In the case of very young subjects whose vision cannot be accurately ascertained I postpone all interference for a time, unless it is quite manifest from the extent of the opacity that sight is bad. It is upon such an examination as this that I base my opinion for operative interference or otherwise.

I recommend destruction of the lens in all cases that are found to be of a progressive character, also in non-progressive cases where vision equal to at least twenty-fiftieths is not obtainable, after dilating the pupil with atropine. I would go further than this in exceptional cases, and say, if I found that twenty-fiftieths was not sufficient sight for the requirements of the patient, and if he or she were between the ages of 10 and 25 (which I consider the most favourable age for operation), with perhaps some myopia, and all other conditions favourable, I would not hesitate to recommend extraction. When the lens, then, has to be dealt with, there is the operation by solution. This is a tedious process, and I hardly ever adopt it in zonular cataract.

I have been most satisfied with the suction operation. Having dilated the pupil, I make a free rupture of the capsule across the pupil extending from margin to margin; a similar rent is made from above downwards, keeping the needle well in the anterior part of the lens. The capsule is extensively ruptured in this way to cause its retraction well behind the iris, and so avoid secondary operations; the needle should not penetrate too deeply for fear of rupturing the hyaloid or dislocating the lens. A light bandage is placed over the eye, the patient is kept quiet, and atropine freely used to dilate the pupil. After two or three days, or more, according to the condition of the eye, extraction is performed by a Teale's suction curette. This is accomplished by making an incision in the outer part of the cornea, halfway between the limbus and centre, with a double cutting edged needle from 3 to 4 millimètres broad. Through this wound the curette

¹ Read in the Section of Ophthalmology at the Annual Meeting of the British Medical Association held in Dublin, August, 1887.

is introduced into the area of the pupil, taking care not to push the open end behind the iris or too deeply into the pupil. Suction is then applied by the mouth, and by this means the whole of the pupil can be easily and rapidly cleared. The patient is then placed in bed, with a light bandage over both eyes; atropine is again used to keep the pupil dilated, and in the course of a week or ten days recovery may fairly be expected.

I have tried a Bowman's suction syringe, but I much prefer Teale's. The advantages of the latter are that suction can be better regulated by the mouth, and the hand is left free to guide the curette, while in the case of Bowman's there is a difficulty in applying suction by the hand, and directing the curette with it at the same time. The advantages of suction over ordinary linear retraction are that the pupil can be cleared with greater certainty, and there is little or no disturbance to the eye by pressure, two conditions, I think, of the greatest importance.

It is said by some there is a danger of suppurative iritis or iridochoroiditis in this suction operation. Speaking from my own experience, I have never met with symptoms so serious as to cause anxiety; and I consider the operation a safe one, if performed with care and judgment. I am careful that the curette is absolutely clean before use, and of late years I have used antiseptics at the time of extraction. On looking over my hospital and private notes during the last eight years, I find that I have performed this operation in forty-two cases, and in the great majority of them I have secured brilliant results as regards sight. The records of some of them are somewhat imperfect, particularly as regards the resulting vision, partly from the youth of the patients, and partly, also, from the difficulty of following up hospital cases. The condition of the eye, however, has been noted in all. In no instance has there been a failure. In three cases there was synechia anterior; in five cases secondary operations had to be performed on account of capsule. In all the others there was a perfectly clear and round pupil, and I attribute this freedom of the pupil from capsule to its extensive rupture in the preliminary operation. The ages of the patients ranged from 5 to 27 years, and I have followed the usual practice of operating upon one eye only at a time.

Regarding iridectomy, I would say that if dilatation of the pupil improves vision to twenty-fiftieths with or without glasses, this operation, generally speaking, should be adopted, with a few exceptions to which I have already referred.

I should prefer iridectomy also, even when only a moderate improvement of sight can be obtained, in all cases accompanied by some mental defect in the patient, arrest in the development of the eye, shrinking of the lens, or when there is evidence or suspicion of posterior disease. When a small iridectomy is desirable, the best method is that recommended by Mr. Anderson Critchett, in a paper he read before this Association, at Worcester, in 1882, to which I would refer you; he uses a broad needle, and a Tyrrell's hook, both instruments bent almost at a right angle, and excises a small portion of the pupillary margin of the iris downwards and inwards, leaving the periphery untouched.

Referring to the current belief that zonular cataract remains stationary throughout life, I have no conclusive evidence to show that opacity has ever become developed in a zone once absolutely transparent; but I believe that later in life, when the lens becomes harder, the opacity extends to the deeper nuclear layers, and so causes serious deterioration of sight. I have seen at least four cases about 50 years of age, in whom sight had become slowly reduced to 20 Jäger, apparently from no other cause than an increased density of the central opacity, involving the whole nucleus.

In operating upon such cases by the ordinary method for hard cataract, I have always found the eye most intolerant of operation. In every case, more or less, iritis followed, and many weeks elapsed before recovery took place.

The main purpose of this paper is a recommendation to perform extraction by suction oftener than is generally done, because I think that cases are frequently treated by the easier method of iridectomy, in which the resulting vision is disappointing to both patient and surgeon. Another object is to elicit information regarding the progression or otherwise of this form of cataract.

Dr. EMRYS-JONES said that his experience led him altogether to question the desirability of injecting any fluid whatever into the anterior chamber after cataract operations; he thought that there was considerable danger of introducing germs in this way, and that there must be greater liability to set up iritis and other complications. He had for the last two years used Mayo Robson's dry eucalyptus spray apparatus in cataract extractions, and he had about 130 consecutive cases without a single case of suppuration of the cornea and

with very few cases of iritis. The resulting vision had been in the majority of cases very good.—Mr. BERRY had seen three cases performed by Dr. McKeown, and must admit that his method was fairly efficient as far as the removal of cortex, which might otherwise give rise to difficulty, was concerned; but as it produced not a little irritation he (the speaker) had not adapted it until more experience had been accumulated. With regard to Dr. Little's excellent paper it was interesting to find that Dr. Little used suction. He (the speaker) had always found linear extraction, which must, however, be done by means of a sufficiently large incision, 4 to 5 millimètres, practically in every way efficient.—Mr. McHARDY considered that, having regard to the published analyses of the water supplied by the various London companies, Dr. McKeown's "pumping proceeding" must be fraught with great danger from the introduction of germs. He had been accustomed to utilise the aqueous humour as a solvent for any remaining cortex; this was rapidly resecreted after its escape, and if the eye be closed for a few minutes after the escape of the nucleus, the admixture of aqueous with the cortex materially facilitates its removal by friction. In the cases of immature cataract in which operation was indicated he adopted Förster's plan of artificial maturation.—Mr. PRIESTLEY SMITH thought that Dr. Chisholm's claim that he had introduced a novel method, which would revolutionise practice, went beyond the merits of the case. His friend Mr. Hodges would bear him out in saying that at the Birmingham Eye Hospital, fifteen years ago, closing the lids with strips of black court plaster, without pad or bandage, was a favourite method of dressing cataract operations. The speaker had employed it largely, and decidedly preferred it in glaucoma iridectomies. It was, he believed, a very old line of practice. In using adhesive plaster, it was important to leave an exit for tears, and he thought itching was rather more apt to occur than under the pad and bandage. As to confinement in bed, it was not of great moment whether we kept our patients in an upright or in a horizontal position, but it was very important to avoid frequent or sudden changes of position. Sudden changes in the pressure of the blood column easily led to reopening of the wound and to hemorrhage into the chambers. Such slight transgressions as stooping to reach a shoe or to move a footstool, or, as in one case of his own, carrying a coal-hox, were dangerous shortly after cataract extraction. If operating surgeons were going to disregard common sense and time-honoured principles, we should soon hear of disasters. With regard to dark rooms, the speaker's own hospital patients lay in large wards, occupied also by medical cases. He gave more or less protection by a bed-curtain, but had never employed dark rooms.—Mr. ADAMS FROST had used Dr. McKeown's method on several occasions, and as far as its mere mechanical effect was concerned, had found it as efficient as friction; the risk of infection, however, rendered it imperative to take elaborate precautions, and as there was always the uncertainty beforehand whether injection would be required, this had led to his abandoning the proceeding.—The PRESIDENT said that Dr. McKeown's method was not one that recommended itself to his surgical instinct, and the results that Dr. McKeown had himself adduced would not encourage him to attempt it in the future.—Dr. McKEOWN, in reply, said with respect to the surgical instinct of the President being against intra-ocular injection, the surgical instinct of the profession, as a whole, in relation to new operations, was invariably wrong for a variable period of time, when the new operations were much at variance with old practice and preconceived notions. The surgical instinct of the profession generally was long against ovariotomy, but the surgical instinct of the ovariotomists had proved to be a safe guide. The same held about more recent questions. The President had taken an entirely wrong view about the bearing of the statistics. A little escape of vitreous was not a serious matter, and, in the eight cases referred to, only two had any relation to the question under discussion, namely, intra-ocular injection. His paper, when carefully read, would show that, taking the whole cases, complicated and uncomplicated, ripe and unripe, idiopathic and traumatic, the statistics were most assuring, and quite equal to the statistics of selected cases of mature cataract. In the whole 81 cases of idiopathic cataract (including 22 cases of most unripe cataract, on the majority of which no surgeon with the ordinary methods would operate), there were only three total losses at the utmost. As to the case of the President, in which injection did not remove any unripe cortex, the probability was that the terminal had not been introduced inside the capsule. The President thought that some of the cases described were not simply immature cataract, but incipient cataract; but, if incipient cataract of one to three or four years, or more, standing could be operated on by injection, nothing further was required to put it on a level above any other operation ever practised. Dr. Emrys-Jones and Mr. McHardy, without having had any experience

of the method, or even having seen anybody use intra-ocular injection, had condemned it. No doubt the most competent critics were those who knew nothing practically about it—of course, they were far better able to judge of it than one who had been using it for three years in a public institution, open to the profession, and who had, on every occasion possible, demonstrated its utility to students and medical men. As to the cases mentioned by other speakers, they only amounted to six or seven, and they were not to be taken into serious consideration in face of the details Dr. McKeown gave in his paper, and of the experience of the most distinguished Continental ophthalmic surgeons. Mr. Priestley Smith inquired respecting the size of the nozzles. It was well known that, if water be driven with force through a very small opening, the force exerted on a limited area was very much greater than if the same force were exercised through a wide opening. The object was to direct a pretty uniform force on the whole of the internal surface of the capsule, and not a strong force on any one point. The nozzle being broad and the slit long, this was accomplished. Besides, the broad nozzle gave support to the vitreous humour. The capacity of the body of the syringe was considerable, as it was a mistake to have only a few drops when force had to be used. When the operator had more than he required, he need not use it; when he had too little, he had to remove the instrument, and replenish it.—Mr. SNELL, replying to the remarks made on the treatment advocated in his brief communication, pointed out that many of the subjects raised had been dealt with in his former article. The mode of cutting the plaster allowed for the escape of tears, and patients did not complain of any discomfort; but those who had been treated otherwise on previous occasions acknowledged the greater comfort of the plaster treatment. He was not aware that Mr. Priestley Smith had used plaster so much in his practice. The method he had advocated, however, appeared more complete than had previously been adopted. Referring to Dr. Little's paper, he remarked that he had not seen the danger from using the suction curette which in some hands had been experienced. For some time he had used suction very little because it appeared unnecessary, for if the lens were well hooked up, the softened matter readily escaped through a small corneal wound. His rule was to introduce as few instruments as possible into the eye.

A CONTRIBUTION TOWARDS THE ETIOLOGY OF PHTHISIS.

By R. W. PHILIP, M.A., M.D., F.R.C.P. EDIN.

Physician to the Victoria Dispensary for Consumption and Diseases of the Chest, Edinburgh.

It is not my intention to discuss the morbid anatomy of the phthisical lesions, nor the dependence of the phthisical process on the presence of the tubercle bacillus, nor the important questions of heredity and of climatic and other influences, which bulk so largely in the etiological chapter.

For the present, I start with an acceptance of the doctrine of the unity of the phthisical process, and of the immediate dependence of the process on the presence of the bacillus. The rigidly exact observations and experiments of Koch and others have, in my judgment, placed this beyond doubt. I prefer, at least, not to raise the question now. But, in spite of the comparative fulness and clearness of our knowledge in these lines, it appears to me that we are far from a rational conception of the actual cause of death in phthisis. It was with the view of further elucidating this higher etiological problem that the present investigation was undertaken.

A glance through the literature of the subject reveals how seldom the attempt has been made to solve the problem, how comparatively seldom, indeed, the question has been raised. Where the matter has been discussed, explanations have been offered, which may be classified roughly under four heads, namely: (1) progressive asthenia; (2) loss of hæmatisis; (3) the lighting up of fresh inflammatory foci; (4) the absorption of waste products. Now, I have no desire to depreciate the value of these as integral factors in the process. My contention is that, in view of the comparative regularity of the clinical phenomena, and in the light of more recent work, they do not afford sufficient explanation. Each of them was fully discussed prior to the discovery of the tubercle bacillus, and Jaccoud, more especially, has the credit of emphasising the importance of the fourth, namely, the absorption of waste products. Since the announcement of the tubercle bacillus, comparatively little has been added in this

direction, though the features and clinical course of an ordinary case of phthisis and those of experimentally induced tuberculosis are well defined and strikingly similar.

What, then, is the *modus operandi* of the tubercle bacillus in leading towards death? Its fatal properties cannot, I think, be regarded as merely irritant or privative. In all probability they are attributable to a power possessed by it of elaborating new products, which are afterwards absorbed.

Before explaining on what facts I base that statement, I ought to mention that Dr. Hermann Weber has hinted at the probability of such elaboration and absorption. In the Croonian Lectures (1885) Dr. Weber speaks of "the chemical poison which probably is originated by the development of the tubercle bacillus in the tissues in an analogous manner, as, according to the researches of Gaspard, Panum, Billroth, Burdon Sanderson, and others, a powerful chemical poison—sepsin—is developed in the process of septicæmia." I am not aware, however, that up to the present any attempt has been made to treat the matter more seriously. Whether the suppositious product or products are secreted by the bacillus or are elaborated from the tissue which it infects raises another question which must be discussed later. It is enough, meanwhile, if we recognise the probable dependence of these new products on the presence and action of the bacillus.

Such a process of elaboration or secretion has its analogue in the more evident varieties of fermentation, which have been studied by Pasteur, Schützenberger, and others; for example, the alcoholic, the lactic acid, the butyric acid, and the ammoniacal. More particularly the view appears to me substantiated by the following weighty evidence. The association of special forms of microzymes with special forms of fermentative action has been conclusively demonstrated by Pasteur and a large school of subsequent observers. A distinct variety of fermentation as certainly follows the admission into a suitable medium of a given microbe, as the exclusion of the same microbe excludes the possibility of its occurrence. Further, the rearing of pure cultivations has shown that different effects are obtained, though some of the observations in this direction are open to question, and, certainly, marked differences in the rate of growth are observed, according to the constitution of the medium in which the cultivation is attempted, while certain organisms are most exclusive in their selective affinities. Moreover, if the same medium, say Koch's gelatine, be utilised for the cultivation in different tubes of different microparasites, the effects produced on the medium are very different in the several instances. Even in the gross, such differences, for example, in the rate and amount of liquefaction in the production of certain gases are marked. And it is in the highest degree probable that careful examination of the medium after cultivation has been carried on for some time would show important alterations in its chemical constitution, as occurs in the better known forms of fermentation. In other words, the living organism has the power of disturbing, or rather, in order to the preservation of its own life, the organism is compelled to disturb, the molecular arrangement of the elements in the medium of cultivation.

These considerations open up a wide and promising field for investigation. This appears the aspect of bacteriological observation, which is pregnant with most results. In illustration of this, the work of Panum, Selmi, Gautier, Brieger, Bergmann, and Schützenberger, need only be cited.

In practically applying this hypothesis to the problem of phthisis, I directed my attention first of all to the urine. The results obtained, which have been given elsewhere, were not sufficiently definite in character to warrant their citation here. Examinations of portions of the diseased organs, or of their glandular appendages, was abandoned, as it was found impossible to have these sufficiently fresh to avoid the objections that would inevitably assail successful results so obtained. This led to the adoption of the sputum as the *materies morbi* for investigation, and that, on the following, among other, grounds:—

1. The sputum is the constant accompaniment of the morbid condition, and stands in a peculiar relationship to the diseased organs.
2. It is always accessible in large quantity, fresh, and, therefore, as much as possible free from such contamination as might be supposed to introduce fallacy.
3. It has been shown that the maximum amount of the contagious element resides in the sputum.
4. Having regard to the conditions of growth of the tubercle bacillus, it seems likely that the muco-purulent secretion is a peculiarly good medium for cultivation.
5. It has been proved that tubercular sputum retains its virulence for months.
6. The presence of the tubercle bacillus can be comparatively easily determined, while with greater care its relative abundance in different specimens may be gauged.
7. The sputum

can readily be subjected artificially to similar conditions outside the body as within the chest. 8. Much of the experimental work already carried out with reference to tuberculosis has been done by the subcutaneous and intravenous injection of unaltered phthisical sputum (cf. the work of Villemo, Chauveau, Biffli, Vezz, Semmer, Tappiner, etc.). 9. Collateral evidence from the side of other ptomaine investigations seems to imply that the ready access of oxygen to the centre of ptomaine production aids considerably in their rapid and abundant development.

After approaching the subject in a variety of ways, with a remarkable constancy of results, I thought it best to institute a series of experiments with extracts obtained from different phthisical sputa by such methods as could be least open to objection in respect of complications introduced from without.

Method.—The sputum was carefully collected in a clean vessel, preferably a closed jar, with central hole for the entrance of the expectorated material, such as is used in some of the Edinburgh Royal Infirmary wards. In the selection of the patient the greatest care was exercised. *a.* Only such cases were made use of as showed undoubted signs of advancing phthisis. *b.* No case was accepted where the temperature chart did not record a more or less persistent elevation. *c.* After the first two or three examinations it was found best to restrict the selection to subjects where possible impurities from smoking were absent.

Similar care was taken in the selection of the sputum. *a.* The sputum was rejected when any foreign admixture was present, such as vomited materials. *b.* It was rejected when saliva was present in appreciable amount. *c.* The reaction of the sputum was tested, and only such admitted as gave an acid or neutral reaction. This last condition was found always associated with a peculiar odour which may be regarded as *sui generis*. *d.* The presence, and approximately the relative abundance of the tubercle bacillus was in every instance ascertained.

The sputum, thus carefully collected for twelve or twenty-four hours, is at once subjected to further examination. Its bulk is measured, and three volumes of rectified spirits are added to it. The mixing process is carried out *guttatim*, so that the separation of the elements of the sputum may be rendered complete, and the admixture made as intimate as possible. If the sputum be neutral, or but faintly acid, a trace of tartaric acid is added to the rectified spirits previous to mixing. The whole is transferred to a Florence flask. Its mouth having been protected by a fine muslin rag, the flask is placed in a Koch's steam steriliser, and exposed to a gentle moist temperature of 36° to 40° C. for twenty to twenty-four hours. At the end of this time the fluid is carefully filtered, first once or twice through fine muslin, and then three or four times through filter paper, till the filtrate runs off perfectly clear. Its volume is then measured, and the whole evaporated down in open beakers to one-fifteenth of its bulk (*circa*). This reduces it to the consistence of a more or less muddy extract, varying in colour according to that of the original sputum. The latter part of the process is conducted slowly, with the view of driving off all remaining trace of spirits, and to prevent the escape of other volatile products.

The extract thus obtained was utilised for injection. With regard to its constitution, it must be observed that it is as pure an extract as can well be obtained of the carefully-selected sputum. The only additions made are measured quantities of faintly acidulated rectified spirit. This, in the process of slow evaporation to one-fifteenth of its original volume, was presumably entirely given off; so that, in observing the results, we have to deal with the effects of a fairly purified extract of phthisical sputum—that is, sputum minus the coagulable elements, separated out by the addition of the rectified spirits and the after-process of filtration.

It should be further mentioned that the extract, when properly prepared, is most unstable; and, being extremely liable to the attack of fungi, breaks down in a few days, giving rise to new products. The extract was, therefore, never used for experimental purposes after it had been prepared for three or four days.

Four series of experiments were conducted with the extracts so obtained: 1. To observe its effects on the system generally. 2. To observe its effects on the circulation; that is, on the cardiac rate. 3. To test the antagonistic effects of certain drugs, especially atropine, as regards the system generally. 4. To test these antagonistic effects as seen more especially in the cardiac rate. It is impossible here to give details of the numerous experiments conducted under these heads, but the general results may be summarised.

SERIES I.—*A. On Frogs.*—Thirteen experiments carried out with varying quantities, and under a variety of conditions, yield results of striking uniformity, and point to the presence in the extract of a

toxic principle, or of toxic principles, of considerable potency. The results differ only in degree, a progressive increase in the intensity of the symptoms being observable with the increased dosage. The general line of symptoms is that of the gradual development of voluntary motor depression. In no instance was a stage of excitement traceable. This condition of depression appears, in part, explicable by a toxic influence exerted on the higher centres. This is evidenced by the general character of the depression, by the sluggish nature of the movements while co-ordination remains little affected, and by contraction of the pupils. The spinal cord appears to be unaffected, the reflexes remaining normal throughout in the less severe cases, and in the graver being unaffected till later on.

B. On Mammalia.—In mice it was found possible to induce distinct symptoms with 0.3 cubic centimetre of the extract. These symptoms resembled in general character those observed in the frog, and passed off gradually in the course of an hour or two. With increased injection, the intensity and duration of the symptoms were correspondingly increased. As in the frog, the scope of the symptoms suggested implication more especially of the higher centres. There was the same early appearance of gradually advancing depression. This, as before, was not preceded by any trace of excitation. In the course of ten minutes the animal invariably became quieter, the stage of quiescence passing on to more or less complete passivity and disinclination for movement, according to the amount injected. In the lighter cases this was gradually recovered from. In the more severe cases it deepened into death, or death followed after more or less complete approach towards recovery. In addition to these symptoms, common to frogs and mice, certain well-marked phenomena were observed. Among the more striking of these should be noted fibrillary twitching of the surface of the body, and convulsive movements of the trunk and limbs. Regarding changes in the respiration, it has to be borne in mind that the estimation of the rate of breathing is always difficult in mice. The general impression, however, was that after the preliminary excitement there remained a certain increase in the respiratory rate, to be followed later, when symptoms were sufficiently prolonged, by retardation. In those animals which died after prolonged symptoms, anorexia was a conspicuous feature, while water was drunk freely.

In rabbits, comparatively large quantities of the extract were required to produce urgent symptoms. On economic grounds this line of experimentation was less systematically carried out. So far as they go, the results obtained were in strict accord with those just detailed. Of greater interest, however, in the case of the rabbit, was the effect of daily repeated small doses. Thus, for example, two rabbits were fed on measured quantities of oats and water, and their weights registered for some days, until the daily register became fairly constant. The same conditions were continued, with the addition that once in the twenty-four hours each animal received subcutaneously small injections of the extract. Presumably as a result of this, their weights progressively decreased by amounts varying from one-fourth of an ounce up to one ounce per diem, and the amount of food consumed was reduced to one-half, and on one occasion to one-quarter, of the amount previously consumed in the corresponding time. After some days the system appeared to grow more tolerant of the morbid material, as it was found necessary to increase the dose to produce the same effect. At the end of ten days the injections were discontinued, and the weights, without increasing, remained almost constant for a week or two. Then a gradual progression downwards, apart from fresh injection, was observed, each animal continuing to lose a fraction of an ounce daily until death. It appears likely that the early loss of weight was due directly to the action of the morbid product, which doubtless led to loss of appetite, etc. This is evidenced by the daily loss of weight corresponding with the dates of injection and by return to a more constant condition when the injections were stopped. The later progressive loss of weight, apart from injection, is more difficult of explanation. We may suppose that, following the earlier injections, a condition of marasmus developed. In neither of the rabbits was there found, on *post-mortem* examination, the slightest trace of caseation to which rabbits are prone.

SERIES II.—Effects on the circulation, that is, on the cardiac rate. A considerable number of experiments were conducted under this head. They prove conclusively the presence of a powerful cardiac depressant. In each instance the fall is striking. Where large doses were used it was remarkable, the cardiac rate being reduced, in the course of four hours under the influence of the extract, from 44 to 18, and even 14. Coincident with the decrease in rate, a marked lengthening of the diastolic interval in relation to the systolic phase was evident. These results, taken along with those of Series IV (*infra*), imply, I think, that the depressed action on the heart is produced

through the medium of the inhibitory fibres, and not by direct action on the cardiac ganglia.

SERIES III and IV.—It is convenient in this brief summary to combine the results obtained in Series III and IV. In each it was attempted to neutralise the ascertained depressant effects of the extract by the exhibition of presumably antagonistic drugs. For the present, I limit myself to the results obtained with atropine. The double series yield results in remarkable consonance with those obtained in the earlier series. In the first place, they afford strong corroborative evidence as to both the general systemic and the special cardiac effects of the extract. But, in the second place, they prove that the combined exhibition of atropine undoubtedly modifies these results in a striking manner. Of this there is evidence in all the experiments, the degree to which such modification is produced varying with the relative quantity of the antagonistic principle. Most perfect antagonism was produced by the combined injection of $\frac{1}{100}$ milligramme of sulphate of atropine with 0.6 cubic centimètres of extract. Under such conditions the general systemic effects—easily produced both in frogs and in mice by 0.6 cubic centimètres of extract—were almost completely absent, while the cardiac rate, which 0.6 cubic centimètres sufficed to depress considerably, remained practically constant. The effects were similar, whether the atropine were exhibited simultaneously with the extract, or at varying intervals before or after. The antagonising influence of atropine is most strikingly demonstrated in those experiments where the injection of the extract preceded that of the atropine by a measured interval of time. In such cases the effects of the extract were first of all well defined, and gradually declined on the addition of the atropine. Similar results, though less striking, were obtained when the atropine preceded the extract. It should be added that, in every instance where counter-experiments were made with atropine, the extract was first tested, with the view of establishing its physiological action.

This experimental record is necessarily too brief, and doubtless is open to much criticism. But the results at my disposal—which I hope to publish in more extended form—appear to me to justify the statement that from the tubercular sputum there is separable one or more products possessed of well-marked toxic properties, those toxic properties being more or less completely opposed by atropine.

The remaining question is, in how far this poisonous principle is dependent on the presence of the bacillus? Might not such toxic effects be produced by extracts obtained from other sputa besides those strictly bacillar? There is, unfortunately, no time to give in full the ground for my statement, but my belief, which rests on experimental basis, is that the presence of the bacilli is causally related to the poisonous product obtained from the sputum. I incline also, for similar reasons, to the belief that there is a relation traceable between the toxicity of the extract and the abundance of the bacillar elements discoverable in the sputum.

On the line of absorption and the therapeutic indications, regarding which I had proposed speaking, I must not dwell; but it may be convenient in closing to tabulate shortly the chief points which have been briefly discussed.

Conclusions.—1. In view of the work of Koch, it is impossible to avoid admitting that a causal relationship exists between the tubercle bacillus and the phthisical process. 2. The mere predication of this relationship is not sufficient in explanation of the clinical facts and the generally fatal termination of such cases. 3. The usually received explanations of the *modus moriendi* in phthisis are insufficient. 4. It appears probable that the lethal influence of the bacillus is due to the production thereby of certain poisonous products. 5. Clinical and experimental evidence appears to indicate that the morbid secretions from the respiratory surfaces afford a good medium for the growth of the tubercle bacillus, and, presumably, for the elaboration of such products. 6. Such a product is separable from the carefully selected and prepared sputum. 7. This product is possessed of well-marked physiological properties, being eminently toxic to frogs, mice, and other animals. 8. The toxic properties of the product are, speaking generally, depressant. 9. More particularly they include a marked depressant influence on the heart. 10. This depressant influence seems to be exerted through the medium of the cardio-inhibitory mechanism. 11. The toxic action of the product is more or less completely opposed by atropine. 12. The amount of the product which may be separated appears to bear a distinct relation to the abundance of the bacillar elements present. 13. Absorption of the poisonous product most probably occurs by way of the lymphatic circulation.

ON CERTAIN NEURALGIAS SIMULATING RENAL CALCULUS.¹

By CHARLES HENRY RALFE, M.A., M.D. CANTAB., F.R.C.P.,
Physician to Out- and In-patients at the London Hospita

THE purpose of the present paper is partly to draw attention to certain painful affections of the kidney which may be taken for calculous disease of that organ, and to seek for information from those who may have had a wide experience of such cases as to the distinguishing points that may be best relied on for diagnosis in cases in which doubt exists. As a rule, the diagnosis of renal calculus is easy; a time usually comes, either early or late, in which the calculus endeavours to escape by the ureter, giving rise to severe colic, and causing blood and pus to appear in the urine; to these is usually added a symptom which writers have been accustomed to consider as absolutely symptomatic of renal calculus, namely, retraction of the testicle on the side affected. Though this latter symptom is of undoubted importance, nevertheless, too much dependence must not be placed on it, since the phenomenon will appear quite independently of renal calculus, and is evoked whenever a tenacious mass of any size passes from the pelvis of the kidney down the ureter; thus, it may be observed in cases of hydatid of the kidney, or when tuberculous or scrofulous masses are passed downwards into the bladder. It is also a well-ascertained fact that a stone in the kidney may exist for a considerable time without giving rise to any of these symptoms, except pain, and that in some instances may be quite unimportant, giving rise rather to a feeling of weight and dragging than to actual suffering; whilst the urine may be examined repeatedly with only negative results. Thus, Dr. Murchison (*Diseases of the Liver*, third edition) refers to a case which was under his care, and other physicians, in which for years the painful affection of the right side was referred to hepatic neuralgia and treated as such, till after years of suffering the patient was relieved by the passage of a renal calculus. One can hardly suppose that such an acute clinical observer as Dr. Murchison would have neglected to examine the urine, and had blood or pus been present to have come to a speedy and right conclusion. An interesting illustration of a similar incident was reported in the March number of the *Chicago Review* for this year (1887), in which the patient for eighteen years had suffered from severe lumbar pain and whose urine had been frequently examined, but with negative results, till at last pyelitis was evoked, and then, after eighteen years of doubt, the nature of the case was fully revealed. I have myself (*Morbid Conditions of the Urine*, Churchill, 1882) recorded a case in which a gentleman suffering from severe lumbar pain consulted an eminent surgeon and a distinguished physician. The surgeon told him he was suffering from locomotor ataxy, the physician that the symptoms were due to syphilitic disease of the spinal cord, and placed him on a course of mercury; two years afterwards he passed an oxalate of lime calculus, which completely relieved him of his pains. He assured me that during the whole time of his sufferings his urine continued bright and clear, and that it was frequently examined by his medical attendants, and it was not till the day he passed the calculus that he noticed it thick and bloody.

It would be easy to enumerate other cases in which stone in the kidney existed without being recognised by the usual symptoms, but the converse of these cases, namely, when lumbar pains of long standing have been attributed to renal calculus, are not so numerous, and are certainly more perplexing. Thus, some years since a patient of the late Dr. Murchison, who was thought by him, and by the other physicians who also saw the case, to be suffering from stone in the left kidney, although the urine was repeatedly examined with negative results, and who went on suffering excruciating agonies of paroxysmal pain, died suddenly one night. At the inquest the *post-mortem* examination showed the peritoneum full of blood, which proceeded from the rupture of an aneurysm of one of the smaller mesenteric vessels, but which evidently pressed on some nerve plexus supplying the pelvis of the left kidney. Here, indeed, is an instance in which a correct diagnosis was impossible; but all cases of renal pain are not so obscure, and I have endeavoured to classify them in the following order.

1. *Neuroses of the Kidney.*—(a) A true neuralgia of the kidney is of very rare occurrence. I cannot say I have ever met with an instance. Delicate women at the menstrual period, and for some time after, suffer from aching pains in the renal region, and these pains by some have been considered neuralgic. But it has been shown that

¹ Read in the Section of Medicine at the Annual Meeting of the British Medical Association held in Dublin, August, 1887.

there is an intimate sympathy between the renal organs and the female generative apparatus, and that during menstruation slight enlargement of the kidney occurs. In delicate women this physiological engorgement may become exaggerated, and the distended capsule give rise to pain. Renal neuralgia, it is said, sometimes occurs in malarial subjects—it may be well to note the possibility; but with seven years' experience of tropical diseases at the Seaman's Hospital, where the opportunities of watching the sequelæ of malarial disease are very great, I never met with an instance of renal neuralgia. (b) Reflected neuroses of the kidney, however, are not uncommon. In 1878 the late Dr. Murchison gave me the particulars of a peculiar form of neural attack which he designated as a renal storm, and which had frequently occurred in a patient suffering from aortic regurgitation. The attack commenced with excruciating pain over the region of the right kidney, exactly like renal colic, but there was no sickness or retraction of the testicle, and the urina passed after the attack was perfectly normal, nor was there jaundice, or anything to suggest that the pain was due to either renal or biliary calculus. After lasting some hours the pain passed off as suddenly as it came on. With reference to this case I may mention the remarks made by Dr. Habershon (*Diseases of the Liver*, p. 13) with regard to the neuralgic pain sometimes met with in organic disease of the heart, and which is referred to as being situated deeply behind the first part of the duodenum. "It is," he says, "severe, almost like that of gall-stone, but it is without jaundice or other symptoms of calculus; it is not connected with the stomach, for it is not affected by food, but paroxysmal, and sometimes recurs with great regularity." In 1880 a man, aged 47, applied as an out-patient at the London Hospital, solely on account of severe paroxysmal attacks of pain, which, commencing at the angle of the epigastric region, where it joined the right hypochondrium, passed downwards into the right lumbar region. No disease of the liver or kidney could be detected, and the urina was perfectly normal. On examining the chest, however, we found the left ventricle considerably hypertrophied, the result of aortic regurgitation. This case and that of the late Dr. Murchison are probably of a similar character. Reflected nephralgia may occur in connection with inflammatory affections of other organs. Thus, in pneumonia, the pain is often at first more lumbar than dorsal, and I have known an acute practitioner taken in, for he sent for me saying that one of his patients was passing a renal calculus, the symptoms being intense pain in the right lumbar region and albumen in the urina. Shortly after, on examining the patient again, he discovered fine crepitation at the right base, but not before he had given the patient a warm bath and a dose of opium for the relief of the supposed colic. In disease of the bladder the pain may be wholly nephritic. A gentleman sent for me some time since on his arrival in town from Edinburgh, suffering from intense paroxysmal pain in the right kidney; the testicle on the same side was retracted, there was blood and pus in the urina; no irritability of the bladder. About a fortnight after he began to get intermittent discharges of pus, the renal pain still continuing severe and no bladder symptoms. Dr. Murchison, who saw the case with me, agreed that there was pyonephrosis of the right kidney. About a week after this the renal pain suddenly transferred itself to the neck of the bladder; a finger passed into the rectum detected a hard mass lying between the rectum and the bladder. I then asked Mr. John Wood to see the case with me, and he came to the conclusion that an abscess had formed in the cellular tissue between the rectum and bladder, and had burst into the latter. At first the discharge had been intermittent, but was now becoming continuous. The patient did very well, the discharged pus soon ceasing, and the urina clearing up, no symptoms of renal calculus or of renal pain ever again declared themselves. Had this case occurred in the present days of nephrotomy, I am sure that when the case first came under observation operative procedures would have been taken under consideration.

2. *Nephralgia from Disease of Contiguous Parts.*—If we consider the anatomical relationship of the duodenum to the right kidney, we shall not be surprised to find that many morbid conditions of that portion of the intestine may give rise to pain simulating a nephralgia of calculous origin. Thus Mr. Cursham Corner asked me some short time since to see a patient who had many symptoms of renal colic; namely, attacks of paroxysmal pain accompanied by vomiting, great tenderness on pressure over the right renal region, a urine loaded with uric acid and turbid with mucus, but no blood or pus. Mr. Corner had his doubts about the case, but rather inclined to the view of renal calculus, and so at first did I; but, on strict inquiry, we found the attacks of pain had a very constant relation to food, and that the vomit was not so purely reflex as we generally meet with in renal colic, but contained undigested food; then, again, the patient was

losing flesh rapidly. The conclusion we finally arrived at was duodenal ulcer, and though we did not exclude the possibility of a stone being present as well, and advised the usual treatment, we added to this treatment substantial doses of bismuth, and a light farinaceous diet. Under this treatment the patient made a complete recovery, losing his pain a very few days after it was commenced. No suspicion of the existence of calculus was left behind after his recovery.

Another instructive case illustrates this point of the connection of duodenal irritation with nephralgia. About four years ago Dr. Ball brought a patient of his to my house for consultation. This gentleman had suffered for some time from severe paroxysmal pain in the right hypochondrium. He had consulted many medical friends, and the general verdict was visceral neurosis, and I, at first thought, had pretty much the same view. The urina was examined, but it was perfectly normal. Then the idea of biliary colic or retained gall stones without jaundice occurred as a possible solution, and a terebinthin mixture was prescribed. To our astonishment, a few days after, instead of a gall-stone out came a large round worm. The symptoms were greatly relieved, though not completely; probably some degree of chronic ulceration of the duodenum was present as well. But the patient being a medical man could not give himself sufficient rest till he could take a good holiday, when I believe he became entirely free from pain.

Gall-stones retained in the gall-bladder are often taken for stone in the right kidney, and *vice versa*; as a rule, however, the direction of the pain serves as a guide. With gall-stones the pain radiates from the right hypochondrium towards the epigastrium and umbilical region. With right-sided nephralgia the pain comes forward from the lumbar region into the right hypochondrium, and is then reflected downwards towards the right hypogastrium.

Caries of the spine with psoas abscess in the early stage sometimes gives rise to lumbar pain that may be taken for nephralgia, but a careful examination of the spine is sure, sooner or later, to reveal a tender spot along the spinal column, and so lead us to a right conclusion.

3. *Nephralgia from the Disease of the Kidney.*—"The tender kidney," caused probably by some displacement of the organ, with consequently a certain degree of perinephritis attendant on the dislocation, is often a condition extremely difficult to diagnose, and still more to treat. Early in February, 1887, Dr. John Williams sent a young lady to me with many symptoms of renal calculus. She had constant aching pain in the right kidney, sometimes severe paroxysms of pain; the urina was turbid, contained some pus cells, but no blood. The right kidney was exquisitely tender to the touch, and its dimensions, which were enlarged, could be easily mapped out. Her account was as follows. One day, during the menstrual period, she was playing lawn tennis, when she felt a sudden rick in her side, so painful as to make her quit her game; since then she had never felt free from pain. I had no doubt that the kidney had been displaced slightly downwards, with partial rupture of the surrounding cellular tissue during the act of using the racket at lawn tennis, the displacement being aided by two conditions—the naturally enlarged state of the kidney during menstruation; tight lacing, pushing the liver downwards. It was quite two months, with absolute rest on bed and sofa, before she could move without pain, and then required the support of an abdominal belt. This case I at first thought was one of renal calculus, the pus in the urina and the paroxysmal pain being misleading. I have seen two similar cases at the hospital; both occurred after working at a mangle during the menstrual period.

Dr. Samuel West, in a communication to the JOURNAL in 1885, drew attention to the frequency and importance of hæmaturia occurring in patients suffering from granular kidney, and observed upon the fact that writers on urinary pathology had neglected to describe a symptom of such importance. So important is it to recognise the fact that hæmaturia does occur in these cases that Dr. West says that in one the operation of nephrotomy was going to be performed under the supposition that the hæmaturia was caused by calculus, when Dr. West saw the case and proved the true nature of the hæmorrhage. Other diseases of the kidney, giving rise to a semblance of renal colic from time to time during their progress naturally occur to us; thus the passage of an hydatid vesicle, a mass of tubercle or cancer, gives rise to a colic often indistinguishable from calculous colic till the offending mass comes under observation.

4. *Nephralgia due to Functional Derangements of the Urine.*—Dr. Proust some years ago drew the following graphic picture: a middle-aged individual, who has lived an easy and somewhat luxurious life, after some slight disorder of the bowels or exposure to cold, begins to complain of uneasiness in the region of the kidneys, which gradually

increases and extends forwards and downwards to the groin and testicle. The stomach now frequently sympathises, and there is either absolute nausea or at least inability to take food. The tongue is much furred; there is thirst; the pulse is full, strong, and usually accelerated. There is a tendency to drowsiness and headache. In conjunction with these symptoms the patient complains of a constant desire to pass his urine, which is scanty, highly coloured, extremely acid, and often loaded with bile. Under these circumstances the urinary symptoms sometimes increase to a great degree of severity, only small quantities of urine being excreted at a time, and the colicky symptoms strongly resembling those of renal calculus, being decidedly pronounced—and yet under careful treatment—when the medical attendant and the patient have come to the conclusion that the symptoms are due to renal calculus, and to renal calculus alone; they clear up and give no further trouble.

A patient exhibiting similar symptoms came under my care last summer. Early in March Dr. Allt, of Clapham, advised a gentleman, aged 47, to consult me, as it was feared that premonitory symptoms of diabetes were making their appearance, that is, the amount of urinary water was increased and the specific gravity considerably above the average, though no sugar was present. The patient had lost flesh, and his appetite was capricious. He had formerly led an active life, riding many miles daily, but since he had left the country he had taken to driving in a closed carriage, took little or no walking exercise, whilst his social popularity being great, he was in demand for dinner parties and other functions that led him in the way of more eating and drinking than was good for a man of his habit and constitution, and which was also against his natural inclination, which was for plain and simple food. During the two years he had been in London his health had certainly failed him, and the attack in March was undoubtedly premonitory of something more serious. I prescribed mineral acids and Carlsbad salts, and advised a less nitrogenised diet than he had been taking. Under this treatment he seemed to be doing well, when one day he took a long drive outside a coach to St. Albans and back. The day happened to be cold, with a north-east wind. On his return he felt chilly, with general *malaise* accompanied by severe lumbar pain; the next day he took a Turkish bath, in which he happened unfortunately to slip; this seemed to increase the pain in the back, which gradually localised itself in the left kidney. When I saw him the next day in consultation with Dr. Allt, he had a quick pulse, a foul tongue, obstinate constipation, constant nausea, often actual retching, scanty, highly-coloured, acid urine, with intense renal pain on the left side shooting down into the left inguinal region. For some days the pains increased in severity and the symptoms were decidedly aggravated, and the late Dr. Wilson Fox was added to our consultation. He held strongly for the view of renal calculus, and though I was rather biased that way myself, still, remembering Prout's description, I had hopes that with due purgation and a light non-nitrogenous diet, the symptoms would pass off and leave no trace of mischief behind. Time proved the correctness of the surmise, and a fortnight after, the patient made a good recovery; and though he occasionally suffers from dyspeptic attacks, still the renal symptoms have entirely subsided.

There is again another form of nephralgia which often gives rise to the suspicion of renal calculus, connected with functional derangement of the urine, which is the converse of the above. In this class of cases the patient, instead of being stout and plethoric, is usually thin and somewhat emaciated; he complains of a sensation of soreness, heat, or chilliness about the spine, loins, or sacrum; in some instances much increased by pressure, and accompanied by shooting pains and sense of heat or flashing extending to various parts of the body, sometimes by an occasional sensation of tinnitus aurium, also with various nervous affections in different parts of the body, as pain and soreness in the epigastric region, along the course of the nerves of the arm, thigh, etc. These symptoms are generally accompanied by great disturbance of the assimilating functions, and a condition of urine leading to the deposition of oxalate of lime and excessive elimination of phosphoric acid. Prout, speaking of these cases, says their termination is often critical, and the crisis unfavourable. I have at present a case of this kind under observation; the pains in the renal region (the right) have now lasted three years, and though resembling in many respects the pains of renal colic, still the urine, with the exception of the deposition of oxalate of lime, gives a negative result. The patient continues to lose weight, though the dyspepsia is not marked, and there is no organic mischief to account for it. The case has been seen by other physicians, who have from time to time given different opinions—rheumatism, gout, aneurysm, etc. The last time the patient was in town Sir Andrew Clark saw him with me. Sir Andrew Clark was doubtful whether the symptoms pointed decidedly to renal

calculus, as the urine gave such a negative result, but he agreed that the case was one resembling the description given by Prout, and that the nephralgia was due to the irritation of the urinary passages by the passage of crystals of oxalate of lime. Treatment in accordance with this view has been adopted, but I hear the patient still continues to lose weight and to suffer from renal pain; and the case, I fear, is likely to terminate both critically and unfavourably.

CASES ILLUSTRATING THE ANTISEPTIC AND ANTIPYRETIC TREATMENT OF PHTHISIS.¹

By W. H. SPENCER, M.A., M.D. CANTAB.,
Senior Physician to the Bristol Royal Infirmary; Lecturer on Medicine at the
Bristol Medical School.

It is only in quite recent times that there could be said to exist any rational treatment of phthisis founded upon scientific knowledge; and the past few years have witnessed a new departure in the rational treatment of phthisis consequent upon the rapid strides made in the new science of bacteriology and in all that relates to the share and influence of micro-organisms in disease. New modes of treatment have sprung up whose principles rest on experimental evidence and scientific deduction therefrom, and now much attention is being bestowed on the use of antiseptics in the treatment of phthisis. Already the results of this mode of treatment justify most favourable expectation, and promise much benefit to the common humanity we work for.

I propose to relate some of my experiences whilst using in acute phthisis remedies now tolerably common, yet still the subject of experiment and discussion—antiseptics and antipyretics, to wit—and whilst using them under circumstances better adapted to continuous trial and careful observation than can generally be compassed in private practice. And any thoughts and suggestions and practical points that I may give as the outcome of my experiences relate not only to these two cases, but are drawn from many other cases and a much wider observation.

CASE I. Acute Pneumonia of Left Lung, passing rapidly into Acute Tubercular Phthisis; Almost Complete Repair by Fibroid Substitution; Bacilli, Abundant during the Acute Stages, Disappearing as Recovery Progressed; Complete Recovery Almost Assured, when Sudden Profuse Haemoptysis Caused Death; Duration of Case, Ten Months; Treatment by Kairin, Quinine, and Iodoform.—E. B., aged 20, a domestic servant, after definite exposure to severe cold, was seized with acute pneumonia on the day following the exposure, and was admitted to the infirmary three days later, on March 15th, 1884. The patient had been previously in good health; she was somewhat subject to cold and cough, but had never been laid up with any illness. On admission the patient was found to be well nourished, but rather anemic. Further was noted: flushed face; herpes on lips; profuse sweating; a short hacking cough; temperature, 104°; pulse, 124; respirations, 44; viscid sputa; at the left base and up to the spine of the scapula physical signs of consolidation, with fine crepitation.

The day after admission the temperature rose to 105°, and the use of antipyretics was commenced. Notwithstanding the daily use of antipyretics, continued for a period of four weeks, the temperature rose daily (sometimes twice in the twenty-four hours) to a point between 104° and 105.4°. At first kairin was used in ten-grain doses, and it was always given when the temperature had reached 104° or over. After each dose the temperature fell rapidly; observations made every quarter of an hour showed that the fall was continuous for about two hours, the total fall being from three to five degrees. There was a striking constancy in the effects produced by a given dose of kairin, whether the dose was five, ten, or fifteen grains; on no occasion was more than fifteen grains given. A dose of ten grains gave always the best results; fifteen grains did no more than five grains, and neither did so much as ten grains. The stationary period varied, but at most it lasted only a few hours; the longest time recorded was ten hours. The subsequent rise of temperature was usually as rapid as the decline. Each dose of kairin was followed, within half an hour, by profuse sweating and symptoms of depression; and when two doses were given in close succession (the interval being three and a half hours) marked cyanosis and collapse occurred. Kairin was exhibited twice daily for ten days. At the end of this time, the fourteenth day of the disease, the maximum temperature was still 105° or thereabouts. Meanwhile, the sputa had ceased to be viscid and rusty, the cough was looser, the crepitation at the left base had become coarse. Then the sputa became viscid and rusty

¹ Read before the Bath and Bristol Branch of the British Medical Association.

again, the cough more teasing, and there was evidence that the left apex had become involved—consolidation and fine crepitation.

On March 29th, the seventeenth day of the disease, the sputa were found to be loaded with the bacillus tuberculosis. The left apex rapidly underwent softening, and by April 10th the physical signs of a cavity were well marked. From the date of leaving off the kairin, the pyrexia had been treated by large doses of quinine. Quinine was given from March 25th to April 5th, almost daily, in twenty-grain doses; and only when the temperature was over 104° and rising. The effect of each dose was to lower the temperature by four or five degrees, to control the pyrexia from twelve to sixteen hours, and to ameliorate the general condition of the patient. Little or no permanent effect, however, was obtained, since, for some twelve days after discontinuing the quinine, the daily maximum temperature was over 103°.

On April 10th treatment by iodoform was commenced. The iodoform was given in pills, each containing one grain, at intervals of four hours. This was the time of greatest lung destruction; the whole of the left lung appeared to be riddled with suppurating cavities; the expectoration was profuse and purulent, temperature hectic, night sweats profuse, emaciation and weakness extreme. Hæmoptysis also had occurred.

After iodoform had been taken for about two weeks, the temperature came down to a lower level, rarely over 102°, the hectic character was less marked, and the patient began sensibly to improve. In two weeks more, the temperature fell and continued upon a still lower level, and the improvement all round was going on rapidly.

On May 28th, forty-eight days after beginning the iodoform, the temperature was normal morning and evening, and it continued practically normal for the next six weeks. The patient now was greatly improved in appearance, took her food well, and was vastly better in every respect. At this time the physical signs showed that repair had commenced, and made some progress at the left base. Weight now, 6 st. 8 lb.

Passing on to June 17th, an interval of three weeks, the physical signs showed almost complete repair in the left lower lobe and as high as the spine of the scapula. The whole left chest was markedly retracted, but there was no curvature of the spine, the right lung extended beyond the left margin of the sternum, and the heart was displaced, the apex being tilted upwards and three inches outside the left nipple. No bacilli were found in the sputa, but after further repeated examinations with the highest powers, a very few small and partially developed bacilli were seen with difficulty.

By the end of June, the signs of repair in the left apex were unequivocal. On August 1st the patient was so much better that she was allowed to get up, but the temperature rose, and the effect generally was such that the bed was kept for some time longer. Weight now, 6 st. 12 lb. Curvature of the spine had become marked. Things went on much in the same way, with occasional recurrence of temperature of the hectic type, and slight hæmoptysis; but with improvement in the general condition and increase of weight for about two months.

Towards the end of September, an attack of colic and diarrhoea occurred—the first during the progress of the case. (Tubercles and ulceration were found in the intestine *post mortem*.) The temperature rose, and the patient was a good deal pulled down. The attack did not last long, however. The iodoform was discontinued now for about two weeks, on account of gastric disturbance, and resumed on October 10th. At this time an effort to get up was attended by syncope. From the middle of October to the beginning of November the temperature was normal; progress was steady, and the weight increased to 7 st. 7 lbs. The patient kept her bed during this time.

Early in November the temperature rose again, and continued hectic for a week. The patient became very drowsy, and slept a good deal, with snoring. She complained of severe pain in the head; the pupils were dilated (contracting to light); there was nausea, without actual vomiting; the pulse became very rapid—144. The retina were examined, and found normal. These symptoms soon passed off; the temperature became normal in ten days, and remained so until the end of the case. From this time to January 6th, the day the patient died, there was steady though slow and gradual progress towards recovery. The patient began to get up daily, and was eventually able to be up a good part of the day. The weight increased at the rate of about 1 lb. per week, and on January 5th it was 7 st. 13 lbs. (6 st. 8 lbs. on May 28th). The physical signs denoted complete repair at the left base; and, as to the apex, they had indicated progressive diminution in the size of the vomice, until only a few dry crackles were discovered at the apex. There was much retraction of the left chest, and much lateral curvature of the spine. On January 6th, 1885—ten months after the onset of the acute pneumonia—the patient was sitting up in bed, talking and cheerful, at 10.15 p.m., when an attack of coughing

came on; this lasted for about five minutes, and was succeeded by a sudden hæmoptysis to twenty ounces. The blood was bright red, alkaline, and formed firm clots. There was no retching or vomiting. The patient's face became livid, and breathing ceased at 11 p.m. There had been no hæmoptysis since September.

Necropsy.—On opening the thorax, the right lung was found to be greatly expanded, extending far over to the left side. The left lung was much contracted, and firmly bound to the chest-wall by adhesions, reaching from apex to base. At the apex of the left lung were two or three very small vomice, and a larger one about the size of a filbert. These contained very small quantities of pus. The lung substance had to a great extent disappeared throughout this lung, and had been replaced by strong firm bands of glistening fibrous tissue; this tissue was well-marked around the bronchial tubes. There was a small deep seated cavity in the apex of the right lung. The contents of the head were healthy. Fat was prominent in the walls of the abdomen, and in the tissue round the abdominal organs. In the intestines there were deeply congested patches here and there. In the ileum there were several small tubercular ulcers, and near the valve a few scattered tubercles; other organs healthy; no trace of the site of the hæmorrhage could be discovered.²

CASE II. *Acute Double Pneumonia, passing into Acute Tubercular Phthisis; Phlebitis; Complete Recovery, maintained at the end of Twelve Months; Duration of Case, Five Months; Treatment by Quinine, Iodoform, and Eucalyptol Inhalations.*—L. D., aged 22, a domestic servant, admitted to the infirmary on January 16th, 1885, having been ill about four days. The patient was reported to have been a delicate girl, but had had no serious illness. There was no family history of phthisis. On admission, she was in a very prostrate condition; she was well nourished, but anæmic; she had much pain in the chest; temperature 103.2°; pulse 132; respirations 85; a trace of albumen. At the left base were found dulness, tubular breathing, bronchophony and fine crepitation; and at the right base also there were signs of commencing pneumonia. For two days the patient was very bad, requiring a good deal of stimulation; temperature between 103° and 105°. The temperature then came down, and in six days from the time of admission, resolution appeared to have commenced.

Eight days after admission, on January 24th, the temperature rose to 103°, pain in the calf of the right leg was complained of, and now the patient suffered an attack of phlebitis of the right popliteal vein. This attack ended favourably.

But on February 1st it was found that at both bases there was still abundance of crepitation, yet not altogether that of a resolving pneumonia of the ordinary type. The temperature had assumed a hectic character, and the physical signs showed that the right apex had become involved; indeed, there was evidence that both apices were implicated. There was also extension and renewal of acute inflammatory mischief at the left base; the temperature rose to 104° and over, and the condition of the patient became extremely critical. For four successive days the temperature remained persistently at between 103° and 104°. Then salicylic acid with hydrobromic acid and ether in mixture was given; in two days the temperature was below 100°, and the mixture was discontinued. The temperature soon rose again, and the salicylic acid mixture was resumed and continued for four days; during this time the temperature was kept below 103°.

At this time there was evidence of extensive breaking-down at both bases and, to a slighter extent, at both apices; the patient was delirious, had little or no sleep, sweated copiously day and night, and was extremely prostrate; there had been some hæmoptysis; the pulse was dicrotic, the tongue dry and brown. Bacilli and elastic fibre were found in the sputa.

February 14th, the patient began to take iodoform in one-grain doses every four hours. For the five subsequent days the patient remained in very much the same critical and prostrate state. Then improvement began. The temperature settled down to a hectic form, with maximum never above 103°; the general condition of the patient became better; the pulse got steady and the appetite improved greatly. The iodoform had to be stopped on March 8th on account of gastric disturbance. No change worthy of note occurred up to March 18th, except that the temperature showed marked oscillations, twice reaching 104° and twice touching the normal.

On March 18th inhalation of the vapour of eucalyptol was commenced. At this time there was dulness with coarse crepitation all over both bases, and signs of excavation in places; coarse crepitation and signs of excavation were present also at the right apex. The patient was greatly emaciated, and, including the temperature, all the symptoms

² The hæmoptysis was doubtless due to shrinking of the cicatricial tissue in the lung, and consequent laceration of vessels.

were those of pronounced hectic. Thenceforward the patient improved.

On March 24th the iodoform was resumed. Now an attempt was made to control the pyrexia. The temperature was distinctly of the hectic type, the daily maximum being about 102°. Quinine in ten-grain doses was given from March 27th for six days, at particular hours corresponding with the definite times in the day at which the maximum temperatures were observed to occur. The idea was to break a habit, so to say. The plan succeeded, but the temperature fell to adopting different hours at which to reach its maximum, keeping at a markedly lower level than before. Accordingly the times at which the quinine was given were changed. The temperature came down to below 100° for four or five days, and the pyrexia seemed for a time to have been "scotched." Again the temperature got into its old ways, and took to rising, sometimes to 102°, at an unusual time in the afternoons. To meet this, an additional dose of quinine was given at 5 p.m.; and now thirty grains were taken daily. The next day the temperature fell practically to the normal, and remained so, with occasional and isolated exacerbations, to the end of the case in the middle of June. The quinine was gradually discontinued, and was stopped altogether on May 16th, the temperature having then been normal for about three weeks. On this day, May 16th, the patient weighed 6 st. 7 lbs., as against 5 st. 9 lbs. a month before. Meanwhile the lungs had been improving steadily. The evidences of repair, first detected at the end of March, were now very marked; there was only a little dry crepitation at the right base close to the spine, and the apices showed no signs of active mischief at all. At the end of May the patient was so much better as to be able to get up every afternoon.

On June 17th, the patient was sent to the seaside. The weight now was 7 st. 7 lbs. The apices were quite clear, and the only remaining sign of any mischief in the lungs was a little dry crepitation at the right side, between the angle of the scapula and the spine. Three weeks later, the patient came up to report herself; she was then looking well, had gained 2 lbs. in weight, and there was no trace of any lung mischief at all.

In July, 1887, twelve months after, the patient was still well, her only trouble being shortness of breath on exertion.

The pathological conditions and the clinical features of these cases, as set forth in the foregoing histories, may be recapitulated, by way of summary, thus: An acute pneumonic condition of the lower lobes of the lungs at first—both lungs in one case—with concomitant general and special symptoms, declaring the disease to be acute croupous pneumonia.

A transition from the pneumonic condition into an acute tubercular and phthisical condition, beginning in the parts first affected, namely, the lower lobes. Thence, invasion of the apices, after the phthisical condition of the bases was well assured. Rapid breaking down and the formation of vomica both at base and apex. Then, the discovery of the tubercle bacillus in the sputa confirmed the nature of the later lung mischief, and gave significance to the general constitutional symptoms— hectic temperature, night-sweats, wasting, etc.—as well as the local characters.

After this, we have the repair of the damaged lung-tissue by fibroid substitution. This repair proceeding simultaneously both at base and apex, and traced by physical signs most distinctly during its progress.

Finally, in the first case, the accident of profuse hæmoptysis; caused no doubt by the contraction of the lung tissue, whose building up, step by step through many months, had brought with it both healing and destruction.

It will, I think, be of advantage to recapitulate what has been set forth as to the treatment of these cases, and at the same time to add some particulars, so that a complete view of the whole treatment adopted may be gained. A distinction into general and local treatment seems hardly possible; yet it may be convenient to apply the term "local treatment" to those means adopted with the special object of influencing the localised mischief in the lungs—the antiseptics, to wit.

As regards the general treatment: For Case 1, a mixture of sulphuric acid, bark, and other was used pretty continuously throughout the case, and along with the other remedies. Cod-liver oil was taken at intervals and for short periods, but it was borne badly. Kairin and quinine were used as antipyretics. The former did always effectually reduce temperature, and quickly; but, as is usual with all antipyretics of its class, the fall of temperature was transient, and the resulting depression was marked. Quinine was used in large doses, at intervals only and for a short time, without any effect as to the general progress of the case.

In Case II, a mixture of sulphuric acid and quinine (four grains), or

one of tincture of perchloride of iron and quinine, was used almost throughout the case. Cod-liver oil was borne well and taken for a considerable time. Salicylic acid and quinine were used as antipyretics. The former produced good effects undoubtedly as regards steady and continuous reduction of temperature. But, notwithstanding its combination with ether, the depressing effects were sometimes a source of anxiety. A special feature in the treatment of this case was the mode of using quinine, in moderate doses, to control the pyrexia—a method attended with unqualified success.

As regards the local treatment: This consisted in the use of, first, iodoform. The drug was given in pill in doses of one grain, six grains in the twenty-four hours. It was given for long periods in both cases. In Case II it was given alone, and was tolerated remarkably well. In Case I it was for a time combined with one grain of quinine and one-eighth of a grain of hydrochlorate of morphine, but no advantage was gained. On more than one occasion the attempt was made to increase the dose to two grains, but this dose always caused pain and gastric disturbance. The iodoform was taken by this patient for nine months continuously, with the exception of two weeks. Secondly, inhalation of the vapour of oil of eucalyptus. This was used only in Case II, and here along with the iodoform. The vapour was inhaled by means of a celluloid respirator inhaler, worn continuously except when taking food or sleeping. No nausea or other unpleasant effect resulted. Finally, a liberal diet was allowed throughout the cases. As soon as the patients began to experience the good effects of the iodoform, the appetite improved remarkably, and good food was supplied without stint. From an early period after the return of appetite some stout was taken with the dinner.

REMARKS.—As regards the general principles of the treatment, everyone knows what they are; and it would ill become me in this assembly to reproduce them. But, as regards the special methods of the treatment by iodoform and eucalyptol, or both together, let me say:

1. I see no reason to doubt that, when iodoform is given in doses which the stomach will tolerate well, and given frequently and continuously for long periods, it is absorbed into the circulation; and in the lungs, in whatever form it be, manifests its antiseptic (shall I also say, antibacillary?) properties. The good effects of iodoform so administered, in phthisical conditions, is too unequivocal to be gainsaid, however they may be produced.

2. I see no reason to doubt that, when the vapour of the oil of eucalyptus (or other antiseptic vapour that can be tolerated equally well) is inhaled continuously and for long periods, it reaches the residual air in the lungs; and so externally, as it were, bathes the affected tissues, or suppurating cavities, which may be open to the ingress of the air.

3. That so, I apprehend, we may have antiseptic remedies, not antagonistic, brought up on two sides to the sites of inflammatory lung lesions, or the sites of bacillary activity; and these antiseptics, mutually co-operative, do affect for good both the inflammatory process and the bacillary activity, and bring about repair by the mode of organisation after suppuration or fibroid substitution.

4. And further, let me say, that I think it is both correct and desirable to treat the pyrexia of acute phthisical processes, whether the temperature be high or moderate, by and for itself. I think Case II goes to show that there is both an agent—quinine, to wit—and a mode of using it, which will do great things for us in regard to this object. I think no other special antipyretic than quinine should be used in phthisis; and quinine serves other purposes as well when used as an antipyretic in moderate doses. And at least it is in evidence that the deliberate intention and plan which was carried out in Case II succeeded perfectly three times in succession in controlling the pyrexia—not the temperature only.

I may now sum up the whole in some remarks on what I conceive to be the practical outcome:

In our treatment and general management of these cases, it is our aim to promote or bring about healing of the damaged lung tissue, and this by means of fibroid substitution. In order to attain this end, we must secure the same conditions and adopt similar measures, if we can by any means compass it, to those we find successful in dealing with suppurations, ulcerations, and the like lesions, in parts exposed to view. To secure these conditions, we should adopt measures for supplying adequate nutrition—that is, adequate anabolism of tissue and the storing of energy—in the body generally, and in the damaged part in particular. We should deal with pyrexia on its own account, as a general and constitutional state, apart from the local suppuration or ulceration (as by quinine). We should bring the lesion under the influence of antiseptic remedies, both by internal medication (as by

iodeform), and by external applications (as by inhalations of eucalyptol); and the application and influence of the antiseptic should be complete, continuous, and prolonged.

DERMEPENTHESIS.

(*Δέρμα—ἐπέπνευσις.*)

By G. F. CADOGAN-MASTERMAN, L.K.Q.C.P.I.

THE valuable expedient of skin grafting is attended with several inconveniences. The donor finds the "snip" rather painful, the little sores are some days in healing, and there is danger, if alien skin be used, of conveying disease with it; and, when there is a large surface to be covered, the process is tedious and often disappointing. Frog's skin has been used, but these amphibia are so repulsive to many people, and especially to women and children, that after two trials and failures I gave it up.

About two years ago I was treating in the usual way a broad wound surface in a young farmer, who while riding sustained, from the shaft of a passing cart, a ragged, lacerated wound extending from the middle of the thigh to Poupart's ligament, and involving the muscles. The wound was cleansed and treated aseptically, but the crushed integument at the back of the thigh and much of that in front sloughed away altogether, leaving a surface of about ten square inches to cover, and, after a week of human skin grafts, this was speedily effected with portions of young wild rabbit's skin. The second case was one of a large varicose ulcer, and quite successful; the third, a middle-aged tradesman, had severe orchitis, the result of an accidental blow. Delirium tremens ensued, and probably as the result of further injury, the whole of the integument of the scrotum sloughed away from the root of the penis to the perineum, leaving the tunic of the testicles covered only by the pale, pink lattice of the cremaster muscle. There was a herder of but half an inch of healthy skin left after the slough had separated, and the case was complicated by large bed sores and the extremely bad state of the patient's health generally. However, I found that a disc of skin, two inches in diameter, would cover the testicles, and again tried the rabbit as its source. The animal was killed by a blow on its neck, and the previously shaved and marked out piece expeditiously cut from the abdomen, pressed smoothly over the wound, covered by a piece of wet lint; then a fair-sized hot poultice, which was in turn kept at a proper temperature by a frequently refilled hot-water cushion. At the end of forty-eight hours the applied skin was cautiously examined, and found to be adherent. It was re-dressed as before, and supported by a special suspensory bag padded with sublimated cotton-wool. On the fourth day the outer layers of the skin separated, leaving a firm, smooth surface more like the mucous lining of the lips than integument, and, except that it has greatly thickened, so it remains to the present time.

The fourth was a pale, flabby ulcer, after a very tedious case of hip-joint disease; and therein, after many trials with rabbits of all ages, the plan failed utterly. The fifth was a very severe case of burning, in a little child; the whole of the skin of the back from the shoulders to the nates, the back of the arms and thighs, had been destroyed, in some places down to the muscles. After the carbonate of soda treatment (which relieved the pain immediately), and the surface had been pretty well cleared from sloughs by lotions of very dilute nitric acid under an outer dressing of iodoformed cerate, a number of rabbit-skin transplantations were made at intervals of about three days. The greater number adhered, and I had succeeded in covering nearly half the trunk, when the child unfortunately died from pneumonia, three months after the accident.

In order to secure success, healthily granulating surfaces should be selected for treatment, and young wild rabbits for the discs of skin. These may be from 0.5 to 1.5 inch in diameter, and, operating alone, rarely more than one can be taken from each animal; for, although it is killed in the customary manner by a blow at the back of the neck, the skin must necessarily be still alive to be of any substitutional value. If it were not for an obstructive Act, the best plan would be to chloroform the animal, remove as much skin as necessary, and then kill it before it had recovered consciousness. As it is, not a moment must be lost in the transference. Young wild rabbits are best, because their skin is very thin, contains no fat, and separates readily from the subjacent fascia; and I think discs not larger than a shilling succeed best. There is no need to remove the fur, it comes away within a week; and the skin should be pressed closely down on the surface of the wound, so as to expel the air, and kept thoroughly warm by a poultice or hot-water bag.

I have used the term "adhering" in place of "growing," for I am in doubt if the transferred skin really unites and grows with the surface it covers; in every case the fur-bearing layer separated after a time—so, it can be only the inner, perhaps the superficial, fascia, which is revitalised; and, although prolongations could be seen starting from the edges of the adhering discs, they were neither so marked nor so vigorous as those from grafts of human skin. The latter I have often noticed to start the growth of new skin from sites in which they have themselves apparently perished; and it is possible that the rabbit skin may act rather by influence than substitution, and so determine the conversion of granulation cells into integument under the smooth soft, and, possibly, still living shield.

CASE OF OBSTRUCTION FROM GALL STONE—SPONTANEOUS FRACTURE AND RECOVERY.

By ARTHUR JAMISON, M.D., London.

THE discussion at the meeting of the Clinical Society on January 13th, on the treatment of gall stones, and the question as to whether we should interfere at once in subsequent obstruction from them induces me to place on record the following case. Probably early laparotomy in very urgent cases is the best procedure, but at times cases crop up in practice with such unanticipated endings, that they may rank as true clinical experiments. The patient, a woman 36 years of age, of very spare habit, had long suffered from gastric troubles, slight jaundice, and occasional attacks of severe pain. In the right hypochondrium she had a swelling over the region of the gall bladder, moving up and down with respiration, and general tenderness around it. I was sent for to see her in great haste, being told she was dying. When I got to her bedside I found her in comparative ease. She told me she had had an attack of the most violent pain and intense retching which had suddenly ceased. The tenderness over the liver was much less and the swelling hardly to be felt. Things went on very well for two days, when another attack of acute pain came on, now referred to the region of the umbilicus, great retching and constant nausea; there had been no motion since the previous attack of pain. The pain now came on in paroxysms, the intestines could be seen moving tortuously about, and she said the pain seemed to "stick in one spot." There was no rise in temperature and the pulse kept fairly good. It was obvious that the case now was one of obstruction from a gall stone. I told her plainly that the issue now might be fatal, and strongly urged her to submit to operation. This she steadily refused to do, having heard of a fatal case, so matters went on for four days longer, no motion had been passed nor any flatus. I kept repeatedly urging her to have laparotomy performed, but she still steadily refused, and I became more and more confident in telling her of the outlook in her case. Judge of my surprise when in the evening I found her much better, she said she was quite well. She told me that shortly after my last examination she felt something give way during a violent pain, and almost immediately afterwards passed a huge bile-stained motion, and within an hour another copious motion. This had not been thrown away, and on examining it I found two pieces of what had been a large gall stone of softish consistence. I fancy the stone must have been gripped and fractured spontaneously from the force of the intestinal contractions. However the patient quickly mended and got comparatively strong. She rather drily asked me if I did not think she "was better unopened."

Of course, during the treatment, she was kept constantly under opium; but she was quite sure that, in the form of morphine suppositories, she got much more ease than when given either by the mouth or hypodermically. This was not the first time I had heard patients prefer opium by the rectum. This patient refused to have any hypodermic injections of morphine, when she said she got so much more relief by a suppository she could introduce herself. When the symptoms of obstruction were obvious, she was kept to as little iced water to sip as possible. She said that all attempts at rectal feeding brought on her paroxysms of pain, and preferred to keep to her iced water. These two therapeutic facts I have seen brought out, in cases of obstruction, over and over again; and I am perfectly sure that, till the pulse and temperature begin to rise, absolute starvation, and morphine by the rectum only, give the best chances of success. But, if the temperature or pulse rise (and I think the pulse is the safest guide), then laparotomy should be resorted to without delay. It is quite possible Mr. Tait's suggestion of trying to crush the stone might be tried first. It would do no harm. At all events, this case goes to show that the chances of spontaneous fracture should not be omitted from our calculations.

COLOUR-BLINDNESS IN THE MERCANTILE MARINE OF THE UNITED STATES.

By S. T. ARMSTRONG, M.D., Ph.D.,

Passed Assistant-Surgeon United States Marine Hospital Service.

The very interesting paper on "Colour-Blindness: its Present Position in the Mercantile Marine Service;" which was read by Mr. T. H. Bickerton, at the meeting of the British Medical Association in Dublin, last August, and the Editorial comments thereon in the JOURNAL of November 12th, have prompted me to present the results of the experience with this question of that branch of the United States Service which has supervision over the sanitary affairs of the mercantile marine.

It was a matter of some surprise to note the high percentage of colour-blind seamen in the results of the Board of Trade examinations, but this seems explicable when it is understood that the names of the colours are required.

Since 1880, all pilots on harbour vessels and steamboats, on the rivers and lakes of this country, have been required to pass an examination for colour-blindness. This examination is required of the officers and seamen of the Revenue Marine Service (coastguard), and of the surfmen of the Life Saving Service. The officers and seamen of the navy are examined by the naval surgeons.

The examination is made with Holmgren's test. The names of the worst skeins are not necessarily referred to, as very often the individual examined does not know the names of any but the primary colours. Occasionally the mental processes of the seamen are so slow, that it is necessary for the examiner to first illustrate the examination by making the entire selection before him, of course this would in no wise assist a colour-blind person to make the proper selections.

From the appended table it is seen that during the past seven years, 20,742 seamen have been examined for colour-blindness, and 478, or 2.3 per cent. were rejected as unfit for service, on account of this disability.

It should be understood that the law does not require the officers or seamen of vessels engaged in foreign trade to pass this test. It must also be noted that in reality the percentage of colour-blindness, as given above, is a little high on account of men who have been rejected

THERAPEUTIC MEMORANDA.

A CASE OF UREMIC CONVULSIONS SUCCESSFULLY TREATED BY PILOCARPINE.

J. M., aged 21, fell ill with scarlet fever on October 13th. He went on well until November 3rd, when symptoms of nephritis showed themselves; the attack was slight, and appeared to improve rapidly under treatment.

On November 10th I found him in uremic convulsions; the fits occurred every few minutes. My friend Mr. Cox saw him with me, and, with his concurrence, I injected one-third of a grain of pilocarpine into the front of the forearm; the patient soon began to sweat profusely, and the convulsions gradually diminished both in force and frequency; they recurred in the early part of the night, about every fifteen or twenty minutes, but with longer intervals towards morning; at 8.30 A.M. I repeated the pilocarpine, and the intervals between the convulsions became still longer; in the afternoon, when he became sensible enough to swallow, I gave him one-third of a grain of elato-

rium; this acted freely, and he probably passed a little urine at the same time, otherwise he had passed none since 7 or 8 the previous evening; as the convulsions still recurred at frequent though longer intervals, I again injected one-third of a grain of pilocarpine at 9.30 P.M. During the night he had a few slight fits, and in the morning, about 11 A.M., I gave him another injection of pilocarpine, and the last fit occurred about 4 P.M. on that day. In the evening I again gave him one-third of a grain of elaterium, which acted freely, and he now passed more urine, the urine having been very scant up to this time.

On November 15th he had symptoms of more convulsions coming on, but I gave him another injection of pilocarpine, and this passed off.

He lay in a semi-comatose condition from November 12th to 17th, swallowing what was put in his mouth, but totally unconscious of everything going on around him, and taking no notice of anything; on November 17th he was maniacal, and on November 20th he could not be kept in bed. During the whole of this time the bowels had been kept open by occasional doses of elaterium, and he had taken a

at one city coming up for an examination elsewhere. This was particularly the case when the law was first passed. Several instances of this character may be cited. Pilot J. F., examined and rejected on July 13th, 1881, was again rejected on July 27th. Pilot G. S. F., rejected April 6th, 1882, was again rejected on July 5th. Pilot J. F., managed to secure examination on August 24th, and December 16th, 1882, and February 7th, 1883, each time being rejected. His experience was equalled by Pilot G. W. H., who was rejected on August 25th, November 20th, 1886, and February 9th, 1887.

In one instance coming under my notice, a pilot, who had been rejected twice, had a friend personate him, and the latter having normal colour sense, obtained a successful certificate; the fraud was discovered, however. Mr. Bickerton's inquiry to ship-owners, relative to the employment of colour-blind men, met with an affirmative response once in my experience. The master and owner of a steamboat, on the Mississippi River, brought a man to me for examination for colour-sense. The man proved to be colour-blind, and on looking over the records, his rejection several years previous was found; the man said he had not expected to pass, and stated that his steamboat had once collided with, and sank, a steamboat, on account of his inability to distinguish the signal lights. His would-be employer was aware of these facts. As the examination of all railroad employes has been required by law in several of the United States, as well as in some European countries; and public opinion has been educated towards a recognition of the necessity of examinations of the ability to distinguish colours by employes of railroads and vessels, it seems desirable that the State should regulate the examination of the first class; and if by international agreement, no person be shipped, either as officer or seaman, who has not passed a satisfactory physical examination, the competency of the second class would be assured.

Of course special provision should be made in the case of a seaman of ten to thirty years' service, who is colour-blind. It would be as manifestly unjust to absolutely debar him from following his vocation, as it would be to prevent a man who has spent the same time in the study and practice of medicine from pursuing it for a similar disqualification. In such cases, in this country, day licences were issued.

It is to be hoped that international legislation will soon be consummated, ensuring the safety of ships, and of those who travel in them, from accidents due to colour-blind seamen.

mixture containing liq. ferri perchlor. and liq. ammon. acetat. On November 22nd he became sensible, and talked rationally, but had no recollection of anything that had occurred since November 10th; on November 25th, for the first time since the commencement of his illness, there was no trace of albumen, and he improved rapidly; on November 28th he got up and dressed, and from that time made a good recovery, and is now again following his trade as a shoemaker.

I think we have in pilocarpine a most prompt and valuable diaphoretic; the preparation I used was one of the hypodermic tabloids prepared by Messrs. Burroughs, Wellcome, and Co.

W. J. FRANKLIN CHURCHOUSE, L.R.C.P.Ed., etc.

Long Buckhy, Rugby.

CLINICAL MEMORANDA.

NARROW ESCAPE FROM CHOKING.

I WAS called a short time since in great haste to an old man who, I was told, had had a "fit" while eating his dinner. On my arrival he was lying with his head over the back of the chair, livid and unconscious, his edentulous mouth wide open. Respiration appeared to have ceased. Nobody had any explanation to offer as to what had occurred, but seeing his empty plate before him, I put my fingers as far as I could get down his throat to search for any morsel which might have become impacted. I could feel nothing, however, and somewhat at a loss what to do, I put him on the couch and tickled his fauces with a feather pen. In a minute or so he gave a desperate gulp or two, and brought up a large piece of half-chewed meat. Unable to cut his meat himself, and impatient that it had not been cut for him as usual, he had commenced masticating one end of the slice, on attempting to swallow which the whole slice was drawn down the œsophagus, and had become fixed. It was fully five minutes before he recovered consciousness, when he showed every disposition to recommence his interrupted repast.

The procedure is a simple one; and although I am not the inventor of it, any more than *le fil à couper le beurre*, as the French say, it might be useful to bear in mind as a ready and available emetic.

ALFRED S. GUEB, L.R.C.P., M.R.C.S., etc.

The Grove, Hammersmith, W.

OPHTHALMOLOGICAL MEMORANDA.

ATROPHY OF THE OPTIC NERVES TREATED BY Pilocarpine.

THE JOURNAL of November 8th, 1884, contains notes of a case of atrophy of the optic nerves treated by hypodermic injections of nitrate of pilocarpine. Prolonged treatment by recognised methods had been fruitless, and when the pilocarpine was commenced (July 15th, 1882) the patient required a guide, and with difficulty could with either eye see the fingers at the distance of a few inches. The improvement was soon such that the guide was dispensed with, and when the patient was shown at the annual meeting of 1884 he could with either eye spell words of No. 3 at a distance of several inches, and sometimes even words of 1.75. The case is one of whose subsequent history there should be some record. There was further treatment by pilocarpine, and further improvement in vision. On the 26th of last May the patient could with the left eye read 1.5 at 4½ inches with trouble, and even make out some words of 1.25; and with the right eye spell 2.25 at 4 inches. He distinguished colours quickly. The discs were white, with the exception of a little piece at the temporal side (reversed image), which was slightly rosy. What is particularly gratifying is, he was then earning his livelihood as a labourer in the ship-building yard of Harland and Wolff.

Manchester.

DAVID McKEOWN, M.A., M.D., M.Ch.

PASTEURISM IN FRANCE.—During the month of November last 115 patients were treated at the Pasteur Institute in Paris. Of these, 28 had been bitten by animals which were proved to have been suffering from rabies, either by the successful inoculation of other animals with the medulla, or by the production of the disease in other persons or animals bitten at the same time; 64 were bitten by animals declared to be rabid by competent veterinary authorities. In 23 cases the bites were inflicted by "suspected" animals. No information as to any case of death has been received at the Institute.

REPORTS

HOSPITAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN, IRELAND, AND THE COLONIES.

NEWCASTLE-ON-TYNE ROYAL INFIRMARY.

(Cases under the care of Mr. PAGE.)

[Reported by Mr. MAYNARD, House-Surgeon.]

Central Sarcoma of Upper End of Femur; Amputation at Hip-Joint.—J. P., aged 16 (nearly 17), was admitted on February 9th, 1887, complaining of a swelling of the thigh of seven months and a half duration. Seven months and a half ago he fell and hurt the left hip; he was confined to bed and has never walked since, though the doctor says he had no shortening or swelling. It was diagnosed as morbus coxæ. Six weeks later, swelling began in front of the hip-joint—painful, worse at night, and slightly tender. It has gradually increased, and shortening came on since. The hip was examined under chloroform, and a spontaneous fracture found. When admitted, the boy was found to be very feebly developed; no hair on pubes; looks about 12 or 13; organs otherwise sound.

The left leg lies on its outer side, with foot everted; 1 inch shortening. The upper third of thigh is occupied with a swelling, which is evenly hard, elastic, not lobulated, and which extends all round the joint, beginning above, just below Poupert's ligament (from which it is separated by an interval), reaching up to perineum on inner side to above the great trochanter on outer side, and to same level behind. Its vertical extent is four inches and a half in front, less at the sides and behind. It is fixed, and the femur, tnmour, and pelvis all move together; no crackling anywhere. The skin is normal, except that a few veins course under it. No enlarged glands to be felt, though there is some tenderness in left inguinal region on deep pressure. The left thigh over it measures three inches and a quarter more than right.

On February 15, Mr. Page amputated at the hip-joint by a short anterior and longer posterior flap—using Esmarch's tubing round abdomen—no bleeding. The tumour proved to be a central sarcoma (spindle-celled) of upper one-third of femur. The bone was expanded and thinned, remaining only as plates on surface of a large blood cyst as it were—sarcoma tissue. The head was completely filled with the growth, but its cartilage was healthy and the joint not involved. The muscles were not involved. He rallied well. February 23rd, had done well. Temperature up a little at nights, and outer end of wound had opened, and some bagging taken place.

April 1st. Appetite improving, but is very thin. Can stand now. Wound nearly healed. April 12th. Wound quite healed. June 3rd. Stump firm and sound. Can bear weight on it, and is in very good health.

January 24th, 1888. The lad has developed considerably since the operation, and is to-day strong and plump, without any signs of return of the disease.

Hypertrophy of Leg. Rare Misplacement of Testis.—J. C., aged 16, was admitted on March 26th, 1886. He was born with the right leg thicker than the left. Nine years ago the foot began to swell after an injury, and the skin on the dorsum broke five years ago, and has never healed.

On admission the legs presented a great contrast; the left was normal, and the right also as far down as the knee. The knee joint contained some fluid. The leg was enlarged, three inches and a quarter more round the calf than the left, with a flabby sort of œdema; no pitting on pressure. The skin is always sweating (left foot) and has erythematous rashes on it every few days, when his temperature rises high. The skin is soft and supple, and contains a few large veins.

The foot is very large, and on its dorsum is a large quadrilateral ulcer with uneven, rough so-called base, irregular, indurated, and elevated margins. There are no sinuses, and no bare bone can be felt. The tibia is smaller than the left, though longer (one inch and a quarter).

Lying at the superior internal angle of Scarpa's triangle, over the saphenous opening, is an oval swelling the size of a pigeon's egg, parallel to Poupert's ligament but one inch below it, and external to the spine of the pubes. It is hard, not very tender, gives rise to a somewhat sickening sensation when squeezed, and is movable. There are several enlarged lymphatic glands lying round it, and there is a hard indurated mass running along its posterior border and ending

above in a rather large "head," very hard. It is evidently the right testis; he says it has been there since he was born, and there is only one testis in the scrotum—the left. After it had been examined orchitis set in, and a sort of cord could be felt running from the testis inwards to the perineum, though whether due to inflamed lymphatics or whether it was the cord was doubtful. Syme's amputation was performed on the foot, and the tarsus found carious. He has never consented to have the testis removed, though he has not infrequent attacks of orchitis.

PRINCE ALFRED HOSPITAL, SYDNEY, NEW SOUTH WALES.

A CASE OF CAISSON DISEASE.

(By G. E. TWYNAM, M.R.C.S.E., Assistant-Surgeon.)

G. H., a strong, healthy man, weighing 14 stone 3 lbs., went to work for the first time in the cylinder at the Iron Cove Bridge on March 6th, 1882, at 9.30 A.M., and came out again at 12.30 P.M. During this time he was working under a pressure of 60 lbs. to the square inch, or four atmospheres.

Whilst in the cylinder he seemed well, and especially did not notice the pain in the ears so often complained of. At 12.30 P.M. he came up into the airlock, and in three minutes the pressure was reduced to the ordinary atmosphere. He left, and shortly after, on the way home, felt a severe pain in the right elbow joint as though he had been struck on the ulnar nerve. Within half an hour his right knee suddenly gave way, and he fell, and in a few minutes became semi-conscious.

In this state he was taken home, when very acute pain set in in both knees and both elbows, but there was no marked swelling in the joints. At 6 P.M. he was almost pulseless and quite chilled. For two days his face was very swollen, and he spat blood slightly for three or four days after the accident; it then ceased, but began again within the month with cough and night sweats. He had shifting pains in various parts of the body for seven days after the accident. From a week to a fortnight after the commencement of the attack the pain suddenly left the other joints and concentrated itself in the right knee, which began to swell and contract. A month later the limb was forcibly straightened under chloroform by Dr. Shewen, and secured on a back splint. Within fourteen days an abscess in the popliteal space appeared, which afterwards proved to be connected with another some inches higher up at the back of the thigh. These were opened early in July and drained, when another swelling with but slight pain was discovered in front of the right trochanter. This was aspirated twice, and about two pints of fluid in all drawn off. The abscess cavity was afterwards drained, and finally in August laid open, when a sinus was discovered leading up to the groin, of which the end was never reached by a probe. At this time the leg again contracted, and remained so during the patient's voyage home to England.

In April, 1883, thirteen months after the injury, he was seen by an eminent surgeon in London, who failed to discover diseased bone, but advised the leg being straightened on a MacIntyre's splint, which was done in nineteen days. He left England May 19th, 1883; during the voyage the leg contracted again, and remained so until I saw him for the first time in November, 1884. He then had two or three sinuses on the outer side of the thigh and one in the popliteal space. I enlarged two old openings, scraped out the sinuses, and followed one beneath the femoral vessels to the inner side of the leg, and up into the pelvis, but could not touch dead bone. This, to my regret, did him no real benefit, for the sinuses continued to discharge, and I saw nothing of him for a year, until October, 1885, when he appeared at the out-patient department of the Prince Alfred Hospital. Dead bone was then detected in the popliteal space, and he was advised to come in.

On October 21st, under chloroform, the sinus was explored, and a probe passed through the condyles.

On October 23th, I amputated by anterior and posterior flaps through the lower third of the femur. On section, the bone looked anything but healthy, being of a greenish colour in the medullary canal and cancellous part, with a smell of sulphuretted hydrogen. I should at once have removed it higher up had I not promised not to do so; however, I scraped out the sinuses near the trochanter thoroughly.

He made a good recovery, his temperature only once reaching 101° F., and that on the second night after operation. He was discharged at the end of November with a sinus at the point of the stump, the old sinus by the trochanter still discharging a little thin pus. He continued thus until the beginning of January, when he

came to be examined again. I then found necrosis when probing the upper sinus, and consequently recommended the removal of the remainder of the femur, as bare bone could be felt at the point of the stump also.

On January 13th, 1886, using a strong india-rubber tube as tourniquet, applied in figure of eight round the limb and pelvis, and held in position by bandages, I removed the bone by Furneaux Jordan's method.

At first the patient was very low, but under opium and brandy he rallied, and the dressings were changed for the first time on the second day. Two openings on the face of the stump were still discharging at the time he left the hospital.

In June, 1886, I found a roughness at the end of one sinus which had not closed. Some new bone deposited from the portions of periosteum left behind; two stout silk ligatures were removed, and afterwards a painful nerve end was excised by Dr. MacCormick when I had left for England. This left him a very good stump or pad, and he has since gained weight considerably, and now weighs 12 stone, 5 pounds.

An examination of the bone after removal showed that the periosteum surrounding the whole bone from end to end was about a third of an inch thick, with a layer of new bone under it closely applied to the old shaft. The compact layer of the old shaft was pale and necrosed, but the cancellous part and medulla were stuffed full of a green coloured fatty material like putty, which no doubt was the original medulla, changed probably by effusion of blood into it. The decomposition of this gave the peculiar colour noticed on section. The surrounding tissues were matted together, and the openings of the sinuses were in such situations that the bone could not be reached by a probe.

REMARKS BY MR. TWYNAM.—The most interesting point of the whole case lies in its causation; for this I must refer you to the Croonian lectures for 1881 by the late Dr. Moxon. Some of his conclusions are, shortly:—1. Having given the anatomical uses of the cerebro-spinal fluid, he goes on to prove that the human brain is capable of withstanding enormous intra-cranial pressure without real damage, provided asphyxia or strangulation be not present. 2. The real danger to the nervous system depends on the pressure being too rapidly removed. 3. Further on he shows how paraplegia is dependent on the poor blood supply of the spinal cord, especially the *corda equina*, in consequence of the great length and small calibre of the spinal arteries. Through the cervical dorsal portions of the cord these arteries are reinforced by small branches which pass in on the nerves, but in the *corda equina*, such as there are, are long and very small. When the pressure is removed rapidly there is a great rush of blood into the tissues of the surface of the body. The spinal cord then being very poorly supplied with blood is in a state of marked anæmia, and I may remind you that anæmia in other cases is an early stage of "white softening," as met with in ordinary paraplegia.

This, then, Dr. Moxon considers the reason why so many men who have been subjected to great pressure have suffered from paraplegia. But there is one factor in this description of which he makes no direct mention as influencing the anæmic state, and which seems to me likely to have considerable bearing on the prevention of these particular symptoms; namely, the prolonged extraordinary pressure of the cerebro-spinal fluid on the cord. It is true that in the earlier part of his anatomical description he shows that as the brain fills with blood, the cerebro-spinal fluid is driven out to press on the cord, and that whilst the brain is gorged with blood the men are lively and work well. One more anatomical fact: in the cord the cavity of the arachnoid is larger below than it is above. Possibly the anæmic condition of the lower end of the cord may in part be produced by the pressure of this fluid, when we consider the hydrostatic relation of the long column of fluid pressing the blood out of the tissues of the cord. Under ordinary atmospheric pressure this effect is not sufficient to damage the cord, as it is met by the emptying of the vessels in the loose tissues surrounding the dura mater. But with the increased blood-pressure in the brain, representing the power, and the lower end of the cord the body to be compressed—lying as it does in that part of the cylinder where the diameter is the larger, and therefore the pressure is the greater—an anæmic condition is produced, and the longer this is continued, the worse for the workman, hence the value of the "short spells," which have been found to be the best preventive under these circumstances. Certain it is that a too long continuance in the air chamber was almost invariably followed by exhaustion and paralysis during the sinking of the caissons for the bridge at St. Louis, whilst this paraplegic condition does not seem to have been met with in any of those who remained under two hours in the cylinder.

If the pressure be taken off at once, instead of the circulation generally being evenly supported by the atmospheric pressure being reduced by degrees, the blood will rush into those parts of the system which have not such long arteries, and into those favoured by gravitation, as shown by Dr. Moxon—so continuing the anæmia. Whereas, if the pressure be taken off gradually, there is more likelihood of all the vessels getting their fair share of nourishment.

With regard to the limb in question, the medullary cavity answers in some degree to the cranium, as the compact bone takes the surface pressure from the medulla, but it had no means for the regulation of its contents, similar to the cerebro-spinal fluid, and I think it highly probable that under the great pressure of the circulation some vessels gave way, and this was the origin of the thrombosis which led to the destruction of the bone, and so to a condition such as Sir James Paget calls "quiet necrosis."

One more point regarding those cases: May not the pains so commonly noticed in the joints be due to an engorgement of the synovial membranes, similar to that found in early joint disease?

[The patient was exhibited at a meeting of the medical section of the Royal Society of New South Wales.]

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JANUARY 24TH, 1888.

GEORGE D. POLLOCK, Esq., F.R.C.S., President, in the Chair.

BEFORE the papers were read, a very interesting case was shown by Dr. W. R. GOWERS and Mr. VICTOR HORSLEY to the Fellows of the Society. It was that of a gentleman of middle age, who had for more than three years suffered with acute pain in about the middle of the back, just below and inside the lower angle of the left scapula. The spot was very tender as well as painful, but below the region of the fifth nerve there was almost complete anæsthesia as well as complete paraplegia; the accuracy of the delimitation was more distinct on the left side than the right. After some discussion, the diagnosis of tumour of the spinal cord was agreed upon, and Mr. Victor Horsley undertook the operation necessary for its removal. On June 9th, 1887, the spines and laminae of the fifth and fourth dorsal vertebrae were removed without laying bare the cause of mischief; but when the greater part of the posterior part of the third vertebra had been removed, a myxoma about the size of a filbert became visible in the spinal canal, lying on the right side, and compressing the spinal cord. This was shelled out without difficulty, and no further new growth was found. The pain was for a time slightly relieved, but again and again recurred with great severity, and the power of motion was only slowly and intermittently regained during the first three or four weeks. The pressure over the wound was treated by a pad and strong jacket; the local pain gradually diminished; the motor power gradually returned to the lower parts; and, after seven months, the use of the lower limbs, though a little stiff, had become almost natural, and the remains of the laminae had come so near together in the well-healed cicatrix that any further external support seemed unnecessary.

On the Occurrence of Tubercular Disease of the Testis as a Local Affection, particularly with Reference to the Desirability of Early Castration in Certain Cases. By WILLIAM H. BENNETT, F.R.C.S.—The basis of this paper was a record of five cases of tubercular disease of the testis which came under the author's observations amongst his out-patients at St. George's Hospital. The cases were selected with great care from a considerable number of patients suffering from this disease, as they possessed the following important characteristics in common: 1. An absolutely perfect family history, and an entire absence of evidence of privation, excess, or other conditions predisposing to the development of tubercular disease. 2. A perfectly clean bill of health up to the time of the onset of the disease in the testicle. In this respect exception might perhaps be taken to the case of patient No. 5, who had suffered from syphilis twenty-three years previously, but had never been troubled by any symptoms since. 3. The cause of the original inflammation in the scrotal contents was due in all the cases to direct local irritation, traumatic in four, gonorrhœal in one. 4. In each case the spinal column showed evidence of disease before the opposite testis, epididymis, either seminal vesicle, or other parts in the immediate neighbourhood of the testis originally involved. The spinal disease was so insidious that, with the exception of case No. 3, in which it was discovered accidentally, its existence was not suspected by the patient. 5. In neither of the cases did the affection manifest itself in other parts until after the original disease had

broken down. These points were fully discussed, and the following propositions submitted: *a.* Inflammation of the testicle or epididymis, the consequence of injury or direct irritation, might result in tubercular disease of a purely local kind, which, if left to itself, tended surely to generalisation. *b.* The greatest tendency to general infection was at a time subsequent to the breaking down of the original disease. *c.* Parts remote from the testis originally involved might be affected before the opposite testicle, epididymis, or either seminal vesicle. *d.* The rational treatment of cases like those under discussion was castration, upon the appearance of disintegration about the original disease—that is, at the commencement of what the author termed, for reasons stated, the "dangerous period."—Mr. HOWARD MARSH had found the results of his experience different from the cases which Mr. Bennett had brought forward. He could remember no case in which spinal disease was resultant upon tubercular testis, and he was inclined to attribute the symptoms in the back to the infection of lumbar glands. He thought it very rare to find a general tubercular disease spreading from such a focus. Among many cases of tubercular disease of the hip-joint that he had watched there were very few indeed in whom there was any phthisis; it would be correct to say that, as a rule, there was no sign of concomitant disease in the body. He thought we were apt to exaggerate the dangers of dissemination of tubercle, and so he led to the unnecessary excision of some parts, for example, the knee, for local tubercle. It was an operation in which it was difficult to be certain that all the tubercle was removed, and it sometimes happened that an operation merely excited the tubercle to fresh growth, to wider spread, and ultimately caused rather than checked a tendency to general tuberculosis.—Mr. CLUTTON had found most out-patients with tubercle of the testis in a condition quite unfit for operation, inasmuch as both testes were already involved when he first saw them. About nine months ago, however, he saw a patient with a hard nodule in one epididymis and a discharging sinus. The organs of the other side were healthy. The cord seemed healthy, and there was only one morbid mass, which was considered to be an enlarged gland, on the affected side. He tried to remove the nodule without opening the tunica vaginalis; but in the course of the operation the enlarged mass proved to be the cord, so that it became advisable to remove both cord and testis; a sinus remained open leading down to the stump of the vas deferens. The disease, in fact, proved to be too widely spread for unilateral treatment, and in most cases he had found disease on one side accompanied by disease on the other. He had not noticed cases in which it had spread to the spine.—Mr. BARKER remarked that if Mr. Clutton's case could have been treated, as Mr. Bennett wished, by castration before the disease spread up the vas deferens a general tuberculosis would probably have been avoided. Mr. BRUCE CLARK had found diagnosis often difficult, for some cases of chronic inflammation were hard to distinguish from tubercle. Another difficulty was to determine accurately whether there were any other foci. It was not difficult to understand the method of dissemination, for a coloured material such as Berlin blue, if injected into the testis, spread upwards easily into the thoracic duct; and that, as he took it, was sufficient reason to explain why the tubercular disease of the testis spread so much more readily than that of the joint.—Mr. W. H. BENNETT, in reply, observed that he was afraid he had not made his meaning clear to Mr. Marsh. He had not said or meant to imply that what he described was the common course of tubercular disease of the testis, but merely what had actually happened in 5 cases out of about 150, from which he thought there was something to be learnt as to the method of diffusion and the mode of arresting it. The symptoms referred to the spine were beyond what could be caused by inflamed glands. In one case there was carious bone shown at a *post-mortem* examination; in another the spinal curvature was half as large as his fist; in a third the stiffness extended up to the upper dorsal region; in a fourth the spinal symptoms had improved, but relapsed, with spread of the disease to the other testis. Mr. Clutton's case was dissimilar in having a nodule in the cord, whereas his own point had been to advise operation before the formation of a nodule in the cord. It certainly needed some practice on the living and the dead to acquire a thorough practical knowledge of the condition of the vesiculæ seminales and the prostate in health and disease, and he had ventured to bring this subject before the Society as raising the question of the method of diffusion of local tubercle and the opportunities of stopping it.

Case of Intra-peritoneal Rupture of the Bladder; Abdominal Section; Suture of the Bladder; Recovery. By W. J. WALSHAM, F.R.C.S.—C. H., aged 22, was admitted March 1st, 1887, into St. Bartholomew's Hospital under the care of Mr. Walsham. He had been drinking the night before, and in a fight was butted by his opponent in the abdomen, his bladder being full at the time. He passed a night

of great agony, and was brought in a cab to the hospital the following morning, but he was then suffering very little shock, and walked into the surgery with the assistance of two friends. He complained of pain in the lower part of the abdomen, and of having been unable to pass any urine since the blow, although his bladder was uncomfortably full at the time. The perineum was natural, and there was no history of stricture. On passing a catheter no urine flowed, although the point was ascertained to be in the bladder by the finger in the rectum. On depressing the handle the catheter was felt to free itself with a jerk, and its point could be then felt more plainly than natural through the abdominal walls. Bloody urine now escaped, the flow varying with respiration. About twelve hours after the injury Mr. Walsham opened the abdomen, and having discovered an intra-peritoneal rent in the posterior wall of the bladder, sewed it up with nine Lembert sutures. The sutures were passed through the muscular and peritoneal coats only, and one was placed above and below the upper and lower angles of the wound respectively. The bladder having been forcibly injected with eight ounces of boric acid solution and found watertight, the peritoneum was irrigated with about two gallons of warm boric acid solution, and the abdominal wound closed as in ovariectomy. A catheter was left in the bladder for two hours, and the patient subsequently reminded to pass his urine every four hours. There was little shock, and the patient recovered. Daily notes were given at length. The author remarked that there had now been seventeen cases in which abdominal section had been performed for rupture of the bladder, three extra-peritoneal and fourteen intra-peritoneal. Of the three extra-peritoneal cases two died and one recovered. In the successful case the wound in the bladder was secured to the abdominal wall but not sutured. In the fatal cases death was due to shock. The rent in one was found securely sutured at the *post-mortem* examination; in the other the rupture had not been discovered on opening the abdomen. Of the fourteen intra-peritoneal ruptures the rent in the bladder was sutured in eleven, and in three a drainage tube was placed in the wound but no sutures employed. Of these three one recovered and two died, death being due to peritonitis and suppression of urine respectively. Of the eleven cases where the rent in the bladder was secured by sutures five recovered and six died, death being due in three cases to peritonitis, in two probably to shock, and in one to hæmorrhage from a perineal incision employed for exploration. In the three cases of peritonitis the sutures had given way in one, and a leakage had occurred in the lower part of the wound in the other two. In the five successful cases Lembert sutures were employed, and the peritoneum was washed out, and in only one was a drainage tube used. The author discussed: 1, the advisability of early operation; 2, the importance of using a suture which will not become softened too soon, and of ascertaining before closing the abdominal wound that there is no leakage from the bladder; 3, the cleansing of the peritoneal cavity; 4, the inadvisability of a preliminary incision in the perineum, or of a subsequent incision in that region for the purpose of drain; and, 5, the question of tying in a catheter after the operation. A table of the seventeen cases was given, sixteen of which are in Sir William Mac Cormac's table appended to his work *On Abdominal Section*.—Mr. HOLMES took a peculiar interest in the subject, and that, not only because he believed that he had been the first surgeon to suggest this method of treatment. It was a suggestion that must have become obvious as soon as we learnt how freely it was possible to deal with the abdomen. The preliminary diagnosis was sometimes very difficult. He had seen a case in which the *post-mortem* examination showed a rupture, but in which the patient during life had passed water without great difficulty. Dr. Weis, of Philadelphia, had suggested the preliminary injection of the bladder with fluid, but that, he thought, added little to the certainty in doubtful cases. The reason of the retention of the capacity to pass water after rupture was still to seek. If, as he was inclined to think, it might depend on the fact that the rent in the wall of the bladder was incomplete at first, then preliminary injection would be very dangerous. If it was due to the temporary plugging of the rent by the intestines, the safer course would be to cut down upon it early. It was important for diagnosis to make a preliminary exploration with a catheter. In his own case that had been sufficient to render the diagnosis quite plain. He doubted whether it was a good plan to inject the bladder after putting in the sutures; it might help to tear them out, and if they were near enough together it would be probably unnecessary. In all other points he cordially agreed with Mr. Walsham's treatment. Perineal incision had better be avoided; it was the cause of death in Mr. Teale's case, and had been merely vexations in his own. He thought we should come to regard these cases as comparatively easy, so great was the improvement in abdominal surgery, compared to distant days when he could remember seeing a patient with ruptured

bladder, but still looking fairly strong, come under Mr. Cesar Hawkins's treatment, who diagnosed his injury rightly enough, but had nothing further to do than to watch him die of peritonitis.—Mr. BUTLIN said that he had made a *post-mortem* on a case of Mr. Willett's, in which an orifice had been found in a sutured bladder after death, and that had led several who had seen it to make up their minds not to refrain from injecting the bladder after suture in any similar case.—Mr. T. SMITH remarked that the operation could not be called completed until the bladder had been proved watertight, as in cases of vesico-vaginal fistula.—Mr. BARWELL approved of the injections before and after operation, though he had had no opportunity of practising them.—Mr. WALSHAM, in reply, had only a few words to say. He thought the preliminary injection might do a little good and no harm; and the injection subsequent to the sutures, he felt important, for in three fatal cases a leak had been shown to exist.

MEDICAL SOCIETY OF LONDON.

MONDAY, JANUARY 23RD, 1888.

J. HUGHLINGS JACKSON, M.D., F.R.S., President, in the Chair.

CLINICAL EVENING.

Case of Congenital (?) Deformity of Shoulder-Joints.—Mr. BERNARD PITTS showed a child who was brought to the hospital on account of a supposed deformity of the spine, remarked since birth. There was a gap below the acromion processes, and the heads of the humeri could be felt in the subacromial position. No trace of the glenoid cavities could be detected. The muscles were atrophied symmetrically on both sides. He asked the opinion of the Fellows as to whether it was a case of congenital deformity or whether it was due to infantile paralysis.

Naevoid Growth of Tongue.—Mr. PITTS also showed a child with a naevoid condition of the tongue. This had gradually increased in size, until it hung out of the mouth, necessitating the removal of a triangular piece of the tongue to reduce its size. It was still increasing in size, and he proposed to try the effect of multiple applications of Paquin's cautery.

Case of Nervus of the Tongue.—Mr. JOHN MORAN showed a male child, on whose tongue a naevoid growth was noticed when 18 months old. As since that time it had only increased in size *pari passu* with the growth of the tongue, and as he had on several occasions witnessed spontaneous disappearance of similar growths, he had decided to await the result of Mr. Pitts's experiment with Paquin's cautery.

Case of Sporadic Cretinism.—Dr. HADEN showed a child, 3 years of age, with some, but not all, the characteristic signs of cretinism. The child was dull and lethargic; the body was swollen and the skin harsh. The child was a "bleeder," and belonged to a hæmophilic family on the maternal side, and although he was unable to define the exact relationship of the hæmophilic condition with cretinism, he called attention to the fact that in myxedema hæmorrhage was also a common occurrence. He also showed a child, 10 months old, who had various convulsive movements of the head and neck to the right, with nystagmus, the pupils often becoming dilated during the attacks. The child talked and walked well. He did not think it was really a case of epileptiform or functional nature.

Case of Congenital Pemphigus.—A child, who had suffered from bullous eruptions, which first appeared within a few weeks of birth, was shown on behalf of Mr. MALCOLM MORRIS. The eruption began on the dorsum of the hands and feet—never on the palms or soles—but had spread, generally symmetrically. The child had been treated in the first instance on the supposition that the eruption was due to hereditary syphilis; but the sequel had shown that this was not the case, no other syphilitic manifestation having shown itself.—Dr. COLCOTT FOX, under whose care the child had been, had tried mercury and arsenic without success. He attributed the success that had followed the mercurial treatment in other hands to the more favourable hygienic condition of environment as an in-patient. He pointed out the differences between pemphigus due to a specific cause and the idiopathic form.

Case of Epispadias and Partial Extroversion after Operation.—Mr. W. J. WALSHAM exhibited a patient, aged 9, on whom he had operated for complete epispadias and partial extroversion of the bladder. The penis was ill-developed, but had a good glans, and the urethra was open in the whole length on its dorsal aspect, except at one spot, where a thin bridge of skin about one-eighth of an inch wide indicated an attempt at roofing in. The anterior wall of the bladder was partly deficient, but the mucous membrane did not bulge forwards, as commonly occurs in complete extroversion. The open pouch which represented the bladder was about the size of the last joint of the thumb. The scrotum was well developed, the testicles

descended, and there was no hernia. On September 21st Mr. Walsham made an incision around the margin of the opening into the bladder, and continued it at each end on either side of the gutter representing the urethra, as far as the glans. The muco-cutaneous tissues having been dissected up, were turned inwards, so as to bring the raw surfaces into contact, and united with chromicised catgut sutures, after the method of Lembert. An incision was then made transversely through the skin of the scrotum at the root of the penis, and a second incision parallel to the first about an inch and a half lower down. The bridge of skin thus marked out was dissected up, and the penis passed under it. It was then united to the skin around the margin of the bladder and urethra by horsehair sutures. The bladder and urethra were thus provided with a double roof, the raw surface of the lateral flaps being covered over by the bridge of skin taken from the scrotum. The flaps united by the first intention except over the anterior third of the urethra, where, in consequence of the excessive thinness of the tissues they gave way. Mr. Walsham intended at a future time to complete the covering of the urethra, by making use of the abundant skin forming the prepuce. At present, however, he thought it better to wait till the penis had become more developed at the age of puberty, and the restored parts had time to consolidate. The boy could now hold his water for five or six hours, and passed from five ounces to half a pint at a time.—Mr. HURRY FENWICK said that in the only case he had operated on he had been obliged to take a supra-umbilical flap to bring over the bladder, and two flaps from the sides, which united very satisfactorily, although an attack of scarlatina intervened.

Case of Recovery from Chronic Pyæmia.—Dr. CLUTTON showed a lad, 8½ years of age, who was recovering from an attack of what he preferred to describe as a case of multiple purulent synovitis. He had suffered for about a year from a discharge from both ears which latterly had become more profuse. He then had an abscess under the chin, and subsequently the right shoulder-joint and both elbows became filled with pus, the right hip-joint becoming also completely disorganised, with the femur on the dorsum ilii. He remained in a very precarious state for six weeks, but ultimately recovered.

Electric Illumination of the Male Bladder and Urethra.—Mr. HURRY FENWICK showed a series of instruments made by Leiter of Vienna, and Hartwig of Berlin, armed with incandescent lamps for illuminating the male bladder and urethra, and demonstrated their capabilities upon patients and "dummies." He observed that endoscopy had attracted the attention and efforts of the profession since the commencement of the century, but the candle power hitherto used had proved insufficient. Quite recently (1887) however, the smallest Edison lamp had been employed, and the result had been brilliant. Instead of a cumbersome, costly, and fickle instrument like the Nitze-Leiter endoscope of 1880, we now possessed a simple, practical, and safe apparatus by which the bladder or urethra could be examined in as strong a light as if it was viewed by direct sunlight. Every detail of the vesical or urethral surface was discernible, under favourable circumstances, even to the small vessels coursing over the mucous membrane. Mr. Fenwick mentioned certain elements necessary for a successful bladder examination, and explained that the vesical endoscope needed much practice and patience before the observer could become proficient with it. He believed that the value of electric endoscopy could hardly be estimated, and he predicted that it would at once assume a high rank in the diagnosis of obscure vesico-urethral disease, and would become almost as indispensable as the ophthalmoscope or laryngoscope. [Mr. Schall of Wigmore Street (Mr. Leiter's agent for Great Britain) was in attendance, and showed various batteries for working the endoscopes.]—Mr. WALSHAM bore testimony to the ease with which he had been enabled to see a stone in a dummy bladder.—Dr. ROUTH asked whether the instrument had been applied to the examination of the uterus.—Mr. FENWICK in reply said that the instrument would doubtless be applicable to the examination of any orifice of the body.

Case of Unilateral Sweating.—Dr. ANDERSON showed a young man who suffered from profuse perspiration limited to the right side of the head, face, and neck. There was nothing in the man's history to give a clue as to its causation, and no history of syphilis. Two years ago, when on frontier service in Mexico, he had noticed what he called "powerlessness" of the right arm. He was unable to raise his right arm on getting up in the morning, but this generally passed off in an hour or two. The man's general health was good. He (Dr. Anderson) asked for opinions as to the cause of this curious condition and suggestions for treatment.

A BILL for the utilisation of the sewage of Paris in the lower part of the forest of St. Germain has been adopted by the Chamber of Deputies.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

WEDNESDAY, JANUARY 18TH, 1888.

JOHN SMITH, M.D., F.R.C.S.E., President, in the Chair.

Patients and Specimens.—Dr. BYROM BRAMWELL showed a patient suffering from Locomotor Ataxia, where Optic Atrophy had appeared, prior to the more characteristic phenomena of the malady.—Dr. AFFLECK gave details of a case of Progressive Anæmia, with marked corpuscular depreciation, both in respect of number and form, where recovery had been effected.—Dr. BYROM BRAMWELL exhibited a plaster cast of a Thoracic Aneurysm of unusual clinical interest. The aneurysm projected as a considerable tumour from the anterior thoracic wall, and finally ruptured. The patient had declined to have operative interference attempted. Dr. Bramwell expressed the hope that ere long they might discover some natural blood ferment, which, on injection into the sac, would be able to initiate coagulation. They would remember that Dr. Gamgee had conducted experiments in this direction; but unfortunately the result showed that the ferment which he employed induced coagulation, not only within the sac, but in the circulation generally. Dr. Bramwell inclined to the belief that they might yet find some ferment which, when combined possibly with gelatine, might be able to effect coagulation in the sac alone.—Dr. BRAMWELL also exhibited photographs of the brain in a case of Cancer of the Left Lateral Lobe of the Cerebellum and the Lenticular Nucleus. During life, vertigo of a peculiar character had been the most pronounced symptom.—Dr. JOHN PLAYFAIR showed the lungs of a child, with a large pin impacted in the left bronchus. The little patient, of 15 months, was said to have swallowed a pin. Various unsuccessful attempts had been made, at home and in the Royal Infirmary, to determine the whereabouts of the pin. Soon after admission into the Sick Children's Hospital the child was seized with grave dyspnoea, necessitating tracheotomy. This relieved the patient much, and in due time it was dismissed, apparently well. About a year later the resident physician was asked to go to see the child, which he found dead. The cause of death was cancer oris; but on *post-mortem* examination a large pin was found impacted in the left bronchus, not far from the bifurcation of the trachea.—Mr. A. G. MILLER showed a Knee-joint removed for Syphilitic Disease. The joint was so extensively disorganised that, when the patient was admitted, Mr. Miller was inclined to think it must be tubercular. Examination showed, however, an absence of any trace of tubercular disease, while the evidences of syphilitic disease were abundant. Comparison with other surgeons showed that such cases were very rare.—Mr. SYMINGTON showed a beautiful section to illustrate the Anatomy of the Ear and Naso-pharyngeal Connections. Among other points of interest, it demonstrated that the antrum does not communicate directly with the internal meatus, but with that passage through the medium of the infundibulum. The section also gave further support to the view that the Eustachian tube is normally a closed tube.

The Place of Specialism in General Practice, with reference to Diseases of the Eye, Ear, Throat, and Nasal Cavities.—Dr. GEORGE HUNTER (Linlithgow) read an elaborate paper on the above subject. By means of illustrative cases, he showed the value which attached to a fair working knowledge of these diseases, more especially in the case of the general practitioner, and he advanced a strong plea for their fuller study in our medical schools.

SOUTH INDIAN BRANCH.

FRIDAY, AUGUST 5TH, 1887.

Brigade-Surgeon ROBERTS in the Chair.

Intestinal Parasites.—Brigade-Surgeon PORTER, M.D., reported the case of a young Singhalese domestic, aged 16, who died of fever followed by dysentery a few hours after his admission into the hospital at Madras. In the duodenum were found after death several specimens of the *anchylostomum duodenale*, some alive and some dead, adhering to the somewhat congested mucous membrane.—Surgeon J. H. POPE made some remarks on the case of a Hindu who was infested by *tenia mediocanellata*. Six of these parasites were expelled after a single dose (5*ü*) of liquid extract of male fern.

Ainhum.—A paper by Surgeon J. SMYTH, M.D., was read, in which he pointed out that ainhhm had not hitherto been noticed in Southern India. He described a typical case observed in a native aged 30, at the General Hospital, Madras, in June, 1882. The disease appeared to be common in Dacca, where the people call it *sukha pakla* (dry suppuration). Of the causation of the disease, which is characterised by a peculiar annular atrophy affecting the toes, and leading to complete disappearance of all the tissues, tendon, skin, and bone, being

all replaced by a strand of fibrous tissue, nothing was known. Dr. Smyth agreed with other observers in comparing the appearance of the toe to that which would be produced by tying a string firmly round the base and allowing it to ulcerate deeply into the tissues.

Injury to Cervical Spine.—Brigade-Surgeon SIBTHORPE related the case of a Hindu, aged 35, who sustained a strain or perhaps a partial fracture of some of the upper cervical vertebrae. This was followed by spinal meningitis and spastic rigidity of the lower limbs. Complete rest to the injured part was procured by the use of sandbags, and mercury was administered; he slowly improved, and after a year was able to walk without help. He had become liable to attacks of bronchial asthma, and on one occasion there was a remarkable slowing of the pulse.

Lymphatic Tumours of Groin.—Brigade-Surgeon SIBTHORPE related three cases of enlargement of the lymphatics of the groin, which had been under treatment at the General Hospital, Madras, during the previous few months. In one case the glands were excised; in another, several attacks of fever occurred, during which the glands enlarged; in the third, and in that only, though careful search was made in all three, embryos of *filaria sanguinis hominis* were found in the blood.

Mulberry Fibroma.—Brigade-Surgeon SIBTHORPE also showed a drawing of a case of congenital tumour of the right eyelid, observed in a Mahomedan, aged 18. Rapid growth had taken place during the four years before he went to the General Hospital, Madras. The right upper eyelid formed a large pendulous mass of fibro-vascular tissue three inches and a half long; the lower lid was also enormously enlarged, and two pendulous masses were attached to the skin of the face, on each side; the skin behind the tumour, and between it and the ear, was papillomatous. The eyeball was atrophied, having been probably lost from inflammation at the age of 3. The youth complained of neuralgic pains in the course of the fifth nerve; these were relieved by hypodermic injection of morphia.

CAMBRIDGE MEDICAL SOCIETY.

FRIDAY, DECEMBER 2ND, 1887.

H. STRAK, M.R.C.S., Vice-President, in the Chair.

Abscess between Liver and Diaphragm.—Mr. J. HUGH read the notes of this case, and showed the duodenum removed after death. There was a small punched-out ulcer, which had perforated. The *post-mortem* examination showed an abscess extending up between the liver and diaphragm, in close connection with the ulcer in the duodenum.

Some Forms of Disproportion between the Fetal Head and Pelvis (other than Pelvic Deformity) as a Cause of Protracted and Arrested Labour.—Dr. BOXALL read a paper on this subject.

Congenital Hydrocephalus.—Mr. G. N. BLUETT exhibited a specimen. The mother was delivered on October 20th. The breech presented. The trunk being born, the head would not enter the true pelvis. It was, therefore, perforated behind the ear, and the fluid let out; even then its size was so enormous that it had to be delivered with the cephalotribe. The child was fully developed, having no other deformity; it measured 27 inches long, weighing 15 lbs. The circumference of the head was 27½ inches, and it contained 4½ pints of fluid. The biparietal diameter measured 8½ inches.

Sudden Death in Diphtheria.—Dr. ROPER said a boy aged 12 years was taken ill with sore-throat on October 23rd. He did not seem very ill, and no medical attendance was obtained for him. On November 2nd—the eleventh day—he appeared weak, and on the evening of that day he made an attempt to walk upstairs, but failed, and asked his father to carry him up. It was observed that his voice was nasal. On the following day, November 3rd, his face was pale and slightly livid. The surface of the body felt cold. The tone of voice was nasal, and fluids returned through the nose. The temperature in the mouth was 97.4°; the pulse was 72, small and weak; respiration 16, shallow; the heart-sounds feeble and rather indistinct. He died at 5.30 the following morning, November 4th. On *post-mortem* examination the cavities of the heart were completely distended with clot, especially on the right side. The lungs were healthy, but the left one was attached to the chest walls by old adhesions. The local lesion in this case must have been very slight, as by the eleventh day there was no evidence in the state of the mucous membrane of the previous exudation; and the patient had taken his food well until the paralytic symptoms set in.

