produce various tissue products, and cancer cells alone amply suffice to explain the constitutional effects of cancer. That cancer is always primarily local in character, and that its dyscrasia was always secondary, was contended for in the *Handbook of Special Pathology* as early as 1854, a time when the "cancerous constitution" was still firmly believed in.

To return to the diagnosis of cancer. Clinical observation alone is insufficient for diagnosis. "A striking example of this is to be found in tumours of the bladder. Till quite recently there has always been confusion on this subject, although I showed the distinction between the two kinds (that is, between an innocent papilloma and a villous cancer) a generation ago in point of time."

Professor Virchow narrates with spirit the battle over the "specific

cancer cell." He came to the assistance of Velpeau against the "micrographists" of Paris with his "three cases of generalised epitheliomata," to be found in the *Gaz. Méd. de Paris*, 1855, p. 208, and thus assisted in demolishing the theory of the specific cancer cell. "But perhaps the polymorphism of cancer cells would have been recognised earlier if the micrographists had been allowed time to look round them," in their newly-entered territory.

But even the anatomical examination may mislead. The author says that he showed by examples in 1851 that there may be mixed tumours, with different types of tissue. "Later on I declared this condition with regard to fibromata, and as this matter is one of importance I will quote my own words (*Tumours*, vol. i): 'Nothing can more easily cause misunderstanding than the fact that certain parts of a tumour may be formed purely of connective tissue, while other parts of it may be quite different. If in our examination we submit only very small defined portions to our inspection, only one or other of the constituent parts of a growth may offer itself to our notice, and its whole character may be determined accordingly. If the part examined happen to be connective tissue, our opinion on the nature of the growth will naturally be in general a favourable one, as a rule more favourable than if we had come across the other parts. This has happened to myself.....in particular I recollect a "recurring fibroma" which at the first extirpation I diagnosed as a simple fibroid tumour, but after a relapse (and a second operation) I found cancerous structure. On again examining the original specimen, preserved in alcohol, I found that very small portions of it showed the cancerous structure, almost all the rest of the tumour being fibromatous.'" The author adds that the case was a very uncommon one, and that a similar experience in regard to a large growth never happened to him again. Carcinomatous sarcoma and myosarcoma are mentioned amongst the mixed tumours in the author's work, and the present opportunity is taken to draw attention to this subject anew. A cancerous papilloma ("Wurdenkrebs") is, we are told, nothing but a mixed tumour, consisting of a cancer and a local hyperplasia of pre-existing parts; and if the anatomist may err, how much more likely is the clinician, who can only see the surface and watch the course of the disease. Great stress has been laid upon the enlargement of neighbouring glands, but even this may be simply inflammatory in character.

The exploratory investigation of a tumour is important. "A portion of its periphery is excised, or a few particles of the interior are withdrawn by puncture. These minute objects are then the only materials submitted for examination.....I say nothing against this kind of examination; it is often the only kind possible; but we ought not to be surprised if the result is deceptive. How easily may it happen that these minimal parts at the disposal of the investigator may not belong to the diseased site." Especially in regard to mixed tumours, "the examination of a portion of a new growth may easily give rise to error, but the real error is on the side of the clinician, not of the anatomist; for the latter can only form a judgment on what is submitted to him." As examples are cited co-existing uterine myoma and cancer, or hyperostoses and sarcomata in the long bones, though diagnosis is not difficult here. It is more difficult in the case of "papillary excrescences co-existing with ulceration." Ulcers of the larynx, especially syphilitic ulcers, frequently exemplify this. In chronic ulcers of this kind we see "a growth of the neighbouring mucous membrane with the most distinct papillary hyperplasia,

giving the impression of independent papillary tumours" (*Tumours*, vol. i).

Friedländer's objections to the theory that cancerous new growths are characterised by an alveolar arrangement with contain "heterotopous" (heterologous) epithelium are not without weight theoretically, but practically mean but little. The question of the derivation of the epithelial cells has become of great interest since the investigations of Thiersch and Waldeyer, but as yet has received no certain answer.

Professor Virchow refers to his early and steady advocacy of an early removal of any solitary new growth wherever feasible; in fact, he had determined such surgeons as C. Mayer, von Graefe, and von Langenbeck to extensive operations for even quite recent tumours of malignant kind. "This is now almost antiquated wisdom, and modern surgeons, in fact, claim credit for establishing the primary local character of malignant tumours." It is less important to know who originates a theory than whether it be true or not.

Cancer extends by the formation of accessory foci, and not by simple enlargement of the original centre. The first clearly described case showing this is the case of a cystic enchondroma of the shoulder-blade (*Archiv.*, 1853, v, p. 218). But these accessory foci are to be distinguished from the disseminated metastatic foci characteristic of malignancy.

Finally, the question of the possibility of spontaneous cure of cancer is touched upon. Dittrich showed that cases of supposed retrogression of cancer of the liver were really due to gummata; but Virchow has observed a cicatricial process in hepatic cancer caused by fatty metamorphosis of the cells in the centre of the tumour. "The formation of accessory foci is what forms the obstacle to a real healing. Cancer itself is no permanent tumour." Indeed, its cells have a very restricted vitality. Regarding medicines, Clay's treatment with Chian turpentine is mentioned, and the author is of opinion that though as yet no satisfactory proofs of cure are afforded, the profession is generally too sceptical on this subject. Von Nussbaum attempts to set up fatty degeneration in a tumour by thrusting the thermo-cautery in different directions beneath it, and thus depriving the periphery of its vascular supply. All such attempts are commended. "If cancer is at first, and often for very long, a local disease, it must be possible at this stage to cure it locally."

A NATIONAL PENSION FUND FOR NURSES.

ON various occasions during the last five or six years we have directed attention to the defenceless position of women engaged in the work of sick nursing when incapacitated by illness or age from continuing in the exercise of their vocation. It was pointed out that with the modern development of sick-nursing into a profession, the old pension system which existed at a few hospitals was not adequate to meet the necessities of the new conditions under which a nurse no longer remained attached to one hospital all her life, but after receiving her technical education most commonly obtained a situation in another hospital not provided with a training school, or became attached to one of the institutions which provide nurses for private cases. The great difficulty in making provision for pensions lay in these newly-formed migratory habits, and in the frequency with which the occupation was abandoned after a few years' trial.

The formation of the Hospitals' Association seemed to promise an opportunity of testing the feasibility of establishing a provident

pension fund for nurses, and it is with sincere satisfaction that we notice that the preliminary difficulties which necessarily surround the inception of such a scheme have been overcome. Four merchants and bankers of the City of London, Messrs. Gibbs, Hambro, J. S. Morgan, and Rothschild, have undertaken to provide the sum of £20,000, which must, in order to meet the provisions of the Friendly Societies' Act, be invested in the name of trustees before such a scheme as that of the "National Pension Fund for Nurses and Hospital Officials" can commence work upon the scale which is proposed.

Great credit is due to Mr. H. C. Burdett for the labour which he has bestowed upon the preparation of the scheme, the success of which seems now assured, if only the persons it is primarily proposed to benefit—that is, the nurses themselves—will come forward and show that they are in earnest. The scheme is founded on the provident principle, and the main resource of the fund will, it is expected, be the contributions of the nurses and other officials serving in hospitals. It is, we are glad to see, intended to make the fund self-supporting, and to fix the premiums and pensions to be paid at sums calculated by the actuary as safe. Contributions from the general public or from hospitals would be regarded in the light of a fund to provide bonuses. Contributors to the bonus fund will, we are informed, constitute the members of the Society, and will elect half the council, the other half being elected by the nurses and other policy holders.

One of the difficulties of the fund will be the relative frequency with which nurses will still continue to leave that occupation in order to marry, or for some other reasons which now operate to produce the very rapid thinning of the ranks which is always going on. This is to be met by providing a special scale of pensions for persons who reserve the right to require repayment at any time of all sums paid in to the fund.

The fund, too, will operate to diminish, though never altogether to do away with, these frequent retirements. In many cases a nurse only gives up her occupation because she has no prospect of making any provision for old age; the consciousness that this can in future be done by the exercise of a moderate amount of self-denial during the working years of life ought to have an important effect in retaining women who have once embarked in the career. If, as it is only reasonable to expect, the public contribute freely to the bonus fund, that will afford an additional inducement to a nurse to remain true to her calling.

Another difficulty which must be met is the relative rarity of habits of providence among women; they have hitherto had no organised help in this direction, and no societies which afford a standard, so that they are apt to think the premium high and the pensions small. It is not necessary to discuss the rates which it has been tentatively proposed to fix; these must be worked out on ordinary actuarial principles. This has been carefully studied by competent authorities, and it appears to be most desirable that as little delay as possible should occur in publishing them; sixty-five shillings a year will undoubtedly appear a large sum to nurses of 25 drawing £25 a year in wages; but when persons of business experience, whose advice they may be able to obtain, are satisfied that the rates are on a sound basis, a great step will have been taken towards gaining the confidence of the nurses. Some kind of test may have to be applied to applicants in order to ensure that only those who can be properly described as trained nurses are admitted as subscribers to the fund. The class which is to be included under the term "hospital officials" must

also be defined; difficulties will, of course, arise on this head, but they are only such as men of wisdom are accustomed to deal with. It would obviously be desirable to limit the fund to persons holding positions of responsibility and trust.

The object of the scheme is good, and its main features are such as will commend it to persons acquainted with the wants of the workers in our hospitals; great care, patience, knowledge, and skill will, however, be required in working out the final details of the scheme; such qualities we may expect to find in those who are now engaged in its elaboration.

The fact that the leading officials and treasurers and house-governors of so many great hospitals are showing an active interest in working out the scheme, and that it has secured the munificent support of merchant princes, proverbially as prudent as they are generous in a good cause, afford the highest guarantees of real and permanent success. The interest shown in the scheme by Sir Andrew Clark and Dr. Bristowe is only an earnest of that good will which the whole medical profession may with certainty be expected to show towards a class of persons—hospital officials and nurses—with whom they are intimately and daily associated in the great work of charity, in their daily lives, whose admirable qualities they appreciate, and whose welfare they may be counted upon to aid and promote by their influence and advice, and, when necessary, their active co-operation.

THE RELATION OF PUTREFACTION TO INFECTIOUS DISEASES.

II.

For a long time putridity was considered to be a special characteristic of putrefaction, and Ogston separated the saprophytes of "ordinary" putrefaction from other organisms. Koch also made it a distinction of his spirochæta that they did not emit an odour like the comma bacilli of Finkler and Prior. But Poehl and Brieger have shown that the former yield a large amount of "cholera red," an indol derivative, and indol and its derivatives are characteristic of all putrid processes. Again, Pasteur's theory of anaerobiosis made putrefaction dependent on the entrance of air. This is too absolute a statement; the entrance of air is but one of the several conditions requisite for the development of specific processes. The opposite view of Cohn, that his aerobic bacterium termo is the only real saprogenous ferment, is equally erroneous. The recent proposition of Wolny that putrefaction is essentially a reduction process, and that destruction is an oxydation process, is acceptable from the chemical aspect, "but biologically can only be received *cum grano salis*." Many bacteria exhibit both processes at the same time, as Herens (confirmed by Leone) has shown. Duncan's view is that the excitants of pyæmia and septicæmia take "no share in putrefaction," but he has omitted to say what constitutes their unsuitability in this respect, seeing that these organisms live in putrefying matters. Rosenbach has attempted to ascertain this, and has found that the differences between sapræmia and septicæmia are by no means so great as was supposed.

The fact is that the word "putrefaction" is misleading, as indicating one process, having one cause, while in reality it embraces several processes of different kinds. The organisms causing putrefaction (not to mention infusoria) have now developed, as shown by cultivations, into a part of the local cryptogamic flora of a geographical district, and not only so, but the same bacteria may be modified by cultivations

under various conditions, so as to exert different effects. Fitz took away their capacity of forming butyric acid from the anaerobic bacilli peculiar to the butyric acid fermentation, while their influence on albuminates remained unaltered. Professor Hueppe has done the same with the aerobic "butyric acid bacilli," and also was able to prevent the bacterium coli commune from causing the fermentation of sugar, while this organism still split up albumen, with formation of a poison. The same specific organisms may at times set up a pseudo-putrefaction, without any bad smell, and at times a true stinking putrefaction. It must be remembered that invasive organisms may act pathologically, not only by formation of poisons, but also by their mere increase.

From all this it is to be gathered that the so-called specific organisms of infectious diseases are not so specific as has been announced. The generally received opinion that filth in itself, though it may aid the spread of infectious diseases, can never cause them, requires modification. "Those sorts of filth which we meet with in putrefaction may at least contain the germs of the specific excitants of the infectious diseases, and these germs under (continued) favourable conditions may even set up the latter." There is a kind of correspondence between the gradations from cholera to cholera nostras and Asiatic cholera, those from epidemic icterus to yellow fever, and those from localised putrefactive processes up to the development of miasmatic or contagious diseases. Sporadic diseases may become endemic; endemic diseases may become epidemic. It is probable that Asiatic cholera was only an endemic disease during the last century, having been previously merely sporadic. Conversely, germs may perish; the plague has disappeared from Europe. But all well-defined infectious diseases have for the time being a favourite locality, a home, and their excitant organisms can owe their original development within this locality only to local putrefactive processes; these processes, as already stated, on other grounds being of various kinds and specific to the locality.

From the above considerations, Dr. Hueppe formulates the following conclusion as a fundamental basis of modern medicine: that "the excitants of infectious disease must be specific organisms, and this specificity may be either absolute or else evolved during thousands of years from local putrefactive processes." Now, seeing what modifications can be produced in bacilli by experimental cultivations, it seems unnecessary for Dr. Hueppe to postulate such long periods of time. He goes on to say: "I may be told that this is the pathology of the pre-Darwinian and pre-bacteriological era, but that does not prove it to be erroneous. Old truths emerge at last triumphant, however overlaid by alterations and systems, and new facts and modes of observation give the key to fresh explanations. In the process of putrefaction the modes of organic life are as follows, to use Garr's nomenclature. Various kinds of organisms grow side by side, and share in the destruction of their own substratum; this is symbiosis. Others prepare material beforehand for the development of others; this is metabiosis. Others, again, struggle for possession of the field with others; this is antagonism, which may be either one-sided or mutual. But different conditions may cause the same organisms to play very different rôles; an antagonistic organism may become metabiotic, and the latter may become symbiotic. Ultimately, persistent forms are attained, the so-called durable condition (*dauer-form*) permitting fresh development after long periods of inactivity." Duclaux kept germs in an inactive condition for twenty years, and found that

when, at the lapse of this period, air was admitted, they began at once to develop, that is, to share in the process of putrefaction—as even Koch's comma bacilli do for a few days. Hence the explanation of latent foci of epidemic diseases otherwise hard to trace.

In all the inductive sciences, it is no less important to arrange all newly-discovered facts in their proper sequence than to gather them by laborious experiments, and we ought not to feel disappointed if, when they apparently upset time-honoured theories, further examination reveals that they but substantiate those very theories. Such is the case with infectious diseases. Of old they were connected with filth, with putrefaction; then the microscope appeared to indicate that they were due to specific organisms, that they could be cultivated apart, that they apparently had nothing to do with putrefaction, but were even antagonistic to it, and succumbed to it in many cases; lastly, renewed examination of the bacteriological and epidemiological facts before us reveals that, after all, the ancient doctrine of Hippocrates had a substratum of truth.

As regards the "durable condition" above mentioned, Pasteur's attenuations of virulency—independently worked out in part by H. Büchner—are of the highest interest. A certain saprophytic stage acquired by organisms during the putrefaction of albumen represents the phyletic commencement of increased virulence. Watson Cheyne has shown that some bacteria, which in small numbers only act locally, may in large numbers cause general disease. Further, Heube and Kitt, as regards cattle-plague, have obtained the same results with a large number of germs of a low degree of virulence as with a small number of high virulence. Again, Pasteur has shown that pathogenic bacteria undergo modifications of virulence by transmission through (susceptible) animals, the lower grades of virulence protecting against the higher. Heube, who had previously argued that the four diseases, cattle-plague, swine-plague, rabbit-septicæmia, and fowl-cholera, must be nearly related, has made a series of experiments (partly with the assistance, partly under the control, of Kitt) which not only support this idea, but show that the bacteria of these four diseases, when attenuated either by culture or by transmission, are mutually protective against each other.

It results from these general considerations that not only may a virus be strengthened or weakened by adaptation, but collateral effects may arise. In other words, modifications of bacterial action may occur in quality as well as in quantity; hence the appearance from time to time of infectious diseases apparently new to medicine. When we also bear in mind that Salomon and Th. Smith were able to protect animals against American swine-disease by means of ptomaines as effectually as by attenuated cultures, it is evident that the boundary line between intoxication from putrefactive processes on the one hand and infection on the other is done away with. Nature herself steers between the purely localistic and the purely contagious theories, and the truth lies, as usual, between the two extremes. "To admit a saprophytic stage in the existence of infectious organisms at one period or another of their phyletic existence is to admit a miasmatic stage of a localised character; to deny it is to deny the recent revelations of bacteriology." "It is a matter of indifference," Heube continues, "whether with Pettenkofer we speak of ectogenous, or with Koch of occasional parasitism, with myself of a 'saprophytic stage,' with De Bary of 'racial selection,' or with Van Seighem, of 'facultative parasitism.'

On the other hand, the purely 'contagious' theory is not opposed to the dependence of the infective organisms upon the outer world, as Nægelli and Pettenkofer postulate. The question whether a disease be transmitted directly or indirectly, whether it is contagious or miasmatic, depends upon the presence or absence of definite organisms (for example, spores), and upon the mode in which infection occurs (for example, by wounds, by the lungs, or by the intestines). And as far as concerns these mere pathological considerations, the broader view of Koch commends itself as the most just, namely, that infection may occur by a plurality of modes."

This comprehensive address closes thus: "Putrefactive processes are necessary as an intermediate stage between plant life and animal life, and as long as these processes go on, so long will organisms exist which, owing to their very origin, will act detrimentally on the structure of the human body, that is, will excite disease.....Let putrefaction then go on as far removed from human dwellings as possible, in its natural place, the ground.....Cleanliness—a genuine cleanliness, not a merely external purity—(*Facaden-Remlichkeit*) is the best means of combatting infectious diseases, and here I adopt the English view of the subject.....The triumphs of hygiene are as brilliant as those of antiseptic surgery, though not so immediately appreciated..... Prophylactic hygienic measures against infectious diseases are worth more than all the protective inoculations, and the scepticism and reserve of Koch and Kitt, as regards the latter, are fully justified."

Thus, Dr. Heube traverses the whole ground of bacteriological discovery, and endeavours to bring unity of conception out of discrepancy, and harmony out of apparent discord. If to do this is the mark of progress in any science, then Dr. Heube's address will be referred to as constituting a meritorious advance in this direction.

THE Royal Astronomer reports that there was no sunshine at all in London during the whole of the week ending January 14th.

DR. DANION read a note before the Académie de Médecine, Paris, on January 10th, in which he endeavoured to prove that galvanocaustic currents of high intensity are dangerous and useless, especially when applied for the cure of uterine disease.

WE are requested by the honorary secretaries of the Association of Members of the Royal College of Surgeons to state that the dinner of the Association will be held at the Holborn Restaurant, on Tuesday, January 31st, at 7 P.M., following upon the general meeting at 6 P.M. of that date. A clerical error in the form of application issued by the Association renders this notice necessary to prevent confusion.

EDUCATION AND REGISTRATION OF MIDWIVES.

DR. J. H. AVELING recently delivered at the Chelsea Hospital for Women a lecture on "The amelioration of the present condition of midwives." Dr. Aveling called attention to the fact that as many as 4,500 women die in childbirth in England and Wales during the year, and that whereas the death-rate is as low as 1 in 650 in lying-in hospitals, and as low as 1 in 900 in one charity, it reached 3 in 600 in cases treated at home. It was plain that this high rate of mortality was due either to the medical men or to the ignorance of the midwives, and he inclined of course to the latter opinion, thinking that if only properly competent midwives were employed the death-rate might be reduced to one in 500, which would mean a saving of

300 lives every year. There were about 9,000 persons acting as midwives in England and Wales, very many of whom were ignorant and possessed no certificate whatever. He was desirous of seeing some system adopted in this country by which midwives would be examined as to their competency and receive certificates.

EXCISION OF THE PYLORUS.

Two women, upon whom Professor Billroth had performed excision of the pylorus, were recently exhibited to a Viennese Medical Society by Dr. Salzer. In the one case, the operation was done for a rapidly growing sarcoma, originating in the muscular coat of the stomach; in the other, the diagnosis of cancer was made, but the disease was found to have been only a simple ulcer.

OIL OF EVODIA, A DEODORANT.

DR. H. HELBIG calls attention (*American Journal of Pharmacy*) to the value of the essential oil of *evodia fraxinifolia* as a deodorant for iodoform. He has had, he says, an opportunity of examining the fruit of this plant, and found that it yields an oil having a most agreeable and powerful odour, which is even able to overcome the smell of iodoform either in its crystalline shape or in solution. For practical purposes he says it is only necessary to add a little (two drops to the ounce) of the essential oil to the disinfectant in order to obtain a complete deodorisation of the latter, the chief objection which has been raised against the use of this valuable remedy thus being obviated. Dr. Helbig adds that he would be pleased to find his observations confirmed by experiments of others.

MALARIAL INSOMNIA.

DR. F. EKLUND, of Stockholm, believes that there is a special form of insomnia due to malaria; in its severest form sleep by night is unattainable, but the sufferer is drowsy by day. In less severe cases a few hours' sleep are obtained on first going to bed, but the patient then wakes, in some instances always at the same hour, and cannot again sleep. He states (*Therapeutic Gazette*) that these patients can be relieved by quinine in small or moderate doses; the prescription he prefers is: R. Quin. sulph. gr. vi—xv, sodii bicarb. gr. xv—xxx, M. F. tal. dos. xii in caps. amyl. Sig. Take one capsule every morning, and if the case require it one in the evening.

THE DISCIPLINARY POWERS OF THE ROYAL COLLEGE OF PHYSICIANS.

AT the next meeting of the Comitia of the Royal College of Physicians, a resolution will be moved by the Senior Censor, requiring that no Fellow, Member, or Licentiate should contribute articles on professional subjects to journals professing to supply medical knowledge to the general public, or should in any way advertise himself, or permit himself to be advertised in such journals. At the same meeting, the Treasurer will move his resolution to present a donation to the Metropolitan Police Convalescent Home. Five new councillors will be elected to fill vacancies.

THE LECTURES AT THE ROYAL COLLEGE OF PHYSICIANS.

THE Goulstonian Lectures at the Royal College of Physicians will be delivered by Dr. W. Julius Mickle on March 6th, 8th, and 13th, at 5 P.M. The subject will be "Insanity in Relation to Cardiac and Aortic Diseases and Phthisis." The Lumleian Lectures by Dr. W. H. Dickinson, on the "Tongue as an Indicator of Disease," will be given at the same hour on March 15th, 20th, and 22nd. The Milroy Lectures on Public Health will be delivered for the first time this year, in accordance with the provisions of the will of the late Dr. Gavin Milroy. The lecturer will be Inspector-General Lawson, who, on February 21st and 23rd, will give two lectures on "Epidemic Influences;" his third lecture will be given on February 28th, on the

"Epidemiological Aspects of Yellow Fever," and his fourth on March 1st, on the "Epidemiological Aspects of Cholera." These lectures also will be given at 5 P.M. The Croonian lectures will, under the new scheme, be delivered in the summer.

EXAMINATION OF THE MALE BLADDER BY ELECTRIC LIGHT.

MR. HURRY FENWICK has lately used electric illumination of the male bladder and urethra for diagnostic purposes with considerable success. We are informed that he proposes to give a demonstration on the living subject and on "dummies" of the capabilities of the vesical and urethral lamps, as recently improved, at the next clinical meeting of the Medical Society on Monday next, January 23rd.

POISONING BY ARTIFICIAL SELTERS WATER.

OVER thirty cases of poisoning were reported recently in Rendsburg, in Germany. Inquiry showed that only those were poisoned who drank freely of Selters water, and an examination of this water revealed the fact that it contained a very appreciable amount of arsenic. The water was a manufactured product, and had been imported from another city.

THE SENATE OF THE UNIVERSITY OF LONDON.

A VACANCY on the Senate having been occasioned by the death of Sir G. Burrows, M.D., the Senate have appointed a meeting of Convocation to be held on Tuesday, March 6th, 1888, when a list of three persons is to be nominated, in order that it may be submitted to Her Majesty for selection therefrom of a Fellow of the University. All propositions of candidates must be sent to the Clerk of Convocation on or before Tuesday, February 21st, 1888.

DEPUTY SURGEON-GENERAL GRAVES IRWIN.

WE regret to learn that Dr. C. Graves Irwin, principal medical officer in Bermuda, has been obliged to resign the post which he has held with such credit to himself and such benefit, not only to the service, but to the whole community on the island. Dr. Graves Irwin must be well known to many readers of the JOURNAL as the President of the Bermuda Branch of the British Medical Association, the success of which is largely due to his tact and energy. Before Dr. Graves Irwin's departure he was waited on by a representative deputation of citizens and professional men, and Dr. Park Tucker, in a suitable speech, presented him with a valuable silver salver "as a token of esteem from some of his many friends in Bermuda."

THE HOSPITALS ASSOCIATION.

A MEETING of the Council of the Hospitals Association was held at Norfolk House on Tuesday, January 17th, Dr. Bristowe, F.R.S., in the chair. Among those present were Mr. F. C. Carr-Gomm, Chairman of Committee of the London Hospital; Mr. T. Holmes, F.R.C.S.; Major-General Keatings, V.C., K.C.B.; Dr. J. C. Steele, Guy's Hospital; Dr. Gilbert-Smith, F.R.C.P.; Mr. A. H. Haggard; Lieut.-Col. Montefiore; Mr. Henry C. Burdett; Mr. Keith Young, F.R.I.B.A.; Dr. G. W. Potter; Mr. P. Michelli, and others. The meeting expressed by resolution its cordial welcome to Dr. Bristowe on his acceptance of the Presidency of the Association, and its high appreciation of the honour conferred upon the council and members by his appointment. Dr. Bristowe stated that, in yielding to the request of the council, he had felt impelled by a sense of duty to accept the honour offered to him. He considered that the Association had done much valuable work for hospitals and all connected with them, and especially instanced the National Pension Fund and the Nurses' Registration Scheme now approaching completion. He also emphasised his conviction that the Association was steadily growing in the esteem and confidence of the hospital world and of the public, and that the recent additions to the council of Sir E. Currie, Mr. Carr-Gomm, of the London Hospital, and Mr. E. H. Lushington, treasurer

of Guy's, would add materially to its strength and judicial authority. Members of the Council expressed their special gratification that, through the energy and perseverance of Mr. Henry C. Burdett, the £20,000 needed to establish the National Pension Fund on a firm financial basis had been finally secured.

"FOUND DROWNED."

"FOUND drowned" is a favourite verdict with the coroner's jury in a "Thames mystery case," and it is what is commonly called an open verdict; as a matter of fact, it is frequently anything but an open verdict, as it takes it for granted that the deceased has come by his death by drowning, which may not be true. One of the metropolitan coroners has just been conducting one of the many utterly worthless inquests which are weekly, we had almost said daily, to be found reported in the newspapers. It was on the body of a ship's stoker, who had been missing for a month. No evidence was taken as to how long the body had been in the water, or whether death had been due to drowning; for the coroner dispensed with a *post-mortem* examination, and the jury, under his able guidance, returned the meaningless and possibly untrue verdict of "found drowned." The only way to check such perfunctory work as this would be to disallow a coroner his expenses for every case in which, as in the one before us, no real attempt has been made to ascertain the cause of death.

THE ILLNESS OF THE CROWN PRINCE.

SIR MORELL MACKENZIE has just received most satisfactory intelligence as to the condition of the Crown Prince of Germany. We are able to state that the rumours which appeared in some foreign journals to the effect that a fresh development of cancerous growth had given rise to urgent symptoms are absolutely without foundation. On Saturday, January 14th, His Imperial Highness caught a slight cold, and on Sunday and Monday there was some elevation of temperature, which, however, returned to the normal standard on Tuesday. We are in a position to contradict the report that Sir Morell Mackenzie will return to San Remo towards the end of this month. The date of his next visit is still quite uncertain, but we may take this opportunity of pointing out that the fact of his going to see his illustrious patient is not to be taken as an indication that the case is assuming a graver character. The Prince is looking forward with much pleasure to the prospect of being able to return to Berlin in the spring.

DINNERS FOR SCHOOL CHILDREN: AN ECONOMIC QUESTION.

WE have several times noticed the efforts that are being made to provide food for school children, and have pointed out that one of the greatest difficulties is the economic side of the question—to do the greatest amount of good with the least possible weakening of the sentiment of self-dependence in the parents. That a large number of school children are underfed or starving appears to be demonstrated; it has also been shown that the power of body and brain suffers therefrom. In too many cases starvation is chronic and incapable of permanent relief; in other neighbourhoods the relief may be required as an exceptional matter, during times of special depression in trade. We have ourselves seen a large Board School in the J. B. quarter of Birmingham where most of the children appeared to be starving, and exhausted in consequence; this was explained as owing to the local depression of trade. Here was a case where a temporary supply of cheap or even free food at the school might have been most useful in arresting the tendency to disease, and in aiding development. The Charity Organisation Society, in a valuable report recently issued on charity and food, points out many facts founded upon evidence which they have collected; reports have also appeared in Birmingham, Liverpool, and other large towns on the work done there. The starving children often appear to show more signs of daintiness than of hunger, which seems to indicate the dyspepsia of inanition. The apparatus used

for cooking makes much difference in the economy of the meals, as well as in their success in point of tastiness. To leave the children attending school without dinner for three months is likely to result in a delay of growth and development of body and brain which would take a long time to overtake. Temporary relief in periods of distress, when the children continue their school work, seems very desirable—a true work of charity, and one not too costly, though requiring much personal labour on the part of managers and visitors. If relief is to be temporary, it cannot be self-supporting; if dinners for school children are to become a permanent institution, they ought not, we think, to be provided by charity or by the State, but by commercial resource. The numerous experiments made by charitable people have afforded much information upon which commercial enterprise may be founded; but it seems hardly likely that self-paying dinners can be provided, unless accommodation is to be had at or near the schools rent free. If it be shown that there is a permanent demand for dinners at or near large schools at a commercial price, the necessity of the case might be met on the same basis as at some of our colleges; let rooms appropriately fitted be provided by the public, and let at low rentals to contractors. It ought also to be arranged that such rooms, being independent of the schools, should be open on Saturdays and during the holidays, if wanted.

ENGLISH PHYSICIANS AT SWISS HEALTH RESORTS.

THE subjoined memorial is being very extensively signed by patients and visitors at Maloja and Moritz. "We, the undersigned British subjects residing in the Engadine, pray the British Minister will petition the Federal Government of Switzerland to permit our own medical men to practise in this country, so that we may, in case of need, avail ourselves of the medical assistance of doctors of our own nationality. Many of us have come to this canton in search of health, with the express understanding that we could place ourselves under the medical care of English doctors, but in mid-winter the law of the Sanitätsrath at Coire has suddenly been put into operation, and our English compatriots are heavily fined and threatened with expulsion from the Canton of the Grisons for practising without being in possession of the Swiss diploma. Under these circumstances we beg the British Minister will represent to the Federal Government the desire named in this petition, and express at the same time that the action taken against our English doctors will prevent many English subjects availing themselves of the climate and attractions of this canton both in summer and winter, which deprivation they would feel acutely." A narrow and jealous policy in such a matter would operate very prejudicially to the interests of the locality, and no doubt the Federal Government will take this into consideration.

STROPHANTHIN AND THE THERAPEUTICAL SOCIETY OF PARIS.

A DEBATE on strophanthin was held by the Therapeutical Society of Paris on December 17th, 1887. The discrepancy of opinions as to the action and value of this powerful drug which exists on this side of the Channel is apparently equalled amongst our French colleagues. M. Dojardin-Baumetz regards strophanthin as a true diuretic, and has even seen hæmaturia arise after its use; accordingly, he considers that the prevailing English opinion that strophanthin is primarily a cardiac stimulant is incorrect. M. Constantin Paul said that he was astonished that Professor Fraser had made strophanthin equal to digitalis in its effects. Strophanthin was in the main a diuretic, its action being less energetic, but more permanent, than that of digitalis (!), but it did not, according to his observer, modify arrhythmic cardiac action in the slightest. M. Paul allowed that it acted as a cardiac tonic, but only in chronic affections, and finally said that it closely resembled convallaria majalis in its action. Other speakers dealt with the chemical constitution of this glucoside, which in dilute acids is converted into glucose and an alkaloid—strophanthidin (MM. Bardet and Arian, *Deutsche Med. Zeitung*, No. 3, 1883.)

OPERATIONS FOR EXTRA-UTERINE GESTATION.

DR. CYEMPIN, of Berlin, describes in the *Deutsche Medicinische Wochenschrift* two cases where abdominal section was successfully performed for removal of an extra-uterine foetal sac. The first patient was aged 51. Her last natural labour was in 1862; after ten years' interval she became pregnant once more; at the third month there were uterine hæmorrhage, pain, and syncope; a fleshy mass was delivered. Extra-uterine pregnancy was diagnosed, but the patient refused to submit to any form of operation. The foetus died, and then, still in the year 1872, no operation appeared advisable. In 1881 the patient sought relief, as before, in Dr. Martin's private institution, and earnestly begged for operative relief on account of severe abdominal pains. The removal of the foetus was readily effected; it lay free in the peritoneal cavity, away from any sac, and there were but trifling adhesions; part of the left foot could not be found. Greater difficulty was experienced in removing a mass to the right of the uterus, which was taken to be the placenta; after long manipulation the mass was peeled away from its connections. The patient made a good recovery. The mass when examined proved to be tube and ovary; not a trace of placental tissue could be distinguished. The ovary was normal, with the exception of a small cyst; the greater part of the tumour consisted of the left Fallopian tube, very much thickened and stretched, forming a swelling as big as a goose's egg; at its abdominal end was a cavity, the size of a cherry, filled with pus. The foetus was much shrivelled, the soft parts had almost disappeared. The case was considered to represent tubal pregnancy, early rupture of the sac, and further development of the foetus, for a time, in the abdominal cavity. In the second case, abdominal section was also performed, and a tumour was removed which proved to be a dilatation of the left tube, and very thick-walled. The seat of rupture—for the sac had burst—was at the upper and abdominal end of the sac. On the postero-external aspect of the tumour lay the skeleton of a foetus, about two inches in length.

LEAD IN THE SHEFFIELD WATER SUPPLY.

THE contamination of the water supply with lead is giving rise to a good deal of discussion in Sheffield just now. Nearly two years ago when Dr. White, the late medical officer of health, issued his report on the liability of water, in passing through the communication pipes, to become poisonous, the Corporation, with creditable spirit and energy, endeavoured to get the water company to adopt some simple means to render the water less liable to be contaminated with lead. At the commencement of this year the undertaking of the water company became the property of the Corporation. During the proceedings necessary to obtain powers to purchase the undertaking, a great point was made of the necessity of adopting means to prevent this action on the lead piping. It may be safely assumed that the people of Sheffield will hardly be satisfied with any half-hearted action on the part of the Corporation, backed as they are by influential medical opinion. The water supply of Sheffield has two distinct sources and two systems of distribution: one from the hills round Redmire, and the other from the hills round Strines and Agden. Mr. A. H. Allen, the public analyst, from a large series of analyses, found that the water derived from the Agden and Strines reservoirs and distributed to the lower parts of the town had practically no action on lead pipes, the water drawn from ordinary house taps containing no appreciable quantity of lead, even when it had been stored in the pipes all night. The case was very different respecting water from the Redmire reservoirs, for in every instance in which water was drawn from taps in houses supplied from this source a very notable quantity of lead was present. When the water had stood all night in the pipes in some cases it exceeded half a grain per gallon. The parts of the town supplied by the Redmire Dam are the high-lying districts. Moreover, the numerous cases of lead poisoning which have been reported occurred in the districts comprised in this water supply. For some reason the Redmire water appears to be acting at present particularly

on the leaden pipes. Mr. Allen states that many of the numerous samples submitted to him during the last few weeks have contained more than half a grain of lead per gallon; and in some cases one grain per gallon has been reached, and even exceeded. The plan advocated by Dr. Sinclair White of filtering the Redmiro water through a bed of limestone before it is distributed was adopted by the Corporation when before the Committee of the House of Lords. They should give it now a trial, and if it fails resort to the more elaborate measures which found favour with the old water company.

THE USE OF ACIDIFIED CORROSIVE SUBLIMATE AS AN ANTISEPTIC.

SOME very interesting experiments of great practical importance have recently been made by E. Laplace (*Deutsche Medicinische Wochenschrift*, 1887, No. 40, p. 866-7) in the Hygienic Institute of Berlin, on the antiseptic action of corrosive sublimate when used in acid solution. It has long been known that the efficiency of bichloride of mercury is much reduced when it is brought in contact with albuminous substances, owing to the formation of insoluble compounds; thus when applied to animal tissues, the mercury becomes mordanted, as it were, on the surfaces with which it first comes in contact, the sphere of its activity being thus greatly diminished. Laplace finds that five cubic centimetres of blood serum is sufficient to precipitate the mercury from five cubic centimetres of the bichloride solution (1-1000). The formation of this precipitate of albuminate of mercury can be prevented by adding dilute hydrochloric acid (5-1,000) to the bichloride solution (1-1,000), whereby the antiseptic power of the latter is greatly increased. Similar results were obtained by the addition of tartaric acid. The solution recommended for use consists of 1 part sublimate, 5 parts tartaric acid, and 1,000 parts of distilled water. The bandages, gauze, etc., on the other hand, are soaked for two hours in a stronger solution; namely, sublimate 5 parts, tartaric acid 20 parts, distilled water 1,000 parts, after which they are wrung out and dried.

ST. JOHN'S HOSPITAL.

A SPECIAL meeting was held this week of the Governors of St. John's Hospital, at which there was much discussion on the subject of the charges brought of financial irregularities and other defects in the management of this hospital. Lord Aberdare took the chair at the request of the Duke of Northumberland, the President, who expressed his opinion that an independent inquiry seemed absolutely necessary; a telegram to that effect was read by Mr. Hamilton Hoare. Mr. Raymond moved and Mr. Maudslay seconded a motion for the appointment of a committee of inquiry into the management of the hospital, to report to a future special general board, and to have power to call for documents and professional aid. A detailed statement was read by the official auditors on behalf of the Board, admitting irregularities of system, but exonerating individuals from any other than the best motives and upright conduct. Much complaint was made by Mr. L. Browne of the extravagant expenditure of the hospital; and it was alleged that the nursing had been placed in entirely unskilled hands, the cook having been instructed with a view of undertaking the duties in replacing the matron. The discussion was long and angry, the meeting appearing to consist of hostile parties. In the end an amendment was moved expressing confidence in the Board and hostile to the original motion of Mr. Raymond and Mr. Maudslay. Dr. Robinson and Dr. Harries, two of the medical officers who objected to the existing management, were silenced, and after three hours' discussion the amendment was carried by a considerable majority. The general result remains to be seen. For our own part, we cannot but feel that the proceedings seem to indicate that the opinion of the Duke of Northumberland, the President of the hospital, that an independent inquiry is necessary, is very much strengthened by the result of this meeting. The managers of a hospital greatly weaken themselves by refusing to co-operate in a full and independent inquiry

where charges of this kind are brought. A full vindication of the affairs of a public institution of this kind is best obtained, not by a partisan vote or by statements at a general meeting, but by the calm detailed inquiry of a committee which has the confidence of all parties, and we hope the Duke of Northumberland and Lord Aberdare will insist on such an inquiry, and that the result may be for the best interests of the public and the institution.

OUR NOMADIC POPULATION.

MR. GEORGE SMITH, of Coalville, giving his experiences of a number of visits made to gipsy encampments in all parts of the country, says he found that the leading traits in the character of many of the gipsies were: living in dirt, heathenish ignorance, idleness, lying, dishonesty, immorality, fortune-telling, and deception. With some notable exceptions, these people huddled together in tents, regardless of any sense of decency or morality. He calculated that there were at the present time about 30,000 children in this country living in vans and tents, not 5 per cent. of whom could read or write. Bad as was the condition of the people here, it was, he said, even worse in Scotland, and he intended to include them in a Bill he was promoting for the poor travelling children's welfare. What he wanted, without interfering with liberty, was, in the first place, that vans and other abodes of the kind should be registered annually in a simple, easy, and inexpensive way, so as to give the sanitary officer power, instead of the policeman, to see to the health and well-being of those who live in them. The healthy appearance of many of our gipsy, van, and other travellers was vanishing, and disease was carried from village to village. He desired to give them all free education. The only means of improving the condition of these people was the sanitary officer's influence upon their homes, and the schoolmaster's influence upon the children.

CLINICAL SOCIETY OF LONDON.

THE annual meeting of this Society was held on Friday evening, January 13th. The officers and Council for 1888, nominated by the outgoing Council, as published in the *JOURNAL* of January 14th, at page 108, were elected. Dr. S. Mackenzie, the Medical Secretary, read the report of the Council, which spoke of the continued and progressive success of the Society, the number of members being 464, of whom 336 are resident. In 1887 death removed six ordinary and one foreign member, namely, Dr. Carrington, Dr. Wilson Fox, Dr. Meadows, Mr. Teevan, Dr. de Castro, Sir G. Burrows (an honorary member), and Dr. Von Langenbeck (a foreign member). The Council had decided to send a copy of the *Transactions* each year to about fifty of the principal medical libraries abroad, and had done so in 1887. It had also sent all the back numbers of the *Transactions* to the chief medical society of Berlin, and also to that of Vienna. The recently published volume contains the report of the Committee appointed to investigate joint disease in connection with locomotor ataxy, which was presided over by Sir J. Paget, and of which Mr. Bilton Pollard was the honorary secretary. The Council, in their report, warmly acknowledged their indebtedness to the latter gentleman for his labours on their behalf. The myxœdema Committee are still at work at their great task, but it is expected that their labours will be concluded during this session. The work of this Committee, especially the extensive tabular record of cases, has already cost a large sum of money, and Dr. Ord, the chairman, has generously volunteered to contribute £100 towards the expenses of the production of the report, his offer has been gratefully accepted. The report will be printed as a separate volume, and a copy presented to every member of the Society, while it will also be offered for sale. The Committee on Scoliosis are still at work, and will, after a time, report the results to the Society. The balance-sheet was read by Mr. Christopher Heath, the treasurer; it showed that the year began with a balance of £94, and ended with one of £37; whilst the Society has

£600 invested in Consols. The chief expense had been incurred in the printing, illustrating, and publishing of the volume of *Transactions*, and the myxœdema tables, and for the use of the Society's meeting room. The reports were adopted. Dr. Glover proposed a vote of thanks to the retiring Vice-Presidents and other members of the Council, and remarked that in the list of the new Council he could find the name of only one general practitioner; Mr. Silcock seconded the vote, which was carried. The President said that it was clearly an oversight that only one general practitioner had been nominated. Mr. Herbert Page, in eloquent and eulogistic terms, proposed that a very hearty vote of thanks be accorded to the retiring Secretary, Dr. S. Mackenzie; Mr. Pearce Gould seconded the vote, which was carried with acclamation. The President added his testimony to the value of Dr. Mackenzie's labours on behalf of the Society, and that gentleman feelingly acknowledged the cordial vote accorded him.

PROPOSED LARYNGOLOGICAL SOCIETY.

WE are informed that a new society is in course of organisation, as a sequel to the resolution passed by the Subsection of Laryngology and Rhinology at the Dublin meeting of the British Medical Association. The Chairman, Dr. W. McNeill Whistler, in his opening address on that occasion, dwelt strongly on the advantages that such a society would afford to workers in these special branches, who at present have no means of bringing their results to the test of direct criticism by competent judges, except at the annual meetings of the Association. It was decided that immediate steps should be taken to carry Dr. Whistler's suggestion into effect, and to Dr. R. A. Hayes, of Dublin, the able Secretary of the Subsection, was entrusted the duty of making the necessary arrangements. His efforts have been so successful that the list of original members already comprises about fifty names, which include those of nearly all the prominent laryngologists in the three kingdoms. The following gentlemen, among others, have signified their intention of joining the society: Sir Morell Mackenzie, Dr. Whipham, Dr. E. Woakes, Dr. Prosser James, Dr. A. Orwin, Dr. Coleman Jewell, Dr. Greville Macdonald, Dr. Dundas Grant, and Messrs. Lennox Browne, Carmalt Jones, George Stoker, W. R. H. Stewart, and Percy Jakins, of London; Mr. C. Warden, of Birmingham; Dr. Ward Cousins, of Portsmouth; Mr. Creswell Baber, of Brighton; Dr. P. McBride and Dr. G. Hunter Mackenzie, of Edinburgh; Dr. T. Barr, of Glasgow; Dr. Philip Smyly, and Messrs. Kendal Franks, Thornley Stoker, and J. B. Storey, of Dublin; Dr. Walton Browne, of Belfast; and Dr. A. Sandford, of Cork.

THE BEHAVIOUR OF THE BLOOD IN LIGATURED VESSELS.

BÖTTCHER'S researches on this subject, conducted according to the latest histological methods, are to be found in the *Arbeiten aus dem pathologischen Institut zu Königsberg*. They fully confirm the conclusions of Dr. Geiterbock, also those of Professor Pick, of Prague, on the processes which occur in the (so-called) organisation of thrombi. Böttcher finds that the blood contained in a portion of a vessel intercepted between two ligatures, applied under antiseptic precautions, does not coagulate. The changes which occur in the stagnated blood are as follows: 1. Arterial blood becomes venous in character by long standing. 2. The red corpuscles may remain perfectly intact, even after the circulation has been suspended for several weeks. 3. The leucocytes early undergo degeneration, even in a week, but their nuclei preserve their capacity for stains. 4. The blood-tablets may be found in well preserved condition, even after several days' stagnation. Finally, enumeration of the various forms of leucocytes in rabbits' blood led to the conclusion that the "lymphocytes," that is, the small, uninucleated forms of leucocytes, poor in protoplasm, represent the majority of the leucocytes existing in the blood. This is contrary to the prevailing assumption on the subject, which puts these very forms in the minority. This is a point, as Geiterbock remarks, of great importance in the study of the products of chronic inflamma-

tion, the leucocyte elements of which are mostly in the form of lymphocytes, as is well known, and this circumstance has been adduced as an argument against their hæmatogenous derivation.

TREATMENT OF INEBRIETY.

DR. NORMAN KERR delivered the second of his course of lectures on Inebriety on January 18th. He said that the predisposing and exciting causes of the disease in each case should be ascertained, and the treatment conducted on thoroughly scientific principles. Proceeding by an unscientific method, numerous alleged "cures" had been oracularly declared to be infallible; yet all these, such as alcoholic frog extract, raw meat and food steeped in alcohol, had been found to be ineffectual. There was nospecific. The first indication of sound treatment was the withdrawal of the narcotic, so that the narcotising process might be terminated. This withdrawal should be immediate with alcohol, chloroform, chloral, and ether, but should be gradual with morphine and opium. The risk and suffering with the last named were as a rule too serious in sudden withholding. Bromides with hyoscyamus were useful in allaying the irritability of the nervous condition. When gastric irritability was present, the bromides could be administered in an effervescent form. Ice, milk, and soda or lime water were of service. The second indication of scientific treatment was the removal of the exciting cause, or its counteraction when it could not be got out of the way. The third indication was the reparation of the physical damage wrought by the disease, the remedying of the pre-inebriate morbid state, and the strengthening of inhibition. Good sound wholesome food was essential to the renovation of healthy tissue. No restricted diet suited all, and a judicious mixture of flesh, fruit, grains, and vegetables was generally the most desirable. Tonics, contra-indicated at an earlier stage of treatment, were useful here. Among the best was un-intoxicating "port with bark." The correction of the pre-inebriate morbid state was of importance. Disordered function should be set right, and complicating disease attended to. The inhibitory power should be strengthened by exercise, by bracing hygienic measures, by mental, moral, and religious influences, and by nerve tonics, as strychnine. When seen early the inebriate could be treated while pursuing his usual calling, but resort was seldom had to medical advice till later. Then it was generally best to advise residence for at least twelve months in a genuine home for inebriates, preferably under the provisions of the Habitual Drunkards Act. When seen at an early stage this disease was as curable as most other diseases.

SPONTANEOUS DETACHMENT OF LARYNGEAL POLYPUS.

AT the meeting of the Berlin Medical Society, December 21st, Professor Fränkel read a very interesting communication from Sanitätsrath, Dr. von Swidersky, of Posen, on a case of extrusion of a polypus of the larynx during the act of coughing. Dr. von Swidersky had known the patient, a cavalry officer, since 1848. In 1862 he began to be affected with hoarseness and dyspnoea, and Dr. Valentiner then diagnosed laryngeal polypus. Other authorities in Berlin and Tübingen were consulted; one of these was of opinion that villous cancer was present, because the growth (plainly visible on the posterior third of the left vocal cord, and attached to its inferior aspect) bled profusely when touched. All who were consulted advised tracheotomy, but this the patient would never hear of. The dyspnoic attacks occurred from time to time, often accompanied by severe hæmorrhage, and the hoarseness increased. In 1870, von Swidersky, tracheotomy being still refused, attempted local treatment. The tumour was first touched with caustic potash (well solidified), and afterwards daily with a concentrated solution of ergotin. On May 12th, 1870, the patient was in imminent danger of suffocation, but next day his medical attendant found him in good voice and spirits, enjoying a cigarette with his coffee. He triumphantly pointed to a substance which he had coughed

up, and which he had placed in water. Microscopical examination showed that it was a fibroid polypus. The patient has remained well since then, and there is only a slight inclination to laryngeal catarrh. V. Smidensky attributed the cure to the ergotin treatment. Professor Fränkel had never in his large experience met with a similar case, and was of opinion that practically we should never trust to such a lucky termination, quite as uncertain as the chief prize in a lottery. But he had seen a case in which a polypus had very gradually retrogressed. Dr. Böcker had independently diagnosed the existence of a polypus in this case, so that there was no doubt about it. Hensch thought that it might have been coughed up without the patient's knowledge, and argued from analogous rectal polypi in children, but Fränkel persisted in his opinion that the improvement in his case had been but gradual, and promised further details in a paper on the subject about to appear.

THE CASE OF TRANCE AT BATTERSEA.

SOME excitement has been caused by the case of Florence Chisnell, a young girl, who has lain in bed, at her home in Battersea, in a state of trance ever since November 20th, 1887. She is tall, well nourished, and well developed, contrary to what has been reported, with plain, intelligent features and reddish-brown hair. She lies on her back with her eyes half open and generally oscillating slowly; the pupils are dilated and sluggish, the conjunctivæ sensitive; the lids seldom close or blink. The pulse is about 84; the temperature on Thursday morning was 98.0°. The arms are very rigid, the forearms bent, the hands crossed over the epigastrium, with the fingers extended. On extending the elbow, we found that the hand remained elevated for three minutes, then returned to its former position very slowly. The hips, knees, and ankle joints are extended and very rigid. The abdomen is somewhat distended with flatus. Deep pressure in the iliac region produces absolutely no effect. On tapping the skin of the cheeks, fingers, abdomen, or feet with the point of a toothpick, or on pressing the point under one of the finger nails, the eyes oscillate a little more rapidly than usual, but no muscular movements occur. The bowels act spontaneously about three times weekly. The periods commenced a year ago, and have continued to appear since the trance began. In the summer of last year she became aphonic; her voice improved a little late in the autumn. On the evening of November 20th, she fell into the trance; the rigidity of the muscles was noticed from the first. Frequent fits of laughing and crying occurred until three weeks ago. Florence Chisnell, in fact, is suffering from a neurotic condition not unknown to science.

THE COMPARATIVE ANTISEPTIC VALUES OF CHLORIDES, NITRATES, AND SULPHATES.

In a recent number of the *Journal of the Society of Chemical Industry* (Vol. vi, No. 11), Mr. C. T. Kingzett, F.C.S., records the results of some experiments which he has conducted in order to determine the relative extent to which certain metallic chlorides, nitrates, and sulphates retard the appearance of mould on flour-paste, and putrefaction in extract of beef respectively. The general bearing of the results is to show that the salts of the alkalis and alkaline earths, excepting magnesium sulphate, appear in many instances to promote and never to retard the growth of mould. The compounds of zinc resemble those of the alkaline earths in their action. On the other hand, the salts of iron, tin, lead, and aluminium exercise distinct but not very powerful effects in preventing the appearance of mould. The chloride of lead is, however, more active, whilst the most efficient are the chlorides of mercury and copper. In preventing the putrefaction of extract of beef, the chlorides of mercury and copper were also the most effective; whilst chloride of zinc was more and chloride of lead less active than in retarding the growth of mould on flour-paste. The value of the investigation is very much reduced owing to the experiments not having been conducted on the modern lines of bacteriological research. Thus the various test-

glasses containing the experimental media were allowed to become accidentally infected from the air to which they were exposed, instead of being all inoculated either with some definite micro-organism or with some definite mixture of microbes, as is now invariably done in experiments of the kind.

HOMICIDAL INSANITY IN CHINA.

ACCORDING to the law of China, the punishment inflicted on the murderer of a father, mother, brother, husband, uncle, or tutor, and on traitors, is that appalling process known as *ling-chie*, or slow death. The fact that the crime has been committed under the influence of insanity procures no mitigation of the dread sentence, and the miserable culprit is sentenced to be cut into 24, 36, 72, or 120 pieces, a large proportion of which must be accomplished ere the executioner dares to touch a vital part, and end the torture of the victim. Only in certain cases does the Imperial clemency grant death after the eighth division. The commonest form of this penalty is that of twenty-four cuts; and the executioner prides himself on the anatomical skill with which they are administered. The victim being bound to a cross, the butcher by the first two cuts removes the eyebrows, by the third and fourth the shoulders, the fifth and sixth the breasts, the seventh and eighth the flesh of the forearm, the ninth and tenth the flesh of the arm, the eleventh and twelfth the flesh of each thigh, and so on.

ANGIOMA OF THE EPIGLOTTIS.

In the *Revista de Ciencias Medicas* Dr. C. M. Desvervigne reports an example of pedunculated angioma of the epiglottis. The patient was a man aged 53, of robust constitution, who for two months before he came under notice had suffered from occasional slight bleeding from the throat. On November 14th he lost a large amount of blood, and the hæmorrhage only ceased on syncope supervening. Laryngoscopic examination showed an ovoid tumour of lobulated appearance and dark-blue colour, and measuring two centimètres in length by one in breadth, springing from the laryngeal surface of the epiglottis to the left of the middle line, about midway between the base and the apex. The tumour was attached by a short pedicle, and there was no infiltration of the tissues around its root. On November 27th, the pharynx and larynx having first been anaesthetised with a concentrated solution of cocaine, the tumour was removed with the galvanocautic snare. The only trace of the operation was a small eschar which came away a few days later, leaving the site of the tumour completely healed. Microscopic examination showed that it was an angioma enclosed in a fibrous capsule.

STROPHANTHUS IN RUSSIA.

DR. A. KAZEM-BEK, of Kazan (*Vratch*, Nos. 40 and 41, 1887) relates seven severe cases treated by tincture of strophanthus (one part of the seeds to ten of alcohol), five drops being given every three hours, four times during the first day, and ten drops three times daily subsequently. The cases included chronic myocarditis, with consecutive cardiac dilatation, with calcareous deposits on the aortic valves and walls; mitral stenosis, with regurgitation (two cases), alone or complicated with parenchymatous nephritis; bronchial asthma, with pulmonary emphysema (two cases); aortic stenosis, with regurgitation; and cardiac neurosis in a hystero-epileptic woman. In only one case, that of a woman, aged 37, with rheumatic mitral disease and chronic nephritis, did the drug partly fail, and, even in that case, it proved beyond all comparison better than succinate of caffeine and sodium, or digitalis with valerian, or grindelia robusta, or convallaria, with which the lady had been successively treated before. In the remaining six cases, strophanthus produced a striking improvement, usually in a very short space of time; dyspnoea ceased; the paroxysms of bronchial or cardiac asthma, as well as œdema, gradually disappeared; the heart's action became much less frequent and more regular, and the pulse fuller and stronger; while the daily amount of

urine considerably increased. When taking the medicine, the patients slept soundly and quietly for many successive hours. This circumstance is attributed by Dr. Kazem-Bek partly to an improvement in their general state, but partly to a direct sedative action of the drug on the brain, since a drowsy condition was observed by him also in dogs after an intravenous injection of the tincture. The experiments on animals (frogs, turtles, and dogs) were undertaken by the writer mainly with the object of elucidating the question whether strophanthus acts solely on the muscular tissue or not. He has come to the conclusion that the drug acts, not only on the cardiac muscle itself, but also on the cardiac ganglia and peripheral endings of the vagi. This conclusion is based on the following facts: 1. That atropine gives rise to a considerable acceleration of the heart's contractions which have been previously slowed by strophanthus; and 2, that strophanthus does not slow the heart's beats which have been previously accelerated by atropine. Dr. Kazem-Bek has also found that strophanthus increases the blood-pressure, but this increase seems to be independent of the heart's contractions; at least the arterial tension continues to rise, while the number of the beats remain unchanged.

THE DYEING OF COFFEE BERRIES.

HAVING succeeded in obtaining four specimens of colouring mixtures employed by coffee dealers for dyeing inferior sorts of coffee beans as well as damaged coffee grains, Mr. K. Sykora (*Farmaceutichesky Jurnál*, No. 48, 1887, p. 756) subjected them to analysis, and found that they consisted of (a) 4.5 to 8.0 per cent. of chromate of lead ($PbCrO_4$), (b) 12 to 15 per cent. of ultramarine, (c) 5 to 12 per cent. of indigo and gamboge, (d) 65 to 82 per cent. of kaolin, and (e) 3 to 10 per cent. of charcoal. Mr. Sykora recommends the following means of detecting this adulteration. First of all, on being touched with a brush moistened in distilled water, an artificially coloured coffee grain becomes spotted or mottled. On washing the grain with distilled water the latter becomes turbid in appearance. On evaporating a portion of the fluid on a watch glass, it leaves a solid residue, consisting of kaolin, charcoal, and various dyes, which may be then recognised under the microscope. Another portion of the water should be dried and subsequently made red-hot in a platinum vessel, to be similarly examined microscopically. On one occasion Mr. Sykora found that coffee berries had been dyed with yellow brown ochre.

UNMERITED SYPHILIS.

M. FOURNIER, in a recent communication, has set forth the statistics which he has taken the trouble to collect of "unmerited" cases of syphilis. In 842 out of 887 infected women, the disease was of venereal origin, leaving 45 who had contracted it in some other way. On analysing the latter group he found that in seven the disease was hereditary; four had contracted it accidentally in infancy; eight were wet nurses who had been infected by syphilitic infants; five were midwives who had caught it in the practice of their profession; twenty-two were cases of "domestic infection," either from nurse to child or *vice versa*, or from diseased servants; two of vaccinal syphilis; two in which the infection was conveyed in catheterising the Eustachian tube; one consequent on rape; and finally four of unknown origin, but certainly independent of sexual contamination. With respect to the first group of 842 infected women, 366 were "gay" women; 220 were married women, and 256 were of "doubtful" social status. Of the married women no fewer than 164 had taken the disease from their husbands. In view of these figures, M. Fournier maintains that the doctrine which forbids discrimination between the different groups of sufferers is one to be unhesitatingly condemned.

CUCAINE TOXÆMIA.

At the last meeting of the American Association for the Cure of Inebriates, Dr. J. B. Mattison, of Brooklyn, read an interesting paper on the toxic symptoms observed after the administration of cocaine. The object of the paper was to disprove Dr. Hammond's assertion that

he did not believe any dose that could be taken was dangerous. If it were needful to produce more proof of the unsoundness of Dr. Hammond's statement, Dr. Mattison has effectually done this. More than thirty cases, reported by various practitioners in different parts of the world, were brought forward. In all these dangerous symptoms were developed, and in several instances there was an exceedingly narrow escape from a fatal termination. Toxic symptoms were exhibited in an adult after even so small a dose as four minims of a 4 per cent. solution, given hypodermically. The leading symptoms were nausea, emesis, headache, blindness, deafness, loss of taste and smell, profuse perspiration, lividity, gastric cramp; pulse frequent, feeble, irregular, intermittent; respiration shallow, gasping, irregular, difficult, convulsive, suspended; impairment of gait, speech, and swallowing; muscular rigidity, palpitation, sense of suffocation and constriction of chest; loss of motion and sensation in limbs; restlessness, prostration, giddiness, faintness, feeling of impending death; convulsive twitchings, paralysis, mania, delirium. The general conclusions arrived at were that there is a lethal dose, though the fatal quantity is uncertain; that toxic effects may appear at all ages and in every state of health; that the drug should be administered with great caution, and never without the antidotes of amyl nitrite and hypodermic morphine for immediate use.

PROGNOSIS.

DR. PYE-SMITH has contributed to the current (forty-fourth) volume of *Guy's Hospital Reports* an interesting article, entitled Observations on Prognosis. It is likely to prove of great service to students, who have better opportunities of studying the main clinical appearances in disease than of acquiring prognostic faculties before qualification. Prognosis requires experience, and experience is just what every student must lack. The look of many diseases may soon be learnt, but prognosis requires the observation of many cases of the same disease in every type of subject which it is likely to attack, and the student cannot observe to this extent. Moreover, hospital patients recover from some diseases, and die from others which are more or less dangerous to private patients neither inured to hardships nor debilitated by poverty; so the limited prognostic power of the diligent student may serve him false after qualification. Dr. Pye-Smith dwells upon the temperature question. He notes how a transitory ailment may send up a child's temperature to 102° or 103°, whilst a high temperature, as 105° in scarlatina or pneumonia, in a child does not add to the gravity of the prognosis as it would in an adult. Women resemble children in this as in other respects. A temperature of 103° in a girl of 18 may be caused by menstrual irregularity, by non-specific sore-throat, or by slight gastric catarrh. A rise of temperature during menstruation is often noted after ovariectomy. Dr. Pye-Smith's observations on fevers and tubercular meningitis are most instructive, but cannot fairly be given here in a condensed form. He concludes his paper with some interesting prognostic aphorisms.

THE LESSON OF THE EPIDEMIC OF SMALL-POX IN MONTREAL.

A PAPER on the Outbreak of Small-pox in Montreal, Canada, during 1885-86, was read by Dr. Henry Tomkins, officer of health to the borough, before the Leicester Medical Society, on January 13th, 1888. For some years previous to the outbreak the city had been free from small-pox, and vaccination had been very much neglected, compulsory powers not being enforced. A man from Chicago suffering from a very slight attack, so mild as to be mistaken for chicken-pox, was admitted into a large general hospital, and from him the infection spread to several other inmates, from thence the disease was disseminated in numerous parts of the town, and extended with such rapidity that before the end of 1885 more than 3,000 deaths had occurred. During the progress of the disease so great was the demand for vaccination amongst those who had previously neglected it that more than 80,000 vaccinations and revaccinations were performed in a popula-

tion of about 160,000 at a great expense and by the putting into force of compulsory notification of infectious disease, vaccination, and efficient isolation and disinfection, the disease rapidly abated, and by the end of April, 1886, not a case was known to exist within the city. Up to the end of 1885, 3,164 deaths were recorded, of which no less than 2,717 were children under 10 years of age, showing how severely these suffered compared with vaccinated communities. From the returns supplied by the hospitals, the following figures were given:—The number of patients treated in hospital was 1,332; the deaths amongst these were 418, or 31.3 per cent.; of these patients, 805 were not vaccinated and 527 vaccinated; of the latter 103 died, or 19.5 per cent.; of the 505 not vaccinated there died 315, or 39.1 per cent. As further showing how many more children suffered than adults, who had mostly been once vaccinated, it is to be observed that out of the 1,332 patients admitted into hospital, 489 were under 10 years of age, and 848 above that age; of the former 202 died, whilst of the latter 216 only died.

SCOTLAND.

CHAIR OF BOTANY, EDINBURGH UNIVERSITY.

VARIOUS gentlemen are spoken of as probable candidates for the Chair of Botany at Edinburgh University—namely, Professor Isaac Bailly Balfour (Oxford), Mr. Patrick Giddes (Edinburgh), and Professor Traill (Aberdeen); but it may be conjectured that the list will be considerably enlarged when notice of formal application has been given.