Malignant Endocarditis.—Mr. LAURENCE HUMPHRY related this case. The patient, a laundry woman, aged 50, was admitted into Addonbrooke's Hospital on May 4th, under Dr. Bradbury. Physical examination of the chest showed pneumonia at the right apex. The

heart sounds were clear at apex and base; the apex beat was not felt. On May 6th she was evidently better; the temperature was normal, pulse 100, tongue moist and clean, and the physical signs at the apex of the right lung were clearing. On May 8th the temperature suddenly rose to 102.6°, and the pulse to 132, and came down, after a profuse sweat, to 98°. On May 11th she had a distinct rigor. The breathing was very feeble at the right apex, and there were occasional friction sounds, with impaired resonance at the second and third intercostal spaces. The heart sounds were clear and regular. On May 14th her temperature reached 105°, and she had a severe rigor, and gradually sank after becoming unconscious. The *post-mortem* examination revealed a small abscess in the anterior mediastinum, extending chiefly to the right under the mediastinal pleura, and backwards as far as the root of the right lung; it contained about 1½ to 2 ounces of green, offensive pus. The right lung was adherent anteriorly, and the upper lobe appeared to be undergoing resolution after pneumonia. The pericardium was normal. The endocardium of the left auricle was roughened, and on the aortic cusp of the mitral was a patch of the size of a threepenny-piece, rough, ulcerating, and fungating; near the centre was a small perforation. The aortic valves were thickened and atheromatous, and covered with soft fungating vegetations, easily detached. The first part of the aorta was very atheromatous, with projecting calcareous plates, but without vegetations. There was slight hypertrophy of the muscular walls of the ventricles, and several white fibrous patches in their interior. The atheromatous disease of the aorta and valves was evidently of old standing; the ulcer and vegetations recent. There were extensive infarcts in both kidneys, and a small one in the spleen. There was diffuse purulent meningitis of the brain and spinal cord, with yellowish pus surrounding the cranial nerves; also a few patches of inflammatory softening in the brain substance. Mr. Laurence Humphry remarked upon the frequency with which these cases seemed to begin in a pneumonia, and the association of meningitis of the brain and spinal cord. In this case the recent mycotic process had evidently been grafted upon old atheromatous disease of the aortic valves.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, JANUARY 13TH, 1888.

EDWARD ATKINSON, M.R.C.S., President, in the Chair.

Trephining for Compound Depressed Fracture of the Skull.—Mr. LAWFORD KNAGGS read a paper on a case. He advocated a more thorough immediate exploration and cleansing of the injured parts (1) by a large skin flap; (2) by a more liberal removal of bone; (3) by a semicircular flap of dura mater, if that membrane should be injured; (4) by careful cleansing of all the exposed and damaged parts by powerful antiseptic lotions. He pointed out that, in the case related, the dura mater was found completely united by healthy lymph in eighteen hours. The proportion of cases in which severe after-effects occurred would probably be considerably diminished if operative interference at the time of injury was the rule. The experience of members was solicited on the suitability of opium in cases of commencing meningitis. Its power of contracting the cerebral arterioles suggested its employment, quite apart from its anodyne effect.—Mr. MCGILL understood Mr. Knaggs's main point to be the desirability of immediate trephining in all cases of compound depressed fracture, with or without cerebral symptoms. Mr. McGill's experience was entirely opposed to this view, his own views being these: (1) that in cases of simple depressed fracture, without symptoms, surgical interference was not advisable; (2) that if, by asepsis, we could practically reduce a compound fracture to the condition of a simple one, we should treat it on the same lines. If it were impossible to purify the wound without removal of bone, by all means let it be removed.—Mr. JESSOP treated his cases on the lines indicated by Mr. McGill. He attached much importance to the complete arrest of hemorrhage, as he thought that the constantly varying intracranial pressure presented a favourable mechanical condition for the rapid spread of extravasation and inflammation throughout the subdural space. He considered that opium was of great value in many cases.—Dr. RABAGLIATI said, with regard to opium, was it not a congester of the veins, and, therefore, a danger?—Mr. MAYO ROBSON thought much depended on the extent and character of the fracture. When there was much splintering or extensive depression, or when the wound could not be efficiently dressed, he advised trephining; in other cases he trusted to antiseptics. He had found opium of service in lessening hemorrhage.—Mr. PRIDGIN TEALE did not think the case for immediate interference was so strong as Mr. Knaggs argued, as many cases recovered completely and permanently without it. He some time ago came to the conclusion that

the dictum, "opium is dangerous in head cases," was a vulnerable one, and began cautiously to use it, especially in cases marked by extreme restlessness and a rapid rise of temperature.—Mr. LITTLEWOOD argued in favour of the free surgical treatment of these cases.—Dr. S. C. SMITH urged that it should be borne in mind what the trephine did. It provided for free drainage, and he thought that many cases of unexpected recovery from severe cranial fracture were owing to the drainage provided by the severity of the accident itself. On the whole, he advocated waiting for symptoms.—Mr. KNAGGS replied.

Supernumerary Teeth.—Dr. HELLIER showed a cast from the mouth of a child in whom there were six upper incisor teeth belonging to the first dentition.

Optic Neuritis in Chlorosis.—Dr. WARDROP GRIFFITH gave an account of a case in which optic neuritis was associated with chlorosis, and remarked on the difficulty of determining the value of this symptom as an indication of functional or organic disease.—Dr. CHURTON thought that in such cases optic neuritis was a mere coincidence.—Mr. BENDELACK HEWETSON remarked on the difficulty of recognising certain poisons, such as lead, which induced both chlorosis and optic neuritis. In some cases he thought constipation, and consequent fecal absorption, was a cause; and he referred to cases in which otitis, leading to cerebral mischief, and a condition of leucocythæmia, acted as causes.—Mr. HARTLEY thought it was easy to mistake the swollen disc often seen in cases of hypermetropia for true papillitis, and that very accurate observation was required.—Dr. A. BRONNER referred to syphilis as a common cause, associated with anæmia.

Lip Language for Deaf Mutes.—Mr. BENDELACK HEWETSON showed a boy from the school of deaf mutes at Doncaster, who was being taught to speak. He had been three years under treatment, and could read fairly audibly, though in a rather low voice.

Pathological Specimens, etc.—Mr. LAWFORD KNAGGS: (1) Calculus removed by Suprapubic Lithotomy; (2) Makius's Enterectomy Clamp.—Mr. ATKINSON: Tumour removed from Prostate by Suprapubic Prostatectomy.—Dr. BARKS: Malignant Stricture of Descending Colon.—Mr. MAYO ROBSON: a Double Hydrosalpinx, recently removed, the tubes containing four and two ounces of fluid respectively; (2) A Dissection of Intestinal Obstruction, due to an omental band passing from the sac of a femoral lesion.—Mr. P. TEALE: Diverticulum causing Obstruction of Bowels.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

THURSDAY, JANUARY 12TH, 1888.

G. H. HUME, M.D., President, in the Chair.

Orbital Aneurysm.—Mr. RUTHERFORD MORISON exhibited a boy into whose orbit there had passed the blade of a clasp knife. The boy could see immediately after the accident; a few weeks afterwards the eyesight was lost. There was no paralysis of the ocular muscles, and there was no atrophy of the optic disc. A well-marked, intermittent *bruit* could be heard all over the head.

Thoracic Aneurysm.—Dr. OLIVER exhibited a woman, aged 30, suffering from a large pulsating tumour in the upper part of the front of the chest. There was no history of syphilis. Three years previously she fell from the first floor of a house. Eighteen months after this she noticed a small pulsating tumour over the manubrium sterni. Within the last few months this had rapidly increased in size, until it now measured $6\frac{1}{2}$ inches longitudinally. Under large doses of sodium iodide she had complete relief from pain.—Professor PHILIPSON remarked upon the sex of the patient, and cited a similar case he had had under observation.

Rheumatic Nodules.—Dr. DRUMMOND exhibited a boy and girl suffering from cardiac disease, and rheumatic nodules were seen to be freely distributed in each. The boy had a tricuspid, and the girl a mitral, systolic murmur. Dr. Drummond regarded the coexistence of rheumatic nodules and cardiac disease as of grave importance.—Dr. MANTLE said he had seen similar nodules in adults.

Psoriasis of Wide Distribution and of Rapid Development.—Mr. COLLINSON exhibited for Dr. FENWICK a case in which the disease had, after beginning at the elbows, extended over nearly the whole of the body in three months.—Suggestions as to treatment were offered by Professor PHILIPSON, Drs. A. CAMPBELL, MANTLE, NEWCOMBE, DRUMMOND, THOMAS WATSON, and JACKSON.

Puff and Dart Needle Removed from Air Passages.—Dr. LYON exhibited specimens partly expelled by and partly removed from a girl, aged 11. Immediately after the insufflation there was no laryngeal distress whatever, but two days after this the temperature rose, and five days after the accident tracheotomy was performed by Dr. Hume, and attempts made to remove the needle, but unsuccessfully. The needle was known to be imbedded at the left apex. An electro-

magnet devised by Mr. Buckmaster, of Oxford, was tried, but to no purpose. Ten days after the use of the magnet the wool of the needle was coughed up, and a week after this, after a fit of coughing and vomiting, Dr. LYON, on examining the throat, saw the needle imbedded in the wall of the pharynx, from which he easily removed it with forceps. The child had made a fair recovery, but there was still dulness at the left apex.—In the discussion which followed, Drs. MURPHY, THOMAS WATSON, CAVE, HUMM, and DRUMMOND took part.

Ulcerative Endocarditis.—Professor PHILIPSON exhibited specimens removed from the body of a young man suffering from pleuro-pneumonia of the left base. The temperature remained high, but oscillated. The patient had a severe rigor when under observation, and a few days afterwards a loud aortic *bruit* was heard. The spleen was noticed to be increasing in size, and blood was found in the urine.—Remarks were made by Dr. OLIVER and Dr. DRUMMOND.

Abdominal Aneurysm.—Dr. VANN exhibited a specimen which was removed from the body of a man, aged 50. He had never complained of pain. The sac had not ruptured. The patient died from exhaustion.

Suprapubic Lithotomy.—Mr. RUTHERFORD MORISON gave details of a successful case in a man, aged 50.

Specimens of Uterine and Ovarian Disease were exhibited by Dr. MURPHY. The series included specimens of pyosalpinx, hydatidiform mole, and a variety of ovarian cysts.

The Galvano-cautery in the Treatment of Diseases of the Nose and Pharynx.—A paper on this subject was read by Dr. WILLIAM ROBERTSON.

REVIEWS AND NOTICES.

THE PRINCIPLES OF ANTISEPTIC METHODS APPLIED TO OBSTETRIC PRACTICE. By Dr. PAUL BAR, Accoucheur to, formerly Interne in, the Maternity Hospital, Paris, etc. Translated by Henry D. FRY, M.D. Philadelphia: P. Blakiston, Son, and Co. 1887.

The author, Dr. BAR, is an enthusiastic advocate of the employment of antiseptics in obstetric practice, and the translator evidently shares his views on the subject. No one would dispute *a priori* the necessity for strict asepsis in obstetrics as in other departments of surgery, but it is necessary to bear in mind that cleanliness is after all the most powerful antiseptic we can employ—cleanliness, that is, of atmosphere, of persons, and of instrument. With it chemical antiseptics, the use of which is not unattended with danger, may be safely dispensed with; without it all such agents are useless, or nearly so. In the hands of the author antiseptics is an aggressive policy, a war of extermination against the hypothetical little organisms whose presence is deemed to be the cause of certain pathological changes. The first chapter is devoted to the discussion of the nature of the infective processes which are apt under certain conditions to follow traumatism—processes which it is clearly shown have a close relationship with the presence of specific organisms. Having discovered the enemy, the next step is to destroy him, or, at any rate, to prevent an invasion. The first point, and the most important, is to place the puerperal patient in perfectly aseptic surroundings, and to keep them aseptic. This advice is excellent, though not always easy of application. Should the object not have been attained, we must "kill the germs which have gained access to the surface of the wound, and if the circulatory apparatus has been invaded, we must destroy the morbid principles which have penetrated therein." This is, no doubt, what ought to be done, but many bacteriologists would shrug their shoulders if asked to advise as to the means of so radical an elimination. The author happily knows no such qualms. He has antiseptics, some of which "fix the germs and prevent them from increasing," and others, much more powerful, which "act upon the germ itself by destroying it." Each genus of microbe requires a special strength of solution to ensure destruction, and consequently "the real value and power of each antiseptic cannot be recognised until a series of experiments have been made upon each known microbe." Luckily we are not obliged to await the reply to so far-reaching a question, since it is always possible to effect one's purpose by a strong solution, on the principle that the whole includes the part. Some elaborate tables are given of the estimated strength of various antiseptic substances, the more important of which are subsequently treated of *seriatim*.

Of late years the mortality returns of maternity hospitals have shown a very marked improvement on those which obtained at an earlier period, due in part to the observance of more scrupulous

cleanliness and the recognition of the danger attending the conveyance of infection from *post-mortem* rooms or the general wards. The author appears to favour recourse to antiseptic vaginal injections even during normal labour—a proceeding which many competent obstetricians do not approve. A good deal of space is given to the various antiseptic measures and the method of their application. While practicable and possibly useful in maternity hospitals, some of them would be difficult of application in private practice, and others would be dangerous unless employed under strict surveillance. The volume is a very complete and well-written monograph on obstetrical antiseptic, and the translation has been very well done.

A HANDBOOK ON DISEASES OF THE SKIN, WITH ESPECIAL REFERENCE TO DIAGNOSIS AND TREATMENT. By ROBERT LIVEING, A.M. and M.D. Cantab., F.R.C.P. Lond. Fifth Edition, Revised and Enlarged. London: Longmans, Green and Co. 1887.

THAT Dr. LIVEING'S handbook on *Diseases of the Skin* fulfils a useful purpose is sufficiently shown by the fact that it has already passed to a fifth edition. This new edition does not, in its arrangements, differ materially from the previous one. New articles have been introduced dealing with those diseases which have in recent years found their place, mostly for the first time, amongst recognised specific affections of the skin.

Erythema serpens, an affection of the hand, which was first, we believe, described by Mr. Morant Baker, and has also been noticed by Continental writers—a form of erythema specially affecting butchers, and evidently due to some specific poison—is noticed, Mr. Baker's description being closely followed.

Dr. Liveing relates four cases of the rare and interesting affection of the skin described by Wagner as colloid millium, and by Besnier as colloid degeneration of the skin, and also well described by Duhring. Dr. Liveing's description refers to small, slightly raised, yellowish tumours, varying in size from a large pin's head to a split pea, somewhat flat, of solid or semi-solid structure, and looking as if they contained fluid. These little tumours undergo change by the formation of a central depression, and, lastly, inflaming, scabbing, and drying up, leaving a marked but not defined scar.

Short notices of rhinoscleroma, mycosis fungoides, xeroderma malignum, scrofuloderma, Paget's disease, leucoplakia, and lymphangioma, in which references to the best descriptions of these diseases are inserted, tend to bring the book up to the level of our present knowledge. The brevity of these notices is, however, probably partly responsible for slight inaccuracies in correcting the proofs. Professor Geber will hardly recognise himself as M. Gaber, of Vienna; nor do we think he will consider his views correctly stated when he is made to assert that "the Aleppo evil is in all cases of syphilitic origin." M. Vidal, surely sufficiently well known to dermatologists at least, after having his name correctly spelt on one page, appears as Vedal four times in three consecutive pages.

In the treatment of that troublesome disease ringworm, Dr. Liveing has no hesitation in saying that the oleate of mercury ointment made by Shoemaker's process is the most generally useful ointment, and he speaks well of Dr. Cavafy's lotion, which consists of a solution of boracic acid in ether and in rectified spirit.

SPUTUM: ITS MICROSCOPY AND DIAGNOSTIC AND PROGNOSTIC SIGNIFICATIONS. By FRANCIS TROUP M.D., St. And. Edinburgh: Oliver and Boyd.

THIS work is not presented as a complete treatise upon the examination of sputum, although its size would lead one to expect that no point in this small department of clinical medicine had been omitted. Nevertheless, the book treats almost entirely of the microscopy of the sputum, and of the application of photography to the recording of its microscopical appearances. The author must forgive us if, in reviewing the work, we give special prominence to its artistic points. It is illustrated by no less than thirty-six photogravure plates and six chromo-lithographs, all executed most beautifully. Microphotography is as yet in its infancy, and while the reproductions in this volume are as perfect as it is possible to make them, it must be admitted that woodcuts or engravings give a clearer idea of the structure. Still, the author must be commended for his painstaking efforts to render his pictures as true to Nature as possible.

While the illustrations form such a marked feature of the volume, it must not be supposed that they overshadow in excellence the real matter of the book. Throughout this bears the impress of careful, laborious work and personal observation. At one part of the work the

author states that he for three years has examined the sputa of every patient admitted into the Longmore Hospital for Incurables in Edinburgh, no matter what his complaint might be, and still further proofs of the author's industry are evident in the volume. The chemical examination of the sputum receives but scant notice, since the author believes it is of little value in practice. He mentions, however, that he himself has never been able to detect sugar in the true sputum of diabetic patients, although it might have been present in the saliva. It is to be regretted that the author did not see his way to insert some account of the researches of Bamberger and of Knssman upon the chemical composition of the sputum, and its relation to that of the lungs. These observations have certainly not proved of practical value, but they are of some importance as indicating the changes going on in the processes of pneumonia and bronchitis.

The author lays great stress upon the search for elastic tissue in the sputum, and considers that we are inclined to overlook its importance in the fascinating hunt for the tubercle bacillus. It may be found, he believes, in cases of tuberculosis, in which the bacillus is absent temporarily or for a length of time. In nine-tenths of the cases in which it is found, its presence is indicative of tuberculosis. For its detection, the author considers Fenwick's method of boiling in a 20-grain to the ounce solution of caustic soda as usually unnecessary and liable to cause solution of the fibre. He examines a particle of the suspected sputum directly, with or without a drop of a 30 per cent. solution of caustic potash. Several photogravure plates are given of substances which may be mistaken for the elastic fibre.

An important and noteworthy chapter is that upon Curschmann's Spirals. These are scarcely mentioned in English works, and but a scanty account of them is given in the Continental textbooks, with the exception perhaps of that of Strümpell. Dr. Troup gives a full account of the work already done respecting them and of his own observations. He showed specimens of them in 1885 in Edinburgh, only two years after the exhaustive paper of Curschmann had appeared. He has found them in asthma and bronchitis, but never in pneumonic sputum, thus differing from von Jaksch and Vierordt. He considers that the spiral is an evidence of bronchiolitis; he finds, moreover, that the central thread is composed of columnar and ciliated epithelium cemented by some fibrinous or albuminous material, and that this core acquires a casing of spirally arranged, round and spindle cells forming an actual cast of the bronchial tubule.

An exhaustive and critical account of the methods of detecting the tubercle bacillus is given. Here the author states—and we agree with him—that Ehrlich's method is the safest, although requiring care in its practice. He also describes and figures a bacillus resembling that of tubercle, but probably of pneumonic origin. It will not be found by any of the nitric-acid methods, but by Gram's method might be mistaken for the tubercle germ. Other chapters are concerned with pneumonic, bronchitic, and pigmented sputa, &c.

The book is good, and the author and his publishers are to be congratulated upon the elegant style in which it is presented to the profession.

NOTES ON BOOKS.

Illustrations to Clinical Surgery. By JONATHAN HUTCHINSON, F.R.S. Fasciculus XIX. Plates LXXI-LXXIV.—Three of the plates in this fasciculus represent different forms of elephantiasis. Plate 72 is a fine drawing of a remarkable case of elephantiasis of the prepuce, simulating elephantiasis of the scrotum. The patient was a negro, and the affected integuments were removed by the author. Filarie were found in the blood. Mr. Hutchinson notes that attacks of inflammatory œdema, repeatedly recurring, are the almost constant precursors and causes of elephantiasis. Plate 71 will be of more general interest. It represents injuries near to the wrist, and fractures and separations of epiphyses. Figs. 2, 3, and 4 illustrate the conditions met with in recent specimens of Colles's fracture, and demonstrate the truth of an important fact often unknown to practical surgeons, namely, the occasional absence of any displacement. Another instructive figure represents complete separation and dislocation backwards of the carpal epiphysis of the radius.

Notes on Inorganic Materia Medica and its Chemistry. By J. SCHÜTZ SHARMAN, M.R.C.S. Second Edition. (London: Edingham Wilson.)—The object of the author in preparing these notes was to explain the elementary chemistry which is connected with the inorganic portion of the materia medica. Under the heading of each compound

the character, manner of preparation, action, dose, and officinal preparations are appended. The principle of the *Notes* is to be commended, as the student should never overlook the essentially scientific or chemical aspect of therapeutic resources, whilst he cannot learn to prescribe without knowing more or less by rote the details of the *Pharmacopœia*. Many a young practitioner, distinguished in his student days as a prizeman in Chemistry and Clinical Medicine, finds with dismay that *Squire's Companion to the Pharmacopœia* is more serviceable to him than his old scientific textbooks. Mr. Sharman's *Notes* demonstrate how far that which is scientific is useful, and how far that which is of direct utility is also a matter of science. The *Notes* are interleaved, so that the reader may add annotations on new drugs or record his own prescriptions, as he may think proper from time to time.

Some Observations on Headaches in Children, and their Relation to Mental Training. Read in the Section of Diseases of Children at the International Medical Congress held at Washington, September, 1887. By WILLIAM HENRY DAY, M.D., M.R.C.P., Physician to the Samaritan Hospital for Women and Children. (London: J. and A. Churchill.)—The author is already well-known for his writings on headaches, and this paper displays his usual accuracy of clinical observation. Dr. Day dwells upon the significance of headache according to its locality, and rightly lays great stress on defective accommodation. We need hardly say that a great deal is said about "overpressure," but the author wisely remarks: "We must admit that enthusiasts are prone to exaggerate when they witness a few cases of breakdown, and fail to remember the thousands of children who pass through their school life happier and better for the regular hours and discipline that is maintained."

The Student's Handbook of Chemistry. By H. LEICESTER GREVILLE, F.I.C., F.C.S. Second Edition. (Edinburgh: E. and S. Livingstone.)—This work is clearly written and accurate in detail, but it does not appear to possess any marked advantages over the mass of chemical textbooks, unless it be the great attention which has been paid by the author to the elucidation of chemical calculations of all kinds. There are printer's errors (which suggest the need of more careful revision), such as we should not have expected to find in a second edition; for example, in a table on p. 97, the boiling point of sulphur is said to be 114° C., a misprint for fusing point.

Handbook of Modern Chemistry: Inorganic and Organic. By Dr. C. MEYMOTT TIDY. Second Edition (Smith and Elder. 1887.)—The second edition of this work is enlarged, but the same general plan is adopted as in the first. The work is written with a special view to the education of students of medicine, but may be read with advantage by all chemical students. In some respects the arrangement of Dr. Tidy differs from that generally followed; for example, hydrogen is described last of the non-metallic elements, instead of first as is usually done. Although some reason for this may be found in the metallic nature of hydrogen considered from the point of view of the chemist, there are so many obvious advantages in introducing the lightest known form of matter to the student's notice at the very commencement of his chemical studies, that the older method of classification will probably be still adhered to. There are no woodcuts or illustrations of any kind in this work, but it abounds in useful and judiciously selected tables.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS, IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

DUCKER PORTABLE BARRACK AND FIELD HOSPITAL.

THE chief advantage offered in these buildings is the ease of transport of the materials, and the rapidity with which they can be erected by soldiers who have no special knowledge of construction, under the direction of an officer who can superintend the work after a short examination of the system employed.

A very practical proof of the merits of the Ducker system was given on Saturday, January 21st, at the Company's establishment in Parliament Street. Dr. Walter Pearce, of the Artists' Corps, with ten volunteers belonging to ambulance detachments of several metropolitan corps, was able to take down a field hospital 35 ft. by 18 ft.,

arranged for twelve beds, in thirty-five minutes, and to re-erect it in fifty-five minutes. The work could have been done more expeditiously after the first experience. Much rain had fallen, which was a severe test of the jointing of the woodwork. The whole structure is put together in sections which do not require special position except at the two ends. The floor is well raised from the ground, and the roof has a good elevation and incline.

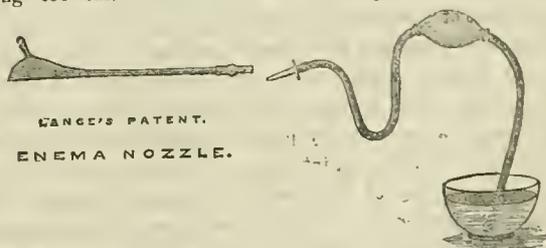

The material (leather board), on wooden frames, is very impervious, and would give great protection in cold climates. Lighting, heating, and ventilation are provided for, but in hot weather it would be necessary to open the sections in the roof, or replace them with canvas.

The portable houses erected in Parliament Street will repay an inspection, and have already received the favourable consideration of the War Office authorities.

PITTROFF'S ALMOND BISCUITS FOR DIABETIC PATIENTS. THESE almond biscuits are prepared by Herr Pittroff, a German baker at Carlsbad. They are a very great improvement on any that we have examined. As a rule, almond bread and almond biscuits prepared for diabetic patients are more or less tough, nauseous, and disagreeable products, and cannot easily be used as continuous articles of diet. The formulæ most in use are those of Dr. Pavy and Professor Seegen, both of which are thoroughly reliable in their freedom from dietetic ingredients likely to be mischievous to diabetics. But the results as to texture and flavour in the hands even of the most skilled bakers, are, as a rule, very unsatisfactory. Pittroff's almond biscuits, prepared with very scrupulous care in respect to their ingredients, have the advantage of being skilfully compounded and admirably baked. They are the only article of the kind strictly suited to a rigid diabetic diet we have yet found which can be recommended without qualification. They are very delicately and slightly flavoured with saccharin, and, strange to say, for an article of diabetic food, they are positively agreeable. We have known cases in which they have been used with satisfaction for many months continuously, and they can be strongly recommended to the notice of physicians who wish to prescribe for their patients almond bread in a form which is agreeable and tolerable for long periods of time. They are forwarded by parcel post as often as desired direct by Herr Pittroff, of Carlsbad, and will be found a great addition to a strict diabetic dietary.

LANGE'S ENEMA NOZZLE.

WITH a view to overcoming the difficulties experienced in the self-administration of an enema by the ordinary apparatus, Mr. H. J. Lange, of 47, Arthur Road, Tollington Road, Holloway, N., has introduced a new enema nozzle. This nozzle, which is simple in construction, can be inserted easily into the rectum with one hand without any fear of its slipping too far. With this nozzle the patient can, using any

apparatus he may happen to possess, sit all the while in a perfectly comfortable position, with both hands free to manage the injecting apparatus or syringe. Experience has proved these nozzles are easy of application and satisfactory in their action. They are made of vulcanite, and sold at a cost of three shillings and ninepence, postage paid.

HARVEIAN SOCIETY OF LONDON.—The following is a list of the names of gentlemen elected as officers of the society for the year 1888, at the annual meeting of the society on the 19th inst.:—President: *William Sedgwick; Vice-Presidents: T. Buzzard, M.D., John Williams, M.D., *Herbert W. Page, *William Ewart, M.D.; Treasurer: G. P. Field; Hon. Secretaries: *M. Handfield-Jones, M.D., *C. B. Lockwood; Council: F. H. Champneys, M.B., J. Hughlings Jackson, M.D., F.R.S., J. Ernest Lane, R. S. Mair, M.D., C. W. Mauzell-Moullin, R. H. Milson, M.D., A. J. Pepper, *Edmund Owen, *Frederick Treves, *Stephen Mackenzie, M.D., *E. Clifford Beale, M.B., *J. H. Drew. An asterisk is prefixed to the names of those gentlemen who did not hold the same office the preceding year.

BRITISH MEDICAL ASSOCIATION.
SUBSCRIPTIONS FOR 1888.

Subscriptions to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the West Central District Office, High Holborn.

The British Medical Journal.

SATURDAY, JANUARY 23rd, 1888.

HERBERT SPENCER ON SANITATION BY
COMPETITION.

It has been the weakness of the philosophers of every age to seek to measure and improve the conduct of the world by the practical application of their own systems and theories, no matter how widely these might be opposed to the common sense of mankind, how injurious their adoption might prove to the welfare of the human race. Herein lies the danger of every system of philosophy except the very wisest, of every theory of causation except the most cautious and enlightened one.

So long, for instance, as Mr. Herbert Spencer was content to occupy himself with the evolution of a theory of religion and life from his own inner consciousness and the writings of M. Comte, he remained a perfectly harmless and more or less interesting and useful thinker; but the moment he began to apply his conclusions to the practical affairs of daily life—the moment he began to formulate laws for the government of society—he became at once a danger to the well-being of the community of just as great dimensions as the extent of acceptance of his views by the rest of mankind.

Dr. Russell, in an able address to the Philosophical Society of Glasgow, has shown how extremely hurtful Mr. Spencer's conclusions on the subject of sanitation, for instance, are; how they attack the whole fabric of our law of public health, seeking to replace it by mere chimerical theories, which could only become operative as rules of life, according to Mr. Spencer's own showing, after the nation had passed through a probationary period of suffering and misfortune of quite incalculable extent and intensity. Mr. Spencer starts from what he designates "a law of right social relationship," namely, "That every man has freedom to do what he wills, provided he infringes not the equal freedom of any other man." From this law comes his conclusion (deemed even by himself "an awkward one") "that either by general government or by local government the levying of compulsory rates for draining and for paving and lighting is inadmissible as indirectly making legislative protection more costly than necessary, or, in other words, turning it into aggression," and, if so, he decides that "it follows that neither the past, present, nor proposed method of securing the health of towns is good."

Having, then, to his own satisfaction, upset the whole sanitary legislation of the last thirty years, he is kind enough to provide a substitute of his own: "How streets and courts are rightly to be kept in order remains to be considered. Respecting sewerage there would be no difficulty. Houses might rightly be drained on the same mercantile principle they are now supplied with water. It is highly probable that, in the hands of a private company, the resulting manure

would not only pay the cost of collection, but would also yield a considerable profit. But if not, the return on the invested capital would be made up of charges to those whose houses were drained, the alternative of having the connection with the main sewer stopped being as good a security for payment as the analogous ones possessed by gas and water companies. Paving and lighting would properly fall to the management of house-owners. Were there no public provision for such conveniences, house-owners would quickly find it to their interest to furnish them, some speculative building society having set the example of improvement in this direction, competition would do the rest. Dwellings without public footways before them and with no lamps to show the tenants to their doors, would stand empty when better accommodation was offered; and good paving and lighting having thus become essential, landlords would combine for the more economical supply of them."

It is nearly as absurd to suppose that to cut off the house drainage from the main sewer would oblige owners to pay a sufficient sum voluntarily for the maintenance of an efficient system of general sewage, as it is to trust to speculative building societies to lead the advance in general sanitary improvements.

The old system of cesspits, still existing in some towns, shows us what landlords would do with the house sewage if there were no stronger law than the laws of competition and convenience to compel them to do their duty. The dangerous sanitary condition of houses run up by speculative building societies, even under the salutary influence of local board inspection, shows how little we can expect "meat from that eater."

It is possible that in the dwellings of the rich and educated, competition and superior knowledge would secure that there was an outward observance of the laws of sanitation, that these houses were, if sepulchres, at least well whitened ones—but in those of the poor there would be no such safeguards. The over-crowding of all large towns, and the consequent struggle to obtain cheap shelter, would make sanitation by competition a mere delusion. A landlord, for whose undrained, ill-built, over-crowded tenements there is keen competition, at rates paying an excessive percentage on his original outlay, must become an enlightened philanthropist before he will expend capital in unremunerative alterations whose sole object is the improvement of his tenants' health.

Even Mr. Spencer allows that in the present condition of general knowledge and education, sanitation by voluntary effort would be imperative. It would only be in a community taught by experience and such masters as plague, pestilence, and famine, that one could hope to find the attainment of this ideal. Meanwhile, mankind must pass through a probationary period of misery and misfortune, to be measured perhaps by years, perhaps by centuries or ages, upon which however, Mr. Spencer looks with much complacency, for he sees in preventable disease left unchecked, not only an education, but also an actual saviour of society and benefactor to the race of man. Like Plato, he censures those who by sanitary reform would keep alive men of crazy constitutions. Diseases, he says, act beneficially, for by them "partly by weeding-out those of lowest development, and partly by subjecting those who remain to the never-ceasing discipline of experience, Nature secures the growth of a race which shall both understand the conditions of existence and be able to act up to them.....Mark how the diseased are dealt with. Consumptive patients with lungs incompetent to perform the duty of lungs, people with assimilative organs

that will not take up enough nutriment, people with defective hearts that break down under excitement of the circulation, people with any constitutional flaw preventing the due fulfilment of the conditions of life, are continually dying out, and leaving behind those fit for the climate, food, and habits to which they were born. Even the less imperfectly organized, who under ordinary circumstances can manage to live with comfort, are still the first to be carried off by epidemics, and only such as are robust enough to resist them—that is only such as are tolerably well adapted to both the usual and incidental necessities of existence remain. And thus is the race kept free from vitiation."

There are here several errors and false deductions of quite astonishing magnitude. Mr. Spencer seems ignorant of the fact that several diseases, such as consumption and cancer, which seldom prove fatal until their victims are well advanced in sexual life, although they destroy the individual, yet tend to infect the race in ever-increasing and widening circles. To numerous offspring the seeds of these diseases are transmitted; from these they pass down to fresh and more numerous generations.

Nor is it true that those epidemic diseases which slay their victims like the blow of the pole-axe and leave no inherited taint behind benefit the race by removing only the weak, the vicious, and the diseased. Take typhoid fever, for instance (that scourge so likely to become prevalent under the competitive sanitation of landlord and speculative building societies). Liebermeister says of it: "It is a fact that can everywhere be demonstrated, that typhoid attacks by preference strong and healthy persons, while it avoids those already suffering from chronic ailments."

Mr. Spencer seems, too, to have studied only one feature of the Darwinian theory, and to understand the lessons even of that very imperfectly. He recognises the selective and destructive phases of natural selection, but he ignores the doctrine of environment, and the phase of improvement under improving conditions.

Under natural conditions suitable for the well-being of any race, its strong and able push the weak and incompetent to the wall, to the benefit of the many; but in environments unfitted for the prosperity of the general organisation, the whole race gradually degenerates and disappears before the advance of some more suitable creation, either of higher or lower type, as the case may be.

In consumption, for instance, it is not isolated diseased beings among a healthy race, who being placed under conditions of life fitted only for the healthy, being unhealthy, die. It is the unsuitable environments which, at least in the first instance, foster and make possible the disease: for consumptives are certainly, either in themselves or their ancestors, the direct result of insanitary surroundings. It is their environments which are or have been incompatible not merely with their own existence, but with any continued existence of healthy humanity at all. Keep the surroundings as they are, and it is not the diseased individual who will disappear, but it is the whole race who will first become feeble, and then vanish. The struggle for existence is not between a healthy and a diseased humanity, but between any humanity and such foes as the tubercle bacillus, under conditions which makes the ultimate triumph of the latter certain.

But if it is true that unsuitable surroundings cause the gradual degeneration and disappearance of unsuitable organisms, it is no less true that the removal of these causes of degeneration not only stops the weeding-out of the weak and feeble, but gradually produces an

improvement in the condition of the whole race. For just as under unfavourable circumstances each generation becomes more and more unfitted for a continued existence, so under fostering conditions each generation will become more and more perfect. Even hereditary disease would gradually wear out and disappear, and our race would emerge from generations of wise sanitary legislation operating in wisest care and forethought—strong, healthy, and vigorous.

But Mr. Spencer's own "right law" that "every man has freedom to do what he wills, provided he infringes not the equal freedom of every other man," is fatal to the sanitary conclusions he draws from it. In no class of cases is the dictum "that no man liveth to himself" truer than in sanitary affairs. One cannot live unhealthily oneself without interfering with the just rights of others to live healthily. Freedom from preventable disease is the condition of life which any citizen has a right to claim. But this can be destroyed by the action of one's foolish neighbours. Carlyle's story of the woman who, starving, went from door to door soliciting help and receiving none, but in return communicated deadliest typhus fever, has another lesson beside that of a common brotherhood. It shows that the consequences of neglect of sanitation, using the word in its widest sense, are not the injury or disappearance of the individual alone who sets its laws at defiance, but a widespread injustice to the community, which only the strong arm of the law can prevent, or, being committed, adequately punish.

IRRIGATION AND AFTER-TREATMENT IN CATARACT EXTRACTION.

THE papers and discussions which we publish on page 176 raise several important questions as to the mode of operating in cataract and the best after-treatment. Improved methods have enabled surgeons to operate without waiting for the condition of the cataract which was formerly considered mature. In the old flap operation it was almost a *sine quâ non* for a successful operation that the lens should escape entire. With the present mode of operating it is by no means uncommon for some of the soft cortex to be rubbed off and remain in the eye as the nucleus escapes. For the removal of this, Dr. McKeown advocates the injection of a stream of water, and he claims for this method not only that cortical matter can be readily removed in cases of moderately mature cataract, but also that it renders comparatively safe the extraction of those which are so little advanced that some would classify them merely as "incipient." The method has now been before the profession for over three years, and does not appear to have come into general use in this country. This may be owing to some extent to the fear of introducing septic agents with the injection unless precautions are taken which are so elaborate as to be to some extent prohibitive, and also to the fact that many of those who have tried the method have not reported favourably of the results. But probably the greatest obstacle of all is the fact that operators generally have not experienced much difficulty in removing cortex by friction, and believe that they obtain results which are at least as good as those claimed by Dr. McKeown. This does not really touch his present position, however, since he claims to remove cataracts successfully at a stage when few surgeons would operate. Many ophthalmologists consider that Dr. McKeown over-estimates the frequency of cases in which, while the fundus is still visible, an operation is desirable because the patient's vision is sufficiently impaired to interfere with his earning his livelihood. In most of these cases the vision can be

considerably improved by using a weak mydriatic; and, although there are some trades for which the patients are incapacitated, it will seldom be found that they can follow them even after a most successful extraction. The introduction of eucaïne has rendered the removal of cortex by friction both safer and more certain. The operator can take his time, and the patient can look down; while the retention of consciousness allows the visual test to detect the presence of residual cortex which otherwise would have been unsuspected.

An iridectomy done two or three weeks before the extraction often hastens the maturation of the cataract, and its effect in this direction can be materially increased by manipulating the lens in the manner recommended many years ago by Förster. At the same time, the cortex can be much more readily removed, and its retention involves less risk when a preliminary iridectomy has been performed. The necessity of giving an anæsthetic twice was an objection to dividing the operation into two parts, but this has of course been entirely met by eucaïne.

As regards the after-treatment of cataract operations there is no doubt that the elaborate precautions that were formerly taken, some of which may have been advisable in the flap operation, are for the most part superfluous. Among such may be mentioned the absolute darkness of the room, and the avoidance of any examination of the eye for ten days or more. The reaction from this, however, may tend to go too far in the other direction, and some surgeons appear to treat their cases as if they considered them less serious than a simple wound of the cornea. It would have seemed obvious, had not recent publications shown that the contrary view is held in some quarters, that movements of the eye must have a tendency to disturb the coaptation of the lips of the wound, and that variations in light, by altering the position and the blood pressure of the iris, must interfere with that perfect rest which surgeons have hitherto thought conducive to the healing of a wounded part. If patients are allowed to go about after a cataract extraction almost immediately it is not likely that they will attach importance to precautions which the surgeon appears to despise; and if this plan of no-treatment comes to be at all extensively adopted we shall before long hear of many cases of escape of vitreous and intra-ocular hæmorrhage. Opinions may differ as to whether one or both eyes should be occluded, as to the amount of light to be permitted in the room, and as to how much support is to be given to the eye; but there ought to be no doubt that the avoidance of sudden movements, and of changes in the blood pressure, and protection from accidents such as may readily happen to a person with defective sight in a strange room, are essential adjuncts to treatment, and these can only be secured, at any rate in hospital practice, by rest in bed and a protective covering to the eye.

MR. THOMAS BEVANT, who was a corresponding member, has been elected a member of the Surgical Society of Paris.

PROFESSOR VIRCHOW will accompany Dr. Schliemann on his archaeological excursion to Upper Egypt in February, and will be absent till May.

ALDERMAN SIR J. WHITTAKER ELLIS, Bart., M.P., has consented to preside at the annual festival on behalf of the Earlswood Asylum for Idiots at the Albion Tavern, on Friday, April 13th.

MR. G. E. ROBERTS, late of Hertford College, Oxford, has been appointed Secretary of the London Hospital, in place of Mr. A. H. Haggard, resigned. There were 179 candidates.

THE Fifth International Veterinary Congress will be held in Paris in September, 1889. Professor Chauveau is President of the Committee.

THE DUKE OF NORTHUMBERLAND has, we learn, withdrawn his name as President of St. John's Hospital for Diseases of the Skin, in consequence of the refusal of the meeting of governors, held on January 18th, to sanction an inquiry into the rules and management of the hospital.

THE injuries inflicted by suicides are often of a very extensive and terrible character, but seldom have they been of a more distressing nature than in the case of Rear-Admiral Versturme, who died at Falmouth this week. Dr. Bullmore found on his arrival that the deceased had thrust the red-hot poker three or four times into his abdomen, inflicting injuries which ultimately resulted in death.

COURT APPOINTMENTS.

THE *London Gazette*, of Tuesday, January 24th, contains the following announcement:—"The Queen has been pleased to appoint Sir Edward Henry Sieveking, M.D., LL.D., Physician Extraordinary to Her Majesty, to be one of Her Majesty's Physicians in Ordinary, in the room of Sir George Burrows, Bart., M.D., deceased. The Queen has also been pleased to appoint Richard Douglas Powell, Esq., M.D., to be one of Her Majesty's Physicians Extraordinary."

SUCCESSFUL TRANSFUSION.

ON Friday, January 13th, Dr. Eustace, a young practitioner at Alresford, Hants, was summoned at midnight, and found the patient suffering from uterine hæmorrhage. This he stopped, but in the morning the patient was almost pulseless and sinking fast. Dr. Eustace, with no one to help him but an old woman, opened a vein in his arm and tried direct transfusion, but lost a quantity of blood, so, allowing over six ounces of blood to drop into a basin, he injected it with a syringe, with the result that the patient after a week had recovered.

COW-POX AND THE PATHOLOGICAL SOCIETY.

DR. KLEIN has written to us with reference to the vaccination of the calf which was exhibited at the Pathological Society on December 15th, and subsequently on January 17th. It will be recollected that Professor Crookshank took exception to Dr. Klein's dealing with this calf, which he evidently regarded as his property. It deserves to be stated that, at the first meeting of the Society, the calf was handed over to Dr. Buchanan by Professor Brown for the purpose of its being tested at the Animal Vaccine Establishment as to its susceptibility to cow-pox. It was, therefore, vaccinated with the lymph of that institution by Dr. Cory, the director, in the presence of Professor Brown, Professor Crookshank, and Dr. Klein, all these gentlemen inspecting it on subsequent occasions.

MEDICAL CLUB PRACTICE IN FRANCE.

THE lot of the French "club doctor" does not appear to be a particularly happy one any more than that of his English analogue. A proposal has recently been made to amalgamate all the clubs in the department of the Seine under the title of "Union Médicale des Sociétés de Secours Mutuel du Département de la Seine." The department is to be divided into a certain number of districts, each of which is to be served by one medical officer, who shall be bound to attend any member of the club living in such district. The yearly subscription is two francs for each adult person of either sex, and one franc for each child under the age of 16. A reduction of from 25 to 50 per cent. must be made when there are four or more children in

one family. Nothing is said as to extra fees for midwifery. For this magnificent remuneration the medical officer is at the beck and call of each individual subscriber, and must obey every summons "*dans le plus bref délai possible*," and look, we suppose, as cheerful as he can for the money. Official statistics are said to show that in such societies in France the medical officer has to visit each adult member of the club on an average five times in the course of the year, and in the case of children the average is considerably higher. In case of illness or absence the medical officer is required to provide a substitute at his own expense. As the *Progrès Médical*, from which we take these details, says, in these so-called benevolent societies all the benevolence seems to be furnished by the medical men. Would butchers, bakers, or shoemakers supply the needs of the members of these clubs on such philanthropic terms as the medical practitioner is expected to be content with? After all, however, the fault lies mostly with the profession itself, which has the remedy in its own hands, if it will only agree to apply it.

THE ILLNESS OF THE CROWN PRINCE.

It is now definitely arranged that Sir Morell Mackenzie will leave for San Remo to-day (Saturday). As we intimated last week, this does not indicate that the Crown Prince's present condition is such as to cause anxiety. The reports from German sources that any special operation for the removal of dead cartilage is in contemplation are, to say the least, premature; and we are authorised to state that no arrangements whatever have as yet been made for another general consultation. As there appears to be a good deal of misconception as to the symptoms which have recently shown themselves, it may be well to point out that they are precisely such as were to be expected—and, indeed, hoped for—on the theory that the disease is perichondritis. A certain amount of disintegrated tissue has been thrown off at the point where the growth was noticed in the early part of November; and it is thought probable that this sloughing process may be connected with disease of the cartilages. It is at present, of course, impossible to say that there is no graver affection underlying the perichondritis, but clinical experience is opposed to the probability of such a complication.

NATIONAL PENSION FUND FOR NURSES AND HOSPITAL OFFICIALS.

THE organisation of this fund is, we are informed, proceeding satisfactorily, and many hundreds of applications for forms and particulars are coming in to the acting secretary, Mr. J. H. Hanning, 38, Old Jewry, E.C., from institutions and individuals who desire to join. A strong council is being constituted, and the deed of incorporation has been settled. Mr. E. F. Coates, of Ewell, Surrey, has given 250 guineas to Mr. Burdett to defray the expenses up to the end of the first year, because he understands from the actuary that that amount will prove more than enough to give the movement an adequate commencement. Lady Rothschild has given her name as a patroness. There are to be not more than thirty vice-presidents, of whom four will be on the Council; their names will be announced shortly.

SCARLET FEVER IN LONDON.

It is satisfactory to note that the epidemic of scarlet fever in London, which recently assumed alarming proportions, shows signs of steady abatement. In the middle of April last, there were 368 cases of the disease under treatment in the Metropolitan Asylums Hospitals, from which date the number rose, week by week, until it reached the formidable total of 2,602 at the end of November. Since that date, however, the epidemic has shown a steady decline, and, as will be seen on reference to the article on the Health of English Towns, page 219, the number of persons suffering from scarlet fever, now under treatment in the Metropolitan Asylums Hospitals amounts to 1,729. The average weekly number of admissions, which had been

294 in October, fell to 223 during November, and still further declined to 148 in December. During the first three weeks of the current year, the admissions have been 147, 143, and 122 respectively.

THE BRITISH MEDICAL JOURNAL.

THE substitution on the front page of the JOURNAL of the figures "over 14,500 copies weekly" for those which previously marked the weekly circulation of the BRITISH MEDICAL JOURNAL as upwards of "14,000 copies weekly" indicates the large addition to the subscribing members which has followed the extra issue to the profession outside of the Association of our number of December 10th. The circulation of the JOURNAL has in plain words once more increased at a bound by nearly 500; the majority of the new subscribers having, after due signature of the certificates and forms with which they have been furnished from this office, and scrutiny by the Council of their credentials, become members of the British Medical Association by election. The continued growth of the circulation of the JOURNAL is phenomenal; its circulation having already some years since reached the limits which it was previously thought possible that a British journal of medicine could attain. It is now estimated that the weekly circulation of the BRITISH MEDICAL JOURNAL is not only larger than that of any other weekly journal by many thousand copies weekly, but very considerably exceeds the combined circulation of all the other medical periodicals published in Great Britain—a circumstance of no small interest to scientific and clinical contributors, as well as to those who desire to discuss departmental, social, and administrative questions in conference with the largest possible aggregation of their professional colleagues. We must, however, once more remind our correspondents and contributors that the difficulties of selection for publication are greatly enhanced by the multiplicity of our readers, which brings with it unfailingly a corresponding increase in the mass of correspondence and contributions. The value of conciseness, brevity, and reticence of style is, therefore, more than ever apparent.

SCHOOL DINNERS: VEGETARIAN VERSUS MIXED DIETS.

THE work of providing dinners for school children in large towns is not only useful; it has become so exceedingly popular that we now see a competition in good works which may lead to the mutual benefit of the various schemes contending in friendly rivalry. We have referred to the difficulties of the economic question in avoiding pauperisation; the competition between vegetarian and mixed diets has been put prominently forward in a report of two conferences held in Manchester on cheap dinners for school children. The Vegetarian Society naturally wish to demonstrate the economical and physiological success of their receipts, while others are not prepared to admit the desirability of excluding animal food. Success or failure in such a matter must be demonstrated by extended experiments. The value of a special diet cannot be demonstrated simply by chemical analysis of the food that ought to be digested, but also must be proved by a prolonged series of observations on the weight and measurements of children, repeated at regular intervals. At present we have no sufficient evidence before us, but we look for such in the future as the outcome of present efforts. It has been found that starving children can eat but little food at these free dinners, and it is said that they digest vegetarian dinners better than animal food. Still many children needing a provision for dinner at or near school are not starving; a separate experience is needed as to the diet most suited to these children, what is best to aid their growth and development, and what do they like best? What diet is followed by most growth and activity in school? Starvation disorders the stomach, producing dyspepsia, loss of appetite, furred tongue, feeble digestion; such is not, we hope, the average condition of children for whom average diets are to be provided. We urge then the desirability of careful and scientific observation of groups of children as to their condition, and as to their

feeding, valuable information may thus be attained. It seems desirable to place the vegetarian and mixed dinners in direct competition, and see how the children like and thrive on each respectively. Let one word of warning be given as to vegetarian diet; it has been amply shown that infants under 7 months in large towns are apt to become rachitic if deprived of their natural supply of milk, or cow's milk as its substitute; vegetable food at this age is highly prejudicial to their growth and future development.

A NEW FORM OF INFECTIOUS PNEUMONIA.

At the recent Medical Congress in Italy, Professor Cantani presented a communication on a new form of infectious pneumonia which had been observed by him. The clinical history showed broncho-pneumonia, which had been preceded by a diffuse bronchitis, with remittent and very pronounced fever, considerable emaciation, and great enlargement of the spleen. The disease was contagious, and was a primary affection of the bronchi, which extended downwards through the lung, and sometimes over the pleura and upwards along the trachea, and even to the larynx and pharynx. Bacteriological examination revealed the presence of numerous diplococci, and especially streptococci, similar to those found in erysipelas. The pure cultures did not, however, produce erysipelas when injected subcutaneously. When they were injected under the skin of a rabbit's ear, only swelling and reddening at the site of puncture were produced. All the cases ran a favourable course.

SEA SICKNESS.

M. OSSIAN-BONNET, on January 10th, read a long paper on Sea-sickness before the Académie de Médecine, Paris. He had studied the subject on board ship for twelve years and had never seen serious results; in this respect his experience differs from that of many British physicians. He believes that sea-sickness is essentially a nerve disease, the gastric symptoms being secondary or accidental. He denies that it is caused by a shaking-up of the cerebro-spinal fluid, or by movements of internal organs, for symptoms identical with those of sea-sickness are sometimes seen in persons who look over a precipice or who stare too long at machinery in rapid motion, although their own bodies are unshaken. Still more important in this respect is the fact that although the movements of the ship are more rapid and violent when she rolls than when she pitches, it is pitching which most readily causes sickness. In rolling, the ship lies against the sea as she heels to port and again lies supported along her own length as she heels to starboard, thus rotating smartly on her long axis, her movements have but a short range, and she is supported evenly on the side towards which she rolls. In pitching, the ship passes across a large wave, her bows descend, she rotates slowly on her short axis over a wide range of movement, and all the time her hull is unevenly supported by the sea beneath. During the several seconds which the ship takes to descend, the sensorium of the sufferer is affected in the way in which it always is affected when the body descends through space, or even when the idea of descending through space is strongly impressed on the patient, as when he looks over an abyss or dreams of falling from the clouds. In this fact lies the primary cause of sea-sickness; the effects are entirely cerebral at first, the head feels empty, then comes a sensation of weight at the temples, and disordered vision of giddiness. A large number of healthy landsmen feel these morbid symptoms mildly or even severely during a short Channel passage, without being sick. But should the head-symptoms exceed a certain limit, especially in the case of a person who has eaten too much or too little before embarking, the stomach soon sympathises and throws up its contents, or if empty undergoes painful contractions, secreting after a time a tenacious, clear mucus. When still longer exposed to irritation, bile is ejected from the stomach. Dr. Ossian-Bonnet has found that antipyrin is the best therapeutic remedy for sea-sickness. Dr. Eugene Dupuy has already spoken in its favour (*Journal*, December 17th, 1887, p. 1356). A dose of from twenty to twenty-five grains is often sufficient to cure a case

when the sea is not very rough and the patient is simply giddy, but thirty grains are needed when sickness is present. Should the first dose in either case fail to produce any effect, fifteen grains should be given half-an-hour later, and this dose may be repeated should the vomiting recur after the temporary relief. Up to ninety grains daily may be given, but such a dose is hardly if ever necessary. Subcutaneous injections of fifteen grains are useful when the stomach cannot retain the dose; this is best done by injecting in immediate succession two doses of seven and a half grains in solution. Surgeon-General Ogilvy, Dr. T. S. Robertson of New York, and Professor Germain Sée have already testified to the value of antipyrin in "bilious headache," migraine and neuralgia. It counteracts "nerve-storms" and hence is useful in neutralising the severe disturbance to the sensorium caused by the pitching of a vessel. Dr. Ossian-Bonnet's opinions will be of interest to the Briton who may still rule the waves, but who certainly cannot always prevent them from making him sea-sick.

HARVEIAN SOCIETY OF LONDON.

THE Annual General Meeting and *conversazione* of this Society took place on Thursday, January 19th, at the Marlborough Rooms, Regent Street. A business meeting for the election of officers for the ensuing year and for the usual complimentary votes of thanks to the retiring officials, was held in the Lower Room; and the retiring President, Mr. Edmund Owen, delivered an address which was heard with close attention by a large audience. Dealing chiefly with the subject of medical education from the point of view of a hospital teacher, Mr. Owen pointed out with considerable force the disadvantages under which students of medicine must labour so long as the preliminary subjects continue to be a part of the hospital course, and showed how impossible it has become for any but the most brilliant to acquire real knowledge, owing to the constant demand made upon his time by periodical examinations which leave no interval in which to assimilate the knowledge thus forced into the mind. He criticised somewhat strongly certain recent enactments of the University of London relating to students failing to obtain honours, which he considered were more advantageous to the examiners than to the students themselves. At the close of the address, which was warmly applauded, he introduced the President for the ensuing year, Mr. W. Sedgwick, who briefly returned thanks for his election on taking the chair. The members and their friends then adjourned to the Upper Rooms, in one of which a *conversazione* was opened, during which, in defiance of ancient traditions to the contrary, smoking was permitted, whilst vocal music was kindly volunteered by Messrs. J. Ernest Lane, A. E. Tietkens, and Orton Bradley. A recitation by Dr. Arthur Evershed, of a scene from *King John*, added greatly to the entertainment of the evening. Exhibits of surgical instruments and electrical appliances, introducing many novelties in electric lighting for medical purposes, were shown by Messrs. Down Brothers, Mr. K. Schall and Mr. G. Bowron, while Messrs. Nelson and Curtiss's photo-micrographic apparatus, specially designed for use with Zeiss projector eyepiece, was lent for the occasion by Mr. C. Baker. The *conversations* which was very well attended, was continued to a late hour.

SPECIAL HOSPITAL SCANDALS.

WE referred recently to the bad impression which could not fail to be produced by the refusal by a partisan vote of a meeting of some of the Governors of St. John's Hospital (whose proceedings were on the whole by no means of a satisfactory character) to assent to the appointment of a Committee of Inquiry into the rules and management of the hospital. It was sufficiently obvious from the admissions made in the official documents put forward at the meeting that such an inquiry is far from being uncalled for in the interests of the public and as a duty to subscribers. The proceedings under which members of the staff who have protested against that management were summarily dismissed by the Board of Managers, the allegations made as to the general financial conduct of the hospital, the admissions

in respect to those allegations in the financial report, the circumstance that the President, the Duke of Northumberland, insisted that such an inquiry should be made, as a condition that he allowed his name to be coupled with the institution as that of its President, and the attitude in support of the Duke of Northumberland's legitimate requirement on behalf of the public of Mr. Hamilton Hoare and Mr. Henry Maudslay ought to have convinced those who were present at the meeting that such an inquiry is absolutely essential before due confidence can be felt by the public and the subscribers. To stifle inquiry under such circumstances is to invite public censure, and is in itself the severest condemnation of the form of management which under such conditions and circumstances refuses the inquiry which the official head of the hospital and its most respected friends consider to be necessary. It is a grave misfortune of small special institutions such as this and the Jubilee Hospital, that they are for ever bringing elements of strife and disparagement into the area of hospital management. Such incidents ought to be a warning to the public against the incessant multiplication of petty institutions of the kind which are so constantly the scene of the struggles of individual interests and small partisan fights, and which become the cockpit of little official contests among those who either professionally or unprofessionally find their interest in establishing little special hospitals, which as often as not, in aspiring, on a small scale to a public character, create at more or less frequent intervals a considerable public scandal. The affairs of the Jubilee Hospital, which is a sort of conglomeration of the specialities, have again figured unsatisfactorily this week in the law courts.

EMMET ON UTERINE DISPLACEMENT.

At the twelfth annual meeting of the American Gynaecological Society, held in New York last September, Dr. Emmet read a "Study of the Causes and Treatment of Uterine Displacement." He maintained that version was a symptom, not a disease. In a case of prolapse, the pulsation of some branch of the uterine artery could be readily detected; but when the uterus was reduced to its natural level the patient felt relief, and after a few minutes the pulsation ceased. If the uterus were raised above that level, distress was again experienced. Anteversion was certainly not an abnormal position; and marked retroversion was often detected accidentally, where it had caused no symptoms. Dr. Emmet referred to the influence of pelvic inflammation in inducing displacement. The only fixed point was in front of the neck of the bladder, where the subpubic ligament bound down the urethra. Any traction on this point led to irritation and a desire to empty the bladder. This often resulted from inflammatory adhesions, the uterus might be retroflexed or anteverted, but the traction would be upon the urethra. Prolapse was, in Dr. Emmet's opinion, the more usual consequence of pelvic inflammation, resulting from the increased weight due to the obstructed circulation. The degree of displacement was usually in proportion to the extent of the cellulitis. In pelvic peritonitis involving Douglas's pouch the uterus was raised; versions always resulted from pelvic cellulitis. In cases where the inflammation was confined to the utero-sacral ligament there would be anteversion. The uterus was, as a rule, comparatively free in backward displacement, so that it could be corrected with the finger if it were then held in its supposed normal position pulsation would soon be detected in some of the neighbouring vessels. Were a pessary introduced under these circumstances, it would soon be necessary to remove it. A similar "correction" of extreme anteversion by any instrument caused traction on the utero-sacral ligaments, and consequent inflammation. Thus in the treatment of cases of displacement following inflammation, pessaries must not be applied, but local applications of iodine, and glycerine pads, with hot water injections were indicated. Dr. Emmet then spoke of the pelvic circulation. Much blood would engorge the tortuous, valveless veins. When the uterus was drawn down to the floor of the pelvis and held there, the cervix and vaginal tissues became congested, through obstruction of

venous circulation; but on increasing the traction till complete proclivencia was produced, the tissues became blanched through the consequent narrowing of the tightly-stretched arteries. A pessary must be so shaped and so applied as just to dispose of the traction whilst relieving the prolapse. The relief which would then follow signified the removal of a cause of congestion, rather than the reduction of the displacement. Under the principles just indicated, and not otherwise, the pessary was beneficial. No attempt should be made to remedy the displacement, so long as any evidences of recent inflammation were present; otherwise, harm might be done, and no good could possibly ensue, as a large number of histories testified. Dr. Emmet had employed cotton plugs soaked in glycerine to support the uterus in suitable cases of prolapse; when the plug was too large, that is to say, more than sufficient to correct the prolapse, irritation was set up. After the discussion on Dr. Emmet's paper, which is fully reported in the *Journal of the American Medical Association*, he replied, admitting that pelvic inflammation was more frequent in America than in Europe. American women went early into society and contracted pelvic inflammation as a result of imprudence in dress. Dr. Emmet had found the effects of pelvic inflammation more common among the single than among the married.

SUCCESSFUL EXCISION OF A TUMOUR OF THE SPINAL CORD.

SURGERY is a science, or perhaps we should say a fine art, which will tolerate no limits to its domain. It has of late taken up the invasion of the brain in earnest; it has just made its first successful dash at a tumour in the spinal cord. Last Tuesday evening, before the meeting of the Medical and Chirurgical Society, a private patient of Dr. Gowers and Mr. Victor Horsley very generously allowed the Fellows and visitors of that Society the opportunity of seeing all that had been done for the improvement of his condition. He had spent about three years in severe pain, which was most intense just below and inside the angle of the left scapula, and was accompanied by absolute loss of motion and sensation of the body and limbs below that level. The upper border of the anaesthesia was distinctly in the region of the fifth intercostal nerve on the left side, on the right it was less accurately defined, but did not extend higher. All the symptoms agreed with those of tumours of the spinal cord, and the intense pain afforded ample justification for making an attempt to excise the tumour. Mr. Victor Horsley accordingly removed the spines and parts of the laminae of the fifth and fourth dorsal vertebrae; but not until the third vertebra had been similarly treated did the tumour come into sight. It was a small oval myxoma compressing and making a deep impression on the left side of the spinal cord below the third vertebra. It was easily shelled out, and under careful antiseptic treatment the temperature did not rise more than 1° F. The wound healed rapidly, except at the uppermost point, where a drain had been left in by which a little cerebro-spinal fluid flowed away very slowly. For three or four weeks the former acute pain did not lessen, and even at times seemed more agonising; but after that it gradually and intermittently decreased, and now, after seven months, is entirely gone; the sensation and motion of the body and legs are almost completely restored. This is, we believe, the first time that such an operation has been attempted, and we must most heartily congratulate both the patient and his advisers on the triumphant character of its success. However far, and however quickly surgery may advance, it will long be a memorable day when it gained its first victory on so new a field and over so formidable an enemy.

THE JURISPRUDENCE OF INEBRIETY.

DR. NORMAN KERR, President of the Society for the Study of Inebriety, delivered his concluding lecture in the rooms of the Medical Society of London on January 25th. The subject was "The Jurisprudence of Inebriety." He said that the old conflict between law and medicine over the insane had now been more vigorously than ever

renewed over the inebriate. By Roman law an allowance was made for intoxication, but there was none under Grecian law. In Pittacus, in fact, for a criminal to have been drunk at the time when the alleged offence was committed, was to receive double punishment. Though inebriety had not been formally acknowledged as a disease by United States law, yet confirmed drunkenness was practically accepted as a fair plea. According to New York State law of half a century back, confirmed drunkards were classed with idiots, lunatics, and persons of unsound mind, as incapable of being entrusted with the conduct of their affairs, and liable to be placed under the control and care of the Supreme Court. By German, Austrian, and Swiss law there was a difference in the punishment for crimes committed during culpable and inculpable intoxication. French law made no difference, but the inveterate French inebriate lost his civil rights. English jurisprudence was characterised by contradictory rulings, and appeared to aim at punishing drunkenness through its effects. It had been laid down that drunkenness was no excuse for crime; that it ought to involve extra punishment, that frenzy from habitual intemperance was a valid plea for exemption. One person was convicted of manslaughter, though he knew nothing of the affair, owing to his drunken unconsciousness, on the ground that his frenzy was brought on by his own indulgence. A recent trial was a reproach to our present jurisprudence. Two men were under the influence of liquor. One met his death; the other was sentenced to death for the murder. The judge subsequently substituted for the capital punishment penal servitude for 20 years. As a rule, an alleged criminal's condition as to liquor did not affect the judicial decision. The remarkable phenomena of inebriate traces ought not to be lost sight of. In this state criminal acts might be committed without conscious volition, no recollection of the act remaining after the termination of the abnormal suspension of consciousness. The following four affections ought to exempt from criminal responsibility: first, the inebriety of insanity, in which the drunkenness was but a symptom of recurrent mania; second, the insanity of inebriety, the admitted and unquestionable mental unsoundness induced by persistent excess in alcohol, morphine, or other narcotic; third, delirium tremens, in the height of which the subject often did not know the effect of his actions, or the nature of the actions, or remember the actions themselves; fourth, *mania a potu*, a common malady of police-court drunkards. During a paroxysm of this form of alcoholic inebriety, consciousness was absent, and violence was done with no knowledge of the deed or after-recollection of it. Many inebriates possessed a minimum of inhibitory power, while others had so potent an innate tendency to excess that, having once tasted an intoxicant, they were impelled to intoxication. An accused person having been proved to have been drunk, no pains were bestowed on inquiring into the condition of the alleged criminal before the drunken act. Yet he might have been a diseased lunatic or inebriate. Our present jurisprudence was constructed on our previous want of acquaintance with the unhealthy state of many inebriate criminals. Science had revealed the existence of a disease of inebriety as of a disease of insanity. The latter, like the former now, had at an earlier period been regarded but as a Divine penalty for the punishment of sinful deeds; but, happily, was at this day seen to be a veritable disease, yielding to remedial treatment. In order that the case of the inebriate accused should be thoroughly investigated, Dr. Kerr suggested the appointment of a mixed commission of legal and medical experts, in the interest of the accused himself, of the bar, of the bench, and, above all, of justice.

SIR SPENCER WELLS AND PROFESSOR BILLROTH.

WE learn from the volume just published of the *Verhandlungen* of the German Society of Surgery, that when, at the Sixteenth Congress of the Society of Berlin, Sir Spencer Wells and Professor Billroth were elected honorary members, 142 members voted. Of these 137 voted for our countryman, and 14 for him only. For Billroth, 123 voted

who had also voted for Sir Spencer, and only one for him only. So that the voting of 142 members resulted in the election of both, as the rules require a majority of two-thirds, with 137 votes for Sir Spencer Wells, and 124 for Professor Billroth.

SCOTLAND.

SANITARY LEGISLATION FOR SCOTLAND.

THE Sanitary Association of Scotland has presented a memorial to the Secretary for Scotland, containing a number of important recommendations as to the necessity for further sanitary legislation for Scotland. It is suggested that, in the event of the Burgh Police Bill being again introduced into Parliament, the section relating to public health should be omitted. It is felt that public health is a matter of sufficient importance to be dealt with in a Bill by itself, when it would have more chance of receiving adequate attention, than forming as it now does a minor part of a large and excessively complicated police measure.

EDINBURGH STUDENTS' SYMPOSIUM.

ON Friday last, in the Drill Hall, Edinburgh, there was assembled a congregation of two thousand students of Edinburgh University for the purpose of doing honour to, and making the acquaintance of, the Lord Rector, the Marquis of Lothian; and also for the social purpose of enjoying a thoroughly good smoking concert. Lord Lothian travelled that day specially from London for the purpose of presiding at the symposium; he was cordially welcomed by his constituents, and addressed them briefly and pleasantly. The evening was spent most happily; the arrangements were conducted by the Amusements Committee of the Students' Representative Council.

EXAMINERS AND EXAMINATIONS IN EDINBURGH UNIVERSITY.

THE following gentlemen were appointed examiners for degrees in Medicine in Edinburgh University by the University Court at a meeting held on Monday: in Practice of Physic, Dr. Alexander Hughes Bennett, London; in Midwifery, Dr. David Berry Hart, Edinburgh; and in Chemistry, Professor W. H. Perkin, jun., Ph.D. The appointment of Examiner in Anatomy was deferred until the next meeting of the Court. The subject of the proposed alteration for the first and second professional examination was also considered, and a letter was read from Professor Sir William Turner withdrawing his appeal against the alteration of the arrangements for the first professional examination, as originally proposed by the Senatus. A letter was also read from the Sub-committee of the Students' Representative Council requesting to be heard on the matter. It was agreed to hear them on Wednesday, February 8th, and also to request Sir William Turner and representatives of the Senatus to attend, the Committee being requested to lodge a written statement of the points they wished to put before the Court. This courteous action to the Students' Representative Council shows the position which has already been obtained by it as a body entitled to make known the grievances and desires of the students.

ROYAL HOSPITAL FOR SICK CHILDREN.

THE work done in the Royal Hospital for Sick Children, Edinburgh, during the past year is summarised in the report presented to the twenty-ninth annual meeting of the contributors held last week. There were treated in the wards of the hospital 756 patients, and in the outdoor department 6,108 patients, while 172 vaccinations had been effected, the total number for all being 7,036. Of new cases treated in the hospital, 386 recovered or were cured, and 142 were relieved. A new feature in the management during the year was the opening of a surgical ward, and Dr. Joseph Bell was appointed to the charge of it as surgeon to the hospital. Great care was now taken in the train-

ing of nurses, and lectures had been delivered to, and classes had been formed for them, six probationer nurses had during the year completed their course of training. The directors draw attention to the necessity that existed for a convalescent home in connection with the hospital, at present convalescent children were sent to the home at Gilmerton, and sixty-nine had that advantage during the year. No surgical cases, however, or medical cases requiring nursing could be received there, as there was no nurse at the Home to look after them. The total income for the year was £3,925, and the expenditure £2,875, this was the first occasion in which the ordinary income had been greater than the expenditure.

IRELAND.

CORONERSHIP OF DUNGANNON.

THIS post is vacant by the death of Dr. David J. Hamilton, and already about nine or ten candidates are in the field. The candidates are pretty evenly divided between the medical and the legal professions. It is to be feared that the contest will be conducted mainly on political lines.

THE OCTO-CENTENARY OF THE UNIVERSITY OF BOLOGNA.

THE REV. DR. HAUGHTON, F.R.S., Senior Lecturer, and Dr. D. T. Cunningham, Professor of Anatomy, have been selected by the Board of Trinity College to represent the University of Dublin at the octo-centenary of the University of Bologna in June next.

DR. CROKER KING.

DR. C. CROKER KING, Medical Commissioner, Local Government Board, has been confined to his house for some time, from an affection of the foot which at one time gave cause for serious alarm. It is stated, however, that he is now much better, the more serious symptoms having abated.

SMALL-POX.

AFTER an interval of some weeks, during which no case of small-pox was reported in Dublin, we regret to learn that two persons have been attacked. Every precaution is being taken to limit the disease.

CHILDREN'S HOSPITAL, CORK.

AN entertainment of an unusual kind was given last week, in aid of this institution. It consisted of a programme of vocal and instrumental music capably rendered by children. One of the most attractive items was a recitation by a juvenile, who was attired in the uniform of the 4th Hussars. The proceeds will be devoted to the purchase of a musical box, for the amusement of the inmates of the hospital.

THE DUBLIN BRANCH.

OUR Dublin correspondent telegraphs that the annual dinner of the Dublin Branch of the British Medical Association was held on Wednesday evening, in the Hall of the College of Physicians. Dr. Mapother, President of the Branch, occupied the chair, and there was a large attendance. The guests included Sir West Ridgway, Under Secretary; Mr. Gray, M.P., Mr. Andrew Reed, Inspector-General of Constabulary, and others. The toasts proposed were: "The Queen," proposed by the President; "The Prince and Princess of Wales, and the rest of the Royal Family," proposed by the President; "The Army and Navy," proposed by the President, and responded to by Colonel Sir J. West Ridgway, K.C.S.I. "The Universities and Colleges of Physicians and Surgeons," proposed by the President, and responded to by the Provost of Trinity College, Dr. A. W. Foot, and Mr. A. H. Corley, President of the Royal College of Surgeons in Ireland. "The British Medical Association," proposed by the President of the Branch, and responded to by Dr. Banks, President of the

British Medical Association, Dr. Duffey, and Mr. Hepenstal Ormsby, Honorary Secretary of the Branch; "The Irish Medical Association," proposed by the President and responded to by Mr. H. G. Croly, President of the Irish Medical Association. "Our Visitors," proposed by the President, responded to by The Rt. Hon. the Attorney General for Ireland, Colonel Frazer, and Dr. Finlay.

NEGLECT OF VACCINATION: WEXFORD UNION.

AT a recent meeting of the Guardians, Dr. Costelloe forwarded a list of 75 children who had not, he believed, been vaccinated in his district. He complained that the people would not give him any information as to whether their children were vaccinated or not. We believe that if the children are vaccinated, the parents are bound to produce a certificate from the medical practitioner who vaccinated them.

BARRINGTON'S HOSPITAL, LIMERICK.

A SPECIAL meeting of the Governors was held recently to select a resident medical officer to this institution. Drs. Hayes, Riordan, and McMahon were candidates, but Dr. Riordan was the only one proposed, and was duly elected at a salary of £100 a year. At the meeting a letter was received from the visiting medical staff requesting the governors to insert an order on the minutes that no one except the physician or surgeon in charge should be entitled to give any information by certificate or otherwise with reference to any patient. This was apparently intended to prevent the resident surgeon being allowed to give evidence or a certificate, and thus obtain a fee, and was refused by the governors, who marked the communication "read."

THE INSPECTOR OF ANATOMY.

THE vacancy caused by the death of Dr. D. F. Brady, Inspector of Anatomy for Dublin, Belfast, and Galway, has been filled by the appointment of Dr. W. J. Martin, Secretary to the Dublin Hospitals Board, Physician to Jervis Street Hospital. No objection is made on personal grounds, for Dr. Martin is very popular, but the daily papers have commented upon what is called the undue haste with which the appointment was made. Dr. Brady died on Monday, and was buried on Thursday, but the vacancy was filled on Wednesday. Mr. Balfour has not added to his popularity with his party by thus piling coals of fire on the head of one who is said to be not one of his supporters. There were many candidates, and the expression of disappointment is correspondingly loud. The duties of the office are very light, and the emoluments are said to be worth £200 or £300 a year.

HEALTH OF BELFAST.

THE death-rate of Belfast still continues abnormally high, the rate for the week ending January 14th having been 37.9 per 1,000. The 165 deaths from all causes included 11 deaths from measles, 3 from scarlatina, 15 from whooping-cough, 1 from "simple" fever, 3 from enteric fever, and 1 from diarrhoea. During the past quarter there have been in Belfast 94 deaths from measles, 39 from scarlatina, 6 from typhus, 29 from enteric fever, 13 from "simple" fever.

A CASE OF ALLEGED STARVATION.

AN inquest was held at Coachford, County Cork, on January 20th, on the body of Mr. Simon D. Croke, who, it was alleged, died of starvation. The deceased was 70 years of age, and the evidence given went to show that he had not been attended to as his condition required, and that he received very little food. Dr. Crowley and Dr. Whyte proved that they had made a *post-mortem* examination, and that, in their opinion, death was caused by starvation in a man previously reduced by chronic pulmonary disease. The jury found a verdict accordingly, and Mrs. Croke was arrested. It is curious to note that she is a cousin of the late Dr. Cross, executed for the murder of his wife on the 10th of January. She has been admitted to bail.

ANNUAL MEETING OF THE DUBLIN BRANCH.

THE eleventh annual meeting of the Dublin Branch of the British Medical Association was held in the College of Physicians, Dublin, on Wednesday, January 25th, at 4 o'clock, Dr. T. W. GRIMSHAW, Registrar General, President of the Branch, in the chair.

Amongst those present were Dr. J. T. Banks, President of the British Medical Association; Sir William Stokes, Sir George H. Porter, Dr. Little, President of the College of Physicians; Dr. Corley, President of the Royal College of Surgeons; Dr. Foot, Vice-President of the Royal College of Physicians; Dr. Fitzgibbon, Vice-President of the Royal College of Surgeons; Dr. J. W. Moore, Professor E. H. Bennett, Professor W. G. Smith, Dr. Myles, Dr. McSwiney, Dr. Kidd, Dr. Nugent, Dr. Ball, Dr. Patton, Dr. King, Dr. Atthill, Dr. Johnston, Dr. S. Gordon, Dr. George F. Duffley, Dr. Nixon, Mr. Thomson, Dr. Cruise, Mr. Wheeler, Dr. Purser, Dr. W. Moore, Dr. Doyle, Mr. Tobin, Mr. Croly, Dr. H. Benson, Dr. W. T. Smyly, Dr. J. A. Scott, Sir Charles A. Cameron, and Dr. Robert MacDonnell, F.R.S.

The HONORARY SECRETARY, Mr. LAMBERT H. ORMSBY, read the report, which referred back at some length to the Dublin meeting of the Association, and to the success which attended it. The following may be quoted:

The subscriptions to the Reception Fund amounted to £1,508 14s 10d., and proved sufficient to defray the various expenses of the meeting, leaving a balance. At a meeting of the subscribers, held November 9th, 1887, it was unanimously resolved:

That the surplus should be applied to procure a portrait of Dr. Banks, the President of the Association, to be hung in the hall of the King and Queen's College of Physicians, as a memorial of the Dublin meeting of the British Medical Association in 1887, and of the able, courteous, and hospitable manner in which he presided over the meeting.

Dr. Walter Smith acted as Honorary Treasurer to the Reception Fund, and the Council cannot sufficiently thank him for the time and labour which he bestowed on the duties of such a responsible post.

In accordance with the resolution adopted by the Branch at its last annual meeting, your Council have had under its consideration the necessity which exists for the provision of systematic instruction in pathology in the various teaching bodies in Dublin. Your Council appointed a Committee, consisting of Sir William Stokes, Messrs. E. H. Bennett, A. H. Corley, William Thomson, and the Honorary Secretary, to consider the subject, and to report to the Council. The Committee made the following report:

The Committee appointed to consider the resolution in reference to the teaching of pathology, passed at the last general meeting of the Branch, have had the question referred to them under discussion. They suggest that, as pathology is now compulsory in the curricula of various licensing bodies, the Council should seek to impress upon the teaching authorities in Ireland the great importance and urgency of this question.

This Report having been submitted to the Council, it was unanimously adopted, and the following resolution passed thereon:

Resolved: That the Council of the Dublin Branch strongly recommend that steps be taken to establish chairs of pathology in the respective Schools of Medicine in Ireland.

The Council, in concluding this report, hope the Branch will continue to progress in the future as it has done in the past. The accounts of the Branch have been duly audited by Sir William Stokes, up to January 24th, 1887, and show a balance in favour of the Branch of £13 4s 11d.

Dr. A. W. FOOT moved and Dr. FITZGIBBON seconded the adoption of the report.

Dr. DOYLE complained of the omission of general practitioners from the honorary offices of the Branch. He wished to know how candidates were nominated.

Mr. ORMSBY explained that anyone could send in his name as a candidate, and that a circular notice was sent to each member a fortnight before the meeting.

The report was then adopted.

The CHAIRMAN stated that the scrutineers had just reported that the following officers were elected for the ensuing year:—*President*: E. D. Mapother, M.D. *President-elect*: W. Moore, M.D. *Vice-Presidents* (two to be elected): J. K. Barton, M.D.; Walter G. Smith, M.D. *Council*: Lomha Atthill, M.D.; John T. Banks, M.D.; E. H. Bennett, M.D.; A. H. Corley, M.D.; George F. Duffley, M.D.; A. W. Foot, M.D.; T. W. Grimshaw, M.D.; E. Hamilton, M.D.; J. W. Moore, M.D.; Sir William Stokes, M.D., F.R.C.S.I.; W. Thornley Stoker, F.R.C.S.I.; H. R. Swanzy, M.D., F.R.C.S.I. *Representatives on the Council of the Association*: George F. Duffley, M.D.; F. W. Grimshaw, M.D. *Representative on the Parliamentary Bills Committee*: George F. Duffley, M.D. *Honorary Secretary and Treasurer*: L. H. Ormsby, M.D., F.R.C.S.I., 92, Merriion Square West.

The chair was then taken by Dr. E. D. MAPOTHER, the now President, who was warmly applauded.

Dr. WILLIAM MOORE then moved and Dr. CORLEY (President of the College of Surgeons) seconded a vote of thanks to Dr. Grimshaw for his valuable services to the Branch.

The motion was passed by acclamation, and Dr. GRIMSHAW replied THE PRESIDENT then delivered his address.

PRESENTATION OF PORTRAIT TO THE PRESIDENT OF THE BRITISH MEDICAL ASSOCIATION.

AT the conclusion of the meeting of the Dublin Branch, on January 25th, Dr. MAPOTHER unveiled a portrait of the President of the British Medical Association, Dr. Banks, which has been presented to the President and Fellows of the King and Queen's College of Physicians of Ireland, on behalf of the subscribers to the reception fund of the late annual meeting of the Association in Dublin. He said he performed the duty of presenting the portrait with pride and pleasure. Since the first years of his studentship, he had enjoyed the acquaintance of Dr. Banks, and he had conferred upon him many kindnesses. They all recognised in Dr. Banks an elegant scholar and eminent psychologist, and one of the most refined gentlemen that ever adorned their noble hall; therefore they hastened to honour him. They elected him President of the Irish Academy of Medicine for three years, and last year with one voice the profession called him to the first place amongst the twelve thousand members of the British Medical Association. The unexampled generosity and distinguished ability with which he filled the position, were fresh in their recollection. Among the pictures and statues which adorned that hall, the beautiful work of art before them would be the only portrait of a living man. That it might long so represent him was the prayer of them all.

Dr. LITTLE, President of the King and Queen's College of Physicians, said he attended by the will of the College to receive this portrait. He would only assure the Council, in the name of the College, that the portrait was received by them with pleasure, and that it would have an honoured place on their walls. Speaking for himself, he felt that the Council of the Irish Branch had made a very wise and natural selection in asking that College to hang a portrait of Dr. Banks on its walls. Dr. Banks was one of the oldest of its Fellows, and had filled the most distinguished offices which it was in the power of the College to confer. He was for many years King's Professor by the appointment of the College. He afterwards filled the office of President of the College, and discharged his duties in such a way as to merit and receive the cordial thanks of the College. Dr. Mapother had referred to the portraits and statues they already possessed. They were exceedingly proud of them, and they looked on them with pleasure, especially those of their number who were old enough to remember most of the men whose statues stood around, or whose portraits hung on the walls. The penetration of Graves, the energy of Marsh, the self-reliance of Corrigan, the subtle intuition of Stokes, had all been presented to them by the chisel of the sculptor, while in the portraits they were reminded of the industry of Churchill, well known to all English-speaking people by his work; of Dr. Beatty, so ready in his art and so judicious in the advice which he gave at the Council Board of the College, and so cheerful at their festive gatherings; of Dr. Hudson, so unselfish and sincere a friend, so fertile in all the resources of accomplished physicians. Side by side with those distinguished men they would gladly hang the portrait of Dr. Banks, whose many and varied attainments had secured for him an entirely unique position in the social and professional world of Dublin.

Dr. BANKS, who was very warmly applauded on rising, said there were occasions when one felt how feebly words could express the gratitude with which the heart was overflowing, and this to him was such an occasion. To the Dublin Branch of the British Medical Association, and to its distinguished President for the gracious words with which he had presented the portrait, and to the President and Fellows of the College of Physicians who had accepted the gift, his most cordial thanks were due. To find a resting place in that noble hall, adorned as it was by Ireland's most illustrious physicians, was an honour of which any man might feel justly proud. He had already been the recipient of every honour and distinction which his own profession in this city could confer, and to be considered worthy of the mark of respect now paid him by those with whom it had been his lot and his great happiness to be so long and so intimately associated would ever remain among his most cherished memories.

The portrait is by Miss Sara Purser, sister of Dr. Purser, Professor of the Institutes of Medicine in Trinity College. It is one of the best

that has come from her hands, and was generally admired. It represents Dr. Banks seated wearing his uniform as Physician to the Queen, and scarlet robes as doctor of medicine.

ORGANISATION OF THE OUT-PATIENT DEPARTMENTS OF HOSPITALS.

THE latest scheme suggested for organising the dispensing of charitable relief in the out-patient department of our hospitals, with a view to avoid imposition, is that put forward by Dr. H. Burnes, a governor of the Great Northern Central Hospital, contained in a circular issued to the authorities of the various hospitals, which is as follows:

"In each district of which a hospital forms a centre an officer should be appointed, styled the superintendent almoner, with an office in or near the hospital. Here he would receive all applications for admission to the out-patient department, and would make inquiries as to the circumstances of the applicants. He would be able to recommend them either free or on payment of a certain weekly fee, according to their means. Cases in the first place would have to be taken with an order, stamped by the superintendent almoner any one of the extra-mural officers affiliated to the hospitals. These officers would be registered medical practitioners of not less than three years' standing in the district; and a list of such officers would be kept in the office, so that the patients might select whom they pleased. The extra-mural officer would see the case, prescribe for it at once, and should be satisfied that it was of an ordinary nature and required no special treatment, he could continue to undertake the case. Should he, however, think fit, he would at once endorse the order for admission to the outdoor department of his hospital. The fees charged by the almoner would be payable to him, and he would account for the same to the Committee; the extra-mural officer being granted a nominal sum per week (say 1s. to 3s. 6d. for home visitation) for his treatment of the case while it remained in his hands. The superintendent almoner would report every case to the Committee, with the extra-mural officer's report annexed, if the case remained in his hands. Of course it would be provided that such patients should attend at the hospital whenever required for examination, etc., and that the extra-mural officer should make a special report of every case which had been in his hands for more than three weeks. The superintendent almoner would be expected to make inquiries as to the case of each applicant, and to fix the fee to be paid per week (if any), in accordance with the result of his inquiries. Hence, his first order for medical relief would be only a temporary one, to be endorsed or cancelled as might be necessary."

As for the financial part of the matter there would be, on the one hand, the expenses of the superintendent almoner and his office, and also the nominal payments made to the extra-mural officers to cover cost of medicine, etc.; while, on the other hand, there would be the money received by the superintendent almoner in accordance with his decision. In case of a deficit he suggests that a grant be made from the Hospital Sunday Fund in proportion to the number of cases.

ARMY MEDICAL DEPARTMENT REPORT FOR THE YEAR 1885.

(Concluded from page 155.)

THE average strength of the non-commissioned officers and men serving in Bermuda in 1885 was 1,385. The admissions into hospital during the year numbered 654, or 494 per 1,000; the deaths 18, or 13 per 1,000; while the average number of men constantly sick was 38.83, or at the rate of 28.04 per 1,000. Enteric fever caused 29 admissions and 10 deaths, and 27 of the admissions took place at Prospect. The medical officer in charge of Prospect Camp stated, in his report, that the sanitary condition of the station was very good, and that the cause of the outbreak of enteric fever was to be looked for outside the camp; while the Principal Medical Officer, in his remarks on the causation of the disease, observed that, "in almost every case of the fever, the origin of the disease was distinctly traceable to causes—milk supply, aerated drinks, and impure water—furnished from outside the military precincts." The drainage of the neighbouring town of Hamilton is reported to be very defective. Out of an average strength of 63 officers, there were 17 attacks of illness, but no death. One woman, out of an average strength of 96, died from general debility; and among the children, averaging 175 in number, there were six deaths. With regard to the water supply, it is mentioned that there are no springs in Bermuda, but a few wells are sunk here and there, their supply, however, being precarious, and more or less brackish at high tides. Rain water, collected on roofs and stored in tanks, forms the principal source of water for use. The tanks under military

supervision are carefully guarded from contamination, and are periodically emptied and cleaned, whereas among the civil population there exists a great want of care in this respect.

The white troops serving in the West Indies averaged 900 in number during the year under notice. The principal stations occupied by these troops were Barbados, Jamaica, and Trinidad, a few men only being in the Bahamas, Honduras, and Demerara. The number of admissions into hospital was 830; there were 7 deaths, and the average number constantly sick was 38.77. Two of the deaths were due to enteric fever, 1 at Jamaica and 1 at Barbados. An outbreak of yellow fever took place at Jamaica in the last quarter of the year, and 2 men died from this disease. The advantage of removing troops from the infected locality was well illustrated on this occasion. The medical officer in charge at Port Royal, where the 2 deaths just mentioned occurred, reports: "The first death from the disease in this locality occurred on October 9th, in the person of a sailor. On November 3rd a child in garrison was attacked, and died on the 7th. This patient communicated the disease to a younger sister. Next, two boys were attacked on the 13th and died on the 16th. On the 17th, an artilleryman was attacked, and the garrison was evacuated that day. Another man in the same ward as the artilleryman was also attacked. Both cases showed extreme malignancy, and both men died. Next, the two attendants on the sick men were attacked, one case being very severe, the other milder; both of these men recovered." No fresh cases occurred in the garrison after it was removed to the camp of isolation at Papine. There were two cases of yellow fever among the officers, and one of these proved fatal. The disease was confined to the island of Jamaica.

The average strength of the black troops in the West Indies was 1,186. The admissions into hospital numbered 1,166, the deaths 18, and the average number constantly sick was 71.41. Two cases of small-pox occurred in a detachment of these troops at Nassau. It is stated in the report that the two cases were very mild, that the disease did not exist among the civil population at the time, and that the origin of the disease in the two instances referred to could not be traced. Four of the deaths were due to pneumonia, and three resulted from heart disease.

In Western Africa the average strength of the black troops was 422; 282 of this number serving at Sierra Leone, and 140 at Cape Coast Castle. The average strength of European officers was 25, and there were 11 white non-commissioned officers of the West India Regiment. One death occurred among the officers from apoplexy, and 10 were invalided to England, 5 for the effects of remittent fever, 2 for enteric fever, 2 for dysentery, and 1 for hepatitis. The report contains a very unfavourable account of Freetown, the capital of Sierra Leone, as regards neglect of sanitary arrangements. The first principles of sanitation seem to be disregarded there. It contains 23,000 inhabitants, and almost surrounds the low conical hill on which the barracks and station hospital are built. The report adds that no attempt is being made to remedy its insanitary condition. No case of yellow fever occurred among the troops, nor is any reference made to its occurrence among the civil inhabitants of the town, where it was stated to have prevailed in a severe form during the previous year, 1884. There were 109 cases of remittent fever among the troops, but they are described as having been generally mild, and yielding readily to treatment. One man died from remittent fever at Cape Coast Castle. Altogether there were only 6 deaths among the troops during the year in this command.

In the Cape of Good Hope and St. Helena command there were 3,939 troops, and the number of admissions into hospital during the year was 3,472, while the deaths amounted to 35. The ratios of admission were, therefore, 881.4, and of mortality 8.89 per 1,000. The average strength of the detachment at St. Helena was 140, the admissions into hospital 46, and there was 1 death. The ratios of sickness were, therefore, 328.6, and of mortality 7.14 per 1,000. Enteric fever caused in the command 29 admissions to hospital, and 9 deaths. The cases were widely distributed over the Cape Colony; none occurred at St. Helena. At Pietermaritzburg there were 11 cases and 9 deaths; and with regard to these cases it is reported by the medical officer in charge that they were mainly due to the arrival of detachments of Argyll and Sutherland Highlanders from Etshowe. The weather was excessively hot while they were on the march, and the men drank the water from every sluit and source on the road. There were also 7 cases and 1 death at Rorke's Drift, and the Principal Medical Officer remarks that this post was so notorious for outbreaks of enteric fever that the idea of abandoning it was mooted, but was given up on account of the political importance of the place. The admissions for primary syphilis numbered 588, and secondary syphilis 195, showing ratios of 149.3 and 49.5 per 1,000, as compared with

59.0 and 24.4 per 1,000 in 1884. If the cases of gonorrhœa and its sequelæ be included, the total number of admissions for venereal diseases was 1,233, being more than a third, or 35.5 per cent. of the total number of hospital admissions for all causes during the year. More than half the total number of cases of both forms of venereal disease occurred at Cape Town, and the medical officer in charge remarks that a large proportion of the cases of primary syphilis was followed by secondary symptoms of extreme severity. Among the deaths from injuries were 4 from gunshot, all suicidal. In each case a verdict of temporary insanity was returned, no motive for the act being discoverable. There were two cases of enteric fever among the officers, and one of these terminated fatally. Among the improvements carried out during the year, the establishment of a sanitarium in a well elevated position at Wynberg is mentioned.

The average strength of the troops quartered in the island of Mauritius was 358, but this relatively small force led to 898 admissions into hospital, a ratio of 2508.4 per 1,000, and to 6 deaths, a ratio of 16.76 per 1,000. The average number constantly sick was 29.51, showing a ratio of 82.43 per 1,000. The Senior Medical Officer remarks that "the general health of the troops is considered to have been more satisfactory during 1885 than in either of the two previous years, for though the actual number of admissions has been higher, the number constantly sick has been lower. The increase in the admission rate was mainly due to malarial fever, which was more than usually prevalent in the earlier months of the year, both in the civil and military population. The improved state of health is believed to be largely attributable to the removal of the main body of the infantry detachment from Port Louis, and the prompt transfer of sick from that place for treatment at Curepipe." The report states that the increase and improvement in barrack accommodation at Curepipe has been progressing during the year, and that in consequence a further reduction in the strength of the troops quartered in the notoriously unhealthy line barracks at Port Louis has been rendered practicable.

In Ceylon the average number of white troops during the year was 809. The hospital admissions numbered 950, the deaths 8, and the number of men constantly sick was 51.13. These numbers show ratios of 1174.3, 9.89, and 63.20 per 1,000 respectively. They all exhibit improvement as compared with the corresponding ratios in 1884; only 1 case of enteric fever was recorded, but that proved fatal. It is remarked that this disease is common among the civil population throughout the island, owing to the bad water supply. Small-pox was prevalent at Trincomalee early in the year, and later at Colombo, but no case occurred among the military. The officers, women, and children were generally healthy throughout the year. The general health of the native troops, consisting of a company of Gun Lascars and the Ceylon Mounted Orderlies, is also reported to have been good. Only one death occurred among them, the cause being phthisis pulmonalis.

The portions of the report which refer to the health history of 57,000 troops serving in 1885 in India, and nearly 10,000 officers and men in Egypt, have not yet been noticed. Want of space compels us to postpone a digest of these sections to some future opportunity.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

An ordinary meeting of the Fellows was held on Thursday, January 26th, Sir William Jenner presiding. C. J. Arkle, M.D., Lond.; R. A. Jamieson, M.D., Royal University, Ireland; S. Little, M.D., Royal University, Ireland; E. Malins, M.D. Edin.; A. Martin, M.D., Lond.; S. H. Owen, M.D., Royal University, Ireland; T. C. Rylton, M.D. Lond.; and H. R. Spencer, M.D. Lond., were admitted to the Membership of the College.

Licences were granted to 106 gentlemen who had passed the necessary examinations.

The following were elected Councillors: Dr. Handfield-Jones, Dr. Pavy, Dr. Church, Dr. Pye-Smith, Dr. E. Long Fox.

On the motion of the TREASURER, the following resolution was adopted:

"That, in recognition of the protection afforded to this College by the police during the recent riotous proceedings in Trafalgar Square, and of the admirable discipline exhibited by that force under prolonged provocation, the College do vote the sum of twenty-five guineas as a contribution towards the funds of 'The Metropolitan Police Convalescent Home,' or towards any project approved by the Chief Commissioner of Police."

The quarterly report of the Finance Committee and the annual report of the examiners were received and adopted.

A report was received from the Committee of Management recom-

monding that the University of Otago, Dunedin, New Zealand, be recognised as fulfilling the requirements of the Board in regard to professional study for the diplomas of the two Colleges, but that the University of Buffalo, New York, U.S.A., from which an application for recognition had been received, be not so recognised. The Committee also recommended to the two Colleges the insertion of the words "for a degree in medicine" after the word "examination" in line 2, paragraph IX, Section II, of the Regulations of the Board, so that the paragraph may read as follows:

"IX. Any candidate who shall produce satisfactory evidence of having passed an examination for a degree in medicine in any of the subjects of the first and second parts of this examination conducted at a university in the United Kingdom, in India, or in a British colony, will be exempt from examination in those subjects in which he has passed."

These recommendations were adopted by the College.

A report was received from the Colleges Land Committee, consisting of delegates appointed by the two Colleges to report as to the best use to which the unoccupied ground belonging to the two Colleges, in the rear of the Examination Hall, can be applied. The Committee reported that the position and shape of the ground do not admit of any great deviation from the original intention of erecting two lateral blocks in continuation of the wings of the present building with a theatre in the space between them; but in view of the fact that, owing to the height of the houses erected or in course of construction on either side of the building, the light in the lower rooms of the wings would be generally insufficient for the purposes of research work, they recommend to the two Colleges the erection of two galleries of rooms over the back part of the theatre from wing to wing at a sufficient elevation to obtain a good south light.

These two proposed additional galleries would provide eight rooms 20 feet long and 15 feet broad, with excellent light, and would not be overlooked except from the Examination Hall. This plan also admits of the wings being slightly reduced in width from the original design, so as to enable the theatre to be enlarged to accommodate four hundred persons, which, in the opinion of the Committee, would be desirable.

The plans which have now been submitted by the architect, embodying the scheme above indicated, appear to the Committee to be perfectly adapted to the purposes of "investigation and exposition," for which they are intended.

The architect's approximate estimates for the construction of the proposed buildings is as follows:

For two wings of four storeys each containing four large rooms which may be subdivided hereafter, a theatre to accommodate 400 persons, and two galleries containing four rooms each, £26,000.

In recommending these plans to the two Colleges, the Committee desire to add that assuming that the subjects of investigation be restricted to such as relate to medicine and surgery [for example, "researches as to the nature, causes, and prevention of disease, and experimental research on the chemical properties, physiological action, and therapeutic uses of remedies"] they are enabled to state generally that an additional expenditure will be required for internal fittings which need not exceed £5,000, and that the annual expenditure for maintenance would not be less than £500, and need not exceed £1,000.

This report was adopted, and Dr. Burton Sanderson, Dr. Lander Brunton, and Dr. Ralfe, with two others to be nominated by the President, were appointed delegates to form, with delegates to be appointed by the Royal College of Surgeons, a Committee to report on the precise nature of the internal arrangements and fittings required.

A communication was received from the Moxon Memorial Committee, with regard to the proposed Moxon Medal, the consideration of which was referred to the Council.

The SENIOR CENSOR moved the following resolution:

"That it is undesirable that any Fellow, Member, or Licentiate of the College should contribute articles on professional subjects to journals professing to supply medical knowledge to the general public, or should in any way advertise himself, or permit himself to be advertised, in such journals."

Considerable discussion ensued, which by resolution was declared to be part of the "Secreta Collegii." Eventually the debate was adjourned.

RABIES is said by the official veterinary inspector to have again broken out among the deer in Richmond Park. No case has previously been reported since September 24th. It was stated that the deer are still isolated.

ASSOCIATION INTELLIGENCE.

ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No member can be elected by a Branch Council unless his name has been inserted in the circular summoning the meeting at which he seeks election.

FRANCOIS FOWKE, *General Secretary*.

BRANCH MEETINGS TO BE HELD.

METROPOLITAN COUNTIES BRANCH: NORTH LONDON DISTRICT.—The next meeting of this District will be held at the Deaconesses' Institution and Training Hospital at Tottenham, N., on the evening of Thursday, February 2nd, at 8 P.M. (Dr. Bridgwater, J.P., Vice-President of the District), when Dr. Dowse will read a paper on Massage, and demonstrate its practice. Several interesting cases will also be exhibited in the hospital.—GEORGE HENTY, M.D., Honorary Secretary.

METROPOLITAN COUNTIES BRANCH: EAST LONDON AND SOUTH ESSEX DISTRICT.—The next meeting will be held at the Town Hall, Walthamstow, on Thursday, February 16th, at 8.45 P.M. (sharp). The chair will be taken by A. Dnrham, Esq., President of the Branch. A paper on Pernicious Anæmia, and the Diseases Liable to be Confounded with It, will be read by Dr. Bristowe, F.R.S. Visitors will be welcomed.—J. W. HUNT, 101 Queen's Road, Dalston, Honorary Secretary.

METROPOLITAN COUNTIES BRANCH: EAST LONDON AND SOUTH ESSEX DISTRICT.

The third meeting of the session was held, by the kind invitation of Dr. Adams, at Brooke House, Upper Clapton, on Thursday, January 19th. Present, Mr. G. WELER in the chair, and between twenty and thirty members and visitors.

Demonstrations.—After the usual formal business, the SECRETARY showed, for Dr. STEPHEN MACKENZIE, some of Dr. Uuna's Preparations for local application in certain Skin Diseases.—Mr. SILCOCK showed a series of patients suffering from Diseases of the Eye, including cases of interstitial keratitis, sclero-keratitis, chronic glaucoma, albuminuric retinitis, exostosis of orbit, pulsating tumour of the orbit, pigmentary retinitis, optic neuritis, and others.—Dr. MAJOR GREENWOOD, jun., showed two cases of Optic Atrophy.—Messrs. PICKARD and CURRY exhibited the Electric Ophthalmoscope.

The room was most efficiently fitted up by Dr. Adams with the electric light and other apparatus for the satisfactory examination of the patients.

Votes of Thanks.—Cordial votes of thanks were passed to Mr. Silcock, Dr. Adams, and to the Chairman.

BATH AND BRISTOL BRANCH.

The third ordinary meeting of the Branch was held at the Grand Pump Room Hotel, Bath, on Thursday evening, January 19th; Dr. G. F. BURDER, President, in the chair. There were also present twenty members and one visitor.

New Member.—W. Cotton, M.B., C.M. Edin., of Clifton, was elected a member of the Association and Branch.

Communications.—1. Mr. ALEXANDER WAUGH read a paper on a case of Puerperal Septicæmia, in which he drew attention to the analogy between erysipelas and puerperal septicæmia; he also laid especial stress on the frequency of *post-partum* hemorrhage after the administration of chloroform for instrumental cases, and asked whether any other anæsthetic, such as the A.C.E. mixture, would be likely to produce the same effect.—Dr. GOODRIDGE, Dr. J. K. SPENDER, Mr. J. H. H. LAWRENCE, Mr. R. J. H. SCOTT, Mr. C. H. COLLINS, Dr. BURDER, and Messrs. CARE, MASON, and BARTRUM joined in the discussion.—2. Mr. C. FLEMING read a paper on the Use of the Glycerium Amyli of the *Pharmacopœia* either by itself or combined with Bichloride of Mercury as a New Surgical Dressing.—3. Mr. J. H. H. LAWRENCE read short notes of two cases: a Burn of the Head, Face, and Hands in a Woman 75 years of age, and an obscure case of Typhoid Fever. 4. Mr. J. HINTON exhibited a case of Feebly United Fracture of the Olecranon treated by Wire Suture. In the unavoidable absence of Mr. Hinton the HONORARY SECRETARY read the notes of the case.

SPECIAL CORRESPONDENCE.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

Etiology of Contagious Pneumonia of Pigs.—Action of Antipyrin.—Antipyrin in Labour.—Toxicity of Exhaled Air.—Analysis of St. Lucie Rum.—Changes in Paris Hospitals.

MM. CORNIL AND CHANTEMESSE have made a series of researches on the etiology of contagious pneumonia in pigs, which have led them to the following conclusions. Contagious pneumonia in pigs is an affection which has been mistaken for measles. It has appeared in France within the last few years. It is contagious, it terminates in fibrinous peripneumonia, and almost invariably proves fatal. At the outset the animals are languid, and remain lying down; there is fever, cough, and loss of appetite. The skin on the side and stomach presents a reddish hue; blackish patches, from which the hair is easily detached, appear on the neck. There is whitish, mucous, horribly offensive diarrhoea, which sometimes continues throughout the illness, and at other times is replaced by constipation. The affection lasts from twenty to thirty days. It is distinguished from measles by its duration, by marked pulmonary symptoms, and by the peculiar nature of the micro-organisms which produce it. This affection destroyed a great number of pigs at the pig-rearing establishment at Gentilly during more than a year. The animals were supposed to have contracted the infection at the market of La Villette, to which animals are sent from all parts of France. MM. Cornil and Chantemesse, made the following experiments with fluid taken from the lungs, liver, spleen and blood of a pig which was killed while suffering from the affection. Cultivations with the blood and spleen remained sterile. The lung and the liver gave pure cultivations, which presented the following characteristics. The cultivation did not liquefy gelatine; a transparent patch, clotted in parts and thin in others, appeared on the surface. When the colonies were equally distributed, they presented the appearance of delicate tracery. On gelose, a milky patch with a lace border was observed; with potato, an abundant grey cultivation was obtained. These cultivations contained the same microbe in a pure state, namely, a small oval bacterium measuring 1μ to 2μ long by 0.3μ wide. It is motionless, aerobic and anaerobic, according to different conditions. A young pig was inoculated with portions of a pure cultivation in some broth, with a Pravaz's syringe. The next day the animal was very ill; the temperature was 40° C. (104° F). Diarrhoea subsequently appeared; the animal grew thin, its breathing was accelerated. There were crepitant and sub-crepitant râles in the lungs, at the spot where the injections were made. The skin was covered with black patches. The animal died four weeks after the inoculation was made. At the necropsy the right lung was found to be attacked with generalised broncho-pneumonia. There were hepatised lobules in the left lung; the kidneys were affected with nephritis, the urine was albuminous. The large intestine was covered with solid tumours, from the size of a lentil to that of a small walnut. Most of the lymphatic glands were swollen. The pathogenic microbe was found in the fluid taken from the lungs, glands, intestinal tumours, liver, spleen, kidneys, and in the urine, bile, and blood. It was also found in large quantities in the fæces. Similar inoculations were made in rabbits, guinea-pigs, mice, and pigeons. All these animals, with the exception of the pigeons, died within a few days. The microbe was most abundant in the blood of the mice, in which case it was larger, and when coloured with methylene blue, presented a clear space in its centre. It was found in the plasma of the blood, and in the white corpuscles. The lesions described show that infectious pneumonia in pigs is rather a general infection than a pulmonary disease. The virus usually gains access by the air-passages; this explains the pulmonary symptoms; but the disease may also be contracted through the alimentary canal or through a wound of the skin. MM. Cornil and Chantemesse believe that this affection is analogous to that which has been described in Germany by Loeffler and Schutz as the "Schweine-seuche," and in America by Salmon and Smith, as the "swine-plague."

Dr. Lucien Denian says that the action of antipyrin on the organism is as complicated as the organism itself. In large doses it may produce constipation, and it is supposed to cure diarrhoea and arrest intestinal hæmorrhage. It is rapidly absorbed by the mucous membrane of the intestines, and is eliminated by the kidneys, skin, and intestinal glands. Cutaneous elimination is accompanied by profuse perspiration in most cases, and in a few cases (one out of ten) by a special kind of eruption. In large doses antipyrin dilates the reins

and capillaries; its antipyretic effects are partly due to the increased emanation of heat resulting from vascular dilatation. Antipyrin is said to modify the action of the heart and the circulation, although Professor Robinson, of Chicago, affirms that this substance acts as a tonic on the heart, and slightly increases the blood-pressure. This assertion may be correct as far as mild doses are concerned. Antipyrin does not act directly on the respiratory function, but it has a decided influence on the nervous system. In large doses it produces vertigo, nausea, or drowsiness in certain patients; in others it causes excitement, hilarity, and a general sense of well-being. These last effects are most frequently observed after moderate doses in patients whose digestive organs or special nerve centres are not over susceptible. Antipyrin, when given in large doses at intervals, reduces the quantity of nitrogenous excrementitious products eliminated by the breath or other excretory agents. The doses vary from 60 centigrammes to 4 grammes in twenty-four hours. Antipyrin is soluble in water and alcohol. It may be administered as a draught, in wafers, or in elixir. It may be injected subcutaneously in an aqueous solution; the solution is negative if the methylated oxymethyquinizide is quite pure. The injection should not contain more than 50 centigrammes, and should be administered every half hour or every hour until the temperature is reduced. M. Germain Sée has shown that antipyrin, in doses of 4 or 6 grammes in twenty-four hours, is a valuable remedy for rheumatic symptoms of the muscles, obstinate myalgia, lumbago, peri-articular rheumatic muscular pain, acute or subacute muscular torticollis. The successful results obtained by M. Sée with antipyrin in cases which were unsuccessfully treated with sulphate of quinine, salicylate of soda, massage, liniments, etc., appear to show that antipyrin may be regarded as almost a specific in these cases. M. Sée also obtained excellent results with antipyrin in neuralgia, sciatica, face and cranial neuralgia. Antipyrin cures migraine, from whatever cause it may arise; it appears also to act as a prophylactic against neuralgia of the scalp. Cases of acute torticollis and obstinate migraine have been cured in less than an hour by antipyrin.

In the *Comptes-rendus* of the Société de Biologie of December 30th, 1887, there is an account of the successful use of antipyrin to ease the pains of labour, by Dr. E. Laget, of the School of Medicine of Marseille. Dr. Laget was called to a young lady, who had already several times miscarried, and who was taken with the pains of labour after about five months' pregnancy. The pains, which were very severe, resisted landanized enemata administered at intervals during forty-eight hours. On the third day, the pains continuing almost without intermission, and becoming sometimes insupportable, Dr. Laget, remembering the recent communications of Dr. Chouppe to the Société de Biologie (July 16th and November 19th, 1887), prescribed an enema containing antipyrin (2 grammes in 100 grammes of water). The pains diminished a little, but still persisted with some violence. One hour later another similar enema was given, and a quarter of an hour later the pains diminished most remarkably. The uterine contractions occurred every eight or ten minutes, with slight but supportable pain; the labour continued regularly in this manner for three hours, when the fetus was expelled; the placenta followed shortly afterwards. The patient had no after-pains, and her convalescence proceeded normally. Dr. Netter calls attention to the fact that, although the use of antipyrin diminished the pains, not only did the uterine contractions retain all their force, but that, the exhaustion caused by excessive pain having ceased, each contraction was more effective. The quantity of antipyrin employed was moderate, and it is possible that it might be administered in larger doses without inconvenience, and with more decided effect.

At the meeting of the Société de Biologie of Paris, on December 24th, 1887, MM. Brown-Séquard and d'Arssonval presented a note on some recent experiments made by them to prove the toxicity of the air exhaled from the lungs of man or of mammals. They assert, first, that the air exhaled nearly always contains ammonia; secondly, this air contains, in very minute quantities, organic matter which, if not already putrefied on leaving the broncho-pulmonary passages, has a great tendency to rapid alteration, even at a low temperature; thirdly, confined air charged with pulmonary exhalations is extremely noxious, even when containing only 1 per cent. of carbonic acid, with a corresponding diminution of oxygen, whereas atmospheric air containing the same proportion of CO₂, and a corresponding diminution of oxygen, but containing no pulmonary exhalations, causes hardly any disturbance. It seems probable, therefore, that exhaled air must contain one or several toxic substances, the toxicity of which, however, has not yet been proved. To test this question the authors injected into the circulation of rabbits a small quantity of a liquid resulting from the condensa-

tion in refrigerated glass bulbs of air exhaled from the lungs of several human beings, and also from the lungs of a dog (taken from the trachea). The results were the following: First, more or less marked dilatation of the pupil; secondly, slower respiration; thirdly, rapid decrease of temperature, varying from 1° to 5° C.; fourthly, paralytic weakness, often extreme, of the posterior members. During the first hours after the operation the heart is uniformly affected; in general its frequency is little modified, being sometimes augmented, sometimes diminished. But generally on the following and succeeding three or four days the cardiac pulsations often attain 240, 280, and 320 per minute, without a corresponding elevation of temperature or febrile symptoms. This strange phenomenon may sometimes persist for two or three weeks. As for the respiration, slower during the first few hours, it becomes afterwards rather more frequent than in the normal condition, and remains so for some days or even weeks. It is evident that the water which serves as a vehicle to the injections has nothing to do with the above phenomena, for M. Ch. Bouchard has proved that water injected into the circulation becomes toxic only when the quantity injected exceeds 90 cubic centimètres per kilogramme of the animal's weight, whereas in the experiments of MM. Brown-Séquard and d'Arssonval only a fraction of this quantity was employed (from 4 to 7 cubic centimètres). On injecting double that quantity of liquid produced by condensation of exhaled air of a dog into the carotid of a strong, healthy rabbit, there was violent tetanus, with almost complete arrest of the cardiac movements and of respiration, and the animal died within a minute. It is evident that this noxious action of the exhaled air must be due to certain toxic organic substances, present in very minute quantities, not yet isolated, and the chemical composition of which is yet unknown. The authors add that Dr. Arthur Ransome, who has best studied them (*Journal of Physiology*, 1870, vol. iv, p. 211), estimates the proportion in which they exist in the air exhaled from the lungs of a man in twenty-four hours at not more than about 2 decigrammes. It is not known whether these toxic substances are alkaloids, like the ptomaines, but it is evident that, considering the very minute quantities in which their action becomes appreciable, this action must be very energetic. MM. Brown-Séquard and d'Arssonval propose to continue their researches on this subject.

M. Oeschner de Couinck presented to the Société de Biologie at the meeting of the 24th of December last the following analytical results of his examination of 13 litres of genuine Sainte Lucie (West Indies) rum six months old: Alcohol, 54 per cent.; glucose, 1.03 gr. per litre; cane sugar, 0.40 gr. per litre; dry extract (at 100° C.), 6 grs. per litre; dry extract (*in vacuo*), 6.90 grs. per litre; ashes, 0.205 grs. per litre. This rum energetically reduced ammoniacal nitrate of silver. A solution of permanganate of potash was immediately reduced when cold; when heated, there was an abundant brown precipitate. The residue after distillation of the rum with water (rum = 100 c.c.; water = 300 c.c.) immediately discoloured the permanganate when cold; it was also rapidly reduced when hot. In order to study the superior alcohols, 12 litres of the rum were examined separately by means of Henuinger-Lebel's apparatus, heated by means of a *bain-marie*. The alcohol distilled was examined apart; it all passed over between 78° and 81° C. The watery residue was distilled on an open fire. The liquid, which was at first clear, soon became cloudy towards 100°. This cloudiness was due to a liquid of neutral composition, slightly soluble in water, lighter than the latter, having a peculiar smell similar to that of butylic alcohol. This composition gave the principal reactions of alcohols. There was not enough to permit of elementary analysis, but the presence of isobutylic alcohol seems probable. It appears, therefore, that perfectly genuine rum of agreeable flavour, sweet and mild, with an agreeable bouquet, may still contain a certain quantity of superior alcohols.

Owing to Dr. Cruveilhier having resigned his post of physician at the Beaujon Hospital, the following changes have taken place at the Paris hospitals. Dr. Richelot is transferred from the Bureau Central to the Bicêtre Asylum; Dr. Reclus from the Bicêtre Asylum to the Hôpital Tenon; Dr. Peyrot from the Hôpital Tenon to the Hôpital Saint Antoine; Dr. Marchand from the Hôpital Saint Antoine to the Lariboisière; and M. Benjamin from the Lariboisière to the Hôpital Beaujon.

EPIDEMICS AMONG SAVAGE RACES.—An interesting example of the peculiar severity of zymotic diseases when they attack savage races is given by Dr. Guppy (*The Solomon Islands and their Natives*), who states that there is no reason to doubt that mumps is sometimes a fatal disease among the races inhabiting these islands. We have been unable to find any record of a fatal case of mumps among civilised races.

VIENNA.

[FROM OUR OWN CORRESPONDENT.]

A Series of Thirty-eight Hysterectomies.—Hydro-therapeutical Treatment of Spasm of the Glottis.—Pathology and Treatment of Contraction of the Knee-joint.—Hygienic Aspects of the Electric Light.

In a recent number of the *Wiener Medizinische Wochenschrift*, Professor Charles Braun gives an account of thirty-eight cases of hysterectomy for fibroid, performed in the General Hospital, with only six deaths, that is to say, a mortality percentage of 15.5. The results which he had thus obtained were 2 per cent. behind those of Hegar, Kaltenbach, Bantock, and Keith, and about 16 per cent. better than the results obtained by the Berlin gynaecologists. Professor Charles Braun is strongly in favour of the extra-peritoneal treatment of the stump, as both the cases in which it was treated intra-peritoneally ended fatally. According to him, the following are the indications for hysteromyotomy: 1. Attacks of pain during menstruation or in the intervals between the periods, which recur frequently and render the patient unfit for work of any kind. 2. Functional disturbances from pressure on the neighbouring organs (bladder, rectum, kidneys, stomach, or lungs) involving risk to life. 3. Severe metrorrhagia, in which a cure cannot be obtained by any less radical procedure. Instead of the aseptic sponges he in most of his cases uses mull gauze which has been for twenty-four hours before the operation boiled in a 1 per cent. solution of sublimate, and which is afterwards washed in clear water. Immediately before and during the operation the gauze is wrung out of a hot solution of thymol (1 in 1,000), and used for stopping the bleeding from the peritoneal surfaces after ligation of the blood vessels. A solution of sublimate or carbolic acid is never brought into contact with the peritoneum. After the tumour has been brought forward the abdominal wound is temporarily closed by means of hooked forceps. The peritoneum of the abdominal wound is sutured above and below the stump, and the latter is fixed to the peritoneum of the abdominal wound by means of a mattress suture. Both the oviducts and the ovaries are separately ligatured with silk threads. Only after the closure of the abdominal wound by means of silk button sutures the tumour is removed, the stump being touched with the actual cautery and covered with benzoate of sodium. The extra-peritoneal treatment of the stump in cases of hysteromyotomy is specially advantageous when the myomata are situated in the wall of the body and the fundus of the uterus, but less so in those myomata which are situated between the walls of the cervix, the lips of the os, and the broad ligaments.

Dr. Adolphus Schrötter, of Vienna, in a recent number of the *Internationale Klinische Rundschau*, reports the case of a girl, aged 3 years, who suffered from severe attacks of spasm of the glottis, whom he had treated by wrapping the little patient in cold linen for half an hour or an hour, and then by rubbing with linen which had been dipped in water of a temperature of ten degrees. In this way he succeeded in cutting short twenty attacks of glottic spasm.

Docens Dr. Dollinger recently made a communication to the Royal Society of Buda-Pesth, on the pathology and treatment of contraction of the knee-joint. His communication was based on ninety-seven cases, which were all under his observation, and, for the most part, also under his own care, since 1881. Seventy per cent. were due to tuberculous inflammation of the joints. As an occasional cause, he noticed measles in two cases; both the children were of a tuberculous stock, and Dr. Dollinger was of opinion that the measles played, in the outbreak of the inflammation of the knee-joints, the same part as many other pathological processes which weakened the organism. As the longitudinal growth of the lower extremity depended chiefly on the epiphysal cartilages near the knee-joint, an inflammation occurring in the neighbourhood of these cartilages and destroying them must necessarily affect the growth of the limb. No statistics were available from which trustworthy inferences could be drawn as to the degree to which the growth of the extremity was impaired in the various intervals of time which elapsed from the date of onset of the inflammation. Dr. Dollinger, for this reason, made exact measurements of twenty-eight limbs, in which the inflammatory process had begun from one to twenty-three years before. He drew from them the following conclusions: 1. The development of the diseased extremity during the whole course of the acute inflammation quite agreed with that of the healthy one, nay, it even surpassed the latter by from 1 to 1½ centimètres. The shortening did not begin until the acute inflammation had disappeared, and a smaller quantity of nutritive material was conveyed to the epiphysal cartilages, owing to the cicatricial shrinking. 2. The shortening of the extremity was not in direct ratio to the number of years which had elapsed since the

beginning of the inflammation. It seemed that the degree of destruction caused by the inflammatory process in the epiphysal cartilages, or in the parts near them, had also to be taken into account. 3. The difference of length which became established between the lower extremities never became less; further measurements made several years later showed that, though both the extremities had in the meanwhile grown very much, the difference between them remained the same, or had increased up to the time when growth was complete. Dr. Dollinger's measurements also showed that, except in rare cases (2 out of 28), after each attack of inflammation of the joint which had completed its course during infancy, the development of the affected extremity was considerably retarded. The amount of shortening varied from 8 or 10 to as much as 19½ centimètres. This showed that there was a good deal of shortening, even in cases in which the knee-joint was not resected, a fact which proved that the most important objection which had been brought against this operation was groundless. In speaking of treatment, Dr. Dollinger said that massage was of no use in tuberculous inflammation of the knee-joints; he used it, however, with good effect in contraction of the knee-joints dependent on articular neuroses, gonorrhoea, or slight rheumatism. In cases of tuberculous origin he did not stretch the limb by *brisement forcé*, but at first stretched it only to a certain degree, and then fixed it in this flexed position with a plaster-of-Paris bandage. Owing to the tension, hyperæmia supervened in the adhesions, which thus became loosened, so that the complete stretching of the extremity could be easily performed after a week. Dr. Dollinger insists that the patients should begin to walk with the bandage on as early as possible. Some weeks after the complete stretching, he had a plaster cast made of the extremity, and a felt knee-cap made after the model of the cast. The support was connected with the shoes by two rods joined at the ankles. The patients wore this support for a long time, with the view of preventing secondary curvatures.