THE PROPOSED NEW CHARTER FOR THE LONDON COLLEGES.

KEEN interest has been excited in Edinburgh regarding the memorial of the London Colleges. Considerable diversity of opinion has manifested itself as to the effect this move, if successful, will have on the Edinburgh Medical School. The *Scotsman* has taken up the cudgels against the London Colleges, and calls on public spirited citizens and members of the profession to resist a measure so destructive to their city's interests. Professional opinion appears divided, if we are to judge from the rumours of compromise; but there is almost complete unanimity of view, even among keen opponents of the primary measure, that whatever is granted to the London Colleges must, of necessity, be granted to the Edinburgh Colleges likewise.

MATERNITY HOSPITAL, EDINBURGH.

THE arrangements in the Royal Maternity and Simpson Memorial Hospital, Edinburgh, during the next three months, will be that Professor Simpson will be succeeded as Physician on duty by Dr. Underhill, with Dr. Barbour as assistant-physician. The present house surgeons, Messrs. John G. Havelock, M.B. and C.M., and Christopher Martin, M.B. and C.M., will be succeeded by Messrs. F. A. Jakes, M.B. and C.M., and Inglis Taylor, M.B. and C.M.

ROYAL INFIRMARY, EDINBURGH.

THE series of entertainments given to patients, nurses, and students which commenced with the kitchen concert in the middle of December in the Royal Infirmary, Edinburgh, and consisting of *soirées* and concerts in various wards, have afforded much entertainment and been on a more extensive scale than in previous years. From the report submitted at the annual meeting of the subscribers to the Infirmary, which was held on Monday, we learn that the total number of indoor patients treated during the year was 8,823, as compared with 8,033 in the preceding year, this large increase being mainly due to the greater number of wards now open. This is the largest number of patients ever treated in the wards in any year, and becomes more striking when it is considered that no cases of infectious disease are now treated in the Infirmary. The proportion of medical and surgical

cases treated to a conclusion was: surgical cases 52.9 per cent., and medical cases 47.1 per cent. The average number of days of residence was much the same as last year, 26.1 as against 26.9. The number of outdoor cases has also increased, and last year reached the number of 25,000. The number of beds now available for use in the wards is 670, with 30 cots in addition available for children. The average daily increase of beds has been 27 compared with previous years, and the rate of maintenance per bed has been £55. The financial condition is not so satisfactory as could be desired, the capital stock having been reduced by £9,711, while the building debt remains the same. There has been an unusually small amount of money derived from legacies during the year, amounting to only £7,670. In 1880-81 it was rather under £7,000, but the ten years preceding that gave an average of £15,000, and since that the average has been as high as £37,896. In their report the directors speak in high terms of their appreciation of the services of the superintendent, Deputy Surgeon-General Fasson.

GLASGOW LUNATIC ASYLUM.

THE annual meeting of the directors of the Glasgow Lunatic Asylum was held last week. The report submitted stated that at the beginning of the year the number of patients at Gartnavel was 480. The admissions during the year numbered 153, the discharges 137, of which 69 were recoveries, and there were 23 deaths. Of the total 470 at the close of the year, 286 were private patients, and 184 chargeable to their parishes. The report on the health of the inmates was exceptionally good, the percentage of recoveries being higher and the death-rate lower than on any occasion ever recorded at Gartnavel. The financial statement showed that the reserve fund of the asylum amounts to £28,796.

CONVALESCENT HOME, GLASGOW.

THE Lenzie Convalescent Home continues to complete the good work done in the Glasgow infirmaries and dispensaries. At the twenty-third annual meeting it was stated that last year 1,441 patients were received at the institution, and their average stay was 18 days. The expenditure during the year included £408 for alterations and additions to the farmsteadings, the cost per head for patients amounted to 1s. 4½d. a day, the total amount expended being £2,170 16s. 6d. The annual subscriptions came to £902 9s. 6d., the contributions from *employés* of works, etc., £306 2s. 11d., and the legacies £438.

THE LATE PROFESSOR DICKSON: A REMINISCENCE.

A CORRESPONDENT writes: Of five or six men distinguished by their labours in various branches of science, who taught in the medical curriculum at Glasgow University, some fourteen years ago, there was none who left a more enduring impression on a certain order of youthful minds than the late Professor Alexander Dickson. In no sense a brilliant orator, or showy dispenser of secondhand information, he yet managed to gain a respectful hearing from audiences, who might perhaps not unnaturally have been thought but slightly appreciative of higher claims upon their regard. There was in him a sleepless intellectual inquisitiveness, and he combined a rare gentleness and modesty with a certain naïve self-possession and unaffected ease of manner, the infallible marks, as all felt, of good breeding, and of a fine character. When interrupted in his discourse by more than usually noisy demonstrations of applause or disapproval, he has been heard somewhat pathetically to ask indulgence, on the ground that he was "not without nervousness," and it was this very excess of sensibility which, pervading the whole range of his mental activities, made him sympathetically alive to the perplexities and difficulties of others, while it, at the same time, had no small share in inspiring those feelings of almost chivalrous devotion, with which he was wont ere long to be regarded by the more "finely touched" among the students. As I write, the memory of our botanical excursions comes back after the lapse of years, fresh as those early spring mornings,

when we left the darkness and din of the great city, to wander in the sunny lanes of Clydesdale, or on the Camprie Hill. The figure of the Professor is still before me, tallish and slightly stooping, dressed in grey tweeds and small round cap, smoking a short pipe, with both hands in trousers pockets, striding rapidly along one side of the road, or pausing to describe some peculiarity of plant structure, with an enthusiasm which regarded neither time nor place, and which would constantly, when the discourse seemed to be near an end, as it were, spasmodically hurry the speaker away on some fresh line of inquiry and speculation, till at length he was brought up by noticing that his audience had dwindled to not more than one or two, whose blank faces indicated awe and dismay at the recondite and interminable course of the argument, and then an amused smile would pass into the dark blue eyes, and as if suddenly recollecting himself, he would resume his walk. There are some to whom the earth will seem colder and even the spring violets less sweet, by the death of such a lover, but in that place where the "shades of the pious" still linger, after their bodies have decayed, the grateful recollection of hundreds whose intellectual life owes something to the kind friend and honoured teacher whose loss they mourn, Dr. Dickson's memory will be a perpetual inspiration while life lasts.

SANITATION IN ABERDEEN.

A CONSIDERABLE amount of work, directed towards the improvement of the sanitary condition of Aberdeen, has been done during the past year. No less than 3,180 nuisances were abated and 4,206 orders were given for amendment of houses and premises. Patients, to the number of 517, who were suffering from infectious diseases, were removed to the hospital, and 4,380 were supervised at home. Unwholesome meat was seized in 105 cases, and fines for dealing in it were imposed to the extent of £19, the total weight seized was 32 tons, an increase of 20 tons on that of the preceding year. Dr. Mackenzie Booth has been appointed interim medical officer of health in place of Dr. Thomson, who has been appointed to a similar office in Sheffield.

FEVER IN PAISLEY.

PAISLEY has lately had an unenviable notoriety for the number of cases of fevers which have occurred in it. During the month of December, eighty-one cases of infectious diseases were admitted to the hospital, comprising sixteen cases of typhus, sixty-three of enteric, and two of scarlet fever. It is stated that no fewer than one hundred and twenty-six cases of enteric fever which occurred during the epidemic were associated with the milk supply from one dairy in the town. It is remarkable that so large a number should have been allowed to occur from one source of contamination. Twenty-four deaths from infectious diseases occurred during the month. There remained in the hospital on December 31st nine cases of typhus, fifty-four of enteric, and three of scarlet fever.

IRELAND.

THE death-rate of Belfast is said to be increasing to an alarming extent. It has been 41.4 per 1,000—more than double the rate in London and one-half greater than in Dublin.

THE LATE MR. D. F. BRADY.

MR. DANIEL FREDERICK BRADY died at his residence, Rathgar, on Monday, at an advanced age. He obtained the diploma of M.R.C.S. Eng. in 1836. He was inspector of anatomy in Ireland.

POISONING BY SEWER GAS.

SEVERAL cases of illness, believed to be due to poisoning by sewer gas have occurred at Sandymount, Dublin, and three children of Mr. O'Callaghan have lost their lives. Dr. Murphy, of Harcourt Street, who was in attendance, found a boy, aged

11 years, suffering from ulcerated sore-throat, and having at the same time sore patches over the body. The child was then in a low typhoid condition and he never rallied. A second child, a girl, aged 15 years, subsequently displayed the same symptoms, and she also succumbed; and the third child died soon after being attacked.

JERVIS STREET HOSPITAL.

A BALL in aid of the funds of this institution is announced to take place on January 25th. In the present state of depression in Ireland all charities are suffering. There is still a balance of £16,000 due on the new building of Jervis Street Hospital.

PROPOSED SCHEME FOR NURSING THE SICK IN COLERAINE.

A MEETING of those interested in the proposed scheme for the better nursing of the sick in Coleraine was held in the Town Hall last week. A report was read from the committee appointed at the last public meeting, which showed the estimated cost of a cottage hospital, with the rules for its management. A committee was appointed to solicit subscriptions and report to a public meeting which will shortly be held.

EPIDEMIC OF MEASLES AT CORK.

DR. DONOVAN, medical officer of health, in his monthly report for December, states that there is at present an epidemic of measles in Cork, which has not occurred previously for seven years. It is difficult to prevent it spreading, owing to the fact of the infection being so intense in its early stage, and also because nearly all the cases are treated at home, where, as a rule, the disease runs through whole families. This clearly points to the necessity of having cases of infectious diseases speedily removed to hospital, which is the only proper means of isolating them. At the police court last week a man named Noonan was charged by the corporation with a breach of the Public Health Act by "waking" his child, who had died from measles. Dr. Donovan expressed his belief that the recent spread of measles was owing to such conduct as the defendant was charged with. All the persons who attended the wake (about thirty) were, he said, liable to spread the infection, and might communicate it to 200 or 300 persons. A fine of forty shillings was inflicted, but remitted on his promising to go to the workhouse.

THE NORTH-WEST SECTION OF THE NORTH OF IRELAND BRANCH.

THE second annual dinner of the North-West Section of the North of Ireland Branch of the British Medical Association was held on Wednesday, January 11th, when the members spent a most pleasant and enjoyable evening. Dr. Bernard, President of the Section, was in the chair, and Dr. Warnock, Donegal, in the vice-chair; the great majority of the members were present. After the usual toasts had been honoured, that of "Success to the North-West Section of the British Medical Association" was received with much enthusiasm. Dr. Donaldson, the able and energetic honorary secretary, responded in a few appropriate and eloquent words. He showed that the success of the Society depended principally on two factors: 1. That the medical men in the North-West of Ireland be imbued with the scientific spirit and with love for their work. 2. That the meetings be conducted properly; and in this respect he dwelt on the importance of showing living cases and pathological specimens at those meetings. He then went on to speak of the success which had already attended the Section, and finished by an account of the outlook of medicine which advancing knowledge rendered possible.

A CORRECTION.—In reference to the case of Dr. Hahn referred to last week, we are informed that the report given in the condensed extract on which our notice was based was incorrect in fact; the operation performed during life was tracheotomy, and that the larynx was extracted after death.

ANNUAL SANITARY REPORT FOR 1886 BY THE SANITARY COMMISSIONER OF BOMBAY.

We have already dealt with the Report on the Health of the European Troops in the Bombay Command for 1886.

There is nothing more notable than the rapid increase of the population of India, in spite of the annual mortality from malarial fevers, and the recurrence of epidemics of cholera, at intervals more or less uncertain, and occasional famines from destruction of the staple grain crop by failure of the monsoon. Fortunately such visitations, although prevailing over wide areas, are not universal, and as year by year the railways are pushed into provinces and districts formerly ill-supplied with the means of carriage, famines, when they do occur, will be more easily dealt with and attended with less mortality. If population in the Indian empire goes on increasing at the present rate, the food supply for the teeming multitudes of people will become a serious question. The number of children born in the Bombay Presidency in 1886 was 572,431. They were 2,122 in excess of the number recorded in the previous year, while they exceed the mean of the preceding ten years ending 1885 by 169,643. The total increase of the Presidency was 10.12 per 1,000 of the population, above the mean of the preceding ten years.

The deaths in 1886 among the civil population in the 285 rural town, and cantonment circles in the Presidency of Bombay amounted to 200,140 males and 151,045 females, or a total 351,185 of both sexes. As compared with the three previous years, 1886 was a tolerably healthy year. The death-rate per 1,000 was 23.17, against 28.78 in 1885, and a decennial mean of 26.16. It is very interesting to note the great improvement in the death-rate in Ahmedabad for 1886, compared with that of 1885 and previous years; the Sanitary Commissioner gives the credit of this improvement to the wide sanitary measures introduced by Räs Bahādur Ranchorelāl, C.I.E., President of the Municipality. Under this enlightened gentleman, Ahmedabad, according to the Commissioner, "has certainly taken the lead of all the municipalities in Western India, including Bombay, in having provided a tramway, by which all the night soil collected in the city is removed to a distance of three miles from it." This would in any city in the world be deemed a sanitary measure of cardinal importance. In an Indian city it is impossible to exaggerate the good effect certain to spring from it. It is safe to prophesy that when cholera next visits Ahmedabad, Mr. Ranchorelāl will have the gratification of seeing a greatly diminished mortality, to say nothing of the good already obtained. The Government have acknowledged this gentleman's benevolent efforts; it would be well to hold up his good example to every municipality in India.

The mortality from cholera in 1886 was a mere flea-bite compared with that of the previous year, which amounted to 37,286, while in 1886 it was only 167. On this difference the Sanitary Commissioner remarks: "We know so little about the laws which govern the prevalence of cholera that it would be useless to speculate as to why the disease, after causing 37,286 deaths in 1885, should suddenly cease in the first month of 1886," and he adds, "the lessened prevalence was not due to any diminution of filth, in and around the villages and towns in the Presidency, and the only way to account for it is by the supposition that the factor necessary for its development (probably atmospheric) was absent." True; but this fact must never be kept out of sight: that in every place in the world, be it city, village, or hamlet, visited by cholera, the mortality has been in proportion to the filth present.

The Sanitary Commissioner, in obedience to a Government order, has given a map, which illustrates the distribution of and mortality from cholera in the different registration circles in which the disease was present. Appended to this is a statement showing each collectorate affected; the name and number of each circle; its population; the dates of first and last cases; the total cholera deaths; their ratio per 10,000 of the population; the period of maximum intensity; the number of villages in each rural circle; and the number of those affected and not affected by the disease. It is needless to say that a map illustrated in this way gives us instructive information as to the course and progress of an epidemic. As is usual in maps of this kind, it is coloured in different shades of green, according as a high or low death-rate obtained in the affected districts.

The deaths from small-pox amounted to 876 persons; the disease was of a mild type. During 1886, 146,986 males and 134,464 females died from "fever," a total of 281,450, while in the previous year the death-rate from this cause was 314,237. This illustrates an old Indian observation that a bad cholera year is also a bad fever year. The same rule obtains as regards bowel diseases; thus, in 1886, a non-cholera year, 36,612 persons died from bowel com-

plainte; in 1865, a cholera year, the deaths from this cause amounted to 45,056.

It is satisfactory to read of the zeal with which vaccination is carried on; 855,972 persons were primarily vaccinated, and 47,938 were re-vaccinated, a net increase of 1,585, or 0.19 per cent. under primary vaccination. It is evident that the people in the Bombay Presidency are wiser in their generation than the citizens of enlightened Leicester. The former know what small-pox is, the latter have to wait a little for their experience; when it comes it will be found in Leicester, as elsewhere, that Dame Experience keeps a dear school.

ARMY MEDICAL DEPARTMENT REPORT FOR THE YEAR 1885.

(Continued from vol. ii, 1887, p. 1399.)

THE foreign stations at which British troops were quartered during the year 1885 were twelve in number, and included a wide diversity of climates. They were Gibraltar, Malta, Cyprus, Egypt, Nova Scotia, Bermuda, West Indies, Cape of Good Hope and St. Helena, Mauritius, Ceylon, China, and India. A separate section of the report is devoted to a history of the health of the officers and men who were serving in each of these twelve military commands. The leading statistical and medical particulars furnished in the report on some of these foreign stations now follow.

The average strength of the troops comprising the garrison of Gibraltar was 4,353. There were 4,587 admissions into hospital during the year, giving a ratio of 1053.8 per 1,000; the deaths amounted to 35, a ratio of mortality of 8.04 per 1,000; and the average number constantly sick was 253.58, showing a constant inefficiency through sickness at the rate of 58.25 per 1,000. These ratios are all higher than the averages of the preceding ten years, and considerably higher, as regards the death-rate, than that of the previous year 1884, when the ratio of mortality was 4.01 per 1,000 less. The death-rate of 1884 was, however, the lowest on record at Gibraltar. Brigade-surgeon Warren, in medical charge of the station hospital, when remarking on the increase in the ratios of sickness and mortality during the year 1885, points out that the rate of mortality was increased by the occurrence of 2 deaths from cholera, 3 from enteritis, and by several deaths from injuries. Diseases of the febrile group led to 730 admissions, and among these were 10 deaths, of which 5 were due to enteric fever. In the preceding year there were only 3 cases of enteric fever; in 1885 there were 25 cases admitted. The medical report states that the disease could not be traced to any defects in the barracks or their vicinity, or in the water-supply. Primary syphilis caused 747 admissions, and secondary syphilis 140, giving ratios of 171.6 and 32.2 per 1,000 respectively, which are considerably higher than the ratios of 1884, and much above the average. Including gonorrhœa and its sequelæ, the total ratio of admissions for venereal diseases was 362 per 1,000, and the ratio of constant inefficiency from these disorders was 21.91 per 1,000, both very much above the average. One officer died from cholera. He was residing at Europa, where another case had occurred five weeks earlier, but no connection between the two cases, nor any cause for either of them, could be traced. No other cases occurred subsequently at Europa.

The average strength of the troops composing the garrison of Malta was 4,602. This number does not include the men of the Malta Fencible Artillery. The force enumerated caused 4,249 admissions into hospital, giving a ratio of 923.3 per 1,000; and among these were 68 deaths, a mortality of 14.77 per 1,000. The average number constantly sick was 272.04, being at the rate of 59.11 per 1,000. All these proportions are higher than they were in 1884, and are above the averages of the preceding 10 years. Enteric fever caused 93 admissions and 24 deaths. The deaths from this disease were equal to 35 per cent. of the deaths from all causes. Of the cases, 14, with 6 deaths, occurred at Valletta; 74, with 15 deaths, at Cottonera; and the principal medical officer attributes the disproportion in the number of cases which occurred at the two places to the improved water-supply of Valletta, while there was no corresponding improvement in the water-supply of Cottonera. The remaining 5 cases took place at Civita Vecchia. The medical officer of Cottonera remarks that the "enteric fever was very fatal during the hot months, and the year 1885 was one of the hottest ever known in Malta." Two cases of small-pox occurred among the troops; they were severe, but both the patients recovered. The disease was said to have been introduced by sailors at the lazaretto. Thirty-nine cases occurred among the civil population, but, careful precautionary measures being adopted, it did not spread among the military beyond the two cases already named. Primary syphilis caused 172 admissions, and secondary syphilis 102, the ratios being 37.4 and 22.2 per 1,000 respectively. Gonorrhœa and its sequelæ

caused 309 admissions, equal to 67.1 per 1,000 of the strength. Seven deaths were due to injuries; 3 being due to falls, 2 over ladders, and 1 from a terrace at the Valletta hospital; 2 resulted from drowning, and 2 were suicidal.

Some remarks, which appear to demand attention, are made by the Principal Medical Officer and other medical officers with regard to the bad state of health of the Dorsetshire Regiment. This corps had the highest ratios of admission and of constant sickness during the year, namely, 1,465.8 and 114.43 per 1,000 respectively. These high ratios are attributed in the report to "the inferior physique and great youth of the men, which rendered them quite unable to endure the unusual heat of the summer." The medical officers in immediate connection with the regiment also point out that the spring of the year was the most unfavourable time in which the regiment could have arrived in the command. The Principal Medical Officer concurs in this view, and adds he has noticed that regiments which have arrived in the island in the spring have suffered much from fever during the following summer and autumn.

The average strength of the Royal Malta Fencible Artillery was 353 non-commissioned officers and men and 20 officers. The corps was not so healthy as it was in 1884, and the admissions into hospital were above the average of the previous six years, but only one death occurred; this death resulted from remittent fever. It would appear from the report on the recruiting for this corps that there is considerable room for improvement in the matter of education in the island of Malta. Out of 111 recruits inspected during the year, only 1 was returned as well educated; and of the remainder, only 25 were able to read and write, while 2 could read but not write, and 83 were unable to read.

The troops quartered in Cyprus averaged 852 in number. There were 918 admissions into hospital, and 18 deaths; being at the rates of 1077.4, and 21.13 per 1,000 respectively. These numbers show a considerable increase by comparison with the corresponding ratios for the year 1884, and also as regards the average similar ratios for the preceding 6 years. With regard to the increase of disease and mortality in 1885, the Senior Medical Officer remarks that "the high ratios are due to the arrival of certain battalions from Egypt, the men being in a very sickly and debilitated condition from the hardships of the recent campaign at Suakin, and to enteric fever having broken out among them. A somewhat similar increase in sickness and mortality occurred in 1882, when a regiment arrived from Egypt under similar circumstances." Enteric fever caused 51 admissions to hospital, and 15 deaths. The greater number of the admissions and deaths occurred at Troodos, and the medical officer in charge at that port remarks:—"During the two years I have been in charge of the military hospitals at Cyprus I never saw a case of enteric fever amongst the men of the garrison except among those just arrived from Egypt." There was no death among the commissioned officers, who were 37 in number, nor among the women and children, whose numbers were 27 and 40 respectively.

The only station in the Dominion of Canada in which there was a garrison of imperial troops during the year 1885 was Halifax. The average strength of the troops quartered there was 1,273 non-commissioned officers and men, and 66 commissioned officers. Among the former there 910 admissions into hospital and 10 deaths, being at the rates of 714.8 and 7.86 per 1,000 respectively. There were 24 attacks of illness among the officers, but no death. Among the women, 89 in number, there were two deaths from phthisis pulmonalis; and among the children, who averaged 183 in number during the year, there were 11 deaths. One soldier, who had managed to conceal his illness for a fortnight, died from enteric fever, and this was the only case that occurred among the troops during the year at this station.

(To be continued.)

THE COLLEGE OF STATE MEDICINE.—The following gentlemen were elected Associates of the College at the meeting of Council on January 13th, 1888, Sir Joseph Fayrer, K.C.S.I., in the chair:—Adams, Charles, M.B., LL.B., Qal. State Med. Dub., Surgeon I.M.D., Madras; Alexander, F. W., Dip. Pub. Health R. Coll. Phya. Surg. Eng., Mile End Infirmary; Birch, Edwd. A., M.D., F.R.C.S.I., Cert. Pub. Health, R. Coll. Phya. Edin.; Corban, Laurence, M.D., Dip. San. Sci. R. Irel., Surg.-Major M.S.; Callen, Peter, M.D., Cert. Pub. Health, R. Coll. Phya. Edin., Surg.-Major I.M.D. Bengal; Evers, Benjamin, D.P.H.Camb., Surg.-Major I.M.D., Bengal; Hehir, Patrick, D.P.H.Camb., Surg. I.M.D., Bengal; McGann, T. G., F.R.C.S.I., D.P.H.Camb., Surg.-Major I.M.D., Madras; McNally, C. I., M.D., D.P.H.Camb., Surg.-Major, I.M.D., Madras; Simpson, W. I. R., M.D., D.P.H.Camb., Med. Officer of Health, Calcutta; Thompson, S. I., D.P.H.Camb., Surg. I.M.D., Bengal; Weightwick, F.P., M.B., D.P.H., R. Coll. Phya. Surg. Eng., St. John's, Horsleydown.

ROYAL COLLEGE OF SURGEONS.

AN extraordinary meeting of the Council was held at the College on Thursday afternoon, January 19th. The minutes of the quarterly Council, held on January 12th, were read and confirmed. A report was read from the Secretary of a candidate found qualified for the diploma of Fellow. It was resolved to issue a diploma of Fellow to Mr. C. L. Hudson, of Middlesex Hospital.

The Council then proceeded to the further consideration of the proposed reply to the Privy Council respecting the statement made on behalf of the Association of Fellows in reference to the supplemental charter. The revised reply, as proposed by the President and Vice-Presidents, was read, and, after some discussion and amendment, was agreed to, and ordered to be sent to the Lord President of the Privy Council, without waiting for confirmation by next meeting of Council.

ASSOCIATION INTELLIGENCE.

COLLECTIVE INVESTIGATION OF DISEASE.

THE Report upon the CONNECTION OF DISEASE WITH HABITS OF INTemperance, which was presented to the Section of Medicine in the Annual Meeting of 1887, and a further portion of the Report upon OLD AGE have been completed, and will shortly be published in the JOURNAL.

Reports upon the two remaining inquiries, namely, that into DIPHTHERIA, and that into the GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES, are in preparation, and will be published as soon as ready.

The following inquiry only of the first series remains open, namely, that on THE ETIOLOGY OF PHTHISIS.

A fresh inquiry into the ORIGIN AND MODE OF PROPAGATION OF EPIDEMICS OF DIPHTHERIA has just been issued.

Memoranda upon these subjects, and forms for recording observations, may be had on application to the Secretary of the Collective Investigation Committee, 429, Strand, W.C.

BRANCH MEETINGS TO BE HELD.

METROPOLITAN COUNTIES BRANCH: WESTERN DISTRICT.—The next meeting will be held on Friday, January 27th, at St. Mary's Hospital, Paddington (by kind permission of the medical staff). The chair will be taken, at 8.30 P.M., by H. Charlton Bastian, Esq., M.D., F.R.S., the Vice-President of the District. Business: 1. Minutes of preceding meeting. 2. Clinical remarks on Chronic Diseases of the Knee-joint in Young People: by Edmund Owen, Esq., M.B., F.R.C.S., Surgeon to St. Mary's Hospital and the Children's Hospital; several illustrative cases of patients will be shown. 3. Demonstration of cases of Chronic Disease of the Spinal Cord: by D. B. Lees, Esq., M.D., F.R.C.P., Physician to St. Mary's Hospital and Assistant Physician to the Children's Hospital. 4. Drs. Waller (Lecturer on Physiology), R. Maguire, Silcock (Joint Lecturers on Pathology, etc.) and Handfield-Jones (Joint Lecturer on Midwifery and Diseases of Women), St. Mary's Medical School, will exhibit microscopic specimens, and give short demonstrations.—C. A. PATTEN, Honorary Secretary, Marpool House, Ealing, W.

DUBLIN BRANCH.—The eleventh annual general meeting of the Dublin Branch of the British Medical Association will, by the kind permission of the President and Fellows, be held on Wednesday, January 25th, at 4 P.M., in the hall of the King and Queen's College of Physicians, Kildare Street. The officers and Council for the ensuing year will be elected by ballot, and any other necessary business transacted. Edward D. Mapother, Esq., M.D., President-elect, will deliver the annual Address. At the conclusion of the business of the annual meeting, the portrait of the President of the Association, Dr. Banks, will be presented to the President and Fellows of the King and Queen's College of Physicians by the President of the Branch, on behalf of the subscribers to the Reception Fund of the late annual meeting of the British Medical Association in Dublin. Subscribers to the Reception Fund, although not members of the Branch, are invited to attend the meeting. Members wishing to bring any subject of professional interest before the meeting, to nominate any member to serve as an officer or on the Council of the Branch, or to propose any gentleman as a member of the Association, or of the Branch, must inform the Honorary Secretary on or before January 13th. The annual dinner of the Branch will be in the College hall, at 7 P.M., on the day of the meeting. The charge for dinner tickets for members who purchase their tickets on or before Tuesday, January 24th, is 17s. 6d.; for members purchasing their tickets after that date, and the guests £1. Applications for tickets and the name and address must be forwarded to the Honorary Secretary. Members' guests are not limited to their professional friends.—L. H. ONMSBY, M.D., Honorary Secretary and Treasurer.

OXFORD AND DISTRICT BRANCH.—The next meeting will be held at the Radcliffe Infirmary, Oxford, at 3 o'clock on Friday, January 27th. Notice of papers to be read and cases to be shown must be given to either of the Honorary Secre-

taries on or before Monday, January 23rd. Members are requested to send their annual subscriptions to the Association and the Branch, due January 1st, to Dr. Darbishire, 97, Holywell, Oxford.—S. D. DARBISHIRE, W. LEWIS MORGAN, 42, Broad Street, Oxford, Honorary Secretaries.

SOUTHERN BRANCH: ISLE OF WIGHT DISTRICT.—An ordinary meeting of this District will be held at Dalish's Hotel, Shanklin, on Thursday, January 26th, at 4 P.M., J. M. Williamson, M.D., President, in the Chair. Agenda: J. G. Sinclair Coghill, M.D.: Antifebrin in the Pyrexia of Phthisis. R. Robertson, M.D.: Heart Condition in Fifty Cases of Pulmonary Consumption. John Ellis, Esq.: The Bacillus of Dental Caries and Leptothrix Buccalis. W. E. Green, Esq.: Vegetable Parasites; Photographs and Microscopic Specimens. Gentlemen who are desirous of introducing patients, exhibiting pathological specimens, or making communications, are requested to signify their intention at once to the Honorary Secretary. Dinner at 6 P.M.; charge 6s., exclusive of wine.—W. E. GREEN, Honorary Secretary.

METROPOLITAN COUNTIES BRANCH: NORTH LONDON DISTRICT.—The next meeting of this District will be held at the Deaconesses' Institution and Training Hospital at Tottenham, N., on the evening of Thursday, February 2nd, at 8 P.M. (Dr. Bridgewater, J.P., Vice-President of the District), when Dr. Dowse will read a paper on Massage, and demonstrate its practice. Several interesting cases will also be exhibited in the hospital.—GEORGE HENTY, M.D., Honorary Secretary.

NORTH OF IRELAND BRANCH.—A general meeting of the North of Ireland Branch will be held in the Belfast Royal Hospital on Thursday, January 26th, 1888, at 12 o'clock noon. Business:—The President (Dr. Palmer) will show a case of Excision of the Knee-joint. Professor Dill will introduce a discussion on the subject of Puerperal Fever. Dr. O'Neill will exhibit two patients on whom he performed Amputation of the Thigh by Sédillot's method; and also a patient treated for a severe case of Wry Neck. He will read short notes of the cases. Dr. Dempsey will show an Ovarian Cyst and also a Uterine Fibroid which he successfully removed, and will read notes of the cases. Dr. Byers will read a short paper on the Local Treatment of the Uterus in Puerperal Fever.—JOHN W. BYERS, M.D., Secretary, Lower Crescent, Belfast.

BERMUDA BRANCH.

A MEETING of this Branch was held at the Town Hall, Hamilton, on December 13th. In the absence of Deputy Surgeon-General C. Graves Irwin, P.M.O., the President, Dr. PARK TUCKER was asked to take the chair. Five members were present.

Thanks to Late President.—Dr. TUCKER said that on the eve of the departure of Dr. Irwin from Bermuda, they had all to offer him their heartfelt thanks for many acts of kindness, and especially for the manner in which he had discharged the duties of his office as President of the Bermuda Branch of the British Medical Association.

New Acting President.—Dr. ELDON HARVEY proposed, and Dr. E. C. WILKINSON seconded, that Dr. Park Tucker be asked to act as president *pro tem*. Dr. Tucker consented.

Cases.—Dr. ELDON HARVEY showed a case of Ulceration of the Palate; also a case of Naso-Pharyngeal Growth of Adenoid Tissue.

Stone in the Male Bladder.—Dr. PARK TUCKER, after an experience of some forty years, had only heard of two cases occurring in persons who had lived all their lives in the island. Stone in children must be extremely rare; no member present had ever seen a case.

Death of Dr. Krueger.—Dr. Richard O. E. Krueger having died since the last meeting, the Secretary was directed to write a letter of condolence to the widow.

New Member.—Surgeon James Porter, R.N., was proposed.

SPECIAL CORRESPONDENCE.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

Professor Charcot's Clinique.—Faradisation of the Right Pneumogastric Nerve and the Urinary Secretion.—Physiological Effects of Gases Resulting from Incomplete Combustion of Coal Gas.