In the annual report for 1887 the "Stadtphysicus" of Prague, Dr. Zahor, urges the introduction of electric lighting into the public reading rooms. He states that Dr. Fr. Renk, assistant to Professor Pettenkofer, has had the opportunity of making a series of experiments on the utility of the electric light from the sanitary standpoint, in the "Nationaltheater" of Munich, which is supplied with 1,700 Edison's lights. He has thus been able to prove that the electric light had hardly any influence on the deterioration of the air, whereas the gaslight raised the temperature of the room, deprived the air of its oxygen, and rendered it injurious by increasing the carbonic acid, especially in the higher regions. It could also be easily imagined that the elevation of temperature produced by the gaslight, the increase of the carbonic acid, and the diminution of the oxygen in the air reached a much higher degree in confined working rooms than in a spacious, well-ventilated theatre. Considering that when the electric light was used such an increase of the local temperature could never take place as when gaslight was employed, and that in the latter case headaches referred to those parts of the head which were directly exposed to the influence of the rays of light, neuralgias, and local hyperæmias supervened; furthermore, that no carbonic acid was developed, and that no oxygen was consumed by the electric light; and lastly, that, although the electric light was very powerful, its intensity could be diminished by shades—it became evident that the more general adoption of the electric light would be very advantageous from the hygienic point of view.

GLASGOW.

[FROM OUR OWN CORRESPONDENT.]

Glasgow Sick Children's Hospital.—Glasgow Convalescent Home, Lenzie.—Glasgow Eye Infirmary.—Glasgow Asylum for the Blind.—Health of Glasgow in 1887.—Epidemic of Measles at Shotts.—Glasgow Medical Societies.—Glasgow and West of Scotland Branch of the British Medical Association.

The annual meeting of the Glasgow Sick Children's Hospital was held at Glasgow, on the 20th instant, under the presidency of the Lord Provost of the city. The report stated that it had been found necessary to provide increased accommodation, and for that purpose an adjoining building had been purchased, altered to suit the purposes of the hospital, at a cost of £17,000. This expense had been borne by the Chairman, Mr. Carlile, in recognition of whose generosity the ward had been called the Carlile Ward. The Chairman had also agreed to give £200 per annum for three years, for maintenance. The number of beds now available in

the institution was 70—32 for medical and 38 for surgical cases. During last year 470 patients had been admitted, compared with 453 during the previous year. The proportion of surgical cases was 53.4 per cent. No fewer than 205 operations have been performed, as compared with 134 the previous year. The average daily number under treatment was 5.7; the average duration of residence was 44.5. The percentage of deaths was 7, as compared with 7.6 the previous year. Deducting those cases in which death took place before the patient had been 24 hours in hospital, the rate was 6.4 per cent. The ordinary expenditure was £2,320 17s., being £210 in excess of income. A dispensary is at present being built in connection with the institution, at a cost of £2,867.

The twenty-third annual meeting of the subscribers to the Glasgow Convalescent Home, Lenzie, was held at Glasgow on the 17th inst. The report stated that 1,441 patients had been admitted to the Home during the year, as compared with 1,515 in 1886. The average stay had been 18 days. The ordinary expenditure had been £1,702 9s. 4d., which was equal to a cost of £1 4s. 5½d. per patient, or 1s. 4½d. per day, as against 1s. 3½d. in 1886, and 6s. 4½d. in 1885. The annual subscriptions amounted to £902, and the subscriptions from *employés* in works, etc., to £306, as against £254 the previous year.

The number of new cases admitted to the Glasgow Eye Infirmary in 1887 was 2,774, which, with 4,956 on the books at the close of the previous year, made a total of 14,730, as compared with 13,701 in 1886. At the date of December 31st last, of the total treated during the year, 5,506 remained on the books of the infirmary. The financial report showed an ordinary income of £2,532 17s. 11½d., and an ordinary expenditure of £2,804 8s. 11½d.

At the annual general meeting of the Glasgow Asylum for the Blind, held on the 15th inst., the report for 1887 was submitted. Here it appears that 161 blind persons had received the benefits of the institution last year. Employment had been provided for 129, who had earned as wages £2,550 12s. 3d. They also received special allowances to the total amount of £1 087. The sales for the past year amounted to £15,303, less by £767 than the previous year. This was due to the work being hindered by a recent fire. In the school there were 31 children.

Dr. Russell reports that in 1887 12,128 deaths were registered within the city, as compared with 13,039 in 1886, a decrease of 971. This represents a death-rate of 23, instead of 25, per 1,000 living. Comparing simply the absolute number of deaths, it was necessary to go back to 1862 to find a lower figure than that of last year. If the proportion of deaths to population were taken, Dr. Russell found that since the commencement of public registration in 1855, the death-rate in Glasgow had never been so low. Up to last year the lowest was that of 1879, when it was 24.6. The years 1887 and 1879 agreed in both being free from any grave prevalence of infectious disease, and especially in the absence of any severe epidemic of the infectious diseases of children, which nowadays was the chief cause in the oscillations of urban death-rates. Meteorologically the two years were very unlike; in 1879 a severe winter leading to a cold year, and in 1887 a moderate winter extending far into spring, followed by a summer of almost unprecedented warmth and drought.

Measles is prevalent in the district of Shotts, about sixteen miles from Glasgow. In one of the schools, out of 300 children, 200 have been attacked, and the school has been closed. A number of adults are also affected. The disease is said to be of a mild type.

At the last meeting of the Glasgow Obstetrical and Gynecological Society, Dr. Garnett Wilson showed an anencephalic foetus, and Dr. L. Oliphant introduced a discussion on pessaries.

The Glasgow and West of Scotland Branch of the British Medical Association held its annual meeting in the Sick Children's Hospital on January 12th, under the presidency of Dr. Joseph Coats. There was a large attendance. Dr. Finlayson showed cases of paralysis, of considerable interest; and Dr. Cameron showed some children with deformities produced by cancerous sores, on one of whom Eschschsch's operation for ankylosis of the jaw had been performed. Mr. Macneven showed a child from whose brain a small tumour had been removed for epilepsy with an entirely satisfactory result. He also showed a case in which considerable interest was manifested by the members. It was that of a boy with urethral stricture, the result of an injury. Dilatation not being permanently successful, Mr. Macneven decided to operate. He cut down on the site of stricture, and entirely removed that portion of the tube, stitching the separated ends of the tube together by means of catgut. The result was quite successful, the position of the operation being detected as a fine thread only when a large sized catheter was passed.

CORRESPONDENCE.

THE HENDON COW DISEASE.

SIR,—Kindly allow me to remove a wrong impression that must have been produced in the minds of some of those present at the last meeting of the Pathological Society by some expressions used by Dr. Crookshank.

Dr. Crookshank expressed great indignation at my having exhibited at that meeting, "without his permission," "his" calf, that is, the calf which he had exhibited at the extraordinary meeting on December 15th as being affected with alleged cow-pox. When I exhibited this same calf on January 17th it showed the same cow-pox, due to vaccination from a calf at the Animal Vaccine Station, Lamb's Conduit Street, on January 12th. Now, the fact of the matter is that this calf was not Dr. Crookshank's property. It belonged to Professor Brown, and had been sent, with other similar calves, by Professor Brown to the Animal Vaccine Station in order to be tested for their susceptibility to cow-pox. Professor Brown had said to Mr. Shirley Murphy and to myself that, short of killing, we might do with the calves as we pleased—I am, etc.,

E. KLEIN.

19, Earl's Court Square, S.W.

P.S.—I ought to mention that the above experiment of vaccination of the calf exhibited at the Pathological Society was performed by Dr. Cory, in the presence of Professor Brown and Dr. Crookshank; and that Dr. Crookshank had with me inspected the calf on three subsequent occasions.

INTRA-CAPSULAR INJECTION IN THE EXTRACTION OF CATARACT.

SIR,—In Dr. McKeown's recent letter on the above subject (*JOURNAL* for January 21st) elicited by your Annual Report on Ophthalmology (*JOURNAL* for December 31st) he again desires to compare results obtained by his method with results obtained by other methods, to the advantage of the former, and refers to a letter of his published in the *JOURNAL* of September 3rd last, in which he also drew this favourable comparison, and complains that your reviewer has taken no notice of that letter. But, although your reviewer took no notice of it, I felt bound to do so in a letter addressed to you, which appeared in the *JOURNAL* for September 17th last (see also *JOURNAL* for October 1st).

I there pointed out that, amongst the results of other surgeons quoted by Dr. McKeown in his letter as inferior to the results obtained by him with his method were those at the National Eye and Ear Infirmary of eleven and twelve years ago; and, as surgeon to the institution named, I protested against these statistics being employed for such a purpose. As Dr. McKeown now again refers to the same statistics with the same object, I must again protest against his doing so. Does Dr. McKeown mean to say that his method of intracapsular injection is the only improvement, if it be one, which has been made in the operation for cataract since the years 1875 and 1876; and that, if my colleague and I would operate now as we did then, with the addition of his intra-capsular injection, our successful results would be increased by 8 per cent.? Or, does he suppose that we abide by all the operative details of 1876, or would now be satisfied with the results then obtained? But if Dr. McKeown does go so far back for statistics with which to compare his own, why not then to a still more remote period? Very probably the results of operators, say, half a century ago, might show up the intra-capsular injection in a better light than those which he has selected.

I can only repeat what I said in my letter of September 17th, that it is with the methods and results of to-day that Dr. McKeown should compare his method and results, and not with those of 1876 and 1876. It may be replied that no statistics of cataract operations at the National Eye and Ear Infirmary have been published since then. That is so. But other surgeons and other institutions have published their recent cataract results, and I submit it is with the best of these that Dr. McKeown should compare his results, if he desires to place his method of intracapsular injection on a sure footing. A German friend of mine, who does not use this method, recently stated that in the 200 extractions he had performed by the peripheral linear operation in the previous year, he obtained a good result in every eye, and there are many other operators, at home and abroad, who could produce statistics almost, or quite, as good. How do Dr. McKeown's results compare with these?

Dr. McKeown's method may be a good one, but, I venture to think, he has not as yet shown it to be so. His communication at the last annual meeting, far from inspiring confidence in the method, had the

opposite effect, because his percentage of losses were greater than we expect in these days, and because (I speak from memory) those losses were due to events which are now rarely met with—for example, loss of vitreous, suppuration, irido-cyclitis.

Your editorial remarks at the foot of Dr. McKeown's late letter are substantially correct in respect of the objects with which Drs. Panas and de Wecker, to whose practice Dr. McKeown refers, employ intra-ocular injection. Dr. Panas uses it "de penser l'antisepsie jusque dans les profondeurs de l'œil." Dr. de Wecker's object is different. He uses injections into the anterior chamber "de provoquer, par la contraction de l'iris et son étalement régulier, une coaptation aussi exacte que possible de la plaie." If some cortical masses happen to come away with the injected fluid, well and good, but neither of these surgeons seem to wash the anterior chamber free of cortex after Dr. McKeown's method. Dr. de Wecker indeed distinctly states he does not irrigate the anterior chamber in this way, and disapproves of it. He sometimes injects a few drops of fluid into the anterior chamber in order the more readily to get rid of the cortical masses by a proceeding which Dr. McKeown condemns, namely, "avec la paupière inférieure appliquée sur la cornée." Indeed, neither in the object with which these two surgeons use intra-ocular injection, nor in the way in which they use it, does there seem to be much in common with Dr. McKeown's method.

I feel quite sure that Dr. McKeown wishes to introduce into ophthalmic surgery something of the value of which he is himself convinced. And I am also quite sure that any unfavourable criticism with which his proposal has met has been given from the point of view of men who, like himself, are aiming, so far as in them lies, at a high standard of excellence in their profession. I believe, moreover, that Dr. McKeown will readily allow that anyone who proposes a new method, especially a new operative method, in our highly cultivated speciality, must be prepared to submit his proposal to the cleansing fire of fair and reasonable criticism.—I am, etc.,

H. R. SWANZY.

23, Merrion Square, Dublin, January 24th, 1888.

ROYAL MEDICAL BENEVOLENT COLLEGE, EPSOM.

SIR,—The Right Hon. the Lord Mayor of London has promised to take the chair at the biennial festival of the Royal Medical Benevolent College on April 17th, at the Hôtel Métropole, in Northumberland Avenue. The Council of the Association will meet on April 18th. May I hope that as many as feel interested in the work carried on at Epsom College will favour us with their support, by allowing their names to appear as stewards. If those who do not as yet know how good the work is, either as regards the aged and distressed, or as regards the foundation scholars who are boarded, educated, and clothed, without any charge, will come to the dinner, they will learn how deserving of success the efforts of the Council are, and how urgently the institution is in need of funds.

I am particularly anxious that the members of the profession should be present in good numbers to show how they appreciate the kindness of the Lord Mayor, and of the sheriffs who will support him, in recognising the just claim of the profession on the public.

Gentlemen who are willing to act as stewards, or who desire tickets for the dinner, will kindly communicate with the Secretary, at the office, 37, Soho Square.—I am, etc.,

C. HOLMAN, M.D.,
Treasurer of Epsom College.

RECIPROCITY OF PRACTICE.

SIR,—The case of Mr. White (whose name must be familiar to all English visitors to Montreux) is an illustration of a widespread and increasing inconvenience and injustice.

Many Continental health-resorts owe their very existence to the English and American visitors who go there on the advice of their physicians at home, yet if these who have "helped make the place" venture to advise professionally their patients in their temporary home, they are subject to troublesome and sometimes very unfair restrictions.

I venture to think the time has arrived when there should be perfect reciprocity of practice for all duly qualified practitioners, whilst the law might be made more stringent as regards those who practise backed by no other qualification than their own audacity and presumption.—I am, etc.,

FRANCIS H. PARSONS.

The Hurst, West Worthing, January 14th.

DEGREES FOR MEDICAL STUDENTS: THE CLAIMS OF SCOTCH LICENTIATES.

SIR,—I beg to endorse fully the remarks of Mr. McFadyen, in the JOURNAL of January 21st, and to venture to press upon the Scotch Corporations the desirability of at once applying to the Privy Council for power to confer the degree of M.D. upon the gentlemen who have obtained, and are to obtain, the double qualification of those Colleges. They undoubtedly possess equal rights with their English neighbours on the Embankment, and should not delay a moment longer in seeking those privileges. They will then be able to steal a march on the universities; for, after their students have passed a qualifying examination for registration, as such, they will be able to proceed with their medical studies free from the cares of further examination in general education; and, at the end, after passing the usual examination required by the two Colleges, to assume the title of Doctor of Medicine. In the universities I find, on looking them up, that three of them actually require a man to go to the trouble of possessing a degree in Arts before he attempts to graduate as a simple M.B. London exacts a scientific examination, which entails a year of study before the student enters on his study of medicine, and after having obtained his certificate in general education. The Royal University of Ireland insists upon a preliminary examination; that passed, a year in Arts must be taken before he is allowed into the first University examination in Arts, and this takes place at the expiration of one year after passing the entrance examination known as Matriculation examination. Victoria requires a scientific examination after the preliminary, and, let us take Aberdeen, and see what it requires. I see by the Calendar that this university insists, first, on a knowledge of the subjects required by Edinburgh and Glasgow, and, before commencing medical studies, in at least two of the following subjects—Greek or modern languages, higher mathematics, etc.; and after all this, and four years of medical study, the student, if successful, finds himself only in possession of M.B. and C.M. He has then to wait two years in general or hospital practice, to write a thesis, and also to be examined again in one subject, such as Greek, modern languages, or moral philosophy; and, worse than all, I believe he has to pay £15 into the bargain in order to obtain the degree of M.D.

The new English method will have every advantage to recommend it.

1. A minimum of general education only is required.
2. A short course of only three, or perhaps at the most four, years of study only necessary.
3. The unnecessary worry and work connected with getting up the extra subjects in general education for the universities.
4. The fact of being able to add M.D. to one's name after the ordinary pass examination of the Colleges.

For these reasons, I strongly recommend the Edinburgh and Dublin Corporations to lose no time in asking for powers to enable them to raise the standard of the profession; and by so doing, to increase the value of their diplomas in the eyes of the public and the profession.—I am, etc.,

W. WYLIE.

Skipton, January 21st, 1888.

SIR,—Mr. McFadyen is not the only Edinburgh licentiate who has marvelled at the absence of action, or at least the absence of declared action, on the part of the Colleges. Would it not be possible to affiliate the Edinburgh Colleges with St. Andrews, just as Durham lately affiliated Newcastle? This would give the Edinburgh student an opportunity of obtaining the M.D. degree of one of the oldest universities in the country, and it would at one swoop raise the university to a real place among the medical institutions of Great Britain.

The one-portal system is, however, the real cure for the disease; and I think it was Professor Syme who sketched a plan something like the following: One board of examiners for the whole of the United Kingdom, sitting alternately in London, Edinburgh, and Dublin; the pass certificate to entitle the holder to practise medicine and surgery in any part of Her Majesty's dominions. Those who wished to practise pure medicine would take, in addition, the Fellowship of one of the Colleges of Physicians; those who wished to practise pure surgery, the Fellowship of one of the Colleges of Surgeons. All Fellowships to be obtained by examination only, and the licences and memberships to be abolished. The M.D. to remain as the blue ribbon of the profession. To place this within the reach of everyone, I would suggest that all universities should rescind their conditions as to residence, and that the London University should abolish its foolish restriction about attendance on classes between the passing of one examination and the appearance for another.

No doubt there would be many objections to this scheme, and many difficulties in the way; but then a scheme which has neither difficul-

A LECTURE on "The History and present position of the Germ Theory of Disease" will be delivered by Professor E. M. Crookshank, M.B., at the Parkes Museum, on Thursday, February 2nd, at 5 o'clock.

ties nor objections is not worth considering at all, and no one will deny that it would set the questions about qualifications and degrees at rest at once and for ever.—I am, etc.,
January 21st, 1888.

AN EDINBURGH MAN.

DEGREES FOR ENGLISH STUDENTS.

SIR,—May I be allowed to draw your attention to a statement in a leader in the JOURNAL of January 14th which may be liable to some misconstruction—a statement to the effect that the University of Durham gives its degrees "after a very moderate amount of evidence of preliminary education." As a matter of fact, four subjects at least are required in addition to and independently of those passed for registration as a student, and failure in any one of these entails rejection in all. The examination must be taken not earlier than six months after registration, and its standards, both as regards the extent of the subjects and the percentage of marks required, is much higher than that of the examination for registration, from which it is quite distinct.—I am, etc.,

W. P. MEARS.

University of Durham College of Medicine,
Newcastle-on-Tyne, January 24th.

SIR,—I should be glad if you would kindly allow me to make a few remarks on that passage in a leading article in the JOURNAL of the 14th inst. on which a correspondent from Aberdeen comments; I refer to the one which speaks of the preliminary education required by the Universities of Durham and Aberdeen. 1. Durham University does not admit candidates to the final examinations for degrees in medicine, unless they have passed certain examinations for degrees or otherwise in arts of a somewhat severer type than the ordinary preliminary examination required by the General Medical Council, without passing what is known at Durham as the "extra arts." Now the Senate at Durham allowed till lately candidates to pass an equivalent examination at any of the recognised Universities if they preferred it to the one held at Durham. Now Sir, it was found that the majority of candidates preferred to pass this "extra arts" examination north of the Tweed. In a matter of examination students would appear somewhat peculiar, since clearly if what Dr. Struthers says is correct, they prefer to pass a harder examination in a subject like general education, which would make no difference to their medical career, instead of an examination which is said to be so much easier. The next point; would you allow me to thank Dr. Struthers for the high compliment he has so unintentionally paid Durham when he points out that it is so different from Aberdeen, a point one has no wish to dispute, I can honestly say, as I am sure all *alumni* of Durham could also, that I would not exchange my Alma Mater for that of Aberdeen even were that privilege granted, in spite of what so unbiased an authority as Dr. Struthers of Aberdeen may say as to the merits of that University.—I am, yours, etc.,

DUNELM.

January 24th, 1888.

VEGETARIAN DINNERS FOR SCHOOL CHILDREN.

SIR,—The interesting article in your issue of the 7th inst., under the above heading, suggests an important and interesting inquiry as to the efficiency of the vegetarian dinners in comparison with "the mixed diets supplied, at equally low rates, to the school children in Birmingham," adding, "it does not appear that vegetarian dinners are more economical as to prime cost." I am glad to be able to throw a little light on this subject by extracting two sentences from a pamphlet entitled, "Cheap Dinners for School Children," containing reports of two conferences held in Manchester. At one of these conferences Mr. G. H. Sargent, the able exponent of the scheme of Farthing Dinners originated by him in Birmingham, was asked by the Rev. Joseph Burke, as to the nature of the dinners supplied, in the wards, "were they thoroughly vegetarian and free from all suspicion of animal taint?" To this, Mr. Sargent replied, "The food we give is not nominally vegetarian food, but something very much like it. I put a little animal food in the soup, because I am not a vegetarian myself; and I am afraid our Birmingham friends would not appreciate it if we tried to do without flesh meat. Sometimes a little dripping goes into the soup. It is not much, being, I should think, about half a pound to a hundred children." Much further information of a valuable character was given at these conferences, a record of all—or nearly all—the various efforts made to provide school children with cheap meals—whether on the mixed diet or vegetarian system—being contained in the paper by Mr. William A. Axon, F.R.S.L. It will give me pleasure to send to any of your readers who may be interested in the subject a copy of the report referred to, on receipt

of name and address. I might add that in Mr. Sargent's interesting pamphlet, "Farthing Dinners," are two recipes for soups, each for eleven gallons. The only animal food which enters into these recipes is "Dripping, 6 oz." and that in one recipe alone. In a former edition of the work containing six recipes (five for eleven gallons each, and one for twelve gallons), the animal food ingredients were:—

- A—None.
- B—Dripping, 6 oz. to $\frac{1}{2}$ lb.
- C—Dripping, 1lb.
- D—Meat scraps, 2lbs.
- E—Dripping, $\frac{1}{2}$ lb.
- F—Meat scraps, 2lbs.

That the recipes contain so small a proportion of animal food is the result of a significant experience which Mr. Sargent records. He says:—"The astonishing fact is, that the very poor, or at any rate their children, cannot and will not eat meat; and that the longer they have been on the verge of starvation, the less meat they can eat." These circumstances bring us face to face with the inevitable conclusion that in order to meet fairly the essential of cheapness in producing meals for poor school children, the meals must be practically of a vegetarian character, and that the flesh food used in such cases is in reality little more than a flavouring ingredient.—I am, etc.,

JOSEPH KNIGHT, Secretary of the Vegetarian Society.

75, Princess Street, Manchester, January 12th, 1888.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.

SIR,—As I was not permitted to make my remarks at the special meeting of the Governors of St. John's Hospital held at the Hôtel Métropole on January 18th, I will ask you to give me space in your JOURNAL, so that I may place before your readers a short summary of my action in this matter.

During the time I have been connected with this hospital, I have brought before the authorities several evidences of what I considered bad hospital management. Before I had been on the staff many weeks I objected to the manner in which the patients were admitted into my room, that is, those who contributed most towards the hospital were allowed priority of entrance. The board of management recognised this as unfair, and my patients have since been arranged in the order of their arrival.

I again objected to the sums of money which were collected from the out-patients, as much as five shillings being received for a week's treatment. This objection the board of management again accepted. I will here state it is my belief that the maximum sum now charged, namely, ten shillings a month for attendance as an out-patient of this or any other hospital, is in excess of what a charitable institution ought to ask for.

My next charge is against the nursing of the in-patients. It fell to my share to scrape away a quantity of scrofulous material from the neck and breast of a girl in the autumn of last year; the case required a good deal of special care. On November 19th I received a letter from Miss Ingleby (the matron), stating that she was leaving the hospital on the following day, and that the Secretary had asked her to instruct "the cook" in the dressing, so that she might undertake the case. This the matron objected to do. The Secretary also wrote to the Registrar on the same day, saying: "We shall be without a regular nurse for a few days. I wish you therefore to tell the dispenser that I shall want him, unless the doctor does the dressings, to be present to-morrow (Sunday) when cook dresses Miss K. (my patient), so that he may superintend the complete antisepticising of all dressings."

I replied that I was very much surprised and vexed by his action, and that I failed to see why my patient should be left without skilled nursing. I also added my request that no unskilled or untrained person should be allowed to dress my patient. I may be permitted to add that the dressing was done during the remainder of the stay of the patient in the hospital either by my assistant or myself. The matter came up at the next board meeting. I understand, on Mr. Milton being asked by the Treasurer what he thought of the cook's capacity as a nurse, he said "he considered the cook was quite as capable as Miss Ingleby."

As evidence of irregularity in the management, I may state that in *Whitaker* and the *Hospital Almanac* for this year it is stated that St. John's Hospital has "a matron and two nurses." At our meeting at the Hôtel Métropole a recital of this nursing episode was received with a shout of derision. It is an innovation to my mind that capable nursing is not one of the essential factors in hospital administration.

I pass over a great many subjects which have created friction be-

tween the board of management and myself, not wishing to trespass too much upon your space.

We heard a good deal at the meeting from the authorities of St. John's Hospital as to the advance of the institution, whereas, according to their report, the gross attendance in 1886 was 44,510, against a gross attendance for 1885 of 46,611.

The receipts for the year 1886 amounted to £3,295 5s. 6d., whilst in 1887 the sum was £3,074 17s. 4½d. A comparison of these two years will demonstrate that we have actually lost ground, so far as subscriptions and patients are concerned. Notwithstanding this, the expenso of management for 1887 was much increased.

It is now necessary to state that Drs. Campbell and Bourns and myself have been dismissed by the board of management because of our action, as detailed by us in a communication printed in the JOURNAL of December 31st, 1887. To be definite, it is necessary to state that Dr. Campbell received his *congé* before Dr. Bourns and myself.

The dismissal by the present board of management, or rather the majority of that board, is in no way objectionable to me. I have been congratulated by my professional friends more on this dismissal than I was on my election.

We ask for an independent committee of inquiry, which should have the power to probe all issues, and report thereon. This committee those now in power refused, and proposed a vote of confidence in themselves and by themselves, after a speech from one of themselves, Alderman Gould, which was the most offensive I have ever heard delivered before a public meeting. The vote of confidence was carried as an amendment to Mr. Raymond's resolution.

Here, Sir, the matter now rests. The present action of the board of management has resulted in the dismissal of three members of the staff, the resignation of a fourth (Dr. Harries), and two gentlemen who were recently appointed have since resigned. These facts alone are significant indications of the line of action taken and the results obtained.

The history of St. John's Hospital has been a stormy one. I am not in a position to affirm how many of our profession have joined the staff and afterwards left it. The sole survivors are Mr. Milton and Dr. Dow.

I cannot hide from myself the hope that this painful discussion will take the issues at stake before an unprejudiced tribunal. It is not a question of individuals; it is the question of the life of the hospital which is in the balance. Personally, I would express my conviction that it is only by restoring the confidence of the medical profession and the public in the equity of the management, that it is possible to hope or believe that St. John's has a prosperous future. This confidence can only be restored by a complete and full investigation of all matters connected therewith. For this investigation, I, and those who have acted with me, most earnestly ask; and surely, if a crisis such as the present one arises in the history of any hospital—a crisis which has eliminated the majority of the staff, which has caused three members of the board of management to act antagonistically to the remainder, we have some right to demand such an inquiry; and until this inquiry is granted, we shall be ceaseless in our endeavours to attain this result.

—I am, etc.,
T. ROBINSON, M.D.
9, Princes Street, Cavendish Square, W., January 24th.

THE ERGOSTAT AND LATERAL CURVATURE.

SIR,—My friend and colleague Mr. Freer, in the JOURNAL of January 21st, comments upon my suggestion that the ergostat may prove useful in some cases of lateral curvature of the spine, and were it not that he has entirely misunderstood the bearing of my letter, I should not have deemed it necessary to reply. It would appear from reading Mr. Freer's remarks that he imagines, because I speak approvingly of the ergostat that I think it will revolutionise the treatment of scoliosis, and, therefore, take a prominent place in the treatment of all cases of curvature of the spine, whether of a slight nature or in the existence of marked bony distortion. His introductory remarks, wherein he states that my views coincide so closely with his own, his knowledge of my practice at the hospital, and the valedictory address which I read before the Q. C. M. Soc., and which was afterwards published in the *Birmingham Medical Review*, prove that he is not warranted in arriving at that conclusion.

In my original letter I was careful to state that "amongst the various callisthenic exercises I recommend to patients suffering from lateral curvature of the spine is that which has received the appellation of the 'top-sawyer' movement." This was supplemented by the statement that I proposed the substitution of the ergostat for the elastic bands, etc., employed in this particular exercise. Having so written, how came Mr. Freer to conjure up in his own mind that I was about to advocate certain stereotyped measures, and would not, in the

future, study and treat cases upon their own special conditions. Another remarkable feature in the letter under consideration is that Mr. Freer obviously declines to criticise or raise any objection to the ergostat *per se*. He is, I know, a strong upholder of kinesipathy, and follows Dr. Mathias Roth, Mr. Bernard Roth, and the system of Swedish gymnastics in every particular. I append an example of one exercise from each of the above authors, and wish to point out that the muscles which are brought into action during the drill are exactly the same as those exerted in using the ergostat, the only difference being that in one case the medical attendant resists, and in the other the apparatus. I believe with Dr. Kjoelstad that the will-influence is very important in retaining the normal form; and as the revolution of the ergostat "must be executed very slowly," it gives ample time for the body to receive from the mind the desired impressions.

Exercise 1.—"Rack, crooked, thigh, opposite, clossa, standing, trunk, back, flexion (G. R.)" (Mathias Roth).

Exercise 2.—Forwards lying, heels fixed, trunk extension and flexion (Bernard Roth).

Exercise 3.—Hips firm. Trunk backwards and forward bend. (Ling's system).

I may conclude by saying I strongly deprecate any attempt, however slight, at stereotyped rules in the treatment of scoliosis; but at the same time consider the ergostat a wise addition to our armamentarium, and that when its use is properly supervised, it cannot be otherwise than useful.—I am, etc.,

AUGUSTUS CLAY,

Assistant Surgeon, Orthopædic and Spinal Hospital.

133, Steelhouse Lane, Birmingham.

A HOAX.

WESTERN SUBURB states that, on January 6th, a respectable looking woman, styling herself Mrs. Ferguson, called to engage his professional services to attend a young lady, the wife of Mr. Alfred Davis, a rich gentleman who had returned from Australia. Before leaving the consulting room, he writes, mention was made of fifteen hundred pounds having come to one of her little girls, which it was desirable should be settled on the child; could I recommend a solicitor to be depended on for drawing up a deed? I was induced to write an address on my card.

On arrival no such people were known at the residence, nor at the same number in Holland Villas Road. Nothing was stolen from my rooms, but thinking some trick was being played and a thief had called, I wrote at once to my solicitor to caution himself and staff. It was, however, too late, as legal advice had been taken in the meantime under the pretence of obtaining a divorce. It was said she had been a patient of mine for years, and I could substantiate the base falsehoods. The plausible tale and introduction given imposed on a kind gentleman, who offered legal opinion and granted a loan of thirty shillings.

I regret having to inform you the woman referred to is continuing her designs in the neighbourhood, and called on a surgeon on Thursday, January 19th, with a similar tale.

Nothing was stolen from the surgery nor from the solicitor introduced, although doubtless fraud was intended.

* * * The trick is a common one. The heaver is still at large.

REGISTRATION OF FOREIGN DEGREES.

J. HERD-WOOD, M.D. Edin., L.R.C.P. Edin. (Leatherhead) writes: I notice in a letter from Mr. William Donovan, on the registration of foreign degrees, the statements that "it is too absurd in this age to allow the monopoly in degrees to remain vested in a few old-fashioned universities, and that every legally qualified physician and surgeon should possess the right to the title of Doctor of Medicine."

Now, why should the medical profession, which is already low enough in the estimation of the general public, be the only one where the possession of money and time enough to graduate at a university bring no corresponding advantage, but that any man who is content or obliged to take the lower diplomas, as, for example, the L.R.C.P. Edin., should be allowed to usurp a title for which he has not worked, and call himself a Doctor of Medicine? Having passed both examinations, I can say with truth that it is too absurd to expect the one to take the same professional status as the other; as well might the man who has passed a preliminary in arts claim to be called M.A.

If the L.R.C.P.'s persist in claiming the title of Dr., I should suggest that it become usual for the one to be simply Dr. A. B., the other Dr. A. B., M.D., as with knights and baronets.

SOCIAL PROGRESS IN SPAIN.—The eminent statesman, Señor Canovas, has just completed the elaboration of a Bill to be brought before the Spanish Cortes, for the purpose of rendering employers of labour responsible for accidents to their workpeople, unless the same be due to the carelessness or recklessness of the latter. Employers will also be made responsible for accident resulting from the execution of orders given by their managers or foremen. If the workman be incapacitated from work, the employer will be required to pay him his wages until recovery takes place; and if the disability be of a permanent character, in addition to the cost of maintenance and attendance, he will have to pay an indemnity of from 600 to 1,000 days' wages. In case of death a like indemnity is to be paid to the family of the deceased workman. It may appear surprising that legislation of this kind should still remain to be done; but as a matter of fact, even in this country, the protection of the working classes against the accidents of their calling have only recently been undertaken.

NAVAL AND MILITARY MEDICAL SERVICES.

THE NAVY.

The following appointments have been made at the Admiralty:—SAMUEL JOHNSON, Surgeon, to the *Pembroke*; S. E. H. HOORS, to be Surgeon and Agent at Douglas, Isle of Man; WILLIAM J. COLBOURNE, Surgeon, to the *Excellent*; J. H. SPENHOUSE, Surgeon, to the *Boscawen*; JOSEPH A. MOON, Surgeon, to the *Excellent*; GEORGE WILSON, Surgeon, to the *Britannia*; D. J. P. M'NABB, Surgeon, to the *Impregnable*; JOHN E. WEBB, Surgeon, to the *Indus*; the last six additional, for disposal; GEORGE HEWLETT, Surgeon, to Plymouth Hospital; CHARLES S. WOODWRIGHT, Surgeon, to the *Asia*, additional; SAMUEL KEAYS, Surgeon, to Devonport Dockyard; CHARLES W. SHARPLE, Surgeon, to Plymouth Hospital; JOHN CASHIN, Surgeon, to the *Cambridge*; JOHN ANDREWS, M.D., to the *Mutineer*.

Fleet-Surgeon ALEXANDER McDONALD, M.D., died in London on January 14th at the age of 46. He entered the service December 8th, 1863; became Staff-Surgeon April 14th, 1877; and Fleet-Surgeon April 1st, 1884; he retired from the Navy September 2nd, 1884.

THE MEDICAL STAFF.

SURGEON-MAJOR GEORGE PERRY, of the Coldstream Guards, is promoted to be Brigade-Surgeon to the Brigade of Foot Guards, *vice* W. R. LANC, retired. Brigade-Surgeon PERRY entered the Army Medical Service as Assistant-Surgeon January 29th, 1855; became Surgeon March 1st, 1873, and Surgeon-Major February 26th, 1876. Beginning as Assistant-Surgeon 2nd Scots Fusiliers, he was soon afterwards transferred to the 1st Battalion, with which he remained till 1874, when he returned to the 2nd Battalion till November, 1878, when he was made Surgeon to the 2nd Coldstream Guards; in 1886 he joined the 1st Battalion, and now becomes Brigade-Surgeon. He served with the Scots Fusilier Guards in the Crimean war from June 16th, 1855, and was at the siege and fall of Sebastopol (medal with clasp, and Turkish medal). He was with the 2nd Coldstreams during the war in Egypt in 1882, and was in the actions at Tel-el-Mahuta, and Tel-el-Kebir (medal with clasp, and Egyptian bronze star).

Surgeon-Major C. S. CLOSE is promoted to be Brigade-Surgeon, ranking as Lieutenant-Colonel, *vice* H. C. HERBERT, M.D., F.R.C.S.L., retired. Brigade-Surgeon CLOSE entered the service as Assistant-Surgeon October 1st, 1862; became Surgeon March 1st, 1873, and Surgeon-Major April 25th, 1876. The *Army Lists* do not assign him any war service.

Surgeon-Major D. G. W. HEATHER is granted retired pay. His commissions are dated:—Assistant-Surgeon, October 1st, 1867; Surgeon, March 1st, 1873; and Surgeon-Major, October 1st, 1876. He was engaged in the Ashantee war in 1873-74 (medal), and in the Zulu war in 1879.

Surgeon S. L. DEERLE, who joined the service May 30th, 1855, is placed upon temporary half-pay on account of ill-health.

Surgeon S. H. CARTER, M.B., who is serving in Bengal, is appointed to the charge of the civil medical duties at Barrackpore, in addition to his other duties.

Surgeon-Major G. B. HICKSON, who is serving in Burma under the Madras Government, is appointed temporarily to the civil medical charge of the Toungoo district.

Surgeon H. E. DEANE, serving in the Bombay command, is transferred from the Presidency district to general duty Sind district.

INDIAN MEDICAL SERVICE.

SURGEON D. G. CRAWFORD, M.B., is appointed to act as Civil Surgeon of Backergunge, during the absence on deputation of Surgeon-Major C. J. W. MEADOWS.

Surgeon-Major A. BARCLAY, M.B., Bengal Establishment Secretary to the Surgeon-General with the Government of India, has leave of absence for one year on medical certificate.

Surgeon L. F. CHILDE, Bombay Establishment, is directed to officiate in medical charge of the 12th Native Infantry.

Surgeon G. E. FOGGA, Bombay Establishment, is ordered to officiate in medical charge of the 16th Native Infantry.

THE VOLUNTEERS.

SURGEON AND HONORARY SURGEON-MAJOR W. C. WISE, of the 2nd Kent Artillery, has resigned his commission, which dates from April 26th, 1877; he is allowed to retain his rank and uniform.

M. C. R. ELWOOD, M.D., is appointed Acting-Surgeon to the 1st Cinque Ports Rifles, and Mr. H. A. DES VERRS to the Queen's Westminster's.

SURGEONCY VACANT.

THE Senior Surgeoncy of the 22nd Middlesex Rifle Volunteers (Central London Bakers) has fallen vacant by the retirement of its Surgeon, after a lengthened term of service, and the commanding officer would have much pleasure in nominating a surgeon of suitable position for the commission who would be willing to undertake its duties. Further information is obtainable of the Adjutant, Head Quarters, 22nd Middlesex Rifle Volunteers, South Square, Gray's Inn.

INDIAN MEDICAL SERVICE: A WARNING.

INDIAN SERVICE writes: Considerable surprise has been excited in India by the announcement that 160 surgeons are to be immediately added to the Indian Medical Service, 45 being required for service in the Bombay Presidency. Though the annexation of Burma and the opening up of Baluchistan have necessitated the employment of extra surgeons, the number of new appointments mentioned far exceeds the requirements on these counts.

It would seem that some attempt to play off the Indian Service against the Medical Staff is contemplated. There is an erroneous impression that this "no rank" agitation has not degraded the Indian Service. The truth is that the position of a senior medical officer in a Native regiment has always been far from satisfactory. Though a regimental officer, he is junior to the last-joined probationer in the mess and at regimental entertainments. Men in civil employ are naturally not influenced by any regulations affecting the military service.

Our medical schools and intending candidates should be on their guard that men are not induced to enter the Indian service with a view of being employed in the place of Medical Staff men. Regarding the Indian Service I would strongly advise any European not to think of entering it unless he will powerful

interest. If a man wants a military career the Medical Staff is the only service he should think of. Few honours are given to Indian men, and not a single member of the Service has ever gained the Victoria Cross; a man can live on his pay in the British Service.

MEDICO-LEGAL AND MEDICO-ETHICAL.

"DOCTORS' BILLS."

SIR RICHARD HARRINGTON, County Court Judge, in his court held at Droitwich on January 11th, had before him two cases of interest to members of the medical profession. The plaintiffs were Messrs. S. Batten and E. Elliott, who formerly were in partnership as general practitioners. The actions were brought to recover sums due for medical attendance and medicine. In the first case, brought against a farmer named Arnold, the claim was for a sum of £2 5s. 6d. for professional attendance and medicine. The defendant had formerly been attended by Mr. Batten, before he entered into partnership with Mr. Elliott; and in the year 1884, soon after the commencement of the partnership, he paid him a sum of £12 16s., which he swore was in settlement of all sums due up to that date, while Mr. Batten stated that it was on account only of what was due to him before the partnership. The judge decided in favour of the defendant, and we cannot say that he was wrong, as it lay upon the plaintiff to prove his case; and, in the conflict of evidence which was presented to him, he might well hold that the plaintiff had failed to do this. He went on, however, to make comments on the claim, which, as he had already dismissed it, were quite unnecessary, but are nevertheless instructive. Part of the claim was for medicines supplied; and these had been charged for at the rate of 3s. 6d. per bottle, irrespective of the cost of the drugs used. The judge said that "the practice of surgeons charging for medicines in this way was unsatisfactory. A registered practitioner was entitled to charge for his attendance, and there was no reason for charging more than their value for medicines. The practice of so charging would not be allowed to stand in his court, and, if cases of this kind came before him, he should have to inquire into the cost of the drugs supplied." The practice thus condemned is one which no doubt is common, and in many cases has been found to be convenient; and it certainly has often come incidentally under the notice of judges of the High Court—especially in claims for personal injuries, where the cost of medical attendance is one of the items of the damages—without eliciting condemnation. As a matter, however, of strict law, where the "doctor's bill" is disputed, Sir Richard Harrington is apparently right. Where a medical practitioner supplies medicines, he does so not as a member of a learned profession, but as an apothecary; and, like other tradesmen, in the absence of an agreed price, he is only entitled to charge what is reasonably the value of his goods. In ascertaining that value, the liability of the goods to deteriorate through keeping, the skill of the dispenser, and other considerations which considerably enhance the price beyond that of the wholesale cost of the drugs used, must, of course, not be lost sight of; but they apply equally to medicines purchased at a chemist's shop, and a medical practitioner who supplies medicines cannot in law claim to make higher charges for them than would be paid to a chemist. It may be a hardship, in the case of patients who object to pay proper charges for visits, that the practitioner should be unable to make some extra profit from his medicines; but the law clearly will not enable him to recover such profit. It is well for those members of the profession who supply medicines to be aware of this fact, and to regulate their scale of fees and charges accordingly. A professional man may, in law, estimate the value of his personal services at any figure he likes, and may refuse to accept less for them than he considers due. If, however, he contemplates the necessity of having to sue for his fees, he must make his client know at the time what their amount will be, otherwise a court will be sure to hold that the only contract is to pay such fees as are usual, and award a much smaller sum than the plaintiff considers due. He may also, as a tradesman, charge what price he likes for his medicines, if he tells his customers of it at the time he supplies them, and so makes the price charged an agreed price. What the law will not sanction is a plaintiff putting a fancy price on his goods or his services after they have been given and when the defendant has no longer an option of declining to have them. If there has been no agreement, it is always open to a defendant to dispute the amount claimed from him, and courts in such cases must decide as best they can as to the amount really due, and often, no doubt, inflict considerable hardship on members of the medical profession in so doing.

In the second case, tried at the same court, the plaintiffs claimed payment from a Mr. Lamb for attendance on his grandchild in March

and April, 1884. The defendant denied having asked Mr. Batten to attend the child, whose parents would, of course, be the persons primarily liable to pay for such attendance; and Mr. Batten, though positive that he had been sent for by the defendant, was unable, after the lapse of four years, to remember the words of the conversation in which he was engaged. This failure of memory was quite natural, but it lost the case, for the judge had no option but to decide against a plaintiff who failed to prove what was necessary in order to support his action. The case is, no doubt, an example of what is constantly occurring. Medical practitioners, and other creditors too, are often reluctant to press a debtor of whose ultimate intention and ability to pay they have no doubt, and constantly omit to press their claim till it has become stale and the material facts are partly forgotten. Eventually they find, when too late, that their money is irrecoverable. We have often pointed out that promptitude, at any rate in sending in accounts, greatly improves the chance of enforcing their payment in case of need. We fear, however, that the practice of not asking for payment at the time debts are incurred is too firmly established to be easily altered. The fate of Messrs. Batten and Elliott ought to be a warning to the profession; but we doubt not that in the future, as in the past, we shall have from time to time to record instances where medical practitioners fail to recover their dues because they have delayed too long.

THE LETTER OF THE LAW.

Dr. T. writes: On going to see a patient of mine whom I had been attending regularly on the morning of December 26th, 1887, I was told a medical gentleman living about fifty doors from me had been called in during the night, and prescribed for the patient. I told the friends I could not see the patient. On returning home I found a letter awaiting me from the medical man in question, of which I send you a copy. I saw the patient at 9 P.M. the previous evening, and was at home until the morning. The patient is now being attended by this medical man. Your opinion on the professional etiquette of the case will be valued.

. Although a careful consideration of the several points involved in the respective notes of Dr. T. and Mr. S. leaves no doubt upon the mind that the latter erred in consenting to visit the patient in question, it is, we think, equally clear, from the courteous note of explanation spontaneously addressed by him to Dr. T. on the morning of the occurrence, that the proceedings arose not from deliberate purpose, but from a regrettable lack of moral courage and determination to resist the earnest entreaties of the apprehensive personal friend to return with him and see the "furiously delirious" patient.

At the same time, we cannot but think that Dr. T. is somewhat to blame in the case, in that, and notwithstanding that the patient was seriously ill and himself altogether blameless in the matter, he (Dr. T.), on paying his morning professional visit and hearing that another practitioner had seen him in the night, thereon refused to see him. Ere declining further attendance he should, in our opinion, have listened patiently to the reasons assigned by the family, and, sifting the alleged facts, have at once sought an explanation from Mr. S., which indeed, as admitted, he found "awaiting him on his return home," and which we are clearly of opinion that Dr. T. would have done well to accept. We apprehend, moreover, that the patient's intimate friend, and not the family, is especially responsible for the untoward incident by which our correspondent would appear to have lost a patient, and at the same time unheededly ignored the friendly spirit of a well disposed, though, mayhap, a somewhat irresolute brother practitioner.

RAISING THE FEES WITHOUT NOTICE.

A MEMBER writes: A. is a practitioner who is called in to attend a patient B. A. in due course renders his account and receives payment, but is asked by B. to specify his charge per visit in future, which A. accordingly does for some years, at a certain figure, practically a nominal sum for a patient in B.'s position. During a recent illness A. is asked to discontinue his attendance, and another practitioner is called in. Is it legal for A. to double his fee, which is still moderate, without first giving previous notice to B. to that effect?

B.'s solicitor asserts that there was an "implied contract" at the former charge, and that A. was not entitled to change the rate without previous notice to B.

Information regarding the above will be esteemed a favour.

. The solicitor's contention appears to be well founded. Unless A. can show that there was something in the nature of the illness, or of the attention demanded by the patient, to render the latter visits more valuable than the earlier ones, no court would be likely to award a larger fee in respect of them than that which A. demanded formerly. If it could be shown that the latter visits occupied twice as long as the earlier ones, or anything of that sort, it would be reasonable to ask for increased fees, but unless this can be done they would not be recoverable.

SOLICITORS' LIABILITY.

Dr. J. BAIN SINCOCK writes: Some two years since, a solicitor of this town consulted me respecting the death of a client of his whom I had attended; the question was whether his death could be ascribed to accident or natural causes. I gave my opinion advising the solicitor to compromise the matter with the office in which the man was insured, by accepting their offer. In February, 1887, I sent in my bill to the said solicitor, charging him one guinea for advice. He denied his liability. There the matter rested till last month, when, having

to pay the solicitor a small sum, I deducted the guinea. He refused to accept the amount I tendered him, and brought an action against me to the county court for the whole amount. There was no question of fact in dispute. On the point of law the judge decided that the plaintiff came to me as agent for his client, and consequently he was not personally liable.

If this is the law, I trust my experience may be of benefit to others. I have made up my mind not to trust a solicitor acting as agent again, unless I have written instructions from his principal.

I think, Sir, I have seen in the JOURNAL the report of a similar case, where the judge decided in favour of the medical man. If this is so, and you could help me to find the report of the case, I should feel much obliged.

. We have no reference to the report mentioned. Such cases turn on questions of fact, and not of law; and one decision would be no guide by which to determine another, unless the facts could be shown to be precisely similar. The law is clear, that the person liable is the one who employs the medical man. Who that person may be is a question of fact in each particular case. The only way to avoid disputes is to give no credit, or else to have a definite promise to pay, given at the time.

FORM OF AGREEMENT WITH ASSISTANT.

A.W.B. writes: There are two important objections to "the usual bond," so often required with assistants: first, that an assistant, if he have money at command, may find it to his advantage to pay the penalty and become an opponent to his former principal; secondly, that if the assistant be without means, he may break the bond and become bankrupt if the penalty be sued for, the bond being, *ipso facto*, null and void. This occurred in a case of which I know. Now the object of the principal is to prevent his assistant becoming a rival—not to get the penalty named in the bond.

A better way to attain this end seems to be that mentioned to me by a magistrate (not a lawyer). It is that an agreement be drawn up somewhat as follows:—

"A.B. hereby agrees to pay, and C.D. to accept, the sum of £— per month, on the following conditions, namely:

"First. That C.D. shall assist the said A.B. as he shall require in his practice as physician and surgeon by visiting patients, dispensing and, attending midwifery.

"Secondly. Such duties to terminate at any time by a month's notice on either side; and

"Thirdly. That the said C.D. shall not at any time, either during the time he is assisting A.B. or afterwards, whether for himself or for any other practitioner of medicine or person, act as physician, surgeon, or accoucheur, within a radius of five miles from the residence of A.B., at X—, except with the written consent of the said A.B.

"(Signed) A.B. and C.D."

If this agreement be broken the principal may, I am informed, obtain a perpetual injunction restraining the assistant from practising as a rival.

1. Would the above agreement be legally binding?
2. If so, would it be equally binding on an unqualified assistant?
3. What would be about the probable cost of obtaining an injunction?
4. Would a 6d. stamp be required?

. 1. and 2. Such an agreement as suggested, if properly drawn up, would be binding on the parties to it, and might be enforced against an unqualified assistant just as much as if he was properly qualified. There have been cases before the courts in which injunctions have been granted.

3. It is impossible to say beforehand what the cost of litigation would be. It is not necessarily an expensive process to obtain an injunction, but if the application be resisted costs will, of course, be increased.

4. A 6d. agreement stamp seems to be the one required.

ARE MEDICAL PRACTITIONERS "TRADERS"?

NON-TRADER writes: It may be interesting to some of your readers to know that a similar point arose a few years ago in a sister profession, in which it was held that a solicitor was a "trader," because it was proved that he was in the habit of making a profit on the parchments on which his deeds were engrossed. It appears, therefore, to be a question of fact whether medical practitioners care to make themselves "traders" or no.

. We agree with "Non-Trader" that the question whether or not any person has been carrying on a trade is one of fact rather than of law. As we have pointed out, its practical importance is now much less than it was formerly.

TOKELAU RINGWORM.—Tokelau ringworm is an inveterate form of body ringworm observed among the natives of the Pacific Islands; it was first identified by the late Dr. Tilbury Fox under the name of *tinea circinata tropica*. It spreads very extensively over the body, probably owing to the moist and warm climate, so that the whole of the skin, with the exception of that of the face and scalp, may be covered with wavy desquamating lines. Dr. Guppy states, in his interesting work on *The Solomon Islands and their Natives*, that sulphur ointment is used by the government agents on the labour ships, and that they report that when the remedy is thoroughly and systematically applied, the skin can be freed from the eruption before the ships reach Queensland or Fiji.

Dr. MURRELL'S *Massage as a Mode of Treatment* has been translated into French by Dr. Oscar Jennings, and will shortly be published with a preface by Dr. Dujardin-Beaumez, of Paris, under the title of *La Pratique du Massage*.

MEDICAL AID FOR THE WOMEN OF INDIA.—The third annual meeting of Lady Dufferin's Association will be held on February 8th, when steps will be taken to have the Association incorporated.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

THE TRUE DEATH-RATES OF LONDON DISTRICTS DURING THE FOURTH QUARTER OF 1887.

In the accompanying table will be found summarised the vital and mortal statistics of the 39 sanitary districts of the metropolis, based upon the Registrar-General's returns for the fourth quarter of last year. The mortality figures in the accompanying table relate to the deaths of persons actually belonging to the respective sanitary districts, and are the result of a complete system of distribution of deaths occurring in the institutions of London among the various sanitary districts in which the patients had previously resided. By this means the precise number of deaths of persons actually belonging to the respective sanitary districts is known, as all deaths occurring in institutions of persons who had previously resided in another district have been excluded from the total number of deaths in the district in which the institution is situated, and credited to the districts from which they came. By this means alone can trustworthy data be secured upon which to calculate reliable rates of mortality.

The births registered in London during the fourth quarter of 1887 were equal to an annual rate of 31.2 per 1000 of the population of the metropolis, estimated at 4,216,192 persons. In the corresponding periods of the three preceding years 1884-5-6, the London birth-rate was 33.3, 32.8, and 31.4 per 1000 respectively. The birth-rates in the various sanitary districts last quarter showed the usual wide variations,

the age and sex distribution of the population differing greatly. In Kennington, St. George Hanover Square, and St. James Westminster, where a large proportion of the population consists of unmarried females, chiefly domestic servants, the birth-rates were considerably below the average; while in Fulham, St. Luke's, Bethnal Green, and St. George-in-the-East, where the population contains a large proportion of young married persons, the birth-rates showed a marked excess.

The 20,732 deaths of persons belonging to London registered during the quarter under notice were equal to an annual rate of 19.7 per 1,000, which, though exceeding the exceptionally low rate recorded in the corresponding period of 1886, was considerably below the mean rate in the fourth quarter of the ten preceding years 1877-86. The lowest death-rates among the thirty-nine sanitary districts last quarter were 12.4 in Hampstead, 15.0 in Kensington, 15.3 in Plumstead, 16.1 in Paddington, and 16.7 in Hackney; in the other districts the rates ranged upwards to 26.3 in Fulham, 26.4 in St. George-in-the-East, 26.5 in Bethnal Green, 29.2 in St. Giles, and 29.7 in Holborn. During the quarter under notice 2,580 deaths resulted from the principal zymotic diseases in London; of these 828 were referred to whooping cough, 656 to scarlet fever, 328 to measles, 326 to diphtheria, 254 to different forms of "fever" (including 4 to typhus, 241 to enteric or typhoid fever, and 9 to ill-defined forms of fever), 185 to diarrhoea, and 3 to small-pox. These 2,580 deaths were equal to an annual rate of 2.5 per 1000, which slightly exceeded that recorded in the corresponding quarter of 1886. The lowest zymotic death-rates during the quarter under notice were recorded in Hampstead, London City, Paddington, Kensington, St. Martin-in-the-Fields, Marylebone, and Westminster, in each of which sanitary districts it was below 1 per 1,000. The zymotic death rate ranged upwards in the other districts to 3.7 in Holborn,

Analysis of the Vital and Mortal Statistics of the Sanitary Districts of the Metropolis, after complete distribution of Deaths occurring in Public Institutions, during the Fourth Quarter of 1887.

3.8 in Stepney and in Mile End Old Town, 3.9 in Fulham, 4.2 in St. Giles, and 4.3 in Bethnal Green. Compared with the preceding quarter the fatality of each of the principal zymotic diseases, except measles and diarrhoea, showed an increase. Only 3 deaths from small-pox were recorded in London during the last three months of 1886, of which 1 belonged to Paddington, 1 to St. Giles, and 1 to Lambeth sanitary districts. The number of small-pox patients in the Metropolitan Asylums Hospitals, which had been but 2 at the beginning of October, steadily increased to 15 before the end of November, after which it declined, and was 7 at the end of the year; the admissions were 30 during the quarter, against 7 in the preceding three months ending September last. Measles showed the highest proportional fatality in Bermondsey, Fulham, St. James Westminster, and Lewisham; scarlet fever in St. George Hanover Square, Bethnal Green, Rotherhithe, Stepney, St. Giles, Newington, St. Olave Southwark, Bermondsey, and St. George Southwark; diphtheria in Lambeth, Wandsworth, Hammersmith, Holborn, and St. Giles; whooping cough in Plumstead, Hammersmith, Islington, St. George-in-the-East, and enteric fever in Chelsea, Clerkenwell, and Strand. The number of scarlet fever patients in the Metropolitan Asylums Hospitals, which had been 1,596 at the beginning of October, had risen to 2,602 by the end of November, and afterwards steadily declined to 2,049 at the end of the year. The admissions to these hospitals of persons suffering from scarlet fever, which had been 531, 475, and 688 in the first three quarters of 1887, rose to 2,186 during the three months ending December last.

Infant mortality last quarter, measured by the proportion of deaths under one year of age to births registered, averaged 145 per 1,000, against 136, 135, and 144 in the corresponding period of the three preceding years, 1884-5-6. Among the various sanitary districts the rates of infant mortality were lowest in St. Martin-in-the-Fields, Plumstead, Hampstead, Hackney, and Wandsworth; whereas they showed the largest excess in Bethnal Green, St. James Westminster, Shoreditch Westminster, Stepney, St. Olave Southwark, and Holborn.

THE RECENT APPOINTMENT OF MEDICAL OFFICER FOR THE CALDICOTT DISTRICT OF CHEPSTOW UNION.

WE learn from the *Chepstow Weekly Advertiser*, and from other sources, that there has been a sharp fight for the appointment of District Medical Officer of the Caldicott portion of the Chepstow Union. The successful candidate, though non-resident, has held the position for twenty-seven years, having been subjected to triennial re-election. Recently a Mr. Slatters, who is described in the *Medical Register* and in the *Medical Directory* as M.R.C.S.E. only, being resident in the parish of Caldicott, has applied for the position, and at the election in the middle of December ran a tie with his opponent, which Mr. Slatter duly advertised in a letter of the 24th ultimo to the *Chepstow Advertiser*, in which this gentleman claims to possess a qualification in medicine and surgery, and as such of taking and holding a poor law appointment, though he very prudently subscribes himself as a Member of the College of Surgeons only. This time he failed to score so many votes as his antagonist had, viz., 31, whilst he had but 19—majority, 12. It should be known that the possessor of only one qualification cannot hold a poor law appointment however well qualified he may be in his own estimation to practise medicine and surgery, unless there is no doubly qualified gentleman resident within a reasonable district to be got, and then the nolder must be subjected to annual re-election.

DIPHThERIA AT ENFIELD.

AT the last meeting of the Enfield Local Board, a letter was read from the Local Government Board, requesting the Enfield Urban Sanitary Authority to instruct their medical officers of health to prepare a report upon the outbreak of diphtheria at Enfield, with a statement of the measures taken for checking the spread of the disease.

HEALTH OF ENGLISH TOWNS.—During the week ending Saturday, January 21st, 6,016 births and 4,145 deaths were registered in the twenty-eight large English towns, including London, which have an estimated population of 9,398,273 persons. The annual rate of mortality per 1,000 persons living in these towns, which had been 23.8 and 23.3 in the two preceding weeks, further declined during the week under notice to 23.0. The rates in the several towns ranged from 17.0 in Brighton, 18.1 in Hull, 18.2 in Bristol, and 18.5 in Oldham, to 25.3 in Nottingham, 25.5 in Plymouth, 26.3 in Manchester, and 28.8 in Portsmouth. The mean death-rate in the twenty-

seven provincial towns was 21.9 per 1,000, and was 2.5 below the rate recorded in London, which was 24.4 per 1,000. The 4,145 deaths registered during the week under notice in the twenty-eight towns included 481 which were referred to the principal zymotic diseases, against 493 and 476 in the two preceding weeks; of these, 195 resulted from whooping-cough, 35 from scarlet fever, 56 from measles, 50 from "fever" (principally enteric), 26 from diphtheria, 30 from small-pox, and 29 from diarrhoea. These 451 deaths were equal to an annual rate of 2.7 per 1,000; in London the zymotic death-rate was 3.1, while it averaged only 2.3 per 1,000 in the twenty-seven provincial towns, among which it ranged from 0.4 in Brighton and in Hull, to 5.0 in Nottingham, 5.5 in Bolton, and 6.3 in Sheffield. Measles caused the highest proportional fatality in Plymouth, Wolverhampton, Nottingham, Blackburn, Derby, and Bolton; scarlet fever in Derby, Blackburn, Bolton, Cardiff, Preston, and Birkenhead; and whooping-cough in Salford, London, Wolverhampton, and Leicester. The 36 deaths from diphtheria in the twenty-eight towns included 22 in London, 4 in Nottingham, and 3 in Liverpool. Of the 30 fatal cases of small-pox recorded during the week under notice in these towns, 25 occurred in Sheffield, 3 in Bristol, and 2 in Nottingham. The number of small-pox patients in the Metropolitan Asylums Hospitals was 5 on Saturday, January 21st, of which 1 was admitted during the week. These hospitals also contained 1,729 scarlet-fever patients on the same date, against numbers declining from 2,602 to 1,792 in the seven preceding weeks; there were 122 admissions during the week ending Saturday, January 21st. The death-rate from diseases of the respiratory organs in London was equal to 7.2 per 1,000, and slightly exceeded the average.

HEALTH OF SCOTCH TOWNS.—In the eight principal Scotch towns, 821 births and 588 deaths were registered during the week ending Saturday, January 21st. The annual rate of mortality in these towns, which had been 27.1 and 24.0 per 1,000 in the two preceding weeks, further declined during the week under notice to 23.3, but slightly exceeded the mean rate during the same period in the twenty-eight large English towns. Among these Scotch towns the lowest rates were recorded in Leith and Greenock, and the highest in Aberdeen and Dundee. The 588 deaths in these towns during the week under notice included 66 which were referred to the principal zymotic diseases, equal to an annual rate of 2.6 per 1,000, which almost corresponded with the mean zymotic death-rate during the week under notice in the large English towns. The highest zymotic rates were recorded in Aberdeen, Edinburgh, and Leith. The highest proportional fatality of whooping-cough occurred in Aberdeen and Glasgow; from measles in Edinburgh and Leith; and from "fever" in Edinburgh. Three deaths from diphtheria were recorded in Glasgow. The mortality from diseases of the respiratory organs during the week under notice in these towns was equal to 6.5 per 1,000, against 7.2 in London.

HEALTH OF IRISH TOWNS.—During the week ending Saturday, January 21st, 525 deaths were registered in the sixteen principal town districts of Ireland, equal to an annual rate of 31.4 per 1,000. The lowest rates were recorded in Armagh and Londonderry, and the highest in Limerick and Sligo. The death-rate from the principal zymotic diseases in these towns averaged 4.8 per 1,000, and was highest in Cork and Newry. Measles was fatally prevalent in Belfast, Cork, and Newry; and whooping-cough in Belfast. The 216 deaths registered in Dublin during the week under notice were equal to an annual rate of 31.9 per 1,000, which showed a further decline from the high rates recorded in recent weeks. The 216 deaths included 29 from the principal zymotic diseases (equal to a rate of 4.3 per 1,000), of which 8 were referred to "fever," 7 to scarlet-fever, 5 to whooping-cough, 4 to diarrhoea, 3 to diphtheria, and 2 to measles.

WORKHOUSE MASTERS AND MEDICAL OFFICERS.

A MEMBER writes: I am medical officer to a country workhouse, and wish very much to know how to act under the following circumstance:

1. I wish to make a *post-mortem* examination on a deceased pauper, who has no friend to object, but the master of the workhouse suggests that it is illegal, and shows me the regulations of the Local Government Board.
2. I take a pupil to see some cases at the workhouse; the master gives me a hint that the pupil cannot come without his leave.
3. An outside pauper proposes coming into the workhouse hospital in order that I may operate on him for cataract; but the master hints that no other surgeon can be admitted to help at the operation without the permission of the guardians.

How long will strife be permitted to continue between the master and the medical officer?

* * * As regards the first question, application should be made to the board for permission to make the *post-mortem* examination, pointing out that it is not the

province of the master to give or withhold his assent where a pauper dies without friends, but the board's only, and that it is customary for a board to permit a medical officer to do so.

Secondly. It is customary in almost every union that the medical officer be allowed to take his pupils with him when going round the infirmary.

Thirdly. It would be advisable to write to the board for the necessary permission, again stating what is the custom. Before writing to the board it would be well to see the chairman or some influential member of the board, and ask him to support the application.

OBITUARY.

SAMUEL HEY, F.R.C.S. ENG.

Is the death of this, one of the best known of her professional men, whether as a surgeon or a citizen, Leeds has sustained a heavy and enduring loss. Samuel Hey was the fourth link in a chain which has stretched in unbroken strength from 1759 till now, and which has bound together the name of Leeds and the practice of surgery in inseparable communion. To his predecessors in the surgical world Leeds owes much of the great surgical reputation which she enjoys all the world over, and in Mr. Samuel Hey they were followed by a not unworthy successor.

He was the son of the Rev. Samuel Hey, Vicar of Ockbrook, in Derbyshire, and grandson of "William Hey (Primus)," of Leeds, and was born on August 22nd, 1815. His mother was Margaret, daughter of Mr. William Gray, of York. His early education was of the ordinary character of the day, and from his twelfth to his sixteenth year was conducted by the Rev. Joseph Cox at Gainsborough. At the age of 16 he went to Leeds, and entered upon his professional career by pupillage under his uncle, William Hey (the second), and throughout his whole life he maintained that this was the most useful part of his professional education. His later training was conducted in London, and at University College and at St. George's Hospital he had the advantage of studying under Sir Benjamin Brodie, Sharpey, Cooper, and other of the men most distinguished in their day as physicians, and surgeons, and teachers. His London life over, he spent three further years in perfecting his education by attendance at the various schools and clinics of the highest reputation on the Continent, in Paris and in Germany; and he thereby acquired a knowledge of the French and German languages, both of which he spoke fairly well, and which proved of great value to him in after-life.

In or about 1840, he joined his cousin, William Hey (the third), in his practice, and therein became one of the best known men in the profession, in the town and country. At about the time at which Mr. Samuel Hey settled in Leeds, the subject of the institution of a medical school was taking form in the minds of his cousin and other leading men in the profession, such as Thackeray, Teale, Williamson, Price, and others, and into this project Mr. Samuel Hey entered with most lively satisfaction. He used to boast that he attended the first lecture formally delivered in the "Leeds School of Medicine," and in later life, as a lecturer on physiology—as one of the surgical staff of the infirmary, and as, in consequence, the teacher of surgery in the school—his interest in it as a Leeds institution never flagged; his best services were ever at its disposal, and for many years he acted as its treasurer.

In 1851 he was appointed surgeon to the infirmary, and in this capacity he will probably be best remembered by the many pupils to whom he endeared himself by the kindness and gentleness with which he fulfilled his duties—virtues which he also sought to impart to them and which he never failed to inculcate as among the highest attributes of a surgeon and a gentleman.

Those who knew him best, say a warm personal friend of the deceased, will remember how carefully and with how great a sense of responsibility he was wont to ponder over all his cases, whether in hospital or in private, and how earnestly he sought at all times to master them in their minutest details. Socially, Mr. Hey, in the days of his activity, loved nothing so much as entertaining his friends. To see his table well spread and surrounded by guests whom he delighted to honour was supreme happiness to him, and as a guest himself, on public occasions, the making of an after-dinner speech was unalloyed pleasure. In all the relations of life he was the soul of honour, and nothing caused him greater grief than the story of unworthy conduct or behaviour on the part of anyone with whom he had been connected. He was a sincerely religious man, and his religion was of a strictly practical and fruitful character.

Mr. Hey, who was 73 years of age, was twice married, and leaves four children—one son and three daughters.

WESLEY M. CARPENTER, M.D., NEW YORK.

We regret to notice the death of Dr. Wesley M. Carpenter, Professor of Clinical Medicine in the Medical Department of the University of New York. Dr. Carpenter was largely occupied in journalistic pursuits. The full report of the meeting of the International Medical Congress at Washington, published by the *New York Medical Record*, was prepared under his supervision. Dr. Carpenter was born at Erieville, New York, in 1839, and received his medical education at Ann Arbor University, Michigan, and at the College of Physicians and Surgeons, where he graduated in 1863. He established himself in New York in 1872, and soon after became connected with the Bellevue Hospital. He served the Pathological Society, the Academy of Medicine, the Practitioners Society of New York, and the Medical Society of the County of New York, in a secretarial capacity. He was the author of an *Index Medicus*, contributed to the *International Cyclopaedia*, and was the editor of the *Epitome of American Medicine and Surgery*.

Dr. Carpenter died very suddenly, of kidney disease. He went to bed, apparently in his usual health, on January 6th, and was found to be dead the following morning.

Dr. Carpenter had more than once visited Europe, and was well known in medical circles in London, where his intelligence, tact, and kindness were much appreciated. He was one of the ablest of the medical journalists of America, and dealt with difficult questions in a spirit which aimed at the best interests of medicine.

THOMAS GODART.

We regret to announce the death of Mr. Thomas Godart, late Librarian to St. Bartholomew's Hospital. Mr. Godart was known not only as an excellent performer of his official duties but also as a skilful artist. He assisted Mr. Luther Holden by engraving the lithographs for that surgeon's *Osteology*. The best samples of Mr. Godart's skill, however, were his coloured pathological drawings. We all know how unsatisfactory are the majority of productions of this kind, repulsive and un instructive even, if not displaying a sensational appearance savouring of quackery. Mr. Godart possessed the art of imitating the delicate though unpleasing shades of colour which are seen in diseased structures, with great faithfulness, therefore his drawings are of real service for purposes of instruction. Mr. Godart died on November 5th at Sydney, New South Wales, having left England on account of ill-health. Before leaving this country he received a testimonial, towards which a large number of past and present students of St. Bartholomew's Hospital contributed.

ROBERT RATHIERAM STILWELL, M.D.

Dr. STILWELL, of Beckenham, whose death it becomes our duty to announce, was the second son of the late Mr. George Stilwell, a general medical practitioner of Epsom. He was educated at the Tonbridge Grammar School, and subsequently entered Guy's Hospital, where he pursued his medical studies. He took his M.R.C.S. degree in 1856, and two years later passed the examination for M.D. at St. Andrews. In 1857 he commenced practice at Beckenham, where he resided up till his death. He was consulting medical officer of the Beckenham Cottage Hospital (which was founded at his suggestion), and divisional surgeon to the local police. Dr. Stilwell had a wide circle of attached friends, by whom his loss will be much felt.

INDIA AND THE COLONIES.

INDIA.

Dr. CHARLOTTE ELLAEBY, who, in conjunction with Dr. Edith Peckey has been doing such excellent work at the Cama Hospital, has left for Hyderabad, Sind, where the municipality is about to open a women's dispensary.

FEMALE MEDICAL AID TO THE WOMEN OF INDIA.—The first of the silver medals presented by His Excellency the Viceroy to the Countess of Dufferin's Fund for supplying female medical aid to the women of India, has been claimed by the authorities of the Grant Medical College, Bombay, for presentation to Miss B. Bradley, the most successful student during the past year at the first examination in the certificated practitioners class. Sir Walter de Souza, whose liberality has enabled many female students to study at the Calcutta Medical College, has placed a cheque for 2,400 rupees in the hands of the Central Committee, being his final donation to the De Souza Trust Fund, which has conferred so much good on scholars and sick in the Indian metropolis. A list of contributors to the Jubilee collection is being prepared for presentation to Her Majesty.

MEDICAL NEWS.

MEDICAL VACANCIES.

The following vacancies are announced:

- BELGRAVE HOSPITAL FOR CHILDREN**, 79, Gloucester Street, S.W.—House Surgeon. Applications by January 31st, to the Honorary Secretary.
- BIRKENHEAD BOROUGH HOSPITAL**.—Senior House-Surgeon. Salary, £90 per annum. Applications by January 30th, to the Chairman of the Weekly Board.
- BIRMINGHAM GENERAL HOSPITAL**.—Two Assistant House-Surgeons. Applications by January 28th, to the House Governor.
- BOURNEMOUTH FRIENDLY SOCIETIES MEDICAL ASSOCIATION**.—Resident Medical Officer. Salary, £200 per annum, with residence and fees. Applications to Mr. F. A. K. Hounseth, Trinity Chambers, Bournemouth.
- BRIGHTON, HOVE, AND PRESTON DISPENSARY**.—Two House-Surgeons. Salary, £140 per annum, with apartments, etc. Applications by January 31st to the Assistant Secretary.
- BRISTOL ROYAL INFIRMARY**.—Dental Surgeon. Applications by February 18th, to the Secretary.
- CLAPHAM GENERAL DISPENSARY**.—Medical Officer. Application by February 3rd, to the Honorary Secretary, 42, Manor Street, Clapham.
- DOWNPATRICK UNION**.—Medical Officer, Killyleagh Dispensary. Salary, £105 per annum and fees. Applications to Mr. James Heron, Tullyvery House, Honorary Secretary. Election on January 30th.
- DURHAM UNION**.—Medical Officer of Health. Salary, £100 per annum. Applications by February 3rd to the Clerk.
- FOREST HILL PROVIDENT DISPENSARY**.—Medical Officer. Applications by February 15th to F. J. Marriott, Esq., 2, Perry Villas, Perry Vale, Forest Hill, S.E.
- MENSTON ASYLUM**, near Leeds.—Medical Superintendent. Salary, £400 per annum, with board and residence. Applications by February 15th, to W. L. Williams, Esq., West Riding solicitor, Wakefield.
- NATIONAL DENTAL HOSPITAL**, Great Portland Street, W.—Anæsthetist. Applications by January 27th to the Secretary.
- NATIONAL DENTAL HOSPITAL**, Great Portland Street, W.—House-Surgeon. Applications by January 27th, to the Secretary.
- NORTH-WEST LONDON HOSPITAL**, Kentish Town Road.—Assistant-Physician. Applications by February 10th to the Secretary.
- ROYAL NATIONAL HOSPITAL FOR CONSUMPTION**, Ventnor.—Assistant Resident Medical Officer. Applications to the Secretary, 34, Craven Street, W.C.
- ROYAL SURREY COUNTY HOSPITAL**, Guildford.—House-Surgeon. Salary, £80 per annum, with board, etc. Applications by February 15th, to the Assistant Secretary.
- RUBERY HILL ASYLUM**, Bromsgrove, Worcester.—Clinical Assistant. Board and residence. Applications to Dr. Lyle.
- ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN**, Leicester Square.—Two Assistant Medical Officers, Applications by February 8th, to the Secretary.
- ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN**, Quay Street, Manchester.—Honorary Surgeon. Applications by February 10th, to the Chairman of the Board.
- WESTERN GENERAL DISPENSARY**, Marylebone Road, N.W.—Junior House-Surgeon. Salary, 60 guineas per annum, with residence. Applications by February 1st to the Secretary.
- YORK DISPENSARY**.—Three Resident Medical Officers. Salary, £130 per annum, with furnished apartments, etc. Application to T. W. North, Esq., Micklegate, York.

MEDICAL APPOINTMENTS.

- ARNOLD, F. S.**, M.B., M.R.C.S., appointed House-Surgeon to the Radcliffe Infirmary, Oxford, *vice* G. H. Redman, M.D., M.R.C.S., resigned.
- AVERILL, C. M.**, M.R.C.S., L.S.A., appointed Senior House-Surgeon to the Macclesfield Infirmary.
- BARTON, G. P.**, appointed Senior House-Surgeon to the Charing Cross Hospital.
- BEDFORD, C. H.**, M.B., C.M., appointed Resident Medical Officer to Gesto Hospital, Isle of Skye, for five months, *vice* Dr. McNeill, granted leave of absence.
- BENNETT, A. H.**, M.D. Edin., F.R.C.P. Lond., appointed Examiner in Practice of Physic to the University of Edinburgh, *vice* T. Barlow, M.D., F.R.C.P. Lond., whose term of office has expired.
- BURTON, Fred. W.**, M.R.C.S., L.R.C.P., appointed House-Physician to Addenbrooke's Hospital, Cambridge.
- CORDER, E. H.**, L.R.C.P., L.R.C.S. Edin., appointed Assistant Medical Officer to the Worcester Amalgamated Friendly Societies Medical Association.
- COURTEN, R.**, M.B., M.R.C.S. Eng., appointed Resident Medical Officer to the City of London Hospital for Diseases of the Chest, *vice* J. O. Harsant, M.B., B.S., resigned.
- CULLINOWORTH, C. J.**, M.D., M.R.C.P., appointed Obstetric Physician to St. Thomas's Hospital, *vice* H. Gervis, M.D., F.R.C.P., resigned.
- GOSSE, W.**, appointed Junior House-Surgeon to the Charing Cross Hospital.
- HART, D. B.**, M.D., F.R.C.P. Edin., appointed Examiner in Midwifery to the University of Edinburgh, *vice* J. H. Croen, M.D., F.R.C.P. Edin., whose term of office has expired.
- LARCOMBE, S. S.**, appointed Senior House-Physician to the Charing Cross Hospital.
- LINWOOD, E. H.**, appointed Resident Obstetrical Officer to the Charing Cross Hospital.

- PENROSE, F. O.**, M.D., M.R.C.S., appointed Curator of the Pathological Museum to St. George's Hospital, *vice* R. Sisley, M.B., M.R.C.S., resigned.
- PERKIN, W. H.**, iun., Ph.D., appointed Examiner in Chemistry to the University of Edinburgh, *vice* Dr. A. P. Aitken, whose term of office has expired.
- SNAPE, E. A.**, appointed Junior House-Physician to the Charing Cross Hospital.
- SWABY-SMITH, C.**, M.R.C.P. Ed., M.R.C.S., etc., appointed an Honorary Medical Officer to the Brixton Dispensary.
- TAYLOR, A. E.**, M.B., B.S. Lond., M.R.C.S. Eng., appointed Senior Surgeon to Out Patients at the Poplar Hospital for Accidents.
- THACKWELL, J. B.**, M.B. and C.M., appointed Medical Officer for the parish of Portul, Isle of Skye, *vice* Dr. Ross, deceased.
- WALKER, P. H.**, M.B., C.M., appointed Medical Officer and Public Vaccinator to the Faringdon Union, *vice* J. B. Miller, M.B., C.M., resigned.
- WELLS, A. P.**, L.R.C.P., L.M. Edin., appointed Medical Officer to the Bromley Union, No. 5 District, *vice* A. Piggott, L.R.C.P., L.M. Edin., deceased.
- WHITWELL, James Richard**, M.B. and C.M. Edin., Honours, appointed Pathologist to the South Yorkshire Asylum, Wadsley, near Sheffield.
- WYNNE, E. T.**, M.B., M.R.C.S., L.R.C.P., appointed Resident Clinical Assistant to the City of London Hospital for Diseases of the Chest.

BRITISH MEDICAL BENEVOLENT FUND.—The annual general meeting of subscribers to this fund was held on Thursday, January 12th, at the residence of the treasurer. The chair was taken by Dr. Jenson, Chairman of Committee, and the first business which came before the meeting was the election of a president, in place of Sir George Burrows, Bart., M.D., F.R.S., deceased. Dr. Broadbent, the Treasurer, proposed the election of Sir James Paget, Bart., F.R.S., an old subscriber and warm friend to the fund, and at the present time a vice-president and trustee. His distinguished advocacy of the claims of the fund, and the successful outcome of his exertions at the celebration of the Jubilee, on which occasion he presided at the banquet, would be fresh in the minds of subscribers, and the committee would find it difficult to select a better president. This was seconded by Mr. J. F. France, J.P., also a vice-president, and carried unanimously. The Treasurer then presented his financial report and the balance sheet for 1887, from which it appeared that in the donation department £704 6s. 6d. had been received, and as subscriptions £1,266 0s. 5d., together £1,970 6s. 11d.; while returned grants and other items made the income for the year £2,139 2s. On the other side, grants to 166 applicants had been made, amounting to £1,791 10s., and the expenses had reached the sum of £137. There was a larger balance than usual at the bank, accounted for by the fact that the last meeting of the committee had been held on December 21st, and also that some of the local secretaries had paid in their collections before the close of the year. In the annuity department the investments had realised £1,233 13s. 2d., and there was an item to be noticed in the payment of £5,000, duty free, by the executors of the late Sir Erasmus Wilson. The annuitants number 64, and the sum distributed amounted to £1,260, which distribution is carried out by the Chairman of Committee, Dr. Jenson, the cost being very trifling considering the large number of instalments. The Report of the Committee noticed that the fund had laboured under some disadvantage, owing to the fact that a special effort had been made during 1886, and also on account of the counter-attraction of Her Majesty's Jubilee. The income of the fund has thus somewhat fallen off, so that the money for disposal was often insufficient, but it was hoped that the subscriptions and donations during the coming year would show an increase, and maintain the average improvement which had taken place up to the present. In the committee, two vacancies had occurred which were filled by the election of Drs. M. Baines and Cooper Rose. It was a matter of regret that there had been no addition to the number of honorary local secretaries, a most useful portion of the machinery of this fund, as, by their means the committee is enabled to ascertain directly, and with the least amount of publicity, the *bona fides* of applicants in the country. Subscriptions to the fund to be specially noted, were £21 from Sir William Jenner, £200 from Mr. Wiater, of Brighton, £100 from "A. O. A.," £50 from the Faculty of Physicians and Surgeons, Glasgow, through Sir G. H. Macleod, £25 from John Morgan, Esq., £21 from Dr. Cumberbatch, £20 from Dr. Frank, of Cannes. The death of Sir George Burrows, President, was felt as a great loss to the fund, which he had joined as a Member of Committee in 1851, becoming Vice-President in 1859, and President in 1869, continuing to serve in that capacity until the date of his death, a period of eighteen years. The characteristics of this fund are—no institution, no salaries, no rent; the only expenses being those for printing and postage, and a small commission to a collector. Applicants have only to send in a form, authenticated by a subscriber, and two or three letters, one of which must have come from a medical man, when, if the case be otherwise suitable, a grant is made at once, and distributed either in one sum or by instalments, according to the judg-

ment of the committee; then, if the applicant's age be over 60, and his income low enough to justify it, the name is placed upon the list of candidates eligible for annuities, from which list annuitants are selected twice a year as vacancies occur.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly Court of Directors of this Society was held on Wednesday, January 11th, Mr. Tegart, V.P., in the chair. Two new members were elected, the deaths of five were reported, and the resignation of two others accepted. Grants were made to the amount of £1,402 10s., to 64 widows, 7 orphans, and 3 orphans on the Copland Fund. An application was read for a grant from a widow for herself and two children, and assistance was given. The expenses for the quarter were £61. A resolution was passed expressing the deep regret felt by the directors at the death of their late president, Sir George Burrows, and their grateful sense of the eminent services which he had rendered to the Society during 35 years in which he was a member of the Court, for 17 of which he was its president. The treasurer announced that the small sum of £10, left to the Society by its first secretary, Mr. Chamberlaine, now reached the desired amount of £100, and in accordance with the terms of the bequest, the interest would now be devoted to providing a frugal supper for the treasurer, auditors, and secretary, at the half-yearly audits.

OBSTETRICAL SOCIETY OF LONDON.—The following are the names of the officers recommended by the Council for election at the ensuing annual meeting of the Society on Wednesday, February 1st, at 8 p.m.: *President:* John Williams, M.D. *Vice-Presidents:* * F. H. Champneys, M.A., M.B.; W. F. Claveland, M.D.; Robert Cory, M.D.; C. J. Cullingworth, M.D., Manchester; W. Stephenson, M.D., Aberdeen; * J. Knowles Thornton, M.B., C.M. *Treasurer:* A. L. Galabin, M.A., M.D. *Chairman of the Board for the Examination of Midwives:* J. Watt Black, M.D. *Honorary Secretaries:* Percy Baulton, M.D.; * Alban Doran. *Honorary Librarian:* * Peter Horrocks, M.D. *Other Members of Council:* * R. Boxall, M.D.; J. Matthews Duncau, M.D., F.R.S.; * W. Duncan, M.D.; * A. T. Gibbings, M.D.; W. S. A. Griffith, M.B.; * F. B. Hallows, Redhill; * E. Hollings, M.D.; J. B. Hurry, M.D., Reading; Evan Jones, Aberdare; M. Handfield-Jones, M.D.; * A. E. Aust Lawrence, M.D., Clifton; A. H. N. Lewers, M.D.; G. Lowe, Burton-on-Trent; * O. C. Maurice, M.D., Reading; W. A. Meredith, M.B., C.M.; J. Phillips, B.A., M.B.; A. Roper; A. J. McC. Routh, M.D. Those gentlemen to whose names an asterisk is prefixed were not on the Council, or did not fill the same office last year.

METROPOLITAN HOSPITAL SUNDAY FUND.—A meeting of the Council of the Metropolitan Hospital Sunday Fund was held on Monday last at the Mansion House, under the presidency of the Lord Mayor. It was reported that the total amount available for distribution, after allowing sufficiently for liabilities and the annual current expenses, was £39,125. Of this total £37,525 was now recommended to 107 hospitals and 50 dispensaries. Four per cent. of the total collected (£1,600) had been set apart for the purchase of surgical appliances. The committee acknowledged with thanks the receipt from Mr. Hankey of a cheque for £200, being a further donation to the funds of the institution. The retiring members of the various committees, together with the officers of the fund, were then duly re-elected.

THE SMALL-POX EPIDEMIC AT SHEFFIELD.—At a meeting of the guardians of the Sheffield Union held on Monday last, it was decided to appoint a number of assistant officers to make a house-to-house visitation with the view of ascertaining the number of vaccinated and revaccinated persons, and of persuading people to take all precautions to prevent the spread of the disease. Arrangements were made for the medical officers to attend at their respective centres as often as possible, and in every way to facilitate revaccination. Similar steps will be taken in the Ecclesall Union.

THE METROPOLITAN HOSPITAL.—At the annual meeting of this charity, held on Monday last, reference was made to the great success which had attended the provident department of the hospital since it had been opened in November last. In three months upwards of 300 books had been issued, representing, in round numbers, 1,400 lives. The new hospital affords accommodation for 160 beds, of which 40, placed in a separate block, will be reserved for members of Jewish persuasion. An appeal is being made for funds towards the £10,000 required annually to carry on the work of the charity.

PRIZE ESSAYS ON MEDICO-LEGAL SUBJECTS.—The Medico-Legal Society of New York announces three prizes of the value of 100, 75, and 50 dollars respectively, for the three best essays on any subject within the domain of medical jurisprudence or forensic medicine. The essays are to be sent to the President of the Society by April 1st, with a motto, the author's name being sent under separate cover. Candi-

dates are required to join the society as honorary, corresponding, or active members. Further particulars may be obtained from the President, Clark Bell, Esq., 57, Broadway, New York.

THE EXTERMINATION OF RABBITS.—M. Pasteur's plan of exterminating rabbits by the spread of fowl cholera has been tried in a walled field near Rheims, where both gun and ferrat had proved ineffectual. M. Loir, nephew of M. Pasteur, went down and poured on a truss of hay some broth full of the microbes of chicken cholera. The next day nineteen dead rabbits were found, and two days later twelve more. In some of the burrows were discovered families of dead rabbits, and not one living rabbit has since been seen.

FIFTH CONGRESS OF POLISH PHYSICIANS AND MEN OF SCIENCE AT LEMBERG.—Towards the end of May, 1888, the Fifth Congress of Polish Physicians and Natural Scientists, together with a medico-hygienic and scientific exhibition, will take place at Lemberg.

NEW TEACHERS IN THE VIENNA MEDICAL FACULTY.—The following *Docentes* have recently been appointed: Drs. Nensser (Medicine); Hochstetter (Anatomy); Kolisko and Paltanof (Pathological Anatomy); Ehrmann (Dermatology and Syphilis); v. Hacker (Surgery); Unger and Fröhwald (Diseases of Children).

THE "holiday colonies" organised by the municipal authorities of Paris have already led to some interesting observations as to the growth of children. The girls gained on the average 2 and the boys 1½ kilogrammes in weight. They continued to increase in weight at a still greater rate for about a month after their return. The boys gained on the average 2 centimètres in chest-girth.

THE will of Mr. John George French, F.R.C.S. Eng., of Cunningham Place, St. John's Wood, has been proved, the personalty being upwards of £24,000.

CHARLES COUPER CRIPPS, M.D., B.S., M.R.C.S., has been awarded the gold medal for the best essay presented at the examinations for the degree of Doctor in Medicine of the University of Durham during the year 1887.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.

MEDICAL SOCIETY OF LONDON, 8.30 p.m.—Lectures by Mr. Reginald Harrison. Lecture III: The Operative Treatment of Stone and Tumours of the Bladder in Relation to some recent Views and Practices.

THURSDAY.

PAKES MUSEUM, 5 p.m.—Professor E. M. Crookshank: The History and Present Position of the Germ Theory of Disease.

FRIDAY.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, 8.30 p.m.—Patients and specimens at 8 p.m. Mr. Percy Dunn: 1. Large Hydatid Cyst of Liver. 2. Secondary Deposit of Scirrhus in Liver. 3. Metastatic Abscess in Liver. Mr. C. R. B. Kettleby (President) will show two cases of Nerve Suture. Dr. Herringham will show a case of Peripheral Neuritis. Papers.—Dr. Richard Paramore: On Insomnia. Mr. Jonathan Hutchinson, jun.: Syphilitic Disease of the Liver and Spleen and its Symptoms.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the announcement.

BIRTHS.

FLETCHER.—January 20th, 1888, at Bathwick, Uttoxeter, the wife of W. H. Fletcher, L.R.C.P., L.R.C.S., L.S.A., L.M., of a son.
MYDDLETON-GAVEY.—On the 24th inst., at 64, St. Matthew's Street, Ipswich, the wife of E. H. Myddleton-Gavey, M.R.C.S. Eng., of a son.

MARRIAGES.

HERRING—RISHOP.—On January 25th, at St. Mary's Church, Atherstone, by Rev. James Edwards, John F. Herring, L.R.C.P., L.R.C.S. Edin., C.San. Sci. Cantab., to Hettle, eldest daughter of the late William Bishop, Esq., of Atherstone.
SPROTT—ARMITAGE.—On the 24th inst., at Pendleton, Manchester, by the Rev. J. W. Kiddle, assisted by the Rev. Herward J. Snell, M.A., B.Sc., W. J. Sprott, M.D., of Beeston, Nottingham, and Bromore, County Down, to Helen Corina, younger daughter of Benjamin Armitage, Esq., of Choulea, Pendleton.

DEATHS.

BOOKEY.—On the 11th inst., at the Terrace, Devonport, William John Brownrigg Bookey, Surgeon R.N., aged 36, Resident Medical Officer of H.M. Dockyard, Devonport.
MARSH.—On the 18th inst., at 15, Fitzroy Square, London, W., Lory Marsh, M.D. M.R.C.P., of 49, Sackville Road, Hove, Brighton, aged 64 years.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY --- 10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's (Ophthalmic Department); and Royal Westminster Ophthalmic.—2 P.M.: Metropolitan Free; St. Mark's; Central London Ophthalmic; Royal Orthopaedic; and Hospital for Women.—2.30 P.M.: Chelsea Hospital for Women.

TUESDAY --- 0 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's; St. Bartholomew's (Ophthalmic Department); St. Mary's; Royal Westminster Ophthalmic.—2 P.M.: Westminster; St. Mark's; Central London Ophthalmic.—2.30 P.M.: West London; Cancer Hospital, Brompton.—4 P.M.: St. Thomas's (Ophthalmic Department).

WEDNESDAY --- 10 A.M.: National Orthopaedic.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: Middlesex.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: London; University College; Westminster; Great Northern Central; Central London Ophthalmic.—2.30 P.M.: Samaritan Free Hospital for Women and Children; St. Peter's.—8 to 4 P.M.: King's College.

THURSDAY --- 10.30 A.M.: Royal London Ophthalmic.—1 P.M.: St. George's.—1.30 P.M.: St. Bartholomew's (Ophthalmic Department); Guy's (Ophthalmic Department); Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Central London Ophthalmic; Hospital for Diseases of the Throat; Hospital for Women.—2.30 P.M.: North-west London; Chelsea Hospital for Women.

FRIDAY --- 9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.15 P.M.: St. George's (Ophthalmic Department).—1.30 P.M.: Guy's; Royal Westminster Ophthalmic.—2 P.M.: King's College; St. Thomas's (Ophthalmic Department); Central London Ophthalmic; Royal South London Ophthalmic; East London Hospital for Children.—2.30 P.M.: West London.

SATURDAY --- 9 A.M.: Royal Free.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: King's College.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Middlesex; Royal Free; Central London Ophthalmic.—2.30 P.M.: Cancer Hospital, Brompton.

HOURS OF ATTENDANCE AT THE LONDON HOSPITALS.

CHARING CROSS.—Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; Skin, M. Th., 1.30; Dental, M. W. F., 9.

GUY'S.—Medical and Surgical, daily, 1.30; Obstetric, M. Tu. F., 1.30; Eye, M. Tu. Th. F., 1.30; Ear, Tu. F., 12.30; Skin, Tu., 12.30; Dental, Tu. Th. F., 12.

KING'S COLLEGE.—Medical, daily, 2; Surgical, daily, 1.30; Obstetric, Tu. Th. S., 2; o.p., M. W. F., 12.30; Eye, M. Th., 1; Ophthalmic Department, W., 1; Ear, Th., 2; Skin, Th.; Throat, Th., 3; Dental, Tu. F., 10.

LONDON.—Medical, daily, exc. S., 2; Surgical, daily, 1.30 and 2; Obstetric, M. Th., 1.30; o.p. W. S., 9; Eye, W. S., 9; Ear, S., 9.30; Skin, Th., 9; Dental, Tu., 9.

MIDDLESEX.—Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; o.p. W. S., 1.30; Eye, W. S., 3.30; Ear and Throat, Tu., 9; Skin, Tu., 4; Dental, daily, 9.

ST. BARTHOLOMEW'S.—Medical and Surgical, daily, 1.30; Obstetric, Tu. Th. S., 2; o.p. W. S., 9; Eye, Tu. Th. S., 2.30; Ear, Tu. F., 2; Skin, F., 1.30; Larynx, F., 2.30; Orthopaedic, M., 2.30; Dental, Tu. F., 9.

ST. GEORGE'S.—Medical and Surgical, M. Tu. F. S., 1; Obstetric, Tu. S., 1; o.p., Th., 2; Eye, W. S., 2; Ear, Tu., 2; Skin, W., 2; Throat, Th., 2; Orthopaedic, W., 2; Dental, Tu. S., 9; Th., 1.

ST. MARY'S.—Medical and Surgical, daily, 1.45; Obstetric, Tu. F., 1.45; o.p., M. Th., 1.30; Eye, Tu. F. S., 9; Ear, M. Th., 3; Throat, Tu. F., 1.30; Skin, M. Th., 9.30; Electrician, Tu. F., 2; Dental, W. S., 9.30; Consultations, M., 2.30; Operations, Tu., 1.30; Ophthalmic Operations, F., 9.

ST. THOMAS'S.—Medical and Surgical, daily, except Sat., 2; Obstetric, M. Th., 2; o.p., W., 1.30; Eye, M. Th., 2; o.p., daily, except Sat., 1.30; Ear, M., 12.30; Skin, W., 12.30; Throat, Tu. F., 1.30; Children, S., 12.30; Dental, Tu. F., 10.

UNIVERSITY COLLEGE.—Medical and Surgical, daily, 1 to 2; Obstetrics, M. Tu. Th., F., 1.30; Eye, M. Tu. Th. F., 2; Ear, S., 1.30; Skin, W., 1.45 S., 9.15; Throat, Th., 2.30; Dental, W., 10.30.

WESTMINSTER.—Medical and Surgical, daily, 1.40; Obstetric, Tu. F., 3; Eye, M. Th., 2.30; Ear, M., 9; Skin, Th., 1; Dental, W. S., 9.15.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS respecting editorial matters should be addressed to the Editor, 429, Strand, W.O., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.O., London.

IN order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the office of the JOURNAL, and not to his private house.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL, are requested to communicate beforehand with the Manager, 429, Strand, W.O.

CORRESPONDENTS who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication. CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

TO CORRESPONDENTS.

OUR correspondents are reminded that prolixity is a great bar to publication, and, with the constant pressure upon every department of the JOURNAL, brevity of style and conciseness of statement greatly facilitate early insertion. We are compelled to return and hold over a great number of communications, chiefly by reason of their unnecessary length.

QUERIES.

CAUSE OF LEAD-POISONING.

M.O.H. writes: I should be glad if any of the readers of the JOURNAL could give information as to the likely source of plumbism in a rural district. Adults affected. Water free from lead. Home-made wines, etc., not used in many cases. Beer in only one instance was found to contain lead. Articles of consumption, such as bread, tea, etc., etc., from different vendors. More men are affected than women, and to a greater extent. In no case is there any apparent cause.

AMBULANCE LECTURES TO LADIES.

M.D. has been asked to give a course of ambulance lectures to a class of ladies, and would be glad to have a list of the works recommended for reference, guidance, and textbooks.

* The best books for a ladies' ambulance class are: *First Aid to the Injured*, translated from the German by H.R.H. Princess Christian; *Accidental Injuries*, by James Cantlie.

M.D. DEGREE WANTED.

GOVERNMENT MEDICAL OFFICER writes: I am a Licentiate of the Royal Colleges of Physicians and Surgeons of Edinburgh, of five years' standing; at present holding an appointment in one of Her Majesty's colonies, and intend proceeding home to England this year on one year's leave.

I am desirous of obtaining a British university degree (M.D., if possible). Can I do so in the time (one year)? Perhaps some of your readers would inform me, if so, what universities, and under what conditions? I should be willing to put in one year's residence.

SPRAY DIFFUSER.

W.R.M. asks to be recommended a spray diffuser for disinfecting air in hospital wards, to be constantly going.

SOFTENING WATER.

DR. S. T. GWYNN (Whitchurch, Salop) asks whether there is any process by which the water supply of a moderately large house in the country can be softened, as it is done by Clarke's method on a large scale?

HAIR-WASH.

MEMBER asks for a prescription for a hair-wash for falling out of hair after scarlet fever.

ANSWERS.

ROMAN CATHOLIC BOARDING SCHOOL.

We are informed that M.S.C. may obtain all the information he requires by communicating with M.A., Chester House, Cambridge.

F.R.C.S. EDIN.

IN reply to a correspondent who asked what were the best books to be read for the final examination of the Fellowship of the Royal College of Surgeons of Edinburgh, Mr. R. Deinson Pedley recommends for the general subjects Erichsen's *Surgery*, Cornil and Ranvier's *Pathology*, Quain's or Gray's *Anatomy*, Heath's *Operative Surgery*. For the special subjects, he must choose for himself. Another correspondent prefers Bell's *Operative Surgery*, MacLachlan's *Surgical Anatomy*, Treves's *Surgery*. Optional subject, if medicine, Carter's *Medicine*.

M. PASTEUR'S TREATMENT OF HYDROPHOBIA.

T.M.R. asks where he can obtain the best authoritative details of the experiments conducted by Pasteur, and his deductions therefrom on the subject of rabies, with a view to preparing a paper to be read at a Natural Science Society.

* In preparing such a paper, our correspondent would do well to make himself acquainted with M. Pasteur's previous work in the same direction. This may be conveniently studied in the article "Attenuation," prepared by Dr. Dawson Williams, for Mr. Watson Cheyue's *Micro-Parasites in Disease* (New Sydenham Society, 1886). This article contains the earlier work on hydrophobia. The report of the Committee on Hydrophobia, appointed by the Local Government Board, contains a review of M. Pasteur's investigations on hydrophobia, with statistics to a later date.

NOTES, LETTERS, ETC.

HERMAPHRODITISM OR HYPOSPADIAS.

WILLIAM TIBBLES, L.R.C.P., L.S.A., L.M., M.O.H. (Nottingham) writes: I have read with interest the case of hermaphroditism, reported in the JOURNAL of January 14th, p. 91, and doubt whether the being so described is a true hermaphrodite, as I am sceptical as to the existence of such freaks of Nature in the human species. A true hermaphrodite would possess the organs of generation of both sexes—would, in fact, be bi-sexual, having a penis and testicles capable of secreting a fertile semen containing spermatozoa; and also possessing a vagina, uterus, and ovaries discharging ova capable of fecundation. I am inclined to the belief that reported cases of hermaphroditism are hypospadias of various extent, and fail to see in the report any evidence that Dr. Lukomsky's case was any other than an aggravated case of that description. But what evidence of the female sex does Dr. Lukomsky report? Merely an opening in the perineum, which corresponds to the vagina, with a short urethra, the lips of the opening corresponding to the labia minora and majora. But have the ovaries and uterus been made out? Has "she" ever menstruated? Has "she" a female pelvis, or well developed breasts? There is no positive evidence of these feminine characteristics; and the mere existence of a perineal opening is not physiological evidence of the

female sex. But, on the contrary, such an opening must exist in males in certain cases of hypospadias, for normally in the male the genital furrow and folds close at the third or fourth month of fetal life to form the spongy portion of the urethra and the scrotum; but in the female they remain open and form the orifice of the vagina and the labia majora and minora. If, therefore, a male be undeveloped and left in the condition of hypospadias, if the furrow does not develop to form the spongy urethra, and the urethra stops short at the membranous portion, there is of necessity a cleft involving to a greater or less extent a separation of the lateral halves of the urethra and scrotum, or even perineum, and giving rise to an appearance resembling the vulva. Is this the condition of Dr. Lukomsky's case?

On the other hand, what are the evidences of the male sex and of hypospadias? 1. A penis, small, without urethra or urethral orifice. 2. Complete erection of penis during sexual excitement. 3. Two testicles of size of pigeon's eggs in scrotum. 4. During coition with women a whitish fluid is ejaculated through the vaginal (perineal) slit. 5. Other evidences of male sex: Powerfully built; absence of rounded contour seen in women; hair on lip and chin; voice rough and deep; Adam's apple prominent; ill-developed breasts; male configuration of pelvis; absence of menstruation; fondness for male occupations. The closure or non-closure of the median raphe must be a source of great perplexity in hypospadias, for the male organs must of necessity closely resemble those of a female, the smallness of the penis and the absence of the penile urethra, especially if the halves of the urethra and scrotum be separated, adding to the difficulty. In any such case, a search per rectum should be made for the ovaries and uterus, and confirmed by means of uterine sound, for these, of course, if found, are positive proof of the feminine qualities. In Dr. Lukomsky's case no such examination is reported, and their absence is negative evidence of the female part of the "being."

On the other hand, we have positive evidence of the male sex in the existence in the scrotum of two testicles, whose function appears to be active, even if imperfect, as proved by the ejaculation of a whitish fluid per urethram during coition with women.

The existence of a perineal opening is not, to my mind, positive evidence of either one sex or the other, and, apart from that fact, the evidences of the male sex preponderate.

A similar case was reported in the JOURNAL of July 9th, 1887, under the title of "A Sexless Being," which I at the time considered was a case of hypospadias, but not having the JOURNAL at hand I cannot just now refer to it.

SUNSHINE AT UNDERCLIFF (ISLE OF WIGHT) AND KEW IN 1887.
MR. J. B. MARTIN (VENTNOR) SENDS US THE FOLLOWING:

Monthly Summary of Clear Sunshine at the Undercliff, Compared with the Record of Kew during 1887.

	Undercliff.		Kew.	
	Hrs.	Ms.	Hrs.	Ms.
January	52	35	35	—
February	52	10	43	30
March	184	33	125	—
April	231	25	157	—
May	196	55	181	—
June	255	35	260	—
July	234	9	251	—
August	306	30	179	—
September	156	8	158	—
October	131	45	97	—
November	78	22	63	—
December	42	—	35	—
	1,916	16	1,579	30

The foregoing tables contain the record only of clear sunshine, and do not include days which might otherwise come under the head of bright sunny days, haze, mist, or the passing of a light cloud arresting the power of the recording instruments.

With regard to the Undercliff, some allowance must also be made in consequence of its falling into shade between six and seven o'clock in the evening during the summer months, depriving the instrument of a considerable amount of sunshine which would otherwise be recorded in fine weather. There is also the same loss from the sun rising in the morning behind the high ground of Dunnoose.

The excess of clear sunshine during 1887 has been very remarkable at the Undercliff.

BOOKS, ETC., RECEIVED.

The Year-Book of Treatment for 1888; Diseases of the Breast. By Thomas Bryant, F.R.C.S. London, Paris, New York, and Melbourne: Cassell and Co.
Hospital Prayer Book, Containing Prayers for Daily and Occasional Use. Arranged by E. J. Waring, C.I.E., M.D. Second Edition. London: J. and A. Churchill.
Gout, and Its Relation to Disease of the Liver and Kidneys. By Robson Roose M.D. Fifth Edition. London: H. K. Lewis.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE "BRITISH MEDICAL JOURNAL"

Seven lines and under	—	—	—	—	£0 3 6
Each additional line	—	—	—	—	0 0 4
A whole column	—	—	—	—	1 15 0
A page	—	—	—	—	5 0 0

An average line contains seven words.

When a series of insertions of the same advertisement is ordered, a discount is made on the above scale in the following proportions, beyond which no reduction can be allowed.

For 6 insertions, a deduction of	—	—	—	10 per cent.
" 12 or 18	—	—	—	20 "
" 26	—	—	—	25 "
" 52	—	—	—	30 "

Special terms for occasional change of copy during series:

20 per cent. if not less than 26 pages be taken	—	—	—	or their equivalent
25	—	52	—	in half or
30	—	104	—	quarter pages.

For these terms the series must, in each case, be completed within twelve months from the date of first insertion.

Advertisements should be delivered, addressed to the Manager at the Office, not later than noon on the Wednesday preceding publication; and, if not paid for at the time, should be accompanied by a reference.

Post-Office Orders should be made payable to the British Medical Association, at the West Central Post-Office, High Holborn. Small amounts may be paid in postage-stamps.

AN ADDRESS ON DIPHTHERITIC AND RELATED FORMS OF PARALYSIS.

Read before the Thames Valley Branch.

By J. S. BRISTOWE, M.D., LL.D., F.R.C.P., F.R.S.,

Senior Physician to St. Thomas's Hospital.

DIPHTHERITIC paralysis is so interesting in itself, and has such interesting clinical relations with other paralytic affections, that I need make no apology for introducing it for discussion, or for plunging at once *in medias res* by giving brief details of a very instructive case of it which was under my care some years ago.

CASE I.—H. A., a clergyman, aged 36, came into St. Thomas's Hospital on November 6th, 1879. He had had in the previous June a bad sore-throat, attended with enlargement of the glands behind the left angle of the jaw. But, although he had felt feverish and ill, he had not consulted any medical man, and could therefore give no trustworthy information as to the nature of his attack. Doubtless he had then suffered from diphtheria. The first evidences of paralysis had shown themselves early in October, and were impairment in the quality of his voice and a tendency for fluids when being swallowed to return by the nose. Towards the end of the month he had further observed that he was getting weak in the legs, that he had numbness in the tips of the fingers and in both feet, and that there was loss of tactile sensation in the tongue and lips, and impairment of taste.

On admission he was a healthy-looking man, complaining of various paralytic symptoms. The tips of his fingers were numb, but he had no obvious loss of power in the hands. His feet were numb, especially the left, so that he could scarcely feel the ground; and he walked with a feeble uncertain gait and with a tendency to fall over to one side. His eyesight would fail (words appearing misty) after reading for a minute or two; and there was some degree of loss of accommodation, but the pupils were equal and contracted to light, and there was no squint. He had numbness of the lips, tip of the tongue, and point of the chin, and was unable to distinguish between pepper, mustard, and salt placed on the tongue. The soft palate was pendulous, and did not contract when irritated; moreover, when he swallowed, the food was apt to pass into the nose, and also to lag about the level of the thyroid cartilage. His voice was nasal. Smell was much impaired. In all other respects he seemed fairly well.

During the next ensuing ten days several changes in his condition were recorded; and careful special examinations were made. The anaesthesia in the fingers gradually disappeared, first on one side and then on the other; but while sensation was returning weakness of the fingers and hands came on. The numbness became more profound in the feet, and extended up the legs, and the lower extremities grew weaker. At the same time he complained of pain and soreness in the feet. The numbness of the chin, lips, and tongue diminished, and he recovered to some extent taste and smell. His eyesight also improved, but his defective voice and deglutition continued. It was about this time also that he complained of numbness of the tip of the nose, of the glans penis and scrotum, and about the anus, and also that he was unable to strain at stool, owing to the fact that during the effort the air imprisoned in the chest escaped explosively through the rima glottidis. Mr. Nettleship's examination confirmed the fact that there was weakness of accommodation in the eyes, but that they were otherwise healthy. Dr. Kilner ascertained that there was some impairment of electric sensibility in both forearms and both hands, increasing from above downwards; but that the only arm-muscles whose electric contractility was impaired were the extensors of the first and second joints of the thumbs; that there was increasing loss of electric sensibility from the knees to the feet, where the strongest current could scarcely be felt; and that, while none of the muscles of the left leg below the knee responded to the induced current, the only

ones that responded on the right side were the tibialis anticus, the peronei, and the extensor brevis. They were all unduly responsive to the continuous current. Dr. Greenfield's laryngoscopic examination gave the following results: There was partial paralysis of the muscles moving the vocal cords, mainly of the abductors, and slightly more on the right than on the left side, and considerable (though not absolute) anaesthesia of the epiglottis and of the soft parts around the vocal cords, but not of the cords themselves. In deep inspiration the cords separated to about one-third of the normal amount, and tended constantly to approximate; in phonation there was complete closure; and the voice (excepting that it was slightly nasal and a little hoarse, owing to slight catarrhal swelling of the parts) was unimpaired.

Subsequently to November 17th the changes were very gradual. The hands and legs became more and more numb, and the patient progressively lost power in them, so that, about the middle of December, he could scarcely use them for any purpose, and his grasp was extremely feeble. Towards the latter end of the month, also, it was noted that all the fingers except the first were flexed, more or less, into the palms, and could not be straightened. The numbness still extended up the legs, and became so profound in the feet and ankles that he could not there feel the prick of a pin. The loss of power also increased, so that by December 9th or 10th he was unable to walk, or even to stand, without assistance. He still also complained of pain and tenderness in the feet. On December 20th he first manifested some difficulty of breathing, and had to sit up in bed. It was thought that the respiratory muscles were weak; but there was no absolute paralysis of either the intercostal muscles or the diaphragm. This difficulty lasted a few days, and then subsided. The impairment of accommodation, and the loss of taste and smell, together with the anaesthesia of the tip of the nose, lips, tongue, and chin subsided gradually shortly after admission. The nasal quality of voice and the dysphagia, as also the difficulty in straining at stool, were not observed after the first week in December. The improvement in the state of the hands and legs took place later, the hands recovering first. He left the hospital well on March 10th.

The case was obviously a typical and an interesting example of the paralysis which supervenes after diphtheria. The nervous symptoms tended to be symmetrical, and spread from region to region, affecting the hands and legs in larger proportion than other parts. The paralysis of the extremities was attended with the so-called "reactions of degeneration," and the anaesthesia of the feet with a sense of soreness and pain. In addition, also, to defective accommodation and to weakness of the soft palate; there was anaesthesia of certain circumscribed tracts occupying the middle line of the body, including among others the epiglottis and parts about the rima glottidis; and some paralytic failure of the muscles of the larynx, which contributed to render straining difficult, and of the muscles of respiration causing dyspnoea.

CASE II.—In 1880 I was not aware that any interest attached to the condition of the tendon reflexes in diphtheritic paralysis. My personal attention was first drawn to the fact that the knee-jerks tend to disappear in this affection, by being called into the country to see in consultation a lady who was partially paralysed, and who was supposed, on account of the absence of knee-jerk, to be suffering from locomotor ataxy. The patient was a middle-aged widow, who had been accustomed to somewhat excessive indulgence in alcohol, but on the whole had had very good health.

On close inquiry I ascertained that just two months previously (under the care of another practitioner) she had been attacked with sore-throat, which had laid her up for two or three weeks, and left her somewhat enfeebled in health. The affection had been declared not to be diphtheritic. A fortnight before my visit she had noticed a little numbness across the upper lip, which disappeared in the course of a day or two. Four days later she had been attacked with numbness in the fingers and hands, not confined to the region of the ulnar nerves, but of general distribution. The anaesthesia was not absolute, for she could still feel, and was unattended with loss of power. Three days later she had noticed impairment of feeling and of muscular power in the feet, and this had since then reached the knees.

She was, when I saw her, a healthy-looking woman. Her hands were still somewhat numb, but they had much improved in this respect, and were not weak. The numbness in her lower extremities reached the thighs, and the weakness in her legs was so great that she could not stand or walk without assistance. The affection of the legs was still increasing. The knee-jerks were wholly wanting.

It was clear (even though a diphtheritic origin had been denied) that the case was really one of diphtheritic paralysis, and, in confirmation of the view that it could not be due to ataxia, I may add that the eyes were healthy in all respects, and that there had never been any gastric, rectal, or urinary trouble, or lightning pains. She recovered.

About the time at which this patient came under my notice, the abolition of the tendon reflexes in diphtheritic paralysis was recognised also by other physicians; and since then it has been generally observed in this affection, and has come to be regarded as one of its distinctive features.

Lately, however, Dr. Herringham first, and subsequently Drs. Money and Barlow, have shown that, although the tendon reflexes do disappear in these cases, their actual disappearance is generally, if not always, preceded by a period of several days' duration, in which they presented excessive briskness. The fact had probably not been earlier recognised, because such patients are apt first to come within medical observation only after the symptoms have been in existence for a few days, and after the stage of exaggerated reflexes has passed.

The case I shall next narrate is interesting, because, not only was there this excess of tendon reflex, but it was maintained practically throughout the whole of the patient's illness, and was only replaced by its abolition after paralysis and numbness had disappeared, and the patient seemed to be in good health.

CASE III.—M. O., a married woman, aged 29, came under my care on February 18th, 1887. She had had what was supposed to be quinsy in the previous December. Her illness had begun with feverishness and shivering; she had had lumps in the neck; and her throat had been "covered with a sort of skin." She had recovered by Christmas, but had continued weak ever since. Her present illness had been coming on for two or three weeks. She had first observed some difficulty in swallowing; that, if she were not careful, fluids would return through her nose; and that often two or three efforts had to be made before even solids could pass from the pharynx into the oesophagus. Soon afterwards she had observed numbness and pins and needles in the fingers, and at the same time similar sensations across the upper lip. According to her recollection, weakness of her eyes had come on a little later. This had comprised loss of distinct vision for near objects, with inability to read, and some degree of diplopia. A week or two before admission numbness had come on in the feet, with a feeling as if of treading on cotton wool; and the hands had become weak, but had since improved. The legs, which had been similarly attacked somewhat later, had continued to lose power. Her friends had noticed some change in the quality of her voice ever since the beginning of convalescence.

She was a weakly-looking person, complaining mainly of defective sight for short distances, numbness in the toes and finger tips, and inability to walk without assistance. Her eyes were in most respects normal; but the power of accommodation for near objects was impaired, and there was slight weakness of both external recti, with double vision on looking to the extreme right or left, or at distant objects in front of her. The facial muscles, the tongue, and the fauces appeared natural, and she swallowed without difficulty, but her voice was still slightly nasal. There was no absolute anaesthesia, but the tips of the fingers and the toes and the front of the left leg were obviously numb. The grasp of the hands was feeble, and the movements of the left arm generally were relatively weak. She could move her legs freely; but in standing or walking (which she could only do with assistance) her knees were bent and inclined to give way, and she tottered on them. The abdominal and thoracic organs were all healthy. The knee-jerks were much exaggerated, the plantar reflexes were normal.

On February 21st it was noted that she complained of stiffness and a sense of twitching in the left arm; that the hand trembled when held out, and especially when carrying a glass of water to her lips; and that the hand and arm of this side remained weaker than her fellows; that there was slight horizontal nystagmus, and still slight diplopia as at the time of admission. Also the left pupil was a little larger than the right. During the next few days she regained the power of accommodation, and lost her diplopia and nystagmus; moreover, the numbness disappeared from her fingers, and there was some improvement in the sensibility and strength of her lower extremities. But the knee-jerks continued unusually brisk.

On March 1st, she was able to stand for the first time without

assistance, and with her eyes shut; but the feet were still numb; the knee-jerks were about normal. She continued to improve, and on the 10th was discharged, apparently well. At this time she had no anaesthesia or obvious loss of muscular power, but the knee-jerks had become much less active than on admission, and were, if anything, less brisk than natural.

I assumed that the case would prove an exception to the rule with respect to the abolition of reflexes in diphtheritic paralysis. But the patient, who still continued in somewhat weak general health, came up periodically to see me at the hospital for some few weeks after her dismissal, and to my surprise, the knee-jerks (although apparently she had completely recovered from her sensory and motor paralysis) disappeared absolutely at the end of a week or two, and had not returned when she finally ceased attendance.

Although as a general rule the paralytic phenomena of diphtheria are remarkable for their tendency to symmetry of distribution, as is illustrated in the foregoing cases, not merely by the condition of the extremities, but also by the patches of anaesthesia distributed along the middle line of the body; the symmetry is not absolute; and already in two of the cases hints are afforded that local paralyses due to implication of single nerves are likely to be met with. The next case illustrates this fact.

CASE IV.—Mr. S., a gentleman, about 32 years of age, had had a sore-throat about a month before I saw him. He had not been sufficiently ill to lie up, and did not know he had had diphtheria, but had looked down his throat and seen a white patch on each tonsil. Within the previous week or two paralysis had been coming on, first in the left leg, then in the right leg, and later in the arms.

I saw him in consultation with Dr. Mennell, in April, 1884. At that time he was confined to bed. Feeling was impaired in his legs, from the knees downwards; he had very little motor power at the knee-joints, and could scarcely move the feet or toes at all; the muscles below the knees were tender, and the tendon reflexes were absent. He had numbness of the hands and forearms, and much impairment of muscular power in them. He also had numbness of the upper lip, tip of the tongue, and in a circumscribed area at the back of the neck. He complained of slight difficulty of swallowing, and he presented well-marked general paralysis of the left portio dura, which had only come on within the previous two or three days. There was no obvious affection of the eyes, no dyspnoea, no implication of the rectum or bladder; and in all other respects he seemed healthy. I did not see him again, but learnt that he recovered perfectly in the course of a few weeks.