PROFESSOR CHARCOT lately delivered an interesting lecture at the Salpêtrière on hysteria and syphilis, and the influence which previous affections or intoxication had in determining the localisation and form of hysterical symptoms. Infectious diseases, such as typhoid fever, pneumonia; intoxication (alcoholism, saturnism or hydrargyrisim), traumatism, and syphilis may determine hysteria which had previously been latent; but hysteria induced by traumatism, saturnism, alcoholism, or other affections remains identical. The localisation of the symptoms may differ, and the form which certain accidents assume will show what part must be ascribed to the previous affection in the symptomatology of hysteria. M. Charcot showed a patient in whom hysterical phenomena had been attributed to syphilis. The patient was 23 years old. He had syphilis at 18, which was not properly treated. On returning home one day seven years ago he fell down unconscious.

There was hemiplegia and hemianæsthesia of the right side; the muscles of the corresponding arm and leg were contracted. The end of the tongue was forced up against the right molar teeth. A few days later nocturnal headache came on, followed by convulsions of epileptic character. Mercury and iodide were administered. Two attacks of convulsions occurred. The paralysis and nocturnal headache persisted. These symptoms were regarded as syphilitic phenomena until M. Charcot pointed out the peculiar signs of hysteria by which they were characterised. Hemiplegia was accompanied by complete hemianæsthesia, which is of extremely rare occurrence in organic lesions. The patient was partially unconscious of the muscular function of the regions affected. Finally, the spasmodic symptoms in the tongue, which closely resembled the glosso-labial spasm of hysteria, and the peculiar nature of the attacks of convulsions rendered the existence of hysteria unmistakable. M. Charcot considers that the hemianæsthesia observed in certain female syphilitic patients, especially during the second period of syphilis may be attributed to hysteria, determined by mental depression and distress in patients of nervous diathesis. The nocturnal headache was accompanied by marked hyperæsthesia of the scalp. This is a characteristic sign of hysteria. M. Charcot believes that the localisation of the neurotic phenomena was influenced by the previous existence of syphilis, and that the hysterical headache was due to the remembrance of syphilitic headache, and resulted from a process of auto-suggestion. M. Charcot cited a curious case described by M. Potain of a patient suffering from lead poisoning, in whom the extensor muscles of the right arm were paralysed. There was hemianæsthesia; the paralysed muscles showed no traces of degeneration. M. Potain showed that this case was one of hysterical paralysis of the extensor muscles in a case of lead poisoning. Hysteria had assumed the appearance of saturnism, but its special nature was in no way changed. In the same manner the hysteria manifested by M. Charcot's patient assumed the appearance of syphilis. In describing a case of hystero-epilepsy in a syphilitic patient, M. Potain plainly showed that "the patient in question was a hysterical patient. The syphilis merely provoked the nervous disturbance and hystero-epilepsy."

MM. Arthaud and Butte, communicated to the Société de Biologie, at the meeting of December 17th, a paper on the effects of faradisation of the right pneumogastric nerve on urinary secretion. The authors, in order to obtain the above effects by purely physiological means, administered curare to animals until they became motionless; then, by means of induction currents, gradually increasing in intensity, they successively excited the entire pneumogastric, and then its peripheral end after being cut. The quantity of urine eliminated was measured by comparing the column of urine running, in a given time, through a long horizontal capillary tube fitted to the right ureter. The first experiment was on a sheep-dog, which had received an injection of 0.03 centigramme of curare. In a normal condition, the urine runs through a length of tube equal to 4 or 4½ centimètres in five minutes. During stimulation of the right pneumogastric by a very weak current, the above length was reduced to 2.3 centimètres in the same time; when the current was a little stronger the length was further reduced to 1.4 centimètre. The pneumogastric was then cut, and the peripheral end on stimulation with a feeble current gave a normal figure—4 centimètres. With a stronger current, the length fell to 3 centimètres, and when the current was raised to its maximum the urinary secretion almost completely ceased. When the current was stopped, the secretion was restored to its normal condition. The experiment lasted two hours, and the animal was then killed. The kidneys, examined under the microscope, showed small red spots in the cortical substance. The urine passed during the experiment was clouded, pale, slightly albuminous, and contained blood corpuscles, and perhaps some epithelial cells. A second experiment on another dog gave similar results. Experiments on other dogs, without injection of curare, but with application of mechanical pressure or the use of chloroform, did not give such definite results. The authors conclude that the right pneumogastric has a distinct action, through its peripheral branches, on urinary secretion.

In the *Comptes-Rendus* of the Société de Biologie there is a communication from M. N. Gréhant on the physiological effects of the gases resulting from incomplete combustion of common coal-gas. M. Gréhant placed in a narrow chamber 12 cubic mètres in capacity a Bunsen burner, which he lighted in such a manner that the combustion of the gas took place underneath and produced acetylene. While the combustion was taking place he prepared the carotid artery of a dog, from which he extracted some blood in a normal state, which contained 41.2 centimètres per cent. of carbonic acid and 19.5 centimètres per cent. of oxygen. A ligature was then applied to the central end of the artery, and a little water was injected into the glass

tube fixed in the artery, so as to be able later on to withdraw some more blood without a clot being formed. The animal was then left in the chamber. At the end of forty minutes the confined air had the disagreeable and very pungent smell characteristic of acetylene. The dog lay down on its side. At the end of an hour and twenty minutes the animal barked plaintively and became unconscious; it was then killed, and a second sample of blood, being drawn from the carotid, gave the following analytical result: 30.3 centimètres per cent. of carbonic acid and 6 centimètres per cent. of oxygen. Further chemical experiments showed that this considerable diminution of oxygen was due to the presence of 20 centimètres per cent. of oxide of carbon in the blood. This experiment proves conclusively that the quantity of oxide of carbon given out by a Bunsen burner burning from below during two hours, in a chamber of 12 cubic metres capacity, is sufficient to almost completely oxycarbonise the blood and endanger the life of an animal exposed to its effects.

VIENNA.

[FROM OUR OWN CORRESPONDENT.]

Antipyrin.—Creolin.—Strophanthus.—Disinfection in Schools.

GENERAL-STABSRZT DR. NEUDÖRFER of Vienna gives, in a recent number of the *Internationale Klinische Rundschau*, some details on the antiseptic effect of antipyrin and creolin. The chemical name of antipyrin was dimethyloxycinchin, being a methyl compound of the hypothetical basis chinic, and oxycinchin, $C_{11}H_{12}N_2O$, and for practical reasons one of its properties served to give this alkaloid its name. This property, however, namely, that of lowering high temperature, was the least of its qualities, and the name "antipyrin" did not represent the whole value of the drug. It had to be administered in doses of at least three grammes, one gramme each hour, in order to produce any temporary decrease of temperature. The daily dose for diminishing pyrexial temperature was from five to seven grammes, and in the case of children from ten to fifteen years of age the daily dose consisted in as many decigrammes. Its anodyne and antiseptic properties were of much greater importance, and Dr. Neudörfer, therefore, proposes the names "anodynin" and "antiseptin," as it equally deserved both these names. These synonyms are also used in Dr. Neudörfer's paper. In all affections attended with pain, one, or at most two, Pravaz syringefuls of the 5 per cent. solution of anodynin, subcutaneously injected, sufficed to remove the pain completely, or at least to diminish it to a great extent. The author has often observed that the hemicrania of women disappeared for a long time after a single subcutaneous injection of this solution. He has performed several injections simultaneously, and repeated them daily without having noticed any disagreeable after-effect. The drug was decidedly preferable to morphine, and was in many respects quite equal to cocaine. Anodynin had local as well as general anæsthetic properties without producing mental disorder and without giving rise to any toxic symptoms, such as nausea, giddiness, vomiting, constipation, anorexia, etc. The anodyne dose for internal use was from 30 to 50 centigrammes, to be administered from two to four times a day at intervals of from 20 to 30 minutes. The synonym "antiseptin" was equally justifiable, because the alkaloid in question prevented putrefaction, killed bacteria, relieved the pains caused by the wounds, and did not affect the surgeon's hands or instruments. Antiseptin could be used in a 5 per cent. solution, just in the same way as carbolic acid, and it was in this degree of concentration much more efficient than carbolic acid, gauze, lint, and ungreased wool, and other materials could be advantageously impregnated with a 5 per cent. solution of antiseptin and a $\frac{1}{2}$ per cent. solution of glycerine, and employed for dressing purposes. The high price of antiseptin was still an obstacle to its being generally used. Owing to the imperial patentee, the wholesale price was at present seventy florins (about £5 12s. a kilogramme, or seven kreuzers a gramme—a little more than a penny). It could now, however, be used as a powder, which could be sprinkled over chancres, and in cases of scrofulous ophthalmia, etc. Antiseptin was also undoubtedly of great value in cases of throat and ear disease, owing to its anodyne and antiseptic properties.

Another antiseptic which Dr. Neudörfer has advantageously tried is creolin. This is a sort of tar which is obtained from the English pit coals by dry distillation, and from which the poisonous hydrocarbons have been eliminated. The chemical constitution is not yet established, but owing to its characteristic qualities it can be very easily recognised by the practitioner. It is derived from the aromatic class of hydrocarbons, and is closely related to creasote, carbolic acid, resorcin, hydrochinon, etc. The very first results which Dr. Neudörfer had obtained with this drug were very favourable, and he had for

this reason at last abandoned all the other antiseptics and used only creolin. The first success he had obtained with it was in the case of a girl, aged 7, who suffered from *erysipelas bulbosum migrans faciei*. The skin of the nose, the upper lip, and over both zygomatic arches was greatly stretched and much reddened; some pustules were also present. The lower eyelids were œdematous, the frequency of the pulse and the temperature were increased, and the patient also suffered from headache. Dr. Neudörfer said to the relatives that the erysipelas would spread over the forehead and the ears, and that it would disappear in from seven to ten days. He ordered a 2 per cent. solution of hydrocarbonate of sodium with syrupus simplex, and directed the erysipelatous parts to be brushed thrice a day with undiluted creolin. The erysipelas did not advance; the pustules dried up; the infiltration of the skin disappeared, and the patient ceased to complain of any pains. The symptoms of fever also disappeared, and the erysipelas was cured in two days and a half. Dr. Neudörfer has, since that time, tried creolin in two other cases of erysipelas with like success. In former times he used always to treat severe cases of erysipelas successfully with subcutaneous injections of carbolic acid, and he had therefore no reason to resort to the method of Krascke. Since he had tried creolin, however, he no longer used subcutaneous injections of carbolic acid, which had recently been again recommended by Fehleisen. The second case which had been antiseptically treated with creolin was that of a butcher, aged 27, who had cut the last phalanx of his left middle-finger and the terminal front of his ring-finger. After treatment with a 2 per cent. solution of creolin and the application of creolin gauze, the wound healed, in eight days, without any suppuration or swelling. In the third case, in which a tumour in the region of the lower jaw was removed from a woman aged 30, creolin was used during operation and afterwards as a dressing, two silk sutures closed the wound, and no drainage-tube was put in. On the third day the sutures were removed; the wound was already closed, and the dressing could also be removed. The author has since used creolin in several minor operations both in the Polyklinik and in private practice, and has always observed that it relieved pain, checked the hæmorrhage, and limited suppuration. At first he used a 2 per cent. solution, but he has now found that creolin is efficient in a $\frac{1}{4}$ per cent. solution. Dr. Neudörfer prepares a fresh solution each time by adding two drops of creolin to 200 grammes of water. He uses only ungreased gauze, which, being folded from ten to twelve times, is wrung out of the milky solution and applied to the wound, which is afterwards covered with several layers of dry gauze. The dressing may be left until healing has taken place. This dressing is very convenient, both for the physician and the patient, and it is also very cheap. The surgeon's wards, the patient's skin, and the instruments can be disinfected with a 2 per cent. solution of creolin. Dr. Neudörfer concludes his paper by stating that he is so satisfied with creolin that he does not desire any other antiseptic. For country practice as well as for use in war creolin is, in his opinion, the most trustworthy and convenient, as well as the cheapest and most harmless antiseptic.

According to observations in Professor Bamberger's clinic, strophanthus was used with success in (1) every kind of disease of the cardiac muscle, in which its effect exceeded that of all other remedies; (2) valvular failures, in which the cardiac muscle could not do the necessary work, either owing to commencing degeneration or to slight hypertrophy; (3) those cases of renal diseases in which the action of the heart was impaired or normal, but where there was in any case an increase of the cardiac activity, and thus indirectly increased diuresis. Success was not to be expected in: (1) too advanced degeneration of the cardiac muscles; (2) valvular failures with great hypertrophy, where the greatest possible quantity of work was already done and an increase of the cardiac energy was no longer possible; and (3) in renal diseases with cardiac hypertrophy. Though the indications for the use of strophanthus were in general exactly the same as those of digitalis, the new remedy had nevertheless the advantage that its effect was produced in from ten to fifteen minutes, and that it had no cumulative effect, and could thus be given for a long period of time. The tincture recommended by Fraser (1:20), or the strophanthin itself was used. After the administration of the first dose nausea and increased action of the bowels were observed in susceptible persons. Strophanthin could be given by the mouth without any disagreeable after-effects. The following were the formulæ used: R Tinct. strophanthi 1.5—3.0 (grammes); aq. distill. 180.0; syr. simpl. or syr. cort. aurant. 20.0—30.0. M. Sig. The whole to be taken during the day. R Strophanthin puri 0.002—0.004 (from two to four milligrammes); aq. distill.

180.0; syr. simpl. 30.0. M. Sig. The whole to be taken during the day.

The Austrian Minister of Public Instruction has forwarded to all school authorities instructions as to the carrying out of disinfection, based on the recommendations of the "Oberster-Sanitätsrath" (Superior Sanitary Council). Those in charge of schools are invited to use these measures for the purpose of preventing the spread of contagious diseases in schools.

SHEFFIELD.

[FROM OUR OWN CORRESPONDENT.]

The Small-pox Epidemic: its Incidence on the Vaccinated and Unvaccinated respectively.—Lead poisoning by the Town Water.

THE opponents of vaccination will not find much comfort in perusing the additional report which, at the request of the Local Government Board, the medical officer of health has just made as to the epidemic of small-pox in Sheffield. Commencing in March, the epidemic did not assume alarming proportions until July. Altogether 2,738 cases were heard of up to the end of 1887. Revaccination has been extensively carried out in the town, and out of the 20,000—a small estimate—that Dr. White presumes have thus protected themselves, only a very few cases of the most trivial character have been reported. Ninety-five per cent. of the children of Sheffield who live are vaccinated and 5 per cent. unvaccinated, or for every 19 vaccinated children there is 1 unvaccinated. Now, 367 children under the age of 10 are reported as having small-pox; 14 are excluded from calculation for want of particulars as to vaccination; of the remaining 353 children, 207 were vaccinated and 146 unvaccinated; the vaccinated formed less than two-thirds of the entire number. If vaccination were valueless, they should have formed nineteen-twentieths of those attacked. As to death-rate: 2 died out of the 207 vaccinated, or about 1 per cent.; whereas no less than 70 deaths are recorded in the 146 unvaccinated, or 48 per cent. Out of the whole total of small-pox cases at all ages, as given above, 2,193 as vaccinated, 382 as unvaccinated, and 143 as not known, the deaths are mentioned as being 157 in the vaccinated, 97 in the unvaccinated, and 23 in the not known. The *Sheffield Daily Telegraph* has brought forcibly home to its readers, in more than one leading article, the lessons to be derived from the small-pox epidemic as to the value of vaccination, and enforces, as the duty of the hour, vaccination and revaccination. Taking it that 95 per cent. of the population are vaccinated, and estimating the population at 300,000, there will be 285,000 vaccinated, and 15,000 not protected by vaccination. The lesson taught by the statistics in Dr. White's report is that the chances of a vaccinated person escaping small-pox are three times the chances of the unvaccinated, and that if he actually take the disease, his chance of survival is ten times greater than the chance of an unvaccinated patient. The report states that 382 unvaccinated persons were afflicted with small-pox, or one in 39 of the 15,000 unvaccinated population. Of these 382, as many as 157 died, or two in every five. Of the 285,000 vaccinated population, 2,193 had small-pox, which is equivalent to one in 130. Only 97 of the vaccinated died, or one in 22. If all the population had been unvaccinated, and the rate of infection had been the same for the whole population as it has been for the 5 per cent. known to be unvaccinated, there would have been nearly 8,000, instead of being 3,000 patients, and about 3,000, instead of not quite 300, deaths. Or, if the death-rate that prevailed among the unvaccinated had done so among the vaccinated, the number of deaths, instead of being nearly 300, would have been 1,000. The report shows that the revaccinated enjoy almost complete immunity. Every effort is being made to complete quickly the new small-pox hospital at Lodge Moor. At night the men work by the aid of the electric light. The hospital is for 100 beds, which will give when completed, together with the present accommodation, 235 beds for small-pox cases, in addition to which are those at the two workhouses.

It is reported that at Dronfield Dr. Rook has had 200 cases of lead poisoning under his care traceable to the water supply. There are several hundreds of empty houses, and the Local Board has been urged to cut off the water supply to these empty houses, and thus diminish the quantity of leaden piping in which the water may settle. The Local Board advise the people to filter the water.

Dr. William Dyson has been elected president of the Sheffield Literary and Philosophical Society.

At a meeting of the North-Western Association of Medical Officers of Health, Dr. Tatham in the chair, Dr. H. Falconer, Oldham (resident

medical officer of Monsall Fever Hospital), moved the following resolution:

That this Association desires to draw the attention of the public to the prevalence of small-pox in Sheffield at the present time, and to the fact that during the past month several cases of small-pox have occurred in Manchester, Salford, and the surrounding districts, of which the source of infection has been directly traced to Sheffield. That this Association, therefore, advises all those who from business or other necessity must visit Sheffield to be revaccinated, and thus protect both themselves and the localities to which they may return from risk of infection. That this Association desires further to impress upon boards of guardians and upon all tramp lodging-house and other lodging-house keepers the importance of exercising special precautions in the cases of all persons who come from or have recently passed through Sheffield, and upon the lodging-house keepers the responsibility that rests upon them of reporting at once to the proper authorities any suspicious case that may come under their notice. And this Association has good reason to hope that the danger which at present threatens of the spread of small-pox from Sheffield will be warded off from any district or town protected by compulsory notification of dangerous infectious disease in which the public will earnestly co-operate in acting upon the principles here recommended.

He said that four cases of small-pox had recently occurred in Manchester and Salford in widely-separated districts, but in each case the infection had been directly traced to a visit made to Sheffield. The cases were promptly isolated, and no further damage had been done. but if many such cases were to arise the time might come when some case would escape detection early enough, and would become a focus of infection from which an epidemic might spring that would rapidly envelop Manchester and Salford and the densely populated districts surrounding those boroughs. He had carefully avoided recommending universal revaccination, because unless it was made compulsory it could not be carried out. The resolution was seconded by Dr. VAOHER, and adopted.

CORRESPONDENCE.

DEGREES FOR LONDON STUDENTS.

SIR,—In a leading article in the *JOURNAL* of January 14th, referring to proceedings at the University of London, it is said: "Inasmuch as the Universities of Durham and Aberdeen, as was pointed out, confer their degrees, the one after a very moderate amount of evidence of preliminary education, and the other on the production of the ordinary certificate of registration as a medical student"—

Allow me to remark: 1. I should not have thought of classifying Durham and Aberdeen together. In history, in nature, in aim, and in what the public and the profession owe to them, they differ diametrically. 2. The regulations for preliminary examination in general education for Aberdeen University are the same as those for Edinburgh and Glasgow Universities. Anyone who will take the trouble to look at the Calendars will see in what their preliminary examination differs from "the ordinary certificate of registration." 3. In the present excited condition of the great metropolitan medical mind on the subject of degrees, we must expect an exacerbation of the chronic *de haut en bas* to the rest of the medical world. On this side the Tweed we have the fortification that the long medical war out of which we have come successfully has spread the reputation of the combined excellence and cheapness of our education. Whatever may be the outcome of the present "plan of campaign" of our London friends, or of its successors when it has failed, London can never in medical education compete successfully with Scotland in the above-mentioned combination.—I am, etc.,

JOHN STRUTHERS.

Aberdeen, January 16th, 1888.

DEGREES FOR MEDICAL STUDENTS.—THE CLAIMS OF SCOTCH LICENTIATES.

SIR,—I am surprised that the determined effort of the Royal College of Physicians of London and the Royal College of Surgeons of England to obtain from the Queen in Council the power to confer the degree of M.D. on their licentiates, that is, those of the new Conjoint Board, has not been imitated by the corporations in Scotland. The Scottish corporations have certainly an equal right to claim a privilege as the English corporations. It may be argued that in Scotland we have four universities granting medical degrees, and that we do not require any further facilities. It may be replied that there are as many universities in England, at which students may obtain a medical degree if they choose to accept the conditions. But they object to these conditions, the expense, &c. Well, if there is anything unjust in the conditions enforced, why not alter these conditions? This evidently will not be done. But instead a great scheme is drafted out whereby great injustice will be done alike to Scottish universities and corporations, namely, the facilitating by this scheme an M.D. degree for a low pass examination. This is denied to the universities—to confer an M.D. at the pass examination. But it is chiefly the

Scottish corporations that will suffer. Students will not care for studying for a degree in Edinburgh to obtain a licence when they can get for a similar examination and same fees an M.D. in London (this of course is unjust also to the universities). The Edinburgh colleges will lose a large proportion of students, and also the licence of these colleges will be at a discount. The only way left to them is to open their examination to third-rate students and grant their licence for the fees proffered, thus establishing an unhealthy competition for the sale of degrees. The universities also will suffer; for a pass examination they can only confer an M.B.; and besides, their examinations are much higher than the Conjoint Board on Thames Embankment examination. They will have, to enable them to compete, to lower their standard of examination or lose the candidates. It is utterly too absurd for the English colleges to make such unreasonable and unjust demands. Let them raise their standard of examination and confer an M.D. and proceed the same as the university, but incorporate the Apothecaries' Society, and do away with lower examinations and try as far as possible to make a one-portal system. Let the Scottish and Irish corporations do the same. What is good for London is good for Edinburgh and Dublin. Let all the licentiates of the Edinburgh colleges urge the councils of these to be up and doing in looking after their interests. This is a beginning on this subject; I hope it will be reiterated again and again until we are placed on equal footing and receive honourable treatment and justice.—I am, etc.,

A. W. McFADYEN.

Lochinver, Sutherlandshire, January 13th, 1888.

HOW SHOOTING ACCIDENTS OCCUR.

SIR,—I am very glad to see that you have opened your columns to a discussion on "How Shooting Accidents Occur," and that so experienced a sportsman as Sir William Dalby has followed up your own remarks on the principle that "prevention is better than cure." No one can doubt that this subject is particularly adapted to the pages of a medical journal, and the frequency of these accidents, no less than their preventable nature, makes the inquiry into their causation one of real importance. My friend, Sir William, writes with the authority of long experience, and I agree with much of what he says. But I cannot help thinking that the dangers included under his first two headings would be lessened, and perhaps removed, by the universal adoption of hammerless guns. This ingenious mechanism makes the half cocking process so simple as to prevent that confusion between the triggers and the hammers which is so great a stumbling-block to beginners, and the slipping away of the hammer from the point of the thumb in cold weather, the pulling back by a twig or branch when going through a hedge, and, last but not least, the peril in which the sportsman is sometimes placed by a careless or inexperienced loader. For it is obvious that as the hammerless gun always closes at half-cock after the insertion of the cartridges, no accident can possibly occur when all tampering with the safety sliding cover is absolutely forbidden. Grouse driving, I agree with Sir William to be the cause of much mischief, and the foot must be put firmly down on the practice of following birds. But to many this habit is quite irresistible, and to avoid mischief the recommendation of the Duke of Beaufort (*Badminton Library Shooting Vol.*) should be adopted, that "there should be some sort of screen between all batteries." This would enable the guns to shoot freely all round, and would obviate the risk which I hardly think is yet enough recognised, of shot, and more especially chilled shot, glancing back or to one side from stones or roots, or even from the ground hardened by frost. Nor am I quite sure that a high wind may not deflect some portion of a charge from its right direction and land some of the pellets in or near the occupant of the next battery. The only accident which I have seen this year was caused by one of the most experienced members of the party, who described to me the horror with which he found that he had freely peppered his neighbour after firing, as he thought, in a perfectly safe direction and well away from the adjoining battery.

But what we have to come to is this: Putting aside all unavoidable causes, are shooting accidents due to want of care, or to ignorance? You adopt the first; Sir William argues in favour of the second. I agree with you. No one can have seen much of cover shooting without regretting the culpable rashness with which some so-called sportsmen handle their guns, and the recklessness which is the result of jealousy and wholesale rivalry as to the individual contributions to the bag. Nor can it be denied that the arrangements of the ordinary *battue* are of a very dangerous character. Outside a wood we place a certain number of guns, and inside an advancing line of beaters, armed and unarmed, walk forward and drive everything to the outside. Then the fire grows fast and furious, for the pheasants rocket up into space, and hares and rabbits swarm in perplexing numbers, and tempt

the oldest hands into rashness. Shot now begins to swish almost as though the opposing parties were seriously under fire, and hairbreadth escapes are made to be afterwards recounted at luncheon or in the smoking-room. Caution and moderation are at this time all essential, and whoever habitually disregards the first principles of sport and pulls trigger at a low-flying bird or any creeping thing after he hears the cry of "guns ahead!" or sees the advancing forms brushing through the rough ground, should be carefully left out when invitations to the next "shoot" are being made up. Whether this is or is not a true picture I will leave to the recollections of your readers, merely reminding them of the old story of the beater who declined to take a message to a well known nobleman stationed in the middle of a wood because, as he said, "Lord — always fires when he sees anything move." This is evidently the motto of some modern sportsmen, and instead of labelling them dangerous, and keeping as well as possible out of their way, I would advise a tonic course of "boycotting" until they recognised the responsibilities as well as the pleasures of sport, and the discredit into which it may fall by their means; and it will do us all good to take stock of our own individual experience, and see whether the most careful among us may not have something to learn or to unlearn.—I am, etc.,

ROBERT FARQUHARSON.

Finzean, Aboyne, N.B., January 11th.

INTRACAPSULAR INJECTION IN THE EXTRACTION OF CATARACT.

SIR,—A few observations on that part of the ophthalmic review (*JOURNAL* of December 31st) which relates to the above subject are desirable.

Referring to the paper which I read at the annual meeting, the writer says that the opinion of the meeting was decidedly adverse to the proceeding, and that the Sectional President, Mr. Swanzy, expressed an opinion that my paper had given the "deathblow" to the method. In the *JOURNAL* of August 20th last a correspondent speaks in much the same strain. These two anonymous contributions may be from one and the same person, who may be one of the hostile critics at the meeting—critics, who either had no experience whatever of the method, or the most meagre one.

The statements in the *JOURNAL* of August 20th last led to my writing a letter (which appears in the *JOURNAL* of September 3rd), in which I compared results by my method and results by the other methods. Of that letter the reviewer has taken no notice, neither has he told us what has been his own experience of intra-ocular injection; but he tells us the method "has not met with much favour, most surgeons who have tried it having reverted to the methods of removing the cortex which have been in use for many years."

I suppose this assertion is based upon the discussion at the meeting, a discussion of which the adverse critics were, I think, pretty tired. If it be not, I shall be glad to see a short statement giving the names of the surgeons referred to, and the grounds upon which they have retraced their steps. I do not know whether the reviewer has thought it his duty to confine himself to work done in these islands. But, even so, he omits to notice that it is much used in Liverpool, particularly by Mr. Lee. I know it is practised by other surgeons who have said and written nothing about it.

Beyond our limits there are some men who have a world-wide reputation, who do a large operative work, and who not only approve of but practise intra-ocular injection. The names of MM. de Wecker and Panas are above cavil. The report of the meetings of La Société d'Ophthalmologie of France and the journals published in France may be consulted with much advantage. From them we learn that intra-ocular injection has been most extensively practised in that country, and we do not read of any condemnation of the method there. Indeed, the invention of instruments to carry out the method more perfectly occupy the attention of some of our Continental *confères*.

Pending the publication of my paper and the discussion thereon, I shall merely add that intra-ocular injection has not only given results in very unripe cataract such as have never been otherwise obtained, but also brings within the range of successful operation cases that without it have been regarded as outside the pale of operation. My paper comprises many cases of very unripe cataract, of which the details are given, which are without parallel in ophthalmological literature.—I am, etc.,

WILLIAM A. McKEOWN.

Belfast, January 10th, 1888.

* * The remarks of our reviewer referred chiefly to British operators. Intra-ocular injection appears to be practised abroad more as a means of introducing antiseptic agents than for its mechanical effect, and the details have been modified accordingly. Those remarks were not solely based on the opinions expressed at the discussion, but, without consent,

it would be unfair to name individual surgeons, and impossible to give their reasons. In the only paper by Mr. Lee with which we are acquainted (*JOURNAL*, 1887, vol. i, p. 103), the experience given is as meagre as that of the "hostile critics." No doubt before long we shall hear Mr. Lee's further experience, as well as that of the other surgeons referred to by our correspondent.

THE ERGOSTAT AND LATERAL CURVATURE

SIR,—My colleague, Mr. Clay, has given so much attention and original thought to the subject of scoliosis, and his views as to its etiology and the broad principles of treatment coincide so closely with those which experience continues to prove to me are correct, that I regret I cannot endorse his remarks in the *JOURNAL* of January 14th respecting the advantages of the ergostat as an instrument of treatment in such cases. The conditions of the spinal column are so diverse and complex in such cases, and the bony, muscular, and ligamentous structures generally, so much involved, that it is almost useless to expect any great measure of success from attempts to treat them in a stereotyped manner, as is unfortunately the case now that surgeons are at last beginning to discard the old system of relegating their cases to the tender mercies of the instrument maker, with "here a ratchet, there a ratchet, everywhere a ratchet," and a fee for each turn of the cog.

While cordially appreciating the spirit which has led to a more rational manner of treating deformities, which, in the great majority of cases, are the result originally of bad positions and weakened muscles, by aiming at improving those faulty positions, and strengthening those weakened muscles, I hold that this treatment is as better carried out by such exercises as are adapted to each individual case, and without such complicated machines as the one alluded to.

Kinesi-therapeutics, to the perfecting of which Ling devoted his lifetime, and which, while they have long been understood and practised on the Continent, owe their enunciation in this country to the untiring efforts of Dr. Mathias Roth and his son, Mr. Bernard Roth, comprise several hundred exercises from which prescriptions may be chosen or modified by the surgeon for each individual case as it arises, commencing usually with simple exercises in a lying position, and as the weakened muscles and the patient's general constitution improve, gradually increasing the dosage and substituting other exercises. I cannot here go fully into a description of the treatment, but would refer those interested to the exhaustive works of Dr. Roth on the subject.

If I may be excused the digression, I should like to state that out of the hundreds of cases I have noted in hospital and private practice, I have traced the majority to bad position of the patients during their scholastic life, and I consider it is our duty to go beyond our attempts at curative treatment, and considering the irrevocable injury that is involved, to impress forcibly upon school authorities the necessity, as a preventive measure, of reducing the length of time that children are kept standing at class, improving their seats and desks, correcting faulty positions, and, above all, of making physical exercise a part of the daily curriculum. I am pleased to say that this last desideratum is being admirably carried out in our Birmingham Board Schools, but the funds have to be provided by a special subscription list, whereas, considering the great importance of its general adoption, it is our duty to impress upon the authorities most strongly the necessity of providing for such systematic physical training out of the grant.

In conclusion, although for other reasons besides those I have mentioned, I do not consider Dr. Gartner's invention suitable to cases of scoliosis, I have no doubt of its utility in obesity, gout, and many other ailments. I would, however, suggest that it might be made of more practical value, if, by a simple addition to the machinery, the obese patient could be enabled to grind his own coffee or churn his own butter.—I am, etc.,

EDWARD L. FREER, Hon. Surgeon,
Birmingham Orthopædic and Spinal Hospital.

7, Newhall Street, Birmingham.

ELECTROLYSIS IN THE TREATMENT OF UTERINE FIBROIDS.