I add the following case, because it is typical, and because it contains an exhaustive account of the electrical condition of the paralysed muscles by Dr. Kilner.

CASE V.—R. O., a school girl, aged 12, came under my care on March 12th, 1883. In the middle of December last she had diphtheria and was in bed for several days. This was followed by some difficulty of swallowing (fluids especially returning through the nose); by loss of visual accommodation, so that she could not see near objects distinctly; and, somewhat later, by loss of power and numbness, first in the arms, and then in the legs. The muscles of the trunk also became feeble, and before long her weakness grew so extreme that she not only was confined to bed, but could not even turn in bed. During the last month her symptoms had greatly improved; she had recovered the power of swallowing and the use of her eyes, and the paralysis in her limbs had diminished.

On admission she was a healthy-looking girl. She was unable to stand, and only able to flex the legs at the knee-joints. She could move her arms pretty freely, but these limbs were obviously much weaker than natural; and the hands, when extended, assumed a claw-like form, the wrists drooping, the first phalanges being extended and the last two phalanges flexed. The muscles were not noticeably wasted, but they were limp and flabby; and there was a total absence of tendon reflexes in the arms and legs. But all the muscles were irritable, and contracted on being sharply struck. No loss of feeling. No loss of control over the emunctories. There was no paralysis of the facial or ocular muscles, or of the palate, and the eyes now acted to accommodation. Thoracic and abdominal organs healthy, excepting that the urine presented a trace of albumen.

A few days after admission Dr. Kilner tested electrically the muscles of the arms and legs, and found them generally

to present the reactions of degeneration.² The patient gradually improved, and left the hospital at her own wish, before she was well, on April 8th; but she could at that time walk with tottering gait, and the patellar tendon reflex was just showing itself in the left leg.

The foregoing cases are all of them typical, and afford between them excellent illustrations of most of the more interesting incidents of diphtheritic paralysis. They show how the affection comes on some little time, usually a few weeks after, the acute illness has subsided; how the paralysis (which involves sensory and motor nerves alike) tends to be of symmetrical distribution, to creep from part to part, and to subside in one region as it invades another; how the sensory disturbances are not limited to the extremities, but are apt to involve districts situated in the middle line of the body, including the tongue and mouth, and senses of taste and smell; how, also, the paralysis is liable to affect not only arms, legs, respiratory muscles and muscles of the trunk, muscles of accommodation, and of swallowing, but also the vocal cords, and even single nerves; how the tendon reflexes in the legs are first exaggerated, then disappear, and the affected muscles acquire the characteristic reactions of degeneration; and how, finally, while many of the phenomena are such as would seem to be best explained on the assumption that they are due to spreading neuritis, others (such as the sensory affections along the middle line, the early undue briskness of the knee-jerk, and nystagmus) seem rather due to some spreading central lesion. I am inclined to believe that, in diphtheritic paralysis, a wave, so to speak, of slight inflammatory mischief, spreads not only through the medulla oblongata and cord, but along the nerve trunks also.

This brief recapitulation leads me on to speak of some of the diseases of the nervous system which present a resemblance to diphtheritic paralysis, and may even, under certain circumstances, be confounded with it.

I have already shown how the association of numbness in the feet, loss of voluntary power over the legs, and abolition of tendon reflexes (in a case which occurred when the condition of the tendon reflexes in diphtheritic paralysis had scarcely begun to be investigated, and was certainly not as yet generally known), led to the fear that symptoms, which were undoubtedly diphtheritic, might be due to tabes. I do not think such mistakes can often be made now. Yet it is well to recollect that paralysis in diphtheria often follows so mild an attack of the acute disorder, that the patient forgets to volunteer any remark as to the previous occurrence of sore throat; and, on the other hand, that occasionally, in tabes, the paralytic symptoms are, or seem to be, of almost sudden onset.

But the cases most likely, I think, to be thus misinterpreted are those of multiple neuritis of other, and especially, perhaps, alcoholic, origin. It will be recollected that the lady whose case was thought to be one of tabes had been what is called a free liver.

CASE VI.—On November, 19th, 1886, a policeman, aged 39, came under my care. He had been a thoroughly healthy man, and had never had syphilis; but, though he was not a drunkard, or even

in the ordinary sense of the term intemperate, it was ascertained, and admitted by himself, that for a long time he had been in the habit of taking a very large quantity of beer in the course of each day. Twenty-six days before (being at the time quite well) he got repeatedly wet through, and was in wet clothes nearly the whole of the day. On the morrow he went to his work, but complained of sore-throat, aching pain in his limbs, vomiting, diarrhoea, and general sense of illness. These symptoms seem to have been the beginning of a severe attack of quinsy, which, first attacking one side and then the other, kept him continuously ill, but without any special change in his symptoms until June 13th. On that day he first complained of tingling in the arms and legs, attended with some loss of power; and, in fact, on trying to walk his knees yielded under him, and he fell down. The muscular weakness increased upon him day by day, until, on the sixth day, of his paralytic symptoms, he entered the hospital.

He was a spare, but well-built, and not unhealthy looking man, complaining of sore-throat and weakness in the arms and legs. The tonsils, especially the right, the soft palate, and uvula were still swollen and congested. He complained of a sense of numbness and tingling in the hands, but could feel. The grasp on both sides, and more particularly on the right, was extremely feeble, and although he could move his arms at the elbow and shoulder joints, their motions could be arrested by the mere pressure of the finger. There was no numbness in the legs, but he complained of pain in them, and their movements were extremely defective. He could not raise them from the bed, though he could bend his knees; his feet were extended, and he could not flex them. The muscles of the upper and lower extremities, and chiefly those of the fore-arms and hands, legs, and feet were exceedingly tender and irritable; the tendon reflexes were wholly absent.

The case was a very long one, and the patient remained continuously under my care for the next nine months, and has lately again been a tenant of one of my hospital beds. The history, however, can be summed up in a few sentences. The throat affection rapidly got well. The muscles of the upper and lower extremities, but mainly those of the forearms and legs, hands, and feet, rapidly lost power, and wasted to an extraordinary degree, and remained exceedingly tender. These conditions continued for the first few months of treatment, at the end of which time almost every trace of muscle had disappeared from the parts above specified; the forearms and legs apparently at length consisting of little more than the bones with the skin stretched tightly over them; the thenar and hypothenar eminences and the interossei being completely wasted, and the fingers bent so as to give the hands a clawlike form; and the feet being in essentially the same condition, but extended at the ankles, while the toes were flexed into the soles. About the end of this time amendment began to take place. The patient, whose bodily health had only been moderately good, began to recover the aspect of health, and flesh and strength. The muscular tenderness slowly disappeared, and the muscles of the upper arms and thighs began to regain bulk and power. Unfortunately, however, no beneficial restoration of the muscles of the forearm, legs, hands, and feet followed; and (with the exception that a few fibres of the muscles of the hands, sufficient only to cause almost imperceptible flickering of some of the fingers, have been spared) the distal parts of the limbs remain to the present time as much emaciated, as absolutely void of muscular tissue, and as useless as they were at the end of the acute stage of disease.

It may be added that, shortly after admission, the muscles of the trunk became weak, so that he could not turn in bed, but recovered comparatively early; that the affected muscles soon showed the reactions of degeneration; and that the patient presented no other indications of nervous disorder besides those above detailed, and no evidence of the presence of any visceral disease.

I suppose it is arguable that the case just cited was really one of diphtheritic paralysis. That view is one which I considered and discarded. The following are the reasons which influenced me. I came to the conclusion from due inquiry that the patient's primary attack had been one of tonsillitis and not of diphtheria; the paralysis came on while the primary disease was still acute, instead of a few weeks afterwards; and the general symptoms and progress of the disease corresponded with what one generally observes in cases of that form of paralysis which his habits had fairly earned for him. I have never known of a case of diphtheritic paralysis in which (if the patient do not die of it) ultimate recovery was not attained.

² (a) With induced current a much more powerful current was required to cause contraction than in health; (b) with constant current.

I quote one other case of so-called "alcoholic" paralysis, because it presented two features which bear some relation to phenomena, also observed in diphtheritic paralysis—namely, loss of power in the respiratory muscles, and a curious kind of dilluculty in swallowing.

CASE VII.—The patient was a married woman, aged 2, who came under my care on September 20th, 1886, and was discharged convalescent on August 19th of the following year. She had indulged excessively in drink, especially of ardent spirits, for some years, and had been suffering from loss of appetite, sickness, and increasing weakness in the arms and legs for three months. She was fairly well nourished. There was some degree of numbness in both arms and legs; the arms were weak, and the weakness increased towards the fingers, which could not be straightened; the legs were so feeble that she could not stand on them, or even raise them from the bed. Her ankles were extended, the toes flexed towards the soles, and she had no power of moving them. The muscles of the forearms and legs were exceedingly tender, emaciated, and irritable, and the tendon reflexes were absent. There was also slight nystagmus. The symptoms were in progress at the date of admission, and within a few days it was found out that she had difficulty of breathing, liable to paroxysmal aggravation, and difficulty in the swallowing of fluids. As regards the dyspnoea, it was observed that there was a rapid expenditure of breath, so that she could only utter a few words at a time, that she had complete paralysis of the diaphragm, so that her breathing was wholly intercostal, and that she was liable to attacks of suffocative cough (induced mainly by swallowing fluids), in which she became livid in the face, and seemed in serious danger of dying. She had no paralysis of the mouth or soft palate, her voice was not nasal, and, as before stated, she could swallow solids without difficulty; but whenever she took even a mouthful of fluid, it was ejected within a few seconds with the symptoms of choking. She had no difficulty in carrying the fluid to the back of the mouth, and performing the act of deglutition; and it was not until a second or two had elapsed after the performance of the latter act, until the fluid had presumably passed some distance along the oesophagus, that the choking came on, that she coughed, and brought up with coughing the fluid she had swallowed. I confess I was puzzled to explain these attacks, and seeing that they did not occur until the swallowed fluid had had ample time to reach the lower end of the oesophagus, I was inclined to associate them with the diaphragmatic paralysis. The dangers which attended her paroxysmal attacks of choking and cough were manifestly due to the mechanical difficulty in the way of effective coughing, occasioned by the paralysis of the diaphragm.

The affection of the respiratory muscles and of swallowing, which had only come on recently, subsided gradually and disappeared in the course of a few weeks. The numbness, wasting, and tenderness of the muscles of the limbs increased progressively for some months; and then, after a period of apparent quiescence, convalescence slowly took place. The arms improved, even while the disease was still in progress in the legs. When she left the hospital her general health was re-established; she had complete use of her upper extremities; and, although the movements at the ankles and knee joints remained much enfeebled, she could walk in clumsy fashion, but without assistance.

I will trouble you with yet one other case, not so much because it has any direct bearing on the subject of my paper, as because it throws suggestive light on the difficulty of swallowing which was observed in the last case, and shows how a similar difficulty might have arisen in my first case, in which it will be recollected there was loss of power in the laryngeal muscles and impairment of sensation in the laryngeal mucous membrane.

CASE VIII.—J. H. A., a clerk, aged 44, was sent to me by my colleague, Dr. Semon, on December 7th, 1886. He had had syphilis ten years previously, followed by secondary symptoms. But otherwise he had had good health up to March last, when he was attacked with sore-throat, the nature of which remains somewhat uncertain. However, during its continuance, he experienced some impairment of voice, and some difficulty in swallowing both fluids and solids. When the soreness of throat had subsided, his voice was left impaired, and he found that, although he could now swallow solids with perfect ease, fluids invariably caused choking. After a time he placed himself under Dr. Semon's care, who recognised some small growths below the vocal cords, and that there was paralysis of the arytenoid muscle, in consequence of which the arytenoid cartilages were not approximated when the vocal cords

were brought into apposition, and a triangular chink remained unenclosed at the posterior extremity of the rima glottidis. This fact, however, though it explained the huskiness of voice, did not seem fully to explain the difficulty in swallowing fluids; for in recorded cases of this form of paralysis such choking had seemingly not been observed. The manner of choking was very peculiar. There was no doubt that the patient could swallow solids with perfect freedom. He could also, when drinking, perform the act of deglutition without any hitch. But invariably, within a second or two after a mouthful of fluid had been swallowed, and at a time, therefore, when it had presumably passed beyond the larynx and reached the lower part of the oesophagus, he began to choke, and presently coughed up some of the swallowed fluid. The phenomena were just what might be expected to happen, and what I have witnessed, when there is a communication between the oesophagus and trachea. And I at first thought that such a communication existed in this case. That, however, was disproved; for Mr. C. Evans, my house-physician, in my presence tested the suggestion, by feeding the patient with milk through an oesophagus tube, first passed into the stomach, and then gradually withdrawn, and thus found that no choking occurred until the lower orifice of the tube reached the level of the larynx. He ascertained, also, on further examination, that there was distinct impairment of sensibility, and of reflex excitability in the laryngeal mucous membrane, more especially in the inter-arytenoid fold—an observation which was confirmed by Dr. Semon. The explanation of the choking was now clear; at least so it seemed to me. I assumed that, in consequence of the non-approximation of the arytenoid cartilages during deglutition, the portion of the laryngeal cavity situated above the vocal cords remained incompletely cut off from the tube along which food was passing; that, in consequence of their ready diffusibility, fluids, while being urged on wards into the oesophagus, were also driven through the inter-arytenoid chink into the space above the vocal cords; and that actual choking was induced by this fluid remaining there up to the moment when the inspiration which naturally follows the act of swallowing sucked it into the windpipe. The obtuse sensibility of the mucous membrane of course explained the absence of irritation due to the presence of the foreign matter in this unwonted locality. I tested the truth of this hypothesis by making the patient drink, and hold his breath as long as he could after swallowing. And although he was apt to choke after a time, even before he inspired, there was no doubt that, by holding his breath, choking was retarded, and that choking always came on, or was aggravated with the first inspiration. The most interesting confirmation of the truth of my hypothesis, however, was furnished later. After he had left the hospital and passed from under my care, he continued to attend as an out-patient of Dr. Semon's; who one day sent him up to me to show me how, though his paralysis remained, he had learnt to circumvent the difficulty in swallowing fluids. He had discovered that, when standing, and at the same time stooping so as to put his head between his legs, he could drink without difficulty; whereas still, if he drank in the ordinary way, choking followed. I expressed my surprise at his having thought of this manoeuvre; when I was reminded that just prior to his leaving the hospital I had, in talking to him and to the students, remarked that, if his affection should not be cured, he would have to swallow (if he wanted to enjoy drink) while standing on his head; and thus learnt that he had simply put into practice the suggestion I had half-jokingly made. My reason for making the remark was that it seemed to me that if the patient's choking were due to the inhalation of fluid accumulated above the vocal cords, it would be obviated if by any means this fluid could be made to escape thence before the patient could draw a breath, and that if he stood on his head while drinking, it would, from the effects of gravity, at once trickle back into his mouth.

I do not know to what my alcoholic patient's difficulty in swallowing fluid was due, but it was so exactly like that presented by the case just given, that I cannot doubt that she also suffered from a combination of anaesthesia with some paralytic affection of the muscles which cut off the communication between the oesophagus and larynx during the act of swallowing. I am sorry that his larynx was not examined at the time.

DR. ROMOLO GRIFFINI died at Varese on January 9th, aged 63. He was for some years editor of the *Annali Universali di Medicina*, and took a leading part in the management of several medical charities at Milan.

LETT SOMIAN LECTURES

ON

SOME POINTS IN THE SURGERY OF
THE URINARY ORGANS.*Delivered before the Medical Society of London, January, 1888.*

BY REGINALD HARRISON, F.R.C.S.,

Surgeon to the Liverpool Royal Infirmary; and Lecturer on Clinical Surgery
in the Victoria University.LECTURE III.—THE OPERATIVE TREATMENT OF STONE AND
TUMOURS OF THE BLADDER IN RELATION TO SOME
RECENT VIEWS AND PRACTICES.

THE surgery of the bladder during the last ten years will, under all circumstances, occupy a conspicuous position in the history of our art by the introduction of litholapaxy, the revival of the suprapubic or high operation under somewhat altered conditions, and by an approach to a more systematic method of treating tumours and growths connected with the interior of the viscus. It has been my privilege to watch the progress of these several procedures, not merely as a passive critic, but as an active participator with others in all the advantages these measures have proposed to confer. Within the period mentioned a vast amount of experience has already been obtained bearing upon these various proposals, and I think the time this evening cannot be better occupied than in drawing some conclusions in regard to them which seem to me may now be fairly and advantageously done; and, in referring to these several procedures, I will endeavour, in speaking of each, to indicate what appears to me to be their strong as well as their weak points, and to what extent our present experience tends to show they have justified the anticipations with which they were promulgated. In the course of these remarks I shall not trouble you with statistics relative to operative procedures, as I do not attach much importance to them. It seems to me that in drawing conclusions from figures of this kind, gathered from various sources, we are putting ourselves much in the same position as the individual who, to make sure about the weather, consults three different kinds of barometer, and is rewarded by finding them respectively indicating at the same time "stormy," "rain," and "very fine." From such variations as these most persons would be disposed to conclude, not that it was safe to go out without an umbrella, but that at least two of the instruments must in some respect be faulty. On the other hand, to the collective work of individuals carefully recorded, with all failures and successes, the greatest importance is to be attached, as indicating not only results, but how these were obtained.

In the first place I will take a brief survey of the position that the crushing operation seems to occupy at the present day. Since the procedure which is justly associated with the name of Dr. Bigelow, of Boston, was brought under notice, exactly ten years ago this month, it has been applied to almost every condition under which stone in the bladder is met with in males, females, and children. Without entering into the history of the modern crushing operation for stone, or referring to discussions as to what led up to the important changes it represents, I think most persons will be inclined to admit that the lithotripsy of to-day occupies a very different position compared with what it did ten years ago. At the latter there appeared to be a tendency to limit its application considerably, whereas now we have rather to fear its extension to conditions for which it could hardly have been intended. The removal of a stone at a single sitting, without leaving behind any cause either for its reproduction or for cystitis, represented such a desirable combination of objects as at once to place the matter before surgeons in a light which it had not previously done. Let me stop for a moment to inquire how far this has been realised. In the case of stones of a moderate size, occurring in adults in other respects healthy, I think it will be generally admitted that to these lithotripsy may now be applied with a degree of success which prior to this decade had never been obtained in the history of either the cutting or crushing operations. Nor can there be any doubt, excepting in children perhaps, that by far the larger number of stone cases requiring operation occur under these

circumstances. But this, unfortunately, does not represent the whole truth, as lithotripsy has and is being applied to a class of cases where the anticipations formed in reference to it in its most modern form have not been realised; and this brings me to notice what I would speak of as the weak side of this proceeding. In corroboration of this, let me read a passage from a recent address by Mr. Cadge (Hunterian Lectures, Royal College of Surgeons, 1886). "Although," he observes, "the immediate and direct mortality of lithotripsy is small, the recurrence of stone is lamentably frequent. In my own list of 133 cases there were 18 in which recurrence one or more times took place, being about 1 in 7. Sir Henry Thompson, with a much larger number of cases, gives about the same proportion. I am disposed to infer, however, that recurrence is more frequent than this, because it is not likely that all who get relapse apply to the same surgeon again. Patients may, and frequently do, apply to the same operator once or twice; but after a time they either apply to their own surgeon or they decline further treatment, and too often their subsequent history is one of painful endurance of chronic bladder disease and gradual exhaustion. If, moreover, there be added to the list those numerous cases of phosphatic deposit or concretions, so frequently noticed after lithotripsy, the relapses would, I believe, reach to nearly 20 per cent. This seems a heavy indictment to bring against lithotripsy, but I am afraid there is no gainsaying it; and, if so, it would be wrong to pass it over or to make light of it." Though, with a very much less experience of lithotripsy than that to which I have just referred, I became impressed some years ago with the conviction that in certain cases we could do something more than merely remove the stone from the bladder.

It will, I believe, be generally admitted that the state of the interior of the bladder relative to its shape, its power of contraction, and the presence or absence of inflammation has, without being precise, a determining influence in the production of stone. In the majority of instances this is merely a matter of experience deduced from observation, whilst in not a few this tendency is not discovered until, as it were, the experiment of removing the stone by crushing and aspiration has been tried and failed. And, in connection with this observation, I think we have been rather too much disposed, if I may judge from a good deal of literature relative to this subject, to allow the physical properties of the stone to determine for us, as it were, the selection of the operation, irrespective of the relative conditions to which I have referred. Though a large hard stone is, as a rule, best treated by lithotomy, this by no means implies that some small and soft ones are the less advantageously removed by a similar proceeding.

Let me take, for instance, the case of a stone in the bladder occurring in an adult, with some chronic cystitis and enlargement of the prostate. The probabilities are that for many months, if we look at the section of such a stone after its removal, the bladder has been engaged in encasing it in a mould of phosphates just as completely as if it were done by plaster-of-Paris. Now is it reasonable to suppose that you can suddenly stop this stone-forming process without leaving behind any contributing cause for its continuance. In connection with the subject more particularly of prostatic hypertrophy, I have examined a very large number of bladders, and, having regard to the distorted or pouched condition of the viscus, which so frequently accompanies this change, as well as the condition of the mucous membrane relative to the presence or absence of phosphatic deposit upon it, it has often struck me, not that lithotripsy has its failures, but that, under these circumstances, its successes are so numerous.

Reflections such as these induced me, some years ago, gradually to alter my mode of procedure in cases of this kind, where either it was clear that the stone was the effect rather than the cause of disease, or where this fact was demonstrated by the failure of lithotripsy. I could not help feeling that the bladder, under these circumstances, was not unlike in many respects, a chronic abscess with a stone in it, and that it was just as necessary to open and drain the one as the other. Let me briefly illustrate this by one of my earliest cases. It was that of a man of 60 years of age, who submitted to lithotripsy on three occasions in two years, when large masses of phosphatic stone were readily removed. In the intervals between the operation, he never was free from vesical irritation. He could not empty his bladder completely without a catheter, the urine was more or less ammoniacal, and, in spite of careful catheterism, he suffered much from urinary irritability. He had some degree of prostatic enlargement, and some pouching or sacculation. Two years after the first crushing, I performed lateral lithotomy for him, and removed more phosphatic calculus

of recent formation. I put a large drainage-tube into his bladder, and he was drained and washed for eight weeks, until he voided normal acid urine, when the tube was removed, and the wound allowed to heal, which it did in the course of a month. This patient has now been perfectly well for over three years. I would refer to this and similar instances, not as being merely examples of successful lithotomy, but of successful drainage.

Three years ago I brought this subject (*Annals of Surgery*, June, 1885) under the notice of the profession, and described at length my mode of operating and of draining; and to these points I would now briefly direct attention. So far as the method of operating is concerned, my object has been to remove the stone by such an incision as will permit the bladder to be readily and efficiently drained; hence the proceeding stands much in the same light as evacuating matter from a chronic abscess does to the important part of the treatment by drainage that is to follow.

In the performance of lithotomy in cases of this description, my aim is to make a wound into the bladder which is not likely to close up before the interior of the viscus is ready for the reception and continence of the urine. Hence I am an advocate for lateral lithotomy, which best fulfils the conditions that are required. But though the mode of opening the bladder is important, the process of draining, where the condition of the viscus or of the parts above it is such as to require this, is still more so. As a rule, cases of this kind require drainage to be continued from four to eight weeks. I have drained them as long as ten weeks before the state of the bladder, as evidenced by the urine, was such as to allow the wound to heal up. The drainage-tubes I employ for this purpose are larger than those which have been used temporarily by some surgeons after lithotomy, and some care is required in fitting them to each case. [Mr. Harrison showed some specimens of his drainage-tubes.] By their use, with the exception, perhaps, of the first few days after the operation, when some urine may escape by the side, I have been able to keep patients absolutely dry during the whole process of treatment, whilst, at the same time, antiseptic dressings have been applied to the perineum; but I do not attach much importance to the latter, so long as the urine drainage is perfect.

Let me illustrate this practice by another case of somewhat recent date. It was that of a gentleman, 70 years of age, who, for over four years had never passed one drop of urine except through a catheter, and who had for the last two years of this period absolutely lived with the instrument in his bladder, both day and night. I examined him in October last, and found that he had a stone in his bladder, but one that I could have quite easily removed by crushing and aspiration. However, in the presence of the symptoms mentioned, and guided by other experience of the kind to which I have referred, I elected to perform perineal lithotomy, and to drain. My colleague, Mr. Mitchell Banks, held the staff for me, and I removed three uric acid calculi of moderate size, coated with phosphates. I made, as I usually do, a very free opening into the neck of the bladder, and put in one of my largest-sized drainage-tubes, with two or three superficial sutures in the wound to keep it in position. He was drained continuously for eight weeks, when it was found, co-incidentally with a much improved state of the urine, that the latter was, occasionally forced out spasmodically through the normal channel of the penis. The drainage-tube was then removed, and the wound allowed to heal. Though the function of the bladder had been in abeyance for four years, he has now complete control over his urine, and can expel it spontaneously without any assistance from the catheter, which he has entirely discarded since the operation. At present he has to pass his urine more frequently than is desirable, a circumstance which is probably due to the empty state the bladder has been in ever since he commenced to use the catheter continuously, day and night, two years ago. Notwithstanding this inconvenience which, I believe, will improve in time, it is remarkable that the bladder should have entirely recovered its power after such a long period of inaction as four years. Had I crushed, as I could have easily and safely done in this case, I feel sure that the power of the bladder would not have returned in the way that it has.

My friend, Mr. Cadge, in referring to recurrences after lithotomy, seems to think that in the matter of treatment we are placed somewhat on the horns of a dilemma, that is to say, if we crush there is a considerable probability of the stone recurring; whereas, if we cut, we adopt a harsh proceeding, and one more immediately perilous to life. As I have said before, I do not attach much importance to statistics, for putting aside what may

be due to the accidents of lithotomy, to which we are all more or less liable, and which are really responsible for no inconsiderable amount of the mortality following this operation, the results will be largely determined by the attending circumstances of the individual case. If a patient comes to be treated for a stone in his bladder with dilated ureters, and with only about one-fourth to one-tenth of his normal amount of kidney tissue, and the balance made up of pus cavities, I do not think it makes much matter what you do to relieve the suffering caused by the stone, as the result will be the same whether you cut or crush. Putting cases of this kind aside as being entirely outside the question, just as they are beyond repair, and taking instances where the only objection against lithotomy is that the stones are likely to return or have been proved to do so, I have not observed that the perils of lithotomy are very great.

In analysing my experience of lithotomy, I can refer to fifteen cases where the process of opening the bladder was followed by a more or less prolonged system of drainage and irrigation, such as I have just described. Of this number, three terminated fatally in the course of from three to five weeks, by reason of the far advanced suppurative condition the kidneys were in. This was considered as probable at the time of operation, and was proved by *post-mortem* examination. I had no desire to operate at all in these instances, but the patients were in such a painful condition that I had no alternative but to do as they wished, and run my chance. However, as drainage was employed after the stones were removed, I must in fairness include them. In addition to observing the relief that was thus afforded to these persons, I would further remark how importantly they illustrate the disastrous consequences that may ensue, when stone and cystitis are complicated with obstruction, or anything that interferes with the process of natural urine drainage, prior to the removal of the stone. In two of these cases, there was some enlargement of the prostate, whilst the third was complicated with an old urethral stricture. Further, they clearly point to the importance of drainage as a necessary part of the process connected with the removal of some stones. The remaining twelve persons so treated recovered, and remain well, or did so up to the time that I had cognisance of them. I think I should be pretty sure to hear of them if they had any recurrence. Three of these cases had been previously treated by crushing; to one of which I have already referred more in detail. In determining how long it is necessary to continue the drainage, I attach considerable importance to two points—first, to the condition of the urine, and, secondly, to certain muscular actions of the bladder, which become more apparent in those cases where atony pre-existed. So long as a patient goes on discharging ammoniacal or very purulent urine, so long must the drainage be continued, as to close the bladder under these circumstances is certainly to favour the reproduction of those local causes which contributed to the formation or growth of the stone. When the urine is becoming normal, one of the earliest indications that the drainage-tube may be withdrawn is the voluntary, or, I should rather say, the spasmodic, expulsion of urine along the natural passage. After three or four weeks' drainage, according to circumstances, I have allowed patients to get up for a little, and sit in a chair, with a clip on the edge of a drainage-tube, directing them to remove it when they feel desirous of urinating. It is under these circumstances that urine is sometimes expelled independently of the tube along the natural passage. This I have found a sure indication that the power of the bladder will be restored in those instances where it had been lost to a greater or lesser degree. And it not only applies to cases where a stone is present as I have illustrated, but to others.

This was evidenced in a remarkable way in the following case, which much impressed me at the time, in reference to what opening and draining are capable of doing. It was that of a man aged 68, who was under my care in the Royal Infirmary in 1883, for an atonied bladder and retention of urine, where the regular use of the catheter had become, in the course of time, extremely difficult by reason of the obstruction. After three weeks' trial of various plans of treatment, I performed perineal cystotomy, divided the prostate, and put in a drainage-tube. This was worn for eight weeks, when it was noticed that a certain quantity of urine forced its way along the urethra. The tube was then withdrawn, and the wound gradually closed. After this the patient never had any further difficulty in urinating, though the power of the bladder had been entirely suspended for some months prior to the operation and drainage. Six months subsequently he was seized with hemiplegia, which confined him to bed for the rest of his life, but

I ascertained from his medical attendant that it had never been found necessary again to make use of the catheter. Other cases of the kind might be adduced in support of the practice I am now advocating.

In two instances where the stones were very large I had to divide both sides of the prostate. I could not help observing that these cases made very rapid progress. It is of much importance that the wound should invariably be made clean and straight, and that the relations of the parts be not unnecessarily disturbed with the finger, as thus pouches are made in which urine may lodge. I should also mention that in one case the progress towards recovery was somewhat retarded by two or three attacks of secondary hæmorrhage, necessitating the use of a plug outside the drainage-tube. However, it was not sufficient to be of much importance. In another instance the patient had two or three slight attacks of orchitis, which was probably due to some imperfection in the drainage apparatus; where the prostate is very irregular this may happen, unless care is taken in making the incision into the neck of the bladder.

In these remarks I have thus endeavoured to illustrate what appears to me to be the weak aspect of lithotripsy, and what alternative seems to me, from some practical experience specially directed towards this point, best adapted to meet the difficulty. Fortunately, I believe these cases are not now so frequent as they used to be, owing, no doubt, in a great measure, to the better means we possess of detecting stone in the earlier periods of its formation, when it can be dealt with by crushing with the most complete success. To eliminate the cases which are not adapted for crushing is worthy; I am sure, of our most careful attention, and as a contribution towards this I must ask you to accept these remarks.

Turning to another debatable point, I would refer to the application of lithotripsy to male children. Some valuable records relating to this operation have been furnished by surgeons practising in India, amongst whom I may mention Dr. Freyer and Dr. Keegan. The latter gentleman has more particularly demonstrated the great success that may be obtained in boys by the crushing operation, and his testimony has been to a considerable extent corroborated by Mr. Walsham and other surgeons. Having regard to the great success of lithotomy in male children, I should not feel disposed to extend the crushing operation in this direction materially, except in the case of very small stones. It has, I know, been alleged that lithotomy means emasculation, but I am not aware that sufficient proof of this has been afforded. If this were proved to be an occasional and unavoidable consequence, the reasons for crushing in boys would be materially strengthened.

The suprapubic operation for stone owes its recent revival in a large measure to the observations of Garson, the practice of Petersen, of Kiel, and the advocacy of Sir Henry Thompson. The fact that the bladder is usually uncovered by peritoneum immediately above the pubes has for a long period been rendered available by surgeons for tapping with impunity in cases of retention of urine. To increase this area, and to permit the bladder to be opened and stones removed without injuring or wounding the cavity of the peritoneum is the chief feature in Petersen's method of performing the high operation. Since the introduction of this method of operating, considerable discussion has been excited in reference to the circumstances under which it is applicable, and much variety of opinion has been expressed. If, however, we merely content ourselves with taking the experiences of surgeons where this measure has been practically tested, we shall have no difficulty in determining its value.

In the first place I do not think that anyone would attempt the removal of a very large stone from the bladder by any other proceeding. We have already had several examples where large masses have in this way been successfully removed; which, judging from previous experiences of the kind, could not have been safely accomplished, even if it had been possible to effect their removal at all. And this applies equally to some cases of distorted pelvis, where the outlet is so contracted as to render perineal lithotomy impossible. I should have been very glad to have availed myself of this method of operating in one of my earliest stone cases some twenty years ago, where I performed lateral lithotomy for a boy with his hip ankylosed in an extended position.

In the second place, experience has already shown us that the suprapubic operation is well adapted for the removal of certain foreign bodies from the bladder more or less coated with phosphates, where it is necessary that we should be able to see as well as to feel, and direct what we are desirous of doing. Perhaps one

of the best illustrations of this practice will be found in a case recently recorded by Dr. Gillon (JOURNAL, July 30th, 1887), where a penholder, over five inches in length, encrusted with phosphates, was removed from the bladder of a man through a suprapubic incision. Not only was the foreign body extracted in this way, but the operator was enabled to satisfy himself that no perforation of the bladder into the peritoneal cavity had occurred.

Thirdly, the suprapubic incision may prove serviceable in some cases of stone in the bladder complicated with a protruding pro-lapse, where the removal of some portion of the latter may be further contemplated.

In the fourth place, the high operation will prove to many practitioners an easier and, therefore, a safer access to the bladder than the lateral perineal route, and thus, for this reason, and in the best interests of their patients, many will avail themselves of it under almost all circumstances. Are not these sufficient reasons for finding a place in surgery for this method, irrespective of the value that most of us, I believe, still attach to perineal lithotomy? I have no belief in the decline of perineal lithotomy, as it seems to me to possess advantages as a ready means of entrance to, as well as exit from, the bladder which no other method possesses.

In the controversy that has been recently raging in reference to the relative advantages of suprapubic and perineal lithotomy, I cannot help thinking that much of the difficulty which some have associated with lateral lithotomy, or Cheselden's operation, is, in a measure, due to a wrong conception of the way this operation should be performed. The point where it seems to me some surgeons are at variance with the description laid down by authorities on this subject is in reference to the employment of dilatation with the finger as a means of entering the bladder. I contend that such a process, whether there are grounds for its adoption, so far as the literature of the subject is concerned, or not, is not only unnecessary, but dangerous. It is unnecessary, because the opening into the bladder can be safely made with the knife, sufficient to permit of the finger being put, and not pushed, into the viscus; it is dangerous, because the risk is not inconsiderable of wrecking the operation by rupturing the urethra; especially in young children, and by destroying with the finger the natural relations of the parts. It is a misconception of this kind which alone imports an element of danger, so far as the mechanism of perineal lithotomy is concerned. Of the advantage that the latter operation affords as a means of draining the bladder I need not again speak.

But though, as I have incidentally hinted, suprapubic cystotomy will probably commend itself to some practitioners, by the comparative facility with which it can be accomplished, we must not be unmindful that experience has already shown us that it, like other procedures having the same object, has its own difficulties and dangers. Instances have been recorded where a weakened bladder, under the pressure of distension, has given way, and death has then followed; and similarly the rectum has suffered in a corresponding manner, but without producing any serious consequences. To most of us the simplicity and ease with which lateral lithotomy can usually be performed is such as strongly to prejudice us in its favour, in the absence of any special reason to the contrary, as I have indicated. Still, on the other hand, as I have already said, there are places for both the high and the low operations in the practice of surgery, which they can fill with relative advantage, and without fear of clashing.

In the last place, let me say a few words in reference to the treatment of tumours and growths connected with the interior of the bladder. And I would take this opportunity of acknowledging the important services Sir Henry Thompson has rendered, in both adding to and applying our knowledge in reference to this subject. In surveying the literature relating to the operative treatment of tumours of the bladder, and comparing it with some little experience of my own in cases of this kind, it seems to indicate the great caution that is necessary in the selection of cases suitable for operation.

Malignant growths connected with the interior of the bladder are, I believe, just as much beyond the reach of surgery as those which are occasionally seen involving the cavity of the nose; I have, in a few instances, opened the perineum and explored them with the finger, but, beyond giving vent to offensive urine, mixed with blood, and the debris from the growth, I cannot say that I have seen any permanent good follow, and I am disposed to think with others they had best be let alone. If exploration with the

finger from the perineum indicates, by reason of the limited connections of the growth, the expediency of attempting its complete removal, or if the mass is considerable, the suprapubic incision may with advantage be proceeded with. The value of the perineal incision for drainage has already been demonstrated in several instances of this kind. Still, on the whole, the less intravesical malignant growths are interfered with the better, so far as concerns both the comfort and life of the patient. Of the curable forms of intravesical tumour of the bladder, the simple papilloma or villous growth furnishes us with an example, and this has undoubtedly within the present decade been brought within the reach of surgery. In the cases of this kind where I have operated, I have been able to accomplish all that I desired by a perineal incision. The following instances illustrate some of the difficulties connected with the diagnosis and treatment of tumours of the bladder. The first was that of a young man I saw in 1883, who was suffering from hæmaturia. I opened his bladder from the perineum, and removed a villous growth, which seemed to occupy the orifice of the left ureter; he was temporarily relieved, but in the course of a month he died of exhaustion in consequence of repeated attacks of hæmaturia. After death, the left ureter was found dilated; the pelvis of the left kidney was also dilated, and contained a villous growth resembling that which I had removed from the bladder.

The other case was that of a middle-aged man, who presented all the symptoms of calculous pyelitis of the left kidney. The pain was so severe that I determined to open and explore the kidney, which I did in the early part of December, 1887. I found the kidney not much larger than natural, but it was simply a bag of pus. I could find no stone or other cause for the renal obstruction. The bladder was examined, but nothing abnormal was detected. The patient had a good deal of hæmaturia after the operation. He got gradually weaker, and died about four weeks after the operation. At a *post-mortem* examination, a small epithelioma of the bladder was found, which had completely occluded the left ureter, and had thus led to the disorganisation of the corresponding kidney. Such are illustrations of some of the difficulties which attend the diagnosis of tumours connected with the interior of the bladder; they certainly seem to indicate the great caution that is necessary in coming to a conclusion that their extirpation should be attempted.

I have now completed the task which you, in your kindness, have imposed upon me. It only remains for me to thank you for the patient and attentive hearing you have given me.

A CASE OF CIRRHOSIS OF THE LIVER, WITH CHRONIC CEREBRAL SYMPTOMS DEPENDING UPON THE CIRCULATION IN THE BLOOD OF DIGESTIVE IMPURITIES.¹

By DAVID DRUMMOND, M.D.,
Physician to the Newcastle-on-Tyne Infirmary, etc.

I HAVE ventured to invite the attention of the members interested in the Medicine Section for a few moments to a case, which I confess puzzled me not a little when attempting to interpret its clinical features. In addition to throwing some light upon certain nervous phenomena that have given rise to difference of opinion from time to time—I refer to some of the nervous symptoms of acute yellow atrophy of the liver, so-called bilious attacks, and allied conditions—it exemplifies the manner in which an organic lesion of one portion of the economy may be responsible for symptoms referable to another that practically mask and overshadow those of the primary lesion; just as in winter the scion mistletoe may usurp the importance of the apple by concealing with its evergreen leaves the naked branches of the stock. I regret that the early history of the case I am about to relate is not as accurate as I could wish, owing to the fact that the patient's memory was considerably impaired, and in consequence we were dependent upon his wife, who lived at a distance, for the major portion of the details. It is also a matter of regret that some of the points were not more exhaustively worked up; but we are all wise after the event, and I suspect a *post-mortem* examination suggests to the minds of a good many of us errors of

omission which good resolutions prompt us to avoid in the future.

J. W., aged 39, a sailor, an American by birth, was admitted into the Newcastle-on-Tyne Infirmary on September 9th, 1886. His previous history, as far as it could be ascertained, was as follows. For eighteen years he had sailed from English ports, and during that time he was much exposed to malarial influences, chiefly in New Orleans. There was no history of syphilis or of alcoholic excesses. Nine years previously he had suffered from a severe attack of intermittent fever, and some time later was admitted into Guy's Hospital for jaundice. On recovering he returned to sea, and remained in good health until the beginning of 1886, when he began to complain of weakness, loss of appetite, etc. He continued to perform his duty, though with difficulty, until February 2nd, when he was obliged to leave the ship on account of illness. On his return home his wife remarked that his skin was sallow, that he looked ill, and that his mental condition was altered. He was fitful, for example, and was inclined to wander about the streets in an aimless way, which he did for two or three days, when an attack of excitement with delirium occurred, and it was with difficulty his friends could restrain him in bed; indeed he occasionally eluded their vigilance, and rushed into the streets in his nightshirt. For some weeks this condition continued, though the excitement became more controllable, and his mental state gradually improved.

On March 30th (1886) he was admitted into the Middlesbrough Infirmary, having presented himself in the first instance as an out-patient for right inguinal hernia, when an enlargement of the spleen was detected. During his stay in the Middlesbrough Infirmary, which was for upwards of four months, his speech and sight were noticed to be impaired, and his mental condition peculiar; his memory was defective, and he was as a rule markedly apathetic, though occasionally emotional. The tendon jerk was increased in both arms and legs.

Whilst under treatment in hospital his general health improved, but his nervous symptoms remained unaltered. He then returned home for some weeks, when his wife found it very difficult to manage him. He took a dislike to his children, and made free use of the most foul language, a practice that was foreign to him. He would lie for hours at a time taking no notice of the surroundings, and then break out into a state of wild excitement. He now rapidly became weaker, and at the same time more unmanageable, so that his wife was glad to transfer him to the Newcastle Infirmary.

On admission he was observed to be a dark-complexioned man, fairly well nourished, with a peculiar earthy sallow pallor of the skin, and looked older than his age. His speech was slow, drawing, and deliberate, and strongly suggested the speech of a general paralytic. His memory was decidedly weakened, though at times he appeared to have accurate glimpses of his past life. He was highly emotional, laughing or crying easily. The sclerotics were tinged yellow. The tongue was clean and was protruded tremulously; there was, however, no tremor of the lips. The arms shook on muscular exertion, as, for example, when he lifted a cup to his mouth. A similar tremor affected the head on sitting or standing. The gait was unsteady, swaying, and tremulous. The tendon-jerk phenomenon was decidedly increased in both upper and lower extremities. The plantar reflex was absent. The limbs were much stronger on the right side than the left; in fact, there seemed to be a slight degree of left-sided hemiplegia. There was no anaesthesia, but, on the contrary, a certain degree of general hyperaesthesia was remarked. The spleen was considerably enlarged, rounded, and firm, and reached to the level of the umbilicus and to within an inch of the middle line. The liver dulness was diminished. The urine was passed in considerable quantities, the daily amount being rather above the average, varying from 50 to 80 ounces in the twenty-four hours. It was the colour of Madeira, bright and clear, and contained more than a trace of bile, but no albumen or sugar.² Several specimens were sent to Dr. Bedson, the Professor of Chemistry in the College of Physical Science, who was asked to examine it for iron, and he kindly furnished me with the following report:

"Several determinations of the iron in the first sample of urine received in December, 1886, were made, and the most reliable give 38 milligrammes of iron per litre. I had some trouble with this sample, some of the iron determinations appearing excessively high. The second sample was examined two weeks later, and

² The test for sugar was only made once by the clinical assistant, and his observation was not verified.

¹ Read in the Section of Medicine at the Annual Meeting of the British Medical Association, held at Dublin, August, 1887.

found to contain 39.6 milligrammes of iron per litre; this sample was examined for bile, and found to contain bile acids. The third sample was received on December 23rd, and was found to contain 10.34 milligrammes of iron per litre. These amounts, expressed in grains per ounce are as follows:

- I.—0.016 grains of iron per ounce.
 II.—0.0173 " " "
 III.—0.0045 " " "

"No. III represents, it would appear, the normal amount of iron found in the ash of urine, whilst in Cases I and II the amounts are between three and four times this quantity."

An examination of the blood showed a diminution in the number of red corpuscles; some appeared to be crescent-shaped, and many were below the average in size. In a cubic millimetre there were 3,460,000 red and 6,600 white, or about 1 white to 520 red corpuscles. There were no changes detected with the ophthalmoscope. For some weeks little or no alteration was apparent in his condition. He took food fairly well, and the bowels were opened regularly every day. The temperature and pulse maintained an even line of health, though as time wore on it was observed that the thermometer in the axilla seldom indicated more than 97.4° F. in the morning. The nervous symptoms gradually increased. The speech became less distinct, more drawling, and syllabic; the sight appeared to grow more and more dim; muscular power diminished generally, and inco-ordination increased, so that he found it impossible to stand or walk alone. His mental obliquity became more decided, and occasional attacks of excitement varied an otherwise monotonous state of helpless apathy. The bilious coloration of the skin developed slowly, and the urine became darker, though the aspect of the patient was more one of profound anæmia than jaundice.

The note on February 12th, 1887—five months after his admission to hospital, and some time after the diagnosis of cirrhosis of the liver was definitely made—is as follows:

Since last observation the patient has been going down the hill steadily; the speech is thicker, and even more suggestive of general paralysis. Is very drowsy, quiet, and inoffensive; the conjunctivæ are more deeply tinged. He trembles very much when he attempts to stand, and is quite unable to walk alone. No ascites. Liver dulness is reduced to one inch of dull area in the neighbourhood of the sixth interspace in the anterior axillary line. Well-marked systolic murmur in the tricuspid area. Temperature normal; pulse 70. Reflexes the same as before.

On February 24th the nurse reported that during the previous few days she had observed that the patient had become more irritable and excited. He was now delirious and wildly excited; the pupils were dilated and fixed; the tongue was dry and brown.

On February 26th, as the delirium still continued, one-sixtieth of a grain of hyoscyamine was injected hypodermically, but with very little effect. Next day, spasmodic attacks, chiefly of the muscles of the back, arms, and face, were observed. During a spasm the back was arched (opisthotonos), and the mouth was twisted to the right side, and in the interval between these attacks, choreiform movements of the head, trunk, and limbs, with marked horizontal nystagmus, occurred. The urine now contained a considerable quantity of blood, and coarse crepitations were audible in the lungs. These irregular choreiform movements, affecting chiefly the legs and fingers, continued until March 9th, when they subsided in great measure, and consciousness partially returned. The jaundice was now pronounced, and, rapidly becoming more and more prostrated, he died on March 16th, fifteen months from the date that was supposed to fix the origin of the symptoms.

Necropsy.—Rigor mortis pronounced; right leg œdematous; universal jaundice, though not of a deep tint.—Heart: Both ventricles dilated; the right contained a quantity of *ante-mortem* clot; aortic valves competent; mitral and tricuspid orifices dilated, their valves normal. Lungs: Right adherent; lower lobe congested and œdematous; muco-pus exuded from the cut ends of the bronchial tubes; a number of patches of catarrhal pneumonia; the left lung presented similar appearances. Abdomen: No effusion; a large tortuous vein, the size of the middle finger, ran in the course of the round ligament of the liver, and, passing on to the right side of the abdominal wall, it descended, covered by peritoneum, in the position of the deep epigastric vein, to join the right external iliac just above Poupard's ligament. On tracing this abnormal vein down the round ligament, it was seen to enter the left branch of the portal about an inch from the bifurcation;

in fact, it was practically the direct continuation of the left division of this vein. The liver was small, granular, and decidedly cirrhotic. It weighed 40 ounces, and on section the substance was seen to be broken up into small yellow islands or nodules, varying in size from a pin's head to a split pea. The larger branches of the portal vein in the liver were filled with firm blood-clot (thrombosis). The gall-bladder contained about 2 ounces of thick, tar-like bile. The larger bile-ducts were not obstructed. The spleen was enlarged, and weighed 39 ounces. It was soft and pale, and a section disclosed a large number of dilated veins. The trunk of the splenic vein was dilated to about twice its normal size. The kidneys were slightly enlarged, but, beyond a somewhat adherent capsule, presented nothing abnormal. The hæmorrhoidal and œsophageal veins were much enlarged. The brain was pale, soft, and œdematous, but otherwise seemed quite healthy; the membranes, grey matter, and vessels showed no morbid changes.

The view taken of the case in the light of the *post-mortem* examination was that the cerebral symptoms resulted entirely from the poisonous effects of digestive impurities circulating in the brain. It was quite obvious that the portal blood entered almost directly into the systemic circulation, without passing through the liver, and therefore was not subjected to the purifying influences of that organ, but passed at once to the brain, whose functions were consequently disturbed. The occurrence of nervous symptoms in the course of a case of hepatic cirrhosis is no new observation, but as a rule they have intervened towards the end of the case, and I am not aware of any cases entirely parallel with the one I have just related, though Frerichs cites the case of a boy, aged 10, who, along with cirrhosis, suffered from difficulty of speech, paralysis of the facial muscles, and general muscular weakness, but without mental symptoms until shortly before death. He has observed, however, noisy delirium with spasmodic muscular contractions; and Dr. Hilton Fagge refers to a man with cirrhosis who lay for two or three weeks in a semi-comatose condition.

The symptoms in my case resembled very closely those of a case of general paralysis. The attacks of excitement, the tendency to melancholic depression, the slow, drawling speech, and the muscular inco-ordination furnished a picture that could not fail to suggest that disease. On the other hand, the noisy delirium and extreme restlessness towards the termination of the case brought forcibly to one's mind the features of a case of acute yellow atrophy. The accessory portal vein running in the round ligament has been met with by Sappey, and Rindfleisch describes a case in which the portal blood passed directly into the cava through a number of dilated anastomoses between the mesenteric and spermatic veins, but I am not aware that there is any record of the symptoms in these cases.

ON ADDISON'S DISEASE AND THE FUNCTION OF THE SUPRARENAL BODIES.¹

By C. A. MACMUNN, M.A., M.D. DUB., Wolverhampton.

No satisfactory explanation has yet been given of the bronzing of the skin and of the peculiar train of symptoms which frequently accompany disease of the suprarenal bodies, and this is not surprising since anatomists and physiologists can give us no idea as to the function of these organs.

In this paper I have collected certain bits of evidence which may help to advance the inquiry a stage, even if my arguments should fail to convince the critical.

I propose to consider the subject under the following heads: 1, the comparative anatomy and development of the adrenals; 2, their physiological chemistry; 3, theories as to their function; 4, results of spectroscopic examination of the adrenals and of the urine in Addison's disease; and 5, teachings of pathology.

Comparative Anatomy and Development of the Suprarenal Bodies.—The great use of the adrenals in the life of animals is proved by their wide distribution among vertebrates; since they are found in mammals, birds, reptiles, amphibians, and fishes.

In fishes they lie on the anterior or posterior surface of the kidneys as small paired or multiple bodies, varying in size from that of a pin's head to that of a bean (Eberth).² In elasmobranchs

¹ Read before the Pathological Section of the Birmingham Branch of the British Medical Association, January 27th, 1888.

² Stricker's *Histology*.

They form a double row of bodies, arranged segmentally, lying on the right and left of the vertebral column, and consist of a mesoblastic and a sympathetic part. They may be wanting in some teleostei, but when present they sometimes represent the metamorphosed anterior (lymphoid) part of the kidney, and sometimes are closely united with the kidneys. It is probable that in all vertebrates they arise in connection with the pro- or mesonephros (Wiedersheim).³

In amphibians they form small yellowish granules, and lie either on the ventral side (Anura) or on the inner side (Urodela) of the kidneys, receiving their blood supply both in amphibians and reptiles from the renal-portal vein (Wiedersheim).

In reptiles the adrenals are of a bright yellow colour, of an elongated or lobulated form, and lie in close contact with the genital glands (Wiedersheim). In batrachians, saurians, chelonians, and birds, the cortical and medullary substances are placed side by side, in rounded heaps or in branched cords or columns (Eberth).

In birds "the weblike arrangement of the branched cortical and medullary columns is still more distinctly marked" (Eberth).

In mammals the suprarenal of each side forms a definite and uniform mass, lying close to the corresponding kidney, and in it an ectodermal (that is, sympathetic) medullary, and a mesodermal cortical substance can always be recognised, the two elements here being closely united together (Wiedersheim).

As we ascend the vertebrate scale the adrenals become gradually better developed; the same remark applies to the respiratory pigments. In fishes and amphibians the muscle hæmoglobin, and the myohæmatin are badly developed, in reptiles better, while in birds and in mammals they reach their highest point of development.

It is not my intention to refer to all recent work on the development of the adrenals. I will merely briefly refer to Balfour's researches on the development of the elasmobranch fishes; they are well known. He showed that in these there are "(1) a series of paired bodies derived from the sympathetic ganglia, and (2) an unpaired body of mesoblastic origin. In the amniota these bodies unite to form the compound suprarenal bodies, the two constituents of which remain, however, distinct in their development. The mesoblastic constituent appears to form the cortical part of the adult suprarenal body, and the nervous constituent the medullary part." Mitsukuri⁴ has confirmed Balfour's views by studying the development of the adrenals of the rabbit and the rat, and finds that the medullary part arises from the sympathetic ganglia, and the cortical part is of mesoblastic origin; the former at first is outside the cortical part, but becomes gradually enclosed by it, but still retaining some connection with the neighbouring ganglia. Hence we know that the bulk of the adrenal is not of nervous but of mesoblastic origin, for in the adult (mammal) the thinner parts of the organ consist entirely of cortical substance (Schäfer),⁵ so that the adult suprarenal may be considered a glandular organ.

Physiological Chemistry of the Adrenals.—Hoppe-Seyler (*Physiologische Chemie*) shows that the medulla of the adrenal contains a substance which is easily changed (by decomposition) after death, and besides albuminous bodies, a substance which is coloured dark blue to blackish green by ferric chloride; carmine-red by oxidising substances such as tincture of iodine, chlorine- or bromine-water; and red by the sub-chlorides of manganese, cobalt, and nickel. The watery extract assumes, by standing exposed to the air, especially if exposed to sunlight, a red colour. On extracting the adrenals with dilute hydrochloric acid, and adding ammonia to the extract, a beautiful red colour is produced. The substance giving these colour changes is soluble in very dilute aqueous acid solutions, insoluble in ether, alcohol, chloroform, bisulphide of carbon and benzol; it has not been isolated, and belongs, according to Virchow, to the fluid bathing the tissue elements. [Krukenberg considers that several chromogens are present in the adrenals.] Cloëz and Vulpian have found hippuric and taurocholic acids and calcium chloride in the adrenals of the sheep, and Seligsolin found benzoic acid and taurin, the latter having also been found by Holm. Kulz found inosit in them. I think it is highly impro-

bable that these constituents could have found their way into the organ "by imbibition;" they must be produced in the organ itself. If so very active downward metabolism must be taking place there.

Theories as to the Function of the Adrenals.—The textbooks agree in stating that we know nothing of the function of the adrenals. In Carpenter's *Physiology* (ninth edition, 1881) it is stated: "Although Brown-Séquard found that ablation of the suprarenals was found uniformly fatal, yet others—for example, Phillipeaux—" have shown that this effect is rather attributable to hæmorrhage and the unavoidable injury to the nerves, and especially to the semilunar ganglia, attendant upon the operation, than, as Brown-Séquard believed, to the retention of some poisonous substance in the circulation, which it is the office of these bodies to remove." But of late Tizzoni has produced bronzing of skin and mucous membrane by artificially removing the adrenals, so that the above statement may be set aside. The idea that the adrenals are concerned in the elaboration of nutrient material is negated by the result of chemical examination, and that of their being nervous ganglia by the results of recent studies on their development.

The view of Dr. Harley, lately supported by Spämann,⁶ that the adrenals are merely persistent foetal structures—even if true—would prove nothing, nor add to our knowledge of their function in adult life. But we have on the other side the opinion of Professor Wiedersheim, who says: "Their extraordinary richness in blood vessels, which is seen throughout life, points to the important function of these organs; but it is impossible to say at present what that function is." Besides, the distribution of the lymphatics of the adrenals, which Klein has studied, shows that these vessels must be concerned in carrying away some product of the metabolic activity of the gland, as Klein, indeed, assumes, a view recently confirmed by Stilling,⁷ who shows that the pigment formed in the adrenals is carried away by the lymphatics to those lymphatic glands which lie along their path.

The fact that the adrenals are relatively large in foetal life—at the end of the third month as large as the kidneys—proves nothing. The thyroid gland is of relatively large size during foetal life also; and although a remnant "of one or more diverticula of the ventral wall of the pharynx or floor of the mouth," and "an ancient glandular organ," speaking from a phylogenetic point of view, "the secretory function of which in relation to the alimentary canal was of great importance in the ancestors of existing vertebrates,"¹⁰ yet we know it must be of importance physiologically, for its atrophy from disease or its extirpation surgically leads to the production of myxœdema.

We ought not to lose sight of the fact that during foetal life the liver has to manufacture red blood-corpuscles, and as the adrenal seem to be supplementary to the liver in one, at least, of its functions even in adult life, it may possibly be concerned in foetal life with the removal of certain waste products instead of the liver.

Results of Spectroscopic Examination.—When carrying out an investigation of the spectra of the organs and tissues of vertebrates and invertebrates, I came upon the interesting fact that the suprarenals show the presence of the bands of hæmochromogen or reduced hæmatin, which I found to be especially well-marked in their medulla. In man, dog, cat, rabbit, rat, guinea-pig, ox, and sheep the result was practically the same. Wherever I had previously detected hæmochromogen in the fluids or organs of the body it had been excretory. There was indeed one exception—namely, in a beetle (*Staphylinus oleus*); as its testes seem to contain this substance mixed with hæmoglobin, but this fact does not bear on the matter under discussion. In the liver¹¹ and in the bile hæmochromogen had been detected previously by me; hence, when I found it in the adrenals, I concluded that here also it must be excretory. Moreover, the appearance of the spectra differed in some cases in such a manner as to lead me to conclude that the substance which was being changed into hæmochromogen was found in different stages of metabolism, and the bands of the latter were certainly made fainter when the blood-vessels of the animal were washed out with salt solution. I subsequently found that it is highly probable that not only hæmoglobin, but also the histohæmatins may furnish hæmochromogen; and one frequently

can detect a histohæmatin, especially in the cortical part of the adrenals. Hence I drew the obvious conclusion that in the adrenals a downward metamorphosis of worn-out pigments—hæmoglobins and the histohæmatins—is taking place, and the function of these organs is to pick out of the circulation these worn-out or effete colouring matters with their accompanying proteids; for if the coloured constituent be present, so also must the proteid, which together originally built up the molecule of a hæmoglobin or a histohæmatin. If then the adrenals discharge this function, we ought to find evidence of the presence in the excretions of incompletely metabolised pigments, when these pigment-metabolising organs are unfitted by disease for the performance of their function. And that is exactly what is found. I have detected, by means of the spectroscope, in the urine of Addison's disease, such a pigment, which I named "urohæmatin,"¹² but, subsequently, I changed its name to "urohæmatoporphyrin," since it is a kind of hæmatoporphyrin. The urinary pigments traceable back to bile and hæmatin are two in number—namely, normal and febrile urobilin, but the above pigment is, as I have shown, produced only from hæmatin by the action of such reducing agents as zinc and sulphuric acid and sodium amalgam. In the JOURNAL for 1883 (December 1st) I showed that it occurs in the urine of acute rheumatism, but subsequent investigation has convinced me that it is present in various febrile conditions, and to sum the matter up, it may be said to be present in urine under at least two conditions: (1) when an excess of effete hæmoglobin or histohæmatin¹³ is present in the circulation, the blood-metabolising glands being healthy, but incapable of dealing with the excess of effete pigment; or (2) when the amount of effete pigments may be not in excess, but the blood-metabolising glands are diseased. In the urine of cirrhosis of the liver, where the secretory cells are encroached upon by connective tissue, it is present, and in the urine of Hodgkin's disease, when the skin had become bronzed, owing to disease of the adrenals, it has been found. In a case of this kind Dr. Saundby actually labelled the specimen "urohæmatin," suspecting its presence from what I had told him, and it was present. In Addison's disease I have found it several times. In the later stages of that disease, when the blood has become deteriorated from the presence in it of various poisonous products of incomplete metamorphosis, of course we may have to acknowledge two sources of this urohæmatoporphyrin—namely, effete pigment present from disease of the adrenals, and effete pigment due to subsequent excessive destruction of the red blood-corpuscles. In many cases the simple addition of a mineral acid to the urine will bring out the bands of acid urohæmatoporphyrin; in other cases it may be necessary to precipitate the urine with neutral and basic acetate of lead, decompose the precipitate with rectified spirit acidulated with sulphuric acid, and filter; this filtrate then shows the bands of acid urohæmatoporphyrin well marked, and from this it can be isolated by agitation with chloroform, as I have elsewhere described. C. Nobel has lately confirmed my conclusions with regard to this pigment, and proposes calling it "isohæmatoporphyrin."¹⁴ Its presence, however, in the urine lends support of a substantial kind to my theory, and teaches that other conditions being absent, it may be due to disease of the blood-metabolising glands; and since in many cases where I have found it the only glands diseased were the adrenals, these must be blood-metabolising glands.

The discovery by Krukenberg¹⁵ of the presence of pyrocatechin, or a nearly related substance, in the alcohol extract of the adrenals of herbivorous animals, has led some to suppose that his results contradict mine. Krukenberg never said so; he only stated that it was incomprehensible to him that I should have found hæmochromogen in perfectly fresh organs, but he does not deny its occurrence. It must be remembered, as Krukenberg himself says, that several chromogens are present in the adrenals, and the one which Krukenberg investigated was soluble in alcohol, whereas hæmochromogen is not. Possibly the adrenals of carnivora may

not contain pyrocatechin, for in the blood serum of herbivora and in their urine various "aromatic" substances are present which, as Hoppe-Seyler has shown, are peculiar to them; but even if present in the adrenals of flesh-eating animals, it would lend support to my theory. We know that other aromatic bodies such as indol, skatol, kresol, etc., are produced from proteids by the action of ferments; and although putrefaction seems necessary for the production of some, yet with our present knowledge we cannot say that they are not produced within the body in the absence of putrefaction; indeed, skatol does not owe its increased production in diabetics, in all probability, to putrefaction. Therefore, the presence of pyrocatechin in the adrenals would merely show that proteid metabolism is taking place there, which is one of the points I wish to prove.

Teachings of Pathology and General Summary.—I do not propose considering the question whether there is a specific disease of the adrenal, such as a "strumous" or tuberculous condition present in that class of cases known now as Addison's disease, or whether Dr. Addison wished after he had published his views to narrow the pathology of that disease to disease of the sympathetic ganglia.¹⁶ Because many believe with Virchow that the peculiar train of symptoms (with bronzing of the skin, which are characteristic of Addison's disease, may be brought about by various morbid conditions of the adrenals, and a perusal of recently recorded cases shows that we must extend our view so as to include such morbid conditions. Nor should I consider the occurrence of diseased adrenals without bronzing of the skin, or bronzing of the skin without disease of these organs, an argument against the theory adopted here, because the adrenals being supplementary organs, other organs may do duty for them to a great extent, under certain unknown conditions. Besides, if Addison's disease were to occur in a patient in whom by previous disease the hæmoglobins and the histohæmatins had been diminished in amount, we should not expect to meet with much effete pigment in that case.¹⁷ And even if the adrenals are apparently healthy, we cannot always say whether there has not been some interference with their nervous (or arterial) supply sufficient to prevent the discharge of their functions. Looking over the recent literature of this subject, one finds some very interesting cases of Addison's disease described. In the case recorded by Dr. Wickham Legg,¹⁸ there were shortness of breath, giddiness and vomiting, bronzing of skin, and paroxysm of fever. In Monti's¹⁹ case there were several febrile attacks during the course of the case, drowsiness and heavy sleeps, excitement, delirium, and loss of consciousness, and death took place in a convulsion. In Rauschenbach's²⁰ case there were rigors and "heat" at the beginning of the illness, restlessness, delirium, and various nervous symptoms. In Cacciola's²¹ case febrile attacks were also noticed, and the patient became delirious before death, and died in a convulsion.

In some of these cases the nervous symptoms and the hyperthermia are very remarkable (especially as it has been said the temperature is subnormal in Addison's disease, which is a very doubtful statement), and these symptoms are explicable only on the assumption that some toxic substance or substances must have been present in the blood. That such is the case seems more than probable from the experiments of Foa and Pellacani,²² which have not met with the attention which they deserve. These observers injected an aqueous filtered extract from certain organs, namely, the brain, the testis, and the adrenals, into the veins of rabbits; and found that death ensued, which was due to coagulation of the blood in the heart and lesser circulation. They proved that a fibrinogenous ferment, both chemically and physiologically active, was present in the solutions, which is due not to the blood circulating in these organs, nor to destruction of white corpuscles in them, but to a substance present in the organs; and when the solutions injected were little active, marasmus was produced, from which the animal died. But here is the most important result; they found that aqueous and alcohol extracts of the adrenals had a most toxic

effect, an effect peculiar to the extracts of these organs. The poison present in the adrenals is more like an organic acid or a "ptomain" in its action; it paralyses the spinal cord, etc., and causes death by paralysing the "bulbar centre," and especially the respiratory centre. In this, then, the product of proteid disintegration which it is the province of the adrenals to pick out of the circulation and metabolise into a harmless substance, and which, when these organs are diseased, accumulates in the blood, and produces nervous symptoms and hyperthermia; for Foa and Pellacani found that it also produced increase of temperature?

We know that the poisonous alkaloids of animal origin, the ptomaines and leucomaines,²² are products of "proteid disintegration." The poison of the adrenals is, however, probably neither the one nor the other, but a nitrogenous, non-crystallisable substance akin to Panum's septic poison; such bodies produce hyperthermia, whereas the ptomaines and leucomaines produce hypothermia. The bodies which are nearer proteids, or themselves of a proteid nature, appear to be even more poisonous than their lower metabolites. As is well known, Wooldridge²⁴ obtained a proteid poison from serum which prevents shed blood from coagulating for several hours; and another proteid poison²⁵ from the testis and thymus of the calf, which, injected into the blood vessels of an animal, causes instant death, due to wide-spread intravascular clotting. Wolfenden,²⁶ too, has shown that the poison of the Indian cobra (*Naja tripudians*) and the Indian viper are of a proteid nature.

The presence of urohæmatoporphyrin in the urine of Addison's disease led me to hope that I should find this or some other metabolite of hæmoglobin in the skin of patients sufficiently bronzed for the examination, but in this I have been disappointed. Professor Victor Horsley and Dr. Dingley kindly procured some skin, and the latter some slate-coloured mucous membrane from the mouth, from patients suffering from Addison's disease; but although I detected traces of iron, I could not see any bands. But this is not surprising, seeing how quickly blood becomes altered in those situations.

Dr. Riehl²⁷ and Dr. Ernest Kummer²⁸ have made some observations on the distribution of pigment in the skin in these cases. Dr. Riehl concludes that the pigment is extracted from the blood by the cutis cells, and that it is not produced *in situ* by metabolic processes in the cells of the rete; he also found thrombi in the blood vessels of the skin. Kummer confirmed these results, and thinks that we may assume a disease of the blood as a cause of Addison's disease. But it seems to me that the pigment primarily deposited in the skin is different in its origin from that deposited later, when the blood itself has become deteriorated from the presence in it of the products of incomplete metamorphosis. It is interesting to compare with Dr. Riehl's statement that of Wiedersheim²⁹ on the pigmentation of the skin of lower vertebrates; he shows that the derma is permeated by leucocytes, especially in fishes. These leucocytes penetrate to the superficial layer of the epidermis, and carry pigment granules. Here they take on amoeboid movements, and break up into numerous small, pigment-containing particles, which are taken up by the epithelial cells.

It would appear, then, that comparative anatomy and comparative embryology, physiological chemistry, the evidence supplied by the spectroscope and by pathology, all point to the same conclusion.

Just as there has been a progressive development of vertebrata in time, the fishes appearing in the upper silurian, the reptiles in the carboniferous, the birds in the triassic, and mammals in the jurassic, or even in the triassic systems,³⁰ so has there been a progressive development in their organs. As the animal body became more complex, and a greater abundance of respiratory pigments had become necessary for internal and ordinary respiration, certain organs had to be set apart, or had to take on a new function, in the increased "division of labour." This function in the case of the adrenals was the removal from the circulation of useless and worn-out pigments and their accompanying proteids.³¹

When the adrenals are diseased, these effete pigments and effete proteids circulate in the blood; the former, or their incomplete metabolites, producing pigmentation of skin and mucous membrane, and appearing often in the urine as urohæmatoporphyrin; the latter producing toxic effects, and leading to further deterioration of the blood with its consequences.

NOTES ON A CASE OF TRAUMATIC EPILEPSY SUCCESSFULLY TREATED BY TREPHINING.¹

By THOMAS OLIVER, M.D., M.R.C.P.LOND.,

Physician to the Infirmary, and Lecturer on Practical Physiology, University of Durham College of Medicine, Newcastle-upon-Tyne.

Two years and a half ago I admitted A. T., a boy aged 16 years, into the Newcastle-upon-Tyne Infirmary, suffering from fits. He was a healthy looking and well nourished lad, but somewhat of a reserved disposition. It appears that until four months before I saw him he had never had a day's illness, and the history I got was as follows. On a certain day he joined some boys of his own age in the game of tug-of-war. When pulling with all their might, some of the boys suddenly let go; and, as a consequence, the patient fell violently upon the side of his head upon the ground. For a few moments he was stunned, but he soon regained consciousness without vomiting, and was able to go home apparently none the worse for the injury. For ten days he was quite well. One morning, after getting out of bed and whilst in the act of dressing himself, he had his first convulsive seizure. It was extremely sudden in its onset, without any prodromata, and was accompanied by unconsciousness. He was put to bed, and on regaining consciousness complained of pain in the right side of his head. From that day he suffered from several fits daily—each series more severe than the preceding—and followed by an alteration in his disposition; moroseness and sullenness replacing a character previously noticed for its liveliness.

His father is a healthy man, his mother, though the subject of mitral stenosis, enjoys good health; one sister, at the age of 9, suffered from fits which were regarded as epileptic, and which suddenly disappeared after a severe fall, which she had in her twelfth year, after the closure of an extensive scalp wound, the consequence of the fall.

When I saw him, his one complaint, in addition to the fits, was severe pain localised over the right temporal bone, over an area, an inch in diameter, located at a point almost midway between a line drawn from the outer angle of the right orbit to the ear, and about one inch and a half superior to it. He could not bear any pressure applied to this point. Before, and immediately after a fit, the pain over this small localised area was increased in severity, but no fit was ever induced by pressure made upon it. There was nothing to be seen or felt here, the skin was perfectly healthy, it had never been broken at the time of the fall. Whilst the fits were of a purely epileptic character, there are yet one or two points that call for attention. An aura was now felt before nearly all the fits, particularly those that became severe, and were accompanied by unconsciousness. He thought he saw a cat, the picture of which was still present in his mind, even after all his motor disturbance had subsided, and while yet in the transitional stage from coma to complete consciousness. It was noticed that in many of the severer fits the left arm and leg were much more convulsed than the right, and that as regards precedence, they were the first to be affected, the two sides of the face suffering equally. In addition, not only were the left arm and leg frequently the seat of marked paresis, which lasted for several days after the fit; but occasionally they were the subjects of choreiform movements over which he had no control, and which at times passed over to the right arm and leg, but were never of the same extensive range as on the left side where they originated. Frequently, after a severe fit, the stage of stupor was very protracted; for two or three days the patient would lie speechless and deaf, able to take liquid food when brought to him, but never asking for it. On regaining consciousness, and whilst yet deaf, he always at first made known his wants to us in writing. I had been told frequently by the nurses of the great difficulty which they had of keeping him in bed during and immediately after the fits, and happening to be in the wards one night when he was seized with

¹ Read in the Section of Medicine, at the Annual Meeting of the British Medical Association, held in Dublin, August, 1887.

a severe fit, I asked the nurses, after the excessive muscular movements had subsided, to leave him alone so as to see what he would do. Whilst thus unconscious, he made an effort to get out of bed, but in doing so he slightly fell towards his left. With a little difficulty he pulled himself together and began to walk down the ward. It was all he could do to keep on his feet, owing to the drooping and want of power in his left arm and leg, and yet whilst thus unable to move his left leg easily, he at once set off half running, the gait being extremely awkward, from the causes that I have mentioned. He suddenly stopped at the foot of one of the beds in the long ward, knelt down and scanned closely the whole of the floor under the bed. With a little difficulty he got on to his feet again, walked to the other end of the ward, to the table where the wash-hand basin and jug were kept, and attempted to raise the jug to his mouth; the accomplishment of which was prevented by the marked feebleness of the left as compared with the right hand. On coming to himself, though quite aware of having had a fit, he knew nothing of all that I have described. He told me, however, that he had seen a cat, the image of which had lasted a long time in his memory.

On ophthalmoscopic examination, beyond perhaps the slightest hyperæmia, the discs presented nothing unusual; the lungs and heart were healthy; urine was quite normal before, after, and during the intervals between the fits; knee-jerk was generally more marked on the left than on the right side; no ankle-clonus was present, but it was noticed that the push of the left foot and the grasp of the left hand were much enfeebled compared to the same on the opposite side of the body.

Painting with iodine, and blisters were applied locally, bromide and iodide of potassium, liq. hydrarg. bichlor., tinct. bellad. were tried alone and in combination, and in increasing doses without the least benefit.

Failing thus to relieve the patient, a general survey of the history and symptoms of the case—namely, a healthy lad meeting with an injury to his head, this followed in a fortnight by a convulsive seizure, recurrence of fits, now accompanied by unconsciousness, and associated with an excess of movement on the left as compared with the right side of the body, lingering left-sided paresis and choreiform movements, these attended by a localised painful spot on the right temporal bone, pain at which was said to be more severe just before or after a fit—led me to entertain the belief that the epileptic seizures were due to a localised irritation, possibly in the membranes lying upon the motor areas in the convolutions of the right side of the brain. The absence of any break in the skin dissipated any feeling that I might have had of fracture of the inner table of the skull. I suggested trephining as the only likely method of dealing successfully with the fits. My surgical colleagues saw the case with me, and agreed as to the advisability of the operation, recommending, however, the application of the trephine over the painful spot, rather than upon that part of the skull lying upon those portions of the brain now recognised as concerned with the initiation of the movements of the arms and legs—I mean the ascending frontal and parietal convolutions. The painful spot, as I have already mentioned, lay anterior and somewhat inferior to these two convolutions. The operation was performed by Dr. Hume, under antiseptic precautions. A piece of bone, the size of a shilling, was without difficulty removed. The bone was quite healthy, and was easily lifted from its bed, being in no way adherent to the underlying membranes. The dura mater was healthy, in no wise thickened. As the dura mater was healthy it was debated for a few seconds as to the advisability of opening it. By degrees, however, it was noticed that the dura mater was becoming tense, and shortly after this membrane was shot out through the opening beyond the level of the bone, the tension now being very great. Accordingly a crucial incision was made into it, and in a few seconds there escaped from the wound several teaspoonsful of serum, containing a few flakes of lymph. The arachnoid and pia mater seemed healthy, as did also the surface of the brain and the small blood vessels which lay upon it. A very small drainage-tube was inserted, the cut ends of the dura mater were drawn together with delicate catgut, the skin flaps were gently drawn together, a sponge applied, and the ordinary antiseptic dressings placed over all. That evening the dressings were found to be soaking, and on removal a few teaspoonsful of serous fluid were squeezed out of the sponge. More than two ounces of serous fluid escaped that day. The dressings were renewed, and never afterwards required to be changed on account of the escape of fluid. The patient had one or two minor fits on coming out of the

chloroform, and also for two or three days after the operation, but after this they became separated from each other by the interval of a day, then two days, a week, a fortnight, and so on, until no fit occurred during a period of six months. The wound had healed kindly and quickly, without even the least rise of temperature. The patient having long left the infirmary, feeling quite well, no longer having any localised pain in his head, followed for a time the occupation of a telegraph boy, but latterly became the cash boy in a confined counting house. Here he was much harassed by the push of business, the one monotonous call which was made upon him, and by the long hours spent in a wretched atmosphere, and the result was that after being free of fits for six months, he had again to be admitted into the infirmary, where he was placed under my care. The fits were now quite changed in character, the muscular movements were slight, and were never attended by loss of consciousness; the visual aura of the cat was no longer present. The fits were rather those of hysteria, and with rest in bed, iodide of potassium and iron, his general health soon improved, the fits disappeared, and for several months have ceased to trouble him.

Trephining, as a method of treating epilepsy, is only applicable to those cases where there is the history of an injury to the head followed by localising symptoms or by convulsions, either unilateral or more pronounced on one side of the body than the other, or where an injury to the head has been followed by a depressed fracture or separation of a portion of the inner table of the skull. Macewen, of Glasgow, has operated successfully on cases of epilepsy due to injury of bone, and in one case of Dr. Ralfe's—a patient who had been trephined for depressed fracture, and who years afterwards was found suffering from epilepsy—an absolute cure was only effected by the cicatrix due to the trephining operation being again opened up and allowing of the removal of a small portion of necrosed bone evidently belonging to the inner table. As soon as this was done the fits ceased. Gowers speaks of having seen or heard of 65 cases of epilepsy owning a traumatic cause, and of trephining as the only line of treatment likely to be successful, and that, be it remarked, as in my own case, where neither disease of bone, membrane, or surface of the brain was found at the time of the operation. Relief comes either from the operation acting as a strong counter-irritant lasting all through the period of healing, or from the reduction of tension consequent upon the escape of pent-up serum.

It is several months since this paper was written and read, but the last account that I had of this patient from his mother was that he was still keeping free from fits.

ON PUERPERAL APHASIA.¹

By F. BATEMAN, M.D., F.R.C.P.,

Physician to the Norfolk and Norwich Hospital; Corresponding Member of the Academy of Medicine of Paris, etc.

APHASIA, as a complication of the puerperal condition, does not find a place in our classical treatises on midwifery, and the literature of the subject is so scant that, in the course of my reading, I have only met with one observation recorded in this country, although it has been made the subject of a most elaborate essay by a continental observer, to which I shall have occasion to refer after the detailing of my own case, which I desire to head as follows:

CASE OF LOSS OF SPEECH OCCURRING AS A PUERPERAL SYMPTOM; LACTEAL DERANGEMENT; RIGHT HEMIPLEGIA; FATAL TERMINATION.

On September 7th, 1886, I was requested to see, in consultation with Dr. Watson, of Norwich, Mrs. S., aged 23, who had given birth to her second child eight days previous to my visit. Upon inquiry I ascertained she had never been the subject of any cardiac or rheumatic affection, that she had never suffered from any nervous disorder, and, in fact, that she had always enjoyed good health during her single life, with the exception of a disposition to occasional headaches. Her mother was insane, and died in the Norwich City Asylum, but beyond this fact there was no neurotic tendency in the family.

She was delivered of her first child in July, 1885, and at the

¹ Read in the Section of Medicine at the Annual Meeting of the British Medical Association held at Dublin, August, 1887.

seventh month of her first pregnancy she had some obscure symptoms with some embarrassment of speech, which lasted about a month. Her first confinement passed off quite naturally, and she nursed her child for nine months, at first with both breasts, but in one breast (it is believed to have been the left) there was galactorrhœa for some weeks, and then the supply ceased entirely in this mamma.

Mrs. S. continued quite well till three months before her second confinement, when a gradual loss of power occurred in the right arm and leg, but principally in the arm. A month before her confinement embarrassment of speech was noticed, which culminated in complete aphasia six days after delivery, which was quite natural, and unattended by any straining or unusual effort; there was no hæmorrhage, and the lochia were quite natural. The total loss of speech was sudden, for on the evening of the fifth day, although her speech was embarrassed, she could converse and make herself understood; but on the morning of the sixth day it was observed that she was completely aphasic; there was no loss of consciousness, and her general appearance was as usual, the only difference being the total suspension of articulate language. This sudden exacerbation of her symptoms could be attributed to no apparent cause; she had not been exposed to any mental shock or disturbance of any kind, but a thunderstorm of very unusual severity occurred the evening before.

On the second day after her delivery there was a sudden turgescence of the breasts, with an unusual quantity of milk, the lacteal secretion being so abundant that, although the child sucked vigorously, the milk had to be removed artificially; the supply was equal on both sides. This lacteal overflow was but of short duration, for the next day the quantity diminished perceptibly, and on the fifth day the child had to be weaned because the supply was gone.

At my visit on the eighth day after parturition, I found her with right hemiplegia and aphasia, and I observed that she was unable to protrude the tongue. There was no pyrexia; the temperature was normal; the pulse was 74, and there was no cardiac trouble of any kind; there was no pain or swelling of the body, and no abdominal or pelvic complication whatever; there was, however, retention of urine, but nothing abnormal in the secretion itself.

Although unable to speak she evidently understood all that was said, and seemed annoyed, and became angry when too many questions were put to her, and to every question, whatever it might be, she invariably said, "The other day." I asked her how many children she had, she replied, "The other day." I asked her what she had taken for her breakfast, she replied, "The other day." She could say nothing else, and this recurring utterance, whether appropriate or not, she repeated on all occasions; it was a stock phrase, and, of course, had no intellectual value.

Without developing any fresh symptom Mrs. S. gradually became weaker, and sank from exhaustion six weeks after her confinement; and within an hour of her death, in answer to an inquiry as to how she felt, she replied, "The other day," which was the only phrase she had uttered since the commencement of her attack.

The above case is interesting from the association of aphasia with the puerperal condition. Hemiplegia is not an uncommon symptom connected with pregnancy and childbirth. Churchill has recorded twenty-two cases of paralysis during pregnancy collected by him from various sources, but although difficulty of articulation may have been noticed in some of these cases, it was simply due to paralysis of the tongue and the muscles which are concerned in the articulation of words, without any real disturbance of the faculty of language.

Aphasia as a complication directly connected with the puerperal condition seems to be rare, at all events, it has escaped the observation of the writers on obstetrics, for, amongst 8,000 cases of midwifery recorded by a French authority, M. Sirey, not a single instance of the coincidence of aphasia is mentioned. The only case that I have met with in my reading is one recorded by Dr. Leith Napier, the subject of which was a lady who, seventeen days after her confinement, on being subjected to considerable vexation, suddenly became speechless; this was followed in three days by partial paralysis, which culminated in complete hemiplegia two days later. Dr. Napier attributed the above symptoms to occlusion of the left middle cerebral artery from embolism. The patient slowly improved, and eventually recovered.

It is only quite recently that prominent attention has been called to the association of aphasia with the puerperal condition by a most interesting and exhaustive article by M. Poupon in

L'Encéphale for July, 1885, entitled "Des Aphasies Puerpérales," under which name he comprises the divers varieties of disturbance of speech which occur either during pregnancy or during the period of lactation, observing, however, that the occurrence of aphasia under the above condition is extremely rare, although he says that the traumatic and moral shock which recently delivered women may experience cannot but seriously influence the nervous system. This important communication is based upon a case observed by the author at La Charité, in the ward of Professor Laboulbène. The subject of it was a woman, aged 24, J. M., who, on the second day after a perfectly natural delivery, was seized with right hemiplegia and aphasia, her vocabulary (as in my own case) being limited to three or four words in answer to all questions, the expressions used being, "Eh bien," "Oui, oui," "Mais jamais." She was also the subject of word-blindness, but not of word-deafness.

This patient is described as having had an attack of articular rheumatism some years before, and as there was hypertrophy of the heart with mitral disease, the author makes the diagnosis of embolism of the left middle cerebral artery, due to a mitral constriction, upon which was superadded an endocarditis, caused by her puerperal condition; he explains the fact of the sudden occurrence of the symptoms of embolism on the third day, by the hypothesis that the embolus might have been nearly detached during the labour, but that a fresh effort was necessary to complete its separation, and as she was suddenly taken speechless whilst at a meal, he thinks the change from the recumbent to the sitting posture may have been sufficient to complete the detachment of the embolus. M. Poupon enters at considerable length into the pathology of the above case, and also gives a short analysis of others that have fallen under his notice, in two of which he says there was an evident relation between the lacteal secretion and the appearance of the aphasia; in one instance, however, the lacteal disturbance preceded the cerebral accidents, and in the other it followed them; in the latter case (which was one of exceptional interest, from the fact of the subject being left-handed, and the paralysis being on the left side) it is stated that from the moment the left hemiplegia and aphasia were observed, the lacteal secretion ceased in the right breast, whilst in the left (the paralysed side) it appeared to increase, and was much more abundant than usual. According to the statement of the patient, the temperature of the left or paralysed side, as well as that of the corresponding breast, was higher than on the right side; the perspiration was also much more copious on the left than on the right side.

In commenting upon this last observation, M. Poupon calls attention to the increase of the lacteal secretion, under the influence of the paralysis, and he considers the pathological condition was probably vasomotor paralysis of the breast, resulting in dilatation of the vessels, and a more abundant secretion of milk. He adds that women who have experienced a first attack of aphasia as a sequel of delivery should avoid a second pregnancy, and he quotes a case occurring in the practice of M. Gignoux, of Lyons, in which aphasia occurred in two consecutive pregnancies. It will be remembered that this was the case in the history of the lady who formed the subject of my own observation. We know but little of the effect of lacteal disturbance on the nervous system; and in a recent interesting discussion at the Obstetrical Society of London, Dr. Matthews Duncan commented upon the neglect of the scientific investigation of the process of lactation, and the deficiency of literature connected with this important department of practice.

On reviewing the symptoms manifested by the patient whose clinical history I have described, it will be noted that Mrs. S. never had any rheumatic affection, or cardiac complication of any kind; the labour was quite natural, and there was no feature in her condition to suggest the idea of septicæmia, or of blood dyscrasia. The only unusual symptom was anomalous lactation, for it will be remembered there was great turgescence of the mammae, and an excessive flow of milk—quite a galactorrhœa for twenty-four hours—and then a somewhat sudden disappearance of the secretion. From the comparative rarity of the association of loss of speech with the puerperal state, I hesitate to venture upon any decided opinion as to the pathology of the above case. The symptoms could scarcely be due to any merely transient cause, for they had existed in a modified form for three months before parturition, and became intensified a few days after labour; the absence of any cardiac lesion, and the gradual development of the nervous symptoms, would rather point to cerebral thrombosis than to embolism.

ON THE ETIOLOGY AND CURABILITY OF PHTHISIS.¹

By W. R. THOMAS, M.D., M.R.C.P.,

Senior Physician to the Sheffield Public Hospital; Lecturer in Medicine, Sheffield School.

PHTHISIS is one of the most prevalent diseases in Sheffield; one therefore has opportunities of treating it on a very large scale, especially in hospital practice. There are several factors which act conjointly in its production among the working classes, so that one cannot be surprised at its frequency.

Many of the men, and women too, have to assume a stooping position when at work, which does not permit of proper expansion of the lungs, and in this way predisposes to disease. They have to work in shops where a number of others are present, and where, consequently, from this cause alone, the air is the very reverse of pure. The workshops and works are situated in parts of the town where the atmosphere is very prejudicial to health during a great portion of the year; for it is moist, it holds in suspension a large quantity of dust, grit, soot, etc., which are inhaled, cause irritation, and are coughed up frequently during the day; and it also is, in fact, composed of different deleterious gases derived from various sources. The inhalation of such an atmosphere must necessarily be injurious to the internal surface of the lining membrane of the tubes and air cells of the lungs, with which it comes in contact.

Drinking to excess has, according to my experience, done its share of work in the production of this disease. Strong men in this way bring on a diseased state of liver and stomach. Such men, generally speaking, die of hepatic or renal diseases, or other diseases, as those of the nervous system; but, not infrequently, phthisis comes on and rapidly carries the patient off.

Amongst the poor, the habit of drinking tea is a very prevalent one. The women have tea with every meal. This is a pernicious habit, which does an infinite amount of harm; the tea being an astringent, and almost constantly present in the stomach, acts upon its glands and mucous membrane; the secretions become depraved; imperfect and often painful digestion follows as a matter of course; anemia is the result, with general malnutrition, and phthisis. These poor persons drink tea because they cannot afford better food often, and think that they are taking nutritious food, little knowing that they are taking a remedy which is so injurious to the gastric mucous membrane, and ultimately destroys the appetite.

I consider that many cases of phthisis may be traced in a great measure to improper clothing. In winter all persons should wear woollen clothing next to the skin, and in summer the same custom should prevail, but the material should be much thinner, and this should extend from neck to toe. I have seen working men in the third stage of phthisis glorying in the fact that they have never worn any warmer clothing than cotton shirts. Ladies, as a rule, do not wear sufficient clothing. Their undervests, bodices, and other underclothing hardly extend high enough to cover the upper part of the chest. The lower classes are very careless, especially when suckling; you frequently see the chest uncovered more or less for hours. I often find delicate ladies who ought to be warmly clad—much more so than I am—going about in the middle of the winter with no close covering to the lower extremities but a pair of loose linen drawers and stockings. The outer loose clothing in the shape of dress, etc., gives comparatively little warmth. Such ladies, in my opinion, should always wear flannel or woollen clothes closely applied to the skin. Children we see daily, delicate little things, running about with hardly any covering to their lower extremities, nothing but short dresses and petticoats hardly reaching their knees, and thin linen drawers, and yet the parents wonder how they catch cold. Improper and insufficient clothing is a very great factor in the production of phthisis. Want of exercise has much to do with its causation. I find that it is a difficult matter to persuade patients, especially ladies, to take outdoor exercise. They will go out shopping, and they will undergo severe exertion for hours in a ball-room, but will not walk into the country. I believe that much of the benefit derived from residence at some of the places recommended for resort is often owing to

the patient taking plenty of exercise, tempted to do so because the weather permits of it, and the cares of home do not detain within doors. I have after much persuasion often succeeded in getting my patients to take exercise when at home, and have always been well satisfied with the result. By such treatment the appetite has been improved, digestion has been rendered less difficult, and owing to the increased circulation through the lungs healthy changes have taken place. I have always endeavoured to prevent the patient from remaining all along within doors, closely confined to one room perhaps, with medicine bottles on the table, by their side, moping and thinking of their ailments; and I think that we might much more frequently make use of the places of resort in our own country, in England, in Scotland, in Ireland, and Wales, at different periods of the year, than we do, instead of sending them away out of reach of relatives and friends.

In no disease is hereditary predisposition more evident than in this. I have simply in this short paper mentioned a few of the most ordinary causes that I have met with, most of them preventable.

Although, as I have shown, there are so many factors which assist in giving rise to phthisis, still I have been astonished at the number of cases which recover. Fully seven-eighths of those I have had under my care have received decided relief—many would say been cured. The patients have gained flesh, a most important sign; the cough has disappeared; there has been entire absence of expectoration; the appetite has been good, and they have been able to attend to their ordinary duties. Many of them I have watched for years, and have had to treat for other complaints. Many—I may say the majority—I have lost sight of after a time.

Certain physical signs generally more or less remain, as no doubt the lungs have been permanently injured; but I have frequently seen all the physical signs met with in the first stage entirely disappear; those indicative of the second stage recovered in a great measure, and vomicae closed by agglutination of their walls, I presume, leaving no physical sign whatever indicative of a cavity, but of other changes having taken place which have been permanent and harmless.

With regard to the treatment of such cases, I have found no local application to the lung in the first or second stages answer much better to begin with than a small blister, say 2 by 2 inches, applied to the infra-clavicular region, or wherever the necessity seems to be. I believe I have seen in some hundreds of cases the cough relieved, the local signs disappear, and the general symptoms much alleviated by such local treatment. Of course it is very difficult to judge, when general treatment is adopted as well, whether improvement should be attributed to this one application; but still I have often adopted a similar general treatment in other cases without as beneficial a result, and, at the same time, in many cases done but little else than apply this local irritant for a time, and yet seen good results ensue.

I have tried the inhalation treatment pretty extensively, have used many of the inhalers generally recommended, and have had patients placed in a room containing a medicated atmosphere. Many patients have stated that they have derived much benefit from such treatment, that the cough has been ameliorated and the quantity of expectoration diminished by it. Others, again, and I believe the majority, although they have been pleased with the treatment at first, have at length given it up, finding that they have not derived the slightest benefit from it. I believe that in many cases it does diminish the amount of expectoration, and feel sure that it makes the expectoration and breath when offensive less so, and I trust that, as our knowledge increases, treatment by inhalation will be productive of more good every year.

I have reason to be well satisfied with the success of my treatment of the cases of phthisis which I have to take charge of, and consider that that success has been dependent not upon any special mode of treatment adopted. I believe every case ought to be specially studied. The medical gentleman who gives cod-liver oil, a tonic mixture and a linctus to every patient, will not be successful as a rule in his treatment. As I said before, about seven-eighths of my patients have practically recovered. In all these cases I have first of all endeavoured to remove the cause, if found. The patient who had lived in an impure atmosphere has been removed from it. A constrained position when at work has been avoided. The working in a close room has been prevented if possible. The habit of taking alcohol or tea to excess has been put a stop to. Daily exercise has been recommended whenever the weather has permitted of it, and good nourishing diet recom-

¹ Read in the Section of Medicine at the Annual Meeting of the British Medical Association, held in Dublin, August, 1887.

mented to be taken at regular hours. A blister has been applied to the chest, and certain medical treatment, as indicated by the symptoms, adopted, and under the influence of this treatment the patient has frequently got well. Quinine I have found to be one of the most useful remedies; it improves the appetite, it tends to check the nocturnal perspirations, and acts as a general tonic; but many patients cannot take quinine, especially those who suffer from gastric derangements, which have to be specially treated before it is administered. Iron in some form or other is indicated at some time. The perchloride I hardly ever prescribe, as it destroys the teeth in time, however careful the patient may be. I prefer the syrup of the phosphates, the citrate of iron and quinine, or of ammonia and iron, or dialysed iron.

I think in the present day there is a great tendency to ride hobbies. One gentleman does little else except recommend the use of certain inhalers, another prescribes a particular remedy. I believe that the physician who is most likely to cure his patient is the one who, having satisfied his mind as to the exact condition of his patient, does his utmost to find out what has brought on the complaint, and having found out the cause, is firm, and if possible compels his patient to avoid it. By avoiding the cause of a disease much is done toward the cure. We should always keep in mind that great benefit is frequently derived from the great altitude treatment of phthisis in suitable cases, as by such treatment the patient is supplied with air pure and rarefied, and receives many other benefits. Sea voyages are also beneficial in certain cases, but at present I am not dilating on these two modes of treatment, but am endeavouring to prove that the physician who makes good use of the knowledge which we already possess of the treatment of phthisis may feel pretty confident of success in the majority of cases, even without sending any away from our own country. Meanwhile, whilst utilising this knowledge, we should watch with care the discoveries which are constantly being made by our friends the bacteriologists and others, and earnestly hope that some day a method will be found by which this disease may be stamped out, as small-pox can be now, and thus the lives of thousands may be saved.

THE ELECTRIC ILLUMINATION OF THE MALE BLADDER BY MEANS OF THE NEW INCANDESCENT-LAMP CYSTOSCOPE.

By E. HURRY FENWICK, F.R.C.S.

Assistant Surgeon to the London Hospital; Surgeon and Pathologist to St Peter's Hospital for Urinary Diseases.

From the very commencement of the century, endoscopy has attracted the attention and the efforts of the medical profession. Since Barrini, of Frankfurt, introduced his "light conductor" in 1805, various instruments have been invented for examining the interior of the bladder and urethra. Practically, however, the attempts have hitherto proved unsatisfactory, for all endoscopes have failed from insufficiency of illuminating power. Twenty-five years ago Bruck, of Breslau, a dentist, conceived the brilliant idea of utilising a loop of platinum wire, maintained at a white heat by means of a galvanic battery, as the source of light. The conception was carried out, and a monograph written upon it. The instrument was tried at the Vienna Hospital, but proving a failure, it was discarded, and the attempt forgotten. In 1877 Dr. Nitze grappled with the same problem, and Leiter, the well-known instrument maker of Vienna, was entrusted with its solution. After ten months of expensive and indefatigable labour, Leiter constructed an electric endoscope, by means of which the bladder could be effectively examined.¹ The instrument was, however, encumbered by the necessary apparatus for conveying currents of cold water around the endoscope to prevent overheating. It was hampered by a large Bunsen battery and rheostat, and it was, furthermore, complicated, costly, and capricious. On the introduction of the incandescent lamp, Dr. Nitze and Mr. Leiter proceeded to work independently of each other, and the result has been, in each case, the production of endoscopes simplified by the employment of the smallest Swan or Edison lamp ("mignon" lamp) as the illuminating power. These

instruments were finished in 1887, and were brought by their respective makers before the German Surgical Congress at Berlin.² Having used both varieties upon a series of normal and pathological bladders, I have brought them here this evening to show how simple, safe, and successful these cystoscopes are as compared with their progenitors of 1862 and 1879-1880. Moreover, as they have not as yet, I believe, attracted the attention of the profession in England, I venture to describe their construction, to demonstrate their capabilities and defects, to lay down a few rules for their use, and to critically compare the merits of each.

The Construction.—The three essentials of the construction of both varieties of the electric cystoscope (Nitze's or Leiter's) are practically identical: 1, a catheter (Fig. 1 A K) of No. 22 gauge (French) in size, with a sharp elbow; 2, a terminally placed incandescent lamp (Fig. 1 L); 3, a window (Fig. 1 P or F), closed by a prism, placed near the bend of the elbow to refract the entering rays, so that they pass along the tube (Fig. 1 T) to the observer's eye.

These points are worthy of a detailed description.

1. In Leiter's cystoscope the catheter is built up of two insulated metal tubes slipped one inside the other. The inner ("telescope") tube (Fig. 1 T) terminates abruptly at the prism P. Both tubes serve as the conductors of the current between the battery and the incandescent lamp.

2. The smallest incandescent lamp ("mignon" lamp) (Fig. 2 L) occupies the end or tip of the cystoscope. It is enclosed in a screwed-on silver hood (Fig. 2 a), which has on one side an elliptical aperture (Fig. 2 CF) fitted with a plate of rock crystal for the transit of the rays of light. But here notable and important differences exist in the two varieties: (a) in Leiter's cystoscope (Fig. 2) the carbon filament burns within its small glass globe, and is protected moreover by the windowed hood (Fig. 2 a). In Nitze's instrument the carbon filament burns within the hood and lacks a globe; (b) the lamp which Leiter uses is a removable and a cheap globe (three shillings) (Fig. 2), which, if it is burnt through, can be replaced in a minute by another, by merely unscrewing the hood. But the lamp which Nitze employs is an integral part of the instrument, being permanently enclosed in the end or tip. If, then, the filament be burnt through, the entire cap must be unscrewed and be sent back to the maker for repair, at an outlay of ten shillings; (c) moreover, in Leiter's lamp the filament is longer, and gives a brighter and larger source of light; (d) the elliptical window (Fig. 2 CF) is larger and affords a greater egress to the light.

3. The window (Fig. 1, P or F) in the bend of the elbow has an arrangement of reflectors and a prism.

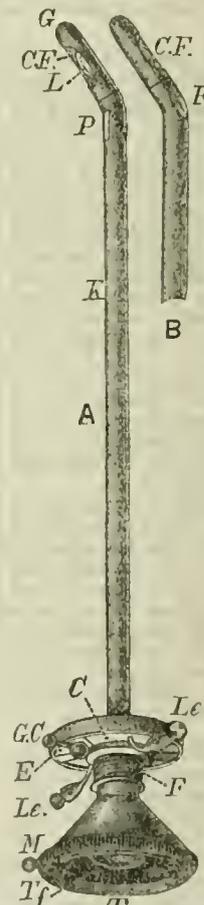

Fig. 1.—The two forms of Leiter's electric cystoscopes, A and B.

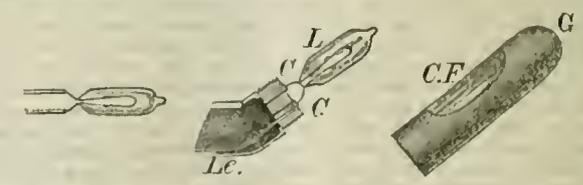

Fig. 2.—Shows (1) the lamp; (2) the lamp (L) adjusted; and (3) the silver hood (a) for the lamp (in Leiter's cystoscope).

4. Each instrument possesses a "key" or "kick-over" (Fig. 1 GC) for turning on or off the current.

5. A small portable four to six-celled battery with carbon-zinc

¹ Abstract of a demonstration of the instruments before the Medical Society, January 23rd, 1886.
² *Wiener Med. Presse*, 1879, No. 27.

³ Dr. Nitze, *Verhandlungen der Deutschen Gesellsch. für Chirurgie*, Congress, xvi, 1887, p. 177; Dr. Breßner (for Leiter), p. 89, *ibid.*

plates and chrom-sulphuric acid, supplies a current of four to six volts intensity.

This is the construction of the electric cystoscope which will prove most often of use, but another form (Fig. 1 B) is made, both by Nitze and Leiter, for examining the posterior upper wall of the bladder. In this, both the light and the window are placed upon the convexity of the bend, and not in the concavity.

Certain objections might reasonably be made to the use of the cystoscope.

1. *Breakage of the Lamp.*—It might be supposed that the mere contact of the urine with the lamp would crack the glass. Such an accident as that would be fatal to the use of the instrument; but happily it is rendered impossible by the closure of the aperture in the hood by means of a plate of rock crystal 2 millimetres thick. These lamps have burnt for thirty hours under water without a flaw. I have tested these plates with over-anxious roughness, and have only succeeded in cracking one by forcible finger and thumb pressure. Such violence could never be encountered in the bladder.

2. *Burning of the Mucous Membrane.*—The cap or hood, with its contained lamp, becomes very hot if exposed to the air; but when it is under water the heat is rapidly absorbed and the cap remains quite cool. This is exactly what happens in the bladder, for the urine carries off the heat of the lamp as fast as it is formed. When I first began to use the instrument my patients complained of a subsequent burning sensation, which I attributed correctly to awkward manipulation of the end, in keeping the lamp resting on or pressed against the bladder wall. "They may be burnt for an hour in a male bladder, holding 7 ounces of fluid, without perceptibly raising the general temperature" (Brenner).

Capabilities.—By means of the electric cystoscope every part of the vesical wall can be examined in as brilliantly illuminated a condition as if it were viewed in direct sunlight. Figs. 3 and 4 show the light thrown upon the floor and anterior wall of the bladder, and represent fairly well the direction of the rays emitted from the end of the instrument.⁴

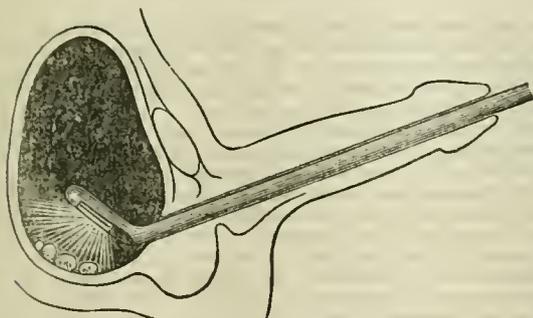

Fig. 3.

As an example of the power of the light, I quote from my notes of a case of right renal hæmaturia which I examined with the cystoscope. "The trigone and base of the bladder appear of

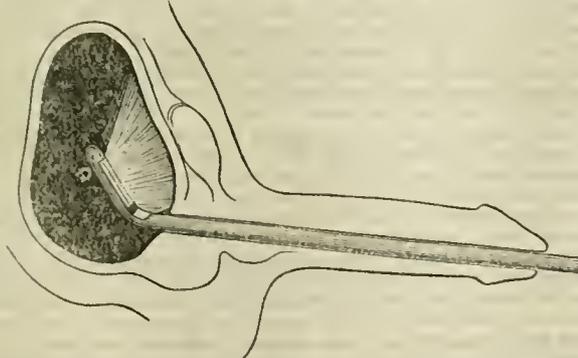

Fig. 4.

⁴ From Leiter's catalogue, as are the other diagrams. In Figs. 3 and 4 the black area is incorrect; it is introduced for the sake of contrast. The entire bladder is lighted up more or less.

straw or sandy colour; and not, as one would suppose, of a rosy or reddish hue. The slit-like orifices of the ureters are clearly visible, and a drop of blood would be apparent if it were entering the bladder. Here and there, this sandy-shore-like surface is relieved by a maroon coloured vessel which courses arborescently across the field; the entire picture reminds one of the optic disc.

A fair number of cases are already recorded in the literature of electric cystoscopy. Dittel has examined cases of chronic cystitis. Finger has investigated gonorrhœal cystitis. Foreign bodies, stones, vesical tumours (16 cases); diverticula, and other obscure vesical diseases, have been discovered by its means, and subsequently verified by operation; but this is not the place either to discuss or add to these results.

What advance has the cystoscope of 1887 made upon that of 1880?

1. The water-cooling apparatus is dispensed with.
2. The cumbersome Bunsen battery is replaced by a small plunge battery of four cells.
3. Little accumulators which slip into the pocket may be used (these are not always reliable).
4. The instrument is one-third cheaper.
5. It is not complicated, and requires no special knowledge for its manipulation.

What are the deficiencies of the electric cystoscope?

1. It cannot be used in irregularly enlarged or carcinomatous prostatic cases.
2. It is difficult to work in contracted bladders.
3. Hæmaturial urine causes a red fog to appear around the light and obscures everything.
4. Stricture of the urethra arrests its introduction until dilatation has been effected.

Rules and Directions for the use of the Cystoscope.—Place the patient on his back with his legs bare. Cocainise the urethra and bladder, or anaesthetise the patient. Make certain that the bladder contains at least six fluid ounces of clear urine; a greater quantity is better. If the urine be bloody, wash out the bladder, and substitute clear water for the murky medium. Regulate the light of the lamp so as not to fuse the filament with an unnecessarily strong current. Do not start the light until the lamp and elbow are well within the bladder. Let the manipulation be gentle and purposive. Do not keep the cap in contact with the wall. Let the instrument remain for half a minute after the current has been shut off, in order to cool the hood completely before you withdraw.

That the cystoscope of either maker will become rapidly popular, and be largely employed in the diagnosis of urinary diseases, may be argued from the simplicity, safety, and success of the instrument; but it is indeed difficult to predict accurately its future rank. It will obviously replace the large collection of instruments or procedures which attempt the diagnosis of the source of hæmaturia and pyuria; for the ureteral orifices are clearly exposed to view. Its use will tend to limit the size and number of vesical papillomata by enabling us to detect and remove these and other growths in their very infancy. It will, moreover, afford us a clearer insight into the physiological and pathological conditions of the vesical mucous membrane, and allow us to control our clinical observations and speculations by direct visual research.

In conclusion, I can only regret that the conception and embodiment of this brilliant innovation emanate from our Austrian confrères, rather than from an English source. I must gratefully acknowledge the kindness of Mr. Leiter, and his agent in London, Mr. Sehall, of Wigmore Street, for their prompt and courteous assistance.

The Annual Report of the Imperial Navy of Japan, compiled by Takaki Kanehiro, F.R.C.S. Eng., the Director-General of the Sanitary Bureau of the Navy Department, shows that the authorities have learned to appreciate the economy and the value of sanitation. A large proportion of the navy effective suffered, until very recently, from kak'ke, due, it is believed, to the bad quality of the food supply. Since improvements have been introduced into the commissariat department, cases of sickness among the sailors have decreased to the extent of 1.37 per 1,000 men—a very considerable saving, amounting in the aggregate to a daily average strength of 708 men, and an economy of 73 lives. Some very elaborate tables are given of the diseases and of the results of treatment, some of which bear favourable comparison with our own.

HYDRONEPHROSIS: NEPHRECTOMY: DEATH FROM ACUTE PERITONITIS AT THE EXPIRATION OF THREE MONTHS.

By R. H. A. HUNTER, M.R.C.S., etc.,
Battersea.

F. J., aged 24, height 5 feet 11 inches, weight 13 stone, a clerk, was seized with a pain in his left loin in May, 1885, when rowing on the river. The pain continued, and in February, 1886, he first discovered a swelling on his left side. Thereupon he went into hospital, and he remained four days, when, after a brisk aperient, the swelling disappeared, although the pain continued. In November, 1886, the tumour returned, and again disappeared at the expiration of ten days under laxative treatment. From that time until the last illness he suffered slight attacks. In August, 1887, the enlargement reappeared, and continued to increase in spite of treatment, until, at his urgent request, I decided to endeavour by operation to remove the disease entirely.

On September 27th, 1887, the date of operation, the following was the condition of the patient. Occupying the whole of his left side was a fluctuating tumour, which extended two inches across the middle line; below, its lower border was sharply defined in the pelvis; above, it extended under the ribs; behind, as far as the spine. The whole of this space was dull on percussion, with the exception of a small part just below the spleen. Along the outer surface of the cyst, and extending from above downwards perpendicularly, was an elevated ridge, which I diagnosed as colon. His urine was normal, and other organs healthy.

Having placed a stout pillow under the patient's loins and administered chloroform, I performed the operation as follows. I made an incision four inches in length along the outer border of the left rectus muscle down to the peritoneum. After securing all bleeding points, this membrane was opened to the same extent as my incision. Upon introducing my finger the ridge proved to be colon, which was firmly adherent to the cyst wall. In order to reach it safely, I was obliged to make another incision three inches long from the centre of the first and at right angles to it outwards into the loin. Having carefully separated the gut and drawn it inwards (in doing which I was compelled to leave a large portion of the peritoneum attached to the cyst), I tapped and drew off about five pints of fluid. Finding that inflammatory adhesions were the cause of the obstruction, I proceeded to remove the kidney. This was done by enucleating it from its capsule, the tissue surrounding it being so dense. When the kidney was brought to the surface I secured the pedicle in two parts with a double silk curbolised ligature, passing another around all, and dividing it with scissors, leaving a small portion of the gland attached. After tying the ureter with a couple of ligatures, I divided it between them. With much difficulty the cyst was freed from its attachments, and, when secured by a double ligature passed close up to the pedicle, was removed. The separation of the cyst proved the most troublesome part of the operation, several vessels requiring to be tied. The cavity was then well washed out with pints of warm water and sponged dry, the pillow under the loin preventing any fluid entering the general peritoneal cavity. The external wound was then carefully closed with silk sutures, and dressed with gauze strapping, gauze bandage, and daniel roller; and the patient placed in bed.

For the first few hours he suffered a great deal from shock, but gradually rallied under the administration of enemata of beef tea, brandy, and opium. During the night he slept well, and suffered but little from sickness, at the same time passing water freely. From this time to the seventh day, when I removed the stitches, he appeared and said he felt better than he had done for months. When the stitches were removed the wound was well united, with the exception of a small part of either extremity of the transverse incision, the intervening portion of the superficial tissues afterwards sloughing and leaving the obstinate ulcer, which had not healed when the fatal event occurred. With this exception all went well until the evening of the tenth day, when, for the first time, the temperature rose to 100° F., pulse 88. On the thirteenth day the temperature was 101°; fourteenth day, 102°; fifteenth, 103°; yet I was unable to detect fluctuation. During the next five days, the temperature 101° was the highest point reached. On the night of the twenty-first day about two ounces of sanious pus

burst through the lower extremity of the incision in the loin. A large drainage-tube was then passed through the opening and out through the back. With the finger in the abscess cavity, while introducing the tube, the examination proved that the general cavity of the peritoneum was firmly closed. During the first few weeks this cavity was syringed out three times daily with carbolic water, afterwards with a solution of iodine, and occasionally with sulphate of zinc lotion. Pus continued to drain away daily to the extent of an ounce and a half. On November 25th the patient was allowed to get up for the first time, wearing a Martin's elastic bandage over the dressing. On December 16th symptoms of pneumonia of the lower lobe of the left lung set in, and, as the sinus still continued to discharge, I laid it open on the 18th. The same evening peritonitis set in, which proved fatal on the 23rd, or three months and three days from the date of operation.

I should remark that, although tapping is the usual treatment recommended in such cases, in this it would have proved unsatisfactory, for the reason that my patient was in constant pain from the commencement of his illness, which, to use his own expression, "made his life a misery." The only position in which he was at all free from pain was on his back. He was also more or less an invalid during the whole time, which necessitated his resigning more than one situation. Again, tapping at most would have only given temporary relief, as the cause of obstruction was permanent; and although, after much suffering and loss of time, the whole kidney tissue might have been absorbed, he strongly objected to the delay, preferring the risks of operation.

In reporting this case I wish to thank Dr. Barkwell and Dr. Grigor, local practitioners, for the invaluable assistance rendered during and after the operation.

TREATMENT OF ALCOHOLISM BY NUX VOMICA.

By C. ROBERTS, F.R.C.S.

It is very remarkable, seeing how quickly new methods of treatment are adopted in these days, that so little attention has been directed in this country to the treatment of conditions of the body due to the excessive use of wine, spirits, and beer, by nux vomica and its preparations, as advocated for some time past by certain Italian, French, and Russian physicians, and incidentally referred to in a note in the *JOURNAL* for January 14th. When I was a student, cases of delirium tremens were treated in the surgical wards, and as a dresser I assisted the late Mr. C. Hunter—then house-surgeon—in his original experiments of treating this class of cases by the subcutaneous injection of morphia—a kind of treatment which first led to the use of subcutaneous therapeutics, and which made all the forms of alcoholism of special interest to me. The treatment of the common forms of drunkenness by nux vomica is not by any means new. Many years ago a medical friend used to treat such cases by full doses of the tincture of nux vomica combined with rhubarb, soda, and full doses of carbonate of ammonia with great success, and I have been equally satisfied with the results of the nux vomica in combination with alkaline solutions of bismuth, hydrocyanic acid, and carbonate of ammonia for the more acute cases, and of the acid solutions of strychnine with iron and quinine in chronic ones. I do not believe, however, with Drs. Popoff, Tolvinski, and Professor Manassein, that strychnine is an antidote to alcohol in the ordinary meaning of the word, and I have been very much disappointed in the few cases in which I have tried the subcutaneous injection of strychnine, as recommended by the Russian physicians. Indeed, I think it is a great error to speak of the various conditions of the digestive and nervous systems resulting from the excessive or injudicious use of alcohol as a specific disease, as they are similar to those which result from the excessive use of other foods, nervous excitement, and mental and physical excesses of all kinds. The setting apart of the treatment of these diseases as a speciality is one of the greatest evils of the prevailing evil of specialisms, as is obvious by the nonsense which is talked by such specialists as to the hereditary character of the disease, and the incurability of some cases. At present we have no evidence that acquired habits are transmissible from parent to child, and moreover there are no definite and uniform lesions resulting from the use of alcohol to be transmitted, if such transmission were possible. That the child of a drunken mother should have feeble health is likely enough, as its nutrition has been inter-

ferred with; and that the children of intemperate parents should acquire their habits from imitation and the facilities for falling into them is likely enough also. But this is not heredity, even in the very loosest way in which the word is used by medical men.

As to the incurability of drinking habits and the disease they engender, they are, I think, just as curable and as incurable as rheumatism or gout, diabetes or Bright's disease, or the hundred and one forms of the diseases of the digestive system. The real difficulty in the treatment of alcoholisms arises from the theory that they are of a specific nature, and require specific remedies, and the forgetting, or perhaps I ought to say the ignorance, of the long time the intemperate habits have been going on before they come under the notice of the medical man, and the obstinacy of the patient and his friends in acknowledging their true beginnings. Chronic diseases require chronic treatment; and nervous sensations of a periodic nature, the result of long habits, cannot be cut short by the sudden removal of the stimulus which caused them. They can only be surely eradicated by the substitution of other and better habits; hence the advantage in the treatment of habits of intemperance of all kinds by travelling and intellectual pursuits, and the removal of the patient from all former associations. As a confirmed disease, alcoholism is, I think, more nearly related to gout than any other constitutional condition, and in its more chronic states it is most successfully treated by iodide of potassium and bark.

THERAPEUTIC MEMORANDA.

IDIOSYNCRASY WITH REGARD TO ANTIPYRIN:

A WARNING.

A MEMBER of my family liable to migraine was attacked in the ordinary way a few days ago, and I administered for the first time a dose of 5 grains of antipyrin in powder, with the following curious result: Five minutes after taking it, the "deadly sickness" which was previously present seemed to give way, and an "expanding sensation" was felt, rising from the stomach upwards. Almost immediately she sneezed violently for about twenty times running without pause. The face and eyes became deeply suffused; tears began to flow; quantities of mucus flowed from the nose; the breathing became hard and laboured, accompanied by a feeling of suffocation; there was complete inability to lie down. A violent cough shortly came on, and large quantities of mucus were expectorated; at the same time there was very profuse sweating.

After these phenomena had lasted for about half an hour, intense itching was felt on the insides of both thighs, and on examination there was found a thick outcrop of urticaria, which soon extended on to the abdomen. There was also a strong coppery taste in the mouth—not continuing, but coming on in violent bouts—and an equally strong smell of the same metallic nature, also intermittent. There was loud singing in the ears, which felt intensely congested. The pulse was quick and very full.

After the symptoms had lasted about three-quarters of an hour from the commencement, they gradually disappeared, some tightness of the chest and running at the nose remaining for four or five hours longer. The sickness accompanying the migraine disappeared completely as soon as the drug had begun to work; the headache also disappeared for a time, but came back slightly about four hours afterwards.

As antipyrin is now being so largely prescribed, I thought the above account might be of use to the readers of the JOURNAL, as showing the necessity for caution when prescribing it for a patient who has not previously taken it.

Nice.

W. ALLEN STURGE, M.D.

GENERAL SYMPTOMS SOMETIMES PRODUCED BY NASAL SPRAYS OF COCAINE.

IN applying sprays of a 4 per cent. solution of cocaine to the nasal cavities, I have not infrequently noticed an accelerated action of the heart as an almost immediate result. I have thus noted a pulse which, prior to the application, was beating at the rate of 86 pulsations to the minute, increase to 110 pulsations in five minutes, after spraying into the nose 30 minims of a 4 per cent. solution, while its volume and strength were for the time increased. This amount

would represent a little over 1 grain of cocaine; but, allowing for a certain amount of waste resulting from the dripping from the nostrils, less than 1 grain probably would have been absorbed. This increased activity of the circulation was attended by a very appreciable sense of exhilaration of spirits associated with a feeling of increased vigour and capacity for mental effort. Cocaine applied in this manner, in the quantity I have mentioned, has had the effect of distinctly rousing the individual; and I have seen the same results in more moderate degree from smaller amounts. Indeed, I have met with rarer instances, where repeated spraying of 10 minims of a 4 per cent. solution to allay nasal irritation has resulted in insomnia, and sometimes in active restlessness lasting for several hours. So far as I have seen, all these effects have been generally quite transient, though a moderate sense of stimulation may persist for an hour or two.

In using stronger solutions I have on two occasions seen their application followed by vertigo and threatened syncope. A gentleman, in whose nose I applied a 20 per cent. solution upon a plug of cotton wool, and also in spray, prior to removing a polypus, complained of vertigo, nausea, and faintness. These symptoms subsided quickly, after he had rested a few minutes on the couch, and he was well enough to undergo the operation before the local anæsthetic effect of the cocaine had passed off. I saw similar effects in a lady after the application of 10 per cent. solution followed by a spray of the same strength. Although I have constantly made these applications of cocaine prior to operations in the nose and as a local sedative, these are the only two cases I have to record where depressing effects have resulted. It has been more especially after using a spray, by which the solution is forced high up in the nasal fossæ, and is more widely diffused, that I have noted the exhilarating effects that I have referred to. From experiments made on myself I have found that the stage of exhilaration, when induced, is of comparatively short duration, but if, after the first effect has subsided, the spray be repeated once or twice in the course of an hour or two, these further applications may be followed by somewhat more rapid action of the heart, producing more or less disagreeable palpitation, while the sense of buoyancy is apt to be less than at first, though some nervous excitement may still remain.