SIR,—The comments on my case of electrolysis in your last issue by Dr. W. S. Playfair are consistent with the doctrine I have been inculcating the last three months at Soho Hospital; and, without questioning the propriety of using the high currents recommended by our American friends, I am at present feeling my way with much weaker currents (from 70 to 120), and should be loth to resort to 250 or 300 milliampères, unless, as I have repeatedly observed to our pupils, everything general and local in the patient was favourable to enucleation.—I am, etc.,

E. HOLLAND.

1, Titchfield Terrace, North Gate, Regent's Park, N.W.

UNIVERSITY INTELLIGENCE.

CAMBRIDGE.

LECTURES ON CHILDHOOD.—At the request of the Teachers' Syndicate, Dr. Francis Warner will deliver a course of lectures on the "Growth and Development of the Intellectual Faculty." The lectures will be six in number, and will be illustrated by casts, diagrams, and botanical specimens; they will be delivered in the Literary Schools at 2.15 P.M., on Wednesdays and Saturdays during Lent term, beginning on January 25th.

APPOINTMENTS.—Sir Frederick Abel has been appointed Rede Lecturer for the present year. H. D. Rolleston, B.A., M.B., Scholar of St. John's College, has been appointed Demonstrator of Pathology. On Monday, January 16th, at a Special Court of Governors of Addenbrooke's Hospital, Mr. Frederick W. Burton, M.R.C.S., L.R.C.P., late house-physician and gold medallist of University College, was unanimously elected house-physician, in the place of Mr. R. H. Martin, who has left for Adelaide. The following have been admitted to the degrees of M.B. and B.C.:—F. R. B. Bishopp, King's; H. D. Rolleston, St. John's; R. H. Martin, Caius; E. Lloyd Jones, non-collegiate. The following have been admitted to the degree of M.D.:—James Harris Lilley, St. John's; Harry Groom, Magdalene.

UNIVERSITY OF LONDON.

A MEETING of Convocation was held at the University building on Tuesday last, January 17th. Mr. F. J. Wood, LL.D., presided. The first resolution, to present the report of the Annual Committee and to move its reception, was to have been proposed by Sir P. Magnus. Being unavoidably detained, he sent a letter, which was read by the Chairman, and which stated that a deputation from the special committee of Convocation on reform of the University, of which he is chairman, had had a second interview with the Senate, and that probably in the scheme which the Senate would eventually adopt several points considered important by Convocation would be embodied. The Senate had deferred the publication of its scheme so as to ascertain if it might not be possible to introduce into it such modifications as might satisfy the legitimate requirements of the University and King's Colleges, and thereby render their petition to the Crown needless. The University should resist the petition of the Colleges, not for any selfish policy, but in the interests of higher education generally. As regards the action taken by the Royal Colleges of Physicians and Surgeons, the letter suggested that a Royal Commission should examine the whole question. The report was then received.

Mr. T. B. NAPIER, LL.D., moved the adoption of the following resolution, recommended in the report of the Annual Committee:—"That Convocation expresses its approval of the Senate's action in objecting to the joint scheme of King's College and University College." He thought that no scheme which could be proposed by these Colleges could have an equal authority with that which had been so carefully discussed on many occasions, both in the Senate and Convocation and of which the main object was the same as that of the promoters of the new scheme—namely, the establishment of a teaching university for London. London certainly did want facilities for higher education, and better organisation of the metropolitan teaching bodies. The views of the Senate and of Convocation were gradually approximating, and agreement might be expected to ensue in a short time, when it would be found that the scheme of the two bodies would give quite sufficient authority and power to the teachers, as much, in fact, as any university could properly concede.—Mr. ROSS, M.A., B.Sc., seconded the proposition.—Professor CAREY FOSTER, in opposing it, said that Dr. Napier's speech was full of misrepresentations. The main objection brought forward by him affected only the minor principles of the scheme whilst he (the speaker) contended that, in the true sense of the term, London had no university to put the highest education within the reach of all. The chief function of a university was not to examine but to teach; the University of Berlin, for instance, would not lose its influence if it gave no further degrees at all. The teachers of the colleges desired to promote the interests of higher education, hence their anxiety to establish the Albert University.—Mr. ROBERTS, D.Sc., moved an addition to the original proposal that no new university should be established in London which did not make provision for the large class of persons who, though compelled to follow their occupations during the day, could attend lectures, demonstrations, etc., in the evening. The university should strike out a new line in this respect, and meet the great wants of the London population by providing evening instructions for all classes of students. If

the curriculum were extended over eight or ten years, too, such students might at the end of that time obtain a degree.—Mr. B. H. COOPER, B.A., seconded the proposal, desiring that educational facilities should be extended in every direction.—Dr. CURNOW thought the establishment of the proposed Albert University would do no harm to the University of London; the former would be only for London students, and would include the medical schools and have a medical faculty. Scotland, with a less population than London, had four flourishing universities. The scheme of the Colleges of Physicians and Surgeons was not promulgated in the interests of higher education, but for professional motives; and such a degree-conferring body the University of London did not oppose, though it did oppose the proposed Albert University, which will promote higher education.—Mr. HUTTON thought the Colleges could organise themselves as much as they might desire to further higher education, without forming themselves into a second university.—Dr. QUAIN thought it was a question of common sense. He had heard no good objections offered to the present University; then why desire the Albert University? The statement of the Senate was good, but it did not speak of the great benefits which that University had conferred.—Dr. SILVANUS THOMPSON thought the great drawback of the University was that it was still under the control of the Treasury in Downing Street; it should be emancipated therefrom, and the sooner the better. The proposed amendment was then withdrawn; and the motion of Dr. Napier was carried by a large majority.

Mr. H. A. NESBITT, M.A., and Dr. A. THOMPSON proposed a resolution by which standing order No. 58 was amended, so that at future elections to the Senate each member of Convocation can vote for three candidates to be placed upon the list to be submitted to the Crown. The resolution was carried.

Mr. J. G. FIRCH, M.A., and Dr. SILVANUS THOMPSON, D.Sc., next moved a series of propositions, the object of which is to economise the expense of circulars and notices, all of which relating to all the proceedings of Convocation are now sent to all the 2,400 members of Convocation. These propositions, with a slight verbal addition to make clear one of the standing orders, were all carried as proposed by the Annual Committee.

The remainder of the business on the agenda paper was then adjourned to the meeting which will be held on March 6th next.

Order of the Bath, a Knight of the Legion of Honour, and an Honorary Surgeon to the Queen.

The following appointments have been made at the Admiralty: THOMAS FINCH, M.B., to be Surgeon and Agent at Torquay and Bahhienbma; H. W. ACHESON, to be Surgeon and Agent at Morris Castle and Cahre; WILLIAM SHAW, to be Surgeon and Agent at Portmuck.

THE MEDICAL STAFF.

SURGEON R. R. K. ELMES has resigned his commission, which was dated February 15th, 1881.

Deputy Surgeon-General A. F. BRADSHAW is posted to the administrative medical charge of the Rawul Pindee Division, in the Bengal command, vice Deputy Surgeon-General J. Ferguson, whose tour of service has expired.

INDIAN MEDICAL SERVICE.

SURGEON-MAJOR A. S. REID, M.B., Bengal Establishment, is appointed to the permanent medical charge of the 2nd Battalion 4th Goorkhas, vice J. C. Morice, appointed Deputy Surgeon-General.

Surgeon R. PEMBERTON, Madras Establishment, Acting Civil Surgeon of Chittoor, is appointed Civil Surgeon of Guntoor, in succession to Surgeon A. P. Adams, deceased.

Surgeon J. W. EVANS, Madras Establishment, is appointed Civil Surgeon of Cochin.

Surgeon H. K. FULLER, M.B., Madras Establishment, is directed to act as Assistant-Physician at the General Hospital, during the employment of Surgeon-Major H. Allison, M.D., on other duty.

Surgeon W. H. KARNEY is admitted to the Madras Establishment from November 2nd, the date of his arrival at Bombay.

Surgeon J. SCOTT, M.B., Madras Establishment, Medical Officer 4th Infantry Hyderabad Contingent, has leave of absence from November 15th for one year on medical certificate.

Deputy Inspector-General HERBERT JOHN GIRAUD, M.D., late of the Bombay Establishment, died at Shanklin, in the Isle of Wight, on January 12th, aged 70.

Surgeon-General R. H. PERKINS, of the Bengal Establishment, died in London on January 14th, at the age of 64. He entered the Indian Medical Service as Assistant-Surgeon November 20th, 1850, and rose to Deputy Surgeon-General December 10th, 1877; he retired with a step of honorary rank May 4th, 1884. He was engaged in the campaign against the Cossyah and Jyntiah Hill tribes in 1862-63.

THE VOLUNTEERS.

ACTING-SURGEON E. TREVES, of the 1st Volunteer Brigade Cinque Ports Division Royal Artillery (late the 1st Sussex Artillery), has resigned his commission, which dated from December 7th, 1881.

Acting-Surgeon D. JACKSON, of the 1st Volunteer Brigade Northumberland Fusiliers (late the 1st Northumberland), has also resigned his commission, which bore date November 27th, 1872; he is permitted to retain his rank and uniform. Acting-Surgeon J. P. ELLIOT, who joined the same corps on September 17th last, is promoted to be Surgeon therein.

NAVAL AND MILITARY MEDICAL SERVICES.

CHANGES OF STATION.

THE following changes of station among the officers of the Medical Staff of the Army have been officially notified as having taken place during the past month:—

	From	To
Brigade-Surgeon F. H. Welch	Netley	Bengal.
" J. S. MacAdam	Hilsea	Aldershot.
Surgeon-Major T. M. O'Brien	Bombay	London.
" G. Andrew, M.B.	Madras	Portland.
" A. H. Ratigan	Bengal	Newcastle.
" T. O'Reilly	London	Bengal.
" T. S. Cogan	York	Bengal.
" T. J. E. Holmes, M.B.	Devonport	Bengal.
" J. A. McCracken, M.D.	Queenstown	Barbadoes.
" J. A. Smith	Newcastle	Madras.
Surgeon F. H. S. Murphy, M.D.	Tipperary	Queenstown.
" H. C. Kirkpatrick, M.D.	Canterbury	Netley.
" O. E. P. Lloyd	Jersey	Sierra Leone.
" M. F. Macnamara	Cork	Tipperary.
" T. Areher, M.D.	Bermuda	Portsmouth.
" T. R. Lucas, M.B.	Egypt	Devonport.
" C. A. P. Mitchell, M.D.	Egypt	Edinburgh.
" E. J. E. Risk	Bengal	Oxford.
" H. J. Wyatt	Honduras	Dublin.
" H. A. Haines	Colechester	Gibraltar.
" H. A. Cummins, M.D.	Cork	Queenstown.
" R. E. Kelly, M.D.	Cork	Mitcheilstown.
" G. H. Barefoot	Pontefract	York.
" C. W. Allport, M.D.	Aldershot	Cork.
" G. Scott, M.B.	Edinburgh	Bengal.

THE NAVY.

THE good service pension of £100 a year, vacant by the death, on December 2nd last, of Sir William R. E. Smart, K.C.B., Inspector-General of Hospitals and Fleets, has been awarded to Inspector-General R. D. Mason, C.B., from that date. The latter entered the service in 1837; became Fleet-Surgeon, February 22nd, 1844; Deputy Inspector-General, September 21st, 1861; and Inspector-General, November 3rd, 1874; he retired February 4th, 1875. He is a Companion of the

MEDICO-LEGAL AND MEDICO-ETHICAL.

MILLICAN v. ADMIRAL SULLIVAN AND OTHERS.

COURT OF APPEAL.

(Before the Master of the Rolls and Lords Justices Fry and Lopes.)

THIS was an appeal by the defendants, members of the Committee of Management of the Queen's Jubilee Hospital, from the judgment of Mr. Justice Manisty at the trial granting an injunction restraining the defendants from interfering with the plaintiff in the performance of his duties as medical officer of the hospital by suspending him.

Sir H. JAMES, on behalf of the defendants, cited various authorities for the purpose of showing that a Court of Equity would not interfere by granting an injunction in a case where, even though there might be a binding contract, relationship between the parties to such contract was of a personal nature. It could not be contended in the present case that the plaintiff, in his position as surgeon, had any rights of property in the institution. On the point of damages, it was not suggested that the plaintiff had sustained any pecuniary loss whatever by being dismissed from his position, and therefore the defendants were entitled to judgment on that part of the claim. The manner in which the breach of contract had been made did not, except in cases of breach of promise of marriage, entitle the plaintiff to damages.

The PLAINTIFF, in person, submitted that as a subscriber of a guinea a year to the institution, he had, independent of his position as surgeon, an actual interest in the property of the hospital, from the use of which he had been debarred by the action of the defendants.

The MASTER OF THE ROLLS, in delivering judgment, said that their lordships were not called upon to give any opinion as to the propriety or the fairness or good sense of what had been done by either of the parties in this matter, and they had nothing to do except to deal with their respective legal rights or legal wrongs. The first question was, what were the rights of the plaintiff. The plaintiff claimed to have the same rights in regard to this hospital as a member of a club had with regard to his club. Members of clubs had

rights of property in their clubs, and it was upon that ground, and that ground alone, that the Courts had interfered on their behalf. No doubt the plaintiff, as a subscriber to the hospital, might have an interest in the property of the institution, but the claim he sought to enforce here was in reference to his rights, not as a subscriber to the institution, but as a surgeon, and it was impossible to contend that as surgeon he had any legal or equitable interest in the property of the institution. As surgeon he had, no doubt, a licence to use certain rooms and furniture in the hospital, but that licence might be revocable at any moment, and there was no ground for contending that he had sustained any pecuniary loss by the revocation of that licence. The relation between the medical officer and the committee of the hospital, whether it was a contractual relation or not, and whether binding or not, was a strictly personal relation, and the Courts of Equity had always distinctly refused to afford relief in the form of an injunction where the relations between the parties were strictly personal. The perpetual injunction which Mr. Justice Manisty had granted in the case could not be right, as the utmost that the plaintiff could have claimed was that he should be permitted to fill the office of surgeon for a year, for which he had been appointed. But, in his opinion, no injunction ought to have been granted at all. There was another remedy by which the Court of Equity did not give its own peculiar remedy when there was a perfect remedy at common law, as was the case here. As the plaintiff had not sustained any pecuniary loss, if he were entitled to damages they would be merely nominal damages, and would not affect the result of this case. In the circumstances, whilst it would be unfair to make the defendants pay the costs of the trial below, he thought that the plaintiff ought not to be called upon to pay their costs in the Court below. The defendants, however, having succeeded in their appeal, were entitled to have the judgment of the Court below reversed, with costs of the appeal.—Lords Justice Fry and Lopes concurred.

Judgment reversed, with costs.

VULVAR DISCHARGE IN CHILDREN AND CHARGES OF RAPE.

G. S. M.—The only thing that can be done is to determine, if possible, with certainty whether the child is suffering from gonorrhoea or not. Vaginal discharges are very common in delicate children (the age of the patient is not stated). If there was no discharge before the date of the alleged intercourse, and if it appeared within a few days of that date, and was purulent almost from the first, and was accompanied by itching and scalding during micturition, the probabilities would be in favour of gonorrhoea. If the discharge is gonorrhoea, there would be a strong presumption that it was contracted in the usual way. In all other respects the case must be decided on other than medical grounds. In law the slightest amount of vulvar penetration is sufficient to constitute rape, and the absence of all signs after the lapse of three weeks would therefore not be any argument that a rape had not been committed. The majority of these charges are false, and, as a rule, the most important function the jury has to perform is to decide on the credibility of the child.

TENURE OF CLUB APPOINTMENTS.

MEMBER (Withnell) writes: A. and B. are in practice in the same neighbourhood. A. holds all the clubs, but several members of one club prefer B. At a full meeting of this club the majority decided to have B. as their medical officer. Will it be necessary that A. should have six months' notice? He is paid every six months, and there is no agreement.

*. Though there is no written agreement, we presume that something must have been said at the time of A.'s appointment which would constitute a verbal agreement, and would, among other matters, define the term for which he was appointed. The fact of his being paid every six months would be evidence that the appointment was for at least that period, and he probably could decline to accept less than a six months' notice.

UNQUALIFIED ASSISTANTS.

MR. H. L. HOORS, L.R.C.S.I., L.K.Q.C.P.I., etc., (Eccles) writes: Mr. Charles H. Harral, in one part of his letter in the JOURNAL of January 7th, says, concerning unqualified assistants visiting, etc., in their employer's stead, and the employers being subsequently non-suited at the court for such attendance, etc.: "Surely this is unfair to the employer and also to the unqualified assistant, who is generally compelled to work for his living until he can obtain his diploma, and who cannot in any other way learn the real practical part of his profession."

Taking the employer first, I fail to see anything unfair in the decision alluded to. Doubtless Mr. Harral is one of those practitioners who does not think it unprofessional and unfair towards the public to employ the services of an unqualified assistant, which can be had for a small stipend. How can the judge's decision be unfair when it is strictly in accord with the law of the land relating to the medical profession, which every practitioner sets at defiance when he employs men not recognised by law (because they have not passed any qualifying examination), and sends them forth to visit and prescribe for such ailments as they meet with, and which they may or may not understand anything about? The real unfairness seems to me to consist in the fact that legally qualified medical men are allowed to take such a mean advantage of their less prosperous medical brethren who have to suffer from the encroach-

ments of the "make believe" doctor. I have suffered not a little through this cause myself, which will account for my taking the subject up.

Now, concerning the unqualified assistant. We all know that most of that class (or shall I say many?) are idle "good for nothings," who not only have passed no examination, but never intend to. There are, I am sure, honourable exceptions to this rule, and for their sakes I shall say little about the class. Why could not such men do as I have known many do in my time in Dublin, namely, get employment in some city where there is a medical school, at some large chemist's establishment, and read during the spare hours and attend classes at night, and dissect as I used to have to do, and others with me, early in the winter mornings for an hour before breakfast, as well as for an hour or two at night after class? I know young men who have done this, and who to-day hold responsible posts in Her Majesty's army, and other branches of medical service. They gained a very practical knowledge of drugs and their uses both behind the counter and at hospital where they attended as they had opportunity.

This much to show that hard-working young men can get on by their own honest endeavours without starting out and becoming unqualified assistants, which, in so many cases, means never getting any further. I only hope that the county court judges will set their faces against such things as are constantly being practised; I have seen two instances lately of young women with their perineums ripped up, in one instance back to the very anus, in the other not quite so far back, through the use of the midwifery forceps during labour, whilst the patient was under chloroform, and all this done by an unqualified assistant upon his own unaided judgment. That such licence may be no longer allowed to unqualified men by the General Medical Council is not only my earnest wish, but that of many another.

Now, Sir, I have shown that a young man wishing to be a doctor can work and get qualified without breaking the law; and there is no reason in life why doctors should have to employ unqualified men when plenty of duly qualified ones are willing to come forward for a reasonable salary, except the reason aforementioned, the love of money, which in this case is the root of a great tree of evil.

SCALE OF FEES FOR MISCARRIAGE.

W. was called to attend the wife of H. Symptoms of a four months' pregnancy aborting were found, and the case was treated until after the miscarriage to entire recovery. In all the amount of attendance required was a special visit, nine visits, and four medicines. When an account of £1 10s 6d. was sent to H. he tendered a guinea in full payment, saying that that was the amount he had hitherto paid a doctor for attending his wife in her confinements. Should W. have charged as for ordinary medical attendance, or treated the case as a confinement, and charged accordingly?

*. If our correspondent will refer to the medico-chirurgical tariffs issued by the late Shropshire Ethical Branch he will, we think, find under the head of "Miscarriages" a solution of his difficulty in the case of his patient H., and which is as follows:—

"Miscarriages.—In simple premature labour the same charge should be made as in ordinary cases of midwifery. In abortions the necessary visits should be charged as such, plus an additional fee for detention."

ADVERTISING IN NEWSPAPERS.

A MEMBER.—It can scarcely be necessary after our repeated comments on similar conduct to assure "A Member" that Dr. J. MacCormack's "card" advertisement in the Belfast paper is contrary to professional rule and custom. We would advise our correspondent to address a brief note to the university or college in question, setting forth the simple facts, and enclosing therewith a copy of the newspapers in which the objectionable advertisement has appeared.

THE BRITISH GYNÆCOLOGICAL SOCIETY.—The following is the list of officers and Council elected at the general meeting of this Society held on Wednesday, January 11th:—Honorary President: Robert Barnes, M.D., F.R.C.P. (Lond.). President: Arthur Wellesley Edis, M.D., F.R.C.P. (Lond.). Vice-Presidents: Fancourt Barnes, M.D. (Lond.); John Chalmers, M.D. (Lond.); J. G. Sinclair Coghill, M.D. (Ventnor); J. Halliday Croom, M.D. (Edinburgh); William Gardner, M.D. (Montresl); W. Chapman Grigg, M.D. (Lond.); William T. Lusk, M.D. (New York); Arthur V. Macan, M.D. (Dublin); Paul F. Mundé, M.D. (New York); F. L. Neugebauer, M.D. (Warsaw); Thomas Savage, M.D. (Birmingham); William Walter, M.D. (Manchester). Treasurer: G. Granville Bantock, M.D., F.R.C.S. Ed. (Lond.). Librarian: Bedford Fenwick, M.D. (Lond.). Council: William Alexander, M.D. (Liverpool); F. A. Newton Bateman, M.R.C.S. (Lond.); Thos. A. Cambridge, M.R.C.S. (Lond.); Thos. M. Dolan, M.D. (Halifax); R. W. Edgington, M.D. (Birmingham); C. Egerton Fitzgerald, M.D. (Folkestone); A. Phillips Hills, M.R.C.S. (Lond.); Francis Imsch, M.D. (Liverpool); R. Milne Murray, M.B. (Edinburgh); Thos. Morton, M.D. (Lond.); F. Albert Pureell, M.D. (Lond.); J. A. Rawlings, M.R.C.P. (Swansea); W. London Reid, M.D. (Glasgow); C. H. F. Routh, M.D. (Lond.); John Shaw, M.D. (Lond.); J. Herbert Simpson, M.D. (Rugby); W. Japp Sinclair, M.D. (Manchester); Bryce Smith, M.B. (Belfast); J. Greig Smith, M.D. (Bristol); W. J. Smyly, M.D. (Dublin); W. Dunnett Spanton, F.R.C.S. Ed. (Hanley); Lawson Tait, F.R.C.S. (Birmingham). Honorary Secretaries: J. A. Mansell Moullin, M.B. (Lond.); J. Bland Sutton, F.R.C.S. (Lond.).

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

ENGLISH URBAN MORTALITY IN THE FOURTH QUARTER OF 1887.

THE vital and mortal statistics of the twenty-eight towns dealt with by the Registrar-General in his weekly return are summarised in the accompanying table. During the three months ending December last, 73,235 births were registered in the twenty-eight large towns, equal to an annual rate of 31.8 per 1,000 of their aggregate population, estimated at about nine and a quarter millions of persons. In the corresponding periods of the two preceding years, 1885 and 1886, the mean birth-rate in these towns was 33.3 and 32.1 per 1,000 respectively. The birth-rate in London last quarter was equal to 31.2 per 1,000, while in the twenty-seven provincial towns it averaged 32.3, and ranged from 25.5 in Brighton, 26.2 in Bradford, and 23.2 in Bristol, to 37.2 in Preston, 38.0 in Portsmouth, 40.2 in Newcastle-upon-Tyne, and 40.5 in Cardiff.

The 48,533 deaths registered in the twenty-eight towns during the fourth quarter of 1887 were equal to an annual rate 21.1 per 1,000, against 21.7, 20.0, and 20.3 in the corresponding quarters of the three years 1884-5-6. In London, the rate of mortality did not exceed 20.0 per 1,000, whereas in the twenty-seven provincial towns it averaged 22.0 per 1,000. The lowest rates in these provincial towns were 16.3 in Brighton, 17.2 in Hull, 18.3 in Norwich, 19.0 in Leicester, and 19.8 in Bradford and in Sunderland; the highest were 26.0 in Newcastle-upon-Tyne, 26.6 in Bolton, 27.4 in Manchester, 28.6 in Blackburn, and 28.8 in Preston. During the three months under notice, 5,757 deaths were referred to the principal zymotic diseases in the twenty-eight towns, equal to an annual rate of 2.50 per 1,000; the zymotic death-rates in these towns in the fourth quarter of the five preceding years averaged 2.60 per 1,000. The lowest zymotic rates in these towns last quarter were 1.09 in Brighton and in Plymouth, 1.24 in Hull, 1.36 in Sunderland, and 1.38 in Cardiff; while they ranged upwards in the other towns to 3.85 in Preston, 4.50 in Blackburn, 4.61 in Derby, 4.86 in Bolton, and 4.92 in Sheffield. The 5,757 deaths referred to the principal zymotic diseases included 1,434 which resulted from scarlet fever, 1,256 from whooping-cough, 951 from measles, 714 from "fever" (including typhus, enteric, and simple and ill-defined

forms of continued fever), 622 from diarrhoea, 531 from diphtheria, and 249 from small-pox. The 1,434 deaths from scarlet fever registered in the twenty-eight towns during the quarter under notice were equal to an annual rate of 0.62 per 1,000, showing a marked further increase upon the rates recorded in the two preceding quarters, which had been 0.26 and 0.39 respectively. The rate of mortality from scarlet fever in London last quarter was equal to 0.63 per 1,000, and almost corresponded with the mean rate in the twenty-seven provincial towns. The scarlet fever death-rates exceeded 1.0 per 1,000 in Salford, Bristol, Oldham, Preston, Blackburn, and Birkenhead. The number of scarlet fever patients in the Metropolitan Asylums Hospitals, which had been 1,778 at the beginning of October, rose to 2,602 at the end of November, and afterwards steadily declined to 2,049 at the end of the year. The admissions into these hospitals, which had been 466, 616, and 1,943 in the first three quarters of 1887, further rose to 2,908 during the three months ending December last. The death-rate from whooping-cough in the twenty-eight towns during the quarter under notice was equal to 0.55 per 1,000, and exceeded that recorded in the corresponding period of any recent year. This disease was proportionally more than twice as fatally prevalent in London as in the aggregate of the provincial towns; for, while the death-rate from whooping-cough in London was as high as 0.79 per 1,000, it averaged only 0.34 in the provincial towns, among which it was highest in Nottingham, Salford, Oldham, Wolverhampton, and Leicester. The rate of mortality from measles, which had been 1.35 and 0.44 per 1,000 in the two preceding quarters, further declined to 0.41 during the last three months of 1887. The measles death-rate in London last quarter was only 0.31 per 1,000, while it averaged 0.50 in the twenty-seven provincial towns, among which this disease showed the highest proportional fatality in Bradford, Blackburn, Birmingham, Bolton, and Derby. The 714 deaths referred to different forms of "fever" in the twenty-eight towns last quarter were equal to an annual rate of 0.31 per 1,000, showing a further increase upon the rates recorded in the two previous quarters of the year, which had been 0.14 and 0.23 per 1,000 respectively. In London the fever death-rate last quarter was 0.25 per 1,000, while it averaged 0.36 in the twenty-seven provincial towns, and was highest in Derby, Sunderland, Blackburn, Leeds, Bolton, and Preston. The rate of mortality from diarrhoea was equal to 0.27 per 1,000, and differed but slightly from that recorded in recent corresponding quarters. The 531 deaths from diphtheria in the twenty-

eight towns during the quarter under notice were equal to a rate of 0.23 per 1,000, against 0.14 and 0.16 for the two preceding quarters; while the rate of mortality from this disease in London last quarter was equal to 0.31 per 1,000, it did not average more than 0.16 in the twenty-seven provincial towns, among which, however, diphtheria was somewhat fatally prevalent in Brighton and Huddersfield. During the three months ending December last, 249 deaths resulted from small-pox in the twenty-eight towns; of these, no fewer than 230 occurred in Sheffield (against 3 and 45 in the two previous quarters), 11 in Bristol, 3 in London, 2 in Hull, 1 in Birmingham, 1 in Preston, and 1 in Leeds. Only 7 cases of small-pox were under treatment in the Metropolitan Asylums Hospitals at the end of December, but 30 cases of this disease had been admitted during the quarter, against only 7 in the preceding quarter.

The rate of infant mortality in the twenty-eight towns, measured by the proportion of deaths of children under one year of age to 1,000 registered births, was equal to 154 during the quarter under notice, against 146 and 160 in the corresponding periods of the two preceding years, 1885-86. While the rate of infant mortality did not exceed 145 per 1,000 in London, it averaged 162 in the twenty-seven provincial towns, among which it ranged from 111 in Brighton, 127 in Norwich, and 127 in Birkenhead, to 189 in Halifax, 198 in Oldham, 217 in Bolton, and 233 in Blackburn.

The cause of 1,084, or 2.2 per cent. of the deaths registered in the twenty-eight towns during last quarter were not certified, either by registered medical practitioners or by coroners. The proportion of uncertified deaths in London did not exceed 1.0 per cent., while it averaged 3.2 in the twenty-seven provincial towns, and ranged from 0.4 and 0.7 in Portsmouth and Norwich, to 4.5 in Oldham, 4.6 in Hull, 5.0 in Liverpool, and 9.1 in Halifax.

THE METROPOLITAN ASYLUMS BOARD.

THE returns presented to a meeting of the Metropolitan Asylums Board on Saturday last showed the gratifying result of a decrease in the total number of patients remaining under treatment for scarlet fever of 528. It was pointed out that, although the metropolis was at the present moment almost entirely free from small-pox, the managers were taking energetic steps to meet any epidemic of small-pox that might arise. The buildings as well as the ships appropriated to small-pox patients were already in preparation; and a letter was read from the Local Government Board, authorising the managers at once to enter into contracts for the erection of a hospital for small-pox convalescent patients at Darenth without the necessity of advertising for sealed tenders.

THE ABERDEEN DOUBLE QUALIFICATION.

W. X. Y. asks: (1) If an M.D., C.M. Univ. Aberdeen is a recognised double qualification for poor law appointment? (2) Whether an M.R.C.S. Eng., L.R.C.P. Ed. has the priority of claim as a double qualification in contesting a poor law appointment?

* * (1) Yes. (2) No.

HEALTH OF ENGLISH TOWNS.—In the twenty-eight large English towns, including London, which have an estimated population of 9,398,273 persons, 5,875 births and 4,194 deaths were registered during the week ending January 14th. The annual rate of mortality per 1,000 persons living in these towns, which had been 24.8 and 23.8 in the two preceding weeks, further declined during the week under notice to 23.3. The rates in the several towns ranged from 14.2 in Sunderland, 15.3 in Leicester, 17.7 in Birkenhead, and 18.3 in Brighton and in Hull to 27.6 in Blackburn, 28.2 in Plymouth, 28.7 in Wolverhampton, and 34.9 in Manchester. In the twenty-seven provincial towns the mean death-rate was 23.0 per 1,000, and was 0.6 below the rate recorded in London, which was 23.6 per 1,000. The 4,194 deaths registered during the week under notice in the twenty-eight towns included 203 which were referred to whooping-cough, 63 to scarlet fever, 60 to measles, 47 to "fever" (principally enteric), 33 to diphtheria, 33 to small-pox, and 27 to diarrhoea; in all, 476 deaths resulted from these principal zymotic diseases, against 503 and 493 in the two preceding weeks. These 476 deaths were equal to an annual rate of 2.6 per 1,000; in London the zymotic death-rate was 3.1, while in the twenty-seven provincial towns it averaged only 2.3 per 1,000, and ranged from 0.0 in Halifax and 0.4 in Brighton and in Sunderland to 4.5 in Wolverhampton and 5.4 in Sheffield. Measles caused the highest proportional fatality in Nottingham, Derby, and Birmingham; scarlet fever in Bristol, Wolverhampton, Birkenhead, and Norwich; whooping-cough in Preston, Derby, Manchester, Norwich, Leicester, Wolverhampton, and London; and "fever" in Preston. Of the 33 deaths from diphtheria recorded in the week

under notice in the twenty-eight towns, 16 occurred in London, 4 in Liverpool, 2 in Newcastle-upon-Tyne, and 2 in Oldham. The 33 fatal cases of small-pox included 27 in Sheffield, 4 in Leeds, 1 in London, and 1 in Bristol. The number of small-pox patients in the Metropolitan Asylums Hospitals was 6 on Saturday, January 14th, of which 3 were admitted during the week. These hospitals also contained 1,792 scarlet-fever patients on Saturday, January 14th, against numbers steadily declining from 2,602 to 1,959 in the six preceding weeks; there were 148 admissions during the week. The death-rate from diseases of the respiratory organs in London was equal to 7.0 per 1,000, and slightly exceeded the average.