Notwithstanding these experiences, I should say, after long trial, that limited applications of strong solutions of cocaine in the nose as a local anæsthetic do not, unless very exceptionally, produce general symptoms. Spray solutions of a strength not exceeding even 4 per cent. are more liable to do so, and should not, as a rule, be applied in greater quantity than ten minims, especially if used by the patient as a topical remedy in acute nasal catarrh; and then this application should not be often repeated. With such restrictions all risk of harm would be avoided. It is easy to foresee, however, that an agent which can exert the primary stimulating effects, which it has been found to do, would appeal to some; and that the unrestrained habit of resorting to nasal sprays of cocaine by patients may lead to deleterious results.

W. MCNEILL WHISTLER, M.D.

Physician to the London Throat Hospital.

FORENSIC MEMORANDA.

SUICIDE BY HANGING: A CASE IN WHICH THE SUICIDE SECURED HIS OWN HANDS.

A FEW days ago I received a warrant to examine the body of a young adult negro, which had been found hanging in the woods not far from his dwelling. The spot chosen by the deceased was a romantic one, at the mouth of a shallow limestone cave, from whose roof numerous stalactitic masses hung. The overhanging ledge at the cave's mouth was topped by thick, heavy vegetation, from which numerous cordlike withes hung dangling; some of these the man had used for his purpose. These cordlike suckers, sent down so profusely by parasitic plants and others in the tropics, will be familiar to all acquainted with tropical vegetation. A strong coffee-shrub, capable of sustaining a man's weight, stood some few feet off from the mouth of the cave. I found the body lying upon the ground, fully clothed. When just discovered, it was still hanging, but the withes sustaining it gave way a little later of their own accord. A slip knot, made with three of the depending withes, intertwined into a naturally-formed rope, tightly encircled the neck, the loop of the slip knot being under the right ear. The hands were fastened down to the sides and

slightly behind by a piece of short withe, which bore a loop at each end, and through these loops the hands had been passed up to the wrists. The straight piece of withe connecting the two loops passed behind the body, and was about a foot in length. The loops and straight connecting piece were made out of a single piece of strong withe. On trial, the loops were found to pass over the hands quite readily.

A probable interpretation of the sequence of events in this un-witnessed tragedy would seem to be that the deceased first made the loop arrangement for his wrists and placed it within reach. Thereafter he seems to have climbed into the coffee-shrub, mentioned above as standing at the entrance to the cave, and whose bark, chafed and dirt-stained at the forks, and newly broken twigs showed it to have been recently occupied. From this tree it was possible to make the slip knot for the neck from the dependent withes. This being made, and its noose arranged around his neck, he must have slipped his hands within the loop arrangement for the wrists, and have gradually eased himself clear of the tree; this last of necessity, as the withes were not strong enough to have stood the strain of a sudden jerk.

Hard by, in evidence of a previous and unsuccessful attempt, lay another cord of withes. Its upper end, attached to one of the stalactites above, had broken off short by the roof; its lower end lay below, abandoned; and inside it there was another arrangement of loops for the wrists, precisely similar to that found upon the body. A boulder standing beneath the stalactite had served as a platform and enabled him to reach it.

With the exception of the bruising at the neck, the body bore no trace of injury or of struggle. The clothes were not disordered. Dissection showed the appearances usually seen in death from asphyxia. There was also a diseased condition of the aortic valves. The heart troubles had given much pain, and had rendered him unfit for work. He seems often to have suffered acute distress at night-time. He had recently lost his wife, and this, with his bodily suffering, seems to have driven him to an act planned with much forethought and carried out with singular determination. He left his hut at some time during the night, a bright moonlight one; and it was only at daybreak that his nurse, an old negress, upon awakening, missed him and gave the alarm.

R. FRANK RAND, M.B. Edin., F.R.C.S. Eng.

Moncague, Jamaica.

OPHTHALMOLOGICAL MEMORANDA.

OPHTHALMIA NEONATORUM: TREATMENT BY ALCOHOL AND CORROSIVE SUBLIMATE.

I PUBLISH this plan of treating ophthalmia neonatorum in the hope that members of the profession will at least try what I hope may prove to be a distinct advance in the treatment of this very unpleasant affection.

Evert the lids to the back fold; dry them with a soft piece of clean rag; wash them freely with ethylic alcohol—a soft camel-hair brush; and flood with 1 to 2,000 of corrosive sublimate watery solution.

The reason for the treatment is; Roux demonstrates that pure alcohol removes all loose gonococci. Pure alcohol has an extraordinary affinity for water, so that it displaces the watery fluid of the lid by alcohol making it intensely hygroscopic. The alcohol is in turn displaced by solution of corrosive sublimate, so that every possible nook and cranny is searched by the germicide. I think this plan would answer equally well with any other germicide, but corrosive sublimate is convenient and cleanly. Our cases have been too few at present to form an opinion. So far we find the discharge arrested, but the granular condition of the lid is not so rapidly reduced as by silver. I take it that that is a small matter, compared to the prompt removal of the infecting organisms. The alcohol has no apparent effect upon the cornea. For home use we order 1 to 4,000 of corrosive sublimate with weak boracic acid solution.

P. H. MILES, M.D.

20, St. John Street, Manchester.

CLINICAL MEMORANDA.

SPONTANEOUS DETACHMENT OF LARYNGEAL POLYPUS.

THE paragraph in the JOURNAL for January 21st, headed "Spontaneous Detachment of Laryngeal Polypus," reminds me of a case similar to the one related, which occurred when I was resident medical officer to the Manchester Royal Infirmary. A patient

presented herself with laryngeal symptoms, and, on examination with the laryngoscope, I clearly saw a polypus in the larynx. I advised her to come into the Infirmary as an in-patient, in order that she might have the growth removed, which she consented to do. A few days afterwards she returned with her laryngeal trouble practically gone, and produced a bottle containing a small mass, which she stated she had coughed up. On re-examining the larynx with the laryngoscope, the tumour was found to have disappeared, and microscopical examination of the substance coughed up revealed the ordinary structure of a polypus.

Manchester.

GRAHAM STEEL, M.D.

REPORTS

OF

HOSPITAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN, IRELAND, AND THE COLONIES.

EYE, EAR, AND THROAT INFIRMARY OF EDINBURGH.

CASE OF CHRONIC LARYNGITIS, PROBABLY TUBERCULAR, TREATED BY TRACHEOTOMY AND BY ENDO-LARYNGEAL REMOVAL OF GROWTH.

(Under the care of Dr. HUNTER MACKENZIE.)

J. D., aged 27, commenced attendance as an out-patient on February 4th, 1887, on account of hoarseness and shortness of breath, which had been of gradual onset, and had existed for a year and a half. There was no history of previous illness, and no phthisical taint in the family.

His general condition was poor, with a tendency to cyanosis of cheeks and fingers. Inside the larynx there was marked general swelling, especially over the arytenoid cartilages, which had a markedly globular outline and a somewhat ashy appearance. The vocal cords were reddened and irregularly thickened; the left was completely fixed in the middle line, and the mobility of its fellow was impaired. There was no ulceration anywhere. Some medium moist sounds were audible at the infra-clavicular region, and rhonchi were present over both apices posteriorly. Tubercle bacilli were sparsely present in the sputum.

In spite of appropriate local and general treatment, the patient became worse, and was admitted as an in-patient in the beginning of April. On the 6th of that month tracheotomy was performed by Mr. Maxwell Ross. The patient rapidly improved after the operation, and in ten days left the infirmary. He continued as an out-patient during the remainder of the year, and was submitted to a course of local treatment, first by lactic acid, and secondly by menthol. It could not be said that either of these remedies had any effect upon the intra-laryngeal condition, for, although this had greatly improved, the amelioration took place whether the remedies were applied or not. A small, warty-looking growth, which had been slowly growing for some time from the posterior third of the left vocal cord, and was now appreciably diminishing the glottis, was, on January 6th, 1888, removed by Dr. Mackenzie with laryngeal forceps, in the presence of Mr. Maxwell Ross and the members of the clinic.

On January 25th, 1888, the tracheotomy tube, which had been plugged for about four months, was removed. The patient's condition at this date was fairly satisfactory. The general intra-laryngeal swelling, as well as the infiltration over the arytenoid cartilages, had greatly subsided, and the range of movement in the right vocal cord had increased. The patient was consequently able to breathe with tolerable comfort *per vias naturales*. Some dry rales were present at the right pulmonary apex. There was no expectoration.

REMARKS BY DR. HUNTER MACKENZIE.—This case is undoubtedly an example of chronic laryngitis which had either undergone or was about to undergo tubercular degeneration. Whilst there was no evidence that this change had actually taken place, the well-marked laryngoscopic appearances and the state of the lung, along with the bacillary sputum, warrant us in assuming that, to say the least, this specific degeneration was not far off. (Unless the laryngoscope be supplemented by the microscope, it is frequently impossible to say whether a given lesion of the larynx is tubercular or not.) Tracheotomy was beneficial in two ways. 1. It relieved the breathing, which, from the amount of swelling and infiltration in the larynx, was greatly embarrassed, and, by

doing so, benefited the lungs by promoting their ventilation. 2. It reduced the irritation of the larynx caused by the acts of breathing and coughing. The inefficacy of local applications of lactic acid and of thymol was seen by alternating periods of their application with others of abstinence from treatment. Iodoform, formerly so much in vogue in this disease, has of late been largely supplanted, especially in the ulcerative forms, by these two remedies. By themselves they are all equally ineffective in this malady. In judiciously selected cases, surgical measures, either on the lines now indicated or by thorough removal and cauterisation of the affected parts after thyrotomy or by endo-laryngeal means, appear to be the only method of radical treatment which promises satisfactory results.

GERMAN HOSPITAL, DALSTON.

TREATMENT OF ULCUS CRURIS IN THE OUT-PATIENT DEPARTMENT.

(By F. A. PHILIPPI, M.D.)

DURING a period of about eight months, the treatment of ulcers of the leg and allied affections was carried out according to the principle laid down by Dr. Unna, of Hamburg, at the Dublin meeting of the British Medical Association. The subjoined table shows the results obtained in a series of sixty patients, taken indiscriminately as they came under treatment.

Nature of Disease.	Healed.	Discontinued Attending.	Unsuccessful.	Total.
Callous ulcer	14	6	2	22
Varicose ulcer	7	—	—	7
Healthy ulcer	7	—	1	8
Sloughing ulcer	2	—	1	3
Indolent ulcer	1	—	—	1
Syphilitic ulcer	—	—	2	2
Diabetic ulcer	1	—	—	1
Inflammatory ulcer	4	1	—	5
Eczematous ulcer	4	1	—	5
Eczema cruris	5	—	1	6
Total	45	8	7	60

The manner of applying the dressing may be briefly described as follows: On the carefully cleaned and shaven leg a moderately thick layer of warm zinc-gelatine (prepared according to the subjoined formula) is applied by means of an ordinary brush up to the limits of the ulcer, which receives a sprinkling of powdered iodoform or any other pulverised antiseptic; for instance, subnitrate of bismuth, boracic acid or naphthaline; this latter being especially serviceable in reducing the offensive smell of many ulcers. A small pad of medicated cotton-wool is then added as a covering for the sore, and a gauze roller (Lister) wound firmly round the whole, care being taken to cause the traction to work in the direction towards the centre of the ulcer. When no more of the zinc-gelatine penetrates through the meshes of the gauze, the dressing may be considered to be completed. It is allowed to cool and become dry, whereupon the patient can be dismissed without further precautions. In some cases, and especially in the latter stages of treatment, the zinc-gelatine can be painted over the whole circumference of the leg, including the ulcer.

This dressing should be removed at the end of three or four days. In the cases on the above list, however, it was mostly allowed to remain unchanged for a week, on account of the patients not being able to attend more frequently, and although it seemed evident that it would have been generally advisable to renew the dressing at shorter intervals, still the progress made was, as a rule, satisfactory enough to permit of the longer period being adhered to.

The dressing can always be very easily removed with a pair of blunt-pointed bent scissors and, in case of need, a little warm water. It is of great advantage, for easy removal, to have shaved the leg before applying the dressing; the gauze which forms, with the zinc-gelatine, quite a compact casing, can then be pulled off the skin as readily as the peel from an orange. If the discharge should penetrate the bandage before the end of the week, a sprinkling of iodoform may be applied to the soaked spot, or a piece of clean linen simply applied as a covering, to be renewed when it becomes soiled. The zinc-gelatine is thus prepared: Oxide of zinc, gelatine, aa 5 parts; aq. dist., 6 parts; glycerine pur., 8 parts; all by weight.

The gelatine is first dissolved in the water at a moderately high

temperature, the loss of water by evaporation being compensated for. When the whole is reduced to a perfectly uniform and even mass, the oxide of zinc, finely powdered and mixed with as much water as is sufficient to produce a thin paste, is added, with the prescribed quantity of glycerine. The whole is well stirred, and after making up for evaporated water, poured out into cakes on a cool porcelain slab. It will be found to be of the consistency of common glue, of a pure white colour, and devoid of stickiness. For application, a sufficient quantity is placed in a small pot, which stands in a sauceman of boiling water, in the same manner as carpenters' glue is treated. When dissolved it would not be thicker than thin syrup or common oil-paint. It generally requires the addition of a little water, especially when the same pot-full has been treated a few times.

The chief advantage derived from this method of treatment is the possibility of curing the ulcer without confining the patients to their beds. Indeed, with the aid of this dressing, even large ulcerations were rendered perfectly painless, so that our patients could perform all kinds of work, even long before the sores were healed. It will likewise be found to be a great advantage that the treatment is not entrusted to the patients themselves, who often lack patience and sagacity enough accurately to carry out the instructions given them. The uniform and firm compression it exercises on the leg will be found to be most serviceable in the treatment of varicose veins. Further, the discharge arising from the sores is effectually prevented from coming into contact with the healthy skin, while, on the other hand, it is able to penetrate freely enough to the surface of the dressing. It was often also noticed that the discharge of pus from the ulcers was considerably reduced, and the disagreeable odour almost entirely removed. The simplicity and cheapness of this dressing are likewise greatly in its favour.

The duration of treatment varied from about three to sixteen weeks, which, it must be confessed, does not seem to indicate a very rapid recovery; but, taking into consideration that some of the patients had suffered for several months and even years from their ulcers, and further that whilst under treatment the patients were not incapacitated for work, I think the results will appear fairly satisfactory.

ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

SPASMODIC TORTICOLLIS, FOLLOWING INJURY TO THE CERVICAL SPINE: SUCCESSFULLY TREATED BY STRETCHING THE SPINAL ACCESSORY NERVE.

(Under the care of FREDERICK PAGE, Honorary Surgeon to the Infirmary, Newcastle-on-Tyne.)

In the year 1866, the late Mr. Campbell de Morgan published, in the *British and Foreign Chirurgical Review*, an exceedingly interesting case of spasmodic wry-neck, following injury to the cervical spine, treated by excision of a quarter of an inch of the spinal accessory nerve. The spasms were cured, but the sterno-mastoid and trapezius remained permanently paralysed. In 1880, a carefully prepared paper, by Dr. Sturge and Mr. Godlee, was read before the Clinical Society, entitled "Stretching of the Facial Nerve for the Relief of Spasm of the Facial Muscles." On April 26th, 1887, D. L., aged 24, a strong muscular labourer, was admitted, under my care, with the following history: While engaged last December in a rough game of football, he was thrown, and fell heavily on his back, twisting his neck violently to one side. He was unable to rise, and had to be carried home, having lost the use of his limbs. He was not unconscious. His head was twisted to the right side. During the night he regained the power of using his legs. In two days the wry-neck had passed off, but his arms remained paralysed for a fortnight. For some days the bladder required to be relieved with a catheter. In the course of a few weeks he recovered sufficiently to be able to resume duty. While at work, about March 19th, the patient struck his head violently against an iron pipe. He fell backwards to the ground, and, on rising, found that his neck was twisted as it had been for two days after his former accident. On admission, the patient was in the following condition: When at rest the right shoulder was elevated, and the face turned to the right side. The deformity was evidently due to tonic contraction of the right sterno-mastoid and trapezius muscles. Any attempt made to straighten his head, a touch or movement, produced clonic spasms of the muscles named, by which the right side of the face and shoulder were almost brought in contact, his chin being at the same time drawn slightly towards the left side. Considerable pain accompanied the spasms. Rest

in bed, counter-irritation, and drugs produced no effect upon the deformity. Adopting the conclusions arrived at by Dr. Sturge and Mr. Godlee "as to the class of cases in which the operation of nerve-stretching is likely to prove efficacious," namely, those where "the spasm is confined to the muscles supplied by one nerve only," this seemed a typical case for treatment by nerve-stretching. Accordingly, on June 21st, six months after the first and three months after the second accident, I cut down upon the right spinal accessory nerve, where it emerges from the sterno-mastoid on its path to the trapezius muscle, passed my finger beneath, and stretched it with considerable force. Not feeling sure that it might not be necessary, ultimately, to resort to Mr. Morgan's expedient, I adopted a plan suggested to me by my friend, Professor Annandale, and surrounded the nerve with a silk thread, so that, should section be found requisite, I could reach the nerve easily without opening up the wound. The next day, though the tonic contraction was unaffected, the patient expressed himself as feeling much more comfortable—freer from clonic spasm and from pain. The wound healed readily, and, fourteen days after operation, the silk thread was withdrawn. On July 21st, the patient was discharged, all clonic spasm having ceased entirely for some time. There was still, however, some tonic contraction of the sterno-mastoid, but it was decidedly less, and gradually decreasing. To-day (January 14th), the patient is free from deformity, in good health, and able to do his ordinary duty without inconvenience.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON. FRIDAY, JANUARY 27TH, 1888.

W. H. BROADBENT, M.D., F.R.C.P., President, in the Chair.

So-called Idiopathic Dilatation of the Colon.—Dr. ANGEL MONEY and Mr. S. PAGET contributed a paper on this case. Mr. M., aged 55, an habitual drunkard, suffered from enormous distension of the colon, with dyspnoea and bronchitis; the girth was over sixty inches, and the measure from the ensiform cartilage to the pubes twenty-six. There was albuminuria. He was treated first by Mr. Paget at St. Thomas's Home by repeated punctures. These gave great relief; he improved so much that he refused further treatment, and returned to his drunken habits. He was admitted into University College Hospital a week later under Dr. Angel Money, with the same enormous distension, lividity, and dyspnoea. He was much relieved with the long rectal tube, but sank and died a week after admission. At the necropsy all the signs of habitual drunkenness were found, including typical "hobnail" liver. There was enormous distension of the colon, principally of the sigmoid flexure, which formed two huge sacs extending right across the abdominal cavity. There was no organic stricture. Dr. Money was of opinion that a twist of the sigmoid flexure or a spasmodic stricture might have been present, or else that some morbid state of the blood, or else the mere presence of an excess of gas, might have started the disease. The bowel was hypertrophied as well as dilated. He referred to Dr. Gee's paper in the *St. Bartholomew's Hospital Reports*, and to Dr. Goodhart's case (*Clinical Society's Transactions*, vol. xiv).—Dr. HADDEN asked if the patient had had habitual constipation. He referred to cases which Drs. Bristowe and Peacock had published, and described two cases seen by himself. The first was that of a girl, aged 17, who had severe pain in the abdomen, with constipation lasting ten days, and unaffected by purgatives. The abdomen was opened, but no obstruction detected. At the *post-mortem* examination the sigmoid flexure was found enormously distended, its circumference measuring twelve inches. There had been no chronic constipation. The second case was that of a woman, aged 20, who had a copious mucous discharge from the bowel, so that she complained of diarrhoea. No faeces were passed, however, and the sigmoid flexure was found to be distended with motion. She recovered under treatment.—Sir DYCE DUCKWORTH referred to the case of a girl who had enormous dilatation of the caecum, with tympanites and constipation, and in whom the rest of the intestinal tract seemed to be normal. Dr. SWART asked if there was any adhesion of the omentum in Dr. Money's case. He had seen cases in which adherent omentum, or its invagination into the canal of a hernia, had seemed to cause distension of the colon. One such patient who recovered from acute obstruction died a few days later of pneumonia. She was then found to have an old hernia, and the

transverse colon was dragged down at its middle to the pelvis and there fixed, so that it was V-shaped, and no longer transverse. He objected to the term "idiopathic" as applied to Dr. Money's case, and thought the distension was due to some adhesion, causing obstruction, and then paralysis of the bowel. In such case, if gas were formed, very acute distension would occur. He would ask again if there was any displacement of the omentum or an omental hernia.—Dr. PEARSE thought the dilatation in such cases as that described by Dr. Money was due to the formation of gas, caused by the imperfect digestion of food.—Dr. MORISON thought that no case should be termed "idiopathic" unless that diagnosis were verified by *post-mortem* examination. He mentioned the case of a gentleman whose supposed idiopathic distension was relieved by abdominal puncture. When obstruction occurred a second time it was treated with opium and belladonna, but without success. After death a stricture was found between the sigmoid flexure and the rectum, which might have been relieved by colotomy.—Dr. K. FOWLER asked if the meso-colon of the sigmoid flexure was so long as to allow the colon to be misplaced and obstruction produced.—The PRESIDENT had seen a case some years ago in which great distension of the abdomen was produced by congenital elongation of the sigmoid flexure, which started in its proper position, thence extended up to the liver, and then passed down again to join the rectum. It was full of gas, and so gigantic that it filled the abdomen. In another case the transverse colon was still more distended; it occupied almost the whole of the front of the abdomen, the distension being apparently due to chronic constipation. This had led to the bending down of the transverse colon, and, after a time, to obstruction of the left flexure. There was vomiting, especially after aperients were given. The obstruction could only be reached by enemata whilst the man was on his hands and knees. Little by little the obstruction was overcome, and was afterwards treated in the same manner.—Dr. B. O'CONNOR referred to cases of constipation caused by the abuse of mineral waters.—Mr. STEPHEN PAGET said that his punctures were made into the colon where the abdomen was most prominent and tympanitic. The gas that escaped was at first foetid, then less so; and the needle was then drawn up as if the colon were regaining its normal position. The patient, who was a drunkard, had had constipation for months, and passed only gas and liquid while under the speaker's care.—Dr. ANGEL MONEY, in reply, said there was considerable alteration in the omentum, which had lost all its sharp outline, and was thickened and tough, though not displaced into a hernial sac. The meso-colon was not unusually long. If Dr. Pearse's suggestion were adopted, the cause of the distension was not much advanced. Dr. Gee's cases, and others which had been published, were apparently similar to those mentioned by the President. Professor Hirschsprung, in the *Archiv für Kinderheilkunde*, had published an interesting paper on the subject in the new-born.

Tricuspid and Mitral Stenosis in which Physical Signs of Pulmonary Arterial Reflux were present.—Sir DYCE DUCKWORTH, M.D., described this case. M. S., aged 23, a married woman, without family, was admitted into St. Bartholomew's Hospital under his care in May, 1887, suffering from general dropsy and dyspnoea. She had had scarlet fever in early life, but there was no history of rheumatism or chorea. She had suffered from dyspnoea from the age of 14, and been worse for the last twelve months. Dropsy set in in the legs three months previously, and then became general. On admission she was very dusky and bloated. The pulse was 128, barely perceptible. The cardiac impulse was diffused, the apex beat outside the left nipple line. There was a presystolic thrill over the left ventricle, with an extended area of cardiac dullness in all directions. At the apex was a presystolic, followed by a systolic murmur. The systolic murmur was over the right ventricle, and there was accentuation of the second pulmonary sound. The liver was enlarged, and felt to within two inches of the navel. There was dullness at the base of both lungs, and crepitation. The urine was scanty and one-fourth albuminous. The legs were much swelled, dusky, and purpuric. She was treated with digitalis and nitrous ether, and two ounces of brandy. Compound jalap powder was occasionally given. Improvement set in after a few days, and the pulse fell to 88. The albumen greatly diminished in the urine. Later on a regurgitant murmur was heard in the area of the pulmonary artery. A second point of presystolic thrill was detected over the right ventricle, and a presystolic murmur was faintly heard in the tricuspid area. The temperature was usually subnormal. In three months the patient left the hospital. Three weeks later she was readmitted in as bad

a condition as formerly, having spat some blood. On this occasion she did not respond to treatment. She was made worse by prevalent fogs in October. The signs of pulmonary arterial reflux passed off. After increasing dropsy, dyspnoea, and jaundice, she died on November 8th. At the necropsy the heart was found much enlarged in all its chambers, weighing 24 ounces. Dilatation and hypertrophy of the right ventricle were found. The tricuspid valve was stenosed, barely admitting two fingers, its edge being thickened. The pulmonary valves were not markedly altered. There was decided dilatation of the pulmonary artery. The mitral orifice was in a state of button-hole contraction, with thickened chordæ tendinæ. Hypertrophy of the left ventricle existed. There was some hepatisation at the base of the right lung, but no infarctions in the pulmonary artery. The liver was enlarged and "nutmeggy." The kidneys and spleen were engorged and hard. The points of interest related to the etiology of the case and the interpretation of the physical signs on the right side of the heart. Sir Dyce Duckworth had several times noted accentuation of the second pulmonic sound along with tricuspid reflux. The signs of tricuspid obstruction were explained by the state of the valve after death. The pulmonary arterial reflux was probably explicable by the dilated state of that vessel, and the disappearance of the murmur was coincident with increasing low blood pressure, as the vital powers failed towards the last. It was surmised that the disease began after scarlet fever, but the author believed that in the great majority of cases of mitral stenosis, so common in women, the disease had a rheumatic origin, often in early life, the attendant articular symptoms being but slight and commonly overlooked. (The heart was exhibited.)

Embolism of Right Axillary Artery connected with Mitral Stenosis. Gangrene of Fore-Arm: Amputation: Subsequent Embolic Pleuro-Pneumonia and Death.—Dr. BURNEY YEO related the case of a woman who was admitted under his care into King's College Hospital in December, 1886, with great pain and loss of power in the right hand and arms, which came on suddenly, accompanied with giddiness. The fingers, hand, and forearm on the right side rapidly became white, and motion and sensation were completely lost. She had had acute rheumatism, and suffered from dyspnoea on exertion. No pulsation could be felt in the radial, ulnar or brachial arteries in the right side; pulsation could, however, be felt in the subclavian. The cardiac action was rapid and irregular, the impulse and sounds were very feeble. The patient also suffered from cough, dyspnoea and great restlessness. In a few days the forearm became blue and mottled, subsequently black, and dry gangrene set in. Opium was given to allay the severe pain and restlessness, and iron, quinine and digitalis to improve the cardiac tone. As the ventricular contractions improved in force and regularity, a distinct, though feeble murmur could be detected which appeared to precede the impulse. After consultation with Sir Joseph Lister it was determined, as soon as the cardiac tone had sufficiently improved from the administration of digitalis, to amputate. This was done, about the middle of the upper arm, by Sir Joseph Lister, under chloroform, on January 14th. The patient recovered well from the operation, but two days afterwards pneumonia with pleuritic exudation occurred on the right side, and she died somewhat suddenly on the 19th. *Post-mortem* examination showed considerable constriction of the mitral valve, and a large, old and firm clot in the left auricular appendage, from which, no doubt, the embolus in the axillary artery proceeded. Hæmorrhagic infarctions were found in the right lung, and considerable effusion of serous fluid and lymph in the pleural cavity, and on the surface of the lung. The kidneys also contained old, small white infarctions. Examination of the stump showed the primary clot to be situated just at the beginning of the axillary artery. Dr. Yeo added some comments on this case and its management.

Disease of the Aortic and Mitral Valves of Long Duration.—Dr. J. KINGSTON FOWLER described this case, which was that of a man, aged 66, a wood turner, working a treadle lathe. Physical examination of the chest gave the following results:—There was a systolic recession of the epigastrium; the cardiac apex was in the fifth interspace in the nipple line; the impulse was forcible, indicating a moderate degree of hypertrophy of the left ventricle; at the apex the first sound was accompanied by a systolic murmur; at the base, in the aortic area, there was a short systolic *bruit*, and the second sound was replaced by a rough diastolic murmur; there was evidence of some hypertrophy of the right ventricle; the valves on the right side of the heart were judged to be competent. The pulse was 84, small and collapsing. The urine was free from

albumen. The interest of the case centred in the fact that in 1834 the patient, then a boy aged 13, was admitted into the Middlesex Hospital, under Dr. (afterwards Sir) Thomas Watson, with acute rheumatism, for which he remained under treatment nearly nine months. During the early part of the illness leeches were applied to the præcordium on more than a dozen occasions, and subsequently blisters were frequently used. The evidence upon which it was concluded that the valve lesions now present occurred during the attack of acute rheumatism in 1834 was entirely circumstantial, no written evidence of the case having been found. It might be summarised as follows: 1. The statement of the patient that on a certain occasion two gentlemen accompanying Dr. Watson on his visit, having auscultated the patient's chest, the one remarked that he heard a sound "like an old woman blowing a bellows in a back room;" the other said the sound was more "like to the whistling of a steam engine." 2. The fact that Dr. Watson told the patient's mother on his discharge from the hospital that he was never to leave home without telling her where he was, going. 3. That for three years the patient carried a card with his name and address upon it, so that "if anything happened to him suddenly it might be known who he was and where he lived." 4. That he had had no return of the rheumatic attack, and had scarcely been absent from work for a single day during the last fifty-four years. The case was reported as being a rather remarkable example of a stationary lesion of the cardiac valves of rheumatic origin, in which compensation having been established, it had remained perfect for fifty-four years, and now showed no signs of failure. The patient had been shown at a previous meeting of the Society.—The PRESIDENT thought that in this case, which he himself had examined with much interest, there was satisfactory evidence of valvular disease and of adherent pericardium through all these fifty-three years. He had seen cases having a distinct history of heart disease for thirty or forty years, who were yet leading an active life and doing good work. In Dr. Yeo's case he thought that death had been rightly attributed to the pulmonary embolism and pleuro-pneumonia consequent on dislodgment of clot from the axillary vein during the manipulation of the limb at the time of the operation. He considered it remarkable that there should have been gangrene in that case. He had seen nearly all the big arteries of the body plugged by embolism, and yet there was sufficient collateral circulation to keep the parts alive. The mitral valve, too, in Dr. Yeo's case, would admit the points of two fingers. The great rapidity of the pulse was probably due to the old plugging of the basilar artery; and the confusion in the heart's action, probably so produced, led to gangrene of the hand and arm. As to Sir Dyce Duckworth's case he thought the physical signs could only have arisen from pulmonary reflux. Whatever the degree of mitral stenosis might be, he did not think it ever gave rise to the purple condition of the limbs without there was tricuspid stenosis as well. The recognition of this latter symptom he based on the same signs as those Sir Dyce Duckworth had described.—Mr. BOWLBY described two cases of gangrene which he had lately seen. In one there was gangrene of the hand and of the forearm up to the elbow; in the other the thigh was implicated. In the former case the aorta was diseased, and clots extended from it into the smaller vessels. The second patient was an elderly gentleman, who had dry gangrene of the thigh and leg, with mitral disease. At the *post-mortem* examination vegetations and clots were found on the valve, and there was a plug in the femoral artery which was also atheromatous. In the first case the smaller vessels were plugged as well as the main ones. This, perhaps, caused the gangrene, or that was due to the atheromatous state of the vessels and the embolism.—Dr. D. DREWITT described the case of a girl at the West London Hospital, admitted with typhoid, wild delirium, and a high temperature. She was delirious for four weeks. She then had a dark patch on the left foot, and the whole limb below the knee became gangrenous. No pulsation of the femoral artery could be felt. Probably a clot from the heart plugged the iliac artery, as the heart was acting very feebly. The limb had been amputated by Mr. Bruce-Clarke, and the patient was on a fair way to recovery.—Dr. DE HAVILLAND HALL described the case of an old gentleman suffering from asthma, and sent to San Remo. After being there four weeks he had pneumonia, with intense pain in one thigh and leg, coming on suddenly at night. In the morning the leg was quite blanched and cold. A line of demarcation formed, but he sank and died.—Dr. PERCY KIDD referred to the combined signs of mitral and tricuspid stenosis. In one case there was lividity, with a presystolic murmur over the right ventricle at the lower part of the

sternum. The diagnosis was verified at the *post-mortem* examination. Another case, however, which he mentioned, seemed to be opposed to this opinion. It was that of a young man who had no marked cyanosis, but marked mitral and tricuspid stenosis, probably of congenital origin.—Dr. YEO, in reply, said that no detailed dissection of the vessels of the limb had been made in his case, but no disease of arteries had been found anywhere.—Dr. FOWLER said that in four cases of mitral and tricuspid stenosis he had found all the signs mentioned by Sir D. Duckworth. In some cases of mitral stenosis the pulmonary artery might become so dilated that the valves might in consequence become incompetent and not close the opening accurately. He thought that this hypothesis would also explain the variability of the murmur.—Sir DYCE DUCKWORTH quite agreed with the explanation.

Living Specimens.—The following were exhibited: Dr. DE HAVILLAND HALL: A Large Nevus on the Back.—Mr. PARKER: An Infant Presenting Symptoms of Struma and of Syphilis Concurrently.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

THURSDAY, JANUARY 26TH, 1888.

PRIESTLEY SMITH, M.R.C.S., Vice-President, in the chair.

A Case of Subretinal Effusion in Chronic Nephritis in a Child.
—Dr. JAMES ANDERSON read notes of this case. The patient was a girl, aged 9 years, admitted into the London Hospital on March 14th, 1887, under the care of Dr. Samuel Fenwick, who kindly allowed the publication of the case. The child complained of sickness and headache, was extremely pale and wasted, but showed no œdema of face or limbs. She passed 50 to 65 ounces of urine in 24 hours, 1010 to 1012 specific gravity, with one-fourth of albumen, some free blood discs and casts of various kinds. The heart was hypertrophied and the arterial tension was high. The ophthalmoscope showed double neuro-retinitis. The child had been healthy till 18 months of age, then had an attack of measles, and was never subsequently well. In November, 1886, she was noticed to have frequent nocturnal micturition, and five weeks before admission she complained of headache and sickness, and that she could not thread a needle. A fortnight before admission into hospital, she had a severe fit, was universally convulsed, and then lay unconscious for three days. When she recovered consciousness, she was practically blind, but partly recovered vision. He first saw the child on April 10th, and found severe neuro-retinitis with numerous hemorrhages and considerable pale exudation in the papilla and retina, best seen with +4 D. On the nasal side of each fundus there was extensive detachment of the retina, greyish pink and glistening, the vessels seen climbing over it with +9 D. The surface of the detachments oscillated freely but slowly when the head was moved. The child was almost quite blind, but mentally clear. The retinal detachments rapidly increased. Drawings of the fundi were exhibited. That of the left eye showed numerous bladder-like bulgings round the lower and nasal periphery. That of the right eye showed four large detachments almost meeting in the middle, leaving only a narrow quadrangular chink, at the bottom of which the fundus could be seen. The child rapidly got worse, the face and limbs got very slightly puffy, the urine diminished in quantity and became almost pure blood. Treatment had no effect. She became more drowsy, had vomiting, epistaxis, and bleeding from the bowel, and died comatose on April 24th, about three months from the first complaint of visual defect. The necropsy showed advanced fibroid contraction of the kidneys, the left weighing only three-quarters of an ounce and being much distorted by a deep fibroid scar at its upper part, the right weighing two ounces and a half, not so severely affected, but both showing (microscopically) marked fibrosis with hemorrhages. The mucous membrane of the pelvis of the kidneys, the ureters, and the bladder was infiltrated with blood, and that of the bladder was raised into soft polyp-like growths. The retinae were separated from the choroid by a clear straw-coloured fluid. The brain and other organs showed no gross lesions. Detachment of the retina from any cause, and fibroid kidney were both rare in children. One similar case in a girl, aged 14 years, had been published in the *Transactions*. The rarity of such cases and the absence of œdema might very readily cause them to be overlooked until declared uræmic symptoms appeared. An exanthem such as measles or scarlet fever was probably the starting point in the great majority of such cases.

On the Prognosis of Neuro-retinitis in Bright's Disease.—Dr. MILES MILNEV, after referring to a case which first attracted his attention to the subject of the paper, explained the method of obtaining his statistics. The names of all the cases occurring in the London Hospital Medical Register under the headings of "Acute" and "Chronic Renal Disease" for the years 1884, 1885, and 1886 were taken, and the notes examined and extracted, in all 447 entries. This number was reduced by 26 for readmissions of patients, and by 46 for acute scarlatinal cases, so that the total number of cases under consideration was 375. In 211 of these, no separate statement regarding the eyes had been made, but there were good grounds for the assumption that the number of eyes examined and the number of eyes examined and found normal were both smaller than they should have been. Of the remaining 164 cases, 105 were stated to be normal, 3 were affected with other changes, 5 from the nature of the notes were rejected, and 51 were definitely stated to have had the eyes affected. The mortality was as follows: 1. Total number of renal cases considered, 375; total number of deaths in hospital in 1884-5-6, 144. 2. Number of cases in which the eyes were unaffected, 105; number of deaths in hospital in same period, 28. 3. Number of cases in which the eyes were affected, 51; number of deaths in hospital in same period, 27. The mortality of the affected cases was, therefore, in hospital double that of the unaffected cases. The 51 affected cases were then separately considered. By various means, including inquiries at Somerset House, 45 deaths out of the 51 affected cases had been traced. The 6 cases unaccounted for were all admitted into the London Hospital for the first time in 1886; and, since the Somerset House indices were only available up to the end of the first quarter of the past year, they could not be traced with any certainty after March, 1887. Sex: males, 38; females, 13. Age: under 20, 2; 20 to 30, 13; 30 to 40, 10; 40 to 50, 16; 50 to 60, 6; 60 to 70, 4. *Duration of Life.* As the majority of the 51 cases were already affected with neuro-retinitis when admitted into the hospital, it was possible only to give the length of life after the first note was taken. One case lived nearly eighteen months, and two nearly fourteen months; all the rest died within the twelve-months. It was further stated that, if all the 6 untraced cases were alive at the "present date," not one would have lived eighteen months from the time the eye changes were first noted. The following 9 cases were quoted as of special interest, because the eye changes occurred while the patients were under observation in the hospital.

Name.	Age.	Sex.	Duration of Life in days after last note of "Fundus Normal."
R. B.	47	M.	51 days.
E. C.	25	M.	195 "
T. D.	62	M.	162 "
G. O.	51	M.	52 "
G. A.	31	M.	150 "
G. C.	49	M.	145 "
J. W. G.	51	M.	Now in hospital; has lived fifteen months since first note of changes.
E. C.	63	F.	361 days.
H. D.	23	F.	60 "

In order to be on the safe side, the enumeration was made from the date when the eyes were last stated to be normal, not from the date when the changes were first recorded. The duration of life, therefore, amongst these nine cases had not averaged more than six months. Regarding the eye changes themselves, the hospital notes were not generally sufficiently full to admit of accurate conclusions being drawn. The first recorded change was in some cases a slight haze, in others a papillary exudation, and in others again one or more hæmorrhages. The only paper that the author could find which had any bearing on the question of prognosis was referred to, namely, that by Dr. C. S. Bull, in the June half-yearly number of the *American Ophthalmoscopic Society's Transactions*. It was stated that, in the discussion following that paper, a case was quoted by Dr. Webster of a clergyman who, ten or fifteen years previously, had had this condition of the fundi recognised, and who was still living at the time of the meeting of the Society. This case was quoted as showing the importance of comparing private with hospital practice. The following conclusions as regards the experience in the London Hospital were then submitted as being justified by the statistics: 1. That the retinal

changes occur late in renal disease. 2. That their presence appears to affect the prognosis very materially for the worse, the mortality in hospital amongst the affected cases being at least doubled. 3. That the prognosis is so bad that not one has lived eighteen months after the changes have been noted. 4. That therefore the ophthalmoscope affords a most valuable index as to the course any given case of Bright's disease is taking (except, perhaps, in pregnancy cases), unless, indeed, it be supposed that the mortality of the cases considered happened to be exceptionally high, independently of the causes at work which produced the coincident neuro-retinitis.—Mr. SIMON SNELL (Sheffield) also read a paper on this subject. He held that the subjects of retinitis albuminurica that came before the ophthalmic surgeon were to be regarded as having, generally speaking, a tolerably defined, or a short limit, to their existence. This referred to cases at all ages. He did not think that the retinal changes ever preceded the kidney diseases, as some asserted they might do. He referred to Dr. C. S. Bull's observations before the American Ophthalmological Society in 1886. Out of 103 cases 86 had died, 57 in the first and 12 in the second year; of the 17 living 14 were seen during the last six months; 1 had been seen seven years previously. Dr. Gruening reported of 100 cases that none had lived over two years. Mr. Snell alluded to the frequency with which the diagnosis of renal disease was made through patients seeking advice respecting sight, and notwithstanding the numbers that thus passed before the ophthalmic surgeon, his knowledge of the cases was for so brief a period, that the final results were not easily noted. He could only just now trace eight cases to the end. The respective ages were 37, 34, 56, 59, 31, 66, 23, 39; and the periods of death after the retinal mischief was diagnosed 6 weeks, 4½ months, 5½ months, 10 months, 2½ months, 5½ months, 8 weeks, 14 months. Reference was made to the better prognosis in the retinitis associated with pregnancy.—Mr. CRITCHETT thought that all ophthalmic surgeons now recognised the gravity of the prognosis in these cases. He recalled three instances occurring in medical men who lived for five, thirteen, and ten months respectively after the discovery was made; in the first mentioned patient only one eye was affected.—Mr. MCLARDY thought a distinction must be made between hospital and private cases. He had only known one hospital patient live for two years after the condition was discovered. In young persons, in those in whom it was associated with excessive drinking and in association with pregnancy, the prognosis was not so bad.—Dr. W. J. COLLINS had seen one case of subretinal effusion in acute nephritis preceded by blindness and severe neuro-retinitis. He remarked that Dr. Miley's paper necessarily only dealt with those who were ill enough to come into a hospital, and concluded by discussing the proximate cause, with especial reference to hypertrophy of the left ventricle, and the hydramic condition of the blood.—Dr. VAN MILLINGEN had seen one case eight years previously where only one eye was affected; the patient was still living.—Dr. ANDERSON, in reply, doubted whether there was much difference in prognosis between hospital and private cases; the prognosis was very bad, though exceptional cases were occasionally met with. He believed it was sometimes impossible to distinguish between cerebral and renal neuro-retinitis.

Toxic Amblyopia.—Dr. VAN MILLINGEN read a paper on this subject. During fifteen years' experience in Turkey and the Levant he had not met with a single instance of alcoholic or tobacco amblyopia in a Turk male or female. As regarded the tobacco this could not be attributed to the kind smoked, for Turkish men and women used such a large quantity, that the amount of nicotine would correspond with the amount in the smaller quantity of stronger tobacco used in this country. He therefore attributed the exemption to the mode of smoking, and believed that poisonous symptoms resulted from the juice of the tobacco being allowed to come into contact with the mucous membrane of the mouth in a moist state. Turkish women did not drink at all; some of the men drank *raki* to excess, but he had never known an instance of alcoholic amblyopia from this cause. On the other hand he had met with eight instances of alcoholic and two of tobacco amblyopia in foreigners resident in Turkey.

Living and Card Specimens.—Mr. CRITCHETT: New Instruments (new Fixation Forceps and Linear Knife).—Mr. HIGGINS: Result of Operation by Caustery for Conical Cornea.—Mr. GUNN: Growth of New Lens Fibres after Spontaneous Absorption of Traumatic Cataract.—Mr. DOYNE: Condition of Retina Suggestive of Cysticercus.—Mr. HARTWELL: Iridæmia with Congenital Dislocation of Lenses.—Dr. WELLS: Case of Frontal Mucocele.—Mr. JULER: (1) Albuminuric Retinitis. (2) Persistent Hyaloid Artery.

BRITISH GYNÆCOLOGICAL SOCIETY.

WEDNESDAY, JANUARY 25TH, 1883.

ARTHUR W. EDIS, M.D., President, in the Chair.

The following specimens were exhibited by Dr. G. GRANVILLE BANTOCK:

Hæmatosalpinx with Cystic Disease of the Ovary.—The patient, aged 30, married, had given birth to a five months' fœtus five years previously. Recovery after the confinement had not been satisfactory. She had suffered from uterine hæmorrhage ever since, which had not been checked by the usual methods of treatment to which she had been subjected. The uterus had been dilated and curetted, but the hæmorrhage persisted. The diagnosis of the case was by no means easy; it was supposed that there was a fibroid tumour. He decided to open the abdomen to find out what really was the matter. It was found that the left ovary formed a blood cyst of considerable size, while on the right side there was a large hæmatosalpinx, the ovary also being much enlarged. These were very adherent, and the peritoneal cavity had to be washed out and drained. The progress of the case after the operation was eminently satisfactory, but he was disappointed to find the patient had not got rid of the hæmorrhage. Menstruation had returned and was very excessive. The tubes were removed as close as possible to the uterus. He alluded to the observations of Dr. Johnstone, of Danville, Kentucky, in which it was shown that the application of the ligatures close to the uterus was likely to check hæmorrhage. He thought the failure in this case might be due to the imperfect application of the ligatures, although he had endeavoured to apply them as near to the uterus as possible, or it might be due to some condition of the uterus. This the future would show.

Blood-Cyst of the Ovary and Hydrosalpinx.—In this case the left ovary constituted a blood-cyst, which in the recent state had contained five or six ounces of liquid blood, and was very adherent. On the right side there was a hydrosalpinx with enlarged ovary. In this case also it had been necessary to wash out the peritoneum and drain. The result of the operation, which was performed on November 20th, had been perfectly satisfactory.

Removal of Appendages for Fibroid Tumour and Hæmorrhage.—The case was interesting from the condition of the Fallopian tube. The appearance of the specimen gave no idea of its appearance at the time of removal. The sacculated left tube exactly resembled a knuckle of intestine, greatly distended, with semi-transparent walls. Adhesions added greatly to the difficulty of the operation. On the other side, the ovary was large and contained a cyst, and the tube was thickened and tortuous. The patient had had a number of children, and was 45 years of age. The hæmorrhage was troublesome, and he could suggest nothing but the removal of the appendages to check it. He had not anticipated finding anything of the kind he saw on operating. The tumour filled the cavity of the pelvis and rendered it very difficult to provide for drainage. He was obliged to put a tube down on the right side of the uterus, and this he removed three days later. The patient did well.

Cystic Disease of the Ovary.—The history of this case was that of an extra-uterine pregnancy. Eight years previously Dr. Savage, of Birmingham, had removed an ovarian tumour of small size. She was then 17 years of age. A year ago she married, and three months ago menstruation ceased. On lifting a weight one day she felt a sharp pain and became ill, being obliged to keep her bed, and having a high temperature. On admission a tumour was found on the right side of the uterus, dipping down into Douglas's pouch behind. It could be distinctly felt over the pubes, and there was a clear resonant note over the tumour, rendering the diagnosis somewhat obscure. This was subsequently accounted for by the discovery that the cæcum was adherent to the front of the tumour and over the right half of the fundus uteri, and had to be separated during the operation. The cyst, which was the size of a goose's egg, burst whilst separating the adhesions; it contained a quantity of hard blood clot. At the bottom of Douglas's pouch the fingers slipped into a cavity. The adhesions forming this were broken down, and the pelvis cleared out with a stream of water. A drainage-tube was then inserted. The patient was convalescent.—Dr. ROYD pointed out that hæmorrhage occurring in cases of fibroid tumour was often due to the presence of small mucous polypi. The cavity of the uterus should always be examined before proceeding to the abdominal operation. This was the probable explanation of the favourable results of electrical treatment

in such cases. Mr. BLAND SUTTON, Dr. MANSELL MOULLIN, Dr. R. T. SMITH, and the PRESIDENT, took part in the discussion.

Cysts from the Labia Minora.—Dr. R. T. SMITH exhibited two cysts which he had removed from the labia minora of a woman aged 28, who had had one child eleven years previously. They were placed symmetrically on either side within a third of an inch of the clitoris. The contents were mucous.

President's Address.—The PRESIDENT then delivered his address.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

PATHOLOGICAL SECTION.

FRIDAY, JANUARY 13TH, 1888.

C. B. BALL, M.D., President, in the Chair.

Dysentery. Mr. CONOLLY NORMAN made a communication as to the cause of the outbreak of dysentery with which he had to deal in the Richmond Lunatic Asylum, Dublin. Mr. Norman stated his belief that the outbreak was due to defective drainage, and laid down the following as probable general laws that regulate the appearance of dysentery: 1. Dysentery is communicated through exhalations from a soil saturated with the products of organic decomposition. 2. The incidence of dysentery at particular times and seasons is due to the increased moisture of the soil at such times. 3. When dysentery breaks out there is commonly a concurrent outbreak of severe diarrhoea. 4. Dysentery appears where dysentery has been before. 5. When dysentery appears over a large area, including its own haunt, it appears in the latter situation in its worst form and to the greatest extent. 6. Like other malarial affections, dysentery attacks by preference those who are not acclimatised to the conditions that have produced it.—Mr. FRAZER believed that dysentery was and could be contagious, for he remembered making a *post-mortem* examination in the Richmond Hospital from which he got a most severe attack of dysentery, and which he believed to have been produced by contagion. He was not satisfied with Mr. Conolly Norman's observations upon malaria. From the most remote times dysentery had been epidemic in Ireland. In the battles during the reign of Elizabeth the soldiers were decimated by it; the same thing occurred during the wars of Cromwell and William III; and yet Ireland had always been remarkably free from malaria. But that dysentery might be associated with malaria, on the other hand, was possible. Malaria, as such, was confined to very limited districts in Ireland. He knew that it existed along the Dublin river; but there had been no coexistence of dysentery in those spots. Another remarkable fact was that it occurred at certain seasons of the year. It was well known to break out in autumn, especially after the first frosts, which was accounted for in former times by persons drinking water containing animal and vegetable material in a state of decay. As for its mortality, he was resident in the hospital during the years 1847, 1848, and 1849, and had to attend specially upon fever and dysentery; and the mortality in cases of dysentery—of which only the very bad were admitted—was three times as great as in the worst fever cases; it amounted at one period to one out of every four cases. Dr. Cheyne used the remarkable expression that dysentery was "fever turned in on the bowels." His preparations illustrative of the disease were in the Richmond Hospital, and were described in the series of the Dublin hospital reports.—Mr. NORMAN replied.

Sclerosis of Brain and Spinal Cord.—Mr. WALTER BERNARD, of Londonderry, read a paper upon an obscure case of cerebro-spinal disease, and exhibited microscopic sections of portions of the spinal cord and central nervous system. The case in some points resembled one of insular sclerosis.—Professor PIRSER said three specimens taken from the subject of the case had been submitted to him by Mr. Bernard. The first was a section of the upper part of the medulla oblongata, and he had been unable to satisfy himself that there was any sclerosis in it. There was a spot in the centre which appeared unstained; but that might have been owing to a defect in the staining. Another spot looked somewhat as if the nerve tissue had gone, and had been replaced by connective tissue. Another specimen was from the middle part of the cervical spinal cord, and the anterior cornu on one side of this had disappeared. He could not satisfy himself that there was any increase of connective tissue; it looked more like atrophy. The third specimen was a section of the optic nerve, and in this there was an accumulation in some places of

round cells, which seemed to indicate neuritis to be [the pathological expression of the optic neuritis which Mr. Bernard saw.—Dr. FINNY made some remarks, and Mr. BERNARD replied.

Suicidal Wound of the Heart with a Pin.—Mr. WILLIAM THOMSON communicated a case of suicidal wound of the heart with a pin. The head of a pin was discovered in the fifth intercostal space, two inches and a half from the nipple—downwards and inwards. The pin had traversed the pericardium, and wounded the anterior wall of the left ventricle. The pericardium contained seventeen ounces and a half of bloody fluid, and there was a small rent in the wall a quarter of an inch in diameter, which was filled by blood-clot. The surface of the ventricle in contact with the pin was torn to the extent of nearly an inch; a small vein was also wounded.—Dr. FOOT referred to the case of Admiral Villeneuve, who commanded the French fleet at Trafalgar, and who some time afterwards pierced his heart with a long needle. A case came under his (Dr. Foot's) notice of a child into whose heart a needle went from its mother's dress as she was clasping it to her breast. She immediately ran with the child to the Meath Hospital. He distinctly saw the oscillations of the needle caused by the action of the heart, and drew it out with a rotatory motion, in order to lessen the chance of hæmorrhage. The woman brought the child to him next day, nothing further happened. In Warsaw the latest treatment for cholera was puncturing the heart with a needle to stir up vitality.—Mr. FOX mentioned a case of a nobleman of Turin—a courtier of King Amadeo—who was killed while asleep by his wife, who drove a golden needle into his chest at a spot ascertained from anatomical plates to be over the heart. Fischer collected 453 cases of wounds of this sort, in the majority of which death resulted from the pericardium becoming filled with blood. In a case by Dr. Moxon, exhibited before the Clinical Society of London, a large pin was seen sticking in the chest of the patient, and moving with each motion of the heart, but apparently causing no trouble whatever to the patient. In another case a knitting-needle, shot from a toy pistol, perforated the right ventricle of a boy's heart, went into the auricle, and transfixed the valves, and yet the boy lived for a considerable time. In another case a boy lived for five weeks after his heart had been pierced by a wooden peg three inches long. In the case of the woman who drove the thirty needles into herself, death resulted from a wound inflicted by only one of them upon the superior vena cava. In another case a pin found its way into the thoracic duct, and the patient bled to death. A most remarkable case was that of a medical student, who, while on a "sprece," passed some pins into his heart. His pericardium was opened, and the head of a pin was found outside the wall of the right ventricle. It was grasped, and a slight incision was made in the ventricle to facilitate its removal; but the systolic action of the heart carried it in, and the pin was still in the young man's ventricle, and occasioned him no trouble. Professor Christison recorded a case of a man wounded by a bullet, which found its way into the right ventricle of his heart, and it remained there for two years, occasioning him no trouble, and he eventually died of pleurisy.—Dr. FINNY said these cases showed how tolerant the heart was of injury, provided certain portions of it were not injured. The walls of the heart were tolerant of injury so long as there was no hæmorrhage to stifle the heart's action. But there were cases of death immediately occurring from very small injuries to the nervous ganglia.—Mr. FRAZER said that amongst the Japanese puncturing of the heart was a primitive mode of treatment for the cure of certain affections. He had a note of a *post-mortem* examination made while he was a student, in which he found a needle an inch and a half long in the surface of the heart, inside the pericardium, the surface of it being covered with old lymph.—Dr. WALTER SMITH mentioned a case of suicide which came within his knowledge. It was a young lady who became insane. One day, while two nurses were in the room with her, she drove a hair-pin, which she had secreted, into her abdomen through the umbilicus, uttering no sound whatever or expression of pain. She told the superintendent next day that "she had done it." He looked at her abdomen, saw no mark, and disbelieved her; but symptoms of peritonitis soon appeared, and she died, and on a *post-mortem* examination the hair-pin was found lying amongst the coils of the intestine.—Mr. MOLONY mentioned a case of a person who attempted suicide by working a hole in the abdominal wall, about an inch on the left side of the umbilicus, with the end of a lucifer match.—Mr. COX gave a case of a man who, while suffering from delirium tremens in an asylum, wounded himself over the heart.

and in the arm with the sharpened end of a spoon.—Mr. THOMSON briefly replied.

Multiple Abscesses of the Liver and Lungs.—Dr. FINNY exhibited specimens illustrating pyæmic multiple abscesses of the liver and lungs, which had run a rapid course of about ten days, and in which jaundice and the expectoration of pus had occurred but five days before death. The patient, who had been admitted under Dr. Finny's care into Sir Patrick Dun's Hospital on November 16th, 1887, gave a history of having been treated for pain and suffering referred to the left side of the abdomen, over four years previously, and of the question being discussed as to the existence at that time of cancer of the stomach. He died on December 21st, and on *post-mortem* examination, in the situation to which pain had been referred, there was found an abscess, shut in by firm and old adhesions of the peritoneum, and limited by the left kidney, the lower third of the spleen, the tail of the pancreas, and the superior surface of the splenic flexure of the colon. The abscess contained a couple of ounces of grumous, cheesy matter. The points of interest were (1) the long duration (over four years) which had elapsed between the primary inflammation of the peritoneum and its subsequent conversion into an abscess; and, as a corollary to this, the danger, remote as well as immediate, attendant on peritoneal inflammations; (2) the mode by which the secondary abscesses of the liver and lungs were developed, namely, by the pus directly entering the portal circulation through the communication with the spleen, and thence again by the hepatic veins it was carried into the lungs; and (3) the short time which elapsed between the direct infection of the blood and the occurrence of lung abscesses, a period which may be set down as under five days; (4) the formation of the multiple abscesses was embolic in its nature, and accounted for the number and small size of the hepatic abscesses.—Dr. WALTER SMITH made some remarks, and Dr. FINNY replied.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

DECEMBER MEETING.

T. W. HIME, B.A., M.B., President, in the chair.

Mesenteric Cyst.—Mr. HORROCKS, Surgeon to the Bradford Infirmary, showed a mesenteric cyst imbedded in the meso-colon. Above it was adherent to the great curvature of the stomach, at its lower border the transverse colon was attached. It extended a short distance between the layers of the gastro-splenic omentum. The cyst was thick-walled, and lined by a smooth membrane, which was shreddy at points. On its posterior wall near the lower part it communicated freely with the stomach. It contained pus. The clinical history was notable in the fact that the pus had never been vomited but passed by the bowel. Its origin was considered doubtful, as suppuration destroys the distinguishing features. Possible origin from mesenteric cyst, hydatid tumour, suppurating mesenteric gland, or localised peritonitis following gastric ulcer was discussed. The patient had been under the care of Mr. W. L. Roberts.

Purulent Ophthalmia of Infants.—Dr. BELL read a communication on some destructive diseases of the eye, in the present case with special reference to the purulent ophthalmia of infants. After having dealt with the symptoms and progress of the disease, he showed by means of figures the great frequency of the affection and of blindness consecutive to it. He urged the necessity of early treatment, which should consist of frequent washings of the eye with warm water dropped from cotton wool at some height above the face, and the application of a solution of sulphate of zinc, gr. xx to ℥ viij, or of sublimate of mercury, gr. j to ℥ viij, or of nitrate of silver, gr. j to 5j. He had for some time been trying to find a thorough means of spreading the requisite information among the poorer classes, and he was glad to be able to inform the Society that he had been able to secure the assistance of the vaccination officer, who attached the following instructions to each vaccination form sent out in Bradford:

Instructions regarding New-born Infants.—If the child's eyelids become red and swollen, or begin to run with matter within a few days after birth, it is to be taken without a day's delay to a doctor. The disease is very dangerous, and if not at once treated may destroy the sight of both eyes.

Dr. Bell added that he hoped this mode of conveying information would in a short time be extended, and adopted throughout the kingdom. He had observed that the application of solution of nitrate of silver to all cases of new-born infants in some lying-in hospitals had reduced the cases of purulent ophthalmia from 5 to 2 per cent.

Cerebral Tumour.—Dr. HERBERT MAJOR showed a specimen

from a case of cerebral tumour. The patient was a man, aged 31, who had suffered from headache and at times giddiness. Temperate; no history of syphilis. About five weeks prior to admission he had an epileptic fit, which was followed by slight weakness of left arm and leg. A week afterwards there was a second fit of greater severity, with a further loss of power in the left limbs. In this, as in the subsequent fits (seven in all) the sequence of the convulsive movements was said to have been: left forearm, left arm generally, left leg, left side of neck, head being drawn to left side; right side of body not convulsed. He complained of very severe headache, and had a dazed expression when admitted. Speech was somewhat slow. There was no definite paralysis of the face, lips, or tongue, but marked paralysis, with rigidity, of the left arm and (somewhat less) of the left leg. The superficial reflexes on the paralysed side were lowered, but the knee jerk was increased, as also the wrist jerk, and ankle clonus was present on the paralysed side. Sensibility apparently unaffected; the special senses normal, and there was no optic neuritis. He was treated with bromide of sodium in 20-grain doses, but grew steadily worse, and died about one month after admission. At the *post-mortem* examination a caseous nodule was found in the upper part of the right ascending frontal convolution. The pia mater over it was thickened, congested, and adherent. The other parts were apparently healthy. The case was brought forward as one in which the growth might possibly have been successfully removed by operation.—Mr. SAMUEL LODGE, jun., detailed a somewhat similar case in which, from failure to observe the significance of certain facial symptoms, trephining had failed to relieve the patient, who *post-mortem* was afterwards proved to have died of cerebral abscess.

Post-Nasal Growths.—Dr. ADOLF BRONNER said that post nasal growths or lymphoid papillomata were a "local hypertrophy of the normal pharyngeal tonsil or retinoid tissue situated at the vault of the naso-pharynx." Post-nasal growths were of great importance in their relation to diseases of the throat and ear. They were often the cause of bronchitis, pharyngitis, asthma, and of diseases of the middle ear. Of 98 cases of diseases of the middle ear in children under 15, seen by Dr. Bronner in the last twelve months, 52 cases, or 55 per cent., had post-nasal growths. Of 81 cases of post-nasal growths 70, or 87 per cent., had diseases of the middle ear. The growths occurred mostly in children under 15. In adults other diseases of the naso-pharynx and also diseases of the nose became more frequent, and were in their way just as important for the treatment of diseases of the middle ear as post-nasal growths were in children.—Dr. MAJOR drew attention to the effect of post-nasal growths in causing contracted chest in children.—Mr. R. H. MEAD and Dr. GOYDER commented on the paper.

PATHOLOGICAL SOCIETY OF MANCHESTER.

WEDNESDAY, JANUARY 18TH, 1888.

A. W. STOCKS, M.R.C.S., President, in the Chair.

Cystoma of the Ovary of a Fœtal Cat.—Dr. A. ROBINSON showed sections of a cystoma obtained from the left ovary of a cat at about the seventh week of fetal life. The cysts were two in number, communicating with each other by a narrow neck; and both were lined by a low cubical epithelium. They were situated close to the hilus, and were developed from the tubules of the Wolffian body.

Adenoma Sebaceum.—Dr. BROOKE showed sections of an adenoma of the sebaceous ducts, which had been excised from the scalp of an infant. It was said to have been noticed very shortly after birth, but had grown somewhat rapidly of late. It measured one inch by three-quarters, and was exceedingly like a xanthoma in its outward appearance. The surface was smooth, bald, slightly raised, and yellowish. Histologically it was found to consist of a pure hyperplasia of the gland, causing atrophy of the neighbouring hairs and sweat ducts by pressure.

Infantile Paralysis.—Dr. ASHBY showed sections of the spinal cord of an infant aged 9 months, suffering from acute atrophic or "infantile" paralysis. The paralysis occurred about six weeks before its death, which was caused by pneumonia. The onset of the paralysis, according to the parents, was somewhat sudden, and accompanied by muscular twitchings and convulsions. The paresis of the legs was noticed first, then arms as well as legs; later she could not sit up, and there was complete loss of voice. The paresis of the limbs continued with but little improvement till death. An examination of the cord showed extensive changes

in the cervical and dorsal enlargement, being well marked in the dorsal and upper cervical region. The vessels entering the anterior horns were gorged with blood and surrounded by many leucocytes. The grey substance contained fatty granules, and detritus, which was very friable. The caudate nerve cells had in many places completely disappeared; in other places they were undergoing degeneration. In the pons and medulla the perivascular spaces were enlarged, and the vessels gorged with blood.

Specimens.—Dr. HILL GRIFFITH showed preparations illustrating the Anatomy of the Suspensory Ligament of the Lens.—Other preparations were exhibited as card specimens.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

THURSDAY, JANUARY 19TH, 1888.

M. M. DE BARTOLOME, M.D., President, in the Chair.

Nerve Section for Wry-Neck.—Mr. PYE-SMITH showed a man, aged 39, in whom he had divided the right spinal accessory nerve for severe convulsive wry-neck. The movements had almost entirely ceased, enabling the man to resume work. The sternomastoid and trapezius were much wasted.

Laparotomy.—Mr. PYE-SMITH related a case of successful laparotomy for acute intestinal obstruction caused by a Meckel's diverticulum from the ileum in a boy, aged 13. The patient was shown at the meeting.

Cases.—Mr. SNELL introduced the following patients: 1. Man with chancre of upper eyelid (healed). 2. Man with piece of steel in lens for nineteen years, lens remaining clear except at the situation of foreign body (encapsuled) at the posterior part; the vision was good. The case was described in the *Ophthalmic Review* of 1884. 3. Staining of conjunctiva with nitrate of silver.

Myradema.—Mr. W. MAKEIG JONES showed a case of myxœdema in a married woman, aged 50. The disease had been gradually coming on for the last four or five years. The symptoms were great anæmia, with limited rosy patches on both cheeks, centre of forehead and lips; swelling of cutaneous surfaces, which did not pit on pressure; commencing atrophy of both optic discs; pupils sensitive to light; systolic *bruit*; exaggerated patellar reflex; urine about a pint in twenty-four hours; specific gravity 1014-1020; full of phosphates but not albuminous (it contained albumen eighteen months ago); temperature in mouth 96°; pulse 48-60; general lethargy, slowness of speech, and stammering; slowness of movement and sensation; unpleasant taste but not smell; the thyroid was larger, especially in its left lobe, than in women of the same age; the hands had the characteristic spade-like appearance. Although speech was slow she could read fluently.

Disease of Femur.—Mr. GARRARD showed a thigh bone which had been acutely inflamed, much thickened, and the medullary canal filled from end to end with cheesy pus, which he had amputated at the hip-joint three weeks previously; the patient had made a rapid recovery.

Colotomy.—Dr. GWYNNE gave the notes of a case where he had performed left colotomy for obstinate constipation of several months' standing relieved by occasional attacks of diarrhoea. The patient was a woman, aged 46, unmarried. The case gradually got worse, with great distension of abdomen, and frequent vomiting. The patient now (a year and a half after the operation) enjoyed good health. There was no history of syphilis. The pain was always referred to the left groin, and since the operation she occasionally suffered from pain in the same region.

HARVEIAN SOCIETY OF LONDON.—The following is a list of the names of gentlemen elected by the Council as officers of the Society for the year 1888:—President: *William Sedgwick. Vice-Presidents: Dr. T. Buzzard; Dr. John Williams; *Mr. H. W. Page; *Dr. William Ewart. Treasurer: Mr. G. P. Field. Honorary Secretaries: Dr. M. Handfield-Jones; *Mr. C. B. Lockwood. Council: Mr. F. H. Champneys, M.B.; Dr. J. Hughlings Jackson, F.R.S.; Mr. J. Ernest Lane; Dr. R. S. Mair; Mr. C. W. Mansell-Moullin; Dr. R. H. Milson; Mr. A. J. Pepper; *Mr. Edmund Owen; *Mr. Frederick Treves; *Dr. Stephen Mackenzie; *Dr. E. Clifford Beale; *Mr. J. H. Drew. Those gentlemen to whose names an asterisk is prefixed were not on the Council or did not fill the same office last year.

SUCCESSFUL VACCINATION.—Dr. J. R. Irwin has received the Government grant, amounting to £41 17s., for successful vaccination in the Whitehaven district.

REVIEWS AND NOTICES.

ARE EPIDEMICS CONTAGIOUS? By JOHN PARKIN, M.D., F.R.C.S., formerly Her Majesty's Medical Inspector for Cholera in the West Indies. Popular Edition. London: Sampson Low and Co. 1887.

THE author, who died in 1886, at the ripe age of 86, had, during his life, seen a great many cholera epidemics, and had evidently pondered over the subject. At the same time, the information contained in the editorial note by the author as to the conclusive results obtained on a "crucial test" of his discovery of the antidotal properties of carbonic acid gas in cholera, gives rise to a feeling of diffidence on the part of the reader. If, as the editorial note would lead one to suppose, his successful treatment of cholera in different parts of the world was "so notorious," that Her Majesty's Government again appointed him Medical Inspector, one can only express surprise that so useful a method of treatment has not become general. The introductory chapter is a very interesting, if somewhat highly coloured, picture of the progress and nature of the epidemics which have devastated the habitable globe.

The author points out that far back in history, when human intercourse was extremely restricted, the idea of contagion did not and could not have existed, since the inhabitants of one town being ignorant of the fact that the disease with which they were afflicted also prevailed in another, must have considered all diseases as endemic or sporadic. Even if this were the case, it is a feeble argumentative weapon with which to overthrow the accumulated evidence of the contagiousness of epidemics. Scarcely more to the point is the contention that, according to the contagion hypothesis, those most exposed to its influence ought logically to suffer most. No allowance is made for the other factors which influence the conveyance and course of any given disease.

The author combats the circumstantial evidence in favour of the dissemination of cholera through a contaminated water supply, in opposition to which he quotes isolated instances in which the water supply does not appear to have been implicated. A great deal of space and argument is devoted to discussing the spread of the plague—a matter which, if interesting, is not possessed of present importance.

It would be tedious and unprofitable to analyse in detail the individual arguments advanced, which for the most part are based on apparent exceptions to the generally observed method of disease conveyance. While the work shows that the author has had an exceedingly extensive experience of epidemics, and had, moreover, carefully read up the subject, it also proves his judgment was warped by a preconceived idea.

A TEXTBOOK OF MIDWIFERY. By the late OTTO SPIEGELBERG Professor of Obstetric Medicine in the University of Breslau. Translated from the second German edition by J. B. HURRY M.A., M.D. Cantab. Vol. I. London: The New Sydenham Society. 1887.

PROFESSOR SPIEGELBERG begins his work, as is usual, with the description of the female pelvis and of its contents, but that of the embryo and its appendages is relegated to the second volume, on the ground that, as it assumes at several points a knowledge of the changes in the uterus brought about by pregnancy, the subject cannot well be discussed earlier. It is, however, a decided advantage to the student to consider the foetus in connection with the canal through which it has to pass, even at the risk of forestalling some of the details. The pelvic measurements given are smaller all round than those generally taught in England, and the same remark applies to the vagina, though the latter is not of much importance.

Leaving the topography of the pelvic cavity, which is very thoroughly gone into, we come to Part II. This section deals with the physiology and hygiene of pregnancy, parturition, and the puerperal state. The vexed question of the relationship of ovulation and menstruation is hardly settled by the author, the two phenomena being described as "closely connected but not necessarily both present," so that we are left in doubt as to what the relationship is after all.

The subject of the development of the ovum, of the budding

up of the embryo, and its several organs, is not discussed, and the reader is referred for information on this point to textbooks on Embryology. Further on, however, the usual explanations are given of the development of the ovum. The description of the physiological development of the uterus during pregnancy does not differ in any essential point from that generally received. The calculation of the duration of pregnancy is made in lunar months and not in calendar months as is usual with us.

The translator obscures his meaning occasionally by the employment of unfamiliar expressions. Thus, on page 131, we are told that the foetus, till about the seventh month, always occupies the pelvic "lie." The author's explanations of the position assumed by the foetus are not altogether conclusive, though given somewhat dogmatically.

Some practical hints are given for the care of the new-born infant, but the author falls into the common error of advising that the milk for artificially-reared children should be drawn from the same cow, although it has been pointed out that much greater uniformity of standard is likely to be obtained from an average dairy supply, in which individual variations are neutralised by the mixture of the milk of a number of animals. The direction to warm the milk "until it no longer causes an unpleasant sensation when applied to the eye" is a trifle inconvenient of application.

The remainder of the volume is devoted to the pathology and therapeutics of pregnancy, parturition, and the puerperal state, and comprises disorders due to a morbid intensity of physiological phenomena; complications due to intercurrent diseases; anomalies of the sexual organs; diseases of the ovum; and hæmorrhage from the uterus.

A copious bibliography is given at the end of each chapter. No index is furnished with this, the first volume, the only guide being the table of contents. The illustrations are fairly numerous, and, besides the stock engravings, there are a number of drawings which will be new to the English reader.

A MANUAL OF VETERINARY HYGIENE. By FRED. SMITH, M.R.C.V.S. London: Baillière, Tindall, and Cox. 1887.

THE appearance of a manual of veterinary hygiene marks one more step in the progress of veterinary science in this country. There has long been a need of a thoroughly scientific work of this character to place in the hands of students.

The author considers that sanitary reform is not bearing fruit in civil life so luxuriantly as in the army, but it is impossible that sanitary measures should be so uniformly applied to civilian animals as to military ones; nevertheless, civil life affords many brilliant examples of veterinary hygiene applied to large studs, under far more disadvantageous circumstances than are found in the army. Quoting from p. 57, we read: "Their healthy state (speaking of army horses) is entirely due to the amount of pure air allowed them, for in no other circumstance of life do they differ from their predecessors of sixty years ago." This seems to amount to an admission that in no other circumstances of the life of the army horse are improvements advisable or possible.

In his further studies we commend one point to the author's notice: that whenever a civilian attempts to feed his horses upon the army "pattern," and work them as civilian horses are worked, they are very soon in a very weak and debilitated condition, and we should infer that if suddenly called upon for work demanding stamina civilian horses would prove greatly superior to army horses, and that such an athletic condition of body as will enable a horse to work well, and continue at it, needs plenty of good food, and is the outgrowth of many months, not weeks, even after he has arrived at maturity.

The first chapter of the book is upon Water, and is excellently written, no point of scientific interest being missed. The succeeding chapters upon Air and Ventilation are also very perfect; they exhibit much painstaking application on the part of the author, and, although written in a too scientific form to be easily assimilated by the general reader, they will at least rouse the well-educated horse-owner and veterinary surgeon to a sense of the high importance of the purity of air in stables, and explain the principles which control that purity. The author does not go so far, but he may have well added that urban stables should be inspected by a properly qualified officer of the local authority, and licensed as to the number of horses they should accommodate; this would cause a cessation of that cruelty of denying horses which work all day adequate room to lie down at night—a form

of cruelty by no means extinct. A law to this effect would do almost as much as the Contagious Diseases Animals Act in diminishing glanders and farcy in large cities, while it would prevent much real cruelty.

The chapters on Stables, Removal of Excreta, Soils, Disinfection, are valuable, and well repay close study. The chapters on Labour and Individual Hygiene especially are too short, and the subjects are treated too superficially. The book closes with chapters upon the Eradication of Epizootic Diseases, Elementary Meteorology, and remarks upon Statistical Inquiry—a matter of considerable importance.

The author must be congratulated upon having produced a work of great value, and exhaustive from the scientific point of view.

MANŒUVRES ET OPERATIONS A L'AMPHITHEATRE. Par le Dr. CROUZAT, Préparateur des Cours d'Accouchement à la Faculté de Médecine de Paris. Paris: Delabaye et Lecrosnier. 1887.

IN this handbook the author describes the various operations which may become necessary in difficult or abnormal labour. After a preliminary dissertation on the fundamental principles of obstetrics and the course of spontaneous delivery, the author goes through the practical instruction given to students in Paris with the aid of the "dummy." This is taken up in French schools with a thoroughness and completeness which we have not so far attempted to imitate. We then come to the question of forceps, and these the author divides into three types: (1) that of Chamberlen (1600); (2) that of Levret (1747); and, (3) finally, that of Tarnier (1877). It is almost incredible that French obstetricians should hold so obstinately to the cumbersome and unwieldy forceps of Levret, instead of adopting the English lock and something of the English gradations in size. From the historical point of view the chapter is poor, and from its being narrowed to the consideration of Tarnier's forceps, which are never likely to come into general use, its value is limited. The directions for the use of the instrument are clear and explicit. They are, of course, for patients in the dorsal position, and are, therefore, hardly available for English readers, who probably prefer that on the left side. The necessary details follow for diagnosing the position of the foetus and the presentation; and in this the student is always well drilled. The various landmarks are gone over, and their significance pointed out. The different methods of effecting version are explained, and the operation described in detail. The book is profusely illustrated with well-executed woodcuts, which add very greatly to its lucidity and value. It is clear that a student who has conscientiously gone through this course—and it is compulsory—must be in possession of an amount of practical knowledge which will enable him to go about his midwifery work with well-grounded confidence.

We can recommend the work to students who propose taking out this course, and by its aid they can familiarise themselves with the technical terms in French, and generally with the Continental methods of procedure.

ROYAL COLLEGE OF PHYSICIANS.

THERE was a large attendance of the Fellows at the adjourned Comitia held on Thursday last to consider the resolution moved by the Senior Censor:

"That it is undesirable that any Fellow, Member, or Licentiate of the College should contribute articles on professional subjects to journals professing to supply medical knowledge to the general public, or should in any way advertise himself or permit himself to be advertised in such journals."

An animated discussion ensued, in which considerable difference of opinion was manifested; but, as the debate was declared to belong to the "Secreta Collegii," we can only record the fact that the motion was, on a division, adopted by the majority.

FEMALE SANITARY INSPECTORS.—At a recent meeting of the Newcastle Sanitary Committee, one of its members suggested the appointment of women inspectors, as they would be far more valuable for going among the housewives, and pointing out what had to be done; to which another member replied that, if females were appointed, some of the members' houses might be kept dirty.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1888.

SUBSCRIPTIONS to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 420, Strand, London. Post-office orders should be made payable at the West Central District Office, High Holborn.

The British Medical Journal.

SATURDAY, FEBRUARY 4TH, 1888.

THE BRITISH MEDICAL ASSOCIATION.

THE minutes of the last meeting of the Council of the Association include items of much promise for the usefulness of the work of the Association during the year, and indications of its continued progress and still rapidly increasing growth. Included in the business of the day was the formal election of 254 new members, following on the recent issue of a special number of the JOURNAL, an unusually large contingent, and one which promises well for the total increment of the year just opened. Another gratifying duty was the formal acceptance of the proposals of the Perthshire Medical Association to constitute itself a Branch of the British Medical Association. The incorporation as a Branch of the Association of the members of this influential local medical society will have the good effect of aiding the general organisation of the profession, so as to give effect to their opinions and wishes.

By taking up a position among the Scottish Branches of the British Medical Association, the members of the Perthshire Medical Association, while retaining all the advantages of social communion and of scientific interchange of thought and experience, join hands with the great fraternity of upwards of 12,000 medical men who are represented in its local and central Councils. They establish a claim for representation of their opinions in the Council of the Association, and acquire a vote in its proceedings. The autonomous powers of the Branches enable each to modify its times and places of meeting and its general proceedings in such a manner as best suits its convenience or its circumstances.

Quite apart from any considerations of addition to the numerical strength of the Association—which is not necessarily much affected by the formation of Branches—there is reason to welcome heartily every accession to the Branch organisation of the Association. Decentralisation is the essential condition of healthy, vigorous, and independent growth. In proportion as the Branches are numerous, active, well-organised, and well-nourished will the whole organisation thrive and flourish. Every thoughtful well-wisher of the Association is fully conscious of this.

The accession of this new Branch is peculiarly welcome and significant in connection with the forthcoming meeting

of the Association in Glasgow, in August next, and testifies that the preliminary arrangements announced have been made with judgment and capacity, and that they meet with the approval and will have the co-operation of our Scottish brethren outside the limits of the city. It affords thus a fresh earnest of the success and the popularity of our forthcoming meeting on Scottish soil, which is looked forward to on all sides with so much hopeful interest.

Another part of the business of the Council was to receive and consider the report of the Subcommittee which it had appointed in August last, to consider the important question of the rank of army medical officers. At that meeting a somewhat dramatic incident had occurred. Sir Thomas Crawford, the Director-General of the Army Medical Department, rose on the presentation of the report of the Parliamentary Bills Committee, and declared with great emphasis that he had no reason to believe that the discontent alleged to exist in the Army Medical Department as to the deprivation of relative rank, or the grievances which had followed upon that measure, had any real existence, and he threw doubt upon the existence of any extensive demand for titular military rank. In the presence of this declaration from so highly authoritative a source, the Chairman of the Parliamentary Bills Committee readily consented that the paragraph of the report thus impugned should be referred back to the Council of the Association for further investigation and report. That course was accordingly taken.

The Council appointed a Subcommittee, consisting of many of its most experienced and judicious members, for the purpose of such inquiry. The result is seen in their report, which was presented to the Council at its last meeting and unanimously adopted. The opinions which Sir Thomas Crawford had thus challenged of upwards of nine hundred medical officers of all ranks, including many of the highest, were obtained. Official rule prohibits them from any collective expression of opinion; so much so, that when a large number of medical officers, present in Dublin at the time of the meeting of the Association, proposed to meet and make a statement on the subject to the Committee, protesting against the statements of Sir T. Crawford, it was forthwith intimated that such a meeting would be considered a breach of military discipline, and the meeting was stopped. The result of the inquiry of the Subcommittee, after a laborious analysis of the facts had been made, was, it will be seen, wholly opposed to the conclusions which Sir T. Crawford had urged upon the meeting. They have reported in some detail, and their report will be forwarded to the Secretary of State for War. Such a report, coming after the intervention of Sir T. Crawford, and as the result of patient and laborious inquiry, can hardly be considered as anything else than conclusive. Armed with all possible information, after having heard all that can be urged against it, and with a fuller knowledge of the whole matter than could be obtained by any other machinery than that which this Association and this JOURNAL command, with the whole mind of the department before them, and speaking in the name of 12,000

medical men, of whom they are directly representative, the Council of the British Medical Association earnestly call upon the Secretary of State for War to give to the surgeons of the Army Medical Department such substantive and titular rank in the army as shall leave their position plain and unequivocal, both to soldiers and civilians. If the War Office does not grant this, the responsibility will rest with them for disregarding in a very flagrant and very indefensible manner the sentiments of the medical officers of the army, now expressed with overwhelming unanimity, and supported by the most influential body of civil medical approval and endorsement which could possibly be arrayed on their behalf. The consequences of such an attitude on the part of the War Office would be far-reaching, and could not fail to make not only the most painful impression on the department itself, and thus to affect injuriously the organisation of one of our most important military departments, but also to influence most unfavourably opinion in the medical schools and colleges, and seriously to injure the prospect of efficient recruiting for the Medical Service of the army. There is no question of finance involved. We may, therefore, hope that the Minister for War will deal with the demands made in a liberal and statesmanlike spirit, unbiassed by the petty prejudices which appear to have hitherto been appealed to in order to influence his judgment unfavourably. The efforts of the Association to obtain a full and clear view of the facts, and its deliberate and carefully considered verdict in favour of the medical officers of the army, will, we feel sure, not only cheer these medical officers by the assurance of well-considered sympathy and the substantial aid which it will afford them in the redressal of their grievances, but it will be also highly satisfactory to the profession at large.

APPLICATION OF THE SCOTTISH LICENSING BODIES FOR POWERS OF GRADUATION.

WE publish in another column a petition from the licensing bodies of Scotland who constitute the Conjoint Medical Board for Scotland, namely, the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, the Faculty of Physicians and Surgeons of Glasgow, for a charter under the Privy Council to enable them to confer degrees in medicine and surgery on such persons as may from time to time pass the examinations of their Medical Board. It is similar to the petition of the Royal College of Physicians of London and the Royal College of Surgeons of England. The petitioners state that they had no desire to disturb the existing arrangements whereby the Universities alone had the privilege of granting degrees in medicine, but in consequence of the action of the Royal College of Physicians of London and the Royal College of Surgeons of England, they have been constrained to apply for powers similar to those sought by these Royal Colleges. In one important respect the application from these Scotch Colleges differs materially from that of the two English Colleges. It has already been pointed out that the constitution of the new degree-

giving body which the two English Colleges seek, is in the highest degree autocratic, unconstitutional, and non-representative, seeing that it is to be constituted wholly out of the self-elected Council of the Royal College of Physicians and the Council of the Royal College of Surgeons, which is representative only of a very small minority of that corporation, and is, in its mode of election and in its general relation to its constituents, open to most serious objections. The whole of the body of graduates of the new university and teaching bodies generally are to be wholly unrepresented on this self-imposed governing body. The Edinburgh Colleges and the Glasgow Faculty have taken a much more constitutional view of the proper construction of the Senate for a new governing body. They propose that it shall include nominated representatives of each of the Faculties, and in addition to them representatives to be elected by the recognised teachers of medicine in Edinburgh and Glasgow, and also by representatives of the graduates of the new body, so soon as the number of graduates of the Senate to be so incorporated shall have attained to 200.

Such a constitution possesses in it the elements of just representation and of equitable and wise government. No doubt the Scotch universities will object to the appointment of any such new degree-giving body in Scotland, and it cannot be said that the difficulties of graduation in Scotland are such as to compare with the disabilities of metropolitan candidates, who have at present no other body to which to apply than the University of London. On the other hand, it would be difficult for the Royal College of Physicians of London and the Royal College of Surgeons of England to show that their examinations differ in any material degree from those of the Scotch examining body, or that their diplomates have any inherent claim to a degree which the diplomates of the licensing bodies referred to do not equally possess.

This application of the three great licensing bodies of Scotland introduces a new and important element into the discussion, and one with which the Privy Council will have seriously to reckon. We have already repeatedly pressed that the whole subject is one of so much national importance and so much complication that it can only properly be solved by reference to a Royal Commission.

It would be regrettable in many ways if the application of the London Colleges were granted in its present form, or if it were to be totally rejected in consequence of its defects in form. Some remedy needs to be applied to the present state of things, which is one of great hardship to the students of metropolitan schools. It is much to be regretted that the remedy which the two Colleges propose should be so framed as necessarily to arouse indignation and antagonism by reason of its crude, imperfect, and autocratic form. But difficulties in form should not obscure the essential equity of the principle involved, and on these grounds we earnestly hope that the Privy Council will cause the whole question to be thoroughly sifted, when an equitable result will, we doubt not, be attained—a result consonant alike with the true constitutional development of university teaching and

graduation and with the pressing and legitimate requirements of the metropolitan medical schools and graduates.

MEDICAL AID IN OUTLYING DISTRICTS IN INDIA.

ALL reasonable people must sympathise with the efforts of the Government of India in the cause of administrative economy. But there is such a thing as false economy, and this kind of economy is often as cruel and unjust as it is false. A striking example of this has caused a good deal of unpleasant comment in India. We notice it to show the authorities there that, although the tragedy occurred in a remote district, it cannot be allowed to pass without grave notice at home.

Backerganj, in the Sunderbunds, is an exceedingly populous but very unhealthy district; the population varies from 700 to 900 per square mile. This being so, it cannot be wondered at that the administrative and judicial work of the collector and magistrate severely taxes the powers of the civil servant charged with the administration of the district. The late Mr. H. I. Fasson had the misfortune to have to discharge, single-handed, the onerous duties of this position. This gentleman contracted a malarious fever in the jungles of Chittagong, which he was unable to shake off. He was frequently prostrated by this fever, and, while labouring under the racking headaches and other depressing symptoms of this depressing malady, went on performing his daily duties, involving great mental exertion.

It will not surprise our readers to hear that he broke down, and in a fit of utter despondency died by his own hand, "sacrificed to the miserly spirit that pervades the present Government in its dealings with its servants." "Will it be believed," says a writer in the *Calcutta Englishman*, that an important district like Backerganj has been without a European surgeon for upwards of a year? Yet so it was. Had a competent medical officer been within reach, this valuable public servant would, long ere matters reached such a pass as we have described, have been properly cared for, struck off harassing duty, and removed to a better climate.

This is not a solitary example of the consequences of this pitiful economy. Another civil servant, not much more than a year ago, was cut off by an attack of fever, which under rational treatment would, in all human probability, have had a happier issue; but as the Government could not afford to give the needful help in the shape of a European medical officer at the station, this unfortunate gentleman, whose legal acquirements were such as to mark him out for the highest honours of his service, was cut off after a brief illness. Appointments in the Indian Civil Service are much coveted, and able and highly educated men strive for them, often to the permanent injury of their health. It does not appear from the above that the Government they serve sets a high value on their lives. Such a narrative as we have related is calculated to cool the ardour of competitors.

It is not only in the manner we have indicated that false and

unjust economy is being carried out in India. The members of the Medical Service are always among the first victims when money is to be saved. Under a new rule recently promulgated doctors are mulcted a hundred rupees per mensem when they go on privilege leave; and this often when they are driven by ill-health and the pressure of work to seek a little relaxation. This rule applies to medical officers only.

We have already called attention to the fact that the Medical Service of India is kept so short-handed that, unless on sick certificate, furlough to Europe is suspended. There are numerous officers whose regulation leave has been due for eighteen months or two years who cannot get it. In time of war no one complains of this; in time of peace it is a flagrant breach of faith. How long is this persistent ill-treatment of an indispensable and most useful and hard-working class of officers to go on? We suppose until the "worm turns," and the Government of India knocks in vain at the doors of the various schools of medicine in the kingdom for candidates for commissions in a service where such treatment awaits them. That day will come soon, and the sooner the better.

HER Royal Highness the Duchess of Albany has graciously consented to become patroness of the Parkes Museum, of which H.R.H. the Duke of Albany was President until his decease.

A MEETING of the Executive Committee of the General Medical Council has been summoned for Monday, February 27th, at 1.30 P.M., for the discharge of ordinary business.

SMALL-POX is said to be completely stamped out in the island of Tasmania, and the temporary small-pox hospitals and quarantine stations broken up.

OBSTETRICAL SOCIETY OF LONDON.

ON Wednesday evening the annual meeting of this Society, for election of Fellows, was held. After some specimens had been shown by Drs. W. Duncan and Carter, and Mr. Meredith, a paper by Drs. Herman and Fowler was read, and the President, Dr. John Williams, gave the annual address. The officers for the ensuing year, whose names were given in last week's JOURNAL, were elected by ballot, and the proceedings terminated by votes of thanks to the retiring officers.

OUTBREAK OF TRICHINOSIS.

AN outbreak of trichinosis is reported from Cunewalde, near Liebau, in Silesia. Up to January 17th, no less than thirty persons had been attacked. The sufferers were all persons who had partaken of some small smoked sausages at a local *fête*, some of which were found, on examination, to swarm with trichinae. The butcher who furnished the sausages is one of the sufferers, and affirms that all the pigs killed by him had been examined and passed by the sanitary authorities.

ALUM IN TYPHOID FEVER.

DR. PAOLETTI has treated sixty cases of typhoid fever, with excellent results, with crude alum alone. He remarks that this drug had formerly been used only as a styptic and an astringent, but now that its antiseptic properties had been recognised it was clearly indicated as a remedy for abnormal fermentations in the intestinal canal.

THE ASSOCIATION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

THE annual meeting of the Association of Members of the Royal College of Surgeons of England took place on January 31st, at the Holborn Restaurant, when the annual report and balance sheet were received and adopted, and a resolution passed in favour of continuing the action of the Association for obtaining the representation of Members on the Council of the College of Surgeons. The meeting, which was not numerously attended, was followed by the first Association dinner, over which Dr. Collum presided, the guests being Mr. Tweedy, Mr. Atherley Jones, and Mr. Richard Davy. A cordial vote of thanks was passed to the secretaries for their energy and perseverance in carrying on the movement.

THE RELATION OF HOSPITALS AND MEDICAL SCHOOLS.

THE next evening meeting of the Hospitals Association will be held in the Board room of St. George's Hospital, on Wednesday, February 8th, at 8 P.M., when Mr. Timothy Holmes, F.R.C.S., will read a paper on the Relation of the Medical School to the Hospital. Dr. Bristowe, F.R.S. (President) will preside. All members of the medical profession, and others interested in this question, are cordially invited. Cards can be obtained, on application, from Mr. Howard Collins, Secretary, the Hospitals Association, Norfolk House, Norfolk Street, W.C.

NURSES FOR THE SICK POOR.

THE Committee appointed by the Queen to advise Her Majesty as to the disposal of the surplus of the Women's Jubilee Fund are desirous of receiving information from all the various institutions for nursing the sick poor in their own homes throughout the United Kingdom. Reports and other information should be forwarded to Grosvenor House, London, W., addressed to the Secretary, the Duke of Westminster.

THE LATE MR. GEORGE GODWIN, F.R.S.

MR. GEORGE GODWIN, F.R.S., who died in London on January 27th, at the age of 73, was one of the pioneers of sanitary science in this country. As the editor for many years of the *Builder*, he did much to awaken his brother architects to the importance of such subjects as drainage and ventilation. As the author of several popular works, he took an honourable share in laying bare the terrible defects in the houses of the poor, describing in forcible language the evil effects thus produced on life, health, and morals.

REDUCTION OF FEES FOR THE OXFORD M.D. DEGREE.

ON January 24th these fees, which have hitherto amounted to £40, and, by their relatively large amount compared with those at other universities, have certainly acted prohibitively, were reduced by Convocation to £25. It is hoped that large numbers of graduates will avail themselves of the opportunities thus offered.

NATIONAL PENSION FUND FOR NURSES.

WE are officially informed that this fund, so munificently inaugurated by the donation of £20,000 by four of the great City merchant princes, is making rapid progress towards the commencement of practical work. The Government authorities have sanctioned its incorporation under the above title. The trust deeds have been approved and settled, and are now in course of signature. The Society having thus received incorporation by Act of Parliament, its Council will hold its first meeting for the despatch of business next week at the office, 48, Old Jewry, E.C., when the actuarial tables and other business preliminaries are to

be completed. Another handsome donation has, we are informed, been made to the Pension Fund of £250 by Mr. John Norbury. The Countess of Rosebery has added her name to the list of patronesses of the fund. The hospital officials and nurses who wish to join can forward their names to the acting secretary, who will furnish any desired information.

THE ILLNESS OF THE CROWN PRINCE.

FROM special telegraphic information which we have just received from San Remo, we are pleased to be able to confirm on the highest authority the favourable reports as to the condition of the German Crown Prince which have appeared during the last few days. The slough which, as we mentioned last week, came away on January 17th from the site of the growth which excited so much alarm in November was more than two centimètres long. The raw surface left by the separation of this piece of disorganised tissue has now almost entirely healed, and the condition of the neighbouring parts is highly satisfactory. There is, however, some thickening about the right side of the larynx; and though the present appearances seem almost to negative the theory that the disease is malignant, a dangerous amount of narrowing of the breath-way may be caused by simple inflammatory swelling. Under these circumstances it is thought not improbable by the physicians in charge of the case that tracheotomy may become necessary, possibly at no very distant date. This contingency, however, while requiring to be kept in view, need not cause any special anxiety as to the prolongation of the life of the illustrious patient.

PROVISION BY MEDICAL MEN AGAINST TEMPORARY OR PERMANENT DISABLEMENT.

A SUMMARY of the general results of the work of the Medical Sickness, Annuity, and Life Assurance Society for 1887, referred to in another column, has just been prepared under the Friendly Societies Act for transmission to the Chief Registrar. The results are in many respects remarkable, and of great interest, as showing the singular success with which this Society has achieved an object which had hitherto baffled the leading assurance societies, namely, the provision of a sickness fund making adequate payments to the professional classes for permanent or temporary disability from sickness and accident, as well as the customary provision for annuity and life assurance. From this it appears that the Society commenced this, its third year of active operation, with an available membership of 728; 122 members had joined during the year; 3 had died, and 18 lapsed or withdrawn, leaving a net membership of 829, or an increase of 101 in the year. The total income to the benefit or assurance fund (including £491 16s. 7d. interest on reserves) was £8,083 13s., as against an expenditure of £2,010 19s. 8d., showing an increase for the year of £6,072 14s., and a total reserve to these funds at the end of the year of £19,118 1s. 5d. The annual income for management purposes had been £911 17s. 6d., of which, however, only £404 17s. 4d. had been expended, leaving a gain placed to the credit of the general assets of £507 on the year, and a balance of saving in the management for the three years of £1,703 10s. 8d. The total expenditure for management during the year had been a little over 4 per cent. The net result, therefore, of the financial work of the year was £6,579 14s. 2d., leaving a gross capital (the whole of which is the property of the assured) of £20,821 12s. 1d. These results are, so far as is known, unparalleled in the insurance world in respect to the remarkable economy of management, the rapid and satisfactory growth of assets as against liabilities, and the complete demonstration which they afford of the success with which the organisation provided under the Friendly Societies Act can be worked when due economy

and efficient management are applied for the benefit of the professional classes.

THE WATER SUPPLY OF LONDON.

THE Bill which the Grand Junction Water Works Company contemplate promoting during the coming session is one of especial interest to Londoners, inasmuch as it may constitute the first step towards securing to the metropolis generally a purer supply of water than that which is at present drawn from the Thames, and which, after a more or less imperfect system of filtration, is distributed to some two-and-a-half millions of persons. The Company seek powers to construct an "intake," and other works at Dorney Common, midway between Windsor and Bray, whereby they would be enabled to utilise the pure water to be found in the chalk in that locality. In 1884 a report showing that it is practicable, and would be economical, to render available for London the vast quantity of pure water to be found in the neighbourhood of Dorney, was made by Mr. J. Thornhill Harrison, one of the engineering staff of the Local Government Board, and was laid before Parliament. But, like many another Parliamentary paper, this valuable and important report has never received the attention which it deserves. As long ago as 1881 Professor Frankland reported that the Thames and Lea were becoming year by year less suitable for domestic purposes, and that opinion has been amply verified by subsequent experience. So long as the crude sewage of Staines, Guildford, and other towns above the intakes of the metropolitan water companies finds its way into the Thames, Londoners cannot feel happy in their water supply. Any indication, therefore, that the ample supply of pure spring water which is obtainable in the neighbourhood of Dorney, and (since no filtration works would be needed), could be substituted for the present Thames supply at little, if any, increased expenditure will in time be made available for the whole metropolis, deserves to be cheerfully welcomed and fostered.

LEGISLATION FOR DRUNKARDS IN ITALY.

WE commend the clauses of the new Italian penal code which relate to drunkards to the attention of Sir Wilfrid Lawson. Such enactments seem to us to be based on a sounder principle, and to be much better calculated to mitigate the evils of drunkenness without undue interference with individual liberty, than sweeping measures of restriction which weigh heavily on the just as well as the unjust. The following are the regulations to which we allude. Anyone found in a condition of complete and manifest drunkenness in a public place shall be fined a sum not exceeding thirty francs. If the drunkenness can be proved to be habitual, imprisonment from six to twenty-four days may be inflicted. If the offender is under 15 years of age, the father or guardian is to be reprimanded, and directed to look after the youth, under penalty, in case of neglect, of imprisonment for a period not exceeding ten days. Anyone who, in a public place or in a place open to the public, maliciously causes the drunkenness of another person, or supplies drink or other inebriating substances to persons already intoxicated, shall be imprisoned for a period not exceeding ten days. If the person to whom the drink is supplied is under the age of 15, or is obviously in an abnormal state, owing to weakness or disorder of intellect, the punishment shall be imprisoned from ten days to a month. If the offender is a person whose trade it is to sell the said liquors and inebriating substances, he shall, in addition to the above mentioned punishment, forfeit his licence. When a person who has been guilty of a criminal act has the penalty remitted on the ground that he was drunk when he committed the offence, he shall nevertheless be liable to imprisonment for a period not exceeding one year or to a fine, in such wise that the punishment shall be, either in its length or its amount, equal to two-thirds of that which would have

been inflicted had he committed the same offence when in the full possession of his senses. It may be remarked that the expression "drinks or other inebriating substances" (*bevande od altre sostanze inebrianti*) might possibly be made to cover a much wider field than "intoxicating liquors."

LECTURES AT THE ROYAL COLLEGE OF SURGEONS.

THE lecture arrangements for 1888 are officially announced by the Secretary, Mr. Trimmer, as follows: The lecture hour will be 4 P.M. precisely each day. Professor John Bland Sutton, F.R.C.S.: Three lectures on Evolution in Pathology, on Monday, Wednesday, and Friday, February 13th, 15th, and 17th. Professor William Watson Cheyne, F.R.C.S.: Three lectures on Suppuration and Septic Diseases, on Monday, Wednesday, and Friday, February 20th, 22nd, and 24th. Professor Walter Hamilton Hylton-Jessop, F.R.C.S.: Three lectures on the Physiological and Pathological Conditions of the Pupil and Accommodation, on Monday, Wednesday, and Friday, February 27th and 29th, and March 2nd. Professor Charles Barrett Lockwood, F.R.C.S.: Three lectures on the Development of the Organs of Circulation and Respiration, including the Pericardium, Diaphragm, and Great Veins, on Monday, Wednesday, and Friday, March 5th, 7th, and 9th. Professor Charles Stewart, M.R.C.S.: Six lectures on Locomotion and Allied Phenomena, on Mondays, Wednesdays, and Fridays, March 12th, 14th, 16th, 19th, 21st, and 23rd. Robert Marcus Gunn, F.R.C.S., Arris and Gale Lecturer, in June; dates and subject will be announced. Professor Arthur Edward James Barker, F.R.C.S.: Three lectures in June; dates and subject will be announced. Professor Thomas Bryant, F.R.C.S.: Three lectures in June; dates and subject will be announced.

ANTIPYRIN AND IDIOSYNCRASY.

PRESCRIBERS who have made much use of antipyrin as an analgesic have been for some time aware that it was liable every now and again to give rise to symptoms of an extremely disagreeable kind. The graphic account by Dr. Allen Sturge, of Nice, of a case in which this idiosyncrasy was very marked, published at page 213, will be read with great interest, because it is, we believe, the first instance in which pulmonary symptoms have been carefully watched from the commencement by a skilled observer. The symptoms referable to the air passages and lungs—the sneezing, coryza, and copious bronchial secretion—which formed so alarming a combination, made their appearance in five minutes; they seem to point to a serious disturbance of the vasomotor system, a surmise which is strengthened by the sudden development of urticaria on the thighs and abdomen. The only cases at all comparable which we at present recall are two recently mentioned in the *New York Medical Record*. In one case related by Dr. C. T. Barber, of Brooklyn, a man took fifteen grains immediately before going to bed; he was no sooner in bed than intense itching, starting from the face and extending over the whole body, began to annoy him; the whole body was soon covered by an erythematous blush, which quickly resolved itself into characteristic urticaria. The face was so markedly swollen that the patient's features were entirely obliterated. The urgent symptoms quickly disappeared after the administration of an emetic, and after mild purgation the patient was again restored to his usual health. Dr. Barber does not state how soon after the onset of the symptoms he saw the patient, so that we cannot do more than surmise that the pulmonary symptoms noted by Dr. Sturge were not present, or at least not very marked. In the other case Dr. Whitehouse, of Santiago, gave seven and a half grains to a child; in two minutes there was intense pain in the stomach, followed by general urticaria, and finally by loss of consciousness; one-seventieth of a grain of atro

pine was administered, and in a few minutes the child was well. Like most other remedies, the action of antipyrin in migraine is very capricious; in some cases it acts like a charm, whenever resorted to, for months at a time, while in other cases it will succeed in one attack and utterly fail in another; that these differences in its action are not due to accidental impurities has been shown by taking care to use in making up the prescriptions antipyrin from the same sample. It will be noted that the dose taken in Dr. Sturge's case was a small one, and only one-third of that taken by Dr. Barber's patient.

CARDIAC VALVULAR DISEASE OF LONG DURATION.

A CASE exhibited by Dr. Kingston Fowler at a former meeting of the Clinical Society, related by him at the meeting on Friday evening last, and reported at page 247, was remarkable from the fact of the long continuance and stationary condition of the cardiac lesion, which was of rheumatic origin. The case may well take its place by the side of the examples described by Sir Andrew Clark and other observers during and since the discussion on the subject at the Brighton meeting in August, 1886. Dr. Fowler's patient was a man, aged 66, a wood turner, accustomed to work a treadle lathe, who had disease of the aortic and mitral valves, which was probably of fifty-three years' duration. In 1834 he had been admitted to the Middlesex Hospital suffering from acute rheumatism, for which he remained under treatment by Dr. (afterwards Sir Thomas) Watson for nearly nine months. The evidence that the valvular lesions now present occurred during the illness in 1834 was circumstantial, but seemed reliable. At any rate, the patient had had no return of the rheumatic attack since that former illness, and had scarcely been absent from work for a single day during the last fifty-four years. His heart was described as still showing no signs of failure.

THE TENTH INTERNATIONAL MEDICAL CONGRESS.

WE have received from Dr. A. L. Gihon, Medical Director United States Navy, a communication in which he takes, as it will seem to most readers, unnecessary pains to refute a statement of the *Journal de Médecine* of Paris, with regard to the next International Medical Congress. Our esteemed contemporary is reported to have said that American physicians had "bent under the Prussian yoke," and that "the next meeting will not be an International Congress, but merely a German reunion." This rhetorical flourish Dr. Gihon sets himself seriously to refute. Congresses have been held in Paris (1867), Florence (1869), Vienna (1873), Brussels (1875), Geneva (1877), Amsterdam (1879), London (1881), Copenhagen (1884), Washington (1887). Germany and Russia are thus the only European countries of the first rank in which a Congress has not been held, unless the recent elevation of Spain in the diplomatic hierarchy entitles her name also to be mentioned. What more natural, therefore, than that the next Congress should be held at Berlin? At the meeting of the Committee appointed at Washington to select the next place of meeting, Dr. Semmola, the representative of Italy, proposed, and Dr. Gihon, the representative of the United States, seconded a resolution naming Berlin as the place where the Congress should meet in 1890. Professor Reyher, representing Russia, supported the proposal, claiming at the same time that the Eleventh Congress (1893) should be held in St. Petersburg. Dr. Cordés, the representative of Switzerland, proposed that the next Congress should be held in Paris in 1889, during the centennial celebration; but, on being put to the vote, the proposal to hold the meeting in Berlin in 1890 was carried, with only one dissentient voice (Dr. Cordés's). The *Berliner Klinische Wochenschrift* of January 23rd remarks: "French men of science—we cannot answer for the press in France—will participate without any objections in the unification of international investigation, and the eminent medical men of France,

with few exceptions, are not disposed to bring national antipathies to bear upon science. Unfortunately, the influence of public opinion (so-called) is paramount in France. It will be a praiseworthy task in the cause of science to lead this opinion in the right direction."

THE EXEMPTION SCHEDULE IN BOARD SCHOOLS.

CONSIDERABLE differences of opinion exist on the subject of exempting children in primary schools, from the operation of the educational code, and, naturally, different views of the matter from those held by the teachers are sometimes taken by Her Majesty's inspectors when reporting on the school work. A list of such exemptions was recently presented to an inspector, and considered unsatisfactory. Of 67 boys in the first standard, 29 were withdrawn from examination. The causes stated were the common ones—"dull," "backward," "delicate," "ill-fed." Of the 67 boys, only 3 were under 8 years, and 1 was said to be over 15 years and an idiot. To speak precisely, it appears that the head teacher reported those boys not as incapable of being prepared for examination—we suppose the idiot was an exception—but as a list of boys who in the opinion of the teacher were likely to break down in health if the ordinary work of the school routine were pressed on them. As to these cases, what is wanted is some impartial authority who, after looking at the children presented by the teacher or school managers as specially feeble in body or in brain power, may decide upon competent knowledge who are unfit for the ordinary school routine. Such points cannot be satisfactorily determined by the teacher, and this duty is hardly a fair responsibility to throw upon any layman; what is needed is that every large school should be visited a few times in the year by a medical inspector, who may then decide such questions upon professional knowledge. Distinctions would thus be made between feeble and exhausted children and those who were merely lazy. It is very desirable that the feeble children, even if they cannot follow the routine work, should still be kept in school; even the idiot is better off there than in the streets, if no better provision can be made for him. We have urged many times that School Boards are bound by their duty to the public to see that feeble children are trained in school, and not deprived of the benefits of such training as may save them from mental and moral degradation in after life. Children below a certain physical standard cannot pass through the code work without harm; when it is known on competent authority that a child is feeble, he should be exempted from examination but not from school training. It cannot be too strongly insisted on that national education is intended for the improvement of the nation, not simply for the advancement of the brightest and best. It is among these children for whom exemption from the routine of the educational code is asked, that we find many who will probably fail in after life if neglected in childhood.

TABETIC ARTHROPATHY.

THE special bone and joint lesions met with in a certain small proportion of cases of locomotor ataxy were, as is well known, attributed by M. Charcot, who was the first to describe them, to neurotrophic influences; the absence of any adequate cause in the majority of the cases, and the extraordinary extent of the destruction of the articular surfaces of the bones without pain, or any of the ordinary signs of inflammation, afforded strong evidence of the accuracy of Charcot's view. It has not, however, met with universal acceptance, partly, no doubt, because it has been found that the implication of the anterior horns, to which he attributed it, has not been always present. During the discussion at the Clinical Society in 1885, Mr. Jonathan Hutchinson and the late Dr. Moxon were among the opponents of M. Charcot's theory. It was urged that the condition might be due to chronic osteo-

arthritis occurring in a joint so completely anæsthetic as to permit of free motion. This suggestion is strengthened by the fact that though destruction of bone is the main characteristic, new formation does also occur. This was the case in a very interesting specimen shown to the Pathological Society of London at its last meeting, by Dr. Collier, of Oxford. It was the knee-joint of a woman, aged 41, who had died in the Littlemore Asylum from general paralysis following on locomotor ataxy. Enormous loss of bone had occurred; the external condyle of the femur had entirely disappeared, and the crucial ligaments had been destroyed, yet a large amount of new bone had been formed in the immediate neighbourhood of the destruction. All this had occurred in about six months. When the patient left the Radcliffe Infirmary in January, 1887, there was some general swelling of the limb, but no alteration of the joint beyond fluid effusion. When she was admitted into the Oxford County Asylum at Littlemore in August, 1887, Mr. Pilkington found that the bones were freely movable in every direction, movement causing no pain, but being accompanied by marked grating. The point of special interest is that in the interval between leaving the Radcliffe Infirmary and entering the Littlemore Asylum, the patient was absolutely unable to move about, owing to the extreme ataxy, so that the rapid disorganisation which had taken place could not be due to the free use of a joint affected by osteo-arthritis. In this case the joint affection commenced at a very much later period than in the cases observed by Charcot. The patient had well marked ataxy two years and a half before she died, and was then quite free from joint disease, which began about eleven months before she died, and had reached its maximum in about six months.

SCOTLAND.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

THE fourth meeting of the current session was held in the Faculty Hall on Wednesday, January 25th. The following gentlemen were duly elected Fellows, namely, John P. Meeklem, L.R.C.P.E., and I. C. Edmiston, L.F.P. and S.G. Dr. Garnett Wilson showed an anencephalous fœtus, a twin of the seventh month. A discussion followed, from which it appeared that most of the Fellows present had had experience of such cases, but none in a twin pregnancy, and nearly all occurred in multiparæ. Dr. Oliphant then introduced a discussion on the action of pessaries, in the course of which the mechanism of the various kinds was debated.

GLASGOW ROYAL INFIRMARY.

IN Glasgow Royal Infirmary last year there were treated 4,790 indoor patients admitted during the year, as compared with 4,817 in 1886; the total number of cases treated by the staff in 1887 was 41,765, as compared with 39,250 in 1886. Like most of the medical charities in Scotland, the ordinary income had fallen off during the year; this was, however, more than compensated for by the unusually large sums of money received as legacies; these amounted to £20,732, which not only made up for the deficiency in the ordinary income, but which allowed a large sum to be added to the capital account of the institution.

IRELAND.

STEEVENS'S HOSPITAL.

IT is stated that Dr. Robert McDonnell is about to retire from the surgery to Steevens's Hospital. The appointment of his successor lies in the hands of the Board of Governors.

THE BOWMAN LECTURE.

MR. H. R. SWANZY, Surgeon to the National Eye and Ear Infirmary, Dublin, who was President of the Ophthalmological Section at the annual meeting in Dublin last year, has been invited to deliver the "Bowman" lecture before the Ophthalmological Society of the United Kingdom. This is a well-merited compliment. Mr. Swanzy is a distinguished ophthalmologist, and will justify the honour which has been conferred upon him.

THE PROFESSORSHIP OF SURGERY IN QUEEN'S COLLEGE, GALWAY.

IT is announced that the Lord Lieutenant has appointed Mr. W. W. Brereton to the chair of surgery in Queen's College, Galway, vacant by the death of Dr. J. V. Browne. The appointment is for seven years. There were about ten candidates for the office from various parts of Ireland. The direct emoluments are very small, but practice is supposed to result. As usual, there is much outcry. Mr. Brereton, who is surgeon to the Oughterard Workhouse Hospital, is objected to, first because he is not a university graduate, secondly because he is a Protestant, while Catholics were passed over. It certainly does not seem in the least necessary that a professor of surgery should have graduated in a university, although it is desirable; and it may be said that Mr. Brereton held office in the College many years ago as demonstrator of anatomy under Professor Cleland, now of Glasgow. The religious question is one with which we will not deal. It is right to state, however, that two candidates—Dr. Mahon and Dr. Eagleton, old students of the College and gold medallists of the University—were candidates; and the name of one of these at least was sent forward by the President as one of three from whom a selection might be made. The President, who is a man of great liberality of sentiment, is roundly censured, as if he had made the appointment. It by no means follows, however, that he is in any degree responsible, as the Government is not bound to accept the first name on the list, and, as a matter of fact, does not do so in all cases. We cannot help expressing some sympathy with those old pupils of the College who are disappointed. Their university career was unusually distinguished, and they naturally look to the Alma Mater for approval of their work.

BELFAST MEDICAL STUDENTS' ASSOCIATION.

THE second annual *conversazione* of this association took place at the Queen's College on January 26th, and proved highly successful. About 500 persons attended, including nearly all the professional staff, a large and influential representation of the medical profession, and many visitors. The decorations were on a very elaborate and artistic scale, and in the Examination Hall an excellent stage was erected for the performance of the *tableaux vivants*. Tea was served at 7.30, and at 8.30 a demonstration of chemical experiments was given by Professor Letts. The rest of the evening was occupied by a series of *tableaux vivants*, music, and a comic lecture by Professor Fitzgerald, on The First, Second, and Third Bridges. The *tableaux vivants* left nothing to be desired in point of completeness and artistic finish, and were loudly applauded. Among the scenes represented were: Medical Students 1848 and 1888, The Penance of the Duchess of Gloucester, Othello and Desdemona, The Rape of the Lock, The Princess, Tweedledum and Tweedledee, and Ferdinand and Miranda. The music was supplied by an excellent orchestral band under the direction of Mr. Edgar Staines, of the Theatre Royal, and by a number of amateur vocalists. An interesting feature of the evening was afforded by three scenes of an Ambulance at Work. The company separated at midnight, after a most enjoyable evening.

APPLICATION OF THE SCOTTISH LICENSING BODIES FOR POWERS OF GRADUATION.

The following petition has been presented to the Privy Council:—

To the Queen's Most Excellent Majesty in Council.

THE PETITION OF THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH, AND THE FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW, UNDER THEIR RESPECTIVE COMMON SEALS,

HUMBLY sheweth,—That your petitioners, the Royal College of Physicians of Edinburgh, are a corporation erected by Royal Charter granted by His Majesty King Charles the Second, 30th November, 1681, ratified 16th June, 1685; and of new incorporated by Royal Charter granted by your Majesty 16th August, 1861.

That your petitioners, the Royal College of Surgeons of Edinburgh, are a corporation erected by Seal of Cause granted by the Town Council of Edinburgh 1st July, 1505, confirmed by Royal Charter granted by His Majesty King James the Fourth of Scotland 13th October, 1506, ratified by Acts of the Scottish Parliament passed on 17th November, 1641, 22nd August, 1670, and 17th July, 1695, of new incorporated by Royal Charter by King George the Third, dated 14th March, 1778, confirmed by Act of Parliament 27 George III, cap. 65, as altered and amended by Act of Parliament 53 George III, cap. 76, and incorporated with new and additional powers, privileges, and immunities by Royal Charter granted by your Majesty on the 11th March, 1851, under the provisions of the Act of Parliament 13 Victoria, cap. 23.

That your petitioners, the Faculty of Physicians and Surgeons of Glasgow, are a corporation erected by Royal Charter granted by His Majesty King James the Sixth of Scotland, under the Privy Seal of that Kingdom, on 29th November, 1599, ratified by an Act of the Scottish Parliament passed on the 11th September, 1672, confirmed and amended by an Act of the 13th year of your Majesty's reign, chapter 20, passed on 10th June, 1850, entitled "An Act for better regulating the Privileges of the Faculty of Physicians and Surgeons of Glasgow, and amending their Charters of Incorporation."

Your petitioners, under the provisions contained in Clause XIX of the Medical Act made and passed in the Session of Parliament of the twenty-first and twenty-second years of your Majesty's reign, united and co-operated in a scheme constituting an Examining Board of the two Colleges in Edinburgh and of the Faculty in Glasgow, and in making regulations for conducting the examinations required for the purpose of qualifications to be registered under the same Act, which scheme and regulations were approved and adopted by your petitioners, the Royal College of Physicians of Edinburgh, on 18th March, 1884, and by your petitioners the Royal College of Surgeons of Edinburgh on March 11th, 1884, and by your petitioners the Faculty of Physicians and Surgeons of Glasgow on 7th January, 1884, and received the sanction of the General Medical Council on 31st March, 1884.

Your petitioners had no desire to take any step to disturb the existing arrangements, whereby the universities alone had the privilege of granting degrees in medicine, but in consequence of the action of the Royal College of Physicians of London and of the Royal College of Surgeons of England, they have been constrained to apply for powers similar to those sought by these Royal Colleges. Your petitioners are therefore desirous, and it is expedient in order to encourage proficiency in the sciences of medicine, surgery, and midwifery, that your petitioners should be enabled to unite and co-operate not only in conducting examinations for the purposes of the Medical Act, but also for the purpose of conferring degrees in medicine and surgery on persons who shall pass such examinations as may from time to time be prescribed by the Colleges and Faculty, and on persons who have already passed the examinations of the said Colleges and Faculty, and who shall have complied with such further regulations or undergone such further examination as it may be deemed proper to impose or require from time to time, and that for this purpose a Senate of physicians and surgeons should be constituted and incorporated, composed of an equal number of Fellows of each of the said two Colleges and Faculty and of persons chosen by all teachers of medicine in Edinburgh and in Glasgow who shall have been recognised as teachers of medicine by either of the said Colleges or Faculty prior to the establishment of the said Senate, who are not members of the Senatus of any university, and by all

teachers of medicine in Edinburgh and in Glasgow who thereafter shall be recognised by the said Senate, who are not members of the Senatus of any university, and also of persons chosen by the graduates of the Senate when the number of such graduates shall have attained to two hundred; also of the Lord Provosts of the cities of Edinburgh and Glasgow for the time being, and the Chairmen for the time being of the School Boards of said cities.

Your petitioners are desirous that they should have power to apportion whatever surplus funds may remain after defraying all expenses of carrying on the business of the said Senate, and of conducting the examinations for degrees as follows, that is to say, five-twelfths to the Royal College of Physicians of Edinburgh; three-twelfths to the Royal College of Surgeons of Edinburgh; and two-twelfths to the Faculty of Physicians and Surgeons of Glasgow, for the purposes of providing and maintaining such buildings, libraries, museums, etc., as may by these bodies be deemed necessary; and one-twelfth to be expended in the aid of medical teaching in Edinburgh, and one-twelfth to be expended in the aid of medical teaching in Glasgow.

Your petitioners therefore humbly pray that Your Majesty will be graciously pleased to incorporate the President for the time being of the Royal College of Physicians of Edinburgh and six other persons, to be elected by the Fellows from among the Fellows of the said College; the President for the time being of the Royal College of Surgeons of Edinburgh and six other persons to be elected by the Fellows from among the Fellows of the said College; the President for the time being of the Faculty of Physicians and Surgeons of Glasgow and six other persons to be elected by the Fellows from among the Fellows of the said Faculty; the Lord Provosts for the time of the cities of Edinburgh and Glasgow, and the Chairmen for the time of the School Boards of said cities; two persons to be elected from time to time by the recognised teachers of medicine in Edinburgh as defined above, from their own number, at meetings of the said teachers to be convened by the Presidents of the Royal Colleges of Physicians and Surgeons of Edinburgh; and two persons to be elected from time to time by the recognised teachers of medicine in Glasgow as defined above, from their own number, at meetings of the said teachers to be convened by the President of the Faculty of Physicians and Surgeons of Glasgow, with the addition (as soon as the number of Graduates of the Senate to be so incorporated shall have attained to two hundred) of five persons to be elected from time to time by such Graduates from their own number, under the name and style of "The Senate of Physicians and Surgeons of Scotland," with perpetual succession and a Common Seal, and with power to grant to persons who have complied with the regulations and passed the examinations prescribed by the Senate degrees in medicine and surgery, and with power to sue and be sued in their corporate name, to take, purchase, and hold lands, buildings, and property, both heritable and movable, and with such further powers, and subject to such provisions as Your Majesty may think proper to grant or impose, and your petitioners will ever pray.

Signed in name and by authority of the Royal College of Physicians of Edinburgh,

ROBERT PEEL RITCHIE, M.D., President.

Signed in name and by authority of the Royal College of Surgeons of Edinburgh, JOSEPH BELL, President.

Signed in name and by authority of the Faculty of Physicians and Surgeons of Glasgow,

JAMES MORTON, M.D., President.

VICTORIA by the Grace of God of the United Kingdom of Great Britain and Ireland, Queen, Defender of the Faith, TO ALL TO WHOM THESE PRESENTS SHALL COME, GREETING, WHEREAS The Royal College of Physicians of Edinburgh are a Corporation erected by Royal Charter, granted by His Majesty King Charles the Second, bearing date the 30th November, 1681, ratified 16th June, 1685; and of new incorporated by Royal Charter bearing date 16th August, 1861, in the 25th year of Our Reign; AND WHEREAS The Royal College of Surgeons of Edinburgh are a Corporation erected by Seal of Cause, granted by the Town Council of Edinburgh on 1st July, 1505, confirmed by Royal Charter granted by His Majesty King James the Fourth of Scotland, bearing date the 13th October, 1506, ratified by Acts of the Scottish Parliament, passed on 17th November, 1641, 22nd August, 1670, and 17th July, 1695; of new incorporated by Royal Charter granted by His Majesty King George the Third, bearing date the 14th March, 1778, confirmed by Act of the British Parliament, made and passed in the 27th year of His said Majesty, King George the Third, Chapter 65, as altered and amended by another Act of the British Parliament made and passed in the 53rd year of the reign of His said Majesty, King George the Third, Chapter 76, and incorporated with new and additional powers, privileges, and immunities by Royal Charter bearing date 11th March, 1851, in the 14th year of Our Reign, and granted under the provisions of an Act of the British Par-

liament made and passed in the 13th year of Our Reign, Chapter 23; AND WHEREAS The Faculty of Physicians and Surgeons of Glasgow are a Corporation erected by Royal Charter granted by His Majesty King James the Sixth of Scotland under the Privy Seal of that Kingdom, and bearing date the 29th November, 1599, ratified by an Act of the Scottish Parliament passed on 11th September, 1672, confirmed and amended by an Act of the British Parliament made and passed in the 13th year of Our Reign, Chapter 20, intitled "An Act for better regulating the privileges of the Faculty of Physicians and Surgeons of Glasgow and amending their Charter of Incorporation"; AND WHEREAS by the Medical Act made and passed in the Session of the 21st and 22nd years of Our Reign it was among other things enacted that any two or more of the Colleges and Bodies mentioned in Schedule A to the said Act (which Schedule mentioned along with others The Royal College of Physicians of Edinburgh, The Royal College of Surgeons of Edinburgh, and The Faculty of Physicians and Surgeons of Glasgow) might with the sanction and under the directions of the General Medical Council constituted by the said Act unite or co-operate in conducting the examinations required for qualifications to be registered under the said Act; AND WHEREAS The Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow have, with the sanction of the General Medical Council under the provision of the Medical Act united and co-operated in a Scheme constituting an Examining Board of the two Colleges in Edinburgh and of the Faculty in Glasgow, and in making regulations for conducting the examinations required for the purpose of qualifications to be registered under the said Act, which Scheme and regulations were approved and adopted by the Royal College of Physicians of Edinburgh on the 18th day of March, 1881, by the Royal College of Surgeons of Edinburgh on the 11th day of March, 1881, and by the Faculty of Physicians and Surgeons of Glasgow on the 7th January, 1881; AND WHEREAS it is expedient in order to encourage proficiency in the sciences of Medicine, Surgery, and Midwifery that the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow should be enabled to unite and co-operate, not only in conducting examinations for the purposes of the Medical Act, but also for the purpose of conferring Degrees in Medicine and Surgery on persons who, by passing the Examinations formerly held by the said two Colleges, and by the said Faculty separately, or by passing the Examination held by the Examining Board of the said two Colleges and the said Faculty or by passing any other Examination to be held by the two Colleges and the Faculty jointly or separately, have already acquired or may hereafter acquire the qualifications for registrations under the Medical Act, and who shall have also complied with such further regulations or undergone such further examination as it may be deemed proper to impose or require from time to time, and that for this purpose a Senate of Physicians and Surgeons should be constituted and incorporated, composed of an equal number of Fellows of each of the said two Colleges and Faculty, and of persons chosen by all Teachers of Medicine in Edinburgh and in Glasgow who shall have been recognised as Teachers in Medicine by either of the said Colleges or Faculty prior to the establishment of the said Senate, who are not members of the Senatus of any University and by all Teachers of Medicine in Edinburgh and in Glasgow who thereafter shall be recognised by the said Senate who are not members of the Senatus of any University, and also of persons chosen by the Graduates of the Senate when the number of such Graduates shall have attained to two hundred, also of the Lord Provosts of the Cities of Edinburgh and Glasgow respectively for the time being, and the Chairmen for the time being of the School Boards of said Cities respectively, with all such powers as are hereinafter conferred on such Senate.

NOW KNOW YE THAT WE by virtue of Our Royal prerogative, special grace, certain knowledge, and proper motive, at the humble petition of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow, do by these presents for Us, our Heirs, and Successors, will, ordain, constitute, grant, and declare in manner following, that is to say:—

1. *Incorporation of Senate.*—The following persons, namely:—First, The President for the time being of the Royal College of Physicians of Edinburgh, and six other persons to be elected from time to time for the purpose by the Fellows from among the Fellows of the said College; Second, The President for the time being of the Royal College of Surgeons of Edinburgh, and six other persons to be elected from time to time for the purpose by the Fellows from among the Fellows of the said College; Third, The President for the time being of the Faculty of Physicians and Surgeons of Glasgow, and six other persons to be elected from time to time for the purpose by the Fellows from among the Fellows of the said Faculty; Fourth, The Lord Provosts for the time being of the Cities of Edinburgh and Glasgow respectively, and the Chairmen for the time being of the School Boards of the said Cities respectively; Fifth, Two persons to be elected from time to time from their own number by the Teachers of Medicine in Edinburgh, recognised as before mentioned, at meetings of the said Teachers to be convened by the Presidents of the Royal Colleges of Physicians and Surgeons of Edinburgh, and two persons to be elected from time to time from their own number by the Teachers of Medicine in Glasgow recognised as before mentioned, at meetings of the said Teachers to be convened by the President of the Faculty of Physicians and Surgeons of Glasgow; And Sixth, When the number of Graduates of the Senate shall have attained to two hundred, Five persons to be elected from time to time by such graduates from their own number, as hereinafter provided, shall become and for henceforth for ever hereafter shall be and remain by virtue of these presents one body politic and corporate by the name of "The Senate of Physicians and Surgeons of Scotland," hereinafter in these Our Letters Patent called "The Senate," and by the name of "The Senate of Physicians and Surgeons of Scotland" shall and may have perpetual succession and a common seal, with power to break, alter, and make anew the said seal from time to time at their will and pleasure, and by the same name shall and may sue and be sued in all courts and in all manner of actions and suits, and may take, purchase and hold lands, buildings, and property, both heritable and moveable, and sell and dispose of the same, and may also exercise the other powers hereinafter mentioned.

2. *Election of Members of Senate by Graduates.*—When the number of Graduates of the Senate shall have attained to two hundred, the President of the Senate for the time being, or any other person whom the Senate may from time to time appoint, shall be Returning Officer for the election by such Graduates of five of their number to be members of the Senate, and such Returning Officer shall, not less than two months, and not more than six months, after the Graduates shall have attained the number of two hundred, intimate by public advertisement that nomination of Graduates will be received by him on or before a day to be specified in such advertisement. The election shall be conducted in such manner

as may be provided for by Regulations made from time to time by the Senate, provided always that the nomination shall be in writing, and the election conducted by voting papers, and that any person entitled to vote at such election may vote for as many candidates as there are persons to be elected. The persons so elected to be Members of the Senate shall enter on office on the first day of November succeeding such election.

3. *Dismissal of Office by Members of Senate.*—Of the six persons elected from the Fellows of the Royal College of Physicians of Edinburgh, of the six elected from the Fellows of the Royal College of Surgeons of Edinburgh, and of the six elected from the Fellows of the Faculty of Physicians and Surgeons of Glasgow, one from each of the aforesaid bodies shall go out of office in 1889, and one in each of the following years till the whole have gone out of office, and thereafter the member from each College and the Faculty longest in office shall go out of office in each year. Of the two members first elected by the Teachers of Medicine in Edinburgh, and of the two first elected by the Teachers of Medicine in Glasgow, one respectively shall go out of office in 1890, and one in 1892, and thereafter the longest in office shall respectively go out of office each alternate year. The period for which any member is first elected shall be determined at the time by the electing body. The five members elected by the graduates shall hold office for the period of five years, and shall be elected together in the manner hereinafter provided for. The date of entering on and going out of office for Members of the Senate shall be the first day of November.

4. *Members of Senate eligible for re-election.*—Any member of the Senate going or about to go out of office shall be capable of re-election, and any member of the Senate may resign his office of Member of the Senate by letter, addressed to the President of the Senate, and upon the going out of office, resignation, or death of any of the elected Members of the Senate other than Members elected by the Graduates, or any other vacancy in their number, including such a vacancy as may be caused by the appointment of any of such elected Members to any office, the holder of which is *ex officio* a Member of the Senate, some other Fellow of the respective College or Faculty, or some other teacher of Medicine in Edinburgh or Glasgow, shall be elected in his place by the Fellows of that College or Faculty, or by the Teachers of Medicine in Edinburgh or Glasgow, as the case may be, and shall hold office for the remainder of the term of office of the person in whose place he is so elected where such term of office has not expired. In the event of a vacancy occurring by death, dismissal of office, or otherwise as aforesaid among the Members of the Senate elected by the Graduates, it shall be filled up by the Senate, and the Graduate so appointed shall hold office till the next quinquennial period of election by the Graduates.

5. *President.*—The President for the time being of the Royal College of Physicians of Edinburgh shall be the first President of the Senate, and shall hold office until the first day of November, 1888, and on the first President going out of office, the next President of the Senate shall be the President for the time being of the Royal College of Surgeons of Edinburgh, who shall hold office for such period not exceeding two years as the Senate shall have determined at a special meeting held previously to his entering upon office, of which meeting not less than twenty-one days' previous notice in writing shall have been given to each Member of the Senate, and on the second President going out of office, the next President of the Senate shall be the President for the time being of the Faculty of Physicians and Surgeons of Glasgow, who shall hold office for such period not exceeding two years as the Senate shall have determined at a special meeting held previously to his entering upon office, of which meeting not less than twenty-one days' previous notice in writing shall have been given to each Member of the Senate; and thereafter the President for the time being of each of the said Colleges and the said Faculty in rotation shall be President of the Senate for such period—not exceeding, in each case, two years—as the Senate shall have determined in manner aforesaid.

6. *Vice-Presidents.*—The President for the time being of the Royal College of Surgeons of Edinburgh, and the President for the time being of the Faculty of Physicians and Surgeons of Glasgow, shall be the first Vice-Presidents of the Senate; and thereafter each of the Presidents of the aforesaid Colleges and Faculty who is not for the time being President of the Senate shall be a Vice-President of the Senate.

7. *President may resign.*—The President may resign his office by a writing under his hand addressed to the Senate, and delivered to the Secretary of the Senate, and in the event of his resignation the then senior Vice-President shall be President of the Senate during the remainder of his term of office.

8. *Chairman in absence of the President.*—At any meeting of the Senate the President, if in attendance, and if not, then one of the Vice-Presidents who is in attendance, shall take the chair, and in the absence of the President and both the Vice-Presidents some other member to be chosen from the members present shall take the chair and act as President.

9. *Meetings of the Senate.*—The Senate shall hold their first meeting within six calendar months from the date of these Our Letters Patent in such place and at such time as shall be appointed by a writing under the hand of the President for the time being of the Royal College of Physicians of Edinburgh.

10. *Rules as to Meetings may be made.*—The Senate may make such Rules and Regulations as to the times and places of subsequent meetings and the mode of summoning the same as to the Senate may seem proper, which Rules and Regulations shall remain in force until altered at a subsequent meeting, and in the absence of any rule or regulation as to summoning a meeting, the President for the time being, or either of the Vice-Presidents, may by a writing under his hand addressed to each other member of the Senate, summon a meeting at such time and place as he may think proper.

11. *Votes of Majority present to be decisive.*—All acts of the Senate shall be decided by the votes of the majority of members present at a meeting of the Senate, and the Chairman shall, in addition to his vote as a member of the Senate, have a casting vote in case of equality of votes.

12. *Quorum of a Meeting.*—No business shall be transacted at any meeting of the Senate unless there are at least twelve members of the Senate present at such meeting.

13. *Proceedings valid notwithstanding Vacancy.*—Notwithstanding any vacancy in the number of the members of the Senate, the Senate may exercise all powers conferred on them by these Our Letters Patent.

14. *Officers may be appointed.*—The Senate may appoint a Treasurer and Secretary and such other officers as they think necessary.

15. *Power to confer Degrees.*—The Senate shall have power to confer on any person who, by passing the Examinations formerly held by either of the said two Colleges or the said Faculty separately, or by passing the Examination held by the Examining Board of the said two Colleges and Faculty conjointly, or by passing any other examinations to be held by the two Colleges and Faculty

jointly or separately, shall have already acquired or may hereafter acquire the qualifications for registration under the Medical Act, or any Act amending that Act, and who shall have also complied with such further regulations and undergone such examination as the Senate may from time to time see fit to impose or require as a qualification for a Degree, both, or such one as the Senate may think proper, of the following Degrees, namely, the Degree of Bachelor of Medicine, and Bachelor in Surgery, and also on those who, having acquired both or either of the Degrees of Bachelor of Medicine and Bachelor in Surgery, shall have also complied with such further regulations or undergone such further examinations as the Senate may from time to time see fit to impose, all, or such one as the Senate may think proper of the following Degrees, namely, the Degree of Doctor of Medicine, Master in Surgery, and Doctor of Sanitary Science.

16. *Fee for Examinations.*—The Senate may demand and take from each candidate for examination the following fees—namely, for the Examination required for the Degrees of Bachelor of Medicine and Bachelor in Surgery, singly or both, a fee not exceeding ten guineas, and for the Examinations required for all or any of the Degrees of Doctor of Medicine, Master in Surgery, or Doctor of Sanitary Science, a fee not exceeding five guineas in respect of each of the said Examinations, but shall not demand or take any fee for granting any Degree. Any stamp duties chargeable on Diplomas shall be paid by the Graduate.

17. *Apportionment of Surplus Fees (if any).*—Any surplus funds which may remain after defraying all expenses of carrying on the business of the Senate, and of conducting examinations for degrees, shall be apportioned as follows, that is to say, five twelfths shall be paid to the Royal College of Physicians of Edinburgh, three twelfths to the Royal College of Surgeons of Edinburgh, and two twelfths to the Faculty of Physicians and Surgeons of Glasgow, for the purposes of providing and maintaining such buildings, libraries, and museums as may by the said Colleges and Faculty respectively be considered necessary; one twelfth shall be expended in such manner as the Senate may consider proper in aid of medical teaching in Edinburgh, and one twelfth shall be expended in such manner as the Senate may consider proper in aid of medical teaching in Glasgow.

18. *By-laws may be made.*—The Senate may from time to time make and alter any By-laws and Regulations (so as the same be not repugnant to the Laws of the Realm, or to the terms and general objects of these Our Letters Patent) touching the qualifications for Degrees and the granting of the same, and any other matters to be done under the provisions of these Our Letters Patent, and all such By-laws when reduced to writing, and under the Common Seal of the Senate, and approved of and countersigned by one of Our principal Secretaries of State, shall be binding on Candidates for Degrees, and for all other purposes within the provisions of these Our Letters Patent.

19. *By-laws to be approved.*—Provided that any By-law or Regulation to be made by the Senate shall not be of any force until our approval thereof shall have been signified to the Senate under the hand of one of Our principal Secretaries of State, or the same shall have been otherwise approved in such manner as shall be directed by Us with the advice and consent of the Lords Spiritual and Temporal and Commons of Our Realm in Parliament assembled.

General Confirmation Clause.—And we do hereby for Us, Our heirs, and successors further grant unto the Senate that these Our Letters Patent, shall be in all things good, firm, valid, sufficient, and effectual in law according to the true intent and meaning thereof, and shall be construed in the most favourable and beneficial sense for the Senate notwithstanding any non-recital, mis-recital, or imperfect recital, or any other omission, imperfection, or defect whatsoever in these Our Letters Patent. AND WE DO FURTHER will and command that this Charter do pass the Seal appointed by the Treaty of Union to be kept and used in Scotland in place of the Great Seal thereof, *per saltum*, without passing any other Seal and Register, for which these presents shall be as well to the Director of Our Chancery for writing the same, as to the keeper of the said Seal for causing the said Seal to be appended thereto, a sufficient warrant.

Given at Our Court at the day of _____, 1888, in the Fifty-first year of Our reign.

By Her Majesty's command.

DEGREES FOR LONDON MEDICAL STUDENTS.

PETITIONS TO THE PRIVY COUNCIL.

THE PETITION OF THE ASSOCIATION FOR PROMOTING A TEACHING UNIVERSITY IN LONDON.

THE Association for Promoting a Teaching University in London, which came into existence in May, 1884, has devoted a great deal of time to the study of the very complex questions involved in the organisation of university education in London. We say organisation for want of a better word to express the objects of the Association, which has perhaps suffered in its appeal for public support, owing to the difficulty of precisely describing to persons who have not previously given attention to the movement the means which it is proposed to take to remedy the evils which all collegiate teachers in London admit to exist. The main contention of the Association is that there already exist in London institutions giving university instruction, but that they suffer from the want of a common centre, such as a university would supply, and that the severance from the work of teaching of the work of examination for degrees, and the assignment of examination to the existing University of London as its sole function has had an injurious effect upon university education in London.

We have from time to time so fully reported and commented on the useful work which the Association has done that it is not now necessary to repeat the whole of the petition which it has recently presented to the Queen in Council. The petition sets forth the opinion that the evils above mentioned cannot be fully remedied except by the establishment in London of a teaching university—that is to say, a university which (1) provides for the student in all

the subjects included in its faculties the best attainable teaching with the necessary aids and appliances; (2) requires a regular course of attendance on such teaching as a preliminary to graduation; and (3) secures to the teacher a direct and adequate representation in its councils and a due share in its administration. The objections urged to the scheme proposed by the Senate of the University of London as a solution of the difficulty are (1) the absence of a curriculum in the faculties of arts and science; (2) the admission of collegiate bodies outside London; (3) the absence of any sufficient conditions for securing that the associated colleges shall be doing effective university work; (4) the want of any provision for the direct representation upon the governing body of the associated institutions, or of university teachers; (5) the granting of an unduly large representation to the graduates of the university. Referring to the proposed Senate of Physicians and Surgeons, the Association deprecates any severance of the machinery for granting degrees in London from academic influences, many serious defects of university education in London being in its opinion due to such a severance. With a view to avoid multiplication of bodies conferring a diploma or a licence to practise, the Association advises that the possession of the joint diploma of the two Royal Colleges should be a preliminary condition for obtaining a medical degree in the university, the conferring of such diploma remaining, as at present, the function of the Royal Colleges.

The Association suggests that the constitution of the governing body of such a university as is proposed should be, in addition to a Chancellor appointed by the Crown, members appointed by (1) the Crown, (2) the governing bodies of colleges associated with the university, (3) the Councils of Legal Education and of the Royal College of Physicians and the Royal College of Surgeons, (4) by the teachers. The conditions to be fulfilled by a college would be as follows:—(1) that the institution is giving instruction of a university character; (2) that it has established a complete curriculum, and possesses a sufficient teaching staff in at least one of the recognised faculties; (3) and that it has furnished proofs of its means and appliances for teaching being established on a satisfactory basis.

It is explicitly admitted that this scheme has the same general effect as that presented by the Councils of University and King's Colleges to the Privy Council last autumn. It has many points in its favour. It meets the objections which have been urged with some force against the creation of a university of one, and that a professional faculty, for it would practically include the scheme of the Royal Colleges as a part of a larger scheme. That it will be viewed with approval by those corporations is impossible, for its realisation would somewhat detract from their dignity, though it would not diminish the beneficial influence which they exercise on medical education.

The same objection may, we regret to notice, be urged against this scheme as has already been forcibly raised against the scheme of the two Royal Colleges; in both the rights of the future graduates are entirely ignored. All through the teachers have the air of graciously presenting something to their pupils; the pupils, it is assumed, exist to increase the dignity and to line the pockets of the teachers. Once the state of pupilage is over then all connection between university and pupil is to cease. This is not a new form of pedagogic arrogance, but it is at the present day more offensive than ever before; no precedent can be found, in this country at least, for such a proposal. The University of London has been called a stepmother; the heart of this proposed university would be harder to her sons than the nether millstone.

THE PETITION OF THE UNIVERSITY OF CAMBRIDGE (in opposition to the Petition of the Royal Colleges of Physicians and Surgeons).

The Vice-Chancellor has published to the Senate the following form of petition proposed by the Special Board for Medicine for adoption and presentation by the Senate; it will be taken into consideration at the meeting of the Senate on this day (Saturday), at 2.15 P.M.

To the Queen's Most Excellent Majesty in Council.

The humble petition of the Chancellor, Masters, and Scholars of the University of Cambridge humbly sheweth—

That your petitioners have been informed that a petition has been addressed to your Majesty in Council by the Royal College of Physicians of London and the Royal College of Surgeons of England, in which the said Colleges acting jointly request that the Presidents and a certain number of Fellows or Councillors of

the said Colleges be incorporated under the name of "The Senate of Physicians and Surgeons," and that the said proposed Senate be empowered to grant degrees in medicine and surgery;

That your petitioners desire to represent that the power of granting such degrees has heretofore been entrusted to universities only;

That your petitioners believe it to be an advantage that in universities the granting of degrees in medicine and surgery is controlled by the opinion of a body of men interested in various subjects, whereas the said proposed Senate would represent a single faculty only;

That there is already in London an examining body, the University of London, which grants its degrees to all whose knowledge is sufficient to enable them to pass its examination;

That in the absence of any arrangement for university teaching, residence, or discipline in connection therewith, the proposed Senate would constitute a second merely examining body in London, which would grant one class of degrees and on easier terms;

That the distinction at present attaching to the degree of Doctor of Medicine granted by this and other universities has enabled your petitioners to require of candidates a longer and wider course of medical study than that hitherto required by the licensing corporations, and your petitioners are of opinion that the science and practice of medicine have thereby been advanced;

That they therefore deprecate any proposal such as that made in the said petition as tending seriously to diminish the distinction of this degree;

That for these and other reasons your petitioners submit that it is contrary to public policy and to the interests of medical and surgical science that the said proposed Senate should be invested with the power of granting degrees;

Your petitioners therefore humbly pray that your Majesty in Council will be graciously pleased to hear them by counsel or otherwise in support of the allegations in this their petition.

And your petitioners will ever pray, etc.

REFORM OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Reply of the Council of the College to the Statement presented to the Lord President on behalf of the Association of Fellows.

THE Royal College of Surgeons of England consists of about 18,000 Members, of whom about 1,200 are Fellows. The governing body of the College consists of a Council of twenty-four Fellows, elected by the Fellows as directed by the Charters of 1843 and 1852. Three members of the Council retire every year, and are eligible for re-election.

The Fellowship Examination was instituted in the interest of surgical education, and to constitute a body from whom and by whom the Council should be elected. The Fellowship represents a higher grade than the Membership. In order to obtain the Fellowship, a longer time must be devoted to professional study than is required for the Membership, and a further and more difficult examination must be passed.

In reply to the complaint of some Members that certain privileges are exclusively in the hands of the Fellows, it should be understood that it is open to Members of the College to become Fellows. Access to the Fellowship Examination has been facilitated to such an extent that any Member of two years' standing, who has been engaged in the study (or the study and practice) of the profession during that period, may present himself for it without any further special curriculum of professional study involving additional expense.

It has of late been repeatedly affirmed that the Members have no privileges within the College. But such a statement is not correct. The Members have the privileges of admission to the Museum, to the Library, and to all lectures delivered within the College walls, of competing for the College prizes, and of being eligible for certain Examinerships and Lecturerships. These

privileges (which include all those of the Fellows with the exception of the election of and the being elected to the Council, and of being eligible as Examiners for the Fellowship) may compare favourably with those of the graduates, not Members of Convocation or the Senate of Oxford or Cambridge respectively.

The authors of the statement to the Lord President appear to complain of the appointment of a number of Fellows by election; but in the first instance this was necessary, as the leading surgeons of England could hardly have been subjected to examination. The present proposal of the Council to obtain power to extend the number of Members annually elected to the Fellowship without examination from two to ten, as a maximum, was mainly to meet the view of some that certain Members of the College were entitled to the honour of the Fellowship by distinguished services in their profession, and yet were too advanced in life to be subjected to any further examination.

The proposal on behalf of the Association, that Members of ten years' standing should take part in the election of the Council, and that Members of twenty years' standing should be eligible as councillors, would substitute mere seniority for professional distinction, as proved by examination or by distinguished professional merit.

If no by-law could be made or modified without the consent of a general meeting of Fellows and Members, the delay and difficulty would be so great as seriously to interfere with the efficient conduct of business. The process by which alone a by-law is made or modified is already a very elaborate one, and affords, in the opinion of the Council, ample safeguard against its abuse, and, in fact, every proposal for such a change is made public before it is submitted to the Secretary of State for his sanction.

To the suggestion that the election of the President should be in the hands of the Fellows at large, the Council submit the following objections, namely:—

(a) That there is no evidence that the great body of the Fellows themselves desire this change.

(b) That no arrangement by which it could be carried out has been suggested that would not be in itself objectionable, and in many instances so disagreeable to the candidates themselves, as to deter some of the most distinguished from coming forward.

(c) That the Council, who are chosen by the Fellows, must of necessity be better judges of the qualification of any one of their number for the office of President than the general body of Fellows.

(d) That election by the Fellows might in some instances tend to interfere with the independent action of those members of the Council who might aspire to the office of President.

(e) That it might lead to contested elections, and thereby encourage the practice of personal canvassing, of extorting pledges, and of holding out promises.

(f) That it would practically place the election, not in the hands of the body of Fellows generally, but of a comparatively small number who would make themselves active in the business of the election.

(g) That the system of annual election by seniority merely, which until recently prevailed, and against which strong objection has existed in the Council itself, has been discontinued, the present President being now in his third year of office.

The Council would submit that the College is a scientific, educational, and professional institution, and not a political one. Their earnest desire is to uphold surgical education, and, with this object in view, to encourage Members to take the Fellowship.

The great purpose for which the College exists being the promotion of the science and art of surgery, the chief means at present at its command for effecting this purpose would be seriously impaired if changes such as those proposed were carried out.

The results of the inquiries made by the Council show that the majority of the Fellows are opposed to the claims set up on behalf of the Members, and there is no evidence before the Council that the majority of even the Members themselves are in favour of them.

The Council think it right to point out the following instances, among others, of inaccuracy in the statement which has been drawn up on behalf of the "Association of Fellows."

It is stated that the necessity for some control over the actions of the Council is shown "by the arbitrary way in which the Council settle such questions as the amalgamation for examination purposes with the College of Physicians, and the exclusion from that Scheme of the Society of Apothecaries," and also "by the scheme now in progress for acquiring powers along with the College of

Physicians to grant degrees in medicine, a scheme which may or may not be acceptable to the general body of the College, but on which they have never been consulted, though the matter is one which touches their interests most nearly."

At a meeting of the Fellows and Members at the College on March 24th, 1884, the following resolution was passed, namely:—

"That this meeting of Fellows and Members of the Royal College of Surgeons of England begs most respectfully to recommend that the Council of the College do obtain a Charter to enable the Council to combine with the Royal College of Physicians of London, with a view to the amalgamation of the two Colleges into one great College of Medicine, to be endowed with authority to examine and grant licences to practise in all branches of medicine and surgery, and to confer on its licentiates the degrees and titles of Doctor of Medicine and Master of Surgery."

The scheme proposed by the two Colleges is in accordance with this resolution.

So that, in taking the steps complained of, the Council are acting in harmony with the desire expressed by the Fellows and Members at their general meeting, and since confirmed by a memorial presented to them containing over six hundred signatures.

Again, it is affirmed that "no longer ago than last year a proposal was attributed to an eminent member of the Council to admit, by a vote of the Council, fifty Members each year to the Fellowship—a measure which, if it had been carried out, would have destroyed the academic value of that diploma. This proposal was vigorously resisted by the Association, and did not pass the Council."

The question here alluded to has never been discussed by the Council.

Should the Lords of the Council desire any further information, the Council of the College will wait on their Lordships.

January 19th, 1888.

WILLIAM S. SAVORY, President.

THE RANK OF ARMY MEDICAL OFFICERS.

REPORT OF RESOLUTIONS OF THE COUNCIL OF THE BRITISH MEDICAL ASSOCIATION.

THE Council of the British Medical Association having had before them the report of the Parliamentary Bills Committee of the Association referred to the Council by a resolution moved at the general meeting of the Association in Dublin on August 2nd by Sir Thomas Crawford, K.C.B., Director-General of the Army Medical Department; and also an analysis of the statements of 922 medical officers of the army, many of them of the highest rank, have unanimously adopted the following report and recommendations, which will be officially forwarded to the Secretary of State for War.

Report of the Committee of Council on the subject of the Rank of Army Medical Officers.

Your Committee in considering this subject have had before them:

1. The paragraphs of the Report of the Parliamentary Bills Committee on the subject of army medical rank, referred to them for consideration.

2. The replies of 922 army medical officers at home and abroad, to a series of questions issued by the Chairman of the Parliamentary Bills Committee with the view of ascertaining precisely what are the sentiments of the individual army medical officers of all grades, in reference to the question of rank, whether honorary, relative, or substantive.

3. An immediate mass of correspondence from officers of all ranks expressing in detail the grounds and arguments by which they support their views.

An analysis of the above documents has been printed for the use of the Committee, and copies are submitted with this report.

Without entering into any prolonged statement or discussion, it may be stated that the abolition of relative rank by the Warrant of January, 1887, was the immediate cause of the present dissatisfaction, and that subsequent steps taken by the War Office have not had the effect of giving satisfaction to the Army Medical Service generally.

From an examination of the documentary evidence submitted to this Committee it results:

(a) That the abolition of relative rank has, in the almost unanimous opinion of those interested, inflicted a grave injury on the status of the Medical Department in the army by leaving the officers without any definable or namable army rank.

(b) That, to an army like ours, serving in every climate and all parts of the world, a thoroughly organised, efficient and contented medical service is essential for the health, discipline and physical well-being of the soldiers; and that, therefore, the present anomalous position of the medical officers in the army is indefensible, an evil to the troops, and against sound policy.

(c) That, as both officers and men of the Medical Department equally share with their combatant brethren the risks of climate, the dangers and privations of field service, and are not infrequently killed and wounded in battle, the deprivation of *bona-fide* rank, title and status in the army is not only unjust and ungenerous, but an administrative reproach.

(d) That namable and definable rank should be accorded to medical officers, whether of a substantive, honorary, or relative nature.

(e) That, should it be determined to give medical officers a hybrid professional and military title, such should clearly indicate the actual rank of the holder by affixing the military title to the professional designation.

(f) That, when medical officers are gazetted, on appointment or promotion, their military rank should be fully stated.

(g) That the substantial military rank and status should be stated in commissions of all medical officers.

Your Committee recommend to the Council to submit these conclusions to the Secretary of State for War, and to urge upon him these considerations, seeing that the efficiency of the Army Medical Department and the prospects of recruiting it in the future from the abler sections of the younger members of the medical profession cannot but be seriously and prejudicially affected by the present anomalous position held by medical officers in Her Majesty's Army, and the general dissatisfaction arising therefrom. It should be pointed out that 75 per cent. of the army medical officers whose communications to the extent of 922 have been received regard the concession of army titular rank to medical officers as essential to the efficiency of the Medical Department.

1 "We cannot conclude the retrospect of the year without once more inviting attention to the fact that it is a much safer thing to serve in the Artillery and Engineers on the general staff than on the medical staff in our little wars. The percentage of deaths to strength in the

—BRITISH MEDICAL JOURNAL, Dec. 31st, 1887.

CENTENARIANS.—The death is announced in Dublin of Mrs. Bridget Dempsey Coolehan, at the advanced age of 106 years. On the family tombstone is recorded the death of her grandfather in 1821, at the age of 126 years.—Mrs. Elizabeth Stillman has died at Newbury within two months of reaching her 102nd year. She was in good health and retained her mental faculties till a short time ago.

The annual report of the City of London Truss Society shows that no fewer than 9,311 patients of both sexes and ages, varying from a few weeks to ninety years, were relieved.

ASSOCIATION INTELLIGENCE.

NOTICE OF QUARTERLY MEETINGS FOR 1888.

Meetings of the Council will be held on April 18th, July 18th, and October 17th, 1888. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before each meeting, namely, March 28th, June 27th, September 26th, and December 28th, 1888.

ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No member can be elected by a Branch Council unless his name has been inserted in the circular summoning the meeting at which he seeks election.

FRANCIS FOWKE, *General Secretary.*

COLLECTIVE INVESTIGATION OF DISEASE.

THE Report upon the CONNECTION OF DISEASE WITH HABITS OF INTEMPERANCE, which was presented to the Section of Medicine in the Annual Meeting of 1887, and a further portion of the Report upon OLD AGE have been completed, and will shortly be published in the JOURNAL.

Reports upon the two remaining inquiries, namely, that into DIPHTHERIA, and that into the GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES, are in preparation, and will be published as soon as ready.

The following inquiry only of the first series remains open, namely, that on THE ETIOLOGY OF PHTHISIS.

A fresh inquiry into the ORIGIN AND MODE OF PROPAGATION OF EPIDEMICS OF DIPHTHERIA has just been issued.

Memoranda upon these subjects, and forms for recording observations, may be had on application to the Secretary of the Collective Investigation Committee, 429, Strand, W.C.

BRANCH MEETINGS TO BE HELD.

METROPOLITAN COUNTIES BRANCH: EAST LONDON AND SOUTH ESSEX DISTRICT.—The next meeting will be held at the Town Hall, Walthamstow, on Thursday, February 16th, at 8.45 P.M. (sharp). The chair will be taken by A. DURHAM, Esq., President of the Branch. A paper on Pernicious Anæmia, and the Diseases Liable to be Confounded with It, will be read by Dr. BRISTOWE, F.R.S. Visitors will be welcomed.—J. W. HUNT, 101, Queen's Road, Dalston, Honorary Secretary.

GLoucestershire BRANCH.—The next ordinary meeting will be held on Tuesday, February 21st, 1888, at 7.30 P.M., at the Infirmary, Gloucester, under the presidency of Dr. CURRIE. Agenda: 1. A petition will be laid on the table for signature by members in support of the Architects and Engineers Bill, a Bill to be presented in Parliament next session by Colonel DUNCAN, R.A., C.B., M.P. 2. A discussion will be opened by Dr. CURRIE on the Present Position of Homœopathy in Relation to Regular Medicine. 3. Cases of Interest in the Infirmary.—G. ARTHUR CARDEW, Honorary Secretary.

BORDER COUNTIES BRANCH.—A meeting of this Branch will be held at the County Hotel, Carlisle, on Friday, February 24th, at 6 P.M. Dr. BYRON BRAUNWELL, of Edinburgh, will read a paper and introduce a discussion on the Process of Compensation and its Bearing on Prognosis and Treatment. The Secretary will be glad to receive notices of papers for reading, and patients or morbid specimens for exhibition. Supper in the hotel at 9 P.M.—H. A. LEDIARD, Honorary Secretary, 41, Lowther Street, Carlisle.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.—A meeting of this Branch will be held at 195, Union Street, Aberdeen, on Wednesday, February 15th, at 8 P.M., the President, Dr. SMITH, of Kinnairdy, in the chair. Business: 1. Minutes, nomination of new members, etc. 2. Ballot for the admission of Dr. J. Marshall Lamb, Banff. 3. Motion of Dr. WIGHT to memorialise the Town Council of Aberdeen that the appointment of medical officer of health at present vacant be filled up by a qualified medical practitioner, who shall be excluded from private practice, and whose whole time shall be devoted to the duties of the office, in terms of the memorandum on the duties of the medical officer of health of the city of Aberdeen, of date March 15th, 1886. 4. Case of Pyloric Obstruction, with great Hypertrophy of the Stomach, by Dr. BALKIE SMITH. 5. Exhibition of Specimens: (1) Ram's-horn Toe-nail, by Dr. GARDEN; (2) Specimen of Compound Dislocation of Ankle-joint, by Dr. GARDEN. 6. Communication by Dr. BARCLAY, Banff.—ROBERT JOHN GARDEN and J. MACKENZIE BORTH, Honorary Secretaries.

Dr. S. L. CRANE, Surgeon-General of Trinidad, has been nominated Companion of the Order of St. Michael and St. George.

METROPOLITAN COUNTIES BRANCH: WESTERN DISTRICT. The second meeting of the session was held (by kind permission of the medical staff) in the library of St. Mary's Hospital, Paddington, on Friday, January 27th. The chair was taken by Dr. CHARLTON BASTIAN, F.R.S., the Vice-president of the district, and about forty members and visitors were present.

Disease of Knee-Joint.—Mr. EDMUND OWEN, F.R.C.S., surgeon to St. Mary's and the Children's Hospitals, gave a very interesting and practical description of certain chronic diseases of the knee-joint in young children. Mr. Owen exhibited several patients, and showed the adaptation of certain apparatus, such as Thomas's and plaster-of-Paris splints, etc. Mr. Owen also showed a case of synovitis, which he treated by aspiration and the immediate application of a plaster-of-Paris splint.—A discussion ensued, in which Dr. BASTIAN, Mr. NOBLE SMITH, and Dr. CAMPBELL POPE took part.

Disease of Spinal Cord.—Dr. LEES, physician to St. Mary's Hospital and assistant physician to the Children's Hospital, then described certain points connected with different kinds of chronic disease of spinal cord, subsequently illustrating his remarks by the exhibition of patients suffering from locomotor ataxia in various stages, infantile paralysis, spastic paraplegia, hemiplegia, etc.

Votes of Thanks.—The proceedings ended by cordial votes of thanks being passed to Mr. Owen, Dr. Lees, and the Chairman.

NORTH OF IRELAND BRANCH.

A GENERAL meeting of the Branch was held in the Royal Hospital, Belfast, on Thursday, January 26th, 1888. Dr. PALMER (Armagh), President of the Branch, occupied the chair, and there was a good attendance of members.

Communications.—The minutes of the previous meeting having been read, the following communications were brought forward: The PRESIDENT (Dr. Palmer) showed a young woman on whom he had performed excision of the knee-joint.—Dr. NELSON read notes of an Ear case, in which perforation of the mastoid and trephining of the skull had been performed for septicæmia, and showed the specimen.—Dr. DEMPSEY showed an Ovarian Cyst and a Sub-mucous Fibroid removed from the Uterus, and read notes of the cases.—Dr. BYERS showed a new Antiseptic Confinement Sheet, and a Multilocular Cystic Tumour of the Ovary, which he had successfully removed by abdominal section.—Professor DILL introduced a discussion on Puerperal Fever, and Dr. BYERS read a short paper on the Local Treatment of the Uterus (illustrated by instruments, etc.) in Puerperal Septicæmia. A discussion followed, in which several members took part, and Dr. DILL replied.—Dr. O'NEILL showed two patients on whom he had performed amputation of the thigh by Sédillot's method, and also a patient treated for severe Wry-neck.—Professor SINCLAIR exhibited a Segment of the Small Intestine removed by Enterectomy for Artificial Anus, of eighteen months' standing; also a Cancerous Tumour of the Rectum removed for excision.

New Members.—At a meeting of council held previous to the general meeting, the following were elected members of the North of Ireland Branch: Dr. Sproule (Saintfield, co. Down), Dr. Hunter (Armagh), and Dr. McAlister (Carrickfergus).

OXFORD AND DISTRICT BRANCH.

An ordinary meeting was held at the Radcliffe Infirmary, Oxford, on January 27th; Mr. CHEATLE, President, in the chair; twenty-four members were present, and one visitor.

New Members.—Thos. O'Kelly, M.D., Q.U.I., Chipping Norton; Bertram Hunt, M.B., Oxon., Oxford; F. S. Arnold, M.B., Oxon., Oxford, were elected members of the Association and Branch. Seven gentlemen were proposed for election at the next meeting.

Alteration of By-law.—Dr. DARBISHIRE gave notice of proposing an alteration in By-law 1 at the next meeting.

Communications.—Dr. BYWATER WARD read a paper on a case of Papilloma of the Bladder, and showed a specimen.—Mr. BLOX-SOME read notes of a case of Anthrax, and showed microscopical preparations of the Bacillus Anthracis.—Mr. MORGAN read notes of a case of Primary Chancre on the Lip, and showed specimens of Disease of the Knee-joint.—Mr. WINKFIELD read notes of a case of Lithotripsy, with specimens of Calculi, and showed a case of Sarcoma of the Shoulder, and of Syphilitic Eruption on the Hands.

Dr. COLLIER showed a specimen of Ligature of the Carotid Artery for Thoracic Aneurysm, and (for Mr. PILKINGTON) a specimen of Charcot's Disease of the Joints.

Vote of Thanks.—A cordial vote of thanks was passed to the President.

THE GLOUCESTERSHIRE BRANCH.

AN ordinary meeting was held on Tuesday, January 17th, 1888, at 7.30 P.M., at the General Hospital, Cheltenham, under the presidency of Dr. Currie. Letters of apology were read for non-attendance from Messrs. Bower, Fowler, and Wilton.

President's Address.—Dr. CURRIE delivered his presidential address, taking as his subject "Scepticism in regard to Medical Treatment."

It was proposed by Dr. WILSON, and seconded by Dr. BATTEN, that a cordial vote of thanks be given to Dr. Currie for his able address, with a request that he should publish it in the JOURNAL. Carried by acclamation.

PROCEEDINGS OF COUNCIL.

At a meeting of the Council, held in the Council Room of the Association, 429, Strand, London, on Wednesday, January 18th, 1888; present:—

Dr. T. BRIDGWATER, President of the Council, in the chair,	Dr. James Hardie, Manchester
Dr. C. Holman, Reigate, Treasurer	Dr. G. F. Hodgson, Brighton
Dr. J. S. Bristowe, F.R.S., London	Professor G. M. Humphry, F.R.S., Cambridge
Mr. H. T. Butlin, London	Mr. W. D. Husband, Clifton
Dr. A. Carpenter, Croydon	Mr. T. R. Jessop, Leeds
Surgeon-General W. R. Cornish, London	Mr. Evan Jones, Aberdare
Dr. J. Ward Cousins, Portsmouth	Mr. H. R. Ker, Halesowen
Dr. G. W. Crowe, Worcester	Dr. W. G. V. Lush, Weymouth
Dr. P. M. Deas, Exeter	Dr. J. McIntyre, Odiham
Dr. J. L. H. Down, London	Mr. F. Mason, Bath
Dr. G. F. Duffey, Dublin	Dr. C. Parsons, Dover
Mr. George Eastes, London	Dr. R. Saundby, Birmingham
Dr. W. A. Elliston, Ipswich	Mr. S. W. Sibley, London
Sir B. Walter Foster, M.D., M.P., Birmingham	Dr. E. M. Skerritt, Clifton
Dr. J. H. Galton, Upper Norwood	Mr. T. Sympton, Lincoln
Dr. C. E. Glascott, Manchester	Dr. T. W. Trend, Southampton
Dr. Bruce Goff, Bothwell	Dr. E. Waters, Chester
Dr. W. C. Grigg, London	Mr. A. Winkfield, Oxford

The minutes of the last meeting having been printed and circulated, and no objection raised, they were signed as correct.

Read letters of apology for non-attendance from Dr. Bryan, Dr. Sheen, Mr. Vincent Jackson, Dr. Withers Moore, Dr. James Taylor, Dr. Needham, Mr. Pranker, Mr. Wheelhouse, Dr. J. Barnes, Dr. Bartolomé, Mr. J. Wright Baker, Mr. Arthur Jackson, Dr. Jones Morris, and Dr. W. Russell.

Read letter from Dr. Gowans, Perth, of which the following is a copy:—

6, St. Leonard's Bank, Perth, January 16th, 1888.
DEAR SIR,—I have much pleasure in forwarding the enclosed petition (signed by 25 members of the Perthshire Medical Association), desiring to be recognised as a Branch of the British Medical Association. Although only 25 signatures are exhibited, still a number more could have been obtained had time permitted and had it been necessary.

I should feel much obliged by your kindly letting me know the result after Council meeting.—I am, yours faithfully,
F. Fowke, Esq., London.

W. B. GOWANS, M.D., Secretary.

To the Council of the British Medical Association.

GENTLEMEN,—We, the undersigned, members of the Perthshire Medical Association, and also members of the British Medical Association, hereby make application to be recognised as a Branch of the latter Association, undertaking that, said application being granted, we shall conform in all respects to the by-laws now existing, or which hereafter may be made, regarding the formation and regulation of such Branches:—

R. M. Bruce Trotter, President.
A. R. Urquhart
John McNaughtan, M.D.
J. Holmes Morrison, M.D., F.R.C.S.E.
D. Sinclair Kennedy, M.B., C.M.
James P. Bramwell, M.D., L.R.C.S.
George Findlay, M.B., C.M.
Leigh Hunt, M.B., C.M.
David Fleming.
Jas. Ferguson, M.B., C.M.
Thos. H. Melkie, M.D.
A. Thom, F.R.C.S. Ed.
Alex. Thom, jun., M.D., C.M. Ed.

John Haggart, M.B., C.M.
Wm. S. Irvine, M.D., F.R.C.S.E.
George W. Dickson, M.B., C.M. Ed.
Joseph H. Keay, M.A., M.B., C.M. Ed.
John Lowe, M.B., C.M. Ed.
J. Begbie Laing, M.B., C.M., L.R.C.P. and S.E.
Thomas Brown, L.F.P.S.
Andrew McMillan, M.D.
Colin MacIver Campbell, M.D.
Robt. Robertson, L.F.P.S.
Peter McCullam, L.F.P.S. G.
Wm. Bruce Gowans, M.D. Edin.

Resolved: That the Council of the British Medical Association has much pleasure in recognising the Perthshire Branch of the British Medical Association, subject to the confirmation by the next meeting of Council, when the members be requested to send a copy of the proposed by-laws of the Branch for consideration and approval.

Read letter from the Registrar-General in reply to the one of

the Council of October 26th last, of which the following is a copy:—

General Register Office, Somerset House, November 19th, 1887.

SIR,—I am directed by the Registrar-General to acknowledge the receipt of your letter of the 10th instant (date of receipt as letter was undated), and to say that he regrets that, after giving the matter full consideration, he is unable to accede to the request that he shall cause the deaths from malignant diseases, which are now tabulated in his Annual Report under a single heading, to be tabulated for a series of years under separate headings, according to the part of the body affected.

Probably the gentlemen who with you signed that letter are not aware of the great and regrettable lack of precision with which very many members of the medical profession state causes of death in their certificates; the result of which is that these certificates can only be tabulated with utility under wide and general headings, and are quite unsuited to serve as materials for precise pathological inquiries. In a very large proportion of the deaths ascribed to malignant diseases, neither the part of the body affected nor the precise character of the malignant structure is stated on the certificate; so that an attempt to break up the heading "Malignant Diseases" into numerous smaller sub-divisions would be practically of little use. But even were it not so, the Registrar-General would be unable to accede to the request now made to him. The headings under which the causes of death are at present tabulated are no fewer than 173; and the labour of arranging the deaths under these is such as to tax to the utmost the clerical force which the Registrar-General has at his disposal for statistical purposes. If any alteration were made in this list of headings, it would be to diminish their number; and a proposal to increase them, and this so considerably, as is involved in the request now made, is one that the Registrar-General regrets that he cannot possibly entertain. He would venture to suggest, however, that returns gathered from the numerous hospitals of this country, in which full and precise records of causes of deaths are kept; or collected, as your letter at its close seems itself to suggest, from the medical practitioners who belong to the Association in all parts of the country, would furnish you with a much more suitable basis for your proposed investigation than a compilation from the very imperfectly filled-in certificates in the possession of this office.

As regards that considerable portion of your letter in which it is argued that the increase in the deaths ascribed to cancer corresponds to a real growth of the diseases so designated, and is not due to improved diagnosis and statement, the Registrar-General cannot of course think of putting any opinion of his own on such a subject in opposition to that of medical men of wide experience and long practice. He would, however, point out that the numerical arguments adduced in your letter are based upon the erroneous assumption that the headings in the Annual Report for 1867 correspond completely to the similar headings in the present Annual Reports; whereas this is not the case, a great change having been made in the classification in 1881, as is fully explained in the Report for that year. And, secondly, he would point out that your letter appears to imply that the Registrar-General has expressed an opinion in his reports that the whole of the increase under the heading "Cancer" has been due to improved diagnosis and more careful statement. This, however, is a mistake. All that the Registrar-General has done is as follows. Finding that the deaths from cancer were year by year increasing in number, and more rapidly than the population; he has in several reports called the attention of medical men to the fact; but, in so doing, has also pointed out that much of this increase—how much he cannot say—is almost certainly due to improved diagnosis and more precise statement of cause; and if it be admitted—and the Registrar-General scarcely supposes that the British Medical Association will not admit—that medical diagnosis has, as a fact, been improving, and that medical certificates are now given with greater care than formerly, it appears to follow almost as a necessary consequence, that at any rate some part of the increased mortality under the heading "Cancer" must be so caused. It may possibly be that the Registrar-General is inclined to attribute too large a share of the increase to this cause; but this is a question simply of degree; and that some part of the increase has been thus caused is in his judgment indisputable.—I am, Sir, Your obedient servant,
W. OGLE, M.D., Supt. Stat. Dept.

The President, British Medical Association.

Also suggested letter in reply, of which the following is a copy:

To the Registrar-General of Births, Deaths, and Marriages in England.
SIR,—We have to acknowledge and thank you for your letter of November 19th, signed by Dr. William Ogle.

In reference to the several parts of it, we may state that we were perfectly aware that the lack of precision in the existing certificates would render them useless in framing statistics for the years that are passed. It is for the future that we hope for more detailed statistics, and we trust that sufficiently precise certificates will be forthcoming when the purpose for which they are needed has been made known.

Your letter speaks of "precise pathological inquiries." We hasten to assure you that we have no intention of asking for such an inquiry. We do not even ask for a division of the cases of malignant disease into their different varieties, but only for a division according to the part of the body affected.

In reply to your suggestion that we should gather returns from the hospitals of the country, we may say that such returns would be incomplete, and might even be misleading. They would deal only with poor people. They would vary according to the relation of each individual hospital to the surrounding population, and to its attraction in cases requiring operation, etc. Moreover, comparatively few of the patients who are treated for cancer in the hospitals die there. Although, then, hospital statistics are of value in showing the comparative frequency of cancer in the different organs of the body, and the various forms which it assumes in different localities, the statistics from this source are valueless as indicating the proportion of the population attacked by the disease.

With regard to the last paragraph, we fully informed ourselves of the changes which had been made in the Annual Reports, and used those tables which most nearly correspond and which contain similar headings of disease in the Reports of different years. In relation to this point, we venture to quote two paragraphs in your Report for 1881. The first paragraph runs as follows:—"One of the most important uses of a classification of deaths by their alleged causes, when it has been carried out year after year for a considerable period, is that it enables those who are engaged in preventive medicine, or who are studying the natural history of diseases, to compare the mortality from each cause in successive years," etc., etc. (page xix). The second paragraph is:—"If these considerations (i. e., caprice of medical nomenclature, improvement in diag-

mosis, etc.) as to the limits within which comparisons can be fruitfully made between the mortality figures of successive years be borne in mind, the changes of classification now introduced will be found to offer no material hindrance to such comparisons" (page 33).

While we quite admit that a part of the increase observable in the mortality from cancer is probably due to more precise statement of cause of death and improved diagnosis, we cannot think that these things account for more than a small proportion of the increase. We, therefore, beg once more to direct your attention to the vast increase in the mortality due to this disease, and to express our hope that you will see your way to provide us with more detailed statistics on the subject, and of a kind which cannot be obtained from any other source. —We remain, Sir, your obedient servants.

Resolved: That the letter be received and approved, and forwarded to the Registrar-General, signed as the last one, and that a deputation consisting of the signatories be appointed to meet Dr. Ogle, if necessary, to discuss the subject with him.

Read letter from the Honorary Secretary of the Reading Branch, requesting that the proposals of a special general meeting of the Reading Branch to change the name of the Branch to the Reading and Upper Thames Branch, and that an annual meeting and dinner be held in the first week in July in each year, and that the Council shall have power to arrange for further meetings if considered desirable, be approved and confirmed by the Council.

Resolved: That the proposals contained in Dr. Heygate Phillips's letter relative to the alteration in the name of the Reading Branch and the annual meeting of the Branch be approved and confirmed.

Read letter from Surgeon J. J. Lamprey, suggesting that in those districts in the Colonies which are too sparsely populated and the medical men live too far apart to form a Branch, a Member of the Association should be appointed as Honorary Secretary for the District.

Resolved: That the letter be referred to the Journal and Finance Committee for consideration.

Read letter from Mr. Nelson Hardy asking for the occasional use of the Council Room for the Metropolitan Police Surgeons Association.

The consideration of the letter was postponed till the reading of the minutes of the Premises and Library Committee.

Resolved: That the 254 Candidates whose names appear on the circular convening the meeting be, and they are hereby, elected members of the British Medical Association.

Resolved: That the Minutes of the Journal and Finance Committee of to-day's date be received and approved, and the recommendations contained therein carried into effect, with the exception of the recommendation relating to the increase of salaries of the officers.

The Minutes of the Journal and Finance Committee contain the accounts of the quarter ending December 31st, 1887, amounting to £6,927 13s. 8d., auditors' quarterly certificate, Recommendations for the investment of £2,000, and the increase of officers' salaries.

Resolved: That the recommendation on the increase of salaries of officers be referred back to the Journal and Finance Committee, and reported upon to the Council at the next meeting.

Resolved: That the Minutes of the Habitual Drunkards Committee of the 17th inst. be received and approved, and the recommendations contained therein carried into effect.

The minutes of the Habitual Drunkards Committee contain a recommendation that the Hon. Secretary be requested to receive a deputation of the Committee upon the subject of further restrictive legislation for Habitual Drunkards.

Resolved: That the Minutes of the Therapeutics Committee of the 17th inst. be received and approved, and the recommendations contained therein carried into effect.

The Committee met to consider resolutions passed by the Therapeutic Section at the annual meeting at Dublin in August last, and to take such steps to carry into effect the suggestions for Therapeutic Reform made in the sectional President's address.

Resolved: That the Minutes of the Premises and Library Committee of the 21st day of November last and of the 17th inst. be received and approved, and the recommendations contained therein carried into effect.

The minutes of the Premises and Library Committee contain several offers of loans, the Report of Dr. Alfred Carpenter relative to the improvement in the ventilation, and recommendations with certain conditions upon which scientific associations may have their meetings in the Council Room.

Resolved: That the Minutes of the Relative Rank Committee of the 25th of October last and of the 17th inst., together with the Report of the Committee (see page 265), be received and approved, and the recommendations contained therein carried into effect.

Resolved: That the Committee be requested to continue their services, and to take any further steps that may be necessary.

Resolved: That the Minutes of the Fees to Witnesses Subcom-

mittee of the 17th inst. be received and approved, and the recommendations contained therein carried into effect.

The minutes of the Fees to Witnesses Subcommittee recommend that the question be placed before the Branches of the Association for evidence as to the practice of the courts in the various parts of the United Kingdom.

The further arrangements for the annual meeting at Glasgow were then considered.

SPECIAL CORRESPONDENCE.

SAN REMO.

[FROM OUR OWN CORRESPONDENT.]

AFTER a week's confinement to his room owing to a catarrhal attack and some change in the laryngeal condition reported elsewhere in your columns, the Crown Prince is again to be seen taking daily drives, apparently none the worse. There has been no suggestion here of any fresh consultation taking place. Sir Morell Mackenzie continues to enjoy the most absolute confidence of his august patient and that of the Crown Princess and the family generally. Sir M. Mackenzie arrived here on Sunday afternoon, being met at Ventimiglia by Dr. Freeman.

On Wednesday and Thursday the annual bazaar in aid of the poor of all nationalities was held here, under the patronage of the Crown Princess, who contributed two terracotta plaques painted by herself, Prince Henry also sending a sketch. The royal party lunched at the buffet, which was kept and served entirely by the English. The room and tables were most tastefully decorated, and the young ladies attired as waitresses and the gentlemen as cooks made an effective scene. In the evening a dance was held, at which Prince Henry thoroughly enjoyed himself, dancing until 3 A.M., when he left by the early morning train for Milan, to meet his future bride, the Princess Irene, who, with her father, the Grand Duke of Hesse, have arrived to stay for some time.

On Wednesday, the thirtieth anniversary of the Crown Prince and Princess's wedding-day, addresses and bouquets were presented, and a display of fireworks with illuminations of the hotels took place in the evening.

On Wednesday next a subscription ball in aid of the Ophthalmic Institute is to be held, and it is expected it will be a great success, Prince Henry and the Princesses having promised to be present.

There have been many visitors to San Remo and to the Villa Zirio the last week or two, amongst others, the Princess Louise and Lord Lorne, the Marquis of Hartington, and Sir Henry and Lady Layard.

Mr. Edward Lear, the eminent water-colour artist, and the author of the famous books of *Nonsense*, long resident here, died on Sunday last.

MANCHESTER.

[FROM OUR OWN CORRESPONDENT.]

Vacant Chairs in Owens College.—Ship Canal and the Pollution of the Irwell.—Small-pox.—University Clubs.

So far no official intimation has been made of the vacant Chairs of Obstetrics and Surgery in Owens College. We believe that the authorities of the College are seriously considering how they can most efficiently fill these important posts with most benefit to the medical students of Owens College. The Owens College is now so large and important a centre of medical instruction (the average number of students attending classes during the winter session on purely medical subjects being about three hundred), that its authorities are bound to secure for these posts the very best available men, men who will throw themselves into their work with vigour and enthusiasm. The following local gentlemen are, we believe, likely to be candidates for the Chair of Obstetrics, namely, Dr. William Japp Sinclair, Dr. Walter, and Dr. Lloyd Roberts. As to the candidates for the Chair of Surgery, rumour is busy with the names of several local surgeons, but, so far, nothing is definitely decided on this matter.

The Ship Canal is likely to have far-reaching effects, apart from its commercial advantages, on the Manchester district. At a conference of local authorities the question as to what means can be taken to prevent the pollution of the Mersey and Irwell was discussed last week. The canal will depend upon the waters furnished by these rivers; and if the water be allowed to remain pol-

luted with sewage and the refuse of manufactories which these rivers and their tributaries pass, then the canal will become the main sewer of the greater part of South Lancashire instead of the great waterway of the county. The rivers must be cleansed, and the directors of the Ship Canal and the various local bodies of Lancashire have taken steps to see how this can best be accomplished.

The Manchester Board of Guardians have adopted suggestions drawn up by their medical officer in view of a possible outbreak of small-pox in Manchester.

The members of the Edinburgh and Aberdeen University Clubs have just held their annual reunions. At the dinner of the former, Dr. Little presided; at the latter, Dr. Sinclair. Dr. Paterson, of Owens College, was elected Secretary of the former, *vice* Mr. Hardy, who has resigned. Mr. Hardy has been Secretary since the formation of the Club.

NEWCASTLE - UPON - TYNE.

[FROM OUR OWN CORRESPONDENT.]

College of Medicine.—Death-rate of Newcastle.—Annual Report of the Dispensary.—The Clinical Society.

THE Council of the College of Medicine have instituted a series of lectures on anatomy and physiology, intended for artists, art students, and others interested in higher education; these will be held in February and March annually, the lecturers being Dr. Oliver, Lecturer on Physiology at the College of Medicine, and Dr. Mears, Lecturer on Anatomy. The course comprises in the anatomical part:—The construction of the skeleton, showing use made of arch, girder, buttress, spring, wedge, and buffer; the formation of the various kinds of joints, the mechanism of the muscles, and the internal mechanisms connected with respiration, circulation, etc. In the physiological part, the forces in action in the human body and their relations to the phenomena of life. Examinations will be held at the end of the course, and certificates awarded to the successful candidates.

The mortality returns of the city of Newcastle have for some time been unusually high; there is reason, however, to believe that the returns have been estimated on a lower population than exists in the city; the Registrar-General has intimated that in future he will deal with the health statistics on the assumption of an increase of 20,000 inhabitants. This alteration will bring the mortality returns more in keeping with the actual state of things, and will enable Newcastle to compare more favourably with the other large towns of the kingdom.

Dr. Ridley, the resident medical officer at the dispensary, presented his annual report to the committee of the institution this week; it is the report for the 110th dispensary year, and shows an increase of 1,973 cases over that of the previous year; there has been an increase of 2,024 in those cases recommended by a subscriber's letter, and a slight decrease in the number of casual patients; the letter-patients are, in the majority of cases, attended by the visiting assistants at their homes; Dr. Ridley ascribes the increase as largely due to an epidemic of measles which occurred in the spring. The report gives a table of the cases attended at home, tabulating them in their proper districts; in each district the work has been much heavier than in past years, and it seems probable that an increase in the number of visiting assistants will be required if the work goes on increasing and is to be properly carried out. During the past year, Dr. Ridley says, he has instituted a series of investigations into the circumstances of patients under the dispensary through the medium of the Charity Organisation Society, and in no case was it found that the charity was being abused. The number of casuists treated during the year was 15,083, the largest number treated in one year, the increase being probably due to the closing of the casual department at the infirmary. The mortality returns for all the patients amount to 2.5 per cent.; amongst the home patients it is 9.4 per cent. The highest death-rate occurs in children under 1 year and from 1 year to 5 years of age, the former being 19.0 per cent. and the latter 10.4 per cent.; 1,314 cases of zymotic disease were treated during the year, with a mortality of 7.3 per cent.; measles was responsible for 733 cases, with a death-rate of 5.6; scarlet fever, 159 cases, death-rate 1.8 per cent.; 15 cases of typhus fever occurred, but were removed to the fever hospital. The report concludes with special reports from the special departments—aural, skin, and dental. Dr. Atkinson, in his report of the aural department, says the cases cannot well be grouped, owing to his ignorance of the condition of many of the patients treated prior to his receiving the care of

this department; he also suggests the inclusion of diseases of the throat in this section. The reports of the dental and skin departments are meagre in the extreme, the total number of cases alone being given, without any attempt at classification; it would be a great improvement if the reports of these departments were treated in the same exhaustive manner as that of the resident medical officer.

The annual dinner of the Clinical Society will be held on February 16th, 1888, the President in the chair; representatives from nearly all the learned societies in the district have been asked, and I understand the evening will be even more successful than that of last year; the January meeting of the society was held last week. Dr. Ridley showed a stone removed by lateral lithotomy successfully, also a case of varicocele cured by subcutaneous ligature. Dr. Limont showed a well-marked case of pseudo-hypertrophic paralysis in a little boy. Dr. Hardie showed two cases of abdominal tumour, one renal the other splenic. Dr. Robertson (Gateshead) read a paper on infantile diarrhoea, which gave rise to an interesting discussion.

CORRESPONDENCE.

THE HENDON COW DISEASE.

SIR,—I had hoped that the Hendon cow discussion would have been allowed to rest for a while. I must, however, ask you to kindly permit me to reply to Dr. Klein's letter in the *JOURNAL* of January 28th. Dr. Klein writes:—"Dr. Crookshank expressed great indignation at my having exhibited to that meeting 'without his permission,' 'his' calf. Now, the fact of the matter is that this calf was not Dr. Crookshank's property. It belonged to Professor Brown, and had been sent with other similar calves by Professor Brown to the Animal Vaccine Station, etc."

The protest which I made, Sir, was a firm but not an indignant one, and is expressed in the *JOURNAL* of January 21st, p. 135, as follows:

"It was one of those calves which had been vaccinated at the National Vaccine Establishment which Dr. Klein had brought to the meeting. He, Professor Crookshank, thought that if this was to have been done it would only have been fair to have shown one of the first calves that had not taken when revaccinated. He thought that for one observer to publish part of the, as yet unpublished, researches of another, and to show one of his animals without his having been consulted, and to be allowed to give his version of the results, was an event unparalleled in the history of the Pathological Society of London."

It was not a question of the actual ownership of the calves. Strictly speaking, they are the property of the Agricultural Department of the Privy Council. But they were handed over to me for my experiments, and I could therefore surely speak of them for the time being as mine. It was I myself who, on the morning of the special meeting, arranged that the calf which was to be exhibited should go straight on to the Animal Vaccine Station, and I (not Professor Brown) further arranged for two more to follow afterwards from the Royal Veterinary College. I did this under the distinct impression that the experiments to be done were to be jointly done; and I distinctly understood at the time that Mr. Murphy would co-operate with me. Mr. Murphy had expressed himself as most anxious to work with me at the cow-pox aspect of the question, and he accepted my invitation to visit the Wiltshire farm and to cross-examine the milkers. He was greatly impressed with what he had seen and heard, and on the journey back even went so far as to say that, if it was not vaccination, he did not know what it could be. Yet his co-operation fell through. Why?

I attended very regularly at the Animal Vaccine Station until the calves were ready. The first inoculation I made jointly with Dr. Cory; the second inoculation I made jointly with Mr. G. W. Collins, Dr. Cory being away at the time; the third and fourth inoculations were made by Dr. Cory, and in each animal in about forty places, and in the presence of Professor Brown, Dr. Klein, and myself.

Now, Sir, my protest was directed to the fact that, although Professor Brown and I met Dr. Klein, and we together inspected the calf on the very morning of the meeting at the Pathological Society, yet Dr. Klein gave us no intimation of his intention to exhibit it at the meeting. Had the proposal been made to me to show the calf, I should willingly have acquiesced; but I should

have shown also the other calf (the first remove from the boy's thumb) which had resisted the test of revaccination. To keep this calf back, and to show only the second remove or pustular calf, which did take, will hardly commend itself to anyone as fair criticism or impartial co-operation for the advancement of science.

The second part of my protest was directed to the fact that Dr. Klein endeavoured to explain away certain experiments of mine which are not yet published, and at which he was not even an onlooker. From some rough notes of these experiments which I sketched out for the benefit of those interested in watching the revaccinations, Dr. Klein presented to the Society a pedigree, with certain comments, which was printed in leaflet form and distributed by an attendant to members of the Society as they entered. I am surely justified in taking exception to this when I have promised that all these experiments will shortly be published in full.

In conclusion, Sir, the subject of cow-pox has been pressed to the front; but it must be remembered that the main question which is at present before the profession is, whether a certain vesicular disease of the teats of cows at Hendon—a disease communicated from animal to animal by the hand of the milker—was the very disease which we in man call scarlatina? In other words, was the Hendon cow disease a disease new to science, which might be called the Hendon or scarlatinal pox? The results of my investigation have forced me to very different conclusions, and these it was my duty to lay before the profession.—I am, etc.,

January 30th, 1888. EDGAR M. CROOKSHANK.

HERBERT SPENCER ON SANITATION BY COMPETITION.

SIR,—Will you allow an admirer of the writings of Mr. Herbert Spencer to point out that your article in the JOURNAL of January 25th does him injustice?

You say: "Mr. Spencer seems, too, to have studied only one feature of the Darwinian theory, and to understand the lessons even of that very imperfectly." Now all that you quote from Mr. Spencer is in *Social Statics*, published in 1850; while the joint paper by Darwin and Wallace on Natural Selection was read at the Linnean Society in 1838, and the *Origin of Species* appeared in 1859.

In the preface to the American edition of *Social Statics*, published in 1864, Mr. Spencer says: "During the fourteen years that have elapsed since the original publication of the work, the general theory which it enunciates has undergone, in his mind, considerable further development and some accompanying modifications." And, again: "In restating the doctrines he would bring into greater prominence the transitional nature of all political institutions, and the consequent relative goodness of some arrangements which have no claim to absolute goodness."

You say, "So long, for instance, as Mr. H. Spencer was content to occupy himself with the evolution of a theory of religion and life from his own inner consciousness and the writings of M. Comte," etc. Nothing could be more unlike than the religious views of Auguste Comte and of Mr. Spencer. The object of Comtist worship is "Humanity"—past, present, and future. Mr. Spencer says: "No such thing as a 'religion of Humanity' can ever do more than temporarily shut out the thought of a Power of which Humanity is but a small and fugitive product—a Power which was in course of ever-changing manifestations before Humanity was, and will continue through other manifestations when Humanity has ceased to be" (*Study of Sociology*, chapter xii).—I am, etc.,

ALFRED R. HALL.

Sunnybank, Shoot-up Hill, N.W.

* * * We must decline to accept our correspondent's apology on behalf of Mr. Herbert Spencer. In the light of Darwin's publications, Mr. Spencer has permitted at least one new edition of *Social Statics* to be published without any modification of his objectionable theories in the text. Nay, so far from that (and this is a proof of that ignorance of the complete bearing of Darwinism with which we charged him), in a publication (*The Man versus the State*) issued thirty-three years later than *Social Statics*, Mr. Spencer refers specifically to Mr. Darwin's doctrine of natural selection as strengthening his objectionable position, and expresses surprise that, despite the general acceptance of this doctrine by cultivated people, "now more than ever before in the history of the world are they doing all they can to further survival of the unfittest."

As to the extent to which Mr. Herbert Spencer is indebted to

Auguste Comte for his Theory of Religion and Life, we must refuse to enter into a controversy unsuited for our pages. We are aware that Mr. Spencer has denied his indebtedness to Comte for any of his doctrines; we are also aware that this was in answer to those who held, on what they deemed to be irrefragable proof, that without the previous existence of Auguste Comte, Mr. Spencer's doctrines would never have seen the light.

DR. CREIGHTON ON COW-POX AND VACCINAL SYPHILIS.

SIR,—The reviewer of a small work of mine on cow-pox has allowed two or three errors in matters of fact to creep into an otherwise learned, witty, and pertinent criticism. I send the corrections, both on account of your habitual care in reporting upon books, and from a natural unwillingness that those who may have read the review, but may never see the book, should go away thinking the thing which is not.

1. "He gives us no assistance towards reducing whatever risk there may be in the operation (of vaccinating) as nowadays practised." Can the reviewer have read the book through? There are numerous examples in it of what follows from neglecting Jenner's "golden rule" (see especially p. 117). In more than a dozen places I advert to the danger of using late lymph. I adopt and endeavour to elucidate the practical teaching of the late Dr. E. C. Seaton, as to the avoidable causes of the great, vaccinal disasters which have occurred mostly abroad, as well as the corresponding teaching on the no less obnoxious than misleading doctrine of invaccinated syphilis. I endeavour to illustrate the folly of vaccinating from a child, with an eruption on its arms by reference to the well-known case of a vaccination inspector, and by reference to the same case, to show the convenience of knowing the date after vaccination at which lymph is proposed to be taken. One of my principal themes, illustrated from the writings of Ceely, Estlin, Bousquet, and Jenner, himself, is the peculiar and even surprising properties of primary lymph; I point out the danger of "going back to the cow," and I may here remark that what I had to say on that point had acquired special relevancy within the last few weeks. Doubtless the author of a set of directions or instructions for vaccinators would have fallen into a more didactic turn of style; but I shall be surprised if my reasoned statement of the natural history of cow-pox does not help vaccinators to understand how and when the risks arise.

2. "Of evidence we have none." This is said of the substance or main contention of the book, which occupies the greater part of it, and to which every part of it leads up. I will charitably suppose that the reviewer here speaks in some non-natural, Pickwickian, or constructive sense. The book is pretty nearly all evidence; it is so compact with evidence, as any ordinary person will understand the word, that it needs close reading to apprehend it. Not more than an eighth or tenth part is taken up with comments; all the rest is a relation of evidence, collected and put together at the cost of much time and pains. The evidence is constantly authenticated by full and precise references in the notes; it is summarised in several pages of contents; it is alphabetically registered in an index; and if the Agricultural Department had only been a few months earlier with its shocking revelations of recent cow-pox, the evidence would have been corroborated in an appendix, dealing also with the humanitarian aspect of cow-pox in the cow, with the contamination of milk by seabs, pus, and blood, and with the scarlet fever traceable to such sources.

3. The word "falsehood," which I am accused of using along with "sophistry," does not occur in the book, nor any equivalent of it.

4. "Readers will do wisely to verify each statement of our author before accepting him"—whatever accepting "him" may mean. In form this is not a misleading assertion like 1 and 2; it is merely a gentlemanly insinuation; it is the sort of caution that one might give, in a parallel case, against a habitual liar or a detected impostor. Readers of this book, as the reviewer pathetically tells them, may have scant means of going to original sources of information; and, in the very same breath, he throws upon them a task which he has thus far declined to take upon himself. Perhaps the simplest way to deal with this gentleman will be for me now to challenge him to point out one single misstatement of fact (for it is to matters of fact that his sweeping innuendo relates)

in those chapters of my book against which he specially cautioned your readers.

In giving a challenge of that sort I know that I am inviting a closer scrutiny than a writer's work is ordinarily subjected to; but I give the challenge deliberately, and I shall feel obliged to you, Sir, if you will undertake to deliver the cartel to the person who has to answer it.—I am, etc.,

C. CREIGHTON, M.D.

January 16th, 1888.

MEDICAL EXAMINATIONS.

SIR,—The address by Mr. E. Owen which appears in the JOURNAL of January 28th refers to several points to which my attention has been oftentimes called during the past few years, and which are so important that they should not, I think, be allowed to pass without comment. With your permission I will refer to them in order.

1. The Conjoint English Board's examinations in chemistry and materia medica. I suppose the experience of every teacher of anatomy must be somewhat similar to my own on this point. I constantly, at the commencement of the winter session and during the month of October, find myself engaged in some such conversation as the following: "Mr. So-and-So, I don't see you dissecting." "No, sir, I am reading for my examination in materia medica" or "in chemistry," as the case may be. "How is that?" "Oh, I got ploughed in July," or "I didn't think I knew enough to go in last summer."

Now the Conjoint Board is careful to fix the examinations in these subjects towards the end of October, the result being that a certain number of first year's students are irregular at lectures, and dissect little or not at all until November begins, thus handicapping themselves more than they are aware in their anatomical work. It is natural that students should wish to clear off their materia medica and chemistry before going on to other subjects, and the Conjoint Board should see that this may be done without interference with other work. If it were compulsory that a student should pass in these subjects prior to registration, as Mr. Owen suggests, the difficulty would be most easily surmounted; but if this is impossible, then surely the examination might be held in the latter part of September, or at least early in October.

2. The subjects of materia medica and therapeutics may now be studied prior to registration and passed in immediately afterwards. Surely it is ridiculous that a student who is or may be totally ignorant of physiology and anatomy should be expected to know the physiological action of drugs, and that he should learn the theory of the administration of medicine before he has made any acquaintance with the diseases for which they are given. If materia medica is to be taught at all, one would think that it might form a primary subject, therapeutics being entirely relegated to the final examination, as is or was the rule in the University of Dublin when I was a student there.

3. I fully agree with Mr. Owen as to the absurdity of permitting students to pass in physiology and anatomy at different times. A man ought reasonably to be expected to know enough of both subjects at one given time to pass in them, or he is certainly not fit to become a medical practitioner.

4. I also endorse every word which he says as to the recent regulations with regard to the honour examinations of the University of London. If the present scheme has been devised solely for the purpose of lightening the labours of the examiners, there is nothing more to be said about it. Its devisers may at least, however, congratulate themselves on having discovered an infallible method for cutting down the number of students competing for honours to the minimum.

It has sometimes occurred to me that if the Deans and Honorary Secretaries and others concerned in the management of medical schools had the opportunity of meeting annually, matters such as these might be considered, and possibly a joint remonstrance or recommendation from such a meeting might have its effect upon the rulers of our licensing bodies.

This is perhaps too much to hope for, but I trust that Mr. Owen's admirable address will not be allowed to pass without some expression of opinion from those directly interested in teaching.—I am, etc.,

BERTRAM C. A. WINDLE, M.A., M.D.,

Professor of Anatomy and Honorary Secretary,
Queen's College, Birmingham.

NAVAL AND MILITARY MEDICAL SERVICES.

RED CROSS ASSOCIATION.

HER MAJESTY the Empress of Germany has placed at the disposal of the International Conference of the Red Cross Association, which met at Carlsruhe in September last, a sum of 6,000 marks, as well as three gold and nine silver medals bearing her effigy. The object of this generous gift is to offer the Conference an opportunity of introducing something calculated to promote the interests of the International Institution of the Red Cross, and more especially the relief of the wounded. The Conference has consequently decided on devoting Her Majesty's gracious gift to a competition on the best interior arrangement for a portable lazaret (hospital), that is to say, the indication of the most suitable objects and the best means of procuring them, for arranging and working a portable hospital intended for a certain number of sick and wounded. Inquiries or particulars as to taking part in the competition should be addressed to the "Comité Central des Sociétés Allemandes de la Croix-Rouge, Wilhelmstrasse 73, Berlin." All correspondence in reference to space in the exhibition should be addressed to the executive committee in Brussels, Rue du Palais 22.

VOLUNTEER MEDICAL ASSOCIATION.

WE are asked to state that the inspection of the class now being held under the auspices of the Volunteer Ambulance Department will take place on Saturday, February 18th, at 5 P.M., at the Guildhall, when the Lord Mayor and Sheriffs will attend in state. The members of the Association and their friends will dine together at the Holborn Restaurant at 7 P.M. the same evening, after the inspection. The Council will be glad to see any army or volunteer medical officer either at the Guildhall or at the subsequent mess meeting, and such gentlemen are invited to communicate with the Honorary Secretary, Mr. Alfred Lingard, at once.

THE NAVY.

The following appointments have been made at the Admiralty: GEORGE S. SMITH, Surgeon, to the *Kingfisher*; JOHN S. FOGERTY, M.D., Surgeon, to the *Reindeer*; GRAHAM E. KENNEDY, Surgeon, to the *Orwell*; H. W. MACNAMARA, Surgeon, to Malta Hospital; ALEXANDER J. J. JOHNSTON, Surgeon, to the *Surprise*; JAMES M. ROGERS, Surgeon, to the *Duke of Wellington*; DUNCAN HILSTON, Deputy Inspector-General of Hospitals, to Bermuda Hospital; R. R. SICCAM, Deputy Inspector-General of Hospitals, to Chatham Hospital; JOHN M. HUTCHIN GILL, to be Surgeon and Agent at Ramsey, Isle of Man.

Staff-Surgeon JAMES BOOTH died at Montrose on January 21th. He entered as Surgeon June 1st, 1825; became Staff-Surgeon, August 15th, 1838; and retired in 1857.

THE MEDICAL STAFF.

DEPUTY SURGEON-GENERAL W. M. WEBB is promoted to be Surgeon-General (ranking as Major-General), *vice* H. T. Reade, V.C., C.B., granted retired pay. His previous commissions are dated: Assistant-Surgeon, March 24th, 1851; Surgeon, January 15th, 1864; Surgeon-Major, March 1st, 1873; Brigade-Surgeon, November 27th, 1879; and Deputy Surgeon-General, July 6th, 1881. He served with the 19th Regiment throughout the Crimean war in 1854-55, and was at the battles of the Alma and Balaclava and at the siege and fall of Sebastopol. He has the medal with three clasps and the Turkish medal.

Brigade-Surgeon F. W. WADE is made Deputy Surgeon-General (ranking as Colonel), *vice* W. M. Webb. He entered as Assistant-Surgeon, September 28th, 1857; became Surgeon, October 5th, 1872; Surgeon-Major, March 1st, 1873; and Brigade-Surgeon, February 1st, 1883. He has no war record.

Surgeon-Major C. A. MAUNSELL, M.D., is promoted to be Brigade-Surgeon (ranking as Lieutenant-Colonel) *vice* F. W. Wade. Brigade-Surgeon Maunsell entered as Assistant-Surgeon, October 1st, 1862; became Surgeon, March 1st, 1873; and Surgeon-Major, April 28th, 1876. He was with the Royal Artillery during the Bhootea campaign in 1864-65, and was at the capture of Fort Buxar, the Bala Pass, the Tuzgaon Stockade, and Fort Chamoorchee (medal with clasp). He was also engaged in the war in Egypt in 1882, and has the medal and the Egyptian bronze star for that campaign.

Brigade-Surgeon F. P. STAPLES is granted retired pay. His commissions are dated: Assistant-Surgeon, April 1st, 1861; Surgeon, March 1st, 1873; Surgeon-Major, April 1st, 1876; and Brigade-Surgeon, September 20th, 1887. He served with the 1st Battalion of the 19th Regiment in the Hazara campaign in 1868, and took part in the expedition against the tribes on the Black Mountain (medal with clasp).

THE INDIAN MEDICAL SERVICE.

DEPUTY SURGEON-GENERAL R. F. HUTCHINSON, Bengal Establishment, has retired from the service, which he entered as Assistant-Surgeon December 3rd, 1853, attaining to Deputy Surgeon-General December 9th, 1882. He was engaged in the Afghan war in 1879, and has the medal therefor.

Surgeon A. R. EDWARDS, Bengal Establishment, is appointed to the officiating medical charge of the 1st Sikh Infantry, *vice* Surgeon A. SILCOCK, who has been posted to Belaspore as Civil Surgeon.

Surgeon-Major C. W. CALTHROP, Bengal Establishment, Medical Officer 4th Native Cavalry, has leave of absence on medical certificate for one year to the Kangra Valley and adjacent hills.

Surgeon-Major A. H. C. DANE, Bombay Establishment, in medical charge of the Bhopal Battalion, has leave to Europe for eighteen months on private affairs.

THE VOLUNTEERS.

ACTING-SURGEON J. M. CAMERON, M.B., 1st Dumbarton, has resigned his appointment, which bore date October 4th, 1884. Mr. J. R. F. CULLEN, M.B., is appointed Acting-Surgeon in his stead.

Mr. J. A. JONES is appointed Acting-Surgeon to the 2nd Volunteer Battalion Welsh Regiment (late the 1st Glamorgan).

MEDICO-LEGAL AND MEDICO-ETHICAL.

UNQUALIFIED MEDICAL ASSISTANTS.

A LEGAL correspondent writes:—A case of very considerable interest to those practitioners who employ unqualified assistants has recently been reported. The case is a most useful one, as showing and defining in a fairly distinct manner the duties which are within the scope of an unqualified assistant, and those duties which should only be performed by a duly qualified medical man.

The action was one brought by the trustee in bankruptcy of Louis Fitzmaurice for fees for services rendered and medicines supplied by an unqualified assistant to the defendant. Fitzmaurice carried on business in Bury, and had a branch business in a neighbouring village, which was conducted by Joseph Alphonso Fitzmaurice, who was unqualified. At the trial it was admitted that Louis Fitzmaurice had not rendered any services personally to the defendant, and that Joseph Alphonso Fitzmaurice who had rendered the services had no qualification at all. The judge of the Salford Hundred Court on these facts, and relying on the thirty-second section of the Medical Act, 1858, non-suited the plaintiff, who appealed to the Divisional Court, and it was contended on his behalf that the only effect of the Act was to incapacitate the unqualified person from suing, the Act containing no provision rendering the employment of a qualified person compulsory, as in the Apothecaries Act (55 George III. c. 194). These arguments, however, did not prevail with the Court, and Lord Coleridge, in his judgment, defined very reasonably the sphere that an unqualified assistant should occupy. It is not necessary that the services should be rendered personally by the qualified practitioner, if he really directs the attendances and prescribes the medicine. The unqualified person may be, under certain circumstances, "the hand employed and guided by the directing brain of the qualified person." In this case, however, the action was for services which the qualified person did not render, and it was found at the trial that the qualified person rendered no services at all, either by directing the services of the unqualified assistant or in any other way.

Mr. Justice Denman said, in the course of the argument, that if the plaintiff was right, a medical man could send his butler to visit his patients and yet recover his charges, and the contention of the plaintiff practically did amount to this.

Mr. Justice Denman's judgment was so clear and concise that the following extract may be useful:—"Here an action has been brought by a qualified medical practitioner for services rendered and medicines supplied, and he must make out he has rendered such services and supplied such medicines. This he does not do, but shows that another person has done the work for him without consultation with him. Can it be urged that this is a compliance with the 32nd section of the Medical Practitioners' Act, 1858? Looking at the provisions of that Act, I do not think it is competent to a medical man to give a roving commission to another, and, in this instance, an unqualified person, to do work in his own name, and then sue the patient so attended. To permit such a state of things to go on would be contrary to the clear intentions of the Act. Again, so far as this case is concerned, it would be a mockery and a misuse of the words 'master and servant' to hold them to be applicable under the circumstances detailed."

Practitioners cannot, therefore, be too careful not to leave cases in the hands of unqualified men, but should carefully superintend and oversee everything entrusted to them to do; otherwise, and rightly so, not only will the fees be irrecoverable, but practitioners may lay themselves open to most serious claims for negligence.

CUMBE v. HANSON AND BRODHURST.

THIS was an action to recover moneys, being the balance due for medical attendance, medicine, and board and lodging. Mr. Coumbe, M.R.C.S., practising at Twyford, was called on September 6th to Colonel Brodhurst, who had been thrown from a carriage, and sus-

tained a fracture of the thigh and other injuries. Being at the time on a visit to Sir R. Hanson, who was going away in three weeks' time, Colonel Brodhurst asked to be taken into Mr. Coumbe's house. Sir R. Hanson told Mr. Coumbe that he would hold himself liable for the expenses incurred. Colonel Brodhurst remained under treatment in Mr. Coumbe's house for eight weeks; his wife and a hospital nurse from Reading were also in the house. He was then removed to Brighton, Mr. Coumbe going with him, for which a charge of £21 was made. A fortnight later Mr. Coumbe again went to Brighton, for which a fee of fifteen guineas was charged. A sum of £89 was charged for medical expenses, and £10 a week for board and lodging of Colonel and Mrs. Brodhurst and nurse. The plaintiff stated that he charged 10s. 6d. a visit. He sent a bill for £210 to Sir R. Hanson, who tendered £100 in payment.

The jury found a verdict for the plaintiff for £55 beyond the £100 paid by Sir R. Hanson and the £25 paid into court by Colonel Brodhurst.

Mr. Justice Stephen gave judgment for the plaintiff, with costs.

DISPENSARY CHARGES.

DR. JAMES LEATHAM, a physician in practice in Rodney Street, Liverpool, sought in the Liverpool County Court, on January 31st, to recover the sum of £22 for medical and surgical attendance from a butcher named Dunbar. The defence was that Dr. Leatham's services were sought through his dispensary in Seacombe Street, and that it was anticipated that the charges would be at the low rates obtaining there, namely, 2s. 6d. a visit, and the defendant had paid into court £5 14s. 6d. in settlement of the claim. Dr. Leatham stated that the defendant was informed that his charge was 10s. 6d. for each attendance, and he made no demur.

The jury held that Dr. Leatham was called in as a dispensary medical man, and gave a verdict only for the sum paid into court, and awarded the defendant his costs.

ETIQUETTE FOR NEWCOMER.

IGNORAMUS asks; Which is the correct etiquette? Should the newcomer call on the resident or the resident on the newcomer, or does one follow the rules of ordinary society?

"* If 'Ignoramus' had been an observant reader of the JOURNAL, he could not well have failed to note that the question he submits has been repeatedly answered therein. At the same time we have pleasure in responding thereto by quoting from the *Code of Medical Ethics*, second edition, page 90, the following extract; and, for further information on the subject, we would refer him to the *Code* itself:

"The custom or etiquette (diverse from that pursued in ordinary social life in relation to new residents) expected from members of the profession on commencing or changing the locality of practice in town or country entails on each newcomer, young or old, an obligation to call, with as little delay as may be, upon every duly qualified legitimate medical practitioner resident within a reasonable distance of his own selected place of abode, and courteously announce his intention to practise in the locality."

ETIQUETTE OF CLUB PRACTICE.

FAIR PLAY asks for an answer to the following: A. has for three months regularly attended a club patient who was suffering from a chronic disease; a brother of the patient called in a local practitioner (B.), who prescribed for the case, and continued in attendance till death without informing A. A., however, saw the patient once more, and informed him that he would not call again as B. was in attendance. A. and B. have never met, and there has not been any communication between them. Has B.'s conduct been contrary to medical etiquette?

"* Assuming that B. was cognizant of the fact that A. was, and had been for some time past, in attendance on the patient in question, his conduct, as related by 'Fair Play,' was contrary to medical etiquette, and should, moreover, have been strictly governed by the following Rule 91, extracted from the *Code of Medical Ethics*, second edition, page 70, to which we may refer our correspondent: "When a practitioner is called in to or consulted by a patient who has recently been, or still may be, under the care of another for the same illness, he should on no account interfere in the case, except in an emergency, having provided for which he should request a consultation with the gentleman in previous attendance, and decline further direction of the case except in consultation with him," etc.

UNQUALIFIED ASSISTANTS: ANOTHER DIFFICULTY.

B. writes: A. and B. are the only medical practitioners in a small town, and have been accustomed to attend for each other in case of absence from home or emergency. A. is also B.'s substitute as district medical officer. Some months ago A. procured an assistant, and informed B. he was a qualified man. B. could find no name corresponding with the assistant's in the 1868 *Directory*. On the first opportunity B. mentioned this to A., who said the assistant was not registered, but had a certain qualification. After examining the regulations of the university referred to, B. came to the conclusion that this could not be correct, and wrote to A. pointing this out; also saying that unless the assistant could satisfy him he possessed a diploma, B. objected to his seeing patients for him. A. replies that he cannot see what B. has to do with the qualifications of his assistant, and as B. objects to the assistant seeing his patients, A. declines to act as B.'s substitute. A. is the senior of B., and though B. is quite independent of A., and can find another substitute,

he has no desire to seek a quarrel. Both are members of the British Medical Association. Should A. have satisfied B. that the assistant was legally qualified, or had B. nothing to do with it as A. contends?

* * * If the above statement correctly represents all the material facts of the case, it is, in our opinion, to be regretted, and especially under the circumstances of the reciprocal professional arrangement between the parties, that either should fail to recognise the expediency, to say the least, of mutual frankness; if, therefore, it be that the assistant in question is not legally qualified, we should in no wise (notwithstanding the convenience of such an arrangement as has hitherto existed between "A." and "B.") be induced to dissuade "B." from severing all connection with the assistant; for it is desirable that the "assistant" should be a duly qualified practitioner to enable his principal to recover his professional charges in case the account for his attendance be disputed. "A." should, therefore, in our opinion, "have satisfied 'B.' that the assistant was legally qualified."

MEDICO-CHIRURGICAL TARIFFS.

M. D. DURHAM.—In response to "M.D.'s" query as to whether "any small book exists containing information on medical tariffs," we are informed on inquiry that the corrected proof sheets of the fourth edition (revised and enlarged) of the *Medico-Chirurgical Tariffs*, issued by the Council of the late Shropshire Ethical Branch, are now in the hands of the printer, and will shortly be published; and, moreover, that he will find therein all the information necessary to guide him in making his professional charges. The Manchester Medico-Ethical Association has also published a tariff of medical fees.

COVERING UNQUALIFIED PRACTICE.

BAGNAL writes: A man who lives about a mile from here, and who is in practice duly qualified, has taken a house here and put in an unqualified man, who practises under his name. On the door of this unqualified man appears the plate of his "cover," Dr. Q. S., M.D., so that strangers imagine when they consult him they are having advice from a duly qualified practitioner. Can anything be done to stop this disreputable conduct?

* * * If proof were furnished to the Society of Apothecaries of the unqualified man himself prescribing for or visiting patients, the Society would at once institute a prosecution against him. There is necessarily, however, great and obvious difficulty in obtaining convictions where a qualified medical man "covers" an unqualified one, conduct justly described by "Bagnal" as "disreputable."

A. W. (Liverpool).—If the solicitor's opinion which has been had on the case is not sufficiently authoritative, the proper course is to take counsel's opinion. The case is not one which we can take upon ourselves to decide.

"CHANGING THE DOCTOR."

A. N. G. writes: 1. Mrs. A., the mother of two children, the younger aged six months, who has been attended hitherto by Dr. B., a leading accoucheur, but who also takes family practice (he was last in attendance about two months previously), requests Mr. C., a junior practitioner living near, to call and see her child. Mr. C. does so, and is told by Mrs. A. that she does not like Dr. B., that his fees are high, and she would like to leave him. Mr. C. prescribes and says he will call again two days later to see the child. On that day Mr. C. receives a note from Mrs. A. saying the child is much better, but she would like Mr. C. to call to see her and give her a tonic. What should Mr. C.'s course be? Should he simply attend as requested, or must he first require Mrs. A. to write to her late medical man and tell him that she has called in Mr. C.?

2. Also what is the etiquette to be observed when a patient wishes to change the family medical man, supposing the late medical man not to have been in attendance for some time, and a fresh illness to break out in the family?

* * * In reply to our correspondent's first question, there can, in our opinion, be no doubt that, under the circumstances related, it is not necessary for Mrs. A. to write to her late medical attendant (B.), and inform him that she has called in Mr. C., inasmuch as such a notification is only required (from a professional point of view) when a family, for some reason or other, are desirous to supersede the practitioner in actual attendance on a case. When, however, such attendance has terminated, consequent on the recovery or death of the patient, or in the event of a new case of illness, the family would, in either event, be justified in changing their medical adviser should such be their wish. The preceding remarks are also applicable as a reply to our correspondent's second question.

PARTNERS' SHARES OF SPECIAL FEES.

A. and B. are partners; one of the partners receives a large fee for attendance during several days at an important case at the Royal Courts of Justice for giving evidence at the trial, and for services connected therewith. Is there any rule which enables you to say whether such a fee is to be considered a partnership asset or not? Or, to enable you to decide the point, must the facts of the case be more fully stated to you? The partners have agreed to refer the matter to you, and to accept your decision.

* * * Fees paid to medical witnesses are paid to them personally as a solatium for the time and trouble devoted to attending the case and giving evidence. Whether the partner of the witness is entitled to a share of fees so paid depends on the partnership agreement. If "all fees received" are to be shared, such fees would be included, but otherwise they would belong to the partner who attended as a witness. If this answer does not solve the difficulty a copy of the material part of the partnership agreement should be sent.

PUBLIC HEALTH

AND

POOR-LAW MEDICAL SERVICES.

HEALTH OF ENGLISH TOWNS.—In the twenty-eight large English towns, including London, which have an estimated population of 9,398,273 persons, 6,106 births and 4,056 deaths were registered during the week ending Saturday, January 28th. The annual rate of mortality per 1,000 persons living in these towns, which had declined from 23.8 to 23.0 in the three preceding weeks, further fell during the week under notice to 22.5. The rates in the several towns ranged from 14.3 in Brighton, 15.2 in Derby, and 15.9 in Bradford, to 29.0 in Norwich, 29.4 in Blackburn, 31.3 in Wolverhampton, and 31.9 in Manchester. In the twenty-seven provincial towns the mean death-rate was 22.8 per 1,000, and exceeded by 0.7 the rate recorded in London, which was 22.1 per 1,000. The 4,056 deaths registered during the week under notice in the twenty-eight towns included 214 which were referred to whooping-cough, 61 to scarlet fever, 47 to measles, 46 to diphtheria, 39 to fever (principally enteric), 39 to small-pox, and 32 to diarrhoea; in all, 478 deaths resulted from these principal zymotic diseases, against 476 and 481 in the two preceding weeks. These 478 deaths were equal to an annual rate of 2.7 per 1,000; in London the zymotic death-rate was 3.3, while in the twenty-seven provincial towns it averaged only 2.2 per 1,000, and ranged from 0.0 and 0.5 in Hull and Cardiff, to 3.7 in Bolton, 3.8 in Nottingham, and 6.6 in Sheffield. Measles caused the highest proportional fatality in Blackburn; scarlet fever in Norwich and Blackburn; whooping-cough in Birkenhead, London, Derby, and Wolverhampton; and "fever" in Brighton and Nottingham. Of the 46 deaths from diphtheria recorded during the week under notice in the twenty-eight towns, 29 occurred in London, 3 in Manchester, and 3 in Oldham. The 39 fatal cases of small-pox included 37 in Sheffield, 1 in Bristol, and 1 in Leeds, but not one in London or in any of the twenty-four other large provincial towns. The number of small-pox patients in the Metropolitan Asylums Hospitals was 9 on Saturday, January 28th, of whom 5 had been admitted during the week. These hospitals also contained 1,641 scarlet fever patients on the same date, against numbers steadily declining from 2,602 to 1,729 in the eight preceding weeks; there were 135 admissions during the week. The death-rate from diseases of the respiratory organs in London was equal to 6.5 per 1,000, and was slightly below the average.

HEALTH OF SCOTCH TOWNS.—During the week ending Saturday, January 28th, 830 births and 567 deaths were registered in the eight principal Scotch towns. The annual rate of mortality in these towns, which had declined in the three preceding weeks from 27.1 to 23.3 per 1,000, further fell to 22.4 during the week under notice, and almost corresponded with the mean rate during the week in the twenty-eight large English towns. Among these Scotch towns, the lowest rates were recorded in Greenock and Leith, and the highest in Aberdeen and Perth. The 567 deaths in these towns during the week under notice included 65 which were referred to the principal zymotic diseases, equal to an annual rate of 2.6 per 1,000, which was slightly below the mean zymotic death-rate during the week under notice in the large English towns. The highest zymotic rates were recorded in Aberdeen, Dundee, and Edinburgh. The highest proportional fatality of measles occurred in Edinburgh; from scarlet fever in Dundee; and from whooping-cough in Aberdeen, Greenock, and Glasgow. Four deaths resulted from diphtheria in Glasgow, and 3 in Aberdeen. The mortality from diseases of the respiratory organs in these Scotch towns during the week under notice was equal to 6.0 per 1,000, against 6.5 in London.

HEALTH OF IRISH TOWNS.—In the sixteen principal town districts of Ireland, the 517 deaths registered during the week ending Saturday, January 28th, were equal to an annual rate of 30.9 per 1,000. The lowest rates were recorded in Sligo and Dundalk, and the highest in Kilkenny and Cork. The death-rate from the principal zymotic diseases in these towns averaged 5.2 per 1,000, and was highest in Kilkenny, Cork, and Newry. Measles showed fatal prevalence in Cork and Newry. The 224 deaths registered in Dublin during the week under notice were equal to a rate of 33.1 per 1,000 (against 35.8 and 31.9 in the

two preceding weeks), the rate for the same period being only 2.1 in London, and 2.2 in Edinburgh. The deaths included 33 from the principal zymotic diseases (equal to an annual rate of 4.9 per 1,000), of which 10 resulted from scarlet fever, 8 from whooping-cough, 6 from diphtheria, 4 from typhoid fever, 3 from diarrhoea, and 2 from measles.

USEFULNESS OF BY-LAWS AS TO NEW BUILDINGS, ETC.

Our correspondent, "L.R.O.P. London," has undoubtedly given his sanitary authority sound advice in recommending them to adopt a proper code of by-laws for their district. The provisions of the Public Health Act are very comprehensive, but in some respects are permissive and not compulsory. Thus, under Section 157, "every urban authority may make by-laws" with respect to the construction of new streets and buildings, "to the drainage of buildings, to water-closets, earth-closets, privies, ashpits, and cesspools in connection with buildings, and to the closing of buildings, or parts of buildings, unfit for human habitation, and to prohibition of their use for such habitation;" and under Section 44 they may make by-laws as to the cleansing of footways and pavements, the removal of house refuse, the cleansing of earth-closets, privies, ashpits, and cesspools, and for the prevention of nuisances arising from snow, filth, etc. Unless, therefore, the sanitary authority exercise these permissive powers, and supplement the provisions of the Act by adopting by-laws applicable to the particular circumstances of their district, their sanitary powers remain so far defective. As a matter of fact, the adoption, and enforcement under penalty, of adequate but reasonable by-laws, based on the models issued by the Local Government Board, is one of the most effective ways of securing wholesome conditions, especially in growing localities.

As regards water supply, the Public Health Act, 1875, gives sanitary authorities power to provide proper supplies; but where a public supply is not provided and surface wells are depended upon, by-laws prescribing the minimum distance to be allowed between new cesspools, ashpits, etc., and sources of water supply are imperatively necessary. It should also be remembered that although the Public Health (Water) Act, 1873, concerns primarily rural sanitary authorities, Section 11 provides that "the Local Government Board may, if they think fit, by order invest any urban sanitary authority with all or any of the powers and duties which are by this Act given to a rural sanitary authority, and such investment may be made either unconditionally, or subject to any conditions to be specified by the Board as to the time, portion of the district, or manner during, at, or in which the powers and duties are to be exercised;" but we believe this course has not often been taken.

As regards the powers of sanitary officials to enter private premises, such powers are given by Section 102 of the Public Health Act, but are severely circumscribed.

APPOINTMENT OF INSPECTORS OF THE LOCAL GOVERNMENT BOARD.

MEMBERS.—The medical inspectors of the Local Government Board are appointed by the President of the Board. The salary begins at £500, and, of course, each has before him the prospect of becoming medical officer to the Board. There is the usual pension on retirement from office.

SMALL-POX AT SHEFFIELD.

DR. L. J. HOBSON (Harrogate) writes: In the interesting note upon Sheffield and its epidemic in the JOURNAL of January 21st appear some rather misleading deductions as to proportionate mortality in vaccinated and unvaccinated cases at all ages. It is first stated that of the 2,198 cases of small-pox in the vaccinated and of the 382 in the unvaccinated, the deaths are 157 in the former and 97 in the latter. This should make the mortality in the vaccinated at about 1 in 14 instead of "1 in 22," and in the unvaccinated at about 1 in 4 instead of "2 in every 5." Moreover, the chances of survival of the vaccinated over the unvaccinated in case of small-pox would then be deduced at three and a half times instead of "ten times" greater.

The figures 157 and 97 would seem to have been transposed in making the erroneous calculations, but, with the above corrections, the facts should remain sufficiently striking to the "antivaccinationists."

"Dr. Hobson is correct in his criticisms. Our correspondent gives first figures taken from the report of the medical officer of health—namely, 2,198 vaccinated with 157 deaths; 382 unvaccinated with 97 deaths. Later he quotes from the *Sheffield Daily Telegraph*, which transposes the figures thus: 2,198 vaccinated with 97 deaths; 382 unvaccinated with 157 deaths.

SANITARY REGISTRATION OF BUILDINGS BILL.

A PUBLIC conference will take place at the Society of Arts on Saturday, February 4th, at 4 o'clock, when an introductory address will be given by Sir Joseph Fayrer, K.C.S.I., F.R.S. Short papers will be read by Mr. Mark H. Judge, A.R.I.B.A., and Sir Vincent H. Kennett Barrington, who will propose and second the following resolution:—

A. That it is desirable that the law should forbid any building being used for public or semi-public purposes, unless and until the arrangements for the water supply, drainage, and ventilation of such building have been certified as satisfactory by some properly qualified person, and that the provision of a public sanitary register for the voluntary registration of private houses would be instrumental to promoting sanitary improvement.

B. That in the opinion of this Conference, the Sanitary Registration of Buildings Bill, 1888 will, if passed into law, have a great influence for good on the health of the community, and, without pledging itself to all the details of the measure, this Conference authorises the Chairman to sign petitions, asking Parliament to pass the Bill into law, with such modifications as consideration in Committee may show to be desirable.

MEDICAL OFFICER OF HEALTH FOR ABERDEEN.

DR. J. WIGNOT writes: This office is vacant just now by the removal to Sheffield of Dr. Thomson. During the past six or seven years the medical officer of health has had to devote his whole time to the duties of his office, and has been disallowed private practice. The present chairman of the Public Health Committee—a medical man—has, it is said, proposed a scheme by which a small salary would be given to a regularly qualified practitioner, but allowed to take private practice, or to get a young man to attend the "City Hospital," for infectious diseases alone, and as a sort of consultant, one of the medical men of the city to consult with the sanitary inspector when he had any difficulty. Compulsory notification obtains here.

As Chairman of the Parliamentary Committee of our Branch here, I brought this matter before my Committee. Did I do right? Is it competent for me to do so? As some objected I agreed to bring it before the Branch at its first meeting, but this does not take place until the middle of February. In the meantime the battle may be fought and won. A representation from us as a Committee might have influenced the matter either way, and as it is the Branch meeting will take place only two or three days before the Town Council meet to decide the matter. Kindly say if I did right, and express your opinion on the whole situation.

"Certainly every effort should be made to prevent the Town Council of Aberdeen from adopting a course so prejudicial to the health interests of the town."

INDIA AND THE COLONIES.

HEALTH OF TROOPS IN CHINA AND STRAITS SETTLEMENTS.

The Army Medical Department Report for 1885 states that the troops serving in China and the Straits Settlements consisted of European and Asiatic troops. The average strength of the white troops during the year under notice was 2,188. The hospital admissions from this force were 2,454 in number, the deaths 25, and there were 94 men constantly ineffective from sickness. The ratios per 1,000 of strength were, consequently, hospital admissions, 112.6; mortality, 11.43; and for constantly sick, 42.95. The ratio of admissions into hospital was much higher in the Straits Settlements than at Hong Kong, but that of mortality was considerably less. The average strength of the troops quartered at Hong Kong was 1,114, the number of admissions into hospital 987, and the total number of deaths 18; while in the Straits Settlements, out of an average strength of 1,074, the number of admissions into hospital was 1,467, but the total number of deaths only 7. This difference in the proportions of mortality in the two divisions of the command is explained by the occurrence of an outbreak of cholera at Hong Kong, while no cases occurred among the troops in the Straits Settlements. The epidemic of cholera at Hong Kong took place in June; it was fortunately of a limited character; altogether only 19 cases were admitted, but of these 12, or 63 per cent., proved fatal. It is stated that cholera was known to be prevalent in Tonquin, Annam, and the Philippine Islands for some time prior to its appearance among the troops at Hong Kong. As soon as the disease manifested itself, the troops among whom it occurred were placed under canvas at Kowloon, on the opposite side of the harbour, and were subsequently moved to Stanley, on the other side of the island. It was here the last case of the outbreak occurred; this case recovered. It is remarked in the report that "with most of the conditions necessary for the development of the disease present, it nevertheless did not get a firm hold on either the civil or military population, and it is presumed that there was some condition wanting either in the atmosphere, soil, or climate that gave the locality an immunity from a severe epidemic. In the Chinese quarter of the town there was overcrowding and every insanitary condition necessary to favour the spread of the disease, yet the number of cases reported were comparatively few." Fevers of various types appear to have been prevalent at Hong Kong, and especially at Tanglin in the Straits Settlements. Enteric fever caused 4 admissions and 1 death. Three cases of typhoid fever, 1 with a fatal result, are reported to have occurred at Tanglin. Other continued fevers returned 419 admissions, and of these 322 were shown in the returns from Tanglin alone; they were attributed chiefly to climatic causes, heat and exposure. Under paroxysmal fevers there were 349 admissions with 1 death; of these 301 were ague and 48 remittent fever, many of the latter being described as very severe, and followed by cachexia, anaemia, and debility. Of the ague, 156 cases, and of the remittent fever, 34 cases, occurred at Hong Kong. It was supposed that the malarial emanations from the rather disintegrated granite of which the soil in Hong Kong is composed, some of which had been freshly upturned, had a share in the production of these fevers. It is remarked in the report that, in cases of debility consequent on fever, change to the sanitarium was found beneficial; but when malarial cachexia was established, a complete change of climate was necessary to restore

health. The average strength of the officers was 91, and among them were 2 deaths; one of the deaths resulted from hepatic abscess, the other from hydrophobia; in the latter case the officer had been bitten by a rabid dog some months previously at Tanglin, but so slightly, the injury being only a scratch, that he did not think it necessary to have it cauterised. Among an average strength of 75 women, there were 67 attacks of illness and 1 death, and among 134 children the number of cases of illness treated was 53 and there were 10 deaths. The Asiatic troops in the command, consisting of the headquarters and two companies of Gun Lascars, were 188 in average strength; among them were 208 admissions into hospital and 8 deaths. The principal cause of sickness among them was malarial fever. Various sanitary defects in the command are referred to in the report, but appear to be in progress of amelioration.

OBITUARY.

PROFESSOR ASA GRAY, M.D.

By the death of Professor Asa Gray, which occurred on Monday last at Cambridge, Massachusetts, from paralysis, America has been deprived of its greatest botanist, and the world of science mourns the loss of one of its most eminent teachers. Born at Paris, in the State of New York, in 1810, he graduated M.D. at Fairfield Medical College at the age of 21. His intense love for botany, however, soon decided his future career. In 1834 he was offered the position of botanist on the United States Exploring Expedition under Captain Wilkes. Though he declined this appointment, he afterwards worked out the botany of the expedition on its return, and the results were published in 1854. In 1842 he was elected Fisher Professor of Natural History at Harvard College, a position he held until 1873. He twice visited Europe—first in 1838-9, and again in 1850-51. He spent many months at a time in England, where he made many friends. He was one of the earliest to give a somewhat qualified support to Darwinism, and stoutly defended it against great opposition in his own country. He was one of Darwin's most constant and esteemed correspondents. He was in 1874 chosen a Regent of the Smithsonian Institute, and in 1878 was elected by the Académie de Sciences of Paris a Corresponding Member in the Section of Botany. Dr. Gray was a prolific writer, and in the Royal Society's List the titles of his contributions to science occupy something like seven columns. Among his best known works are his *Elements of Botany*, published in 1836, subsequently enlarged into the *Botanical Textbook; Structural and Systematic Botany; Manual of Botany*; and other textbooks. In 1838 he began, with Dr. Torrey, *The Flora of North America*; and in 1884 he published the *Synoptical Flora of North America*.

DR. JOHN THOMAS IRVINE BOSWELL.

The eminent botanist, Dr. J. T. I. Boswell, died on January 31st, at Balmullo, Fifeshire. Dr. Boswell was for many years Curator to the Botanical Society in London, and was a lecturer at the Charing Cross and Middlesex Schools of Medicine. His largest work was the rewriting of Sowerby's *Botany*, consisting of twenty volumes, a task upon which he was engaged for twenty years. Dr. Boswell's family has been located at Balmullo in one successive line since the reign of David II, and his mother was the daughter of Lord Balmullo, one of the Lords of Session. He leaves a widow and several children.

UNIVERSITY INTELLIGENCE.

UNIVERSITY OF CAMBRIDGE.

DR. HUMPHRY, Professor of Surgery, has been nominated an Examiner for the Winchester Reading Prizes in 1889. Lord Rayleigh has been nominated a member of the Board of Electors to the Jacksonian Professorship of Natural Philosophy.

On Thursday, January 26th, F. C. Servaes, M.A., King's College, was admitted to the degrees of M.B. and B.C.

PROPOSED SMALL-POX HOSPITAL FOR DERRY.—The corporation have agreed to pay half the cost of a hospital for small-pox cases.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following candidates for the College Licence, having conformed to the by-laws and regulations, and passed the required examinations, were granted the Licence to Practise in Physic:

Name.	Medical School.	Name.	Medical School.

* Approved by the Examining Board.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH, AND FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW.—The Quarterly Examinations in Edinburgh for the Triple Qualification took place in January, with the following results:

First Examination. Of the 58 candidates, the following 37 passed:

- P. F. O'Hagan, Longford; G. S. Pope, Madras; G. T. Tuke, Edinburgh; A. H. Barstow, Spofforth; J. F. Roden, Edinburgh; G. A. Ings, Canada; E. V. Eames, Donegal; T. J. Tonkin, London; T. S. Allan, Glasgow; J. Stevenson, Dundee; W. H. Walker, Ripon; F. J. Flavin, Doncaster; J. F. Curry, Limerick; T. H. Hosford, County Cork; R. R. Workman, County Derry; H. Stedman, London; H. Shaw, Enniscorthy; H. A. Holmes, Manchester; P. R. Crofton, Ireland; C. J. A. Coates, County Cork; W. Yeates, County Down; R. S. Jaques, Scarborough; A. E. Douglas, Newcastle-on-Tyne; D. C. Caraduff, Berhampore; R. Milling, County Down; G. G. Sinclair, Hamilton; W. W. Margenout, Ceylon; G. Maingot, Trinidad; R. Love, County Antrim; A. Burns, Chatham; Miss Beatrice Mary Harrison, Brighton; C. E. Dodd, Cheshire; F. C. Rogers, Cheshire; N. J. Newbold, Cambridge; J. H. Hart, Yorkshire; A. H. Dubourg, London; and C. E. G. Bateman, Norwich.

Second Examination. Of 63 candidates, the following 34 passed:

- J. Round, Dudley; J. P. McLaren, Glasgow; R. Aldous, Norfolk; C. J. Milligan, Belfast; T. S. Hogg, County Derry; S. W. Wolfe, County Cork; C. L. Strangman, Waterford; C. E. Dodd, Minshill Vernon; N. H. Newbould, Cambridge; F. C. Rogers, Cheshire; W. C. Lancaster, Dublin; E. Trehanne, Glamorganshire; R. W. Morrow, County Down; J. B. Griffiths, Stroud; J. H. Carson, County Down; W. W.

Margenout, Ceylon; K. R. Carroll, County Cork; J. L. Smith, County Limerick; T. S. MacMahon, Longford; T. B. Brooke, Cambridgeshire; J. Mackenzie, Sutherland; H. E. Wright, Oldham; J. Stobo, Bothwell; J. C. Thompson, Yorkshire; J. Quigley, Londonderry; J. O'Sullivan, Dublin; A. Ramage, Kilmarnock; A. M. Ford, Glasgow; T. F. Southam, Cheshire; R. J. Stirling, Peebles; J. Maher, Waterford; W. S. Crawford, County Down; J. B. Meredith, Queen's County; and A. H. Duhourg, London.

Final Examination. Of 86 candidates, the following 40 passed, and were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P. and S.G.:

A. A. Jervis-Pereira, India; J. Hoy, Ashby-de-la-Zouch; Miss Mary Crowley, Northampton; S. Evans, Madras; W. A. Gibson, Dublin; R. L. Caunter, Cornwall; A. J. Ryan, County Limerick; M. J. O'Connell, Cork; K. J. Courtenay, Sheerness; E. Brooks, Blackburn; W. J. France, Shrewsbury; J. H. Lloyd, Aberystwith; J. M. Crawford, India; J. C. Scotchburn, Yorkshire; C. Mattel, Malta; J. C. Paloner, Melbourne; T. S. Hogg, County Kerry; J. Stoddart, Dumfries-shire; J. C. MacDiarmid, Argyleshire; M. H. Spencer, Tavistock; J. Cotter, Cork; J. McDowell, Newry; M. McLaughlin, County Donegal; J. C. Heynsbergh, Ceylon; M. B. Leicester, London; R. K. Mitter, India; A. W. Douglas, Aldershot; M. T. Casey, County Limerick; A. S. Taylor, Walker-on-Tyne; B. J. E. Wright, London; J. C. French, County Durham; G. E. Rawlinson, Oxford; J. T. Kennedy, Kerry; C. Doherty, County Donegal; J. P. Ferguson, Ireland; W. K. Lockhead, New South Wales; J. W. Kelly, Queenstown; C. Beasley, Southsea; T. Ireland, Germany; and G. F. Hilliard, Ireland.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—During the January sittings of the Examiners, the following gentleman passed the Final Examination, and was admitted L.R.C.S.E.:

W. G. Sym, Edinburgh.

For the Licence in Dental Surgery, the following gentleman passed the First Professional Examination:

A. Turner, Aylesbury.

The following gentlemen passed the Final Examination and were admitted L.D.S. Edin.:

E. A. White, Stoke Holy Cross, Norwich; and J. Turner, Edinburgh.

SOCIETY OF APOTHECARIES OF LONDON.—The following gentlemen having passed the Qualifying Examination in Medicine, Surgery, and Midwifery have received certificates entitling them to practise in the same, and have been admitted as Licentiates of the Society.

Bamptlyde, James, Malabar House, Bexley, Kent.
Blacklock, John, East Bank, Haslingden.
Bryden Francis Wm. Augustus, Beech House, Uffculme, Devon.
Garvey, Henry Patrick, 11, Thorne Terrace, Barnes, Surrey.
Hancock, George, Leathley Lodge, Hunslet, Leeds.
Killeck, Charles Rowe, 33, London Road, Dover.
Modlin, Isaac Gibson, 5, Featherstone Street, Roker, Sunderland.

The following gentlemen passed the Surgical portion of the examination.

C. R. Adams, of St. Thomas's Hospital; W. S. Brown, of Guy's Hospital; W. Marris, of the Middlesex Hospital; T. W. Mead, of St. George's Hospital; C. F. Stovin, of the London Hospital; W. Watkins, of St. Bartholomew's Hospital; J. Westwood, of Queen's College, Birmingham; T. C. Winn, of the London Hospital.

The following gentlemen passed the Medical portion of the examination.

W. Metcalfe, of St. George's Hospital; H. C. Sugden, of Edinburgh University.

The following gentleman passed the Primary Examination.

B. S. Snell, of University College.

The following passed the first part of the Primary Examination.

P. P. Baly, of Queen's College, Birmingham; C. A. Threlgate.

The following passed the second part of the Primary Examination.

A. C. Baes, of St. Bartholomew's Hospital; E. C. Curtis, of Aberdeen University; W. M. Keal, of St. Bartholomew's Hospital; W. O. Lattey, of St. George's Hospital; F. H. Lazenby, of University College; H. B. T. Symons, of the Charing Cross Hospital.

MEDICAL VACANCIES.

The following Vacancies are announced:

BIEMINGHAM BOROUGH ASYLUM.—Clinical Assistant. Application to H. B. Whitcombe, Esq.