HEALTH OF SCOTCH TOWNS.—During the week ending Saturday, January 14th, 345 births and 607 deaths were registered in the eight principal Scotch towns. The annual rate of mortality in these towns, which had been 24.3 and 27.1 per 1,000 in the two preceding weeks, declined to 24.0 during the week under notice, and slightly exceeded the mean rate during the same period in the twenty-eight large English towns. Among these Scotch towns the lowest were recorded in Greenock and Perth, and the highest in Dundee and Paisley. The 607 deaths in these towns during the week under notice included 78 which were referred to the principal zymotic diseases, equal to an annual rate of 3.1 per 1,000, which exceeded by 0.5 the mean zymotic death-rate during the week under notice in the large English towns. The highest zymotic rates were recorded in Edinburgh, Leith, and Paisley. The highest proportional fatality of measles occurred in Dundee, Edinburgh, and Leith; from diphtheria in Glasgow; from whooping-cough in Glasgow, Aberdeen, and Paisley; and from "fever" in Paisley. The mortality from diseases of the respiratory organs in these Scotch towns during the week under notice was equal to 6.6 per 1,000, against 7.0 in London.

HEALTH OF IRISH TOWNS.—In the sixteen principal town districts of Ireland the 592 deaths registered during the week ending Saturday, January 14th, were equal to an annual rate of 35.4 per 1,000. The lowest rates were recorded in Sligo and Waterford, and the highest in Armagh, Newry, and Dundalk. The death-rate from the principal zymotic diseases in these towns averaged 6.7 per 1,000, and was highest in Cork and Newry. Measles showed fatal prevalence in Limerick, Cork, and Newry; and whooping-cough in Belfast. The 242 deaths registered in Dublin during the week under notice were equal to 35.8 per 1,000 (against 36.2 and 38.6 in the two preceding weeks), the rate for the same period being but 21.0 in London and 21.5 in Edinburgh. The deaths included 32 from the principal zymotic diseases (equal to an annual rate of 4.7 per 1,000), of which 10 resulted from scarlet fever, 7 from whooping-cough, 8 from "fever," 4 from measles, 4 from diarrhoea, and 2 from diphtheria.

OBITUARY.

PROFESSOR TITO VANZETTI, M.D.

THIS distinguished Italian surgeon died at Padua on January 6th, after a long and painful illness, at the age of 78. His family belonged to Padua, and he was educated in the celebrated university of that city. At the age of 26 he settled in Russia, where he soon acquired a great reputation. He was Professor of Surgery and Ophthalmology in the University of Kharkov for fifteen years. On his return to Italy he was appointed Professor of Surgery in the University of Padua, a post which he filled with the highest distinction till 1866, when political intrigues led to his dismissal. He was thereupon immediately named Professor of Surgery at Palermo, and advantageous offers were also made to him to migrate to Paris. He preferred, however, to continue practising in his native town, and he was afterwards restored to the position from which he had been so unjustly removed.

Vanzetti had a European reputation as a practical surgeon. To him we owe the suggestion of digital compression in the treatment of aneurysm, and as a means of cutting off the blood supply from inflamed parts. He was not only venerated as a teacher of the highest order, but was the object of the warmest personal affection on the part of his numerous pupils. Professor Vanzetti was a member of many learned bodies not only in Europe but in America, but, strangely enough, no English society seems to have thought him worthy of such a distinction, though his name is familiar to every student of surgery in this country. By his will he left 100,000 *lire* (£4,000), together with a most valuable scientific library to his Alma Mater. He directed that his body should be cremated.

T. K. WHEELER, M.D., Belfast.

PROFOUND regret was universally felt in Belfast when it became known, upon the morning of Friday, January 13th, that Dr. T. K. Wheeler had just died from a dose of hydrocyanic acid administered by his own hand. So improbable did the event seem that the chief feeling on the part of many was at first one of simple incredulity, but all doubt upon the subject was soon dispelled. It seems that the deceased gentleman left his own house early on the morning of January 13th, and repairing to the medical hall of Messrs. Wheeler and Whitaker ordered a lotion containing hydrocyanic acid. The dispenser left the stock bottle containing the acid upon the counter, and went to another part of the shop to complete the preparation of the lotion. When he returned he found the bottle had disappeared, and feeling alarmed he proceeded to search the back premises, where he found Dr. Wheeler insensible and evidently dying. Dr. O'Neill and Dr. Strafford Smith were hastily summoned, but their efforts were unavailing, and death resulted about twenty minutes after the acid had been taken. From the evidence given at the coroner's inquest it appeared that the deceased gentleman, although naturally one of the most genial and cheerful of men, had lately been in very depressed spirits, and his altered condition had excited the attention and alarm of his friends. The *post-mortem* examination, conducted by Dr. O'Neill and Professor Sinclair, showed extensive disease of the vessels of the brain and old-standing heart disease. The verdict of the jury was "Suicide while in a state of unsound mind"—a conclusion which the medical testimony amply warranted and in which all will concur.

Dr. Wheeler was one of the original graduates of the late Queen's University, and was one of the oldest practitioners in Belfast. He had an extensive family practice, and was greatly esteemed and beloved. He was in a very special sense not only the adviser, but the personal friend, of all his patients, by whom his loss is deeply lamented. His relations with his medical brethren were invariably cordial and kindly, and his sudden decease has come as a painful shock in medical circles. The tragic nature of the melancholy event is much increased by the fact that Dr. Wheeler had been present at the marriage of his son on the day preceding his death. The most profound sympathy is felt for the afflicted family in their sorrow and bereavement.

PROFESSOR GUSTAVUS WERTHEIM, M.D.

PROFESSOR GUSTAVUS WERTHEIM, chief physician in the dermatological and venereal wards of the "Rudolf-Stiftung" Hospital, in Vienna, died on January 8th. In 1851 he became house-physician in the dermatological wards of the General Hospital under Hebra, and from that time date several valuable suggestions as to treatment, such as epilation in syphilis, etc. Among his later works may be mentioned: experiments on the causes of death in severe burns; experiments on the expired air in various febrile diseases; the external application of carbonic acid in sexual impotence in the male; examinations of the blood in psoriasis vulgaris, and of pus in syphilitic and non-syphilitic infective ulcers.

INSPECTOR-GENERAL HERBERT JOHN GIRAUD, M.D.

DR. GIRAUD, Inspector-General of Her Majesty's Bombay Army, has died at Shanklin, in his 71st year, from general paralysis. Dr. Giraud was born at Faversham, Kent, in 1817, and educated at the University of Edinburgh. In 1842, after graduating in honours, he entered the medical service of the East India Company. In that year his "Observations on Vegetable Embryology" appeared in the *Transactions of the Linnean Society*, and were subsequently largely embodied in textbooks on botany. Dr. Giraud filled the office of Professor of Chemistry and Botany, and subsequently that of Principal of the Grant Medical College, Bombay, and he was also chief medical officer of Sir Jamsetjee Jeejeebhoy's Hospital, Chemist Analyst to the Bombay Government, and in 1863 Syndic and Dean of the Faculty of Medicine in the University of the province. Dr. Giraud was a frequent contributor of papers on botany and chemistry to the *Transactions of the Botanical Society of Edinburgh* and other kindred publications.

OPEN SPACES FOR THE METROPOLIS.—At a recent meeting of the Metropolitan Public Gardens Association, presided over by Mr. Ernest Hart, it was announced that an anonymous donor had generously offered fourteen acres of land as a public recreation ground for Camberwell. The Mansion House Committee of the Gardens and Pleasure Grounds Fund have since placed £3,000 at the disposal of the Association for converting the above and a part of the Tower Garden into open spaces for the public.

MEDICAL NEWS.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Examination in Anatomy only, at a meeting of the Board on January 12th.

*A. H. Bird, W. D. Lockhart, H. R. Carter, and G. Gerrard, students of St. Mary's Hospital; H. Richardson, of Guy's Hospital; A. Gurney, A. C. Fox, *C. Welch, P. A. Colmer, and *J. G. Wilson, of the London Hospital; E. J. Hayford, and T. W. E. Morton, of St. Thomas's Hospital; H. E. Tracey, of St. Bartholomew's Hospital; C. H. White, C. L. Howe, and H. B. Shepherd, of Middlesex Hospital; and H. de R. Morgan, of St. George's Hospital.

Passed in Physiology only.

J. M. James, *W. R. M. Berridge, P. J. Atkey, E. W. Livesey, B. Goddard, and H. S. Lindsay, of St. Thomas's Hospital; R. L. Thomas, of University College Hospital; *J. P. Watkins, of Guy's Hospital; A. E. Hancock, and H. Wiggins, of Charing Cross Hospital; H. C. Barnes, and H. Vallance, of London Hospital; L. E. James, and E. L. Hoghes, of Westminster Hospital; *W. A. Andrews, and *J. L. Rubel, of King's College; *R. F. Burry of St. George's Hospital.

Passed in Anatomy only on January 13th.

H. B. S. Stradling, W. P. T. Toller, and J. Terry, of St. Thomas's Hospital; J. H. Maund, E. Collins, J. R. Williams, C. S. Wood, and G. J. Amy, of St. Bartholomew's Hospital; E. W. Brunton, of Charing Cross Hospital and Mr. Cooke's; P. P. Harris, and J. B. M. Kennedy, of King's College; F. R. Lathbury, and R. C. Middlemist, of London Hospital; *H. S. Challenor, of Middlesex Hospital; *S. T. Richardson, of Owens College and Mr. Cooke's; *D. Thomas, of University College and Mr. Cooke's.

* Under Old Regulations of Royal College of Surgeons.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentleman, having passed the necessary examination and having since attained the legal age (25 years), was, at a meeting of the Council on January 19th, granted his diploma as Fellow of the College.

Hudson, Charles Leopold, L.R.C.P.L., Middlesex Hospital.

MEDICAL VACANCIES.

- The following vacancies are announced:
- BELGRAVE HOSPITAL FOR CHILDREN, 79, Gloucester Street, S.W.—House Surgeon. Applications by January 31st, to the Honorary Secretary.
- BIRKENHEAD BOROUGH HOSPITAL.—Senior House-Surgeon. Salary, £90 per annum. Applications by January 30th, to the Chairman of the Weekly Board.
- BIRMINGHAM GENERAL HOSPITAL.—Two Assistant House-Surgeons. Applications by January 28th, to the House Governor.
- BRIGHTON, HOVE, AND PRESTON DISPENSARY.—Two House-Surgeons. Salary, £140 per annum, with apartments, etc. Applications by January 31st to the Assistant Secretary.
- BRISTOL GENERAL HOSPITAL.—Assistant Physician. Salary, £50 per annum, with board, etc. Applications by January 23rd, to the Secretary.
- BRISTOL ROYAL INFIRMARY.—Dental Surgeon. Applications by February 15th, to the Secretary.
- BRITTON, STREATHAM, AND HERNE HILL DISPENSARY.—Resident House-Surgeon. Salary, £150 per annum. Applications by January 26th, to the Secretary, Dispensary, Water Lane, Britton, S.W.
- DOWNPATRICK UNION.—Medical Officer, Killyleagh Dispensary. Salary, £105 per annum and fees. Applications to Mr. James Heron, Tullyvery House, Honorary Secretary. Election on January 30th.
- DURHAM UNION.—Medical Officer of Health. Salary, £100 per annum. Applications by February 3rd to the Clerk.
- FOREST HILL PROVIDENT DISPENSARY.—Medical Officer. Applications by February 15th to F. J. Marriot, Esq., 2, Perry Villas, Perry Vale, Forest Hill, S.E.
- HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.—Medical Registrar and Pathologist. Honorarium, £52 10s. Applications by January 24th, to the Secretary.
- HUDDERSFIELD INFIRMARY.—Junior House-Surgeon. Salary, £40 per annum, with board, etc. Applications by January 27th, to the Honorary Secretary.
- MACCLESFIELD GENERAL INFIRMARY.—Junior House-Surgeon. Salary, £70 per annum, with board, etc. Applications by January 21st, to the Chairman of the House Committee.
- NATIONAL DENTAL HOSPITAL, Great Portland Street, W.—Anæsthetist. Applications by January 27th to the Secretary.
- NATIONAL DENTAL HOSPITAL, Great Portland Street, W.—House-Surgeon. Applications by January 27th, to the Secretary.
- ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Assistant in the Pathological Department of the Museum. Applications by January 21st, to the Secretary.
- ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road, E.C.—Physician. Applications by January 26th, to the Secretary.
- ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, Ventnor.—Assistant Resident Medical Officer. Applications to the Secretary, 34, Craven Street, W.C.
- ROYAL SURREY COUNTY HOSPITAL, Guildford.—House-Surgeon. Salary, £50 per annum, with board, etc. Applications by February 15th, to the Assistant Secretary.
- STOURPORT FRIENDLY SOCIETIES' MEDICAL ASSOCIATION.—Resident Medical Officer. Salary, £170 per annum, and extras. Applications by January 21st, to A. Bonckley, Esq., Areley Kings, Stourport.

MEDICAL APPOINTMENTS.

BROOKMAN, William A., M.B., appointed Physician's Assistant to the Public Dispensary, Plymouth.

GABRIEL, Leonard, M., M.B. Lond. M.R.C.S., appointed House-Surgeon to the Hospital for Sick Children, Great Ormond Street.

KANTHACK, A. A., B.A., M.R.C.S., appointed Clinical Assistant to the Central London Throat and Ear Hospital.

MURRES, James, M.R.C.S., appointed Clinical Assistant to the Central London Throat and Ear Hospital.

PHELPS, J. B., L.K.Q.C.P.I., L.F.P.S.O., L.M., L.A.H., appointed Medical Officer to the Anchorage Dispensary of the Clegher Union, etc. L. M. Cordner, L.K.Q.C.P.I., L.R.C.S.I., L.M., resigned.

POWER, Charles J., M.A., M.D., L.R.C.P., M.R.C.S., appointed Certifying Factory Surgeon for the Nailsworth District.

SAVEBY, Frank, M.R.C.S., L.R.C.P., appointed Junior Assistant House-Surgeon to the Hull Royal Infirmary, vice H. Pearson, M.R.C.S., L.R.C.P., resigned.

LIVERPOOL MEDICAL INSTITUTION.—At the annual meeting held on Thursday, January 12th, the following list of officers, council, and microscopical committee was adopted. President: William Carter, M.D., F.R.C.P. Vice-Presidents: R. Robertson, M.D.; William Williams, M.D.; F. J. Bailey, L.R.C.P.; G. E. Walker, F.R.C.S. Honorary Treasurer: J. N. Cregeen, L.R.C.P. Honorary General Secretary: A. Bernard, M.B. Honorary Secretary Ordinary Meetings: G. Harrison, M.R.C.S. Honorary Librarian: R. Williams, M.R.C.S. Council: K. A. Grossmann, M.D.; W. Irvine, M.D.; C. G. Lee, M.R.C.S.; W. P. Rowe, L.R.C.P.; W. Whitford, M.D.; R. Eccles, M.D.; J. B. Nevins, M.D.; E. W. Hope, M.D.; E. H. Dickinson, M.D.; W. H. Fleetham, M.K.Q.C.P.; Robert Jones, M.R.C.S.; C. Pussey, M.R.C.S. Microscopical Committee: W. Alexander, F.R.C.S.; A. Barron, M.B.; P. M. Braidwood, M.D.; H. Briggs, F.R.C.S.; G. Gibson-Hamilton, F.R.C.S. Ed.; J. S. Hicks, F.R.C.S. Ed.; J. R. Logan, M.B.; Rushton Parker, F.R.C.S.; F. T. Paul, F.R.C.S.; W. Williams, M.D.; J. Wigglesworth, M.D. Auditors: W. Whitford, M.D.; T. H. Bickerton, M.R.C.S.

MANCHESTER MEDICAL SOCIETY.—At the annual meeting of the Manchester Medical Society, held on January 11th, the following were elected office-bearers for the present year:—President: Julius Dreschfeld, M.D. Vice-Presidents: C. J. Cullingworth, M.D.; James Ross, M.D.; George A. Wright, M.B.; Alfred H. Young, M.B. Treasurer: Charles E. Glascott, M.D. Secretary: Frederick A. Southam, M.B. Elected Members of Committee: H. A. G. Brooke, M.B.; Thomas Jones, M.B.; W. N. Maccall, M.D.; Frederick Melland; Simeon H. Owen, M.D.; Frederick M. Pierce, M.D.; Thomas C. Raiton, M.D.; Thomas Smith, M.D.; Graham Stoell, M.D.; Alfred W. Stocks; John Williams, M.D.; William Yeats, M.D. The above, with the past Presidents of the Society and two representatives of the Owens College, form the Committee. Library Committee: A. M. Edge, M.D.; A. Emrys-Jones, M.D.; Siegmund Moritz, M.D.; James Ross, M.D.; William Yeats, M.D. Auditors: William Coates; H. R. Hutton.

PROTECTION IN THE STATES.—Not long since, in virtue of a recent law forbidding the importation of contract labour, a trained nurse who had been engaged in London to take charge of the nursing department at the Pennsylvania General Hospital, was forbidden to land at New York, and was sent back by the next steamer, on the ground that her engagement constituted an infringement of the law. The same fate is probably in store for Dr. Heneage Gibbes, late of Westminster Hospital, who accepted an engagement as Professor of Physiology at the University of Michigan. The local press, stimulated probably by disappointed candidates or unscrupulous rivals, have lately called attention to the terms of his engagement with a view to putting the law in force should he venture out. A more preposterous law it would be difficult to imagine.

LECTURES TO ART STUDENTS AT NEWCASTLE.—A series of public lectures on anatomy and physiology adapted for artists, art students, school teachers, and others, will be given in connection with the Newcastle College of Medicine. The course will extend over two months, and the lecturers will be Dr. Mears, Lecturer and Examiner in Anatomy; Dr. Oliver, Lecturer and Examiner in Physiology in the Faculty of Medicine of Durham University; the subject to be dealt with being "The Mechanism and Force of the Human Body." The lectures will be given on successive Wednesday evenings, beginning on February 1st.

In a paper recently read before the Vienna Hygienic Society it was stated that the split part of a loaf is an excellent disinfectant for polished wood, paper, and like substances, and that experiments made in several hospitals had given very satisfactory results.

MAJOR HECTOR TULLOCH, R.E., has been appointed by the President of the Local Government Board to be the Board's Chief Engineering Inspector, in place of Sir Robert Rawlinson, K.C.B., who has resigned. Major Tulloch is well versed in the duties of the department, having acted as inspector since 1873.

SPAIN.—Among other signs of medical progress, Spain now possesses a lady doctor in the person of Señorita Dolores Leonart, who has just embarked on "medico-gynecological" practice in Barcelona. This means, no doubt, that the fair *profesora* will confine her professional work to midwifery and diseases of women.

PETER LAING, of Elgin, who has just celebrated his 103rd birthday, is still able to follow his occupation as a carter.

A TELEGRAM from Lima, dated January 17th, states that the cholera is now decreasing at Santiago and Valparaiso.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.

MEDICAL SOCIETY OF LONDON, 8.30 P.M.—Clinical Evening.—Mr. Walsham will exhibit a Case of Epispadias and Partial Extrusion after Operation. Mr. Clutton will show a Case of Recovery from Chronic Pyæmia. Mr. Hurry Fenwick will give a Demonstration of the Urethroscope and the Vesicoscope. Cases also will be shown by Dr. Haddeo, Mr. Bernard Pitts, and Mr. Malcolm Morris.

TUESDAY.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—Mr. William H. Bennett: On the Occurrence of Tubercular Disease of the Testis as a Local Affection, particularly with reference to the Desirability of Early Castration in Certain Cases. Mr. W. J. Walsham: Case of Intra-Peritoneal Rupture of the Bladder; Abdominal Section; Suture of the Bladder; Recovery.

WEDNESDAY.

BRITISH GYNECOLOGICAL SOCIETY, 8.30 P.M.—Introductory remarks by the President, Dr. Arthur W. Edis. Specimens will be shown by Dr. G. Grauville Bantock, Dr. W. Japp Sinclair, Dr. R. T. Smith, Dr. Massell Moullin, and others.

HUNTERIAN SOCIETY, 8 P.M.—Mr. De Berdt Hovell: The Therapeutical Indications of Neurosthenia contrasted with those of Hysteria.

THURSDAY.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM, 8.30 P.M.—Living and Card Specimens at 8 P.M. Mr. Critchett: 1, Small Fixation Forceps for Cataract Extraction; 2, A new Form of Linear Knife. Mr. Higgins: Result of Operation by Cautey, for Conical Cornea. Mr. Gunn: Growth of New Lens Fibres after Spontaneous Absorption of Traumatic Cataract. Papers. Dr. Miles Milroy: On the Prognosis as regards Life in Albuminuric Retinitis. Dr. James Anderson: On Sub-Retinal Effusion in Chronic Nephritis. Mr. Lang: On a Case of Hemorrhage in Region of Macula.

FRIDAY.

CLINICAL SOCIETY OF LONDON, 8.30 P.M.—Dr. Money and Mr. Paget: A Case of So-called Idiopathic Dilatation of the Colon. Dr. Barney Yeo: A Case of Embolism of the Right Axillary Artery, connected with Mitral Stenosis; Gangrene of the Forearm; Amputation; subsequent Embolic Pleuro-Pneumonia and Death. Sir Dyce Duckworth: A Case of Tricuspid and Mitral Stenosis, in which Physical Signs of Pulmonary Arterial Reflux were present. Dr. J. K. Fowler: A Case of Disease of the Aortic and Mitral Valves, of prolonged duration. Living Specimen: Dr. de Havilland Hall, Large Nevus on the Back.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the announcement.

BIRTH.

CHEYNE.—January 13th, at 59, Welbeck Street, W., the wife of W. Watson Cheyne F.R.C.S., of a son.

MARRIAGES.

BULLOCK—GREATHEAD.—On January 11th, at St. James's, Westgate-on-Sea, Joseph Ernest Bullock, M.D., of Ladbroke Grove, Notting Hill, son of the late Joseph Billingsley Bullock, Solicitor, of Berkhamsted, Herts, to Ada, only daughter of J. J. Greathead, R.N., of Sevenoaks.

JONES—EDWARDS.—On January 11th, at Bethel Chapel, Dolgelly, J. Kenrick Jones, L.R.C.P. and S., L.F.P.S., Eirlanfa, Llanrhadr, Oswestry, to Mary, second daughter of the late Mr. Edwards, Plas-y-nu, Dolgelly, Merionethshire.

DEATHS.

GRAVE.—On January 12th, at Heathfield, Shanklin, Isle of Wight, Herbert Girard, M.D., late Deputy Inspector-General H.M. Bombay Army, in his 71st year.

McDONALD.—On January 14th, at 26, Gladstone Road, West Kensington, Alexander McDonald, M.D., Fleet Surgeon (retired), Royal Navy, aged 45.

RYDER.—At Barnwood House, Gloucester, on January 17th, Richard Ryder, M.D., late of Hazelwood, Nailsworth, after three months' illness, aged 47.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY—10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's (Ophthalmic Department); and Royal Westminster Ophthalmic.—5 P.M.: Metropolitan Free; St. Mark's; Central London Ophthalmic; Royal Orthopaedic; and Hospital for Women.—2.30 P.M.: Chelsea Hospital for Women.

TUESDAY—9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's; St. Bartholomew's (Ophthalmic Department); St. Mary's; Royal Westminster Ophthalmic.—2 P.M.: Westminster; St. Mark's; Central London Ophthalmic.—2.30 P.M.: West London; Cancer Hospital, Brompton.—4 P.M.: St. Thomas's (Ophthalmic Department).

WEDNESDAY—10 A.M.: National Orthopaedic.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: Middlesex.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: London; University College; Westminster; Great Northern Central; Central London Ophthalmic.—2.30 P.M.: Samaritan Free Hospital for Women and Children; St. Peter's.—3 to 4 P.M.: King's College.

THURSDAY—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: St. George's.—1.30 P.M.: St. Bartholomew's (Ophthalmic Department); Guy's (Ophthalmic Department); Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Central London Ophthalmic; Hospital for Diseases of the Throat; Hospital for Women.—2.30 P.M.: North-west London; Chelsea Hospital for Women.

FRIDAY—9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.15 P.M.: St. George's (Ophthalmic Department).—1.30 P.M.: Guy's; Royal Westminster Ophthalmic.—2 P.M.: King's College; St. Thomas's (Ophthalmic Department); Central London Ophthalmic; Royal South London Ophthalmic; East London Hospital for Children.—2.30 P.M.: West London.

SATURDAY—9 A.M.: Royal Free.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: King's College.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Middlesex; Royal Free; Central London Ophthalmic.—2.30 P.M.: Cancer Hospital, Brompton.

HOURS OF ATTENDANCE AT THE LONDON HOSPITALS.

CHARING CROSS.—Medical and Surgical, daily, 1; Obstetric, Tu, F., 1.30; Skin, M, Th., 1.30; Dental, M, W, F, S.

GUY'S.—Medical and Surgical, daily, 1.30; Obstetric, M, Tu, F., 1.30; Eye, M, Tu, Th, F., 1.30; Ear, Tu, F., 12.30; Skin, Tu, 12.30; Dental, Tu, Th, F., 12.

KING'S COLLEGE.—Medical, daily, 2; Surgical, daily, 1.30; Obstetric, Tu, Th, S., 2; o.p., M, W, F., 12.30; Eye, M, Th., 1; Ophthalmic Department, W, 1; Ear, Tu, 3; Skin, Th, Throat, Th, 3; Dental, Tu, F., 10.

LONDON.—Medical, daily, exc. S., 2; Surgical, daily, 1.30 and 2; Obstetric, M, Th., 1.30; o.p., W, S., 1.30; Eye, W, S., 9; Ear, S., 9.30; Skin, Tu, 9; Dental, Tu, 9.

MIDDLESEX.—Medical and Surgical, daily, 1; Obstetric, Tu, F., 1.30; o.p., W, S., 1.30; Eye, W, S., 8.30; Ear and Throat, Tu, 9; Skin, Tu, 4; Dental, daily, 9.

ST. BARTHOLOMEW'S.—Medical and Surgical, daily, 1.30; Obstetric, Tu, Th, S., 2; o.p., W, S., 9; Eye, Tu, Th, S., 2.30; Ear, Tu, F., 2; Skin, F., 1.30; Larynx, F., 2.30; Orthopaedic, M., 2.30; Dental, Tu, F., 9.

ST. GEORGE'S.—Medical and Surgical, M, Tu, F., S., 1; Obstetric, Tu, S., 1; o.p., Th, 2; Eye, W, S., 2; Ear, Tu, 2; Skin, W., 2; Throat, Th, 2; Orthopaedic, W, 2; Dental, Tu, S., 9; Th., 1.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

Communications respecting editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

In order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the office of the JOURNAL, and not to his private house.

Authors desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL, are requested to communicate beforehand with the Manager, 429, Strand, W.C.

Correspondents who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

Correspondents not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

TO CORRESPONDENTS.

Our correspondents are reminded that prolixity is a great bar to publication, and, with the constant pressure upon every department of the JOURNAL, brevity of style and conciseness of statement greatly facilitate early insertion. We are compelled to return and hold over a great number of communications, chiefly by reason of their unnecessary length.

QUERIES.

C. W. asks for reference to any authentic records of diphtheritic paralysis without previous angina.

W. I. C. asks to be enlightened as to the causes and prevention of cœzema iris, and whether any treatment will shorten the attacks.

ASSOCIATE asks for the formula of a good cheap cough tincture or mixture for club, union, and hospital practice.

L.R.C.S. EDIN. asks any reader who has very recently passed the final examination for the Fellowship of the Royal College of Surgeons of Edinburgh to inform him as to the best books to read on the various subjects of the examination.

MR. HUGH HEALD (Ormskirk) writes: If any of your readers who are connected with a small cottage hospital would be willing to give me some information with regard to cost of establishing and of carrying one on, I should be very much obliged. They might communicate with me direct.

SUITABILITY OF FLORIDA FOR ASTHMA.

INQUIRENS writes: A patient who is liable to occasional attacks of spasmodic asthma, and who is married, with three children, is anxious to know the suitability or otherwise of Florida, between degrees 29 and 23, as a place of permanent residence.

ANSWERS.

DR. R. I. STEVENS should in the first instance communicate with Dr. R. Burnet, 6, Upper Wimpole Street, who was the treasurer of the fund referred to.

DR. V. G. FITZGERALD, Surgeon-General.—Regulations as to Defects of Vision which Disqualify Candidates for Admission into the Civil or Military Government Services, by Sir Joseph Fayer, K.C.S.I., is published by Messrs. Churchill. Our correspondent might have ascertained this by referring to the "Index to Advertisements" in the JOURNAL for January 7th (ex gr.).

EAST ANGLIA, who inquires about the removal of superfluous hairs, might refer to the numerous notes on the treatment by electrolysis which have appeared in the JOURNAL during the last few years, for example—1886, vol. 1, pp. 151, and vol. 2, p. 978.

SYPHILIS.

DR. C. R. ILLINGWORTH (Accrington) writes: In answer to "M.D." I beg to be allowed to recommend the following method of treatment, which I have found rapidly efficacious for some years past.

Internally, the binoiodide of mercury in iodide of potassium, thus:—Sol. hyd. bichlor. B.P., 3i; potass. iodid., ʒss; ferri am. cit., ʒi; aq. menth. pip. et euyrupi, ad ʒviii; ʒss ter, quater die. Locally, to the sloughing ulcers, after painting with a 4 per cent. solution of eucaine, apply a 20 to 30 grain solution of nitrate of silver every day or other day. To any secondary patches of syphilitic psoriasis on the face or body let the patient apply a 10 per cent. ointment of the oleate of mercury twice a day.

UNDESCENDED TESTICLES.

MR. S. OSBORN thinks that, 1. It is undoubtedly the duty of the medical attendant to examine the scrotum, to see if the condition of affairs is still as previously diagnosed. 2. It would also be the duty of the medical man to explain fully the result of such a condition, producing as it does sterility. Both contracting parties should be made cognisant of the fact, otherwise legal proceedings might in the future be taken to set aside the contract.

NOTES, LETTERS, ETC.

APPLICATION OF ELECTRICITY BY MEANS OF DOUCHES.

DR. J. G. DOUGLAS KERR (Bath) writes: I have recently been making some experiments which prove that the water of the douches employed in the massage douche baths is in sufficient continuity to conduct an electric current. So far as I know, this is the first attempt which has been made to utilise this powerful therapeutic agent in this way. Either the continuous or interrupted currents may be used. The procedure is very simple. One pole of the battery is attached to the metallic nozzle of the douche, and by moving the other to different positions, any part of the body can be made to complete the circuit, and thus be brought under the action of electricity. When it is desired to act upon the legs the patient sits upon a flat pole, and the limbs are douched. For the arm the pole is held in the hand. When there is no need to limit the action to a single limb, the movable pole is placed in the water which covers the patient's feet, and the douche brought to bear on the different parts in succession.

This mode of application, which combines the effect of douching with electricity, has the advantage over ordinary electric baths of being under better control, and also of localisation. Much stronger currents can be used when the limbs only are acted upon than would be safe in a general body-bath where the great nerve centres are also involved.

CHLOROFORM IN DENTAL OPERATIONS.

MR. SIDNEY SPOKES, M.R.C.S. (Anæsthetist to the National Dental Hospital) writes: Permit me to record a protest against the use of chloroform in dental operations as suggested under Therapeutic Memoranda in the JOURNAL for January 7th. Mr. Stephens alludes to "nervous ladies who are prejudiced against any form

AN ADDRESS ON SURGICAL INSTINCT.

*Delivered at the Annual Meeting of the Staffordshire Branch,
October 27th, 1887.*

By W. DUNNETT SPANTON, F.R.C.S. ED.,
Surgeon to the North Staffordshire Infirmary.

GENTLEMEN, I hope to be able to interest you for a short time in considering what I will venture to term surgical instinct.

Now what constitutes a surgeon? I would say that the acquirement of surgical knowledge, so far as is evidenced by the possession of a diploma to practise the art and science of surgery, is no true guarantee that the possessor of it understands his work. You may perhaps mould an unlikely mortal into a being who calls himself a surgeon, but his actions belie him; and sooner or later, if he does not discover it himself, his friends or his enemies will discover for him that he has mistaken his vocation.

To begin with, the surgeon must have that inherent love of the work he has to do which will render it not an irksome task, but the pleasure of his life; he must have "a heart at leisure from itself to soothe and sympathise" with those whom he has to treat. With his surgical instinct to guide him, our ideal surgeon will seek to extend his knowledge, and to allow no obstacle to turn him from the pursuit of it through life. "Let men be assured that the fond opinion that they have already acquired enough is a principal reason why they know so little" (Bacon, *Essays*, p. 251); and "if a man has not such a degree of enthusiasm and love of his art as will make him impatient of unreasonable opposition, and of encroachments upon his discoveries and his reputation, he will never become considerable in any branch of natural knowledge" (Dr. W. Hunter, *Medical Commentaries*).

How far surgical instinct is a matter of evolution I cannot say, but it is curious to find an illustration of it among fishes, such as the telescope fish, where the male acts as accoucheur to the female in a most amusing manner by rolling her over and over, and a still more surgical proceeding in the *bufo obstetricans*, one of the toads, where the male severs the gelatinous cord by which the ova are attached to the female. I cannot, however, imagine that man's primitive surgery was ever quite so simple as this, especially when we find among some of the oldest writings extant, which carry us back at least twenty-five centuries, indications of advanced knowledge very little behind what we know now. 460 B.C. we find Hippocrates, while strenuously advocating Nature as the physician of disease, yet in surgery a bold operator. He trephined fearlessly, opened the chest in hydrothorax and empyema, and treated fractures and dislocations by means of wax bandages as we now treat them with plaster of Paris, while in the treatment of infantile clubfoot he practised and advocated a plan of bandaging and fixation such as the most advanced surgeons now chiefly rely upon.

This example will suffice for my purpose, to show that enormous as are the advances which experience has afforded to the present generation, we must not overlook the fact of instinctive surgery, and that the ancients who were the fortunate possessors of it have paved the way for modern advances far more than those who confine their reading to the journals and modern textbooks would be led to believe.

In the ages when mysticism in its varied forms was rampant, although we find glimpses of the knowledge that Nature herself would do all that was necessary, no practitioners were bold enough to hazard their reputation by acting up to this belief, but almost invariably resorted to some application or some mysterious performance to give it due effect. To Hippocrates is due the everlasting credit of having broken through these bonds, which the Asclepiadae had so carefully striven to maintain by making the practice of medicine a secret art. In his famous first aphorism is a sentence not often quoted, though to my mind far more significant than the better known "*ars longa, vita brevis*." He says: "The physician must not only be prepared to do what is right himself, but also to make the patient, the attendants, and externals co-operate." Herein he displays his true perception of surgical treatment, the secret of his success. At this time and for centuries after, the surgeons proper were only, as Spence

calls them, "hands for the learned doctors," and thus their sphere of observation, and of power to act independently, must have been very limited. It was, in fact, a mechanical kind of surgery, confined chiefly to cutting for stone, cure of rupture and other specific operations, many of which would probably have been far better left undone. The true surgical instinct seems to have been handed down through the physicians, and by a gradual process the modern surgeon has been evolved, retaining the true hereditary instinct; necessity, experience, and above all a keen knowledge of all his surroundings having done the rest.

There may be some danger, perhaps, that surgeons of the present day may become too mechanical, and that, while the physician looks upon every affection he meets with as one amenable to therapeutic treatment, or, as some would put it, the *vis medicatrix naturæ* only, the surgeon is apt to go to the opposite extreme. The medical mind is apt to fall into the error which even in the great minds of Abernethy, of Pott, and of Astley Cooper, almost led them astray—that of largely ignoring local disease in the importance of considering constitutional influences.

It is perfectly true, as Sir Astley Cooper has so well pointed out, that the susceptibility of different individuals is a matter of vital moment. At present we have no means of gauging the resisting power of individuals, some of whom seem almost injury-proof, while others succumb almost from being looked at. I remember a striking instance of this in a patient who was to have had an abdominal section performed, but she died suddenly the night before. Nothing was found after death beyond an ordinary ovarian cystoma and a fatty heart. If this had occurred after the operation instead of before, there would have been one more case added to the list of deaths ascribed to surgery, no doubt.

In some instances we meet with the whole system seems imbued, as it were, with a tendency for disease—for example, tubercle—to manifest itself somewhere, as in the metastasis from the chest to the abdomen, or as in a case of a man whose leg I amputated for tubercular synovitis, who went on very well as far as the leg was concerned, but died of acute tubercular meningitis in three weeks after. This is one mode of origin of local disease which is not infrequently ignored; the system is so full of the tendency to it that it must come out somewhere. But may not the converse be equally true? While the one condition is essentially constitutional, probably accumulating through many generations, in the latter case it would be purely local; and, although it might be of a character to become constitutional, several generations may be needed to endue it with an hereditary character. Experience teaches us that it is far safer to trust here to the surgical instinct, which says, "Remove the disease forthwith;" and as the wisdom of our patients increases, so as to lead them to speak of local diseases while in their earliest stages, who knows but, in course of time, their hereditary constitutional character may be stamped out!

The surgeon meets with a case of local mischief; take, for example, epithelioma of the lip. His instinctive knowledge tells him he has something to deal with which may (very improbably) remain as it is, or may, on the other hand, be a focus for the diffusion of changes throughout other parts of the system. How is he to judge of the probabilities of either event happening? In the present state of our knowledge there can be no hesitation as to the course to pursue. We have a state of negative good, which may at any moment lead to one of positive evil; and on this ground the surgeon would eradicate it forthwith, just as he would a weed in his garden, before it has had time to seed and be beyond his control. I am aware that some eminent surgeons and pathologists still maintain the necessity for constitutional tendency before local disease can assume a malignant character; but their precepts, I fear, differ from their practice, and their true surgical instinct will guide them into the safer course I have indicated. I might refer to many instances in support of this principle, but will mention only two or three.

An old lady, 64 years of age, came under my care for a very large typical cystic sarcoma of the breast. She informed me that a small lump, not larger than a nutmeg, had existed for forty years, and that three months before I saw her it began to grow, and had become the enormous mass it was in that short time. I removed the breast, and she made a rapid recovery, and, so far as I am aware, she has remained well since. Her general health was good throughout.

Another instance: a man about 40, who came for an ulcer on the tongue, which I and my colleagues thought specific (as there was a distinct specific history). Under medical treatment the ulcer improved, and he returned home under the impression that it would be cured. Six weeks afterwards he presented himself again, the sore having rapidly increased, and assuming a decided malignant character. I removed the entire tongue; but rapid glandular implication took place, and death occurred shortly after. Of course I ought to have

operated while "in doubt." Then it was the transition from a passive to an active malignant condition probably took place.

The only other case I will refer to is one of a man over 60, an old soldier, whom I saw in consultation for a growth over the ascending ramus of the lower jaw, involving the skin, which was beginning to ulcerate. The jaws were fixed, so that for some time only liquids could be poured behind the teeth. The man was reduced to a skeleton, and was kept alive by morphine and stimulants, suffering excruciating pain. He was seen by some very good surgeons, who considered the disease malignant, and declined to interfere, as the submaxillary gland was also enlarged on the same side. The man's extreme suffering, and his willingness to submit to any measure which might give even a temporary respite, made me resolve to operate. I removed one half of the lower jaw, with a large elliptical piece of skin involved in the growth (which was sarcomatous, growing from the periosteum), and the patient rapidly got well. After the operation the local glands increased greatly in size, and alarmed us considerably; but, in spite of all these adverse conditions, recovery was complete, and he is now, five years after, a hale, active man, in perfect health. The disease here was clearly local, in spite of all its deceptive surroundings.

On the other hand, the surgeon will meet with many cases referred to him which more properly belong to the physician. One of the most common of these is gout or rheumatism, so often the result of an injury, but where general treatment is of course demanded.¹

Some time since I met with a very interesting case, in which the tables were, as it were, turned upon us by that goddess "Nature." A lad whom I saw in consultation was suffering from the usual indications of ordinary leukaemia. He was extremely feeble, pale, puffy, breathless on exertion, with rapid heart action and feeble pulse, and had that well-known waxy look characteristic of the disease. He had been a healthy, country-born lad, and his surroundings were favourable. On examining the blood from his finger, I was struck, not only by the great disproportion of white to red corpuscles, but by their relative increase to the serum of the blood. Under the ordinary treatment he made no progress whatever, took little food, and seemed reduced almost to the last extremity. Then Nature, wiser than we, somehow caused violent epistaxis, and from that time recovery was rapid. I confess that it never entered my mind to adopt such a remedy, and my instinct was clearly at fault. How did it effect the cure? The only explanation I can offer is this: assuming the blood to be too viscid, as it was, for free circulation to take place, nutrition would be *pro tanto* seriously interfered with; the heart would fruitlessly endeavour to overcome the difficulty (giving rise to its own symptoms), and a general suspension of the assimilative functions of the body would occur. The bleeding from the nose released the mechanical impediment by at once getting rid of the surplus of solids in the blood, and the organs were left free to act again.

I am led to think this is the true explanation, because it affords a key also to those otherwise obscure cases we meet with in girls rising into womanhood, which are common enough. The symptoms are similar; the girl keeps too fat, too flabby, pale, and weak, iron does her no good, and her good appetite only seems to add to her trouble. There is in these cases invariably amenorrhœa. As soon as that passes away, the natural flow does for them what the epistaxis did for the boy, and they rapidly get well.

The number of cases which fall into the hands of the surgeon, having a local character, often completely overlooked or undiscovered owing to the manner in which a purely medical mind inspects them, is rather remarkable. Chief among these are uterine or abdominal cases. How often do we meet with cases of menorrhagia which have been under general treatment for weeks or even months, and find an unsuspected malignant disease of the cervix, or perhaps a small polypus uteri.

I saw some time ago a lady who had been the subject of almost constant hæmorrhage, ascribed to "change of life," but which at length alarmed her and her friends. On examining her I found nothing more or less than a small highly vascular urethral caruncle, which was removed, and her troubles ceased. No surgeon would have allowed a case of that sort to remain undetected. I could mention scores of these cases where the reliance on simple therapeutic or homœopathic treatment (so called) almost led to the death of patients in whom a timely surgical examination and local treatment would have put the matter right without risk and at once. In the opposite condition, amenorrhœa, I am afraid even worse blunders of omission as well as commission occur. Quite recently a patient came under

my care with an enlarged abdomen, who was sent for operation as a case of ovarian tumour. The whole surface of the abdomen was studded with pustules, which were, I found, caused by hypodermic injections which had been employed by a man with a medical turn of mind for many weeks, whether to disperse the tumour or no I cannot say. She was pregnant simply. One instance I met with of a woman who had been diligently treated with emmenagogues, etc., in whom I failed to discover any uterus at all. She never had menstruated, and never would. Other frequent causes of either of these conditions, and almost always accompanied with dysmenorrhœa, are flexions of the uterus. The medical mind prescribes tonics, perhaps change of air and scene (often the very worst things), and trusts entirely to general treatment of symptoms to effect a cure. But how often does this succeed? The patient, after wearying of this unsatisfactory state, comes to the surgeon, who simply applies his instinctive surgical knowledge to this, as he would to any other part of the body, and finding a mechanical cause, treats it mechanically, when the subordinate symptoms speedily disappear. I have a strong suspicion that many practitioners who meet with cases of this kind act from a sort of kindly wisdom, that it is safest not to meddle with what they do not understand, and leave Nature to do for them what they are themselves unable. But is this fair to the fair patient?

Another class of cases are not uncommonly referred to surgeons to deal with as a *dernier ressort*—abdominal obstructions of various kinds. In the course of my practice I have seen a large number of these, some of strangulated hernia treated, for several days, in one case by three medical heads, without any suggestion of an operation until when I was asked to see the patient he was moribund; some of hydro-cèle, one of whom has lately seen me having worn a truss for sixteen years, which has at last caused a hæmatocele. These are commonly the product of that wisecracking surgical instrument chemist, who always thinks if he does know one thing better than another it is a rupture. I look upon the truss in the hands of chemists as a most dangerous weapon; the results of their ill-judged applications are often most disastrous. Not long ago I operated on a patient of my friend Dr. Orton, in whom a truss had actually been applied by a London chemist on an already strangulated hernia, which almost cost the patient his life.

Similarly with intestinal obstructions. The surgeon only sees them, too often, when the friends of the patient find death imminent under tentative treatment. I saw quite recently a lady at a distance whom I was sent for to operate upon. There was a distinct obstruction in the right iliac fossa, as plainly indicated as anything could be, with a history of old local peritonitis, probably a band. She had been well dosed with purgatives until sickness was incessant—ememata, etc., likewise. When I saw her she was moribund and almost pulseless, and I declined to operate. The medical man in charge of the case seemed to have no idea of the real state of affairs; to his purely medical mind it was inflammation, and he told me with the blindest simplicity "it was nothing more." In another instance a more fortunate result occurred; that of an elderly man who had been under treatment for absolute constipation for nearly three weeks. Obstruction was complete, vomiting incessant, and when I saw him he was reduced almost to the last extremity. He had been under treatment by two medical men the whole time on the usual expectant plan, rational enough from a medical point of view, only it did no good. Another surgeon was called in who asked me to see him; and finding from the history indications of obstruction on the left side of the colon, ill as he was we decided to operate. Colotomy was performed, and an enormous quantity of undigested potato-skins came rushing out, very much to our amazement. On inquiry we found that the last meal he had more than three weeks before had been some potatoes whole, of which he ate freely. Hence the result, and the wisdom of treating the case surgically. He is now quite well.

In no department has the surgical instinct been shown more conspicuously than in what is usually termed abdominal surgery. This has undergone a complete revolution during the last twenty-five years. The subject is now too familiar to need many words, but it is only due to our distinguished member, Mr. Lawson Tait, to say that it is mainly to his energetic and powerful advocacy that the reformation is due. Sir Spencer Wells made ovariotomy a justifiable and successful operation, Marion Sims gave the impetus to other pelvic surgery, but to Lawson Tait the credit is certainly due of having inaugurated a wider scope, which brings almost all abdominal, certainly almost all pelvic, diseases within the range of not only justifiable but eminently successful operative surgery. When I was obstetric assistant at Middlesex Hospital in 1862, two very illustrative cases came under my care, which indicate the state of feeling in the profession at that time, and which I will briefly relate. A married woman, aged 28, had five children

¹ Similarly we meet with instances of osteomyelitis treated as rheumatism, and I believe not infrequently the rash of septicæmia is mistaken for scarlet fever. They may nevertheless be looked upon as first cousins.

naturally. The midwife who attended her in her sixth labour, finding her after delivery still measuring forty-five inches, sent for me, supposing there was another child. I saw her with Dr. Priestley, and we found she had a large ovarian tumour. At the end of three weeks she was about again, her size undiminished. The poor woman died suddenly two months afterwards, from rupture of the cyst and peritonitis, as I found *post mortem*. During the whole time such a thing as an operation was never discussed, so far as I remember; and she died, as so many used to do and even now do, from rupture of the cyst.

The other case was one in which ovariectomy was performed by Mr. Mitchell Henry, with Sir Spencer Wells at his elbow—the first ever performed in Middlesex Hospital. The case was one which we now should consider a simple one, with rather extensive adhesions. All went well until at night, as I was watching the patient, every indication of internal hæmorrhage came on. I sent to the surgeon to know what to do, and to ask if he would reopen the abdomen. The reply was that nothing could be done beyond giving brandy, etc., *secundum artem* A.D. 1862. The young woman died in a few hours, and we found, *post mortem*, one bleeding vessel in the omentum and a quantity of blood in the abdominal cavity. I venture to say that, under the influence of Tait's teaching, such an event now would amount to surgical treachery. I can recall, also, the instance of a young woman whom I saw soon after this period, blanched, with a history of suppressed menses, and evident internal hæmorrhage. I will quote the words of the standard textbook at that time, referring to such cases of what I assumed to be rupture of the Fallopian tube: "This accident is almost always fatal. If there be time for remedies, of course the most active antiphlogistic treatment is the most appropriate; such, in fact, as would be prescribed for peritonitis under ordinary circumstances" (Churchill, *Dis. Wom.*, 1864, p. 494). I trusted to this teaching, and, as a consequence, my young patient died before night. Now that the ordinary rules of surgery are applied to the interior of the abdomen as to the exterior, such a lamentable result cannot occur without culpable negligence somewhere. In those days we knew no better.

So with regard to other affections of the female pelvic organs, it is quite clear that many of these, which have formerly been in the hands of the physician, will become proper subjects for the surgeon. A new light has dawned on many obscure conditions which have been too often guessed at, frequently mistaken, and perhaps in many instances entirely overlooked. The unhappy patient suffering from chronic ovaritis, from pyosalpinx, or some allied disease, is often the victim of everlasting medical treatment, sometimes a little better, much more often worse, until the cause of her trouble is removed; and our united experience as a Society I am sure fully confirms Mr. Tait's decided statement that nothing short of the removal of the offending parts will be permanently effectual. Indeed, he has made this no longer a question of doubt, but an established rule of surgery. For my part, I fail to appreciate the sickly sentimentality of those who raise objections to all such operations for removal of ovaries, whether diseased or not, on the ground of unsexing a woman, because I think the reasoning is founded on a false assumption. Has anybody shown one of the converted masculine women as a complainant on her own behalf? I never heard of one and never expect to see one.

Now to turn for a moment to some of those cases in which we are so greatly indebted to physicians and physiologists, such as cerebral tumours. Although the brain has been dissected and known for three thousand years or more, it is only within a recent period, since the localisation of the functions of the brain has been carefully ascertained by physiological investigations after pathological observations failed, that a sufficiently precise knowledge has been obtained to justify any specific surgical operation for their removal. We now know from experience that the interior of the brain may be surgically dealt with like other interior parts of the body, provided proper skill and precautions be exercised.

My friend and colleague, Mr. John Alcock, some time ago had a case in which he removed a depressed portion of the skull which had been the cause of epileptic attacks continuing many years, and did so with complete success. There is every reason to hope that in this happy union of physiological knowledge and practical surgery many lives will in future be saved from some of the most distressing ills which torment the human body.

Since I read a paper at Cork in 1879, by which I acquired a rather unenviable title, the smouldering fire of attempts to cure hernia under modern systems has been fanned into a flame, as will be readily seen by the mass of literature which has since appeared on that subject, and I am disposed to hope that the old misdirected surgical instinct (like that which does not prevent swallows flying against objects in their way) has been so far modified by recent knowledge and expe-

rience that operation for this affection has now become what it never was formerly, not only a justifiable proceeding, but one which the State has a right to look for in the interest of future generations. But I have already had a good deal to say on this matter elsewhere, and will now only add that the evidence of the last few years is largely in favour of some operative procedure, and that deaths from strangulated hernie ought in time to be almost unknown.

Let us now proceed to consider how the surgeon is to "make the patient, the attendants, and externals co-operate." With regard to the first point, the great thing is to keep our patient in a good humour, especially if any operation has to be done, not mentally only but physically. His stomach, his kidneys, and other working gear must be put into as favourable a condition as the circumstances will permit, as everybody knows.

The second object is an important one. However much may depend on the skill of the surgeon, his efforts may be entirely frustrated by an officious nurse or an ignorant but willing friend. Let him take care, therefore, to ascertain for himself that the attendant is one on whom he can safely rely. Trained nurses are very much like trained medical men, some are excellently practical, while others are uselessly æsthetic. Many of the best surgical nurses are ill-fitted for a tedious medical case, and *vice versa*. It is a great advantage to have a nurse well acquainted with one's foibles, who knows by a sort of surgical instinct what to do and when to do it, and does not irritate the operator by fussiness on the one hand or a listless inertness on the other. There are plenty such, and a great comfort it is to have them.

How much depends on the "externals!" The experience of recent years has caused an entire change in the ideas which formerly prevailed with regard to a patient's surroundings. In ancient as in modern times the most salubrious sites were chosen for hospitals, and yet the internal sanitary arrangements were such as to bring about the very evils they were intended to overcome. I will not weary you by reiterating the defects of old buildings intended for the sick; they are now well known; but I would refer to the necessity which still exists for the surgeon to ascertain for himself the sanitary condition of any house or institution in which his surgical patient is placed, possibly operated upon.

His surgical instinct will help him here, very much as it helps a ferret under certain circumstances. He will not think it beneath his dignity to see for himself that the drainage is right; that there are no direct communications between soil-pipes and lavatories and such like within the house; that no middens or other such objectionable accumulations lie under his patient's window; that the ventilation of the room is good, without draught; that, if needful, the room is fumigated, whitewashed, and so on, before his patient enters it; and that no contagious illness has previously existed in the place. The slightest hint of erysipelas, of blood-poisoning, tetanus, or obscure conditions euphemistically termed "low fever," ought to put the observer on his guard at once. I am quite sure sufficient attention—personal attention—is not paid to this important subject; and I am equally sure that those surgeons who can boast of the most successful work make it a *sine quâ non* to satisfy themselves on this vital question. That we all need this reminder is evidenced by circumstances within my knowledge, where a first-rate surgeon actually performed a capital operation in a room which was appropriated primarily and principally to a water-closet and a lavatory basin, from which the waste-pipe ran directly on to a not over clean grid immediately below!

And a painful case occurred to myself some time ago, which also indicates the need for circumspection. I was called upon to amputate the breast of the wife of a farmer whose house I had never visited. I made sure of a good nurse, and a reliable assistant, who thoroughly understood Lister's antiseptic spray treatment, with which we went fully equipped. On approaching the house, which was a large and good one, to my horror and consternation a certain well-known mal-odorous exhalation led me to exclaim, "Surely this must be a sewage farm!" and, having ascertained this to be the fact, I hesitated about operating with such precious "externals;" but a blind faith then in Listerism made me bold; with every minute detail most implicitly and specially observed, my unfortunate patient the next day gave evidences of my temerity in a high temperature, an oily serous exudation from the wound, and, in short, every indication of septicæmic mischief, which culminated in acute septic pneumonia, and a tedious convalescence. That this was attributable to the state of the atmosphere surrounding my patient I have no doubt whatever.

It taught me two lessons: one never to operate if possible without knowing the sanitary state of the residence, and the other to shake my faith in Listerism. I am almost afraid to enter on this question, but must say a few words about it. How did the foul atmosphere affect

my patient! According to Listerian doctrines, such an effect was impossible. But it occurred, nevertheless, and to my mind it affords a clue to some important considerations in connection with this subject. We all know that Lister's theory is based on the principle that to produce morbid results after an operation or a breach of surface germs of some kind must find an entrance; and the object of his practice is to keep out if possible, or to render inert, any such morbid bodies. But I have long thought, and am now very much inclined to agree with Sir Henry Roscoe (Address, Brit. Assoc., Manchester, 1887) when he says: "Present research points to the conclusion that the microscopist must give way to the chemist, and that it is by chemical rather than by biological investigations that the causes of diseases will be discovered and the power of removing them obtained." I do not think sufficient regard has been had to the influence of ptomaines, which must be far greater than that of mere germs, and which have been proved capable of producing their specific poisonous effects "in entire absence of living organisms." Take, for example, yeast, in itself inert, and so far as I know quite harmless in a wound; but place it in some saccharine solution, and you get an active poison (alcohol) speedily developed. Are there not analogous conditions of the blood or fluids of our own body in which, when a certain germ is introduced, poisonous ptomaines are developed which exert an influence which the germ itself was quite powerless to effect? Given a certain condition of the body, whether due to influences from within or surroundings without, and the introduction of a certain kind of germ immediately leads to such changes in the state of the pabulum as to create a poisonous product. Take, for example, a case of osteomyelitis. We often wonder why, in a case of this kind, in which there has been no contact with outer air or any outside germs, we should have pyæmia, perhaps septicæmia, set up. Now, we know how subtle must be some of the agents which affect us in this world. Even Dr. Dallinger has not yet discovered the size or shape of an atom of scent. But let a minute portion of some substances be inhaled only, and you will find evidences of their having passed into the organism. If we assume, therefore, that a quiet process of living death is going on in the bone marrow, so long as it is permitted to go on quietly no harm results; we know this often goes on for months, or perhaps years, unsuspected even; but so soon as certain products to which the body may be exposed find access to the part through the blood, then I imagine that change takes place which enables the micrococcus to set up its poisonous fermentative action, and the result is soon manifested in the development of the ordinary symptoms of septicæmia. It is not necessary for the bacilli or other organisms to find their way in; they are probably there already; but only for that special poison in the presence of which they can do evil to find access to them. Therefore, it is quite as important to see that the conditions under which organic germs can work are absent as to trouble quite so much about the organisms themselves. Antiseptics will do much, but common sense will do more to effect this in dealing with wounds. The latter being a not over-abundant commodity, it is as well perhaps for the majority of us to use antiseptics in our work, notwithstanding what may be argued in favour of their abolition. The perfect surgeon has not been evolved yet, and until he is I certainly advocate the use of those antiseptics which are best adapted for individual cases.

At this point, whenever anything surgical has to be done, surgical instinct will show itself in strict attention to minute details. A careful preliminary examination is made—under an anæsthetic, if necessary; nothing is taken for granted, and the course of proceeding determined upon. The surgeon must have brains in the tips of his fingers as well as in his organs of sense, give definite instructions to his nurses and his assistants beforehand, so that his sponges may be properly prepared, silk ligatures previously boiled, instruments faultlessly clean and methodically arranged; the patient's surroundings in accordance with directions given as to bed, temperature, light, and accessories. No detail ought to be too trivial to have his attention; it is the completeness of his preliminaries which goes far to ensure success. In the case of hospital nurses it is useful to have definite rules drawn up, so that each one may know her duty, more especially in abdominal surgery, when everything should go on like clockwork, and as silently.

In the method of dressing wounds I believe we shall revert to the simplest, of which none is better than scorched lint. Some of the best results in my practice have followed its use. Gangee tissue is extremely useful for almost all purposes, though more comfortable often when reverse. Much is said about drainage, and a recent writer (Professor Turazza, *Lancet*, vol. i, 1887, p. 947) endeavours to show that it is altogether a mistake. It may be so in his country, but I think not here. Drainage-tubes need discrimination in their use, far beyond the pedantic daily shortening of some surgeons. The

sooner the tube is removed the better—at any rate in private practice; and I usually take it out at the end of twenty-four or thirty-six hours after it has served its purpose of draining away the first effusion. Chassignac has immortalised himself by its invention, though it was devised originally for sinuses and such like. There is a small point regarding silver sutures I may mention, which is very useful; and that is, as soon as tension occurs, to nick them through. They maintain a sufficient hold, and need not be removed until union is firm. Many wounds are torn open in removing them too soon, because they cut, as they will sometimes in the best-regulated surgical *cliniques*. Then, again, in the after-treatment of his cases, there is a tendency now for our surgeon to revert to the practice of many years ago. The simplest possible diet takes the place of repletion and bleeding, the use of purgatives after abdominal operations superseding opium and aromatics. On this point Abernethy wrote (*On the Constitutional Origin of Diseases*, p. 13): "In many instances opium will not prevent continual efforts to vomit; yet when, by sulphate of magnesia, etc., stools are procured, vomiting ceases, the stomach retains both food and medicine, and general tranquillity of constitution is as suddenly restored." This accords with the most recent opinions on the subject of abdominal operations by Lawson Tait and others, and the view is commonly expressed that those patients who vomit freely after an abdominal section make more rapid and more certain recoveries. The most striking results obtained by the modern surgeon are the rapid healing of wounds and the larger proportion who recover. It is usually safe, for example, to promise a patient whose breast has been removed in private practice that she shall be quite well in a week, and I have here some extracts taken at random from my notes of such cases which show that four or five days often suffice for such wounds entirely to heal.

Extract from Notes of Breast Cases in Private Practice.—1. Miss B., aged 40, had fibroma of breast removed, with large part of mammary gland, November 17th, 1885. Whale-tendon ligatures, wire sutures, and sublimate gauze dressings and drainage-tube. 18th. Removed tube. 21st (4th day). Took out all sutures; wound perfectly united, without a drop of pus. Quite well.—2. Mrs. M. C., aged 41, on October 16th, 1883, had large fibrocystic tumour of breast removed, weighing a pound, and involving a long incision. Catgut ligatures, silk-worm-gut sutures, eucalyptus gauze dressings and drainage-tube. 18th. Tube removed. 21st (fifth day). All sutures removed. Quite well; no further dressings.—3. Mrs. M., aged 42; removed entire breast for scirrhus, September 26th, 1887. Wire sutures, catgut ligatures, alembroth gauze dressings. Tube removed next day. On October 1st (five days) perfectly well; all sutures removed. No further dressing.

Among such cases I have no death to record in private practice, and I find there have now been forty consecutive breast amputations at the North Staffordshire Infirmary without a death.

In looking over notes of operations in the old days of unhealthy hospitals, one is struck by two significant facts; the patient's record is either a very long or a very short one; or, in other words, a large number quickly succumbed to the evil influences around them, while those who did recover had a long and oftentimes hard struggle for life. To show what a change has taken place, I have collected some statistics of our own North Staffordshire Infirmary, and some which have been published as typical by Sir J. Lister.

Sir Joseph Lister has given the statistics of deaths from larger amputations in the Glasgow Royal Infirmary, before and after the introduction of his antiseptic treatment. Here are the figures: For the two years, 1864 and 1866 (old style), total amputations, 35; deaths, 16; mortality rate, 47.70 per cent. For the years 1867, 1868 and 1869 (Listerian), 40 amputations; deaths, 6; mortality rate, 15.00 per cent. And in 1879 the same surgeon published the results of 80 amputations performed at the Edinburgh Royal Infirmary, under his own method, of which 16 only were for injury, the other 64 for disease; 80 amputations: deaths, 9; mortality rate, 11.2 per cent.

I think, however, the figures I am about to give from the records of the North Staffordshire Infirmary will convince you that other modes of treatment are even better. The old infirmary at Hanley was a much patched up building, containing about 130 beds, with nearly all the defects of insufficient cubic space and sanitary arrangements of such institutions built seventy years ago. The only redeeming feature was its open situation. In 1869, this building was abandoned on the opening of the new infirmary at Hatfield, built to hold about 190 patients; and the addition of detached wards for children and for ovarian cases has increased the number of beds to 212, of which a large proportion are usually filled. The Listerian period began in 1871, and was continued with more or less strictness up to 1881. It was then gradually relinquished, and for the last four or five years has been used only

in such operations as osteotomy and some excisions. Now, so far as the spray is concerned, it is not employed at all, or only as an offensive instead of a defensive weapon. I have been obliged to take for our purpose the figures given in those years which contain the best kept records—some are defective—but they are taken irregularly for no other reason. They represent, I think, fairly the periods for which they are given.

Summary of Major Operations and Rate of Mortality during the Foregoing Periods.

Years inclusive.	1854 to 1858 (Old Infirmary)	1859 to 1863 (Old Infirmary)	1870 to 1874 (New Infirmary)	1879 to 1881 (New Infirmary)	1885 to 1887 (New Infirmary)	1887 only.
Total Number of Operations named in foregoing Tables	95	119	136	263	161	59
Deaths ..	14	20	24	16	4	2
Rate of Mortality per cent.	14.73	16.80	17.65	6.08	2.42	3.39

If you will refer to the tables, you will observe in the first two quinquennial periods, when the old building had been practically condemned as unfit for its purpose, an average mortality of 14.73 per cent. and 16.80 per cent. respectively. These are far better than most of those published for that time. Then we come to the time immediately after entering the new building, and we get a mortality rate of 17.65 per cent. This was sufficiently alarming to cause an investigation to be made as to the cause. A contaminated water supply, unventilated drains, and other defects in the drainage arrangements were discovered, and partially remedied. This, no doubt, led to the more favourable figures we get for 1879-81: 6.08 per cent. But cases of septicæmia occasionally occurred and other indications pointed to the conclusion that all was not yet right. After some demur, the Committee sanctioned further improvements, by having every waste pipe disconnected, closets ventilated, and, in fact, all that we asked for; and the result of this is found in the figures for the last three years since the work was done. A mortality of 2.42 per cent., in 161 cases, for three years' major surgery, with a full proportion of cases of injury included in them, is the gratifying reward for the large outlay involved. This statement is one of the most satisfactory ever recorded for an aggregate of such cases. We can all select favourable years with a run of good fortune, as for example, in 1885 and 1886, when there were 32 major amputations, about equally divided for injury and disease, with only one death. But, if we take the two last series of 1879-81 and 1885-87 as representing our recent work, we find: 97 amputations, 8 deaths; 57 amputations, 3 deaths. In six years, 154 amputations and 11 deaths. Mortality, 7.14 per cent.—a record of which no hospital need be ashamed.