BOURNEMOUTH FRIENDLY SOCIETIES MEDICAL ASSOCIATION.—Resident Medical Officer. Salary, £200 per annum, with residence and fees. Applications to Mr. F. A. K. Hounseth, Trinity Chambers, Bournemouth.

Bristol Royal Infirmary.—Dental Surgeon. Applications by February 15th to the Secretary.

CANCER HOSPITAL, Brompton.—Pathologist. Honorarium of £80 for twelve-months. Applications by February 21st to the Secretary.

MEDICAL APPOINTMENTS.

ABBOTT, Charles Edward, L.K.Q.O.P.I., M.R.C.S.Eng., reappointed Medical Officer of Health for the Braintree Rural Sanitary District, Essex, for one year.

BRIGHT, Eustace, M.B., M.R.C.S., appointed Resident Clinical Assistant to the Hospital for Consumption, Brompton, vice B. de B. Carey, M.B., M.H.C.S., L.S.A., resigned.

BLOMFIELD, Arthur G., M.D., appointed Physician to the Devon and Exeter Hospital.

DALY, J. P., M.D., House Surgeon, North Infirmary, Cork, appointed Medical Officer to one of the Dispensary Districts, Cork Union, vice Dr. Riordan, resigned.

DAVIES, A. T., B.A., M.B., M.R.C.P., appointed Physician to the Royal Hospital for Diseases of the Chest, vice J. J. Pringle, M.B., resigned.

EDWARDS, P., M.R.C.P., L.R.C.S., appointed Assistant Medical Officer to the Manchester Royal Infirmary (Moussal Fever Hospital), vice H. L. Williams, M.R.C.S., L.R.C.P., resigned.

FOX, R. G., M.B. and C.M. Edin., appointed Junior Assistant Medical Officer to the Sussex County Lunatic Asylum, vice M. O. Manson, M.R.C.S., L.R.C.P., resigned.

SAUNDERS, C. E., M.D., M.R.C.P., M.R.C.S., appointed Medical Superintendent to the Sussex County Lunatic Asylum, vice S. W. D. Williams, M.D., resigned.

STRUGNELL, W. T., M.B., M.R.C.S., appointed Senior House Surgeon to the Royal Hospital for Diseases of the Chest, vice P. G. Lewis, L.S.A., resigned.

TREVELYAN, B. R. T., M.R.C.S.Eng., L.R.C.P.Lond., appointed Assistant Physician to the Bristol General Hospital, vice J. B. Webb, M.R.C.S.Eng., L.R.C.P.Lond., resigned.

WALKER, P. Hunter, M.B., C.M., appointed Medical Officer to the Lechlade District, Faringdon Union, vice J. B. Miller, M.B., C.M., resigned.

WALLACE, A., M.A., M.D. Oxon., M.R.C.P.Lond., appointed Physician to the Essex and Colchester Hospital.

WETHERED, Frank, M.B., M.R.C.S., appointed Resident Clinical Assistant to the Hospital for Consumption, Brompton, vice W. A. Evelyn, M.B., M.R.C.S., resigned.

THE METROPOLITAN ASYLUMS BOARD.—The return presented to the Board on January 28th, with respect to fever and small-pox, showed that at the beginning of the half-year (the end of June) there were 528 cases of fever in the hospital. During the quarter ending September, 2,095 cases were admitted, of these 1,921 were scarlet fever, 147 enteric, and 8 typhus. During the quarter ending Christmas there were admitted 3,215 cases, of these 2,943 were scarlet fever cases, 4 typhus, and 244 enteric cases. At the end of the Christmas quarter there were 2,205 cases under treatment, of which 2,045 were scarlet fever cases and 146 enteric cases. The returns up to Thursday midnight (January 26th) showed that in the fortnight there had been 297 cases admitted, as against 362 the previous fortnight. There had been discharged 505 in the last fortnight, as against 519 in the previous period, and there remained on Thursday under treatment 1,833, as against 2,083 a fortnight since. With regard to small-pox, 7 cases had arisen within the fortnight, as against 4 in the previous fortnight. In the same period 6 had been discharged and 10 remained under treatment—an increase of one since the last return.

A MEDICAL CLUB.—A club, called the Circolo Medico Milanese, has been established at Milan, and many of the medical men in the town have joined it. Its objects are stated to be to provide a place of social intercourse, together with the ordinary conveniences of a club for its members, and to promote a feeling of professional brotherhood among them.

REQUESTS AND DONATIONS.—Colonel Machen has bequeathed £1,000 to the Warneford, Leamington, and South Warwickshire Hospital.—The British Home for Incurables has received £380 8s., being the balance of share of "residue" under the will of Dr. G. G. Gardiner, one of the physicians.—Mr. Christopher James Corbally has bequeathed £100 each to the Dispensaries, the Royal Infirmary, the Infirmary for Children, the Northern Hospital, and the Southern Hospital, all of Liverpool.—Miss Clara Frances Gladstone, of Bowden Park, Chippenham, has bequeathed the "residue" of her estate to her sister Alice, but with the request that she would give £200 to the West of England Sanatorium at Weston-super-Mare, and £100 to the West London Children's Hospital and Dispensary for Women at Shadwell.—The Worcester Infirmary has received £200, less duty, and the Dispensary £100, less duty, under the will of Mrs. Eliza Woodward; and the former has received 100 guineas, and the latter 50 guineas, from Mr. J. Waldegrave Stone.—The Northampton General Infirmary has received £100 under the will of Mrs. R. Pell.—Miss Elizabeth Norman has bequeathed £100 to the Adelaide Hospital, Dublin.—Lord Burton has given 100 guineas for the second time to the British Home for Incurables.—Mr. Henry Brown has given £100 to the Victoria Hospital, Southend.—The Doncaster Infirmary Ball realised £67 5s.—"G. W. C." has given £30 for the third time to the Convalescent Home Fund of the Chelsea Hospital for Women.

THE Third Report of the Medical Mission at Tai-Yuen-Fu, Shansi, North China, for 1887, shows an amount of practical work which is creditable to the workers both as medical men and missionaries. Altogether, about six thousand patients (including 298 in-patients) came under treatment, and the diseases varied from typhus fever to dyspepsia, and from phimosia to ulceration of the cornea. They are enabled to record a successful case of operation for strangulated hernia, and twenty-three cases of successful restoration of sight after cataract. It is easy to understand that surgical work in these distant regions is hampered by the lack of efficient assistance, and the want is one not easily remedied. Dr. E. H. Edwards may be congratulated on his zeal and ability in compiling a report amid the absorbing duties of his responsible position.

ROYAL METEOROLOGICAL SOCIETY.—At the monthly meeting of this Society, held on January 18th, the following officers and council were elected for the year 1888:—*President:* William Marcell, M.D., F.R.S., F.C.S. *Vice-Presidents:* Francis Campbell Bayard, LL.M.; William Ellis, F.R.A.S.; Charles Harding; Richard Inwards, F.R.A.S. *Treasurer:* Henry Perigal, F.R.A.S., F.R.M.S. *Trustees:* Hon. Francis Albert Rollo Russell, M.A.; Stephen William Silver, F.R.G.S. *Secretaries:* George James Symons, F.R.S.; John William Tripe, M.D., M.R.C.P. Ed. *Foreign Secretary:* Robert Henry Scott, M.A., F.R.S., F.G.S. *Council:* Hon. Ralph Abercromby; Robert Andrew Allison, M.P.; Edmund Douglas Archibald, M.A.; William Morris Beaufort, F.R.A.S., F.R.G.S.; Henry Francis Blanford, F.R.S., F.G.S.; Arthur Brewin; George Chatterton, M.A., M.Inst.C.E.; William Henry Dines, B.A.; Henry Storks Eaton, M.A.; Baldwin Latham, M.Inst.C.E., F.G.S.; Edward Mawley, F.R.H.S.; Charles Theodore Williams, M.A., M.D., F.R.C.P.

MANCHESTER MEDICO-ETHICAL ASSOCIATION.—At the annual meeting of this Association the report of the Committee showed continuous prosperity, with a steady increase of funds. The following gentlemen were elected office-bearers and members of Committee for the year:—*President:* H. Simpson, M.D. *Vice-Presidents:* J. Foster, Esq.; T. N. Dean, Esq.; J. Broadbent, Esq.; and A. Emrys-Jones, M.D. *Treasurer:* D. Lloyd Roberts, M.D., F.R.S. Edin. *Secretaries:* A. Wahltsch, M.D.; and F. H. Collins, M.D. *Committee:* R. Crean, M.D.; A. Denholm, Esq.; F. M. Pierce, M.D.; C. Holmes, M.D.; H. P. Iderton, Esq.; E. Jackson, Esq.; W. Lauder, M.D.; W. Y. Martin, M.D.; S. H. Owen, M.D.; T. C. Railton, M.D.; R. C. Smith, M.D.; and W. Walter, M.D.

PROSTITUTION IN BRUSSELS.—The Royal Academy of Medicine of Brussels have unanimously passed a resolution to the effect that "the regulation of prostitution is necessary to check the propagation of venereal diseases." Other resolutions were passed, with few dissentient voices; in favour of prohibiting prostitutes from frequenting "streets, promenades, and public places," and providing for the periodical medical examination of recognised prostitutes.

MANCHESTER WATER SUPPLY.—The Manchester water supply is said to be lower in quantity than it has been for many years

past. The consumption is upwards of 2,000,000 gallons a day in excess of what it was in 1879, when the stock fell very low, but this year the water in stock is even less than in that year.

SUCCESSFUL VACCINATION.—Mr. C. Hayercroft, of Bow, North Devon, has obtained a Government grant for successful vaccination in his district.

The Ormskirk Guardians have increased the salary of Dr. Moore, medical officer for the Southport District, from £60 to £100 per annum.

DR. WILLIAM H. FITZPATRICK, the late medical officer for the rural district of the West Derby Union, has obtained a superannuation allowance of £80 per annum.

DR. C. E. SAUNDERS, medical officer of Health for the Middlesex and Herts combined sanitary districts, has been appointed medical superintendent of the Sussex County Asylum. Dr. Saunders has discharged his duties as medical officer of health with ability and assiduity, and has had some experience in lunacy as medical visitor of the private asylums in the eastern division of Sussex.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.

MEDICAL SOCIETY OF LONDON.—Dr. Churton, of Leeds: Empyema. Mr. Pearce Gould: Four Cases of Thoraco-Plastic Operation for Empyema. Dr. F. de Havilland Hall and Mr. J. Astley Bloxam will relate Similar Cases.

ODONTOLOGICAL SOCIETY. 8 P.M.—Casual communications by Mr. Storer Bennett: Dilaceration in the Incisor of a Porcupine; and Dr. St. George Elliott: A System of Crowns. Papers by Mr. J. Bland Sutton: Odontomes; and Dr. Harlan, of Chicago: The Management of Pulpless Teeth from the Standpoint of Daily Practice.

TUESDAY.

PATHOLOGICAL SOCIETY OF LONDON.—Mr. E. H. Fenwick: Etiology of Vesical Growths. Mr. R. W. Parker: Specimens of Bone Disease. Mr. Eve: Specimens of Dry Caries. Mr. Spencer: Deformity of Sternal Ends of Clavicles in Rickets. Mr. Treves: Melanosis of the Skin. Mr. E. Owen: Anomalous Appendages in a Case of Spina Bifida. Mr. Shattock: Imperforate Urethra. Mr. D'Arcy Power: Parosteal Lipoma. Card Specimens—Mr. Eve: Bilharzia Hamatobia. Mr. Treves: Tumour of Spermatid Cord. Mr. D'Arcy Power: Angioma of Cerebral Membranes. Mr. J. H. Morgan; Femur from Case of Pyæmia in an Infant. Mr. Mansell Moullin: Transverse Fracture of Patella United by Bone. Mr. W. K. Sibley: Double Intussusception in a Baboon.

WEDNESDAY.

BRITISH GYNÆCOLOGICAL SOCIETY. 8.30 P.M.—Dr. James Aveling: The Diagnosis and Electrical Treatment of Early Extra-Uterine Gestation. Adjourned discussion on Mr. Lawson Tait's Cases of Ruptured Tubal Pregnancy, successfully dealt with by Ligation of the Broad Ligament. Specimens will be exhibited by Mr. Lawson Tait, Dr. G. Granville Bantock, and others.

EPIDEMIOLOGICAL SOCIETY OF LONDON. 8 P.M.—Justin F. Donovan, M.D., Surgeon R.N.: Yellow Fever and the Microbian Doctrine.

ROYAL MICROSCOPICAL SOCIETY. 8 P.M.—Annual Meeting. President's Address. Rev. Dr. Dallinger, F.R.S.

HUNTERIAN SOCIETY. 7.30 P.M.—Annual General Meeting. 8 P.M. The Annual Oration: R. Clement Lucas, B.S.

FRIDAY.

CLINICAL SOCIETY OF LONDON. 8.30 P.M.—Mr. Mayo Robson: Cases of Ruptured Intestine without External Wound, Diagnosis and Treatment. Mr. Bennett: Case of Intestinal Obstruction, in which the Colon Gave Way outside the Peritoneum. Mr. Walsham: Case of Intestinal Obstruction; Nelon's Operation; Death; Volvulus of Cecum; Malposition of Ascending Colon. Living Specimen.—Mr. Bernard Roth: Case of Arrested Growth of Ulna.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 6s. 6d., which should be forwarded in stamps with the announcement.

BIRTHS.

ADAMS.—On January 27th, at 184, Aldersgate Street, E.C., the wife of John Adams, L.R.C.P. Lond., of a daughter (Mary Dora).

DAVIDSON.—At 2, Bon Accord Square, Aberdeen, on January 28th, the wife of James McKenzie Davidson, M.B., C.M., of a daughter.

DEATHS.

MURPHY.—On January 23rd, at Aspatry, Cumberland, William Ponsonby Murphy, L.R.C.S. Ireland, aged 68 years.

PALMER.—On January 28th, at Putney, Caroline Margaret Palmer, recently of Barnwood, Eastbourne, Sussex, widow of Henry Smith Palmer, M.R.C.S., of St. Leonards, Mortlake, Surrey, aged 65.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY.....	10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's (Ophthalmic Department); and Royal Westminster Ophthalmic.—2 P.M.: Metropolitan Free; St. Mark's; Central London Ophthalmic; Royal Orthopaedic; and Hospital for Women.—2.30 P.M.: Chelsea Hospital for Women.
TUESDAY.....	9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's; St. Bartholomew's (Ophthalmic Department); St. Mary's; Royal Westminster Ophthalmic.—2 P.M.: Westminster; St. Mark's; Central London Ophthalmic.—2.30 P.M.: West London; Cancer Hospital, Brompton.—4 P.M.: St. Thomas's (Ophthalmic Department).
WEDNESDAY.....	10 A.M.: National Orthopaedic.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: Middlesex.—1.30 P.M. St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.; London; University College; Westminster; Great Northern Central; Central London Ophthalmic.—2.30 P.M.: Samaritan Free Hospital for Women and Children; St. Peter's.—3 to 4 P.M.: King's College.
THURSDAY.....	10.30 A.M.: Royal London Ophthalmic.—1 P.M.: St. George's.—1.30 P.M.: St. Bartholomew's (Ophthalmic Department); Guy's (Ophthalmic Department); Royal Westminster Ophthalmic.—3 P.M.: Charing Cross, London; Central London Ophthalmic; Hospital for Diseases of the Throat; Hospital for Women.—2.30 P.M.: North-West London; Chelsea Hospital for Women.
FRIDAY.....	9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.15 P.M.: St. George's (Ophthalmic Department).—1.30 P.M.: Guy's; Royal Westminster Ophthalmic.—2 P.M.: King's College; St. Thomas's (Ophthalmic Department); Central London Ophthalmic; Royal South London Ophthalmic; East London Hospital for Children.—2.30 P.M.; West London.
SATURDAY.....	9 A.M.: Royal Free.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: King's College.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Middlesex; Royal Free; Central London Ophthalmic.—2.30 P.M.: Cancer Hospital, Brompton.

HOURS OF ATTENDANCE AT THE LONDON HOSPITALS.

CHARING CROSS.—Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; Skin, M. Th., 1.30; Dental, M. W. F., 9.
GUY'S.—Medical and Surgical, daily, 1.30; Obstetric, M. Tu. F., 1.30; Eye, M. Tu. Th. F., 1.30; Ear, Tu. F., 12.30; Skin, Tu., 12.30; Dental, Tu. Th. F., 12.
KING'S COLLEGE.—Medical, daily, 2; Surgical, daily, 1.30; Obstetric, Tu. Th. S., 2; o.p., M. W. F., 12.30; Eye, M. Th., 1; Ophthalmic Department, W., 1; Bar. Th., 2; Skin, Th.; Throat, Th., 3; Dental, Tu. F., 10.
LONDON.—Medical, daily, exc. S., 2; Surgical, daily, 1.30 and 2; Obstetric, M. Th., 1.30; o.p. W. S., 1.30; Eye, W. S., 9; Ear, S., 9.30; Skin, Th., 9; Dental, Tu., 9.
MIDDLESEX.—Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; o.p. W. S., 1.30; Eye, W. S., 8.30; Ear and Throat, Tu., 9; Skin, Tu., 4; Dental, daily, 8.
ST. BARTHOLOMEW'S.—Medical and Surgical, daily, 1.30; Obstetric, Tu. Th. S., 2; o.p., W. S., 9; Eye, Tu. Th. S., 2.30; Ear, Tu. F., 2; Skin, F., 1.30; Larynx, F., 2.30; Orthopaedic, M., 2.30; Dental, Tu. F., 9.

ST. THOMAS'S.—Medical and Surgical, daily, except Sat., 2; Obstetric, M. Th., 2; o.p., W., 1.30; Eye, M. Th., 2; o.p., daily, except Sat., 1.30; Ear, M., 12.30; Skin, W., 12.30; Throat, Tu. F., 1.30; Children, S., 12.30; Dental, Tu. F., 10.
UNIVERSITY COLLEGE.—Medical and Surgical, daily, 1 to 2; Obstetrics, M. Tu. Th., F., 1.30; Eye, M. Tu. Th., F., 2; Ear, S., 1.30; Skin, W., 1.45, S., 9.15; Throat, Th., 2.30; Dental, W., 10.30.
WESTMINSTER.—Medical and Surgical, daily, 1.30; Obstetric, Tu. F., 3; Eye, M. Th., 2.30; Ear, M., 9; Skin, Th., 4; Dental, W. S., 9.15.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS respecting editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

In order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the office of the JOURNAL, and not to his private house.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL, are requested to communicate beforehand with the Manager, 429, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication. CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

TO CORRESPONDENTS.

OUR correspondents are reminded that prolixity is a great bar to publication, and, with the constant pressure upon every department of the JOURNAL, brevity of style and conciseness of statement greatly facilitate early insertion. We are compelled to return and hold over a great number of communications chiefly by reason of their unnecessary length.

QUERIES.

G. R. G. asks as to the suitability of the climate of Melanesia and Norfolk Island for a patient in the first stage of phthisis.

TREATMENT OF TINNITUS.

MR. FRANCIS W. CLARK, L.R.C.P.L., M.R.C.S. (East Croydon), asks for suggestions for the treatment of the following case. A man, aged 46, of neurotic temperament, has been suffering from ringing noises in the ears of varying intensity, and alternating from one to the other aide for the past three months. About a month prior to the onset of this trouble he suffered from detachment of the retina, necessitating complete rest for two months, and it was during this period that the noises suddenly developed. The heart and blood vessels are normal, and so also is the urine; and the patient has never suffered from gout. After excluding local causes, such as concretions in the meatus and blocking of the Eustachian tube, the following remedies were successively tried, but all without success: Colchicum, hydrobromic acid, bromide of potassium, and faradism. The patient is at present taking small doses of salicylate of soda.

TREATMENT OF PROFUSE SWEATING.

MR. J. E. CLENDINNEN (Coseley) asks for advice in the treatment of the following case. A lady, aged 46, not having yet reached the menopause, suffers from profuse perspiration on awaking in the morning, generally lasting from 4 to 8 o'clock. The sweating is preceded by a hot burning condition of the skin, and is so profuse that her bed cannot be made until it and the bedclothing have been dried. It does not occur every morning, but about two or three mornings in the week. She has been nervous, but is now in excellent health, looks well, eats well, and sleeps well till the sweating begins. The following remedies have been tried: Belladonna, bromide of potassium, strychnine, oxide of zinc, valerianate of zinc, and hot sponging. Most relief has been derived from the zinc valerianate.

CONVALESCENT HOME WANTED.

DR. E. L. ARCHER (Kensington) wishes to hear of a convalescent home at Bournemouth where a young man, who is probably in the early stage of consumption, would be admitted on payment of a moderate fee for a few weeks.

DISINFECTING CHAMBER.

M. O. H. wishes to learn the name and address of the maker or agent of the Schummel Steam Disinfecting Closet of Berlin.

MESSAGE.

NOVICE, having gathered, from *Massage as a Mode of Treatment*, by Dr. William Murrell, that the art can only be acquired after at least two years' practice, and only by practical instruction, asks if this is really the case, as he had hoped to be able to use it after studying the subject from books?

ANSWERS.

H. E. MATTHEWS.—Obviously the proper course is to pursue the necessary treatment, and not to violate professional confidence, which, under the circumstances, is sacred.

HAIRWASH.

DR. MYRTLE (Harrogate) writes: The best application for falling hair or promoting growth of hair is a quinine hairwash made by Schütte and Co. Widmore Quinine Works, Bromley, Kent.

TREATMENT OF STAMMERING.

M.R.C.S. writes: In reply to Mr. E. regarding a publication likely to be of service in the training of a little boy who stammers, I can recommend the *Grammar of Elocution*, by John Millard, Professor of Declamation in the Royal College of Music (fourth edition), which contains, embodied as an appendix, directions and exercises to assist in the removal of stammering. Having been for years, when a child, a stammerer myself, I am able to judge to some extent of their worth, besides having had practical proof of their efficiency. The book referred to is published by Longmans, Green and Co.

TEACHING THE DUMB TO SPEAK.

MR. A. J. JOHNSTON (Nethway, Kingsley Road, Prever's Gates, Liverpool) writes: I am much interested in a girl of about 18 years of age who, through some malformation of the mouth or tongue, has never been able to speak, with the exception of a few words. I believe she has all her faculties and, though small for her age, is undeformed. I am trying to persuade her friends to send her to school, so that she may at least be able to talk with her fingers. My object in writing is to ask if you know of a suitable school where she would be kindly treated.

* It would be a mistake to teach the girl to talk on her fingers, and thus divert her from lip-reading and natural speech. Dr. E. Symes Thompson, to whom we have referred the question, recommends that the friends should pay a visit to the Training College for Teachers of the Deaf, Castlebar Hill, Ealing, W.; the Principal of which, Mr. Kinsey, would be able to give much useful information.

L'HOMME-FEMME: Our correspondent is probably right in his surmise. A certain American writer has stated the percentage of "cultivated" married (American) women who do not possess any sexual feeling to be as high as fifty-six. It should be clearly recognised that the absence of such feelings in a woman does not imply sterility.

NOTES, LETTERS, ETC.

REPAYMENT OF INCOME TAX.

THE INCOME TAX REPAYMENT AGENCY (25, Colville Terrace, W.) write: Allow us to mention in your columns a most important point we have just carried. A medical man in the north of London was last year assessed at £350; this year the notice came in for £400. We made out his statement on our forms, and his assessment was reduced to £300, not only a saving of tax on £100, but giving him a right to abatement on £120, consequently 26 ss. 4d. in pocket this year. But the following is the point we wish to call attention to. We advised our client to make a claim for repayment of tax overpaid last year, basing his claim on the fact that he had paid on £350, whereas he had now proved to the satisfaction of the General Commissioners that his average was only £300. We have just heard from him that he has received a post office order for the amount. We shall be glad to assist others in the same way. Our being able to cite the case to surveyors is a great advantage.

DIPHTHERIA DURING PREGNANCY.

DR. P. O'CONNELL (Chicago) writes: The following may possess points of interest to merit record in the JOURNAL. On December 21st, 1885, I saw Mrs. McQ., aged 29. Both tonsils were so enlarged as almost to meet, and were covered with well-marked, characteristic exudation. Temperature 102° F. The attack was a sharp and severe one. She was out of danger on the seventh day, and sat up for an hour on the eighth day. The urine was albuminous until January 6th, 1886.

When told on the third day of her illness that she was two months pregnant with her fourth child, I was startled, and expected an abortion, with probably fatal termination. During her illness, besides topical applications, she took internally iron with two grains of quinine every four hours. On July 29th, 1886, I delivered her, at full term, of a healthy female child of average size.

Here permit me to ask: Has quinine any action on the gravid uterus? Four or five years ago, if I correctly remember, some of the Indian medical officers said it was dangerous to give quinine for intermittent fevers during pregnancy, as it was pretty certain to induce labour. During the annual meeting of the British Medical Association at Dublin last year, Dr. T. More Madden (*vide* JOURNAL, November 12th, 1887, p. 1045) advised the use of quinine, with iron and chlorate of potash, during the last two months of pregnancy, as a good prophylactic to puerperal fever. I frequently employ it with ergot, strychnine, and capsicum in cases of subinvolution of the womb: also to rouse the uterus to action on sudden cessation of pains during the progress of labour, and always with success. I cannot say, however, if alone it would induce contractions, since I always used it in combination with one or more of the drugs mentioned.

DRUMINE.

JOHN REID, M.A., M.D. (Melbourne) writes: In consequence of the publication in the JOURNAL of Professor Alex. Ogston's report on Drumine, and also of reports published elsewhere, I instituted inquiries as to the action of rectified spirit solutions. I may preface by stating that I have used weed obtained in Victoria (*euphorbia drummondii*), and that I have obtained the alkaloid by boiling the weed in dilute acetic acid, percolating and precipitating with sodium bicarbonate. Solution of the acetate was then made and employed. I have not been so successful in obtaining so well formed crystals of this salt as of the hydrochlorate obtained from South Australia (E.D.).

Substantaneously a solution in boiling rectified spirit has produced the smarting of sp. vin. rec. modified, but no after-effects. Similarly a solution of the alkaloid or salt (previously decolorised by animal charcoal), applied to the scrotum on an eczematous patch, from which the scab was removed, caused first slight smarting and afterwards no pain. Subsequent applications were not felt. Compare the action of rectified spirit alone, in which subsequent applications are very painful. In addition, the disease is cured, scabs, etc., disappear, the intolerable itching and annoyance vanish, and a life of ease succeeds. One or two applications to the nostril cure a common cold. In tonsillitis a single application caused pain and annoyance by swallowing to vanish. Solution in rectified spirits is well preserved, and acts well enough when not used hypodermically; the transitory smarting is not very great excepting where the patient is over-sensitive. A fresh aqueous solution is, of course, preferable.

Recent observation has brought to light that when drumine is heated strongly (to ebullition) with glycerine (as I did in order to obtain solution needlessly), it is evidently in part decomposed, emitting the odour of burnt feathers, or transmitting to the solution, as a friend on whose gun I applied some for toothache said, the flavour of urine. This is interesting only in so far as pointing to a chemical reaction, and ought not to occur if the solution is made at a proper temperature. Some was no doubt decomposed. The fact that the alkaloid causes a precipitate with phosphomolybdic acid has not as yet been reported in the JOURNAL.

This year has been very fatal to the growth of *euphorbia drummondii* on account of the excessive wet; but in all probability it will soon be possible to place drumine in the market, and to allow the profession an opportunity of testing its qualities for themselves. Were it only used for "common colds" and "eczema of the scrotum," its value could scarcely be estimated.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.

A LATE MEMBER OF THE STAFF writes: As the existing Board of Management of this institution has again advertised for two assistant physicians, I think it only fair to candidates that they should know something about the system of management and the circumstances which have brought about the present vacancies.

It is important to know in the first place that these appointments are made by the Board of Management and not by a meeting of governors, and that this board, though supposed to be elected periodically, has not been reformed for some time; moreover, two members of this board can form a quorum. It is doubtful, therefore, whether it has the right to appoint. The appointment again is for no certain period, and the medical officer is liable to instant suspension or dismissal. The vacancies created a few weeks back were filled up, but two of the gentlemen elected finding out the state of affairs and the circumstances under which their predecessors were dismissed, almost immediately sent in their resignations.

The matter appears in reality to come to this. If you do not act with two or three members of the Board of Management, who have, practically,

uncontrolled sway, you will find your position rendered unsatisfactory, and you will sooner or later either feel yourself obliged to resign, or you will be summarily dismissed.

The financial affairs of the institution will probably be investigated before long by an independent inquiry, but the staff of the hospital will never take a high place in the profession nor be respected unless its election, tenure of office, and general course of action are altered.

MR. MORRIS OF ST. BARTHOLOMEW'S HOSPITAL.

MESSRS. ANTHONY A. BOWLBY (St. Bartholomew's Hospital, E.C.) and JOSEPH MILLS (15, Henrietta Street, Cavendish Square, W.) write: A circular has recently been distributed to old students of St. Bartholomew's Hospital stating that it has been resolved to present a testimonial to Mr. Mark Morris, the Steward. It is suggested that the testimonial should take the form of a portrait or bust, to be placed in the hospital; and it is to be hoped that the funds subscribed will be sufficient to allow of some personal gift to Mr. Morris in addition. The precise form, however, of the testimonial will be left to the decision of the subscribers. Mr. Morris's connection with the hospital and school extends over a period of forty-seven years; and although it is hoped that he may long continue to fill his present post, it is felt by many that the time has arrived when his long and valued services should be thus formally recognised. All who have been brought into contact with Mr. Morris must be well aware of the tact and judgment he has always displayed. His kindly consideration for others, his constant good nature, and unvarying willingness to render assistance must be especially well known to those who have held office on the resident staff. Subscriptions, which should not exceed two guineas, may be sent to either of the Honorary Secretaries.

COMMITTEE.

COMMUNICABILITY OF SYPHILIS THROUGH THE SALIVA.

DR. P. M. CARLETON, Surgeon M.S., in reply to Mr. Cooper's question with regard to the ease of communication of syphilis by the saliva, published in the JOURNAL of December 24th, writes: The tattooer contracted the primary sore some years ago, and before he became a soldier. At the time he was admitted to hospital, which was a few days after the tattooing was performed, he had painful nodes on the frontal bone, and one on the left clavicle extending to and implicating the sterno-clavicular articulation. There was rather obstinate enlargement of one testicle. There was no lesion of the mouth, but there was a mucopurulent discharge from one nostril, and other symptoms of post-nasal mischief were present. This may no doubt have been the source of contagion.

With regard to the other man, who has been discharged from hospital, he had a characteristic copper-coloured rash distributed in patches over his whole body about the time that the sores on the forehead had healed. In this stage he was seen several times by a civilian professional friend.

I have no doubt (1) this man contracted syphilis as the result of the tattooing; (2) that it was through the saliva of the operator. But, that the saliva *per se*, and not as the vehicle for some other discharge, has the power of conveying the virus from a syphilitic patient, the evidence is not quite conclusive.

HOW SHOOTING ACCIDENTS ARE TO BE AVOIDED.

DR. JOHN RUXTON, late Leicestershire Regiment, recommends, as means to prevent shooting accidents:

1. Impose a tax on all firearms except sanctioned by Government, and on all who use or borrow them, besides their owner, levying a heavy fine in case of non-compliance.

2. Make the very act of pointing a firearm at, or in the direction of, any person, a criminal offence.

3. In cover-shooting, the head of a party ought to call both shooters and beaters together, and obtain their sanction to the rule "that anyone using a gun who is seen interfering with trigger or hammer while the gun is pointing in the direction of any person, either when walking in line or crossing a fence, should be at once disarmed, and become a heater for the rest of the day." The discipline of keeping in line must be very strict; the gunners who walk with heaters should halt 120 yards from end of beat; heaters advance, leaving all winged game going forward to guns placed in front, and all going backward to those behind, neither firing till bird has risen well; ground game to be shot only when it has passed either set of shooters. After beat is completed, the forward guns and beaters may again drive back to other guns, observing similar rules of shooting. Excitement will thus be minimised, and a good average of game bagged.

4. To grouse driving the butts must be sufficiently low in front to allow free scope for shooting game coming towards one, and sides so high that shooter cannot fire into butt at either right or left, even if wishful to do so. To accomplish this, the floor of the butt must be excavated, and trenches dug at the lowest parts to allow escape of water. The back of the butt must be open to give full swing at game which is passing low, or has passed. The keepers and beaters to whistle loudly when within 150 yards of butts, after which no forward shots may be fired. The shooter on no account to leave his butt till heaters have passed him.

THE PARASITIC ORIGIN OF MALIGNANT GROWTHS.

DR. HARRY CAMPBELL, M.D., B.S. (Lond.) writes: The following is an abstract of a paper which was prepared some time ago independently of any published writings on the parasitic theory. As much has been recently written on this subject, it is unnecessary to give more than an abstract of my paper. I shall dwell chiefly on such points as have hitherto received little or no attention.

Malignant tissue is of inferior value to that of the surrounding parts; the change is retrogressive; it is not, as in development, a change from the homogeneous to the heterogeneous, but the reverse. Herbert Spencer, indeed, especially singles out the malignant growths as exceptions to his great principle of evolution, assuming that the change is from the homogeneous to the heterogeneous. A careful study of their structure and mode of growth would seem to show that this is not so. The tissue of sarcoma is of a very elementary order, but the carcinoma have no such simple structure, but there can be little doubt that, in their case also, the change is a backward one. In the squamous epitheliomata the epithelial cells dip down as in the development of all open glands, but the down-growing cylinders never become hollowed out. The glandular tissue is therefore of a very crude immature form. In the cylindrical-celled variety a more perfect variety of tissue is approached; for the cylinders contain a distinct lumen; nevertheless, the process is disorderly and the gland tissue, taken as a whole, is decidedly imperfect. In the acinous form of cancer the glandular type is maintained, but it is of an erratic kind. Wherefore we may say that the carcinomata consist of an immature and disorderly form of gland tissue. But the malignant change is not of the nature of a simple degeneration, for along with the deterioration in structure there is an actual increase in tissue activity.

In considering the etiology of malignant growths, it is very necessary to decide how far the malignant tissue is due to a simple transformation of the affected tissue, and how far it results from a multiplication of the few cells initially constituting the tumour. Although primary carcinoma is largely a transformation, yet it is certain that many of the cells are derived by a multiplication of the cells already constituting the tumour. Elements are everywhere present to share in the formation of the growth; for when it spreads to tissues in which there are no epithelia, the growth is evidently solely by a multiplication of the cells already belonging to the tumour.

My view of the matter is this: Under the bacterial irritation the tissues are unable to keep at their normal level, and revert to a tissue of a lower order, thus exhibiting some one or other of their many potentialities. The type of morbid tissue thus produced depends (1) upon the nature of the tissue primarily affected, (2) upon the nature of the parasite. We have seen that the secondary growths are not always due to the transformation of the affected tissues, wherefore the theory of reversion cannot apply to such cases. Such secondary growths depend, I believe, upon the transference of tissue cells *plus* the bacteria from the seat of the primary affection. Under the specific parasitic stimulus these transported cells take on the same morbid action as at the primary seat of infection by virtue of their potentialities. It is impossible, however, to deny that cells of the tissue secondarily affected take some share in the process. There are probably several varieties of "malignant" bacteria; the carcinoma parasite must be quite different from that causing sarcoma.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE "BRITISH MEDICAL JOURNAL."

Seven lines and under	£0	3	6
Each additional line	0	0	4
A whole column	1	15	0
A page	5	0	0

An average line contains seven words.

When a series of insertions of the same advertisement is ordered, a discount is made on the above scale in the following proportions, beyond which no reduction can be allowed.

For 6 insertions, a deduction of	10 per cent.
.. 12 or 13	20 ..
.. 25	25 ..
.. 52	30 ..

Special terms for occasional change of copy during series:

20 per cent. if not less than 26 pages be taken	} or their equivalent	
25 ..		in half or
30 ..		quarter pages.

For these terms the series must, in each case, be completed within twelve months from the date of first insertion.

Advertisements should be delivered, addressed to the Manager at the Office, not later than noon on the Wednesday preceding publication; and, if not paid for at the time, should be accompanied by a reference.

Post-Office Orders should be made payable to the British Medical Association, at the West Central Post-Office, High Holborn. Small amounts may be paid in postage-stamps.

AN ADDRESS ON OUR HOSPITALS AND THE INTERESTS OF PATIENTS AND PUPILS.

*Delivered at the Annual Meeting of the Dublin Branch of
the British Medical Association, January, 1888.*

By EDWARD DILLON MAPOTHER, M.D.,

President of the Branch; Ex-President of the Royal College of Surgeons,
Ireland; Consulting Surgeon to St. Vincent's Hospital, Dublin.

DURING the past year our Branch has been moved towards the provision in Dublin of proper opportunities for pathological study, and a Blue Book of extreme value, touching the curative and educational facilities of our hospitals, has been presented. On these topics I propose to briefly comment, being, of course, solely responsible for any suggestions offered. The financial points, and the modes of government and of election of officers, will not be dealt with, having regard for your patience and my own unfitness.

The teaching of pathology, macroscopic and microscopic, is at a low ebb in Dublin, a city in which an active society originated an interest in the former. The number of hospitals, general and special, will bar all progress unless consolidation or, at least, association is brought about. The physicians and surgeons cannot, and I fear their pupil assistants will not, give time to a full examination of all the organs, and the decent re-arrangement of the cadaver. The proceedings will occupy from one to two hours, even when, after removal of the viscera, the spinal cord is taken out by cutting the bodies of the vertebrae from the pedicles by chisels, spurred for each side—a quick way I lately saw worked in Vienna. It is usually thought better that the officers of lying-in hospitals should not undertake *post-mortem* examinations. In each of the ten general and six special hospitals there could not be a teacher of pathology. It seems to me that the two great bodies in Dublin which alone have pathological museums should found chairs. In one there is a great teacher of the most cognate subject, whose competency is unquestionable, and who might find time; in the other there is an officer of good promise; but teaching has been forbidden, although a hundred years ago the system of demonstrating such specimens was there in vogue. The stipends should come from the conjoint bodies and the University, on condition of free admission to all candidates who had passed the first half of their examinations; and from the usual school fees from others. The physicians and surgeons would give notice of any case desirable for examination, and of course they will rejoice to have their diagnosis tested by a pathologist who only sees the specimens. The rough duty should be done by trained workmen who would bring the valuable parts for full examination and preservation to those colleges respectively.

As such specimens would be varied and irregularly supplied, it is only in these museums that systematic courses could be given. A line drawn north-west to south-east from the Midland Bridge, North Circular Road, to Leeson Street Bridge, fairly bisects the city. The hospitals which might thus group with Trinity College would be the Mater, Rotunda, Jervis Street, Sir Patrick Dun's, Baggot Street, St. Joseph's, the Adelaide, and Mercer's; and with the College of Surgeons, the Richmond, Stevens's, Combe, Meath, Cork Street, and St. Vincent's, each group containing about 550 beds occupied, but let the selection be by fitness, affection, or in any other way. The pupils of each hospital would attend the necropsies in it, but only those franked by the colleges or by the special fee would be present in the museums at the systematic courses, including pathological histology.

As children's bodies are not procured as dissecting subjects, examinations of them in some of these dead-houses would supply a want in anatomical science. Hereafter changes in the Royal University might demand readjustment of the project.

It could not be contended that in three of the schools of Dublin, as at present constituted, a full course of pathology could be delivered, or that the teacher could be fairly paid for exhaustive labour in this most expanding of our sciences. The same being

true of many other subjects, especially the purely scientific ones, wherefrom the stipend cannot exceed £100 a year, so that earnest and original work cannot be hoped for, is it not time that individual interests and sentiments should be merged towards an amalgamation of schools? Amongst other great things then attainable would be the establishment of a residential hall. However, these topics are to be discussed in a practical way elsewhere.

Post-graduate courses have long been popular in America and on the Continent; for instance, three hundred often attend the Polyclinic in New York. In the great hospitals of that city the ordinary clinics are very thinly attended—examination instead of education being in view—and the better class, after passing, either work in their own hospitals or come to Europe to adapt themselves for immediate scientific practice; but some may trespass on the public field without fitness.

Our licensing bodies could encourage clinical and pathological work by setting those studies alone for the final year's examinations; but do our hospitals give opportunities? If an officer of a few years' standing in the army, navy, or dispensary services hopes to refresh or to mark his fitness by passing for the Fellowship of the Royal College of Surgeons, he can in Dublin efficiently study the diseases of the eye, of the female organs, and of children; but in the present subdivided way, groups of diseases of skin, heart, lungs, joints, digestive and urinary organs could not be presented in number and variety for the three or four weeks' course which the practitioner could attend. Several hospitals could unite in giving instruction for a common fee. The Fellowship examinations will now be held at three stated periods, and the courses might be fixed accordingly. In London and in English provincial towns, Leeds for example, large hospitals have afforded these opportunities.

In Dublin it would seem that, with an examination ahead, none but the old lines will be voluntarily followed. For a fee of five shillings, third and fourth year students can attend the splendidly instructive meetings of the Royal Academy of Medicine—a privilege unknown elsewhere—but of some six hundred students who could do so six have entered. Attendance should be made compulsory for fourth year students, if pathological courses cannot be arranged.

In the winters of 1852-53 such masters as Crampton, Corrigan, Stokes, O'Ferrall, Mayne, R. W. Smith, Adams (omitting the living), taught in the Pathological Society pupils of my day, and, besides the knowledge we could imbibe, they filled us with pride that our country had such grand exponents of medical science. As a sanitarian, twenty years ago, in my Lectures on Public Health, and in my Carmichael Essay, I urged that fever wards, or even adjoining buildings, should not be connected with general hospitals; otherwise, despite all efforts, infection will be spread by nurses or students. Still less should they be parts of our work-house hospitals. I never tire in quoting Corrigan's axiom, laid down in 1846, regarding this point—"Sickness should not be made a chain to drag a man into a poorhouse." Convalescence from fever being slow, such patients would be necessarily associated with paupers; Cork Street Hospital, come the money, whence it may, must be supported as a well-sited and admirably worked institution, having separate buildings, all extensible for epidemic pressure of any variety. It largely serves the adjoining townships, Rathmines and Kilmainham. So also is the Hardwicke needed for the north half of the city and suburbs. Its site is very good, sufficiently isolated from the union buildings and from houses. If there was not accommodation enough on the north, the south side would have to bear the expense of its patients, which is plainly unjust to the taxpayers there.

But surely there is wanted for the east, and for the Pembroke Township, a fever hospital. If Sir Patrick Dun's be not fully available and a new site be wanted, the waste ground on the Pigeon House road, either east or west of the Coastguard Station would suit; and so infectious cases—small-pox and cholera especially—reaching us by sea could be easily intercepted. The new road, running from near Irishtown Church, makes the place easy of access, and after disinfection there is a safe outlet for the excreta by the main of the Rathmines and Pembroke Townships to near Dublin Bar.

The two late small-pox warnings (for happily they were no more) give some hints of value. On August 20th, 1887, a Dublin shopman stayed with an officer of an institution in Ulster who had visited a small-pox patient, he being safe, so that our citizen suffered through a middle person. He lay ill for five days, and on September 1st, when the rash had been three days very largely out,

was admitted to the Hardwicke. Vaccination and very complete isolation of the eight inmates of his house, burning of their clothes and bedding were instantly carried out, and thence no other case has arisen.

In October a foreign sailor, with some unrecognised rash, lodged in Grant's Row, and the illness of an unvaccinated child was afterwards concealed for days. On the 26th she was removed to Cork Street Hospital to die, that being the only fatal case. From this focus nine cases were traced. One came to hospital well smeared with sulphur ointment. Oh for the diffusion of dermatological knowledge!

The only case arising far off was that of a lad who sent his washing to that district, and he produced the disease in Portobello. After seven weeks' freedom a child with the disease was unnotified from this district, and up to the present five cases are traceable to this nest. Small-pox being palpably enthetic, and cholera being as clearly importable, any person, peer or pauper, suffering therefrom should be forced to go to hospital, if he happened to be one of the first ten cases after an absence of the contagion for three months. So many foci would have been then set up, and the preventive steps would be so expensive—for instance, £20 was demanded for loss of clothes by one of the recent patients—that the ordinary steps for stemming epidemics must suffice.

After many years of freedom some imported cases were, in 1872, concealed in Malpas Street, and thence arose an outbreak (the word "epidemic" has no meaning here, if, indeed, it has anywhere), and over 20,000 cases were recorded for Ireland. In 1885 a case taken into a general hospital, Montreal, infected many patients; by them outside it spread, 3,000 deaths occurring in a few months. We are not sure that other zymotics may not in like way be scattered.

In Cheltenham all classes submit to isolation in hospital, and thanks to this, after six separate introductions of the disease, it has never gained a footing. Some of our hospitals which admit other zymotics refuse small-pox, as it has nearly always burst the bounds.

The Public Health Act, 1878 (sect. 141) authorises the removal of an infectious case improperly lodged to hospital, but does not enforce its retention there. However, any unsafe patient leaving could be punished under the next section, or arrested for larceny of hospital clothing, if such had been supplied. A hospital for treating children with infectious diseases is most desirable, but Dr. Gairdner, our President-elect, reported in 1864 (being then Medical Officer of Health for Glasgow) as to the difficulties in its way:—

"As a general rule, the habits and traditions of the family life, even in the most poverty-stricken and degraded classes, oppose an insuperable barrier to the removal of very young children; nor, even if the consent of parents could be obtained, are the means of treatment in hospitals adapted to such cases. It is, therefore, with a feeling of complete helplessness that the sanitary officer sees such diseases as measles, whooping-cough, and scarlet fever running riot in the houses of the poor; he feels that in most instances nothing can be done beyond a general instruction to open the windows, and attend, if possible, to cleanliness. In some instances he is paralysed in the face of greater emergencies; he has no power to enforce removal, even should an infected family settle in a crowded neighbourhood hitherto free from disease; he cannot disperse a school in which cases of infection have occurred, and any attempt even to give publicity would only result in their more careful concealment. Even, as has repeatedly happened within our observation, provisions are publicly sold from infected apartments. In one instance a woman with the eruption of small-pox actually on her hands was found selling sweetmeats to the children of a school in her neighborhood. In this instance a threat, partly of exposure and partly of legal consequences, put an end to the scandal; but legal remedies can have a very limited application, and self-interest will often be much too strong for all suggestions proceeding merely on public grounds. In truth, the spread of epidemic disease among children can hardly be met otherwise than by the gradual diffusion of enlightenment, and by the improved habits which may arise from the remodelling of the dwellings of the poor over a long course of years."

Every general hospital should have observation wards in which cases indefinable for two or three days could be lodged, and there the students would learn much, but only in great special hospitals would they see enough of all infective maladies. Let us, however, restrict the attendance at fever hospitals to third or fourth year

men. Fresh country youths take infection most readily, and cannot profit in exchange for the risk. When they have worked at such subjects as the non-infective lesions within the thorax and abdomen, the ordinary rashes, the treatment of bed-sores, distended bladder, and the like for three months, or at most six months, they should acquire the power of applying such information in the fever hospital, where such complications arise. An equal period usually suffices for the gain of ophthalmic and aural, and of obstetric knowledge. The fee should be subtracted from that of the general hospital, and on hygienic grounds the fever months should never tally with those of work at midwifery. Kept at fever alone students will master the subject in a few months; but, reaching the hospital after earnest work at a general hospital for a couple of hours, their receptivity of learning would be very much less.

In this country fevers are fortunately becoming less endemic, and our graduates who go abroad will have to learn what they could not study here of other localised pests.

The hospital which Surgeon George Doyle founded in 1755, the Lock, was the most difficult which the Commissioners had to deal with. However, every benevolent citizen will feel that such a separate refuge must exist, as it would be grossly wrong to mix the fallen with the virtuous poor, and to put them into separate wards would be equal to branding them with "the scarlet letter." The dress and manner of their female visitors, decently as they might strive to act, must be objectionable. There should be power to keep these patients till cured, or at least contagionless, provided they had signed on entering an agreement analogous to that by which the drunkard can imprison himself for twelve months.

But surely the cases in the Lock can be studied by senior students, or at least by post-graduates, without fear of moral contagion. In other hospitals venereal diseases, except those in the female genitals, can be freely seen, and there can be no objection to carry suitable patients, with faces fully veiled, to the theatre, the students having access there alone. The small fee which should be charged should be allowed in the total expense of hospital education. If surgeons are not taught the mode of recognising chancres in females who subsequently become mothers, racial degeneration must ensue, and wrong diagnoses in family practice may ruin many a household.

Two facts point towards a change to be wished for as regards the eye and ear hospitals, and against their specialisation; they are but 370 yards from each other, and four of their six officers teach in general hospitals. In two other hospitals there are ophthalmic surgeons, so that in Dublin we have eight eye clinics. What can be the objection to attach all their strength in the latter places consolidated, as vastly more available to patients and pupils, all appliances being, of course, fully provided in place of those generously supplied in the present special institution?

Again, is it not regrettable that so many orthopedic cases are diverted from the general hospitals, where students could profit by them, to the one special institution; the more so as the specialist there would be so remarkable a gain to the staff of any large hospital which established such a department?

Since Evory Kennedy's great paper in 1869, with a most exhaustive debate for seven nights, I have felt that lying-in hospitals ought to be limited to cases in which difficulties had been foreseen, or in which very special circumstances compelled the removal of the expectant mothers. In the normal state of any community, surely the home, be it ever so humble, is the fit place for the function of childbirth; affectionate aid is assured for the mother, and she is able soon to direct at least the care of the household. Removed from it, her anxieties must tell against her well-doing. When Mosse founded the most famous lying-in hospital in the world, the rooms of the poor were so filthy and crowded that removal of the parturient was necessary. White-law's survey in 1798 showed great density of population. For instance, in St. Luke's Parish, 15.95 per house; in St. Michan's, 12.56; and in Plunkett Street, over 28. Half a century before, when Mosse began his enterprise, the population was, it is believed, 200,000 in much fewer houses. Now our working class are better housed, and every year improvement goes on; so that we hope for better things, even in this poor-laden town. Take the cases of the two healthiest English towns: in the lying-in hospital of Brighton, with about 120,000 inhabitants, twenty-five deliveries yearly take place; and in Hastings, with 60,000 people, there is no such institution at all. I do not urge the crippling of such general hospitals as the Rotunda or Coombe, but that they should tend toward spreading their functions as hospitals for diseases of women, and

by their maternities succouring those who lie-in at home by the best medical and nursing skill, and by food and clothing. The Bill of last session would disendow them unless they had at once 80, and after five years, 100 occupied beds, although the Commissioners waived that point in their favour.

In 1854 the Master of the Rotunda, at the House of Commons' Committee, was asked: "Do you afford any external relief to lying-in women?" He replied: "Not ordinarily; in an extreme case, if they send to the hospital for assistance, we send one of the senior pupils or assistants."

Since then changes have gradually tended towards using hospitals for the troubles of parturitive science. Is not the adjective just used better than that perversely derived word "obstetric?"

I still warmly favour the plan which Earl Spencer conceived, and which mainly moved him in appointing the Commission—namely, the abolition of the Richmond Hospitals (a title far better than their usual inclusive appellation or separate names), and of Steevens's Hospital, and the erection of a new medico-chirurgical building, Cork Street, to be the fever hospital in connection. Some degree of unfitness of the Richmond surgical block, and the sites of all on the edges of the city remote from medical schools, were good reasons for the change. A site near Christ Church has been proposed, and Steevens's would be 1,370 and the Richmond 900 yards distant therefrom. A large, cheaply available space in and about Meath Market, Thomas Street, would give a healthier site, more convenient to the terminus, the great breweries, distilleries, and barracks, and the Kilmainham township. Even greater advantages would result by the clearance of ruinous tenements. The Richmond, Steevens's, and Cork Street Hospitals would be respectively 1,150, 840, and 660 yards distant.

This Western Hospital, as it might be named, could be built on the most modern hygienic principles without extravagance, and the sums got by the sale of the Richmond and Whitworth (that the North Union wants these premises is only an enhancement of their value), and Steevens's would go a good way. The great manufacturers and merchants who abound in the district would be generous towards a building fund. For maintenance, surely institutions which for over a third of a century have been well earning half the Government grant would be still worthy a large share, and the properties of Dr. Steevens and Edward Cusack (the larger donor, whose name is so usually ignored), although now depressed, are of considerable value. The financial fact just stated appeals against any sentimental objection to the abolition of a name. In olden times the remoteness of Steevens's, although its teachers were illustrious, kept away a class except that resident—now the staff is strong and progressive, but their energies are wasted for want of learners.

If there was any hospital at all contiguous in which the governors and officers (if these designations were there separable) did not form a happy family, perhaps an adroit peacemaker might bring about a union more or less complete. No hospital should be "an incompatible," to use a pharmacist's expression.

In contrast to the medical staff domination just hinted at stand out the charters of Sir P. Dun's and Jervis Street, which exclude the medical officers from their committees.

If the fusion of the Richmond Hospitals and Steevens's be not favoured, surely the former tried friend of the poor need not be wiped out because the adjoining workhouse covets its premises. Rather let the guardians send their serious acute medical and surgical cases on fair payment, as at present they do their fever patients; the pauperising point would not arise, as State funds would be still available; or let them buy one or two of the buildings, when the remaining could be converted into an improved medico-chirurgical hospital. The facilities for taking grounds for hospitals should be at least equal to those under Railway Acts, and thereby the persistently noxious dairy yards in front of the Whitworth Hospital would be cleared.

If the Richmond Hospitals be abolished or consolidated in the south-west, north Dublin could be hospitalised by the Mater Misericordie, of great available capacity, and by Jervis Street Hospital, also of great capacity. They are 1,370 yards asunder, and they are distant from the Richmond 1,150 and 800 yards respectively. Then as a North Fever Hospital, the Hardwicke or the Whitworth (which slight changes would make a more suitable building) should be maintained. It would serve for the classes of the Mater and Jervis Street, and fever might be ex-

cluded from the former. The Sisters of Mercy nurse these hospitals and those of the North Union, and we may feel sure that these devoted ladies would gladly extend their ministrations to the adjoining fever hospital, funds for the patients' support being derived from the State, the Corporation, or the North Dublin Union, or all proportionately.

Both the Commissioners and the framers of the Bill of last session propose to deal justly with the officers of the Richmond Hospitals, and doubtless the Treasury will do so if a Government Bill be introduced. To deprive these eminent physicians and surgeons of their clinical facilities would be somewhat like closing law courts to some leading Queen's Counsel, and our brethren should get as ample compensation as the latter assuredly would in a like case. The agitation for change during the past three years has, of course, lessened the classes, and the suspense has injured the interests of the officers.

On the south side two institutions, which are but 700 yards asunder, showed symptoms of conjunction—Sir P. Dun's and the City of Dublin. To avoid costly building, surely they could join their classes, and keep one hospital for surgical, the other for medical cases; or let Baggot Street be enlarged to accommodate both these classes, and let Dun's be the great Eastern Fever Hospital. If, as urged, infectious cases be treated apart, poor patients thus afflicted should not be carried to the Hardwicke and Cork Street Hospitals, across two-thirds of the city from the eastern edge and the Pembroke District. Of course that wealthy township should be roused into greater generosity than appears in Dr. Haughton's justly indignant evidence.

The Meath Hospital is of good size, and is just completing considerable additions, and serves a most extensive area. If its fever cases, which mainly come from country districts where they should be treated, were diverted to Cork Street, and the £600 a year it has received for their treatment was applied to general cases, this old and famous clinical institution should be regarded as a large hospital.

Of St. Vincent's, with which I have been connected nearly thirty years, I will only say that, although it is large as regards occupied beds and paying pupils, the managers desire to acquiesce in any conditions which may increase its usefulness to the sick poor and to the cause of medical education. Its distances from neighbouring hospitals are, to Mercer's 740, to Meath 1,000, yards.

Here a *précis* of South's separate report, which has not been brought enough to the front, perhaps because two large hospitals had not been then founded, and others have been enlarged. He would lessen our general hospitals as follows:—North side: Move the hospital at Jervis Street eastward to a larger building on a better site, and leave the House of Industry for the north-west. On the south side of the Liffey, combine, as regards funds, management, and staff, Steevens's and Cork Street—the former as the surgical house, the latter as the medical and fever departments. Such would be the south-western hospital, and the south-eastern he would constitute of "Sir Patrick Dun's, the Meath, and Mercer's, or, in its stead and united with it, the City of Dublin Hospital." The first to be the medical, the second the fever house, and the surgical building to be provided by the enlargement of Baggot Street buildings, that in Mercer Street being abandoned. Mercer's and the Adelaide are within 340 yards of each other, and the latter is 500 yards from the Meath.

His views were, however, dominated by the erroneous idea of having the scientific medical schools necessarily combined with hospitals—a system not to be thought of here.

There is only one piece of evidence in the Blue Book to which strong language might be applied. It is as follows:—"The police have instructions to bring all cases (accidents) occurring on the south side of the city to (blank hospital), except those occurring near the steps of another hospital, and to (blank hospital) on the north side of the city." The instructions always have been to bring accidents and other cases wanting prompt relief to the nearest hospital.

It may be well to state very briefly some of the advantages which would follow the reduction, say by half, of the general hospitals, by consolidation or otherwise.

Clinical positions are too numerous—twenty-five physicians, thirty-eight surgeons—beds being, therefore, relatively too few. Mr. Thomson's evidence on this point is exhaustive. With wider fields, greater additions would be made to medical knowledge. Although Dublin has done her duty in the training of practitioners, her original observers and positive additions to science might have been more numerous. Thus may be partly explained the striking

fact that not one Dublin practitioner holds a British or foreign honorary degree. Last year alone our licensing bodies conferred thirty-three upon strangers. Such distinctions here would tend towards checking party and personal favouritism, which is extinguishing the ambition of honest scientific workers. In England, and still more on the Continent, every year hospital and Governmental medical posts are becoming more assured as the rewards of special fitness.

A large hospital could afford a resident physician and a resident surgeon, either to be present at all hours to instantaneously meet emergencies.

If in an enlarged institution the class becomes unwieldy it could, and indeed in any case should, be divided amongst different teachers, according to the four years' curriculum now definitely settled.

Some patients are over-treated, or often treated, as they have so many hospitals or dispensaries close by and free, and are trained to become the veriest hypochondriacal bores.

Amalgamation will be justly brought about if the general hospitals must show, seven years hence, a minimum of 150 occupied beds. It is always well to quote points which may be cited against as well as for an argument. On November 4th, 1811, the College of Surgeons decided not to recognise any hospital which had less than twenty beds. How grateful should the poor patients and pupils of Dublin be that they do not live under the system of "the good old times." The application for recognition was from a building in Peter Street with twelve beds, the property of the surgeon.

It is clearly just that the Corporation grants, reaching £5,000 a year, should be in favour of citizens only, and that other authorities, townships, poor-law guardians, and the like, should contribute to the support of patients from a distance. This is already done with us in the ophthalmic hospitals, and in the case of a few fever patients, and is universal in Continental hospitals.

If the hospitals be governed by a board for the allotment of the public funds, the Continental system of a central bureau whence applicants would be drafted to the several institutions seems inadvisable, as the poor as well as the rich should have the power to seek advice from any physician or surgeon whose fame had attracted them. Our city is too small to need such a system.

That Dublin has a right to the grant every one of the State reports show, especially for the support of the education of public medical officers; that it has a need for it was most forcibly expressed by the House of Commons' Committee (numbering fifteen), in 1854. "It is a metropolis for the poor, but not for the rich. The value of its property has within the last fourteen years decreased, while local taxation, population, and pauperism have increased." How sadly intensified does the statement apply today, the only statistical fact changed—smaller population—telling for the argument; year by year our higher class go, the poorer crowd in.

All the suggestions in this brief address are made with due humility when so great a topic has to be faced, and if any one of them shall prove of value it will not have been written in vain. Incidentally, approval of the report of the Commissioners has been noted, but it is right to say that this Blue Book, unanimously signed, is, from that astounding circumstance and its own merits, a gem.

BEQUESTS AND DONATIONS.—Mrs. Hannah Sarah Chadwick, of Balham, bequeathed £1,000 each to the Earlswood Asylum for Idiots, the Royal Free Hospital, the Hospital for Consumption and Diseases of the Chest, the Charing Cross Hospital, the Middlesex Hospital, and the Western Dispensary, and £600 to the London Fever Hospital, all free of duty, and £26,966 13s. 4d. consols subject to the life interest of her sister, and to the payment of legacy duty, to the Westminster Hospital.—The Bolton Infirmary has received £3,500 under the will of Miss Alice Lowe, of South Shore, Blackpool. Mr. Francis Deakin, of Eastbury, Watford, Herts, bequeathed £100 each to the General Hospital, the Free Hospital for Sick Children, the Eye Hospital, and the Queen's Hospital, all at Birmingham. Mr. Thomas Mack, of Seabank, bequeathed £200 to the Kilmarnock Infirmary.—The Sheffield General Infirmary has received £100 under the will of Mr. Edward Hudson, of East Cliffe.—The annual report of the Committee of the Northern Hospital, Liverpool, acknowledges the receipt of £1,000 under the will of Mr. G. H. Thompson, £900 under that of Mrs. A. M. Heywood, £500 under that of Mr. Roger Lyon Jones, and £200 under that of Mr. Robert Little.

A LECTURE

ON

THE THIRD STAGE OF LABOUR.

Delivered at the Post-Graduate Course in Edinburgh.

By A. H. FREELAND BARBOUR, M.D., F.R.C.P.E.,

Lecturer on Midwifery in the Edinburgh Medical School; Junior Assistant-Physician to the Maternity Hospital; Assistant-Physician for Diseases of Women to the Royal Infirmary, Edinburgh.

THE third stage is undoubtedly that part of normal labour which is of the greatest interest and importance to those of us who are engaged in midwifery practice. While with regard to the management of the first and second stages there is not room for much difference of opinion, each of us has his own ideas with regard to the third and has formulated for himself rules for its management.

To turn this demonstration into a vigorous and interesting discussion, I should only need to propound the question, What would you recommend as the best mode of managing the third stage? But if we were asked on what basis our principles of management rest, we should have some difficulty in replying. Probably, we should not venture to say more than that our midwifery experience has taught us that it is best to do so-and-so; in other words, our management of the third stage is not yet scientific, for our knowledge (or science) of this stage is as yet in its infancy.

Let me suggest some very elementary points which we do not know. 1. When is the placenta separated? 2. By what means and in what way is it separated? 3. How are the membranes separated? 4. How are the placenta and membranes expelled? 5. What is the natural mode of stopping bleeding from the placental site?

And I need only mention, in passing, a number of more remote questions, questions bordering more on pathology, which start up at the same time. What is adherent placenta? Why are membranes most often adherent round the lower portion of the uterus? Why should a bit of retained placenta in one case endanger the patient's life, immediately from hæmorrhage or after a day or two from septicæmia, and in another be apparently harmless? What is the relation of endometritis to retained fragments of membranes?

I should like this morning to say something with regard to a few of these questions; not so much, perhaps, in the way of answering them as of seeking to define the present state of our knowledge.

1. First with regard to the time at which the placenta is separated. And here we must frankly admit that we know at present nothing definitely as to when this occurs. It has been taken for granted by many that the placenta begins to be separated during the second stage; that is, when the child is being born. Of this no proof has been advanced. The only clinical fact apparently supporting it is the appearance of asphyxia in the child if it lies for a little with only the head born. But the interference with the placental circulation which this asphyxia implies, may be due to compression of the cord, or to disturbance in the circulation of the placental site from uterine contraction and retraction.

We shall see when we have discussed the mode of separation that there is reason to believe that the placenta is usually not separated until, at least, the commencement of the third stage.

2. By what force, and in what way is the placenta separated? Though I have thrown these two into one question, they are quite distinct; and the non-recognition of the difference has led to great confusion. When we are asked, "What is the cause of the separation of the placenta?" we have, like the proverbial Scotsman, to answer with a question, What do you mean by "cause?" Do you mean the forces which effect the separation or the mode in which they do so?

There can be no hesitation, I think, in answering the first of these queries: the force is labour pains or uterine contractions; not the pains of the second stage but those of the third, the evidence for which we shall refer to later on. Gravity, which is the only other efficient force in labour, scarcely deserves serious con-

sideration, from the small weight of the placenta relatively to its extent of attachment and from the patient's being recumbent.

As to the second part of this question, "In what way is it separated? How do the pains act?" The old view was that they operated by diminishing the area of the placental site. The placental site diminished in area; the placenta was unable to follow it, and hence it separated. In the German school, of midwifery, effusion of blood between the placenta and its site has been held to play an important rôle. Baudelocque speaks of the occurrence of blood-effusion, but it was Schultze who formerly taught that it was an important factor in separation. Most of you will be familiar with his drawing, which has passed into many of our textbooks; in it the uterus is represented like a thick walled inverted bell-glass, and the placenta at its mouth like an inverted sucker with a large blood-clot behind it.

While still asserting the importance of this retro-uterine hæmatoma, German writers are changing their standpoint, as to its mode of production. From Ahlfeld's account of it, we should gather that the uterine contraction made the placenta spring up and aspirate blood between it and the uterine wall. But this implies that there is bleeding during a contraction. Cohn, a more recent writer on this subject; makes the placenta sink down by its weight in the interval between the pains, and thus draw blood in. Further, a fall in the intra-uterine pressure, consequent upon the emptying of the uterine contents, has been brought forward by another recent German authority (Stratz), as explaining why the placenta, which should (if the German view be correct) separate during the second stage, does not as a matter of fact do so till the third.

And here let me warn you against the fallacious view of regarding the placenta in the uterus as a piston in a pump—the placental site of course being the marshy ground, in which the sinuses are like springs. It is a fascinating theory, and I could construct a beautiful picture from the similitude; but the analogy breaks down at every point. For the placenta has not the consistence of a piston; the genital tract is not like an iron cylinder. The pump theory will not work. In fact, the physics of the third stage offer so many pitfalls to the unwary, that a man would need to know his ground well before we could accept as a guide either him or his new hypothesis.

With regard to this question of how the pains act, let me give you two facts:—

(a) That the placental site can diminish to an area of $4\frac{1}{2}$ in. by 4 in., or until the uterus has nothing in it but placenta, without the placenta being separated; (b) that there is no cavity in the post-partum uterus.

These are facts the demonstration of which you will find in the first pamphlet¹ put into your hands this morning. These are facts. Now let me give you my view of the production of separation. You will find it stated in detail in the concluding paragraphs of the third pamphlet.² "Diminution in area beyond that (4 in. by $4\frac{1}{2}$ in.)+the action of the uterus as a whole on the placental mass, I regard as the formal cause; the pains of the third stage as the efficient³ cause of separation." "The third stage I regard as a second labour in miniature. After the pain that expels the child comes a pause, during which the placenta is still as a whole or in great part attached; then labour comes on again, and the placenta is first detached and then expelled. This second labour is not always marked off by a distinct interval from the first; sometimes one long pain expels the child, and then detaches and expels the placenta." Note that it is the "action of the uterus as a whole," not merely "contraction."

3. How are the membranes separated? In one word, by crumpling up and stripping off. What I am about to describe is what happens in the Porro uterus, as we have not yet seen the process in the normal uterus. When the uterus is emptied of its contents in Porro's operation the different layers of its walls behave differently. You will find the detailed account of how they behave in the second pamphlet (page 4).⁴ Here we have only time to mention that the chorion with decidua is thrown into folds, and

the decidua tears through, so that a portion of it is left on the muscular wall. In what plane exactly it tears through is of histological interest; the practical point for the obstetrician is to examine the membranes as well as the placenta after delivery, to see that the decidua has come. Not that, supposing we find a portion of it absent, we should think of passing our hand into the uterus to remove it; lest in steering clear of the Charybdis of endometritis we might be dashed on the Scylla of septicæmia.

4. How are the placenta and membranes expelled? Here, again, gentlemen, is a double question: By what power, and in what manner, are the placenta and membranes born?

A. By what power? And here we must keep before us the differentiation of the uterus into two parts which occurs in labour. It would take us too much aside to bring forward the anatomical and physiological proof of this. We must content ourselves with stating the proposition, that the uterus in labour becomes differentiated into two parts: an upper, which is active and shortens and thickens; and a lower, which is passive, elongates, and thins. A glance at these frozen sections (See Figs. 1 and 2) of the uterus

Fig. 1.

Frozen Section made immediately after Delivery (1).

The section shows the pelvis and lower part of the abdomen. The body is in the dorsal posture, with the promontory of the sacrum to the right and below, and the symphysis pubis to the left and above. The genital canal falls into two portions at the line a (see text). U is on the firm, thick, contracted portion; c on a fold of canal below; v on vagina. Note the folding and doubling up of the canal at and below a, showing its limpness. The small diagram to the left, representing the genital tract alone, is intended to make clear the special point.

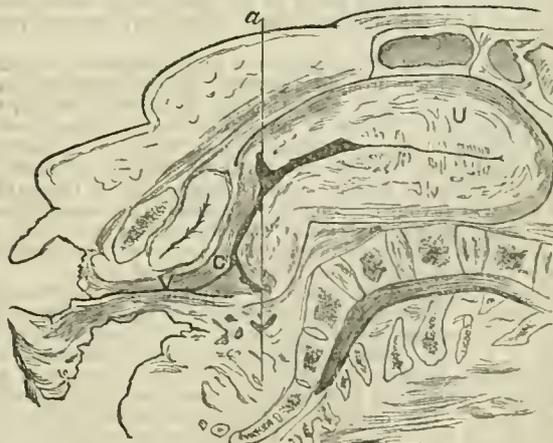

Fig. 2.

Stratz's Frozen Section made immediately after Delivery.

Position of pelvis and letters as in Fig. 1. Note the thinness of the walls of the canal below a. The horizontal direction of the vagina (vertical, of course, were the body erect) is abnormal, being due to the fact that the projection of the rickety promontory has kept the uterus high in the abdomen and the walls of the canal below taut.

² The Sectional Anatomy of the Third Stage. Reprint from *Edinburgh Medical Journal*, October and November, 1887.

³ It may not be polanitic to recall the Aristotelian distinction between the efficient and the formal cause. The former is the force or agency by which a result or effect is produced; the latter the manner in which or the instrument with which it is produced.

⁴ Some Practical Points with regard to the Membranes in the Third Stage of Labour. Reprint from the *Edinburgh Medical Journal*, June, 1885.

immediately after delivery shows the difference between the firm, contracted, upper portion of the body, and the thinner, flabby, lower segment and cervix folded below it. This proposition is not only of scientific, but of practical importance; it has a wide bearing in pathology, for example, on rupture of the uterus and on placenta previa.

Look now at the third stage of labour in the light of this proposition. The lower segment, in its passiveness, is more allied to the cervix and vagina than to the active part of the uterus above it. The genital tract falls into two parts through a line corresponding to the upper end of the lower uterine segment (*a* in the woodcut). Above that line the muscular wall of the genital tract is able to force on a body lying in it, while, below, it is unable to do so.

Now for the practical bearing of this. The placenta can be driven out of the upper portion of the uterus by the action of the walls alone, that is, by the pains of the third stage. But once it has passed that line, some other force must operate—either increase of intra-abdominal pressure, gravity, or artificial interference.

(*a*) Increase of intra-abdominal pressure is the first force we think of. The pinch of snuff which the old wives gave to bring away the after-birth is quite sound treatment. It rests on this scientific basis: the placenta will be born (expelled from the lower segment, cervix, or vagina) by any action of the abdominal muscles which suddenly increases the intra-abdominal pressure, for example, the forced expiration of sneezing; and there is no more effective stimulant of the centre for sneezing than snuff. In fact, whatever makes the patient bear down favours the birth of the placenta. In this respect, the lower segment, cervix and vagina resemble the bladder after delivery, and an interesting parallel might be drawn between them. May not the difficulty of emptying the bladder *post-partum* be due, not, as is often said, to the removal of the weight of the pregnant uterus, which allows the bladder to expand, but to the removal of the volume of the pregnant uterus, which makes it more difficult for the elongated abdominal muscles to increase the intra-abdominal pressure sufficiently to force the urine out of the bladder? The change in intra-abdominal pressure by the substitution of a volume of ten cubic inches for one of eighty-three (I estimate the bulk roughly from two frozen sections I have made of the uterus at the commencement and at the completion of labour) is considerable, and its effect on the abdominal circulation and the action of the viscera is well worthy of study.

(*b*) Gravity will be brought into play by the patient's being made to sit up.

(*c*) Artificial interference belongs to the management of the third stage, which lies beyond our present paper. Will you just note in passing that the Dublin method assists the natural mode of expulsion; and the Credé one, also, in its two parts (first grasping the uterus antero-posteriorly, then pushing downwards in the axis of the pelvis) adapts itself to the two stages of expulsion, corresponding to the placenta being in the active or passive portions of the canal.

4. In what manner are the placenta and membranes expelled? Two views have been brought forward: one by Schultze, that it comes foetal surface first; the other by Matthews Duncan, that it comes edge first. There is no doubt that it comes out in both these ways. My own observations, recorded in the third pamphlet, make me believe that Duncan's way is the more frequent; but we must remember that the presence of the hand in the uterus will favour that mode. Champneys has recently made a much more extensive series of observations on this point; and his tables show that in 85 per cent. (59 out of 69) the presenting part was either the edge or within two inches of it.

5. What is the natural mode of stopping bleeding from the placental site? Though this is a question of the most immediate practical importance, involving often directly the life of the mother, it has not been specially investigated. We know that strong contractions stop bleeding—a cricket-ball uterus and *post-partum* hæmorrhage are incompatible—but how they operate we do not know. The question is a more complicated one than appears at the first glance. We know of at least three factors which operate: the change in the muscular wall of the uterus in uterine contraction and retraction; thrombosis within the vessels, which occurs "spontaneously" even before separation of the placenta begins, and is a very important factor during and after the third stage; the condition of the blood itself. All of these must be taken into account, and their action is different; the

first compresses the vessels, the second chokes the channel, the third is subordinate to the second. Free bleeding from a firmly contracted uterus, noted in a case of phosphorus poisoning, shows, I think, that this last has an important, though as yet unrecognised, action.

THE MANAGEMENT OF ANTERIOR AND POSTERIOR DISPLACEMENTS OF THE UTERUS.¹

By J. HALLIDAY CROOM, M.D., F.R.C.S.E.,

Physician to, and Clinical Lecturer on Diseases of Women, Royal Infirmary, Edinburgh.

I AM fully alive to the responsibility which anyone incurs in venturing to lay down definite lines of treatment concerning anterior and posterior displacements of the uterus, for I believe I am safe in saying that upon no subject in gynaecology has greater diversity of opinion existed, and upon none have more opinions been expressed with equal confidence. This subject has been the bone of contention between different schools of gynaecology for many years. That this should be the case is easy of explanation, and that for various reasons: 1. Because many teachers and practitioners have regarded the conditions as merely mechanical, and directed their treatment accordingly; 2. Others have considered the conditions as the result of inflammatory action, and their treatment has been in strict accordance with their views; 3. Others, perhaps the largest class of all, have regarded symptoms alone, and treated the conditions empirically; 4. It must be further kept in view how frequent are deviations in the position of the uterus, and how prone we are to seize any seemingly pathological condition as an explanation of symptoms and to treat it vigorously when the condition is all the time only a coincidence, not a cause.

Now, in venturing to offer to you a sketch of the treatment of the displacements under consideration, I would have it clearly understood that anterior and posterior displacements occur in two great groups:

1. Displacements in virgins or nulliparæ.
2. Displacements in parous women.

In regard to the first class I am inclined to look upon them, speaking generally, as being congenital conditions; the ante-flexion being in the direction of non-development, and the retro-flexion in the direction of deformity. These conditions in virgins are not infrequently associated with diseased conditions of the annexa, and when they are it is the inflammatory condition of the annexa which requires treatment, and not the congenital deformity or non-development. A well-marked illustration of this came under my observation lately when a patient had for eight years been under treatment with pessaries for an ante-flexed undeveloped uterus. Her distress was so great and persistent that I removed the ovaries, which were extensively diseased, and the woman has had comfort ever since, the uterus still remaining ante-flexed. The progress which gynaecology has made in recent years in advancing our knowledge of the uterine annexa has shown conclusively that many cases of pain and dysmenorrhœa which were formerly attributed to uterine displacements are due entirely to conditions of the ovaries and tubes independently of a concurrent displacement which may mean nothing. Deviations in the position of the uterus of minor degree give rise in the single woman to no symptoms, and require, therefore, no treatment. Marked versions uncomplicated with some pathological condition, such as a fibroid, are rare in single women, and when uncomplicated give rise to very slight symptoms, and need no mechanical interference. When the flexion backward or forward is very acute, I do not deny that it may be associated with severe dysmenorrhœa. Even admitting that these displacements in virgins give rise to some discomfort, what treatment is at our disposal? Vaginal pessaries are seldom if ever curative, and intra-uterine pessaries are surrounded with such risk in the direction of inflammation, hæmatocele, and ovaritis, that so far as I am concerned I have discarded their use altogether. Let it be distinctly understood that I by no means wish to say that, in the hands of an

¹ Read in the Section of Obstetric Medicine at the Annual Meeting of the British Medical Association held in Dublin, August, 1887.

experienced gynaecologist, there are not cases, especially of retroflexion in virgins, in which the pressure symptoms from hypertrophy and enlargement are to be remedied in no other way than by stem pessaries, but these cases are, so far as my experience goes, extremely few, and do not fail to be discussed in a general view of the case. It is only fair to say that intra-uterine stem pessaries have within my knowledge, in some exceptional cases, rendered benefit; but on looking back over an experience of nearly twenty years I mean to say that I have known them do more harm than good, and as a teacher of gynaecology I have found it my duty to warn students and practitioners against their use.

But the question naturally arises as to the cure of dysmenorrhœa, which unquestionably is often associated with, although not necessarily dependent on, these displacements. Is no mechanical treatment to be adopted? Now, upon this point there seems to be too great a tendency to local interference for dysmenorrhœa in virgins. I should withhold local treatment altogether unless its severity be such that, after all other means failed, it interferes with a rich woman's social engagements or a poor woman's means of livelihood, for it must always be kept in view that dysmenorrhœa is but a relative term. When, however, local examination and treatment become necessary, then vaginal pessaries are of little avail, and intra-uterine stem pessaries are unsafe. Dilatation of the cervix with a dilator bougie or an occasional passage of the sound, with the persistent use of the hot vaginal douche, will often effect a cure both effectively and safely. Here I must enter a caveat against the indiscriminate use of the sound and dilators, unless accompanied by careful precautions; and these are (1) that there be no recent or remote peri-uterine inflammation; (2) that the greatest care be taken as to the perfect cleanliness of the instrument.

Much as we owe to the sound, yet I feel sure that its indiscriminate and routine use has been a fertile source of uterine mischief.

In a word, then, in unmarried women and nulliparæ, with some exceptions too few to affect the general statement (the conditions being usually congenital), vaginal pessaries are of no avail, and intra-uterine are always dangerous and usually hurtful. When aggravated dysmenorrhœa is concurrent with a simple displacement, then the use of a sound, bougie, or dilator, along with hot water, will often effect a cure. If there be the least pathological condition to be found in the annexa, there should be no mechanical treatment, but only the hot douche.

With regard to parous women, the case stands differently. In them, unlike the others, the displacements are usually, if not always, acquired. In the case of ante flexion and anteversion, which in parous women are so often induced by various forms of peri- and parametritis, and by inflammation of the utero-sacral ligaments specially, mechanical treatment in the shape of pessaries is seldom indicated. The sphere for anteversion and ante flexion pessaries in parous women—if, indeed, they have a sphere at all—must be when the displacement does not depend upon any inflammatory condition outside the uterus, but is solely due to an increase in its weight. Even in such cases, which are rare, the trouble and annoyance to both physician and patient attending their use is more than sufficient to outweigh their temporary comfort. Of stem pessaries in forward displacements of the uterus in parous women, I have no experience, and I have yet to see the case in which I consider their use desirable. The majority of these anterior displacements give rise to very unimportant symptoms. When they do, the symptoms are due to some inflammatory products outside the uterus, and the treatment is to be directed to its removal (1) by the hot vaginal douche; (2) by blisters; (3) by iodine applied to the vaginal roof; and (4) by small doses of iodide of potassium and perchloride of mercury internally. Sometimes a soft glycerine ring pessary, by relieving tension and elevating, may do good, but as a rule even this is contra-indicated.

Coming now to posterior displacements in parous women, namely, retroversion and retroflexion, we are bound to recognise the fact that they are specially prone to arise mechanically. This will appear obvious if we consider the frequency with which these conditions occur after pregnancy as a result of imperfect involution, dorsal decubitus, increase in weight, and too early rising.

The origin of these parous posterior displacements being usually, though not always, mechanical, and the symptoms to which they give rise, such as sterility, leucorrhœa, menorrhœgia,

and pressure, to a greater or lesser extent being well recognised, their treatment must be mainly based on mechanical principles.

1. Tone must be given to the uterus by the use of ergot and hot-water douching.

2. The uterus must be carefully adjusted in one of several ways: (a) by pressing up the fundus; (b) by pressing back the cervix; (c) by the genu-pectoral position; (d) by dragging down the lip of the cervix with a volsella; and lastly, by the sound. In any case, accurate and careful reposition of the uterus in any of the ways I have mentioned is essential. I place the sound last because I really think that the bimanual replacement of the uterus is the safest and most thorough, and because the introduction of any body into the cavum uteri is always to be avoided when practicable.

3. The uterus must be retained in position by a pessary. In the case of a well-marked retroversion, a well-adjusted Hodge, or some of its many modifications, will be found to act efficiently, whereas in the case of a well-marked retroflexion the ordinary ring pessary will act better than the Hodge. The Hodge in such circumstances is inapplicable because of the difficulty of adjusting it so as to act with much advantage on the fundus, and it is apt to get into the sulcus between the cervix and uterus, and so aggravate the condition it was intended to cure. In such cases the ordinary ring pessary, by elevating the whole uterus, will give most relief.

In some aggravated cases of acute flexion with hypertrophy, stem pessaries may, under exceptional circumstances, be required, but this must always be regarded as a *dernier ressort*.

In that class of cases—which is exceedingly frequent—where there is some degree of flexion and version combined, the Hodge will most frequently meet the requirements of the case. Should there be any adhesions or any ovarian prolapse the soft india-rubber glycerine ring will be most generally serviceable.

Dr. LOMBE ATHILL expressed his disbelief in ante flexion as a disease, or even as a condition demanding treatment. If it occurred in connection with dysmenorrhœa in a multiparous woman, and depended on uterine causes, those causes would generally be found to be a conical cervix and a contracted cervical canal. The virgin uterus being naturally ante flexed, pessaries in such cases were useless, and stems most objectionable. Cases of retroflexion were always acquired, and in many of them a pessary, such as a Hodge, was very useful, and a great aid in curative treatment, but it must never be looked on as being itself curative; in some cases the retroflexed fundus pressed against the rectum, and interfered with defecation. In these a well-adjusted pessary often gave marked relief; but the mere fact of the uterus being retroflexed, provided that it caused no discomfort or symptom, did not necessarily demand treatment.—Dr. BARNES said Dr. Halliday Croom objected to Hodge's pessary in extreme retroflexion, because it got between the cervix and the retroflexed body, and resorted to the ring pessary. Now he (the speaker) contended that all depended upon a proper choice of pessary. The true idea of a good pessary was Hodge's; it must act as a lever, and, therefore, the uterus must be movable, and the pessary must move with it, forming, as it were, part of it; and for this it must be well adapted to the particular case. The ring pessary had become to him an abomination; it stretched the vagina, weakened the natural supports of the uterus, and thus left the patient worse than before. On the other hand, by first reducing the uterus, the patient lying on her hands, a gentle touch of the finger would push the fundus over to the left side of the promontory, where it would easily rise to its position, and then a glycerine-pad pessary passed in would keep the fundus from falling back. Dr. Barnes believed that cases of distress from ante flexion were quite rare, and he had seen good from Graily Hewitt's cradle pessary, but great care was required in adapting the pessary to the case. With reference to the statement that, before applying a pessary, you must reduce the congestion or swelling of the uterus, that was attempting what could not be done. The removal of congestion depended on keeping the uterus *in situ*. All depended upon judgment in selecting the pessary.—Dr. JOHN A. BYRNE said that whilst he had learned a great deal from Dr. Barnes, he could not agree with him about the non-necessity of previously replacing the uterus. (Dr. BARNES here explained that he did not mean to assert this.) He (the speaker) had a good deal of experience of uterine affections, and he was of opinion that retro-displacements were very frequent, whilst anterior displacements were extremely

case. No doubt this displacement was sometimes observed in those cases where the uterus and appendages were bound down by old inflammatory products; but as an originally abnormal displacement, it was in his opinion extremely rare. He could not agree with Dr. Atthill, even in cases where a retroversion or flexion was observed, and where no urgent symptoms were manifested, that still he should not attempt replacement; the reposition and retention could not by any possibility do any harm. We should do all in our power to remove any hyperplastic uterine condition, although he was of opinion that too much importance was attached to this so-called metritis; and in an organ like the uterus we should expect that there must be occasionally engorgement and, perhaps, hyperplasia; but he thought that there was a good deal of exaggeration on this subject. He entertained a very strong objection to the use of the stem pessary. There was one circumstance that occasionally accompanied retro-displacement, namely, sterility; when in consequence of the curvature the woman did not conceive, the replacement had in his hands been attended by the most beneficial results.—Dr. MORE MADDEN said the importance of flexions in relation to the causation of sterility was a subject brought daily under his observation, and one which could not be too strongly insisted on; for in the great majority of cases of sterility and dysmenorrhoea, whether there was stenosis of the cervical canal or not, he was firmly convinced that any operative treatment would generally be useless unless the coexisting displacement or flexion were at the same time remedied, as either might be by a properly adjusted, well-fitting Hodge lever pessary.—Dr. WILLIAM DUNCAN said it always seemed to him remarkable that, when gynecologists discussed uterine displacements, some considered all cases required mechanical treatment, and others deprecated any treatment whatever. Dr. Duncan, whilst admitting that cases sometimes required local treatment, considered the majority of cases of versions or flexions caused *per se* no trouble, and required no treatment. He thought that it was bad practice to introduce a vaginal or stem pessary in any case of antelexion, but that the raising up of the uterus in the pelvic cavity by a Hodge or ring pessary in cases of backward displacement relieved the circulation in the uterine and ovarian veins, and thus did good. He did not believe that a pessary ever cured a version or flexion. He thought that a grave responsibility rested on teachers who practised and advised the frequent use of pessaries in the treatment of versions and flexions.—Dr. ROUTH said no one would think of treating a case which had no symptoms. Patients came to us when they had severe symptoms which required treating; but even here pessaries were not always to be at once applied. Simple measures, such as local depletion, purgatives, etc., should first be tried; if these failed, then pessaries might be tried. As to stem pessaries, they were condemned mostly by those who had never used them, or only to a very small extent. If proper measures were taken at first to prevent inflammatory complications, and the stem pessaries were not too long, and rest were insisted on for some days after their application, accidents were few and far between.—Dr. HANCOCK endorsed Dr. Barnes's remarks upon the importance of the mechanical treatment of uterine displacement, and bore testimony to the value also of the stem pessary, and particularly to that form invented by Dr. Gordon Black, of Harrogate. He had used this in two cases, which had only been partially relieved with Hodge's pessaries, but which were rapidly relieved by this form of stem.—Dr. M. CAMERON said cases of displacement did not remain as when first met with, but went on from bad to worse unless properly treated. He would also like to state that satisfactory results had been obtained in Glasgow from shortening of the round ligaments, the use of the tampon, and hot-water injections. He had every confidence in the use of pessaries.—Dr. W. J. SMYLY said the uterus was maintained in position by intra-abdominal pressure, but its displacement was prevented by the ligaments. When the latter were subinvolved, then they could not perform their functions when the uterus was replaced, so that the intestines came to press upon the posterior surface; a Hodge's pessary, by practically shortening the utero-sacral ligaments, would prevent its displacement. When the uterus was in position, and the pessary acting properly, the fundus was about three inches removed from the posterior bar, and therefore to speak of supporting the fundus was erroneous, and to invent soft pessaries filled with glycerine, so as not to hurt it when tender was unnecessary.—Professor A. WALLACE said he agreed almost entirely with Dr. Halliday Croom's methods of treatment. There

was one plan which had not been noticed—namely, the use of tampons, which were first used by Marion Sims. These were made by saturating cotton-wool with glycerine, which might be medicated by various substances, as astringents, antiseptics, etc. He had used this method for many years as a preliminary to the use of a pessary. The pessary which he always used for cases of posterior displacement requiring mechanical support was the Albert Smith's modification of Hodge's, made of soft, pliable metal which could be bent and fitted according to the requirements of the individual case.—Dr. J. WALLACE (Liverpool) referred to the difficulty of discussing this large subject in the short time permitted. As a teacher and practitioner he had been guided by certain principles. First, the pathological conditions, and secondly, the mechanical, were to be observed and treated as stated *seriatim*. But no case could be scientifically put under treatment unless its etiology as well as its morbid conditions, pathological as well as mechanical, were determined. In virgins displacements were often produced by straining at stool, by prolonged standing, as in shop girls, schoolmistresses, and in ladies who followed fashion in tight lacing, dancing to excess, and a relaxed muscular system and health generally. Antelexion of cervix, the os uteri pointing forward to the pubes, slight procidentia of the body of the uterus, and retroversion of the fundus uteri, often retroflexion—in short, the sigmoid uterus. This form did not always give rise to symptoms, but they came at last, local or reflex, and required treatment. These might be cured by constitutional and local treatment without pessaries. In married women with sterility, posterior section of cervix would frequently cure. In women who had had numerous children in a few years, sub-involution of the uterus and of the Fallopian tubes and ligaments, with diseased conditions of the endometrium, was common. Dr. Wallace drew particular attention to the open Fallopian tubes, which he had found to be almost the rule in these *post-partum* cases of displacement. Engorgement might depend upon flexion, but he felt sure it arose from displacement. Local treatment such as the hot douche, applications to the cervix according to the intensity of the morbid conditions, and sedative pessaries would relieve the local tenderness, after which a pessary adjusted to the requirements of the individual case might be safely placed. He confessed that he was surprised at the statement that pessaries did not cure. They certainly did, provided the pathological conditions were also cured.—Dr. GRIGG stated he quite agreed with all that fell from Dr. Wallace and Dr. Smyly with reference to the important function the ligaments performed in relation to the retention of the uterus in its proper position, and instanced cases of primiparous women, whose uteri were perfectly normal antecedent to pregnancy, recovering from the puerperium with retroversion, coupled with the descent of the whole pelvic organs. With regard to Dr. Wallace's statement that he could pass a uterine sound through the Fallopian tubes shortly after delivery, this Dr. Grigg controverted, and stated he had never succeeded in passing even a probe through the Fallopian tube in the cadaver of women confined within a few hours to three or four weeks.

THE DIAGNOSIS AND TREATMENT OF DISEASES OF THE ENDOMETRIUM.¹

By W. J. SMYLY, M.D.,

Gynaecologist to the City of Dublin Hospital.

I KNOW of one method only by which the diseases of the uterine mucous membrane can be diagnosed with accuracy, and that is by the microscopic examination of portions removed by means of the curette. In the majority of cases a fairly correct diagnosis may be arrived at without resorting to the microscope, but not with certainty. When, for example, a medium-sized curette can easily pass into the uterus, and is there found to be freely movable in an enlarged cavity, and over a soft and velvety but irregular surface; and when its cutting edge is used long strips of hyperplastic membrane come away, we should probably be correct in supposing the case to be one of fungous endometritis, but it might be one in which the decidua had been retained, or a simple or malignant adenoma; for the appearances of these to the naked eye present a very close resemblance to each other, but microscopically they differ very widely. Should only a few small shreds of

¹ Read in the Section of Obstetric Medicine at the Annual Meeting of the British Medical Association held at Dublin, in August, 1887.

thin membrane be obtained, even after very vigorous scraping, we believe the case to be one of atrophy, but could not tell to what variety of this condition it appertained. Small, friable, whitish particles are strongly suggestive of cancer, but even then the microscope will be necessary; and here we meet with the most important, and often I believe the most difficult, problem, namely, to determine with certainty from specimens obtained the malignancy of the disease. I must confess that I never have done this myself, but I do not think that during the four years since I have adopted this method such a case has come under my care. It has, however, been done by others; the uterus excised in consequence, and the diagnosis confirmed by the subsequent examination of the specimens obtained, and it is a very remarkable fact that, considering how few are the recorded cases of malignant disease limited to the body of the uterus, so many as eleven should have been diagnosed during the last seven years by a single individual, namely, Dr. J. Veit, of Berlin. This is to my mind strongly suggestive of the belief that a large proportion of such cases are not detected until after the disease has involved the cervix or the neighbouring organs, because of imperfection in the methods of diagnosis usually employed; and that were the curette and microscope used more systematically, we should more often succeed in discovering this terrible malady at a time when its removal would offer a reasonable prospect of permanent relief.

This method of diagnosis was introduced by Récamier about forty years ago, and it is from it that most of our knowledge of the diseases of the uterine mucous membrane has been derived. He devised the curette by means of which he removed "*fongosités*" or vegetations, and subsequently applied some caustic to the denuded surface. The particles removed were examined microscopically by Robin, who gave a very exact description of their structure, corresponding with what is now generally known as fungous endometritis. De Sinéty and Rugé have distinguished in the same way three distinct forms of endometritis, according to the relative development of the glands and inter-glandular tissue; but as all these forms may occur simultaneously in the same uterus, this division appears to be rather too artificial. If, however, Martin's opinion that the more the glandular development predominates, the more liable is the disease to assume a malignant character, and Wyder's that the more the interstitial tissue is developed, the greater is the hemorrhage, prove to be correct, then it will be a very important one.

Retention of the decidua after abortion is one of the commonest affections of the uterine mucous membrane. When examined microscopically it contrasts very strongly with fungous endometritis, owing to the absence of glands, and it will, I believe, always be found in a state of inflammation. Whether this is the cause or the result of its retention, I am unable to say; but, in either case, it indicates the advantage of its early removal. Of the atrophic forms of endometritis, two appear to me of especial interest—first, that described by Schroeder as dysmenorrhœal endometritis, in which there is a development of the inter-glandular tissue leading to the obliteration of the glands themselves, and a subsequent cirrhosis or atrophy of the membrane; and secondly, a condition described by Zeller as "*psoriasis uterina*," in which the uterine cavity is lined with scaly epithelium. I mention these forms especially, because it was by the microscopical examination of particles obtained by means of the curette that they were discovered. The curette and microscope are accordingly most efficient means of diagnosis, but their use is, in this country at least, generally regarded as advisable in exceptional cases only, and after the ordinary methods, by means of the sound and introduction of the finger after dilatation of the cervix, have failed. Now, as regards the latter method, it is not only more painful, and involves greater risk to the patient and a much greater expenditure of time on the part of the practitioner than curetting, but, what is of more consequence, it seldom yields much useful information. Only gross pathological changes can be distinguished by the finger, and in proof of this I would refer you to the writings of those who practise either method exclusively. There you will find that by those who advocate the curette and microscope not only are definite pathological conditions described and figured, but there is a remarkable unanimity in their opinions as to the nature of these conditions, whilst amongst those who do not employ them we find such vague and unsatisfactory terms as "*granular conditions*," "*pulpy states*," "*irritable membranes*," etc., expressing not the nature of the condition present, but only the impressions which they conveyed to

their fingers; whilst in such conditions as are not palpable in this way only two courses are open to them, either to deny their existence altogether, or use some indefinite term such as "*intra-uterine disease*," without any attempt to define it more exactly. Let me quote an example from the work of such an eminent gynecologist as Dr. Emmet, who speaks of the curette as "*an instrument which has proved a most objectionable one*;" and as regards the instrument of Dr. Sims, "*he honestly believes that the ingenuity of man has never devised one capable of doing more injury*." His knowledge, therefore, we may assume, has not been derived from the use of this instrument. He mentions four forms of disease to which the uterine mucous membrane is liable. First, a form of disease usually the result of pregnancy, and characterised by hemorrhage, which, he says, "*is common but little understood, microscopists not having, to his knowledge, fully investigated the subject*;" a second condition is frequently met with, "*which some writer has compared to granular conjunctivitis*;" and a third "*resembles the pile of velvet, and when floated in water it seems to consist of prolongations of blood-vessels from the muscular tissue*;" and lastly, "*a thickened condition of the membrane, which could be easily detached in long strips like the skin which has been scalded, and is blanched in appearance*." Now I would point out that in not one of these cases is the real nature of the disease described. In the first he says it is unknown, the second is like granular lids, the third like velvet, and the fourth like scalded skin; but what we want to know is, not what a disease is like, but what it is. What should we think of an oculist who described granular ophthalmia as a disease resembling decidual endometritis? I have selected Dr. Emmet's work in order to show that no matter how brilliant and observant a man may be, ignorance and confusion must result from the rejection of the only source of knowledge.

In spite of the obvious advantages of the curette as a means of diagnosis, its advance towards general acceptance has been but slow. Récamier's results were very brilliant, and although he perforated the uterus in a few cases, I believe that no evil resulted therefrom. However, its introduction met with such a storm of opposition that, in spite of the advocacy of Sir James Simpson, Olshausen, Marion Sims, and others, it made but little way until about four years ago, when a revulsion of feeling in its favour occurred. Certain dangers naturally suggested themselves as likely to follow its use, and especially that the mucous membrane having been thoroughly removed, it would be replaced by cicatricial tissue, and thus sterility would result. Reasoning from analogy we should expect this to occur, but analogy does not hold good in this instance. The uterine mucous membrane differs from every other in its rapid and complete regeneration, as was clearly proved by Dr. Martin, of Berlin, and his assistant Dr. Düvelius, and it was the publication of the investigation of this subject by the latter which marked the epoch to which I have already referred, since which this method of diagnosis and treatment has rapidly gained in popularity. The most remarkable cases recorded by Dr. Martin, were those of two women who had been repeatedly curetted and cauterised for adenoma of the mucous membrane; but were at last reduced to such an anæmic condition that as a last resource the uterus was removed. In one of these cases the last scraping took place two months, in the other four months, previously. The microscopic examination of the organs after extirpation showed that the newly developed membrane was related to the muscular and inter-muscular connective tissue in the usual manner, nor was a cicatrix to be found anywhere in the mucous membrane, or between it and the muscle. Theoretically there is no reason why pregnancy should be interfered with, but on the contrary it should rather be favoured by the removal of a diseased membrane, and its replacement by another which we have every reason to hope may prove a healthy one. Now as a matter of experience this has been found to be the case. Dr. Düvelius found that out of the patients operated upon by Dr. Martin and himself between 1879 and 1883, 60 were known to have subsequently become pregnant, and of my own cases I know of six, but as I could not trace all my patients, the number is probably greater. It is therefore evident that, no matter how thoroughly the curetting may be carried out, the membrane will be regenerated, that this new membrane is not cicatricial in structure, and that the operation favours rather than hinders the occurrence of pregnancy.

Let us now consider the treatment of these diseases. The chief indications are, first to remove the diseased membrane

as completely as possible, and then endeavour to induce a healthy growth in the new one. These two indications are best fulfilled by the use of the eurette, and by subsequent injections of strong solution of iodine or iodised phenol. Why should we spend months and years in making applications to a membrane which may be removed in a few minutes, with the certainty of its being speedily replaced by at least as good, but probably a better one? That the new membrane may be diseased is true, but this objection will apply to every form of treatment, and speaking generally we may say that the success which has attended any therapeutic agent has been in direct proportion to its power of destroying the diseased membrane. This explains to us the marked benefit derived from the use of powerful caustics, especially the fuming nitric acid. In Dublin we have had remarkable success with this agent, but it is inferior to the eurette in three ways. 1. It necessitates previous dilatation of the cervix. 2. Its action is rendered uncertain by hæmorrhage and other discharges. 3. It destroys the tissues upon which we depend for diagnosis. My present practice is to eurette in every case of disease affecting solely or chiefly the uterine mucous membrane, which does not yield to attention to general health, douching and astringents, and I can strongly recommend it to others as having the following advantages, which I may briefly recapitulate. (1). It is efficacious both as a diagnostic and as a therapeutic agent; and (2) its employment is safer and simpler than any method which involves the dilatation of the cervix.

ON MARTIN'S METHOD OF DEALING WITH THE PLACENTA AND SAC IN LAPAROTOMY FOR EXTRA-UTERINE PREGNANCY.

By ERNEST ANNACKER, M.D. BERLIN, M.R.C.S.,

House-Surgeon and Resident Obstetric Assistant-Surgeon to St. Mary's Hospital, Manchester.

ONE of the most interesting questions in connection with the treatment of advanced extra-uterine foetation by laparotomy is the method of procedure in regard to the placenta, upon which the failure or success of the operation is believed largely to depend. My object in this paper is to draw attention to the plan proposed, and successfully adopted by Dr. A. Martin, of Berlin, according to which it becomes possible to remove the placenta with the foetus, at any period after its formation, without any serious risk of hæmorrhage.

Most recent writers on this subject, including Thomas, Hicks, Barnes, Keberlé, and Tait, are agreed that the placenta should in most cases be left behind on account of the severe hæmorrhage which frequently attends its removal, instances being indeed very numerous where death has resulted from this cause. That it is a point on which the experience of competent observers differs very widely may be gathered from the fact that Schroeder removed the placenta as early as three weeks after the death of the foetus without experiencing any untoward result, while Depaul, on the other hand, removing the organ four months after the activity of the placental circulation had had time to diminish by reason of the death of the foetus, had the misfortune to lose his patient from hæmorrhage. This is a by no means isolated experience.

The disadvantages of leaving the placenta behind are (1) the tedious and protracted convalescence; (2) the danger of death from hectic and exhaustion owing to long-continued suppuration of the sac and its contents during the process of disintegration and throwing off; (3) the possibility of secondary hæmorrhage such as occurred, for example, in a case related by Braxton Hicks.

Parry, of Philadelphia, writing in the year 1876, states that the frequency of secondary hæmorrhage after spontaneous separation of the placenta, as compared with that after its forcible separation, is as one to five.

Most authorities are agreed that the organ may be safely removed some months after the death of the foetus, when the vessels traversing the placenta have atrophied and contracted, the venous sinuses having become thrombosed, and the whole organ very much diminished in size; but it was reserved for Dr. Martin to devise a means by which the placenta may be removed at any period with hardly any greater risk of hæmorrhage than attends an ovariectomy or an extirpation of the uterus.

The reasons which led Dr. Martin to work at this subject may be given in his own words, quoted from a communication read before the International Medical Congress held at London in 1881. He says: "It is, however, evident to all that convalescence is considerably endangered by this procedure (avoidance of the placental site) for even if the sac, as such, were closed, and the diligent irrigation of the sac should prevent stagnation of the secretions in the cavity, still it is clear that the recovery is thus retarded greatly, and the patient liable to such dangers as accompany the processes, even with strictest antiseptic precautions." He acknowledges that the ligation of separate bleeding points on the placental site is not feasible, but by ligation *en masse* "large bleeding surfaces can be tied quickly and safely, so that we need not fear secondary danger from the hæmorrhage."

It might be objected that the placenta may be fixed to the intestines, or some part from which it is irremovable; but to this Martin replies that it is more of theoretical than practical importance; not that he denies the possibility of its occurrence, but, not having met with a single case of this nature in eighteen laparotomies for extra-uterine foetation, he comes to the conclusion that, in discussing the question broadly, too much stress must not be laid on these rare and exceptional cases, in which, if necessary, and if the placenta cannot be removed without danger of fatal hæmorrhage, it may be left *in situ* and allowed to disintegrate.

I had the privilege of being present at the operation on the following case of Dr. Martin's, in which the successful removal of the placenta, which I wish to emphasise, is well illustrated, as well as the method of treating the sac by partial resection, a procedure generally employed by Dr. Martin in these cases. For the notes of the case I am indebted to Dr. Czempin, house surgeon at Dr. Martin's clinic.

The patient was a married woman, and sterile up to last March. Since that time she had complained of pain in the hypogastrium, especially on the left side. She had menstruated regularly for fourteen years; but in March, after menstruating at the commencement of the month, there was again some loss a fortnight later, while throughout the whole of April she did not menstruate at all. In May there was slight hæmorrhage on two occasions, but none between that time and her admission to the hospital in July.

The vagina was fairly capacious; the cervix behind the symphysis pubis; the body of the uterus was short, and behind the uterus a tumour, rather larger than a man's fist, was felt on the left side, and diagnosed as tubo-ovarian.

On July 7th the operation for removal of the tumour was undertaken. Chloroform was administered, and the abdomen opened by an incision four inches long in the middle line, when the peritoneal cavity was found full of recent and old blood-clot—the tumour having evidently burst. The intestines were spread out on the wall of the abdomen, and covered with a damp cloth, after which the clots were easily removed from the pelvic cavity with sponges. To the left side of and behind the uterus was seated a tumour corresponding to the one felt on examination; on attempting to loosen the latter from its connections a rent occurred in the anterior wall, and through it a four-month-old foetus and some blood-clots escaped. The foetus was still attached by the umbilical cord to the placenta, which remained in the cyst. Introducing the hand into the cyst it was possible to remove the whole placenta without any severe hæmorrhage. A large portion of the sac was next resected, and the remainder stitched together with continuous catgut suture, after introducing a drainage-tube through the pouch of Douglas into the vagina, so as to shut off the sac as much as possible from the abdominal cavity. The abdominal wall was then united by silk sutures. The operation lasted eighteen minutes. The patient recovered without a bad symptom, the temperature never rising above 38.2° C. The tube was removed on the thirteenth day after the operation, and on the sixteenth day the patient left the hospital convalescent.

In another case upon which Dr. Martin operated at the end of the sixth month of pregnancy, the placenta was seated upon the anterior wall of the sac, which was formed by the back wall of the uterus and the left lateral ligament. After the removal of the foetus hæmorrhage took place in spurts, quickly filling the sac. As soon as Dr. Martin recognised the nature of the case he cut off the communication with the uterus by three deep sutures, carried by means of curved needles through the broad ligaments, and embracing the left side of the uterus. The placenta was then removed and found to be very friable, but entire; no hæmorrhage followed its removal. The sac was treated by resection, and the

operation was concluded in an hour and a quarter. The patient made a perfect and speedy recovery.

The method of dealing with the sac of an extra-uterine foetation employed by Dr. Martin is different from that of many operators. Instead of stitching the sac to the abdominal incision, he removes as much of the walls as possible, drains through the pouch of Douglas into the vagina, and unites the edges together at the highest part of the sac, thus being enabled to close the abdominal wound entirely. By this means healing by first intention is possible, drainage is obtained through the most dependent portion of the sac, and recovery is much more speedy.

During the last six months I had an opportunity of examining a patient on whom Dr. Martin had operated some months previously for extra-uterine pregnancy in the manner here described. The uterus was fairly mobile, and the only remains of the patient's abnormal burden was a thickened cicatricial band, about the size of the little finger, extending backwards from the cervix, on the left side of the uterus.

Three years ago Dr. Martin described his method in a paper read before the Copenhagen Congress, but it was the opinion of Werth and most of the authorities present that time was needed to test its efficiency.

Dr. Martin has now had nearly twenty cases in which he has put in practice his method of dealing with the placenta and the sac, and he considers that the results quite justify him in maintaining its superiority over the methods hitherto in vogue.

ABSTRACT OF AN ADDRESS

ON

THE RELATIONS OF GYNÆCOLOGY TO GENERAL THERAPEUTICS.

Delivered before the British Gynæcological Society.

By ARTHUR W. EDIS, M.D., F.R.C.P.

President of the Society; Obstetric Physician to the Middlesex Hospital;
Physician to the Chelsea Hospital for Women.

AFTER thanking the Fellows most cordially and sincerely for the honour they had conferred upon him, the President proceeded to make a few suggestions as to the objects of the Society.

He drew attention to the importance of avoiding the error of cultivating this specialism to the exclusion of a more general consideration of the subject, asserting that a specialist, in the only true sense of the word, was one who was a good all round surgeon and physician, and something besides—one who paid special attention to the study of gynæcology, and who consequently attained superior knowledge of it, and possessed greater skill in dealing with it.

He referred to the narrow views of specialism held by some, whose opportunities of studying disease from a general standpoint should guard them from that fallacy, citing instances of menorrhagia, which, without sufficiently inquiring into the probable causes, and endeavouring to ascertain the conditions which led up to this result, the practitioner was too apt to treat empirically by some accredited formula, such as sulphuric or gallic acid, ergot, or hazeline.

Stress was laid on the importance of ascertaining the condition of the heart, liver, kidneys, and other organs, so that we should not overlook the existence of some mitral incapacity, hepatic congestion, or renal degeneration which possibly might account for the menorrhagia, and necessitate general in place of local treatment. A few grains of calomel, some saline aperient, abstinence from alcohol, and attention to simple hygienic details often proved of more service in checking any inordinate menstrual flow than the most elaborate prescription for uterine hæmorrhage.

So with dysmenorrhœa, which was but a symptom of many and various conditions, not only of the uterus and its so-called appendages, but also of the general health. In place of gravely recommending patients to submit to some surgical operation for the relief of pain, all that was necessary, in many instances, was to relieve the anæmia, due often to imperfect nutrition, improper clothing, and neglect of ordinary hygienic precautions.

The tendency of gynæcology for many years past had been to advance in a surgical direction, and unquestionably much had been gained by this. Cases which scarce a generation ago were regarded as hopeless, over which medicine had no power, were now rescued from their impending fate, and restored to health and usefulness. The triumphs of abdominal surgery were still the wonder of the age. Ovariectomy alone had been the means of saving countless thousands of lives. Removal of the uterine appendages—whether in the case of bleeding myoma, or of chronic incurable diseases of the ovaries or tubes—had enabled the surgeon to convert useless, suffering, and miserable invalids into useful members of society, able to earn their own living, or to fulfil the duties of their station, with comfort and freedom from suffering. The treatment of extra-uterine gestation by abdominal section, bold in its conception and successful in its issue, appealed alike to the profession and the public.

Shortening of the round ligaments, raising the prolapsed ovaries and attaching them to the parietes by a plastic operation, repairing the ruptured perineum, removing the hypertrophied cervix uteri, or restoring it to its normal condition, when extensively lacerated, by the operation of trachelorrhaphy—all these and numerous other operations of a like nature might well be quoted as evidence of what surgery had accomplished in the domain of gynæcology. Might we not hope that in time, when gynæcology was systematically taught in our medical schools as an integral part of medical education, we should be enabled to prevent the development or retard the progress of numerous conditions which now inevitably eventuate in surgical interference?

Our practice, in many instances, did not keep pace with our knowledge. As a fact, we knew that the process of involution of the uterus, subsequent to delivery, took at least six weeks under favourable circumstances, and still longer in anæmic, underfed, or unhealthy patients, where the hygienic surroundings were unsatisfactory; and yet we kept still to the traditions of the past, and allowed our patients to get up after the ninth day, provided there was no hæmorrhage or elevation of temperature to suggest a more prolonged recumbency.

Could it be doubted that we had here a most potent factor in the production of uterine disorders? The heavy, subinvolved uterus not only dragged upon the already weakened and distended ligaments and supports, giving rise to prolapsus uteri and other displacements, but the ovaries also, in place of remaining in a position of safety, became prolapsed, and gave rise to considerable discomfort.

Even the growth of uterine myoma, apart altogether from the more direct methods of treatment, might be lessened or retarded by attention to numerous details as to diet and hygienic management, such as abstinence from alcohol, lessening the amount of nitrogenous food, preventing congestion of the pelvic organs by wearing appropriate clothing, and refraining from unnecessary fatigue or exertion at the ordinary monthly periods, regulating the bowels, and improving the tone of the general health by means of such remedies as quinine, arsenic, strychnine, and other agents of this class.

The extreme importance of forming a correct diagnosis was then insisted upon. We should at all times endeavour to ascertain the truth, the whole truth, and nothing but the truth. It was not sufficient to detect a retroflexed uterus and treat this, when possibly some old-standing pyosalpinx or cirrhotic condition of the ovary was in reality the chief cause of the patient's suffering. Instances were not infrequently met with where the ovaries and tubes had been removed, and rightly so, for some well-marked pelvic trouble, and yet the condition of the patient some months afterwards was not anything like as favourable as we were led to predict—and why? Because some chronic uterine trouble, coexistent with the ovarian mischief, had been overlooked or not attended to, and now interfered with the perfect convalescence of the patient, thus robbing the gynæcologist of his full measure of credit, and, in some cases, unquestionably bringing the operation of removal of the appendages into needless discredit.

The reflex symptoms due to uterine derangements were then considered and their importance insisted upon, as deserving of more attention by the practitioner than generally met with. The synergic action between the stomach and the uterus, both as regards secretion, sensation, and motor action, were amongst the most remarkable phenomena of reflex nervous action. Nature gave us a very palpable illustration of this in the morning sick-

ness of pregnancy. In place of pouring into the stomach—whose only fault was a too manifest sympathy with its suffering neighbour lower down—bismuth, hydrocyanic acid, ingluvin, oxalate of cerium, and other vaunted specifics, attention should be directed to remedying any condition of the uterus likely to produce vomiting. The application of cocaine, carbolic acid, or other appropriate agent to the cervix uteri, or the insertion of a morphine suppository in the vagina, would more often check the sickness than any of the above remedies administered by the mouth.

Cases of chronic metritis, where nausea or sickness were prominent symptoms, were too often treated by remedies directed to stimulating the action of the liver or improving the digestion, in place of treating the disease of the uterus, which was really the *fons et origo mali*. All the diet lists and lengthy prescriptions too often suggested, even though tried patiently for many consecutive months, and in some cases years, were as nothing compared with appropriate uterine treatment in affording relief. Mr. Henry Power's remarks in his recent Bowman Lecture On the Relation of Ophthalmic Disease to Certain Normal and Pathological Conditions of the Sexual Organs were alluded to and endorsed.

The operative treatment of cancer, more especially of the uterus, was then considered. Although the results, thus far, were encouraging, we should never be able adequately to cope with this terrible malady until the practitioners scattered over the length and breadth of the land had their faculties quickened to appreciate the very earliest manifestations of the disease, and even to anticipate its advent by a more careful consideration of the predisposing causes which, where a strong hereditary predisposition existed, were likely to eventuate in such a condition.

Sir James Paget had indicated the direction in which our minds should tend. He had recently stated that "all cancerous diseases, were apt to form in parts congenitally defective, and still more as a result of injuries. More commonly still they appeared in parts that had long been the seat of some irritation, as we called it, as in the scars of burns, or in syphilitic tongues or gums, or cheeks irritated by bad teeth, or in lips irritated by pipes, or tongues by hot tobacco smoke." And to this list might be added, in mammae where eczema of the nipple had existed, and in the cervix uteri from old standing laceration and irritation.

In his recent Morton Lecture, Sir James Paget encouraged the hope that we might yet find some medicine as efficient against cancer as mercury or quinine were against syphilis and ague. Professor Clay, some seven years ago, asserted that he had discovered the long and anxiously sought for remedy in the form of Chian turpentine. Only recently, in one of our leading medical journals, he had reported three cases of cancer cured by this remedy. If this was all his charity could afford, his poverty must be great indeed. If it were really such a specific as he asserted, why had we not thousands of cases reported as cured, not an insignificant trio like this. Surely the matter ought not to be allowed to remain in its present unsettled and unsatisfactory condition. The remedy had been fairly tried in the cancer wards of the Middlesex Hospital, as had many and various vaunted specifics which had been brought before the public during the present century, and still Dante's motto inscribed above the portal in the *Inferno*, "Lasciate ogni speranza voi ch'entrare"—"all hope abandon ye who enter here"—might not inappropriately be placed over the entrance to the cancer wards.

The subject of electrotherapy in gynaecology, recently brought prominently forward by Dr. Apostoli, was one which was attracting considerable attention. Not only were we promised the dispersal or arrest of growth of fibroid tumours, and the arrest of hæmorrhage by the influence of electricity, but also the resolution of peri-uterine inflammation and the relief of ovarian pain, so as to preclude the necessity of removal of the appendages. Amenorrhœa, dysmenorrhœa, and menorrhagia were amenable to its influence as well as numerous other conditions too often intractable to other remedies.

The desirability of studying the effects of remedies upon uterine and pelvic disorders was then insisted upon. Much might be done by careful clinical observation, recording minutely the symptoms, and how these were modified or relieved, not by a combination of half-a-dozen different drugs, as was too often the case, but by some specially selected one, given with the definite idea of testing its true value under certain well defined conditions. The importance of leaving the culinary department of the organism free for its intended purposes, and not converting it into a drug

store for the reception of nauseating compounds was urged. There were many and various methods of applying remedies directly to the locality affected, which should always be resorted to when feasible; for example, rectal and vaginal suppositories or pessaries, injections and enemata, hypodermic injections, local applications, whether as plasters, fomentation, or poultices, or applied to a blistered surface, medicated baths and fumigations, or as local applications to the cervix uteri.

The injection of a drachm of glycerine into the rectum, as recently advocated, would often succeed in affording relief to the bowels *cito, tuto, et jucunde* where pills and aperients proved of little service.

In many critical cases, where the life of the patient often hung upon the powers of assimilating nourishment, much harm was done by drugging the stomach with opiates unnecessarily and unreasonably. We first impaired the digestive capacity of the stomach by drugs, and then attempted to convert the rectum into a stomach by injections or suppositories of peptonised materials.

The employment of antipyrin in gynaecology as relieving pain, dysmenorrhœa, quieting the nervous system, procuring sleep, arresting hæmorrhage, bringing down the temperature in febrile conditions, and in many other ways proving very serviceable, was dwelt upon.

The so-called "dry treatment" in gynaecology was then referred to and advocated in place of glycerine tampons. Powders such as bismuth, iodoform, horacic acid, borax, alum, tannin, oxide of zinc, soda and others, applied either by the aid of an insufflator or blower, or incorporated in cotton-wool tampons, or placed in the vagina, and kept in by means of dry cotton-wool tampons, were often of great service.

Much had yet to be accomplished in gynaecology before we could sit down satisfied that we had learnt all that was necessary, and had attained to such skill in diagnosis and treatment that we had nothing more to desire.

A CASE OF ACUTE TUBERCULOSIS.

By OWEN LANKESTER, M.R.C.S.

WITH REMARKS BY SIR DYCE DUCKWORTH.

ON November 4th, I was sent for to see H. H., aged 25, single, a cook, who was complaining of a sharp shooting pain at the tip of the left thumb, so severe that it kept her awake at night. On inquiry, she had been out of sorts for several days, her appetite had failed, and she had felt listless.

Examination of the thumb revealed nothing to account for the pain; her tongue was slightly furred, and the temperature 102° F.; she was told to go to bed and have a poultice applied to the thumb, to take an aperient at bedtime, and to use a fluid diet. Her history was good; her father and mother were both alive and well; seven brothers and sisters were also living. There was no history of phthisis or rheumatism in the family; her previous medical history was also good. She had been in a cottage hospital two years before, with what seemed to be aggravated dyspepsia.