It is abundantly clear that, however fine a building may be in its

arrangements for cubic space and general comfort and convenience, it avails little so long as the drainage system is wrong; in this as in many things, we know more than we did a few years ago, and it is well for the community when an enlightened committee will second the efforts of the medical staff, as our Committee has invariably done. Were it otherwise, I should have a very different story to relate to you to-day.

The surgeon ought to be able to speak with authority, and he will best do that who can speak from his own knowledge. We are often asked about watering places, voyages, and special articles of food and drink; and the surgeon will derive great advantage from gaining experience in all these as far as he can in his own *corpus vile*; only in doing so I would advise him not to do as I once did at a famous foreign health-resort, drink of every spring in the place, and then go home to breakfast. He may wish he had not.

Then as to different climates. There is a tendency to send everybody to the South, whereas quite as often as not it is a bracing, dry air which is most needed, not a warm, relaxing one. Too often, fashionable and otherwise attractive places have some great drawback which is carefully concealed in guide-books, and can only be discovered by one's own personal observation. Therefore it is well to visit all the pleasant resorts he can, to make trial conscientiously of everything about which he is pretty sure to be asked; but having done so, let the surgeon beware of putting his opinion into writing, or he may find himself made famous in a way he never intended in the pages of some advertising medium. So with regard to clothing. Here the married man has an advantage over the bachelor, whose knowledge of infantile and feminine garments is usually secondhand, and his advice of little use. It is well to note how susceptible to cold convalescents, especially children, usually are, and need advice accordingly.

It is an amazing thing how persons ordinarily gifted with common sense and good judgment are led away by some specious form of humbug, in the shape of a lapsed surgical instinct, such as that of bone-setters, *et hoc genus omne*. The death of one of these notable characters gave rise not long ago to some ridiculous articles in the daily press. Everyone of us is well aware in what the strength of these quacks lies, and there is no reasonable doubt that in some cases of stiff joints and such like, their rough methods succeed where others have failed. But how many of their failures do we hear of? Where do we find recorded the histories of inflamed joints, of permanently injured limbs which are not infrequently the outcome of their attempts to cure? I know of one instance where the ligamentum teres was torn completely through, and the patient lamed for life, by one of them.

It is too often forgotten that in the case of a surgeon who honestly and rightly makes a forcible attempt to overcome an old standing ankylosis or similar condition, and sets up thereby acute mischief, he is very naturally condemned by the patient and the friends for having made matters worse; whereas, in the case of the bone-setter such a result is looked upon only as an accidental failure in what is recognised by an ignorant *clientèle* as his legitimate sphere.

No men, I imagine, belonging to any profession, have been the subject of so much popular ignorance, and the objects of such sarcastic attacks at the hands of popular writers as medical men, although I gladly acknowledge that we are greatly indebted to some of the most powerful literary organs for fair and generous treatment. Take, for instance that wretched caricature of "Heart and Science" written by an author who is supposed to know what he writes about. I do not hesitate to say there; never was written in a novel a more vile representation of a modern scientific physiologist. Morbid sentimentality (which he is pleased to call "heart," forsooth!) is raised upon a pedestal for admiration, while the "science" of the advanced physiologist, simply because based upon vivisection, is reduced to the level of simple indulgence in brutal experiments. Such fictions as these may be all very fine for the edification of our young men and women, but we have a right to expect that an educated author will at least refrain from introducing such rubbish by a preface declaring their foundation in fact. We may very well, however, with our tried friend, *Punch* :—

Leave sham humanity its lies,
And cry God speed to men of healing.

I do not suppose for a moment that my experience of more than a quarter of a century's responsible hard work at practical surgery differs much, if at all, from that of other surgeons who have enjoyed similar opportunities, and the lesson I have learned and would impress on those who have not yet passed through such an ordeal is this—do to your patient as you would be done to yourself; make up your mind as to the course to pursue, then act as quickly, as safely, and as plea-

santly for the patient as your surgical instincts impel you. Let his or her welfare be paramount. Allow no golden apples like those of Hippomenes to hinder you in your course of duty. Remember how Atalanta lost the race, and let not such a fate be yours.

Gentlemen, we cannot stand still. The world will not wait for us, and whether we will or no, we must go onward. I devoutly hope that our course may be at the same time upward.

ABSTRACT OF AN ADDRESS ON THE MEDICAL STUDENT AND HIS ENVIRONMENT.

Delivered before the Harveian Society, January 19th, 1888:

By EDMUND OWEN, F.R.C.S.,
Retiring President.

ONE subject on which I wish to speak is that of medical education. If it be asked how this can interest the Harveian Society, I shall urge that every question concerns this Society which affects the welfare of our profession. Similarly it might have been questioned twenty years or so ago, what has this Society to do with so outlying a subject as that of baby-farming? But our Society not only interested itself in that matter, but instituted an inquiry upon it, and issued a report thereon, which went a long way towards the passing of a Bill in Parliament by which a scandalous waste of infant-life was, if not entirely done away with, at least brought within comparatively narrow limits. Honour to whom honour is due. Let us not forget that the two members to whom not only our own thanks, but also those of the whole State, were chiefly due are Messrs. Ernest Hart and Curgenvin.

In this age of specialism the student is taught that there are special centres for almost every operation and function throughout the economy, a centre for heat, another for respiration, and one for micturition. It may be that this is all correct, and that its acceptance will be co-existent with the science itself. Certainly it is correct at present, at least, as a subject matter for examination purposes, and as affording a good working hypothesis. But it is quite within the range of possibilities that, before another generation is set to work, the entire science of physiology will have to be rewritten in the light of fresh acquirements, and with entire disregard of such centres.

Froude truly says, "Philosophical belief at the bottom means a 'perhaps' and nothing more"; nevertheless, we are teaching it as if we were assured of its being truth itself. Thus I have heard it urged by an enthusiastic apostle of science that Haeckel's interesting work should be straightway constituted the recognised authority upon the history of creation, and that a knowledge of it should be rendered compulsory in every student of art and science. Let it be read and enjoyed by all means, but at the same time let us remember the words which its translator uses in another place (*Degeneration*, by E. Ray Lankester, M.A.): "In everyday life we have often to be content without fully testing the truth of our guesses, and hurry into action based on such unverified suppositions."

Twenty-five years ago physiology, as taught in our medical schools, was not worthy of the name of science; now she has developed into a subject of vast importance, and anatomy has had to make way for her. But I think that physiology has now raised herself to fully her proper position as a subject in the education and examinations of the ordinary medical student. The average student wishes to qualify himself as a trustworthy practitioner of medicine and surgery, not merely as a man of science. But with this increasing intellectual pressure the student of to-day is himself somewhat changed. In obedience to a natural law the individual student has adapted himself to the environment. The medical student of to-day is, by his previous education and by intellectual development, vastly superior to his homologue of a few generations back, and to what he was as I first knew him twenty-five years ago.

The medical student of to-day is crammed with a store of teaching which would do credit to a nineteenth century Solomon. He is expected to know a good deal about most branches of natural science, from the coniferæ—I would say, but for some reason it does not happen to be "official"—from the cedar of Lebanon to the bacillus that grows on the wall of the tubercular cavity; and yet, with all this, the day still contains but twenty-four hours, and the average weight of the

human brain has not perceptibly increased. His studies err in the way of diffuseness, and he does not know how much or how little will be eventually required of him—unless, perchance, he has had the advantage of attending the special course of instruction by the gentleman who is going to examine him. His examinations ought, therefore, to be conducted on the broadest lines and in the most liberal spirit. Unfortunately, he is not sufficiently left alone at his work. It is a case of lecture and demonstration, demonstration and lecture all day long, and sometimes in preparation for examinations, which are a test of cram rather than of knowledge.

There are several matters in which the environment has, however, recently been endeavouring to adapt itself to the student, in each case with the best intentions; but in each case with unfortunate results, at least in my opinion. Its method of procedure seems spasmodic and speculative. First, in the praiseworthy endeavour to insure that a student works in his first summer—a part of the year which in my time was chiefly dedicated to cricket and outdoor amusements generally—the powers that be have instituted a compulsory examination in materia medica and chemistry, which is held at the end of the first July. The idea of this first summer examination is excellent, if only the men would pass it. But, as a matter of fact, they do not; and the result is that, at the beginning of the second winter session, when they ought all to be settling down to the important work of the dissecting-room and the physiological laboratory, they are frittering away golden time over flowering tops and sliced corns, over test tubes and sulphuretted hydrogen. The occupation is harmless in itself, I have no doubt; but it amounts to little less than a crime when it is carried on at such a time.

If the men who have failed at this summer examination start work in October on the studies proper to that season, they do it in an uneasy, half-hearted way.

I sincerely believe that a knowledge of materia medica and chemistry is of the greatest advantage to us all, but I greatly regret that the medical student should be submitted to the risk of having his entire career wrecked over an attempt to acquire it. Yet so it is. And I therefore take this opportunity of urging that the requirements in these subjects be reduced to the minimum, and that the student be compelled to pass the examination in them before being registered at a medical school. This semi-professional examination would then be a boon to the medical student, for it would set him free for his proper school work; to his parents and guardians it would be a sort of test for his fitness for the profession which blind chance or stern necessity seems to have chosen for him; to the teachers of physiology and anatomy the change would be most blessed.

Another "adaptation" is that by which the student is permitted to break up the subject matter of his various examinations into small fragments. Chemistry now, materia medica later; anatomy without physiology; surgery divorced from medicine, and medicine from obstetrics. There is one particular in which, with all respect I say it, this new system is directly productive of harm to medical education. I refer to the power which the candidate now possesses of passing his examination in physiology when he is absolutely ignorant of anatomy, and *vice versa*. The fallacy, it seems to me, is abundantly manifest, but to make it absurdly clear let me cite an instance that occurred only last week. A candidate was asked by an examiner in physiology a simple question, the answer to which involved an elementary knowledge of the brain. Thereon the candidate politely informed the examiner that he did not know anything about the anatomy of the brain, that he was "only up for physiology" on that occasion.

There is an excellent way, it appears to me, of escaping from the dilemma without injustice to the student, and that is by issuing a syllabus of those physiological functions and processes in which a sound practical knowledge will be required. Better a sound knowledge in a dozen of the chief physiological functions than what I will call an official minimum thinly spread over the entire science.

Before ending my remarks upon medical education, I feel it my duty to lay bare before you what I consider to be the most heartless regulation of modern days. It has been issued by the University of London. After that terrible ordeal of the Preliminary Scientific Examination, there comes another of only slightly diminished rigour in anatomy, physiology, materia medica and organic chemistry. At the July holding of this examination, when the weather is apt to be hot and sultry, and the examiners would fain be getting away, they find their labours shortened for them in a most delightful manner, but entirely at the expense of the unhappy candidates. Formerly, those who had succeeded in passing the examination, and had sufficient energy left, were allowed to enter the lists for honours. But the Senate has recently enacted as follows:—

Every candidate for the July examination, on sending in his name for the

examination, must state whether he intends to compete for honours in any subject or subjects; and, if he does so intend, must specify the subject or subjects.

A candidate who enters for, but fails to obtain, honours in any subject, may be recommended by the examiners for a pass in that subject, if they are satisfied that he has shown such a competent knowledge thereof as is required by the regulations for the pass examination.

That is to say, that if a young fellow thinks that he knows enough organic chemistry to warrant his aspiring for honours in that subject, and happens to have over-estimated his attainments by but a few degrees, he not only fails to obtain those honours (which must now look very empty, I should think), but he even fails to get a pass-plate. You notice that the regulation says that the examiners *may* recommend him for a pass in that subject. But, for my own part, I would have little belief in the tender mercies of a gentleman who could, without a murmur, make himself a party to such a scheme. Moreover, a foot-note to the regulation honestly hints that when the weather is hot and sultry, Burlington House is no place for rest and grateful shade. Here is the foot-note:—

Candidates must bear in mind that the standard of attainment for the honours examination is much higher than that for the pass examination; and they should, therefore, exercise due caution in making their choice.

Of course they should be careful! But it is hardly necessary for the Senate to tell the student that it is much more difficult to attain to a pass standard in an honours paper than in a pass paper. "Every schoolboy" actually does know that.

To call an institution which could elaborate such refinement of unkindness, *alma mater*, is to misapply two sweet words. Let us rather call her *injuncta noverca*, for she is still the stony-hearted step-mother of our student days. And this, be it remembered, is the only institution through which London students can at present obtain a degree in medicine.

ON ONE HUNDRED CONSECUTIVE CASES OF CATARACT, MATURE AND IMMATURE, TREATED BY INTRAOCULAR INJECTION.*

By W. A. McKEOWN, M.D.,

Surgeon to the Ulster Eye, Ear, and Throat Hospital, Belfast.

THE question of intra-ocular injection in the extraction of cataract, brought by me before the profession in 1884, has occupied so much attention, particularly on the Continent, that I embrace the opportunity now presented of stating my views and my most recent experience before the representatives of ophthalmology of various nationalities.

From the time I began the practice in 1884 till the present time, I have used intra-ocular injection in every case in which it was indicated. I have followed generally the lines laid down in my address to the Ophthalmological Section at Belfast in 1884. My views at that time are my views now. I have proceeded cautiously step by step, operating on cataracts less and less mature, until I have reached the practical point of extracting lenses which are sufficiently clear to admit of patients going safely about, but presenting too much opacity to enable them to follow their occupations. I consider it a blemish on ophthalmic surgery that patients with opacities of the lens requiring very many years to develop to anything like maturity, as hitherto understood, should be obliged to go about doing nothing, losing health, strength, spirit, and, if without means or helping friends, to become inmates of workhouses or private charitable institutions.

I purpose now presenting to you the statistics of the last 100 operations for cataract, of all degrees of maturity and immaturity, in which I used intra-ocular injection, and I would remind you that you have no analogous statistics. There is a large number of cases of striated cortex with clear triangles interspersed, and of cases in which the surgeon could see more or less the details of the fundus. All these would be rejected by the surgeon practising ordinary methods as unsuitable for operation.

Of the 100 cases there were 81 cases of idiopathic cataract uncomplicated, 5 complicated by affections of the eye or its appendages, and 14 traumatic. Of the 81, 13 patients before operation could see to go about, and could count fingers from two to fifteen feet, but had not been able to work for a considerable period, and the fundus could be seen with more or less distinctness; 9 had striated cortex with triangular areas transparent; making in all 22 of various degrees of immaturity. In the 81 cases there were 8 escapes of vitreous, all

slight but one, and of these only 2 occurred during injection. The proportion of escapes of vitreous, though a little more than usual, has, therefore, no bearing on intra-ocular injection. As to the sequences of the 81 operations, there were:

1. One case of panophthalmitis occurring three weeks after operation. On the sixth day I opened the eye, expecting everything right, there having been no complaint. I found vitreous projecting in wound enclosed in unruptured hyaloid membrane. Bandage for two weeks having been continued without material improvement, I cut off projecting vitreous; panophthalmitis supervened. The operation had been perfect in every respect, and I think the prolapse occurred from some injury to the eye.

2. Three cases of pretty severe iritis; fair vision still remaining, and capable of improvement. One counts fingers at four feet, another at one foot, and another at six inches. The first was owing probably to syphilis and rheumatism, and the other two to impaction of iris in angle of wound.

3. Three cases of irido-cyclitis and choroiditis. *a.* One in case of patient (in whom double extraction was performed) who would not allow bandage to remain on for six days after operation. Fortunately only one eye suffered, and when he left hospital the eye was quiet and field good. *b.* Another in case of old congenital cataract with thickened capsule in man, aged 30. Removed thickened capsule with forceps; vitreous began to come; used scoop syringe, as I have sometimes done successfully in escape of vitreous, but in this instance was obliged to leave considerable part of lens behind. An iritis with a nodule of pus and inflammation of ciliary region developed after some weeks. Made a section; removed remains of lens with syringe with complete relief. Saw him lately, when I found eye perfectly quiet, perception of light good, and tension normal; but as other eye, also operated on, had good vision, I did not propose further operation. *c.* The third in case of man, aged 70, very nervous, and accustomed to stimulants in the morning, as I learned afterwards. Operation normal. On sixth day wound unhealthy, showing a slight focus of infiltration at one part of cornea, and a little pus in anterior chamber. Iris became involved; no pain. Treated by stimulants and hot steeping. Field of vision good, and could see bulk when I saw him a month ago. I have not seen him since, and cannot give further particulars.

Having entered into these details regarding the whole 81 cases, I shall refer in particular to the 13 very unripe cataracts.

CASE I.—Female, 65. (Counts fingers at 2 feet before operation); after operation reads 0.5 at 8 inches with + 18 D.S.

CASE II.—Male, 63. (Before operation counts fingers at 1 foot, pupil undilated); reads 0.8 at 8 inches with + 18 D.S. after operation.

CASE III.—Female, 70. (Before operation counts fingers at 15 feet); after operation reads 0.5 at 7 inches with + 18 D.S.

CASE IV.—Male, 61. Opacities in lens ill-defined, slight central haze of cornea; sees No. 3 Sn. at 4 inches; can see disc; extensive posterior staphyloma. After operation reads 2.25 Sn. at 4 inches with + 16 D.S.

CASE V.—Male, 57. Before operation counts fingers at 3 feet; after operation reads 1.75 with + 18 D.S.

CASE VI.—Male, 51. Able to go about. After operation, iritis. Syphilitic and rheumatic subject. After operation counts fingers at 4 feet; iridectomy indicated; other eye perfectly successful.

CASE VII.—Male, 63. Before operation counts fingers at 2 feet, can see large part of fundus; after operation sees 0.5 at 5 inches with + 18 D.S.

CASE VIII.—Male, 55. Sees 1.75 at 3 inches, very myopic always, vision same for years, can see fundus; after operation sees 0.6 at 4 inches with + 18 D.S.; will probably be further improved by tearing capsule. After tearing capsule he came to see 0.5 at about 10 inches with very weak convex glass.

CASE IX.—Male, 61. Iridectomy performed by another surgeon four years ago, probably for simple glaucoma; always very myopic; small radiate opacities only; can see fundus. After operation reads 1.75 at 4 inches with + 16 D.S. The vision was only slightly improved by operation; slight irritation and fluctuation of tension for a long time after operation; slight haziness of cornea.

CASE X.—Male, 55. Obligated to give up work a year ago; left eye simply a central cloudiness and some peripheral streaks of opacity; can see fundus. After operation sees 0.5 at 8 inches with + 18 D.S.

CASE XI.—Same patient. Right eye same condition; find he can read with great effort smallest type, but could not see far off, which he required to do for his work, and he desired operation. After operation and subsequent needling of wrinkled capsule sees 0.5 at 8 inches with + 18 D.S.

CASE XII.—Male, 50. Not able to work for four years, and vision stationary; can see fundus; superficial radiate opacities. On injection

* Read in the Section of Ophthalmology at the Annual Meeting of the British Medical Association held in Dublin, August, 1887.

some vitreous came with transparent cortex. After operation could read small type, but I have not note of exact particulars.

CASE XIII.—Female, 64. Other eye operated on previously successfully; can see fundus, but in a haze. On sixth day after operation severe pain, which I found owing to impaction of iris in one angle of wound; removed incarcerated iris; eye became quiet, but requires iridectomy. Counts fingers at six inches.

Several of these thirteen cases represent the ultimate point to which ophthalmic surgery in the matter of cataract operations can be expected to reach.

As to the other nine cases of immature cataract, with striated cortex and transparent segments, the results were all excellent.

I have nothing to remark about the five complicated with serious affections of the eye and its appendages, save that in one complicated with a chronic dacryocystitis, which latter affection was treated in the usual way for a week before operation, the eye was lost from suppurative of the cornea, notwithstanding thorough antiseptic treatment before, during, and after operation, including injection of M. Panas's solution into the interior of the eye, and application of Galezowski's gelatine antiseptic disc over the wound.

Of the fourteen cases of traumatic cataract, a considerable number were immature, but I have only to note one mishap—namely, a panophthalmitis starting from the wound, notwithstanding thorough antisepticism, so far as it could be carried out. The patient was beyond control. He would not allow bandage to remain for ten minutes at a time after the operation.

I have entered into these particulars because without them bare statistics would be very misleading. Of the three cases of panophthalmitis in the whole hundred, not one can be attributed to the injection, and not one could have been avoided except by not operating, or by putting the patients under a sort of prison discipline. Of the three cases of iritis in the 81 vision may be improved, and of the three cases of iridocyclitis I can only speak definitely of one; but assuming that the other two, which I have not seen for some time, have taken the worst form, I should only have a total of 3 complete losses in 81 operations on idiopathic uncomplicated cataract, including the 22 unripe.

I shall now touch very briefly on some general questions.

1. Is injection of distilled water previously boiled and reduced to the temperature of the body attended with any appreciable danger as regards the introduction of germs within the eye? In all cases except thirty (in which I injected M. Panas's solution), I have used distilled water, and in not one case have I seen any evidence of intra-ocular inoculation.

2. Is injection dangerous because of the force employed to remove cortex? As may be observed from the notes of unripe cataracts operated on, the water must have exercised considerable force to clear out transparent and sticky cortex, yet the results are quite as good as in the ordinary operations for mature cataract.

3. Is the injection of M. Panas's solution desirable? I have injected it only 30 times in 100, and therefore cannot speak very decidedly about it. I would remark, however, that in two cases it did not prevent suppuration of the cornea and panophthalmitis; true, in one case there was an affection of the tear passage, and in the other the patient was unmanageable. I fear it has an influence, though it may be a small one, in causing iritis. I have seen extensive posterior synechie and muddiness of posterior surface of the cornea arise from its injection into the anterior chamber after removal of a cyst of the iris. At any rate, I have found no advantage from it, and have abandoned it.

4. Is the injection of M. de Wecker's solution of eserine desirable? I have injected it nine times, and I have used the solution a considerable number of times by simply pouring it into the conjunctival sac, and easing the pressure of the eyelids on the ball, so as to facilitate the entrance of the solution into the anterior chamber, and I have found that the latter mode is quite as effectual in contracting the pupil as the former, indeed, perhaps more so. I do not apply the bandage till the pupil is well contracted. I have noticed in some instances some adhesions, and have been obliged, because of pain, occasionally to apply atropine; but I have so far found no positive disadvantage from the eserine. I wish to do strict justice to M. de Wecker's eserine treatment, and therefore add that in one respect I have not followed his advice, namely, in removing a piece of the anterior capsule. I have simply torn it freely.

5. Should force be used in the injection? I consider it impossible to remove the cortex in the majority of cases of immature cataract on which I operate without force. The more cortex left behind, the less likely is force to do harm, and the more it is required. I am never troubled because of the quantity remaining after the nucleus is expelled. It is a mistake to suppose that one injection—at least by the

old syringe, whose piston was too easy—is always enough. Sometimes two or three are required; but it is probable, with the improved piston of the new syringe, the clearing out of the cortex may be more easily accomplished. Experience teaches the surgeon what he can safely do. He should use injection at first in cases in which he is not likely to experience any difficulty; then take up cases of striated cortex not far from being ripe; and, finally, cases of very slowly progressing cataract, such as those of which I have given particulars. In this way he will acquire confidence and the dexterity born of experience.

6. Allied to the question of force is that of the instrument to be used. One of the most striking things about this question of intra-ocular injection is the number of instruments devised since 1834. I at first used the force of gravitation, and changed to injection. M. Wicherkiewicz uses the force of gravitation from his "undine," and the force may be considerable. M. Panas describes his instrument as follows: "L'instrument laveur du globe est analogue à un compte-goutte muni d'un tube en caoutchouc durci." M. de Wecker's consists of a body like a small sized ear speculum, the wide extremity being covered by india-rubber, and the small end having a silver terminal to introduce into the eye. He says: "C'est évidemment le meilleur instrument de contrôle car la pulpe si sensible du doigt indicateur appliquée sur le tambour permet de régler avec la plus grande précision le degré de pression qu'on veut exercer pour introduire le liquide à injecter dans la chambre antérieure."

M. de Wecker also points out as an advantage of his instrument and method, that the danger of suction is avoided, and the tension of the eye estimated and regarded. If the tension is high, the small aperture in the nozzle of his instrument may be obstructed. I hold that the instrument should be so constructed and capable of exercising such force as to clear out the remains of the lens, without regard to tension. The very small instruments, with small capacity, with tiny nozzles and small slits and holes in the sides and in front are insufficient to cope with ease with unripe cataract, but are doubtless useful in washing out the anterior chamber and interior of the capsule in ordinary operations. My instrument is so constructed as to yield a free and broad flow regulated in its force by the finger on the piston, just as the force in M. de Wecker's instrument is regulated by the finger on the india-rubber covering of his compte-goutte. The finger is just as delicate a regulator of force in one case as the other.

In the new instrument I present to you you will find many changes. There are two bodies of syringe of different lengths, and various nozzles of different lengths widths and forms to suit different hands and sections of different position and size. I have found that the syringe and nozzle hitherto in use are unsuitable for the upper section in very prominent eyes, particularly if the hand of the operator is short, and likewise for lower and for lateral sections. I have, therefore, provided short nozzles of various widths and lengths. The chief idea to be borne in mind is: that the various nozzles are only the channel for conveyance of the water power, and are not to be regarded as ordinary scoops or levers, and are therefore not to be considered as agents for exercising the ordinary mechanical force of scoops. The terminals with a little ledge at the end, like that of Critchett's scoop, may be used as scoops, but they are only meant by a little to aid movement, and not by a leverage action, to aid the removal of masses of adherent cataract set in motion by the water. A new form, with a scooped out part at each side, is meant to break the force of the water in cases requiring little force.

7. Should iridectomy be performed? In one of my papers I stated that I considered iridectomy should be performed in all cases of intra-ocular injection. M. de Wecker points out, however, that intra-ocular injection has a marked influence in causing contraction of the iris, and therefore ensuring a greater immunity from the old blot in the old flap operation—prolapsus of the iris. He adds to the beneficial effect by using a solution of eserine instead of plain water. He, however, considers iridectomy necessary in immature cataract. I entirely agree with his view as to the restriction of iridectomy, and now I always operate on cataracts, mature or nearly mature, in patients on whose obedience to instructions reliance may be placed, without iridectomy; but in very immature cataracts with iridectomy. I do not now, as a rule, inject eserine into the eye, but instil it freely, as I have already stated.

8. General applicability of intra-ocular injection. A point which cannot be too much impressed is the wide sphere of usefulness of intra-ocular injection. It may be used in every sort of extraction except the extraction of the lens in its capsule; for example, in the flap operation, old or new, with or without iridectomy; in Graefe's operation, in simple linear extraction, as a substitute for the old spoon extraction and the suction operation. It may be applied in unripe idiopathic cataract and unripe traumatic cataract. Its universal

applicability is one great feature. The gentle, moderate, and diffused power of a fluid is substituted for leverage instruments and pressure outside the eye. It rejuvenates old methods discarded, unsettles old notions about ripeness of cataracts, and brings us nearer the goal of the surgeon—to give speedy and effectual relief to sufferers hitherto doomed by imperfect methods to long years of delay and misfortune.

I do not wish to say that any one of all the instruments devised for intra-ocular injection is perfect. I wish to emphasise the method as that of the removal of cortex by the force of a fluid. The operation for cataract is a purely mechanical procedure, and I hope that year by year we shall more and more perfect our appliances, and that all the instruments we have hitherto devised may be replaced by others more effectual, and that by our labours we shall increase the sum of human happiness.

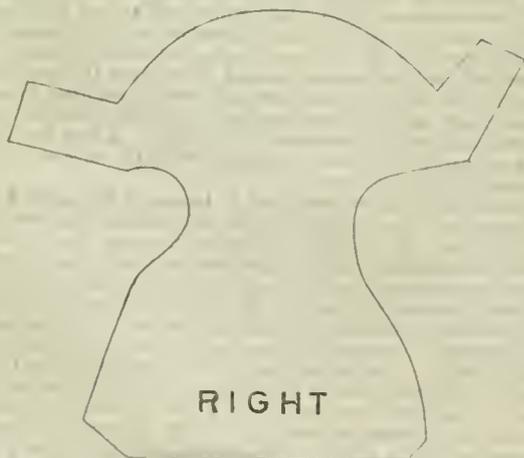

ON THE AFTER-TREATMENT OF CATARACT AND OTHER OPERATIVE CASES TO THE EXCLUSION OF DARK ROOMS, BANDAGES, Etc.

By SIMEON SNELL, M.R.C.S.,

Ophthalmic Surgeon to the Sheffield General Infirmary, and to the Institution for the Blind.

WHEN a new method of treatment has been advocated, especially when at variance with the plans usually adopted, it appears to me to be only fitting that he who is responsible for such advocacy should, at a subsequent date, state whether or not further experience has confirmed his views. These are the reasons for my reading this brief communication. For it may be recollected, by some at all events, that in an article in the *Lancet* nearly twelve months ago (September 18th, 1886), I spoke in high terms of a mode of treating cataract and other cases after operation without the stereotyped bandages, dark rooms, etc. Instances of operation cases in support were recorded, and I said I was disposed to adopt Chisholm's words, "From this times hence all bandages, compresses, and dark rooms will be among the things of the past, to be remembered only for the discomfort they occasioned."

My subsequent experience confirms all I stated in my first article. The plaster method has now been used in my hands in forty-eight cataract extractions in hospital and private practice, and in over one hundred other operations, including several for traumatic cataract, needlings for congenital cataract, opaque capsule, iridectomies, sclerotomies, and others. The stay in hospital of the cataract cases has been shortened, and the comfort to the patients has been great. Those who had previously undergone treatment under the old *régime* readily appreciated the altered conditions of the new plan. The mode of cutting and applying the plaster recommended by me I have found very convenient.

The engraving gives the metal shield for cutting the plaster in the desired shape. By reversing it the same does for each eye, and is marked a and b on the respective sides.

I have reason to believe that others in different parts, since the appearance of my paper, have adopted the plaster treatment.

Chisholm (*American Journal of Ophthalmology*, June, 1887), who

¹ Read in the Section of Ophthalmology at the Annual Meeting of the British Medical Association held in Dublin, August, 1887.

with Michel, was in America the advocate of this revolution in the after-treatment, has advanced beyond the position to which I alluded last year. Now he finds closing one eye sufficient, and no longer requires the patient to take to his bed; he lies on a lounge, and retires at ordinary bed time, and dresses before breakfast in the morning. "His present practice is to treat the wound made in the extraction of cataract as if it were an ordinary corneal wound, such as we daily see resulting from accident." At the end of the first week the patient can be allowed the privilege of the entire house.

From the first in cases of operation for traumatic cataract, and in some iridectomies and sclerotomies, I have not always seen the necessity of fastening up both eyes, and bed, has, after the day of operation, been dispensed with. As far as cataract extractions are concerned, there have appeared to me to be advantages in securing both eyes, and I should rather hesitate to regard them merely as ordinary corneal wounds.

ON THE OPERATIVE TREATMENT OF ZONULAR CATARACT.¹

By DAVID LITTLE, M.D.,

Senior Surgeon to the Royal Eye Hospital, Manchester; Lecturer on Ophthalmology, Owens College.

IN bringing the subject of zonular cataract before you, it is my intention to make a few remarks on the operative treatment, and I shall confine my observations chiefly to those cases of ordinary uncomplicated zonular cataract in which there is no arrest in the development of the eye, no shrinking of the lens, and no vitreous opacity or deeper seated disease.

I may say at the outset that I have nothing new to offer in the way of operation, beyond advocating a method which I have found from experience to be the best for gaining good vision. It is this, that when destruction of the lens is decided upon, I recommend a free crucial rupture of the capsule with a needle, so as to make the whole lens opaque and more soft, and two or three days afterwards to perform extraction by means of a Teale's suction instrument.

The disturbance of vision caused by zonular cataract depends altogether upon the extent and density of the opaque layer. If, on dilating the pupil, the zone is broad and perfectly transparent, vision may be fairly good; on the other hand, if the central opacity is great, considerable reduction of sight must exist.

My experience in the examination of the refraction in these cases is that some are emmetropic, a few only are hypermetropic, but the great majority are myopic. I never fail to test the vision before and after atropine, at the same using lenses to correct any defect in the refraction.