On November 5th she expressed herself as better; the aperient had acted, and the pain had left her thumb, having passed to the ring finger of the same hand. She complained of breathlessness in coming upstairs, but after a careful examination no sign of any mischief in any organ of the chest or abdomen could be detected. The temperature at night was 102° , and in the morning 100° . She was given quin. sulph. gr. ij thrice daily.

On November 7th she again expressed herself better; there was no pain in the fingers, but the calf of the left leg was so painful she could not put her foot to the ground; there was no swelling, no redness to be seen, and the calf of the left leg was precisely the same in measurement as that of the right, but it was very tender on pressure. Her general condition was much the same; the temperature was 100° in the morning and 102° at night; pulse 96, regular, full; the tongue was furred in the centre and red at the side; there was no enlargement of the spleen; no abdominal tenderness; the urine 1020, acid, natural. Bellad. and glyc. was applied to the leg, which was wrapped in wool and raised on a pillow.

The patient's condition remained much the same for the next few days; the pain in the calf continued, but as she did not get out of bed it was not very troublesome; the temperature remained raised; the pulse was strong and regular, but rapid; the tongue became gradually drier, and cracked. She was always cheerful,

declaring herself better, and took her food, which consisted of milk and beef-tea, very well.

At this period typhoid fever seemed possible, but there was no splenic enlargement, no spots, and the stools were solid and had no special characteristics.

On November 14th the patient complained of a sharp pain in the left forearm, in the bones, as she said, quite different from the pain in the calf, which was of a dull, aching character. I again examined the chest and abdomen carefully, but discovered nothing abnormal; she had no cough, slept well, and took her food well; the temperature in the morning was 100°, and at night 102.3°; pulse varying from 98 to 102, strong; urine 1020, faint cloud of albumen. Treatment as before.

On November 18th Dr. Oswald Browne saw her with me. At this time she complained only of pain in the muscles of the calf of the left leg, where there was marked tenderness, with some increase of resistance on palpation, nothing more. There was no suspicion of tubercular disease. Respiration was perfectly natural, and there was no cough. Physical examination of the chest revealed true pericardial friction at the cardiac base, over an area of the size of a crown piece. The temperature taken in the mouth was 103°.

Though articular symptoms were absent, Dr. Browne considered that the pericarditis and pyrexia were manifestations of acute rheumatism, and advised the application of a blister over the area affected, and treatment by full doses of salicylate of soda every four hours. This treatment was adopted.

On November 19th friction was still slightly audible. The temperature had fallen from 103° the previous evening to 100.3°. On November 20th friction was no longer heard. The temperature in the morning was 99.6° and at night 100°, the lowest record since the commencement of the illness. Pulse 89. She took nourishment well, and slept well.

For the next few days the improvement was maintained. The temperature never quite reached normal. It was 99.4° in the morning and 100.2° at night, varying a few points from time to time.

On November 23rd salicylate of soda was given thrice daily. On November 25th the temperature began to rise again, reaching 101.8° at night, and for the first time her appetite failed; she slept badly, and wandered slightly. There was no cough, and the physical signs in the lungs were natural. On November 27th the temperature in the morning was 101° and at night 102.4°; pulse 104. A small patch of friction (pleural) was detected in the left axilla. There was no pain on breathing and no cough; the respiration was 22. On November 28th the temperature was still high, the pulse 106, and she seemed confused. The friction was spreading in front; pain was still present in calf. The retinae were examined ophthalmoscopically with negative result. Salicylate of soda, which had been given thrice daily since the 23rd, was discontinued, and quin. sulph. gr. iij was ordered thrice daily. On November 29th there was slight crepitation in the right axilla; in the left axilla there was pleuro-pericardial friction; the heart's apex was in the nipple line, and there was no murmur; the spleen was not felt; the tongue was dry and cracked; respiration 23. On December 2nd, it being impossible owing to domestic reasons to keep her where she was, she was removed to St. Bartholomew's Hospital, under the care of Sir Dyce Duckworth. Dr. Tylden, house physician, has kindly allowed me to use his notes.

The urine contained a cloud of albumen. The spleen could be felt on deep inspiration. She was ordered quin. sulph. gr. iij every six hours, milk, beef-tea and brandy; the temperature in the morning was 102°, and at night 103°; the pulse was 104.

On December 5th the spleen was still palpable; the temperature in the morning was 102.4° and at night 103.2°; the pulmonary signs were rather less; sibilus was still present. On December 6th the temperature was still high; there was no remission; she was more dusky; there was sharp crepitation over the right front as high as the apex; the spleen was still felt; crepitation over old area of friction; slight subsultus; the temperature in the morning was 103° and at night 103.4°. On December 7th she still took nourishment fairly; the crepitation in the lungs was increased; the pulse was 120, the respiration 32; the temperature in the morning was 103° and at night 103.4°.

On December 8th rales were heard over both backs, especially the right, and harsh breathing over the upper scapula. On December 9th she was worse; the physical signs were increased; the respiration was 36, and the pulse was 120; she passed a normal motion; the temperature in the morning was 103.2° and at night

104°. On December 10th the temperature was 101.4°; several (doubtful) rose spots were noted; breathing had been much worse during the last twenty-four hours. She died at 4.30 P.M.

A *post-mortem* examination was made on December 12th by Dr. Ormerod. The visceral pleura and the whole of the right lung were full of miliary tubercle. The right pleura contained a largish, thickened spot on the anterior surface, also some recent shreds of lymph. The parietal pleura was deeply congested. The pleural surface and the interior of the lung were full of miliary tubercle. Tubercle was spread uniformly through the whole of both lungs; there was no caseation, no breaking down. The bronchial glands were not enlarged nor caseated. The pericardium and heart were normal, except slight beading of the mitral edge. There were some patches of tubercle on the serous surface of the intestine, and small deposits of tubercle in the ileum, one just ulcerating. There was also tubercle in the capsules of the liver, and one or two spots in substance, and tubercle in the capsule of the spleen. There was no enlargement of the mesenteric glands. In the kidneys were several small deposits of tubercle, some beginning to look yellow. There was a cyst in one ovary; the mucous surface of the uterus was red. (No incision was made in the left calf, owing to objections by the family.)

REMARKS BY SIR DYCE DUCKWORTH (added by request of Mr. O. Lankester).—The case narrated above was one of extreme interest. The patient was admitted under my care with a history of rheumatic symptoms, including pericarditis. There were no articular pains, and no signs of pericarditis on admission. The pain referred to in the calf was still present. No physical signs explained it; in particular, no venous thrombosis. The patient was clearly very ill. My first impression, which remained for a few days, was that the case was one of enteric fever. The general condition went to support this view, the state of the tongue and spleen, and several of the motions, too, being ochrey and powdery, still further lent support to it. The pyrexia was not, however, characteristic of enteric fever. In discussing the case at the bedside, I stated that the diagnosis lay between acute tuberculosis and enteric fever. Ulcerative endocarditis was considered, but negated by the condition of the heart. For some time, indeed, an exact diagnosis was hardly possible. The occurrence of patches of dry pleurisy on each side was significant of tuberculosis. When, to this, signs of involvement of both lungs with bronchitic symptoms, manifested by fine crackling rales, which increased day by day, were added, the diagnosis became almost certain. With these signs, there came on extreme frequency of respiration, a very significant indication of acute pulmonary tuberculosis. The necropsy fully verified the diagnosis. The case is very noteworthy, because nothing in the family history pointed to the malady, and no evidence was forthcoming of any original seat of tuberculosis in the body. The diagnosis between enteric fever and acute tuberculosis has always been in certain instances a matter of extreme difficulty. It was so for some time in this case. In the earlier period of the case a diagnosis was impossible. The patient appears to have plunged suddenly from previous good health into tubercular fever, and succumbed in about five weeks. The treatment latterly was by quinine in full doses, and large quantities of strong nutriment with stimulants were well taken to the last.

NAPIER, AND KURIPAPANGA (HAWKES BAY PROVINCE, NEW ZEALAND) AS HEALTH RESORTS FOR PULMONARY INVALIDS.

By J. H. LESLIE ALLEN, M.B., M.D.

ABOUT two years ago I wrote a letter to the BRITISH MEDICAL JOURNAL on the climate of the seaport of Napier, the capital of the Hawkes Bay Province. I had at that time been only four months resident in Napier, but had derived so much benefit from even that short visit that I felt fully justified in recommending the climate. The air is bright and clear, from the abundance of sunshine and cloudless skies; and it is dry, as the result not only of the comparatively small amount of rainfall, but from the fact that the rain usually occurs in bursts, and is succeeded by long periods of fine weather. The soil also is light and absorptive, and tends to prevent accumulation of water on the surface.

The position of Napier is favourable. In latitude about 39° S.

its average temperature is intermediate between the greater heat of Auckland and the colder region further south. There is a marsh in close proximity to the southern extremity of the town, which is decidedly a disadvantage, especially in the heat and drought of summer, though the seaward hills and northern parts of the island are beyond the range of its influence. It is unwise to remain in Napier all the year round. The autumn is simply perfect, and the winter months are generally fine. My principal object is to draw attention to a locality which is already much favoured as a health resort by the inhabitants of Napier during the summer months. The plateau of Kuripapanga is situated in the Ruahine mountains, at an altitude of about 1,700 feet above the sea. It is fifty miles inland from Napier, with which communication is maintained once or twice a week by coach. The plateau proper, in itself of small extent, is bounded on three sides by precipitous mountains, and on the fourth by the river Ngarororo, which runs partly round the northern angle and divides the plateau from the more open and undulating ground, through which winds the road to Napier. The climate here during the summer is dry and invigorating, and, although the temperature may probably be as high as it is at the coast, there is no relaxing or exhausting effect. The surrounding hills protect Kuripapanga from the hot winds of the north-west in summer, and from the cold winds of the south in winter. The average temperature is, therefore, higher and more equable than that of the surrounding country. This is a great advantage in winter; and, though the heat in summer is for the same reason greater, yet a ride or climb of a quarter of an hour will make a considerable difference, as a cool breeze is nearly always to be met with among the hillsides. During the winter the mountains around Kuripapanga are covered with snow, which falls in the valley also, but quickly melts there. There are occasionally heavy storms of thunder and rain, and of course bleak and cold days during the winter; but the configuration of the country tends to promote dryness of the soil and of the air, as the mountain sides rise abruptly, in some places sheer from the river Ngarororo, which winds among them, the result being that, when a heavy fall of rain occurs, the water rushes bodily down the gulleys and ravines, and is carried away at once by the river. The plateau is elevated about 80 or 100 feet above the bed of the river. The soil of the valley is productive, and good country fare can be always obtained.

The health-seeker must have some resources in himself, and must make up his mind to forego in some measure the pleasures of society. There are, however, many ways in which he may amuse himself. He can always procure a horse to ride. Should he care for sport, he may have a day's pig-shooting, or may pick up wild duck along the river banks. Then, should he be anything of an artist, he will not be likely to suffer from *ennui* amidst the magnificent and varied scenery. The geologist also, or mining engineer, will find plenty to occupy his leisure, as the mineral resources of the range are supposed to be great. Traces of gold have been frequently found, while coal and iron are known to exist in considerable quantities.

Leaving Kuripapanga, the road into the interior ascends to an elevation of about 3,000 feet above sea-level. A stretch of the true New Zealand bush or forest can be reached by a drive of about eight miles, and a little further on a view can be obtained of the great volcanoes Ruapehu and Tongariro, rising snow-capped to the height of 8,000 feet.

A personal experience enables me to speak in the highest terms of the Kuripapanga Hotel. New arrivals are astonished to find a really first-class hotel in the heart of those mountains. This hotel, however, is not a sanatorium; and, as I write without the knowledge of the proprietor, I cannot affirm that he would be prepared to receive confirmed invalids.

The cases which should do best at Kuripapanga are those in which the lung is merely threatened, or when the disease has made but little progress; and in such cases a residence there all the year round would be desirable. Patients differ much, however, in their power of resisting cold, and those who feel a winter in the mountains too trying may return to Napier at that season. A residence at Napier and at Kuripapanga alternately will secure a fine climate all the year round.

ATHY WORKHOUSE.—The hospital accommodation having been found insufficient, steps are being taken by the guardians to extend it, and the Local Government Board has given its sanction to the proposed addition.

STRANGULATED CÆCAL HERNIA IN A CHILD: RADICAL CURE BY TWISTING THE NECK OF THE SAC.

By A. QUARRY SILCOCK, M.D., B.S.LOND., F.R.C.S.ENG.,
Surgeon to St. Mary's Hospital, and Assistant Surgeon to the Royal London
Ophthalmic Hospital, Moorfields.

CÆCAL HERNIA should be rare in children, if one may judge of the frequency of such an occurrence by the sparseness of recorded cases in medical literature. Mr. Treves, in an excellent summary of the subject, states that cæcal hernia is practically limited to adults; he quotes a case by Sandifort (*Icones Hernie Congenite*, 1781), in a male infant, aged three months, and refers to others reported by Mr. Lockwood, Cloquet, and Wrisberg. Mr. Wright, however, gives five examples verified by operation, cases which occurred at the Children's Hospital, Manchester, and avers that "cæcal hernia is not very rare in male children" (*JOURNAL* of March 5th, 1887, p. 506). It is noteworthy that in all these cases the hernia was of the congenital variety, as in the present instance.

A male infant, aged fifteen months, was brought to the children's department of St. Mary's Hospital, having a large right scrotal hernia, on May 4th, 1887. The child had suffered from sickness during the day previously to admission, and had passed no motion since May 2nd. The rupture had been noticed since birth, but the mother stated that it had become much larger on May 3rd. The hernia was irreducible when the child was placed under the influence of chloroform, and therefore herniotomy was decided upon. The strangulated portion of gut was found to consist of the cæcum with vermiform appendix, contained in a perfectly distinct sac, at the fundus of which was the testicle; the vermiform appendix lay somewhat posteriorly to the exposed portion of the cæcum, and could not be seen until the relations of the parts were disturbed in order that the protruding intestine might be thoroughly examined. The gut involved was moderately congested, and much difficulty was encountered in reducing it, even after the external ring had been notched with the knife, a difficulty which was no doubt incidental to the large size of the hernia; and, although carefully manipulated, the coats of the cæcum were bruised, and its peritoneal covering—which completely surrounded it—was lacerated during reduction.

With a view to producing a radical cure, the sac was dissected up from its attachments, divided circumferentially above the testis, and its neck twisted by the fingers, a catgut ligature being tied tightly around the twisted pedicle just inside the external ring: the sac was then cut away immediately below the ligature.

The whole operation was carried out antiseptically, but convalescence was retarded by an attack of orchitis and suppuration in that portion of the sac which lay around the testis—circumstances attributable to the failure of the antiseptic precautions after the third or fourth day.

When seen on December 28th, the scrotum and testis were perfectly normal, and there was no evidence of any tendency to hernia on the right side. On the left side a congenital scrotal hernia existed, but this was considerably smaller than it was when the child was first seen. A double inguinal truss had been worn since the wound had healed.

The radical cure obtained in this case may be cited as confirming the experience of Mr. M. Ball, of Dublin, of a method of procedure adopted and fully described by him in the *JOURNAL* of December 10th, 1887. He there advocates the use of torsion forceps as a means of twisting the sac; but the same result was easily attained in the present instance by the fingers alone. Whether or no the diminution in the size of the hernia of the left side can be ascribed to the "far-reaching effect of torsion of the sac," as Mr. Ball maintains may be the case, is, of course, an uncertainty.

VACCINATION GRANT.—Mr. W. F. Sheard, L.R.C.P.Ed., public vaccinator, Putney district, has received an award of £14 6s. for efficiency in vaccination, this being his fourth award.

A NEW medical ward has been opened at the Rotherham Public Hospital and Dispensary, affording increased accommodation to the extent of twenty beds.

"A LADY" has given one hundred guineas to the British Home for Incurables.—Mr. E. Armitage and the Rev. F. Jacox have each given £50 to St. Mary's Hospital.

OBSTETRIC MEMORANDA.

ERGOT AND ACETIC ACID IN POST-PARTUM HÆMORRHAGE.

It must have occurred to everyone with a few years' experience in practical midwifery to have encountered cases of *inertia uteri* after delivery. The labour may have been normally rapid and strong, and the placenta and membranes discharged entire after the usual interval, leaving a firmly contracted uterus; but presently, notwithstanding the continued pressure of the hand, the uterus elongates and acquires a feather-bed feel, and, refusing again to contract, hæmorrhage results; or the uterus may have been inert from the first, barely effecting delivery, or requiring instrumental interference; and all this notwithstanding the previous administration of large doses of ergot. In cases where the uterus does contract firmly at first, I take it to be but a continuation of the routine of labour, and the uterus, finding no opposition and nothing to expel, relaxes instead of passing into a state of tonic contraction. I should like to insist on the value of a pasty or of a hectic complexion as a warning, and that an accelerated pulse, be it strong or weak, is an almost certain forerunner of hæmorrhage.

The liquid extract of ergot is very unreliable in these cases, and I have been grievously disappointed with preparations of ergot and ammonia in several instances. I have been equally pleased at the quick action of vinegar, given after ergot has failed, especially when followed by brandy or ether. Having experimentally given a wineglassful of vinegar several times, without ergot, I have found little benefit result. Arguing by analogy, I made the following mixture: R Liq. ergotæ, acid. acetic. concentr. aa ℥j; æther. sulph. (s. g. .735) ℥iv. This should be put into a three-ounce bottle, well corked, and shaken thoroughly. I administer of this mixture three teaspoonfuls in a wineglassful of water, and having used it now for a considerable time I am delighted with its efficacy in causing contraction and giving a refreshing sleep after a short interval, with little or no complaint of after-pains. I combine this with the good old-fashioned pincushion pad wrapped round with a napkin. I look upon the ordinary binder, with or without the two or three napkins usually offered by the nurse when a pad is asked for, as a delusion and a snare. With the lower edge well below the hips (where it ought to be to prevent slipping up), the direct pressure on the uterus is almost *nil*, and it serves merely to hinder the pressure of the hand in manipulating the uterus.

Ladbroke Grove Road, W.

JOHN A. FRANCIS.

THE USE OF ACIDIFIED CORROSIVE SUBLIMATE AS AN ANTISEPTIC.

The annotation under the above heading in the JOURNAL of January 21st opens up several important questions. The first is this. In what chemical form does corrosive sublimate enter the system? The primary effect of bringing bichloride of mercury into contact with albuminous substances is doubtless the formation of an insoluble albuminate. Thus, to borrow the words of the annotation, "the mercury becomes mordanted, as it were, on the surfaces with which it first comes in contact." The matter, however, does not rest here. This solid albuminate is soluble in excess of albumen. Now, as in every part, the albumen must sooner or later gain the ascendancy, the mordanted mercury is gradually redissolved and carried away by the circulation. Thus, the mere fact of fixing the mercury for the time being ultimately results in a large influx into the system.

Does, then, the sphere of its activity become greatly diminished? Before a definite answer can be given to this important question, it is necessary to determine whether albuminate of mercury in excess of albumen is itself an antiseptic, and also whether the antiseptic action of corrosive sublimate is exerted directly and solely by its coagulating action on albuminous matters with which it comes into contact. In the latter case its sphere of action would necessarily be limited to the part to which it is directly applied. Until these points are settled no definite conclusion seems possible. Therefore, if to the sublimate solution sufficient acid be added to prevent precipitation of the mercury, I am still in doubt whether its antiseptic power is thereby increased. It may be that under these conditions the mercury would be readily taken up into the system in a large dose at the time of application (possibly giving rise to sudden mercurialism), but its action would not be con-

tinuous. On the other hand, the coagulating effect of the non-acidulated solution may exert a beneficial influence by sealing the surface against the incursion of noxious matters, and in the meantime mercury is gradually absorbed into the system in the form of soluble albuminate.

Corrosive sublimate, in common with many other antiseptic agents, has been hitherto employed to a great extent empirically. It is most desirable that such potent agents should be applied on scientific principles, which alone will serve as finger-posts to warn against the many pitfalls which lie in the way of their employment. An era is now dawning when a rational understanding of their mode of action will prevail. The experiments of Laplace may be hailed as a step in the right direction, but much still remains to be accomplished.

In the discussion which took place at the Obstetrical Society of London in December, 1886, following Dr. Dakin's paper on Mercurialism in Lying-in Women Undergoing Sublimate Irrigation, I advocated acidulation of the solution on totally different grounds. It is well known that when London water (which is slightly alkaline) is employed to dilute a concentrated sublimate solution (even when chloride of ammonium has been previously added), a precipitate sooner or later appears. This precipitation, which must necessarily deteriorate the solution, may be entirely prevented by the addition of a small quantity of acid, sufficient to neutralise the alkalinity of the water. Dilute hydrochloric acid (*B.P.*) in the proportion of ℥iv to ℥j of solid sublimate (which would give no more than ℥ij in ℥iv of 1 in 1,000 solution) is quite sufficient to effect this purpose, and to maintain the strength of the standard solution. In this form it has been employed at the General Lying-in Hospital for the last two years, the acid being added by the chemist to the concentrated glycerine solution. The amount of acid added is but one-tenth of that recommended by Laplace, and is insufficient to prevent the primary precipitation of albuminate of mercury.

SURGICAL MEMORANDA.

CASE OF DISLOCATION OF THE THUMB FORWARDS.

H. P., aged 9 years, was brought to me on January 27th last. He stated that he had been thrown down by a boy in the school playground, falling on his right hand. On examination, I found a deep depression on the dorsal aspect of the thumb, at the metacarpophalangeal joint, the first phalanx of the thumb being dislocated and displaced, so that the base of that bone reached nearly to the centre of the palm. Failing to reduce it without, I put him fully under chloroform, and then found the base of the first phalanx apparently held tightly by the two heads of the flexor brevis pollicis, exactly as the head of the metacarpal bone is held in the common backward dislocation. I pressed the phalanx still further into the palm of the hand, and tried extension; but the most powerful effort I was capable of failed to produce any result. I then placed the fingers of both my hands on the dorsal aspect of the joint, and held the muscles firmly forwards and towards the centre of the palm; then, applying both my thumbs to the base of the phalanx, I pressed it upwards and towards the radial side, when I was pleasantly surprised to find the bone slide easily into its place. The thumb was then flexed a few times to disengage any tissues that might have been in the way, and the hand put up in a stiff case for a few days.

The case may be of interest from its rare occurrence. Mr. Holmes, in his *Treatise on Surgery*, dispatches it in three lines, merely saying that four examples are related by Nélaton, one of which remained permanently irreducible.

FRANCIS TAYLOR SIMSON, L.R.C.P., etc.

110, Lavender Hill, S.W.

INFLATION OF THE EUSTACHIAN TUBES.

SOME time ago, a medical man consulted me on account of deafness, with distressing vertigo and tinnitus. I found it quite impossible to pass the catheter through his right nostril, on account of malformation of that side; it was, therefore, necessary to catheterise the right tube from the left nostril. I found it so easy to do this that, ever since, when it has been necessary to inflate both tubes—and cases have been abundant—I have adopted this measure.

Having inflated the one tube, the catheter is withdrawn about half-an-inch, so as to disengage its point, a half turn is made with the point downwards, and the orifice of the other tube is found at once. It is advisable to use two otoscopes, as it is difficult to change its position when only one is used during the process.

I claim for this method these advantages: 1. The pain and annoyance to the patient of passing the catheter twice is avoided. 2. Having observed the direction of the catheter in the one tubal orifice, the exact position of the other is much more quickly found than when the instrument is withdrawn and passed again through the other nostril. 3. The free movement or otherwise of the point of the catheter, behind the posterior nares, is helpful in the diagnosis of the presence or absence of post-nasal growths or abnormalities. I have no doubt that this method is practised by many aurists, but to some I hope it may be a useful hint.

THERAPEUTIC MEMORANDA.

ANTIPYRIN AND IDIOSYNCRASY.

On February 2nd I saw a girl who for twelve days had taken three doses of antipyrin daily to reduce high temperature in a typical case of typhoid fever. The antipyrin invariably reduced the temperature, and showed no bad effects until the twelfth day of its use, when a rash appeared on the thighs and abdomen, and on the following day every part of her body (arms, hands, legs, and feet) was covered with a most copious rash of characteristic urticaria, except the face, which remained quite clear of the rash. There were no symptoms referable to the air passages in my case. In the cases of Dr. Sturge of Nice, Dr. Barber of Brooklyn, and Dr. Whitehouse of Santiago, the urticaria seems to have come on after the first dose of antipyrin, whereas in my case the patient had taken it with impunity for twelve days. I discontinued the antipyrin, and the rash rapidly faded away. I was extremely puzzled to account for the rash until I read the paragraph in the JOURNAL.

Kirkoswald, R.S.O., Cumberland.

ALEX. MACDONALD.

AN OBJECTION TO THE USE OF SACCHARIN.

I SHOULD like to call the attention of the profession to the singular effect which saccharin has had on a patient of mine.

In a case of glycosuria I had prohibited the use of sugar, and substituted saccharin, with apparently excellent results; but after about twelve or fifteen doses had been used, my patient began to feel so much nausea that he was obliged to leave off taking it. His mouth got to have an "abominably sweet taste always in it," and, without the addition of any sweetening material, everything he touched tasted of saccharin; indeed, so pronounced was this that his pipe, usually such a solace, had to be given up in disgust, on account of the smoke having such a sweet flavour.

This intensity of sweetness occurred on the fifth day after beginning the saccharin; and probably an explanation will be found in the fact that it passes unchanged through the system, and will, I am afraid, produce a sweet saliva, unless it is used with occasional intermissions.

JOHN HEDLEY, M.D. Durh.

Yoster House, Middlesbrough,

CLINICAL MEMORANDA.

CASE OF ALCOHOLIC PARALYSIS, WITH PHTHISIS, TERMINATING IN FATAL LEFT HEMIPLEGIA.

Mrs. W., a widow, aged 44, complained first, in March, of shortness of breath, mentioning incidentally she was unable to move much in bed, owing to loss of power in her legs. There was a cavity in the left apex and moist râles at both bases. The heart was weak, but free from valvular disease. The temperature was slightly raised, the pulse rapid, the breathing shallow. She had been in bed some weeks, having first been laid up with "rheumatic" pains about the legs, and with cough. The urine was loaded with lithates, though otherwise healthy.

The lower extremities were paralysed, and there was considerable difficulty in raising one foot over the other; there was tenderness over the whole body on deep pressure, and sharp pains occurred frequently about the legs, lasting but a short time, but bad enough to make her call out and to keep her awake.

No patellar, plantar, or other usual reflexes could be obtained, and there was no ankle clonus, but acute pain was caused by slight attempts to get this phenomenon. The toes were reflexed and the feet hung helplessly. She could distinguish heat and cold fairly well, but the prick of a pin gave an indistinct impression. The palmar grasp was feeble; the co-ordination of muscles of the upper extremity was fairly good. The sphincters acted satisfactorily. The muscles were greatly atrophied.

On April 28th she was attacked with left hemiplegia, which left her speechless, and with only the right upper limb unparalysed. The left pupil was dilated to twice the diameter of the right. There was no recovery from this attack, and the patient died about twenty-four hours from the onset; no necropsy was permitted. In all, the paralysis ran a course of six or seven weeks. When I was first called in it was so slight as hardly to attract the patient's attention, but rapidly became worse, so that in about a month from the first symptoms the patient was practically helpless. S. H. APPLEFORD, L.R.C.P. Lond., M.R.C.S. Finsbury Circus.

REPORTS

OF

HOSPITAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN, IRELAND, AND THE COLONIES.

SAMARITAN FREE HOSPITAL.

OVARIOTOMY AT THE END OF THE SEVENTH MONTH OF PREGNANCY.

(By GEORGE GRANVILLE BANTOCK, M.D., F.R.C.S. Ed., Surgeon to the Samaritan Free Hospital.)

MRS. C., aged 28, was admitted on December 11th, 1886, under my care, and gave the following history. She was married on December 26th, 1885, and was then apparently in perfect health. Soon afterwards she began to feel some fulness in the lower abdomen, and became sensible of some decided enlargement. She continued to increase very gradually, but at the end of summer the enlargement became more rapid. About the third week in October the distension of the abdomen was so great that she could scarcely lie down, and immediate relief became necessary. Accordingly, Mr. Reynolds, of High Wycombe, tapped her of twenty pints of ovarian fluid, and in the course of two or three weeks sent her to me. I was unable to admit her before the above mentioned date. She had in the meantime increased considerably, and on admission measured 40½ inches at the umbilicus, and 12½ inches from the ensiform cartilage to the pubes. Her last menstruation occurred at the end of May, and up to that time she had been quite regular. The evidence of pregnancy was complete and need not be detailed, while the size of the uterus, which occupied the left side of the abdomen, corresponded with the above date.

The question now lay between tapping again and ovariectomy, and the following arguments presented themselves to my mind. If tapped again there was no guarantee that she would escape some degeneration or inflammatory process in the cyst. But, provided no inflammatory or other mischief ensued, or premature labour did not supervene, the history of the case made it probable that before the natural term was reached, this proceeding would have to be repeated, and probably more than once. Assuming that she escaped these dangers—an assumption scarcely warranted—and labour came on at full term, she was then liable to injury to the tumour in the throes of labour—how probable will be seen by the account of this process—which would prove to be a formidable complication, and if she even recovered from this accident and its consequences, it must be evident that her prospects under ovariectomy would not be improved.

On the other hand, it was probable that a cyst of this kind could be removed through a small incision, and it was certain that if she recovered from the operation—a not unwarrantable assumption—the abdomen had been already distended beyond what would be reached by the enlargement of the uterus at full term, so that the cicatrix would not be subjected to any great strain, but would have time to get quite solid before labour supervened. But premature labour might be induced by the

operation, as had already happened more than once in the Samaritan Free Hospital. Yet this was less likely to happen when the peritonæum was not irritated by the carbolic acid, and especially by the spray, as under the Listerian method. Even in this event the stitches, being closely placed, would hold the wound together and it would suffer no harm, while the labour occurring within the eighth month, would probably be rapid and easy. For these reasons, then, I had no hesitation in deciding upon the radical treatment, as presenting the fewer dangers and the greater probability of success. Accordingly I operated on December 20th.

An incision under three inches in length exposed the cyst. From its not having been distended to its capacity of six weeks ago the cyst was flaccid, and the wall yielded to the thrust of the trocar, so that I was obliged to seize it with a volsella, and, drawing it to the surface, open it with a knife. After the evacuation of the thick mucine colloid contents of the large cyst, there remained a multilocular mass too large to pass through the incision. Accordingly, I broke up several minor loculi, one of the largest and most deep-seated of which contained a thick, dark fluid, showing that degeneration had already commenced. As the now collapsed cyst was being drawn out, a large patch of parietal adhesion on the right side, several square inches in extent, was separated, and then two tags of omentum came into view. These were ligatured and divided.

The uterus at once assumed a central position. The pedicle, from the right side—about the thickness of two fingers, and about an inch and a half long—was first compressed by large pressure forceps, then transfixed with a double thread, which was arranged and tied with my usual figure-of-8 knot, and finally secured by encircling it with the same thread, and divided. The peritonæum was now carefully sponged clean, and a large flat sponge was placed between the uterus and the torn surface in the abdominal wall while the stitches were being put in, to the number of eight, placed close together, about a quarter of an inch apart. This done, the sponge was removed, and, as the oozing had apparently ceased, the wound was closed, and three superficial sutures were added to ensure perfect coaptation of the edges of the skin. Two large cotton-wool pads were placed over the simple gauze with which the wound was covered; a many-tailed bandage was applied, and the patient was placed in bed at the end of about twenty-five minutes.

Little remains to be said of the period of convalescence, which was without any special incident. No opium was administered, as has been my habit for several years; there was no sickness; the stomach was kept empty for about eighteen hours; the highest temperature observed (taken nearly every two hours for two days) was 100° F. on two occasions, and the highest pulse was 94 for about twelve hours. On Christmas day the three superficial and five of the deep sutures were removed, and the wound, which now measured barely two inches and a half, was quite dry and without the slightest bluish in the skin. A strip of plaster was put on to support the wound. The patient felt very well, enjoyed her Christmas dinner of turkey, etc., and only complained of the activity of the child, which kicked unmercifully. On the 27th the remaining three sutures were removed. On January 5th she was out of bed, and on the 10th returned home in excellent health.

Mr. Reynolds, under date March 13th, wrote as follows: "Mrs. C. . . . has safely got over her confinement, which took place on February 28th. She was several hours in labour, and was finally delivered by forceps of a large female child. The abdomen was well supported during labour, and not the slightest inconvenience or discomfort was experienced in consequence of the operation. Both mother and child are doing well, the former leaving her bed to-day for a short time, having previously had her abdominal belt altered to her present size."

For the benefit of those who are interested in the doctrine of chances, it may be worth mentioning that my patient was her husband's second wife, and that her predecessor died after ovariectomy performed in one of the London general hospitals.

REMARKS BY DR. GRANVILLE BANTOCK.—The record of cases of ovariectomy during pregnancy is now so long that little interest attaches to any single case, except there be peculiar circumstances connected with it. The foregoing case appears to me to possess features worthy of special notice. Adverting here to the period of pregnancy only, it may be remarked that the cases hitherto recorded were instances in which the operation was performed in the early months of pregnancy, while I am not aware that it has ever been done so late as in this case.

LEICESTER INFIRMARY.

SUPRAPUBIC LITHOTOMY: BLADDER WOUND SUTURED: PRIMARY UNION: NO CATHETER.

(Under the care of Mr. C. J. BOND, F.R.C.S., Honorary Surgeon.) R. M., a boy aged 10, was admitted, with a history of symptoms of stone in the bladder of three months' duration. The bladder was distended with 8 ounces of boracic fluid, and a small sponge introduced into the rectum. The bladder was then opened above the pubes in the usual way, and a uric acid stone weighing 5 drachms removed by forceps, after enlarging the wound in the bladder upwards on the stone to a sufficient extent. The bladder incision, measuring an inch and a quarter, was now held up by a blunt hook at its upper angle, and very carefully sutured with fine carbolised silk, the sutures being introduced by means of a long-handled needle, with the eye at the point, having a double curve, a horizontal lateral one in the extremity and a vertical one in the shaft, allowing the point to dip down through the wound in the abdominal wall. Ten sutures were used, especial care being taken that the incision was kept stretched to its full extent during their introduction. This is an important point, for, as the bladder soon contracts after the escape of the fluid, if the sutures are introduced in the contracted state, dangerous gaps are apt to be left on subsequent distension. The bladder was then again washed out and distended with boracic fluid and found to be water-tight; the wound in the abdominal wall was closed and dressed antiseptically, a drainage-tube having been inserted.

No catheter was left in the bladder, nor was one passed at any time after the operation. The patient passed the first urine (6 ounces) with but little pain five hours after the operation, and 2 ounces four hours later. On the day following, urine was passed at intervals of from two to three and four hours, in quantities of from 1½ to 3 ounces, and the security of the bladder wound was proved by the fact that in the following night a small scale of calculus was passed, with some straining. This had been detached from the stone by the forceps at the time of the operation, and was thought to have been removed with it.

The further recovery was uninterrupted, the wound healing by primary union, and the temperature remaining normal throughout. The boy was up and about in thirteen days.

REMARKS.—The points of interest to which I would draw attention in this case are: First, that the bladder was allowed to empty itself from the first without the aid of any catheter; and this, I fancy, will be found to be the best way of dealing with these cases, provided that the bladder wound has been accurately and closely sutured while in the distended or stretched state, with frequent sutures of very fine material. For we had previously noticed that it is at the time of passing the catheter on the first or generally second occasions after the operation that the greatest risk occurs, the straining produced forcing the urine between the sutures; this accident, though very undesirable, does not necessarily do away with primary union, as will be seen on referring to a case of primary union in the adult, reported by me elsewhere in February, 1887. Secondly, the sutures, especially the lowest ones, are difficult to introduce, especially in the stout adult, unless one uses some such curved needle as the one here described.

In conclusion, it appears to me that we are justified in trying to get primary closure of the bladder wound in most of these cases of suprapubic lithotomy, as the superiority of the operation when so conducted comes out very strongly in the after-recovery of the patient; and if we fail—which, after careful suturing, in an unbruised, healthy bladder, should be a rare occurrence—no great additional risk is run, provided that a good-sized drainage-tube has been inserted down to the bladder through the abdominal incision.

ENTERIC FEVER AT BORDEAUX.—Bordeaux has for some months past suffered rather exceptionally from enteric fever, especially during December, when as many as 750 patients are said to have been under treatment at one time. The epidemic appears to have greatly abated during the last few weeks, but there is still a large number of cases in the town. Bordeaux is in some respects in a better sanitary condition than many other of the large French towns, but the persistent prevalence of enteric fever shows that it is far from perfect. The local authorities will do well to ascertain where the defect lies, and apply the needful remedy; even if the expenditure involved be heavy.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, FEBRUARY 7TH, 1888.

W. MORRANT BAKER, F.R.C.S., Vice-President, in the Chair.

Etiology of Vesical Growths.—A series of specimens intended to show that irritation of various kinds played a most important part in the production of vesical growths were demonstrated by Mr. HURRY FENWICK. He pointed out that the very earliest form of villous papilloma was to be found in a small patch of stunted papilloma known as subvilloid or cropped villi, and in most of these specimens there existed definite evidence of irritation. Thus, in a case of Dr. Beaven Rake's the patch was found at that part of the bladder which impinged against a straw coated with phosphates four inches and a half long. In Dr. Newman's case the tumour was at the apex of the bladder, and seemed due to the irritation of a large oval stone. Mr. Fenwick then alluded to age and to the position of villous papillomata as corroborative evidence. In carcinoma he believed that the irritation of residual urine was a most important causative factor, and quoted cases in the museums of Stockholm, Glasgow, and London.—Mr. MARMADUKE SHEILD referred to a case of carcinoma of the bladder which had followed at a considerable interval on epithelioma of the penis; amputation of the penis was followed by stricture; the new growth was attributed to the prolonged irritation of instrumentation and of putrid urine. The specimen had been shown to the Society two years ago.—Mr. EVE said that in the specimen he showed of a urinary bladder from a case of bilharzia the thickening of the organ was purely inflammatory.

Osteitis and Periosteitis.—Mr. R. W. PARKER showed specimens of bone disease in children which he described as chronic osteitis and chronic osteo-periosteitis. Case I was a child, aged about 9 years. After a very slight injury severe symptoms set in, and a large extra-periosteal abscess, involving the whole thigh, supervened. After many months' treatment amputation at the hip-joint had to be resorted to. The femur, on examination, was found greatly thickened, and in its interior a small central necrosis was detected. The abscess cavity was situated between the muscles and the periosteum; the latter was firmly adherent to the bone, which was greatly thickened and altered in character. Case II, a boy, about the same age. Following a fall, a chronic thickening of the femur took place; no definite cause for this could be discovered until after removal of the limb, when a small central necrosis was discovered. In this case, also, the bone was greatly altered in character; it appeared to consist entirely of cancellous bone; the periosteum appeared unaltered, and easily separated from the shaft of the femur. Case III, an example of acute necrosis of the shaft of the femur. The periosteum was widely separated from the bone, which appeared dead; there were no signs of repair either in the periosteum or in the bone itself. Mr. Parker contended that the specimens showed that repair in such cases depends very largely on vitality in the bone itself, and that such part as the periosteum played in the repair depended on its being in contact with living bone. The third case, he thought, seemed to indicate that in cases of acute necrosis the periosteum often perished with the bone, and that then repair was impossible. Text-books, he thought, attributed too much function to the periosteum and too little to the bone itself, a circumstance all the more curious considering that bone was the foundation on which the body was built up, and that the periosteum was only an accessory structure.—Mr. MORRANT BAKER coincided with Mr. Parker's view of the first two cases, that the disease was primarily an osteitis.

Dry Caries.—Four specimens of dry caries were shown by Mr. EVE, who referred to the occurrence of this condition in syphilis and tuberculosis. One specimen, from the museum of the London Hospital, was an example of angular curvature taken from a man, aged 39, in which no abscess ever formed, and no pus was found after death. A second specimen, from the Museum of the Royal College of Surgeons, was also an example of angular curvature from the dorso-lumbar region. There was caseous material and necrosis, but no evidence of suppuration. Two other specimens showed extensive destruction of bone without suppuration. In one (presented to the Museum of the Royal College of Surgeons by Mr. Jonathan Hutchinson) there was complete destruction of the cancellous tissue of the os calcis, which was replaced by fibrous

tissue; there was no evidence of tubercle. The casts ought not to be confounded with rarifying osteitis occurring in connection with simple inflammatory action, or with tuberculosis.—Mr. MARMADUKE SHEILD said that many of the cases of dry caries of the spine were associated with caseation, as in one of the specimens shown. In such a case, where the caseous matter was enclosed in a distinct sac, he thought it most probable that there had been suppuration, and that the fluid part had been absorbed, leaving a caseous mass. Paraplegia was not infrequent where abscess was not present, or at least apparent, while where suppuration was present paraplegia seldom occurred.—Mr. MORRANT BAKER thought this was an interesting clinical observation which his experience confirmed.—Mr. R. W. PARKER had found from the examination of a large number of reported cases that abscess occurred less frequently the higher up the vertebral column was diseased, which might account for it.—Dr. ANGEL MONEY agreed with Mr. Marmaduke Sheild's statement.—Mr. WALSHAM thought there was no doubt about its being correct.—Mr. EVE briefly replied.

Ricketty Deformity of Sterno-Clavicular Joint.—A ricketty child, presenting a deformity at the sternal ends of the clavicles, was shown by Mr. W. G. SPENCER. The ends appeared to be displaced forwards at the sterno-clavicular joint; the sternal end was bent forward and thickened. The deformity first began to develop at about six months of age. He attributed it to rickets.—Dr. PENROSE suggested that in these cases there was a green-stick fracture; in one such bone which he had examined there had been a green-stick fracture, and callus had been thrown out. He also mentioned a green-stick fracture of the humerus in a ricketty child with very soft bones.—Dr. ANGEL MONEY had examined one similar case where the deformity was produced about one inch from the sternal end. He believed that the mechanism of the deformity was a green-stick fracture in the first place, followed by the outgrowth of callus.—Mr. BRODIE asked whether the action of the sterno-mastoid muscles had anything to do with producing the deformity.—Mr. J. B. SUTTON thought that the deformity was thus produced during whooping-cough, from which the patient had recently suffered.—Mr. SPENCER said that the deformity was noticed before the whooping-cough. As to the theory of fracture, he pointed out that the deformity was symmetrical.

Case of Anomalous Sacral Appendage.—An infant under the care of Mr. EDMUND OWEN was shown to the Society. On the lower part of the back was a rounded swelling measuring $3\frac{1}{2}$ by $3\frac{1}{2}$ inches, and projecting about seven-eighths of an inch. The lower limit was just above the fold of the nates; the tumour, which was situated a little to the left of the middle line, presented in the exact centre an umbilication. Half way between the dimple and the lower border, and slightly to the left of the middle line was a soft appendage about 2 inches long, and having somewhat the appearance of a fat "little finger"; the base of the appendage was constricted. On the left side of the base of the appendage was a second small excrescence a quarter of an inch long. Both hands were badly developed, being smaller than natural, all other parts of the body appeared to be normal. The child was born at full term, and there was no history of deformity in the family. Mr. Owen suggested that the rounded swelling was the result of spina bifida, while the appendage, and perhaps the tumour also, was the result of an imperfect attempt to produce a double monster; the sacral region was by no means an infrequent site for the attachment of a fairly developed or rudimentary foetus.—Mr. MORRANT BAKER and Mr. J. B. SUTTON both agreed that the case was an example of parasitic foetus. Mr. Sutton observed that if during development the medullary fold remained cleft, two complete foetuses were formed from a single ovum; this was probably the explanation of twins of the same sex in one amniotic sac. From this there was every degree of combination, from Siamese twins to such a case of very rudimentary foetus as that shown by Mr. Owen.

Imperforate Urethra.—Mr. SHATTOCK showed a foetus of about 4 months; the abdomen was greatly distended, and when opened was found to contain a relatively immense cavity which almost filled it; opening into this large cavity the two ureters could be seen. The kidneys were in a condition of cystic disease. The intestine terminated in a well-formed rectum. The urethra was closed. Mr. Shattock discussed the mode of production of this and other similar deformities in a paper of some length, and great ability, but involving very technical embryological matters.

Card Specimens.—Mr. WALTER K. SIBLEY: Double Intussusception in a Baboon.—Mr. C. MANSELL MOULIN: Transverse Fracture of Patella with Bony Union.—Mr. F. S. EVE: Urinary

Bladder and Kidney, from a case of Bilharzia Hæmatobia.—Mr. D'ARCY POWER: Angioma of the Cerebral Membrane.—Mr. JOHN H. MORGAN: Femur with Newly Formed Bone, from a case of Pyæmia in an Infant.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, FEBRUARY 1ST, 1888.

JOHN WILLIAMS, M.D., President, in the Chair.

Specimens.—Mr. MEREDITH showed two large Pedunculated Fibroid Tumours, in both of which axial rotation had occurred, and in one to an extent involving occlusion of the cervical canal and retention of menses.—Dr. LEWERS exhibited the Cervix Uteri removed by Supra-vaginal Amputation on account of Carcinoma, from a patient in whom abortion had been induced at the fourth month a fortnight previously.—Dr. CARTER showed an Epitheliomatous Growth removed from the Cervix by Galvano-cautery.—Dr. W. DUNCAN exhibited Ovaries and a Piece of Jejunum, the latter showing perforation after ovariectomy.—Dr. W. S. GRIFFITH showed a specimen of Myxoma Fibrosus of the Chorion.

On the Effect of Ergot on the Involution of the Uterus.—A paper on this subject was read by Drs. G. E. HERMAN and C. O. FOWLER. They pointed out that the recommendation of a mixture containing ergot during the lying-in period was based upon a general knowledge of the action of such drugs and of the process of involution. No observations had been made, so far as they were aware, as to the actual effect of this treatment upon the process of involution. They had sought to ascertain its effect by measuring the height of the uterus above the pubes on successive days of the lying-in, in two sets of patients—one set (fifty-eight in number) treated with an ergot mixture for a fortnight after labour, the other set (sixty-eight in number) given a single dose of ergot after labour and no more. They found that in the cases treated by the continuous administration of ergot, the uterus diminished more rapidly in size than in those in which one dose only was given. They compared the two sets of cases as to the duration of the lochial discharge, but on this they did not find that the ergot treatment produced any appreciable effect.—Dr. BOXALL contrasted two series of cases, each referring to 100 patients. Every alternate patient admitted to hospital was given a mixture three times a day, containing ext. ergotæ amm. ℞xv for a dose, during the first three days of lying-in. To avoid fallacy in the comparisons, the two series of observations were carried on simultaneously. The ergot mixture was given in the first series. In the second its routine administration was omitted, but in the series were included thirty-one patients, for whom, on account of hæmorrhage, severe after-pains, etc., ergot was subsequently prescribed. The results were presented in a tabular form. By contrasting the two series of cases Dr. Boxall concluded: (1) That though the routine administration of ergot during the first three days of the puerperium exercised no appreciable effect on the date at which the lochia ceased (in this respect confirming the observations of the authors of the paper), the practice of giving ergot mixture during the three days following delivery tended to prevent the formation of clots, and to hasten their expulsion and to diminish the frequency, intensity, and duration of after-pains. (2) That if omitted at first, but given after, the ergot mixture tended to promote the expulsion of clots and to relieve after-pains. Dr. Boxall considered that (a) the routine practice, which he had followed, of administering a douche at 110°–115° F. not only immediately after labour, but also twice a day during the puerperium until the lochia ceased (a powerful stimulant to the uterus); (b) the ergot which was given in every case immediately after labour, and (c) the ergot mixture which was prescribed subsequently in thirty-one of the cases included under the second series, all tended to lessen the difference which he had shown to exist between the two, and that in consequence the beneficial effect of the ergot mixture was even greater than that shown by the figures given in the tables.—Dr. DAKIN had made observations as to the effect of systematic administration of ergot for some days during the puerperium on cases in the General Lying-in Hospital while he was house-physician. They did not support the view which the authors took, but showed that the average day when the fundus had sunk to the brim was 9.12 when ergot was given once only, and 10.3 when ergot was given daily for three days. There were, however, other fallacies than those named by the authors, for, in addition to the condition of bladder, rectum, thickness of abdominal wall, and weight of the uterus in the pelvis, there was the condition of the uterine axis, whether flexed or inclined

antero-posteriorly or laterally. He had found in a number of consecutive cases taken at random that one-sixth of the uteri were in the axis of the body. These ought not to be compared with cases of anteversion and version usual to the uterus during the puerperium, as there might be a difference of three inches or more on this account alone. In one of Dr. Dakin's cases the fundus was found one day in the left hypochondriac region nine inches from the pubes, whereas in the next it was to the right of the middle line, and only measured five inches and a half. He agreed with Dr. Boxall that the lochia were a better criterion of the rate of involution, and in this his own figures did not agree with the authors, for with one dose of ergot the average was 9.8, with three days of ergot 11.6. With reference to the retention of clots and the occurrence of after-pains, he found that, out of 92 cases where ergot was given for three days, 51 (55.4 per cent.) had after-pains and 22 (23.9 per cent.) passed clots. Out of 103 cases where only one dose of ergot was given, 64 (62.136 per cent.) had after-pains and 141 (3.592 per cent.) passed clots, so that the ergot cases had fewer after-pains but passed more clots. The unergotised cases, like Dr. Boxall's, passed clots up to the tenth day, whereas the ergotised ones passed no clots after the sixth day. It seemed that the continuous use of ergot, by keeping up a tonic state of contraction, instead of allowing normal alternate contraction and relaxation, would tend to favour retention of clots, and to prevent the normal process of involution. This was, to a great extent, borne out by his figures.—Dr. SWAYNE wished to know if chloroform was used during delivery, and in how many of the cases? In order to ascertain accurately the effect of ergot given after delivery, in his opinion it was necessary to remove all disturbing influences, such as the administration of anæsthetics during labour.—Dr. HERMAN, in reply, said that the cases observed by Dr. Dakin (which seemed to support an opposite conclusion to that arrived at by Dr. Fowler and himself) were only given ergot for three days, while their cases took it for a fortnight, and he did not therefore regard the two sets of cases as strictly comparable. The sources of error from the mode of measurement pointed out by Dr. Dakin had been present to the minds of Dr. Fowler and himself, but there was no other mode which was not attended with sources of fallacy. Such errors as arose from anteversion and anteversion of the uterus were equally distributed among the two sets of cases, and so did not vitiate the comparison. Dr. Fowler and himself had paid particular attention to the occurrence of lateral displacement, and had found that it depended, in the majority of cases, on the position in which the patient had been lying. They had not referred to it in this paper, as it did not seem to have any important bearing on the subject of the paper. In reply to the question of Dr. Swayne, chloroform had been given in six of the cases, namely, three of each series.

The business of the annual meeting then commenced.

Financial Report.—The report of the auditors of the accounts of the Treasurer for the year ending December 31st, 1887, was read, and showed a considerable increase of invested funds and balance at the bank.—It was proposed by Dr. C. H. RORTH, seconded by Dr. ROGERS, and carried, that the report be received, adopted, and published in the *Transactions*.

Election of Officers.—The list of officers for 1888 nominated by the Council were declared to have been elected by ballot.

The Library.—A satisfactory report was read regarding the Society's library, together with a list of donations of volumes and specimens received during the year.—Dr. HERMAN proposed, Dr. GIBBONS seconded, and it was carried, that it be adopted.

Examinations for Midwives.—The report of the examinations in midwifery for the diploma of the Society showed that 96 candidates had satisfied the examiners during the year, and that in this department valuable work was being done.—Dr. GALABIN proposed, and Mr. MEREDITH seconded, the resolution adopting this report.

President's Address.—The PRESIDENT then delivered the annual address, at the conclusion of which a vote of thanks was passed on the motion of Dr. BRAXTON HICKS, seconded by Dr. SWAYNE.

Votes of Thanks.—Dr. POTTER proposed a warm vote of thanks to the retiring officers, which was seconded by Dr. BOXALL, and responded to by Dr. CHAMPNEYS and Mr. ALBAN DORAN.

The *Medical News* (Philadelphia) states that the first recorded case in America of fatal œdema of the larynx was that of General Washington. He was treated in accordance with the antiphlogistic methods of his time. No local treatment, beyond the inhalation of the vapour of vinegar and water, was employed.

MEDICAL SOCIETY OF LONDON.

MONDAY, FEBRUARY 6TH, 1888.

J. HUGHLINGS JACKSON, M.D., F.R.S., President, in the Chair.

On Empyema. Dr. CURTON divided empyema for practical purposes into three categories, according to their position on the outer, the basal, and the inner aspects of the lung. He said varieties were caused by adhesions and by differences in the pus, by differences in the size and shape of the chest wall. Disease of other organs might also exist either as causing or complicating its treatment. The first kind gave rise, as a rule, to little trouble, but the second and third were different. He alluded to two cases of basal empyema, where the abscess cavities were with difficulty got at. He dwelt upon the necessity for any methodical exploration in such cases. In three cases out of eighty under his care the pus-like fluid was in two cases found to contain no pus-cells but cholesterine, and in one case minute fat-globules. The latter case and one of the former were cured by aspiration alone. He mentioned five cases of fetid empyema, four of which readily recovered. The treatment of double empyema, and the dangers of aspiration and of too sudden removal of tension even by incision in cases associated with heart-disease or great debility, were dealt with and illustrated by cases.

Thoracoplasty.—Mr. PEARCE GOULD read a paper on thoracoplasty, or Estlander's operation, and related the histories of four cases under his care. CASE I.—A girl, aged 9, under the care of Dr. Gilbert Smith, at the Royal Hospital for Diseases of the Chest, had in May, 1886, suffered from left empyema for two years. The left chest was considerably retracted, and there was a profuse discharge of pus from a sinus in the eighth interspace in the anterior axillary line. Mr. Gould made a vertical incision up from the sinus, and removed about an inch and a half from each of the fourth, fifth, sixth, and seventh ribs. The girl left the hospital in August, much improved in her general health, and losing only a small quantity of sero-purulent fluid from the old sinus. She was readmitted in January, 1887, as the discharge had become purulent and more abundant, and the cavity had not shown any further tendency to close. Mr. Gould repeated the former operation, and removed parts of the second, third, fourth, fifth, and sixth ribs, dividing them at the anterior and posterior limits of the empyema cavity. The child recovered, and was recently shown at a meeting of the Society. The cavity in the chest is completely closed, and the girl's condition is very good. CASE II was a boy, aged 9, also under Dr. Gilbert Smith's care at the Royal Hospital for Diseases of the Chest. He was admitted in January, 1887, for fistulous empyema, from which he had suffered for two years. The left side was retracted; in it were two sinuses in the second and sixth spaces, which discharged pus freely. The boy was anemic, thin, and very delicate looking; his urine contained one-third its volume of albumen, and his liver was considerably enlarged. The sinuses were dilated, and the cavity was carefully drained and cleansed daily. Under this treatment he improved, but after two months matters came to a standstill, and on March 28th Mr. Gould explored the chest, found a considerable cavity, and through a vertical incision removed considerable lengths of the second, third, fourth, fifth, and sixth ribs. The ribs were severed in front at their junction with their cartilages, and behind at the limit of the cavity. The very thick pleura within the ribs was also freely excised. The boy recovered well, and was shown to the Society. The left side of the chest is greatly flattened on all sides, and there is still a sinus which discharges a few drops daily. His general condition is excellent. The urine is free from albumen, and the liver is not to be felt below the ribs. CASE III was a boy, aged 12, who had measles followed by pneumonia, and pleurisy six years before. Paracentesis was performed twice. Further surgical aid was refused, and a year after the empyema burst externally, and had continued to discharge freely ever since, a period of five years. On admission the left chest was quite fixed, and presented three sinuses. The heart-beat was displaced outwards and upwards. On July 14th the sinuses were connected by an incision, and led into a cavity through the second space, and the tissues were removed from the second to the seventh ribs, which were then removed *in toto*, together with much thickened pleura. Haemorrhage was considerable but was controlled by irrigation; a counter-opening was made, and the opening closed. The lad left the hospital on August 15th with the wound almost healed, and in very much improved health. CASE IV was an adult, aged 25, who had pleurisy in 1881, which was aspirated. After a varied hospital experience, she was admitted

with considerable flattening of the right chest, and with a fistulous opening at the angle of the scapula, and another in the seventh space below the nipple, which discharged abundance of fetid pus. By means of an incision ten inches long in the axillary line, the ribs from the second to the ninth were excised, fifty-four inches in all. The pleura, which was nearly an inch thick, was also freely excised. She died suddenly the next morning. The heart was adherent throughout, and much displaced and fatty. Mr. Gould explained the object of these operations and their indications, but he deprecated resort to them merely to save time. He insisted on the necessity for exploring the cavity before operating in order to adapt the operation to each case. The success of the operation varied, but he maintained that this would be increased as it was more extensively practised. —Dr. H. DE HAVILLAND HALL related the case of a man, aged 25, who was treated for empyema at the Westminster Hospital in 1884. He gave a history of fistulous empyema on the left side from November, 1882. He was a thin pale man, with a trace of albumen in his urine. A counter-opening was made by Mr. Boyce Barrow in the eleventh interspace behind, at the angle of the scapula, the tenth being gouged to allow the passage of the drainage-tube through the pleural cavity. The patient immediately improved, but it was found impossible to dispense with the tube, so he invited a more radical operation. Mr. Barrow consequently removed about an inch of the eighth and ninth ribs, after which the cavity filled up, and the patient made a perfect recovery. —Mr. J. ASTLEY BLOXAM showed a man, aged 27, who had coughed up 30 ozs. of pus on one occasion. The right side of the chest moved badly, and was dull on percussion. There was also bulging. He made an incision below the angle of the scapula, giving exit to a quantity of fetid pus, and inserted a drainage-tube. On June 20th it was found necessary to remove three inches of five ribs, after which the patient quickly recovered, though the operation was very severe. A piece of necrosed rib had subsequently to be removed, and recovery was then complete. —Dr. SYMES THOMPSON observed that it was often difficult to know how many ribs to remove. He agreed that it was best to remove a few ribs to begin with, and then remove more if necessary. —Dr. WHITE said it was as good to remove small portions. —Mr. R. W. PARKER suggested that a free incision should be made, and the cavity scraped. He quoted a case of sponge-grafting which had proved successful. In reply to Mr. Bloxam he explained that the sponge was introduced after the cavity had been scraped. —Mr. BLOXAM expressed some incredulity on this point, as he had never before heard of a successful attempt at sponge-grafting in such cases. —Dr. SYMES THOMPSON had seen several unsuccessful attempts when the cavity had not been scraped. —Dr. CURTON, in reply, said that he thought the eleventh space too low; it did not matter where the opening was so long as it was high enough. —Mr. GOULD, in reply, explained that he did not intend the operation to be considered as a routine operation, but only as applicable to particular cases. —Dr. HALL, in reply, said he preferred to open in a dependent part with through drainage. —Dr. CURTON added that the site he preferred was the ninth space in the posterior axillary line. —Mr. BLOXAM said that it had only been by cutting away a rib until enough had been removed that he had effected a cure.

HUNTERIAN SOCIETY.

WEDNESDAY, JANUARY 25TH, 1888.

HENRY GERVIS, M.D., President, in the Chair.

The Therapeutical Indications of Neurasthenia contrasted with those of Hysteria.—Mr. DE BRUET HOWELL said that as long as the pains and disabilities of the disorder termed hysteria were treated by coercive severity, by indifference and inattention, on the ground that they were due to wilfulness, obstinacy and fancifulness, so long must that condition not only remain unrelieved, but be aggravated and prolonged. On the other hand, if irresolution and incapacity, that is, loss of physical power and moral control represented the condition of the nervous system, whether it were termed "neurosis," "neurasthenia," "neurorhthlisis," or any other name be given that philologists might determine, the nature of the case undoubtedly demanded that means should be taken to improve the strength and raise the moral tone. Bearing in mind the division of this class of case into (1) simple, (2) irritative, and (3) depraved, it was obvious that, before this could be done, all sources of irritation, both physical and moral should be removed. The great susceptibility

of this condition to both pain and irritation made this imperative. Nothing could be more annoying, or was actually the cause of more mischievous irritation to the patient, than that her valid complaints should be received with incredulity, and treated with indifference. The cases of M. Charcot, alluded to by Dr. Graily Hewitt, in which pressure over the ovaries produced convulsions, might very properly be termed "hysterical." At the same time, it was clear that this effect would not be produced if the nervous system were not in a very excitable condition. They clearly pointed out that a broad distinction should be drawn between the state of the nervous system, and the source of "hysterical" irritation. It was much to be regretted that these two things, so perfectly distinct, should have been so frequently confounded. There was something very morbid about these cases, and he (the speaker) did not discover any therapeutic indications in the treatment adopted. It was also to be regretted that some practitioners still regarded the valid complaints of patients deemed to be hysterical, as fictitious, and that others avowed that they still treated them with severity, because, within the last six months he had seen patients so treated, who declared that their lives had been marred thereby; some were rendered indignant, and others were humiliated by the treatment they had undergone. The true therapeutic indications were to improve physical strength and raise moral tone. This was best done by restoring confidence and resolution, and promoting and cultivating self-reliance. Lady nurses might be trained to assist most carefully in this work, and it was especially desirable that the milky treatment so strongly advocated should partake of that of human kindness.—The PRESIDENT, in thanking Mr. Hovell for his very interesting and learned paper, said that he did not think that so great an authority as Dr. Playfair could have stated that patients cured of this affection never relapsed. In considering the etymology of the word "hysteria," he believed that its use was liable to lead to mistakes, but adopting the term "neurasthenia," it must be remembered that the change was a moral as well as a physical one, yet it was a real and not an imaginary disease. He thought that love of sympathy was certainly a motive in cases of malingering.—Mr. GILBERT, from his experience in general practice, did not believe that Mr. Hovell's treatment was of any effect in a large number of cases. There was no real disease or paralysis except that of the patient's will. They might suffer pain for years, yet did not get thin, but on the contrary fat. He asked what was the explanation of cases lasting for years, and then often suddenly getting well. There was the greatest difficulty in diagnosis when this condition was associated with or came on after organic disease or injury.—Dr. GRAILY HEWITT said the subject was an exceedingly complicated one, the meaning of the terms used being very indefinite. There were strong reasons for using the term "hysteria." His attention was directed to cases of hysteria associated with attacks of convulsions and due to conditions of the uterus; these patients he found were almost always cured. Hysteria comprehended cases in the male, such as Professor Charcot's cases of hystero-epilepsy, in which the character of the convulsions was the same in the male as the female. An hypothesis might be brought forward to cover both of these classes. Might there not be a central exciting cause indistinguishable from the reflex form. He then referred to cases under Professor Charcot. The condition of the central nervous system was the most important consideration; the nervous tissues were in a state of extreme malnutrition, and hence liable to disturbance, and irritable to reflex stimuli. The Weir-Mitchell mode of treatment by enforced food certainly rendered the disturbances less. On the other hand, the pains and disabilities of the patients were often very real, and due to conditions of the uterus. In this he agreed with Mr. Hovell.—Dr. HALE WHITE thought it difficult to separate hysteria from neurasthenia; differences however could be distinguished, for instance, hysteria was common amongst persons of an emotional type, so was to be met with mostly in females, and was more common in France; neurasthenia, on the other hand, was more common in persons who worked hard, as in New York. Therefore he would not put aside the term "hysteria." The disease was certainly not voluntary, hence punishment and coercion were wrong methods of treatment. He thought Mr. Hovell had overdrawn the picture. Coercion, properly so-called, was not adopted in homes; it was really an attempt to make the girls help themselves. The medical profession did not disbelieve in the reality of the disease. It was hypothetical to suppose that either of these was due to the sympathetic nervous system, as nothing was known of the working of this system.—Dr. R. J. RYLE discussed and contrasted the etymology

of the terms "neurasthenia," "neurophthisis," and "neurotabes."—Mr. DE BERDT HOVELL, in reply, said that his object was not to insist on the actual meaning of the terms, but to separate cases of hysterical origin from those of neurasthenia.

HARVEIAN SOCIETY OF LONDON.

THURSDAY, FEBRUARY 2ND, 1888.

WILLIAM SEDGWICK, M.R.C.S., President, in the Chair.

Intestinal Obstruction.—Dr. DOWN read a case of fatal intestinal obstruction, due to a rare form of internal hernia. The patient was a woman, aged 56; no children. The symptoms of obstruction were fairly acute. Manual exploration of the rectum gave no result. Abdominal section was discussed, but not performed. After death the cæcum was found near the middle of the abdomen, and, together with the ilium, was obstructed by a band, which proved to be the right Fallopian tube, which was greatly elongated and adherent to the ilium and duodenum. Death was due to perforation of the cæcum, followed by fecal extravasation. Dr. Down thought the *post-mortem* appearances showed that abdominal section might have been successful, although the Fallopian tube would have required division.—Mr. LOCKWOOD remarked upon the position of the perforation, and said it was in the usual place. He thought an exploratory operation would have afforded a chance of relief.—Mr. D'ARCY POWER wished to know whether there was any history of previous attacks of peritonitis.—Dr. HANDFIELD-JONES spoke of the rarity of the condition, and wished to know whether the Fallopian tube was adherent to the cæcum.—Dr. DOWN, in reply, said there was no history of previous attacks of peritonitis, and that the Fallopian tube was adherent.

Treatment of Loose Cartilage in Knee-Joint.—Mr. HERBERT ALLINGHAM read a case of suture of the internal semilunar cartilage of the knee to the head of the tibia. The patient was a man, aged 35, who had been constantly laid up by slipping of the internal fibro-cartilage of the knee. An incision two inches long was made, with its centre over the cartilage. The knee-joint was opened, and a strong catgut passed through the fibro-cartilage and the periosteum of the upper end of the tibia. The joint was washed out with carbolic lotion, and the synovial membrane united with deep catgut sutures; the wound was then closed without drainage. The patient, who was shown to the Society, made a good recovery, and can now follow his employment.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SURGICAL SECTION.

FRIDAY, JANUARY 20TH, 1888.

A. H. CORLEY, M.D., President, in the Chair.

The Treatment of Advanced Conditions of Equino-Varus.—Mr. SWAN read a paper on the treatment of advanced conditions of equino-varus, which he maintained to be curable by proper treatment, carried out before the expiration of the first year of life, or before walking had commenced. After three or four years had elapsed a modified result might be obtained, but the treatment would be prolonged and difficult. When the patient had reached the age of 10 the tarsal bones were thickened; the large adventitious bursa was dense, and included in its base the cuboid and the tarsal end of the fifth metatarsal bones. In such a case ablation of a portion of the tarsal bones was indicated. The portion removed should consist of the anterior three-fourths of the cuboid bone, all the external cuneiform except its posterior part, the proximal extremities of the third, fourth, and fifth metatarsal bones; and the apex of the wedge would consist of a portion of the middle cuneiform. The mobility of the foot would remain almost unimpaired; and, as the metatarsal bones had their epiphyses at the distal end, it was probable the development of the foot would not be interfered with. He had performed this operation in thirty-four cases since 1876.—Mr. W. THORNLEY STOKER and Dr. GUNN took part in the discussion, and Mr. SWAN replied.

The Surgery of the Thyroid Gland.—Mr. FOX read a paper on the surgery of the thyroid gland. After tracing the history of operations for the ablation of the gland and extirpation of tumour, he compared the modern operation of Dr. P. H. Watson with that recommended and practised by Desault at the Hôtel Dieu in 1791. He condemned the many minor operations of setons, caustics, injections of irritants, and tapping, and gave the history of a suc-

successful removal of a cysto-adenoma from the right lobe of a young married woman's thyroid.—The PRESIDENT said that Dr. P. H. Watson had advocated the operation for the complete removal of the gland, while at the same time indicating that the surgeon must be prepared to see the patient die on the table—a fatality which occurred at least once in that distinguished surgeon's practice; and he dwelt strongly on the necessity of leaving the capsule uncut, especially the capsule surrounding the vessels.—Mr. STORY inquired what the indications were for operating on tumour on the thyroid gland.—Mr. KENDAL FRANKS did not think the size of a tumour in the neck a guide to operative procedure. Small tumours indicating a tendency to press backwards and sometimes down under the top of the sternum caused great dyspnoea and endangered life.—Mr. W. THORNLEY STOKER had operated in several cases of goitre, both by removal and by division of the isthmus, and in his experience the operator must be prepared for terrible hemorrhage. He condemned, with Mr. Franks, the practice of passing a seton through the gland. The rationale of the operation of the division of the isthmus was that it limited the blood-supply of the gland. He found it gave relief for the time and set the trachea free. As regarded the opening of the capsule he had no decided opinion, being unable in his operations to find out where or what it was; for, when he cut down on the diseased structure, he came on the gland covered by enormous veins, some as big as his thumb; and whether these were inside or outside the capsule he had not been able to determine.—The PRESIDENT said that thirteen years ago he had a case of acute goitre, and, at the suggestion of Dr. Purser, he had given five or ten grains of quinine three times a day, and in a week or ten days the growth stopped. Happening to be with Sir William Mac Cormac in St. Thomas's Hospital, he saw a patient with a tumour on the front of the neck that grew rapidly, and he mentioned the quinine cure. Sir William Mac Cormac tried it, and in fourteen days the growth ceased and the patient recovered.—Mr. FOX, in reply, considered that the operation was justified when the tumour was growing quickly, when dyspnoea or dysphagia was marked, or when any evidence of malignancy was present, and also when the most improved internal and external medication had not given good results. In the swampy districts of the Carolinas a malarial type of goitre was prevalent, which was amenable to treatment by quinine; but the occurrence of such cases in this country must be very rare. Setons, tapping, and caustics were not free from danger, and in many cases did not give favourable results. As for Sir Morell Mackenzie's method of injecting perchloride of iron, he mentioned it only as a treatment most unsuitable and to be avoided.

SECTION OF ANATOMY AND PHYSIOLOGY.

FRIDAY, JANUARY 6TH, 1888.

H. ST. JOHN BROOKS, M.B., President, in the Chair.

Notes of some Nervous and Arterial Anomalies.—Dr. AMBROSE BIRMINGHAM read a paper on this subject, which was discussed by the PRESIDENT and Professor CUNNINGHAM.

An Effect produced by Direct Stimulation of the Heart.—Dr. PURSER made a communication on the results which follow direct stimulation by single induction shocks of the different parts of the heart of the frog. Attention was particularly called to the pause which is sometimes observed without the occurrence of any extra contraction.

First Dorsal Interosseous Muscle supplied by the Median Nerve.—Dr. Brooks read a short paper on a remarkable case of variation in nerve-supply that he had recently observed. The branch of the median to the first lumbrical muscle was larger than usual, and, after supplying that muscle, pierced it, and united to form a nervous arch with a twig from that branch of the median which divides to supply the contiguous sides of the index and middle fingers. The latter twig had no connection with the nerve to the second lumbrical. The arch thus formed by twigs from the median nerve lay under cover of the long flexor tendon of the index finger, and gave off in this situation two twigs to the metacarpo-phalangeal articulation of the index finger, and a strong twig to the first dorsal interosseous muscle. The nerve was traced into the muscle, and was found to end chiefly in its distal part; the proximal part of the muscle was supplied by the normal branch from the deep palmar division of the ulnar. The ulnar twig communicated by two or three excessively fine filaments with the abnormal median twig in the substance of the muscle. A microscopic examination showed that there were not any

"nerves without ends" in the loop above described. The two factors of the loop entered about equally into the composition of the nerve to the interosseous muscle. He believed this variation to be unique. It appeared as if there were in the limb several main lines diverging from the brachial plexus, and meeting again at their terminations in the hand, and that at the points of divergence a shunt of fibres, as it were, might take place, and almost any nerve pass to its destination by an unusual route.

On the Distribution of the Cutaneous Nerves on the Dorsum of the Human Hand.—Dr. BROOKS also read a paper on this subject, in which he showed that the areas of distribution of the nerves often overlapped one another. In five cases, which he had dissected for the purpose, he had found the radial and dorsal branch of the ulnar nerves overlapping for a certain extent. In the case that he had examined with the greatest care, they overlapped in their distribution for the extent of three fingers (index, middle, and ring), with a corresponding area on the back of the hand. He had also succeeded in tracing filaments of the musculo-cutaneous and external cutaneous branch of the musculo-spiral overlapping the radial and ulnar; the musculo-spiral in one case reaching the metacarpo-phalangeal articulation of the little finger. He found that the dorsal nerves extended in the case of the thumb and little finger as far as the nails, in the index and ring fingers as far as the second interphalangeal joints, and in the middle finger only as far as the first interphalangeal articulation. He had found the palmar nerves taking part in the dorsal supply of all the fingers, not excepting the thumb; in several cases he had traced strong branches of the median passing under the thumb nail, and ramifying in the bed of the nail. It was well known that the median and ulnar nerves encroached on one another's domains; some remarkable and instructive cases of this had been recently described by Dr. Hepburn, but he had not met with any record of the nerves overlapping in the literature of the subject except that in one of Henle's figures it was shown to a very slight degree, but not described in the text. Through the kindness of Mr. Wheeler, the author had had the opportunity of examining a patient in the City of Dublin Hospital who had undergone the operation of section of the ulnar nerve. Sensation was completely lost in the little finger, and half the ring finger, and over a corresponding area of the back of the hand. Over the greater part of the dorsum of the hand, as far as the base of the index finger, the sensation was very perceptibly dulled.—Dr. CUNNINGHAM said there was not the least doubt that Dr. Brooks had made out a perfectly new point in regard to the intercrossing of nerves. All were familiar with the great variation in the nerve-supply of the skin, but they considered hitherto that when one nerve advanced into the territory of another, the nerve so invaded retreated. Now Dr. Brooks had shown how completely erroneous in this respect their impressions were.—Dr. Brooks, replying, said the point he contended for as new was the overlapping of the nerves; for it was already well known there was a struggle between the two nerves—sometimes the ulnar nerve going to the radial side, and the radial to the ulnar side.

SOUTH INDIAN BRANCH.

SATURDAY, SEPTEMBER 3RD, 1887.

Deputy Surgeon-General S. B. ROE, C.B., in the Chair.

Lithotomy.—A series of cases of suprapubic and lateral lithotomy were related and specimens exhibited.—Assistant Surgeon STANTON submitted two cases of Suprapubic Lithotomy: (1) a Brahmin boy, aged 13, who had suffered from symptoms of stone for probably nine years; after the stone had been removed (with lithotomy forceps), a large drainage-tube was inserted at the lower end of the wound, and the upper part brought together by thick silk sutures, including the whole thickness of the abdominal wall; the highest point touched by the temperature curve was 103° F. on the fourth day; the drainage-tube was removed on the twelfth day, and the fistula was quite healed on the twenty-third day; (2) an emaciated man, aged 21, who had suffered from symptoms of stone from the age of 7 or 8; at the operation the bladder, which was much inflamed and thickened, contained fetid pus; two narrow tubes were inserted, and the upper part of the wound brought together with deep silver and superficial silk sutures; the patient did not do well, the wound did not heal, vomiting and insomnia persisted, and he passed into a typhoid condition and died on the twelfth day. Mr. Stanton considered that it was best to distend the rectum before filling the bladder.—Brigade-Surgeon FOX related two cases in which he had removed

a mulberry calculus by the lateral operation; in one case the stone weighed an ounce and a half; both cases came from the same village in the North Arcot District, where calculus was very rare. He also showed a stick, $6\frac{1}{2}$ inches long, thickly coated with phosphate, and having a piece of cotton at one end and a phosphatic calculus, measuring $4\frac{1}{2}$ inches by $3\frac{1}{2}$ inches in circumference, at the other; it had been removed from the abdomen of a young woman, aged 22. A midwife, with the object of procuring abortion, had intended to pass the stick, armed with some irritant, into the womb, but had passed it into the bladder instead, where it appears to have remained rather more than two years; then a fistula formed at the navel, through which pus and urine, and subsequently faeces, escaped. In order to extract the stick an incision four inches long in the middle line of the abdomen was found to be necessary. She remained in hospital a little over three months, and shortly afterwards the fistula closed completely. She was again seen about fifteen years after the operation, when she was in good health.—Brigade-Surgeon SIBTHORPE showed a calculus the size of a hen's egg, weighing four ounces, and consisting of a nucleus of oxalate of lime, coated with phosphates, which had been removed by the suprapubic operation from the bladder of an emaciated Hindu, aged 40, of intemperate habits. The patient made a remarkably good recovery, the wound healing in twenty-three days. It was found to be impracticable to suture the wound in the bladder owing to its length; a drainage-tube was accordingly used. This patient also came from North Arcot. Dr. Sibthorpe also showed specimens from a case of urethral calculus, an account of which will be published subsequently.

Ovariectomy.—Surgeon J. SMYTH, M.D., read the notes of a case of large multilocular ovarian cystoma in which he had performed ovariectomy. The patient made a good recovery, though she was for some time troubled by severe neuralgia of the anterior crural nerve.

Severe Injury to the Spinal Cord.—Brigade-Surgeon SIBTHORPE related the case of a young man who was admitted into the General Hospital six days after a severe blow in the interscapular region, which was immediately followed by extensive paralysis. When admitted he was paralysed in both upper and lower extremities, respiration was almost purely diaphragmatic, the accessory muscles of respiration also moving the upper part of the chest somewhat; there was anæsthesia below the nipple level, and in the upper extremities below the elbows. He gradually sank and died on the seventh day. A few hours before death the temperature began to rise rapidly, and finally reached 109° F. in the mouth. At the necropsy the anterior part of the body of the fourth cervical vertebra was found to be bruised, and the membranes of the cord were at this level injected; the cord appeared normal externally, but on section a patch of red softening, the size of a large pea, was seen in the centre, just below the third pair of cervical nerves. The cord appeared to be otherwise healthy. The internal organs were congested, especially the posterior border of the right lung.

Cases of congenital sebaceous cyst and of impacted intra-capsular fracture of the femur, also reported by Dr. Sibthorpe, will be subsequently published.

THE CLINICAL SOCIETY OF MANCHESTER.

TUESDAY, JANUARY 17TH, 1888.

S. WOODCOCK, M.D., President, in the Chair.

Etiology of Pelvic Disease in Women.—Dr. LE PAGE read a paper on the etiology of those pathological conditions in woman which had their origin in the pelvis. The principal points in which woman differed physiologically from other females were considered. In the lower animals, the rut was short, the anti-rut long—that is, sexual activity was of short duration; sexual repose was prolonged. In woman, there was no interval during which the sexual passion was in abeyance. The life of a woman naturally divided itself into three periods: 1, the pre-menstrual; 2, the menstrual; 3, the post-menstrual; and many of the diseases of women may be traced to the first period, the whole of which was occupied in the development of the organs of sex. The causes of pelvic disease, operating in the period bounded by the maturation of the sexual organs and the decadence of generative functional activity, were then reviewed.

Hydronephrosis.—Mr. BISHOP showed the kidney of a patient suffering from hydronephrosis, which he had removed a month before; also, a microscopical section of the degenerated renal tissue, showing the atrophied Malpighian tufts and tubules. The

operation was post-peritoneal and extracapsular. Some collapse followed, but the patient made a good recovery.

Convulsions in Pregnancy.—Mr. W. BAIN read notes of a case of convulsions in a pregnant woman, associated with albuminuria.—In the discussion which followed, the PRESIDENT, Drs. RAILTON, BRIERLEY, BODDY, and Mr. FRANK HOLMES took part.

REVIEWS AND NOTICES.

THE VOLCANIC ORIGIN OF EPIDEMICS. By JOHN PARKIN, M.D., F.R.C.S., formerly Her Majesty's Inspector for Cholera in the West Indies. Popular edition. London: Sampson Low and Co. 1887.

THIS volume is a sequel to the author's essay on the non-contagiousness of epidemics. It is the outward and visible sign of a desire to supply a hypothesis in place of the one which has been demolished—to his own satisfaction—in the earlier work. The various and changing theories which have prevailed on the subject of the causation and nature of diseased conditions give a certain plausibility to the author's attack on the views which now obtain of the operation of contagion and the communicability of epidemics. The author first deals with the influence of the different factors which go to make up matter, and he shows that neither heat nor cold, dryness nor humidity, are *per se* possessed of a constant power in the spread or otherwise of most of the so-called contagious diseases. Having disposed of electricity as a possible causative agent, the author arrives at the conclusion that the morbid influence is contained in the atmosphere, an inference which he supports by numerous instances of the effect of particular winds on the course of prevailing epidemics, and by statistics which tend to prove that during certain cholera epidemics in England the persons who suffered most severely were those whose occupations were outdoor.

Having demonstrated to his own satisfaction the existence of the morbid agent in the atmosphere, the author proceeds to inquire into the nature and origin of this agent. Not being able to account for it by any alteration in the chemical affinities and properties of the air itself, nor by anything generated on the surface of the earth or on the bodies of men, he suggests a glance into the interior of the globe. The willingness of the reader to follow the author in this Jules-Verne-like excursion is promptly repressed by the information that, as we cannot very well act on his suggestion, we must content ourselves with what information we can glean from the manifestations of intra-terrestrial changes as seen in volcanic action. Close observation of these phenomena has enabled the author to formulate the following laws: (1) That the effects of volcanic action are felt and witnessed along particular lines of the earth's surface; (2) that these phenomena are regular in their progress, both chronologically and geographically; (3) that they are characterised by a limited duration and a periodical return.

These peculiarities, the author urges, are strictly noticeable in the evolution and progress of epidemic disorders, both sorts of phenomena being governed by the same general laws. He argues, therefore, that the onset is an effect of the operation of the other set, and, as it would be hazardous to pretend that epidemics started volcanic activity, volcanic action is credited with producing the epidemics. It would be unkind to discuss the logic of such a proposition from a scholastic point of view; it resembles the well-known transition from pigeon pie to fish pie.

The author has collected a large number of intelligent observations which, while useless and even pernicious as evidence, are nevertheless of value, if only to demonstrate that the exception proves the rule.

BEQUESTS.—Mr. John Godfrey Morris, of Birkenhead, bequeathed £500 to the British Home for Incurables, £300 to the Stratford-on-Avon Dispensary, and £300 to the Evesham Lying-in Hospital.—The Halifax Infirmary has received £449 10s. under the will of Mrs. Hargreaves.—Mr. James Johnson Ellis, of West Parleigh, bequeathed £100 to the West Kent General Hospital, and £100 to the Kent County Ophthalmic Hospital.—The Queen's Hospital, Birmingham, has become entitled to £100 under the will of Mr. Francis Deakin, and £100 under that of Mr. John Stubbs.—Mr. Robert Caddell, of Harbournstown, Meath, bequeathed £50 to the Mater Misericordiae Hospital, Dublin.

NOTES ON BOOKS.

Contemporaneous Portraiture.—Under the title of Men and Women of the Day; a Portrait Gallery of Contemporaneous Portraiture, Messrs. Richard Bentley and Sons are issuing a series of photographs by Mr. HENRY BARRATT, the well-known photographer of 263, Oxford Street, whose medical photographs have long held a very high position, and whose portrait groups of the International Medical Congress were a great success. The present issue consists of permanent photographs printed on thick mill-board (any of which can be framed) issued in monthly parts at two shillings and sixpence; each part contains three large panel portraits, so that the annual volume will contain thirty-six panel portraits for thirty shillings, each picture being considerably less than half an ordinary cabinet in price. The portraits in this first part are of political and other public personages. The forthcoming numbers will contain portraits of Sir James Paget, Sir William Gull, Sir Morell Mackenzie, Sir Joseph Lister, and we believe also, at an early date, M. Pasteur and many foreign medical celebrities. Such a book forms a delightful record of our most eminent contemporaries as seen in the life, and the three photographs issued are triumphs of photographic portraiture and of permanent printing.

Calf Lymph Culture and Vaccination. By O. PENFOLD, M.R.C.S. Eng.—This pamphlet appears to be written for non-professional readers. Mr. Penfold has probably not studied the manner in which calf vaccination is carried out in England, or he would know that the eighth day is certainly not the best time to take lymph, as, by that time, it has undergone marked degeneration in its powers of keeping; and, if transmitted from calf to calf, the resulting vesicles, in the course of a few generations, become useless. The addition of any preservative substance to lymph is unnecessary, and strongly to be deprecated; for, if lymph be taken on the fourth or fifth day (ninety-six to one hundred and twenty hours after vaccination), on ivory points, and allowed to dry, or in capillary tubes, and hermetically sealed, it may be used with satisfactory results, the former method of storage being preferable for the vaccination of children. The author prefers calves from eight to twelve months of age; this is, in Europe at any rate, too old, the best age being about four months, the skins being much softer and the animals more easily managed. The case of vaccination with human lymph which is quoted is decidedly not typical of the current vaccination in this country; the lymph was probably taken from a degenerated source. Lastly, we are surprised to find Mr. Penfold upholding the antiquated quarantine system, which has so conspicuously failed whenever tried, except on the very smallest scale. Upon vaccination and revaccination only can a community safely rely for freedom from small-pox.

REPORTS AND ANALYSES

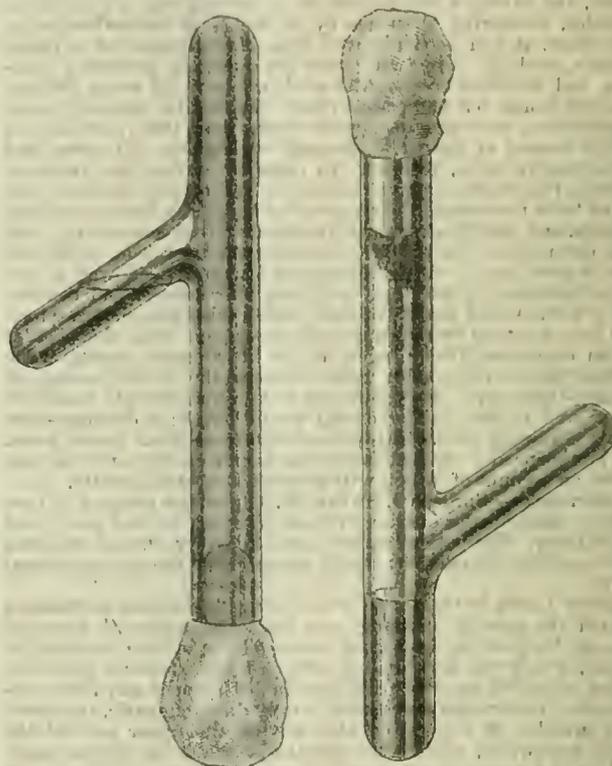

AND

DESCRIPTIONS OF NEW INVENTIONS,
IN MEDICINE, SURGERY, DIETETICS, AND THE
ALLIED SCIENCES.

NEW CULTIVATING TUBE.

IN the belief that any simple contrivance which is likely to diminish the risk of accidental contamination in the employment of liquid cultivations will be welcomed by bacteriologists, I am induced to send you a drawing and description of a form of apparatus which I have recently made use of. It may be described as an ordinary test-tube with a blind lateral arm about two inches in length. This arm joins the main tube about two inches from its lower end, and forms, with the proximal part of the tube, an angle of about 45°. The tube is plugged with cotton-wool and sterilised. It is then filled for about an inch and a half of its depth with the liquid medium, and sterilised in the usual manner. When the tube is to be inoculated it is slowly inverted, so as to allow its liquid contents to flow into the lateral arm. While the tube is thus inverted, the cotton-wool plug is removed, and the seed material is introduced up to the bottom of the main tube, in precisely the same manner as one inoculates a tube of solid gela-

line or agar material. The inoculating needle having been withdrawn, the plug is replaced, and the tube returned to what may be called its erect position, the liquid being thus brought into contact with the seed material.

Tube inverted for inoculation.

Tube erect.

The only special precautions to be observed in using the tube are—(1) to use of the liquid medium a volume slightly smaller than the capacity of the lateral arm, and (2) to invert the tube slowly, turning it in a vertical plane towards the lateral arm. By attending to these points one can avoid the risk of part of the contents being poured out of the tube. The tubes necessarily cost a little more than the ordinary test-tubes, but, if made of stout glass, they can be used again and again. There is no difficulty in cleaning the lateral arm by shaking with a small quantity of shot. Edinburgh. J. McFADYEAN, M.B., C.M.E.D.

GAMEBLE'S IMPROVED METHOD OF WARMING AND
VENTILATING DWELLING HOUSES, OFFICES,
AND THE LIKE.

THIS is a system of warming and ventilating rooms by means of heated air which has been patented by Mr. J. H. Gamble. It is in principle a modification of Galton's grate and the Manchester school grate, in which fresh air is warmed by circulating round the back of a stove, and is then admitted into the room about on a level with the chimney breast. In Mr. Gamble's method the external air is conducted to a compartment surrounding a stove of special construction or an ordinary kitchen range situated in the basement of a house, and then passes up a shaft to be distributed to the upper rooms. The products of combustion of the stove in the basement are carried off by a metal flue which passes up through the warm air shaft, and by this means the waste heat is made to contribute to the heating of the fresh air supply. It is claimed by the inventor that rooms thus supplied with warm air will not require open fireplaces, which serve under his method for the admission of warmed air, and are provided with valves for regulating the same. In Mr. Gamble's system means are also provided for carrying away the vitiated air by exhaust shafts, but about these there is nothing special. It is difficult to see how the system could be applied to existing houses without great structural alterations, but for new buildings in course of construction,

especially for workhouses, hospitals, public offices, etc., the system might very probably be effective and cheap in working.

ST. JAMES'S RUM.

It is a well-known fact attested by M. Girard, the official analyst in Paris, and much deplored by French growers, that, owing to the ravages of the oïdium a comparatively small part of what is sold as French brandy is the unadulterated produce of the grape. Enormous quantities of cheap rectified potato spirit are imported into France, and re-exported after manipulation as cognac. Such doctored and manipulated spirit, which constitutes a very large proportion of what is now being innocently used in hospitals and sick rooms as old cognac, is made up of this falsified and deleterious material. Under the circumstances it may be well to turn attention to the unadulterated product of our own colonies, and it will not be surprising, if the pure, old-fashioned, and well-matured rum of the British colonies should come into more general use where it is desired to prescribe a stimulant. Rum and milk used to be a favourite form of medicinal stimulant, and nutritive, and in the navy grog made with rum is we believe at least as popular as cognac, and has the advantage of being cheaper and purer. The "St. James's Rum," of which specimens have been sent us by Messrs. G. W. Christie and Co., 25, Milton Street, Cripplegate, E.C., has an established reputation for age and purity, and we are inclined to think that the considerations to which we have referred should frequently recommend it in place of the artificial compounds which now so largely pass current as French brandy.

AURAL TUBES.

We have received from Messrs. Creswick, of Great Portland Street, W., a collection of their ear tubes for deafness. They are constructed of thin pasteboard, with ear pieces of tinned iron covered with india-rubber tubing. They are made in various sizes and shapes, and some of them by means of a telescopic arrangement can be drawn out and lengthened when necessary to several feet. They are light and portable, can be used for close or distant conversation, and are entirely free from the confusing roar of the ordinary metal tube. They were originally made from a pattern supplied by Dr. C. J. B. Williams, who speaks of them in his *Memoirs* in high praise. We can fully endorse his opinion: "The superiority of these pasteboard cones over those of metal lies in their conveying the sound vibrations through their light material by conduction as well as by reflection and in their being more free from the echoes and ringing sounds developed by metals." These tubes possess the further recommendation of cheapness, varying in price from 4s. 6d. to 10s. 6d.

EXTRACTUM COLLINSONIÆ CANADENSIS LIQUIDUM (HOCKIN).

COLLINSŌNIA CANADENSIS is a perennial herb of the nat. ord. Labiatae, growing in North America from South Carolina westward. Although it is not official in the *British or United States Pharmacopœias*, it has acquired some reputation as being of value in affections of the genito-urinary tract. Messrs. Hockin, Wilson, and Co., of Duke Street, Manchester Square, have prepared a liquid extract of such a strength that the dose is half to one fluid drachm, and recommend its employment in cystitis, gonorrhœa, leucorrhœa, and similar affections.

ROYAL COLLEGE OF SURGEONS.

An ordinary Council Meeting was held on February 9th. The minutes of the extraordinary meeting of January 19th were read and confirmed.

The Museum Committee presented an ordinary report.

Mr. J. H. Targett was appointed assistant in the Pathological Department in the Museum.

The Council authorised the architect to proceed with the construction of the new buildings on the Embankment.

The Council elected Mr. C. A. Ballance as Erasmus-Wilson Lecturer.

Mr. STBLEY moved:—

"That, in view of the increasing complication of the accounts of the College, it is desirable that a Finance Committee be appointed to superintend the accounts and finance of the College, and to report thereon not less than twice in each year to the Council."

The motion was carried.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1888.

SUBSCRIPTIONS to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office orders, should be made payable at the West Central District Office, High Holborn.

The British Medical Journal.

SATURDAY, FEBRUARY 11TH, 1888.

DR. MAPOTHER ON THE DUBLIN SCHOOLS AND THEIR TEACHING.

WHILE the General Medical Council keeps a peremial and expensive watch over the portals of our profession, lest any should enter them who are unfit or remain within them who are unworthy, we are startled from time to time to discover, by how chance as it were, how somnolent is the guard it maintains, how careless it is of the interests entrusted to it.

It comes to us, for instance, as a shock, when an ex-President of the Royal College of Surgeons in Ireland assures us that, in the great teaching centre of Dublin, the study of pathology is almost wholly neglected; that of the six or seven medical schools of that city, only two possess pathological museums; that in the case of three of these institutions at least a proper course of pathology is an impossibility; that the Pathological Society, now a section of the Royal Irish Academy of Medicine, throws open its doors in vain to the students of medicine, only 1 per cent. of whom avail themselves of the generous offer of the Society, although it was to this body that Graves looked so long ago as 1843 for the new birth of Irish pathology, when he levelled his satire against its absence from the curriculum of many an Irish surgeon. It seems almost as though forty years had passed in vain, and that it was to the student of 1888, not to those of 1835, that that distinguished physician drew his picture of the clinical practitioner, taught solely at the bedside, armed with a knowledge of a formidable system of symptomatology, of nosology, and of therapeutics, but ignorant of morbid anatomy, the mother of them all. He describes such a man attacking a case of dropsy, trying remedy after remedy, while the patient grows worse and worse under his treatment, and finally dies. "But," says Graves, "the friends are not dissatisfied with the medical attendant, who excuses himself by asserting that he has successively resorted to every remedy which has been recommended in dropsy; and, in truth, if you look over the list of medicines exhibited in rapid succession, you will probably find that his excuse is not unsupported by facts. But, gentlemen, these cases in which everything has been tried are precisely those in which nothing has been tried, in which medicine has followed medicine, and each symptom of disease has indiscriminately

been the object of attack, until death approaches with accelerated steps, and charitably closes a scene disastrous to humanity and disgraceful to the cause—I was going to say of science, but who will venture to give so ennobling a name to this pseudo-practical knowledge, this worse than actual ignorance?"

And we have reason to fear that these just reproaches apply not only to the schools of Dublin, but to several of the smaller institutions of a like nature in other parts of the United Kingdom. What worth, then, can the Medical Council's visitation of examinations have when the original teaching, of which examinations are only a test, is totally and confessedly non-existent?

Is it right that men should be poured into our profession ignorant of so important a part of its essentials? That they should be declared fit to hold appointments under the State; to give evidence in cases of jurisprudence, where life and death hang in the balance; or to treat the sick and suffering throughout this vast empire, where necessarily in many instances the possession of legal qualifications is the only test of knowledge the people can apply?

It is well that Dr. Mapother should have exposed, with a rare courage and faithfulness, this weakness in the teaching of his colleagues; but it is not well that, with officials excessively paid, whose principal duty it is to see that such scandals do not occur, it should have depended on the patriotism of a private individual to publish them to the world, and to devise means for their removal.

The Medical Council could, with one stroke of the pen, have removed the reproach. It had only to declare that no medical school should be recognised which did not possess an efficient and growing pathological museum, and did not provide a properly qualified pathological lecturer, and to decide that in future, to merit recognition, the teaching of morbid anatomy, both macroscopic and microscopic, must be far other than the sham it too often at present is.

We can only trust that the elective members of the Council will rouse that somnolent body to a due recognition of its responsibilities and shortcomings in this and some other instances.

Another suggestion of Dr. Mapother's cannot be quite so easily accepted. That the amalgamation of several of the Dublin schools and the refusal to receive certificates of attendance on clinical institutions containing fewer than 150 beds would in some ways be beneficial, we cannot doubt; but the advantages are not all on the side of large schools. No one who has observed the overcrowded condition of the *cliniques* in the Edinburgh University, for instance, or has inquired into the opportunities the individual student has in that vigorous school for obtaining a practical acquaintance with the smaller operations, such as catheterism, etc., which are so necessary in practice, can deny that something at least can be advanced on behalf of smaller and less crowded schools. It was Graves, again, who said with much truth: "Everything like monopoly tends to retard the advancement of science, and I see no reason why a

hospital with 50 beds should be inferior to one with 100. It is not the quantity of disease a teacher treats which renders his lessons instructive; his diligence and accuracy of observation are the best means of instructing his pupils." And perhaps one of the strongest arguments against Dr. Mapother's proposition is that it would close the Meath Hospital itself, rendered illustrious as it is by the teaching of Graves, and where Stokes received a great part of his clinical training.

Certain members of the Medical Council have proposed to meet the difficulty by making a close and exhaustive inquiry into our medical schools, and the opportunities and appliances they possess for instructing their students. It ought to be recognised that the existence of any particular medical school is only a necessity in so far as it ministers to the welfare of humanity by thorough and successful teaching. Such inspection of schools would do much for the settlement of controversies like the present, but would be very costly.

It has been proposed to extinguish every school, be it large or small, where the teaching is inefficient, paying especial attention to some smaller schools, whose sole excuse for existence seems to be that they may afford a back-door for the admission of middle-aged druggists and unqualified assistants into our already overcrowded ranks. We hope and trust that the medical schools of Dublin, under this or like necessary pruning, will soon take their proper place among those of Europe. There is, indeed, no reason why they should not. National questions ought not to affect them, for science is independent of Governments, and should flourish in every political climate. From autocratic Russia, from aristocratic Germany and Austria, from constitutional Britain and Belgium, from republican America and France, have come the leaders of scientific thought, without distinction and without preference.

Let not then that Irish school which produced Graves and Stokes, Corrigan and Mac Cormac, Crampton and Mayne, be contented with anything lower than the first position in our empire. If her children, wise in cheapening the means of learning, are equally sensible in exacting a high standard of attainments, her future is secure. For those children are exceptionally fitted to adorn our great profession; their warmth of heart, their brightness of wit, their vigour and versatility of intellect, are qualities which, if properly directed, will raise their many-headed mother, "dear old Dublin," to that place in the medical republic which she now occupies in the loyal hearts of her faithful sons.

THE GERM-THEORY A CENTURY AGO.

In a pamphlet of 87 pages, published in London in the year 1788, there is a curious anticipation of the modern germ theory of disease. The author does not give his name, but the pamphlet is announced to have been produced as an answer to certain questions, proposed by the Royal Society of Paris, on the cause and most effectual method of preventing the progress of infectious disorders. It is entitled *A Treatise on Fevers, wherein their Causes are exhibited in a new point of view, to prevent Contagion:*

and Putrid Sore Throat, Inflammatory Fluxes, Influenza, Consumptions, as well as the Low Nervous Fevers that terribly affect the Spirits, may be cured with Ease. It is written in a popular way, and was issued at the price of a shilling, and declared to be "necessary for all families." To fulfil this intention, it is written in a "plain and intelligible rather than ornamental style," for the writer lays no claim to eloquence, and thinks too great a show of learning out of place; "if the world does not chuse to make the application, he is content to have done his duty in making the communication;" but he "is sure that it is a key to health, and, if adopted, fevers will then no longer be the terror of mankind." He is certain that contaminated air is the sole source of all "fevers, consumptions, fluxes, gouts, rheumatisms, whooping-cough, diseases of the stomach, lungs, liver, head, and kidneys, of putrid sores, St. Anthony's fire, and nervous disorders generally." A tolerably comprehensive list, which perhaps is meant to include surgical fevers, though these are not expressly mentioned; and so, by directing our attention to the removal of the cause, "epidemic disorder will be prevented, just as small-pox is prevented by inoculation."

At the commencement of the treatise, the author states that the remarks he offers were suggested principally in the years 1779-70, when all parts of England, and some foreign countries as well, were extremely affected by contagious disorders of all sorts; animals (especially horses) as well as men being struck down, often suddenly and fatally. Numbers of men were killed in a few days by putrid sore-throat; some were affected in the head, and became delirious; others in the stomach, and were seized with sickness and purging; others had gout, palsy, or rheumatic fever, or were attacked in the eyes, or laid down with erysipelas; many others suffered in the lungs and became consumptive; and many more grew depraved in spirits, had low nervous fevers, and became hypochondriacal. Almost all the cases were contagious, and though usually each disease bred true, yet the maladies were sometimes interchangeable—for instance, an attack of erysipelas was caught from a patient suffering from a sore-throat. Such is the general result of the author's observations; and it will be readily admitted that he had a considerable practical acquaintance with the phenomena and spread of epidemics, and did not spoil his wide experience by a too hasty judgment.

Then follows the speculative and explanatory part, consisting of an exceedingly ingenious argument, an example of that most useful and profound of logical methods, analogy, based on admitted facts, followed by a clear and coherent chain of reasoning, and is perhaps as convincing, and even more free from fallacies, than if he had attempted to prove his case by microscopical demonstration. He states, in the first place, that the cause of these multiform disorders is generally allowed to be some invisible noxious matter in the air; of its intimate nature there were various opinions, but perhaps very little curiosity felt: "Some consider it to be a sulphurous exhalation from the earth; but this cannot be, for, if so, acrid and sulphurous fumes would increase it instead of checking or annihilating it. Another theory is that it is due to the products of putrefaction; but how can

dead and putrid matter ever get such activity as to work such astonishing results?" It must, therefore, be something endowed with a more powerful activity than anything belonging to the mineral kingdom or simply putrefying, and must, therefore, be something actually living. In this he shows considerable penetration; and there being no "cell theory" in his day, he does not stop to consider whether the poison may be embodied in vitiated cells or particles detached from the body, though retaining their specific activity, but concludes that it must be organisms having an independent existence. For this view, surprising and novel enough at first, loses some of its singularity if we search for resemblances elsewhere. Now, just as it was well-known that itch is due to the presence of acari, insects visible by aid of the microscope, so "close attention to these matters in numberless cases during many years has proved beyond a doubt that the gaol distemper, putrid fever, plague, and infectious epidemics generally, proceed not from matter putrid in itself, but from invisible insects also, that, floating in the air at times, are lodged in the skin in immense quantities; feeding here in clusters, they produce pimples, pustules, etc.; for instance, the eruption of small-pox." He overlooks, or at any rate makes no mention of the possibility of their entering the body by the air passages, and working their way from the lungs and alimentary canal.

Moreover, "medicines which poison insects without injuring the constitution have always proved specific." He asks if this is the way that mercury will cure obstinate and foul sores, thus anticipating an explanation of the *modus operandi* of this specific remedy for syphilis, which has lately been put forward again; and that James's powder cuts short fevers; for these drugs are so acrid and corrosive that their action can be nothing else than a destructive tendency, and this is the very reverse of a healing nature. These insects which constitute contagion are communicated by the air, the raiment, or by contact. Not only animals, but vegetables also, suffer much from the ravages of such animalcules, the smallest being most mischievous, from their greater numbers and being least suspected. Marsh effluvia are due, not to putridity simply, but to the myriad forms of minute life to which the abundant decomposition gives life and nourishment. A corpse which has died of an infectious disease is known to be able to convey the same disease to persons brought into its vicinity; but it is noteworthy that it is most infectious while quite recent, and the specific infectiousness ceases as soon as genuine putrefaction has fairly begun, thus proving the radical difference between the specific virus and ordinary putridity. By magnifying glasses it may be seen that many disorders to which corn is subject are due to animalcules "so small that by the solar microscope they equal in size a pig two or three months old, though they are as well-proportioned in their limbs as elephants, and have their internal organs as perfectly constructed as in animals of ordinary dimensions; and they have probably the same senses, ideas, and passions, only their sphere of action is more limited." These are only instances of what had already been shown to exist; but he thought it not only reasonable, but

extremely likely, that still smaller ones exist, though of course more easily eluding discovery; and it is such as these that are answerable for our acute specific diseases. Of course, therefore, the author does not attempt to particularise or define their characters rather than to designate them as "animalcules," though it may be remarked by the way that he always speaks of their originating from eggs, never hinting at their appearance *de novo*.

The existence of bacteria as such, with special forms and attributes, does not rouse his attention, though they had already been seen and described by Leeuwenhoek a hundred years before (1682). He was tolerably familiar with the habits of these minute parasites in many of these diseases which blight plants and attack animals. Those commonly found in wheat flour arise in the soil, where the eggs remain during the winter; being hatched by the warmth of summer, the young insects creep up the stalks of the growing plants, feed on the ears, and sometimes leave their eggs in the grain; these escape destruction by grinding, and may be seen in plenty during the winter, the animalcules themselves being discoverable only in the summer. They are not produced in all kinds of land, or on the same land in every season. These facts being known, an easy method of preventing smut and blights is easily suggested and adopted; for instance, steeping the seed, before it is sown, in wood ashes boiled with arsenic, or quicklime spread over the land will be equally efficacious; or else the insects after being hatched, and while invading the corn, may be killed by burning vegetables to windward of the fields. Soot placed in trenches round the trunks will preserve fruit trees. The foot-halt of sheep is infectious to others in the same track; in this instance also the cause is nothing corrosive, for it is destroyed by a corrosive agent, thus a single application of diluted oil of vitriol to the affected feet will cure the complaint, or else laying quicklime on the track the sheep pass over. Similarly, strong tobacco water will cure the scab of cattle; and in the same way our epidemic fevers may be cured, as suggested above, by destroying the animalcules by mineral or vegetable antidotes given internally, though attention must always be paid, in selecting appropriate remedies, to the particular constitution of the patient. As experience shows, cooling measures are indicated in fevers, and, on the other hand, anything which tends to increase the heat is prejudicial, and this is to be explained by the heat helping to bring some eggs to life, and thereby aggravating the disorder. He says, "I have an account in writing of many extraordinary complaints cured on the same principle; ulcerated lungs cured thereby, and some cases of dropsy and gout so caused." Unfortunately, in the treatise now under examination he gives no details of the remedies which prove so successful, or the method of using them. He promises to give the rest in another book, to draw the attention of medical men, but it is not apparent that this was ever written, the author's name being omitted.

The rot of sheep (a disease of the liver—? flukes) is produced by insects inhabiting marshy ground, and is to be got rid of by removing the flocks to hilly ground or by spreading quicklime on

the surface. The swampy grounds on the borders of the hill breed large quantities of these pestiferous creatures, but the periodical overflowing of the river washes them away, and thus cleanses the ground and purifies the air. In the same way heavy showers will wash away diseases in our country. The mischievous matter of the plague is "effluviated" from the earth; and thus he explains the fact that earthquakes are frequently succeeded by the outbreak of a severe epidemic. The appearance of the aurora borealis in the air is due to the warmth in the bowels of the earth, and indicates a disturbance and escape of it, and it is commonly attended by a prevalence of infectious complaints. To clear infection from a house, wash the interior well with vinegar or soap, and fumigate the air by burning sulphur or frankincense (which is as efficacious as the former, while it is better tolerated by our respiratory organs, and does not blacken furniture). Smoking tobacco is an excellent preventive, and the author remarks that a tobacconist's shop generally remains free. Living near a tanner's yard, according to common belief, gives equal safety. He also recommends as precautions to chew bay leaves, wormwood, or tobacco, and to smoke and drink brandy.

In summing up his theory, he says that, generally speaking, there are only two sources of the animalcules: subterranean, which operates in all sorts of weather, and is chiefly accompanied by electric phenomena; the other is the surface of the earth—swamps, filthy lakes, stagnant ponds, etc. The eggs left on the soil develop in the summer, and "the multitudes effluviated into the air." Though recommending draining the land, and fumigating or watering the air, it is rather strange that the author overlooks the value of heat in disinfecting clothes, etc.

The above account justifies, we think, the belief that the author was sufficiently practical and experienced to command respect and confidence, as well as to interest us in his views; he rightly cared more for simplicity and usefulness than for refinement and barren speculation. Could he have lived to-day, he would no doubt have trodden much of the ground of Pasteur, and would have thrown himself into the still unsettled question of the exact relation of micro-organisms to disease.

SMALL-POX AND VACCINATION AT SHEFFIELD.

THE President of the Local Government Board, when speaking at Sheffield on Monday last, naturally referred to the severe epidemic of small-pox which for some months past has prevailed in the town, and has caused considerable alarm in the northern and midland counties. The opponents of vaccination have eagerly embraced the opportunity of endeavouring to create in the public mind a distrust of the efficacy of vaccination, and the bare fact that small-pox has invaded a well-vaccinated town and gained a foothold there has been held to be a sufficient condemnation of the system. Sheffield, in fact, has been held up as an awful example. It is well, therefore, that the responsible minister has had an opportunity of publicly refuting these sophisms, and of testify-

ing to the beneficial effects of vaccination as demonstrated by the Sheffield experiences themselves.

Bearing in mind that the protection afforded by vaccination in infancy is most effective during the early years of life, and that after the age of ten it decreases unless renewed by revaccination, Mr. Ritchie examines the statistics concerning the children under ten years of age. He finds that there are about 100,000 children under that age living in Sheffield; that 95,000 of these children are vaccinated; and that 5,000 are unvaccinated. Out of the 95,000 vaccinated children there have been 189 attacks and 2 deaths; out of the 5,000 unvaccinated children under ten there have been 172 attacks and 70 deaths. If for a moment it is assumed that all children under ten were vaccinated, there would have been 200 attacks, and hardly more than 2 deaths. If all under ten had been unvaccinated, there would have been 3,277 attacks and 1,330 deaths, or exactly 600 times greater mortality.

Here is a reproduction of the metropolitan experience of 1881. In that year there were in London some 916,000 children under the age of 10 years, and of these 861,000 were vaccinated and 55,000 were unvaccinated; whilst in that year, amongst the 861,000 vaccinated, there were only 125 deaths, among the 55,000 unvaccinated there were 782 deaths, that is to say, upon equal numbers of the two classes, the mortality from small-pox amongst the unvaccinated was about a hundredfold the mortality from small-pox amongst the vaccinated.

As regards persons above the age of ten, the Sheffield experience also supports the efficacy of vaccination, though not so conclusively as does that of the younger persons, inasmuch as the protective value of primary vaccination diminishes year by year, and re-vaccination has not been the rule. The lesson, therefore, is once more taught by these experiences, that if protection against small-pox in the later years of life is to be secured, revaccination must not be delayed beyond the age of ten or twelve years. We are glad that the Government are about to facilitate this early revaccination by reducing the minimum age at which the operation can be obtained at the public expense.

Apart from the question of decreasing protection, it is important that the operation should be performed in each case before the actual business of life is entered upon. If it is not so performed it is likely to be indefinitely postponed, if not altogether forgotten, until a scare of small-pox increases the applicants for revaccination, strains to the utmost the resources of the public vaccinators, and increases the risk of the operation being inefficient.

We would venture to impress upon Boards of Guardians the importance of promoting revaccination systematically during non-epidemic periods much more than has been the practice hitherto. Practically no efforts have been made in the past in this direction, except in the presence of small-pox, and consequently revaccination is by no means as general as the public welfare requires.

DR. W. TINDAL ROBERTSON, M.P., attended at Osborne on Wednesday to receive the honour of knighthood.

THE Budget Committee has recommended the Chamber of Deputies to vote a small sum of money to provide the professor of hygiene in Paris with the means for opening a laboratory for practical instruction.

THE Committee of the Association of Fellows of the College of Surgeons met on Tuesday to deliberate on the recent action of the Council of the College. The proceedings were adjourned till Monday next.

WE are glad to learn that the drainage of Margate is to undergo further improvements, the Town Council having decided to procure plans for a thorough system of drains, which it is suggested should be submitted to Sir Douglas Galton or some other eminent authority for approval.

THE first number of the *Revue Médico-Pharmaceutique* was published in Constantinople on January 31st; it is designed to make known in Europe the work done by the physicians and pharmacists of the East, and at the same time to give a fair reflex of the progress made in medicine and pharmacy throughout the world. The new journal is edited by M. Pierre Apéry.

MR. JAMES ANSTIE, B.A., Q.C., a Charity Commissioner, and formerly Examiner in Law to the University, has been nominated by an influential body of graduates for election by Convocation to be a member of the Senate of the University of London, in the room of the late Sir George Burrows. Mr. Anstie has taken an active share in the recent reform movement in Convocation.

THE twentieth annual banquet in connection with the French Hospital in London will take place this (Saturday) evening at Willis's Rooms, His Excellency the French Ambassador in the chair. The Lord Mayor has also promised to attend. Special efforts are being made at present to provide funds for building the new hospital premises on land which has been purchased in Shaftesbury Avenue. Upwards of £12,000 have already been subscribed.

BRITISH NURSES' ASSOCIATION.

A MEETING will be held at St. George's Hall, Langham Place, on February 13th, at 4 P.M., Mr. Savory in the chair, with reference to the formation of the above Association. It is announced that H.R.H. Princess Christian will be present.

FRENCH SURGICAL CONGRESS.

THE third session of the French Surgical Congress will be held in Paris, from March 12th to the 17th, in the large amphitheatre of the Administration de l'Assistance Publique, 3, Avenue Victoria. Professor Verneuil will preside. The following questions are down for discussion: 1. The Treatment of Gunshot Wounds of Viscera. 2. The Value of Radical Treatment of Hernia as regards Permanent Cure. 3. Treatment of Chronic Empyema. 4. Recurrence of Malignant Growths after Operation: its Causes and Prevention. Surgeons wishing to take part in the Congress are requested to communicate with the General Secretary, Dr. S. Pozzi, 10, Place Vendôme, Paris. The subscription is 20 francs.

SNOWED UP FOR TWENTY DAYS.

AN extraordinary case of prolonged fasting is reported from Vienna. On December 22nd a peasant woman from Obergrabern went to receive some money which was owing to her at a small village a few miles distant. The amount was not paid, and the woman had only four kreutzers in her pocket, with which she bought two rolls of bread. On the way home she was caught in a heavy snowstorm, and took shelter in a small hut in a vineyard. The storm continuing, she decided to spend the night where she

was, and divested herself of some of her upper garments to wrap up her feet. The next morning when she awoke she could not rise, being partially paralysed by the cold. Her cries for help were unheard, and it was only on January 11th that she was found by a woodcutter's wife, having been twenty days without food.

THE WILL OF SIR GEORGE BURROWS, M.D.

SIR GEORGE BURROWS, M.D., by his will dated April 6th, 1882, with a codicil made October 14th, 1886, bequeaths to the library of St. Bartholomew's Hospital such medical books and pamphlets of his father-in-law, John Abernethy, his father, and himself, as may not be selected by his son-in-law, Mr. Arthur Willett. To his son, Ernest Pennington Burrows, he bequeaths the silver inkstand presented to the testator by Gonville and Caius College. He devises and bequeaths all his real estate and the residue of his personal estate in trust to make up the portions of his daughter, Mrs. Willett, and his younger son, Ernest Pennington Burrows; and the residue in trust for his elder son, now Sir Frederick Abernethy Burrows, and his male issue, with remainder to the said Ernest Pennington Burrows, or other the successor in the baronetcy. The value of the personal estate has been declared at £104,628.

MR. CHADWICK ON THE SANITARY NEEDS OF THE DAY.

MR. EDWIN CHADWICK, C.B., speaking at the annual dinner of the Association of Public Sanitary Inspectors on Saturday last, observed that it was important that time should be given to the Boundary Commissioners to make their examinations full and complete, as much of the reform needed would only come from larger areas than the present small administrative ones being provided for poor-law and sanitary purposes. He also urged that the scattered and weakened functions now spread over several Government departments should be consolidated under a Minister of Health. In conclusion he referred to the fact that the Lancashire manufacturers had an offer now made to them to work their engines by gas at two-thirds the price of working them by the flame of coal. This plan was proposed by the speaker thirty years ago; and there was no doubt that this might be done, and, when done, down would fall the big chimney which befouled all around with its smoke and dirt.

VIEWING THE BODIES.

MR. D. WIGHTMAN, coroner, held an inquest at Sheffield on February 6th, on the body of a man who had committed suicide by cutting his throat whilst suffering from small-pox. He proceeded to swear the foreman, and omitted the usual words "of whose body you shall have present view." The rest of the jury were sworn. The Coroner then remarked that he had no law to warrant him allowing the jury to escape viewing the body, but in this case, when he looked at the consequences which might probably arise, he was not at all surprised at the jury objecting to go into a room reeking with small-pox, and in which was the body of a man who had died from that disease. He thought that was a reasonable excuse for not going to see the body. It was his duty, he knew, to insist, but he intended to brave the consequences and see what was said. He would not, as a jurymen, like to go and view the body, not so much for himself as for his wife and family. If the jury said they did not like to go, he felt he would not be justified in making them do so. The inquest proceeded, and at the close the jury thanked the coroner for his consideration.

VACCINATION PAYMENTS IN ITALY.

NOTWITHSTANDING a Government decree enjoining local authorities in Italy to provide funds for the payment of the vaccination officers, in no less than 4,192 communes—that is to say almost half the total number—no such funds are voted. In 2,244 other com-

munes the vote is a simple farce, while in 1,822 the sum allotted varies from threepence to fivepence. In consequence vaccination, which is not compulsory, is not systematically performed in the rural districts. It is highly probable that the vaccination laws will shortly be amended and enforced in a more satisfactory manner by the central authority.

METROPOLITAN POLICE SURGEONS.

AT a meeting of the Metropolitan Police Surgeons' Association, held on Thursday, at the Offices of the British Medical Association, Mr. Timothy Holmes in the chair, a discussion took place with reference to some recent orders affecting divisional surgeons made by Sir Charles Warren. It was proposed to send a deputation to the Home Secretary; but a satisfactory statement having been made by Mr. Mackellar, Chief Surgeon of the Metropolitan Police, further action was, on Mr. Holmes's suggestion, postponed.

INJURY TO SIGHT BY SHUTTLES.

MR. J. WINKLEY LANGDON, the honorary ophthalmic and aural surgeon to the Preston Infirmary, in his annual report notes the large number of extirpations rendered necessary by wounds from shuttles in the weaving rooms of cotton mills. The contemplation of this fact, he says, leads one to wonder that some ingenious spirit has never devised means to avoid so dread a calamity, rendering subsequently, as it does, the sufferer almost useless in this walk of life.

OPEN SPACES AND THE PUBLIC HEALTH.

ONE of the most gratifying signs of the increase in the park and open space accommodation of large centres of population is shown by Mr. Ellis Lever to be manifested in a correspondingly diminished death-rate, the metropolis being a striking illustration of this. London possesses nearly 10,000 acres of parks and breathing grounds, or about 2½ acres per 1,000 of the population, and the death-rate during the year ending October 1st last was 19.3 per 1,000. Leeds, with a population of 345,080, has 528 acres of parks and recreation grounds, or 1½ acre per 1,000 of the population, and the death-rate is 21.7. Manchester (parliamentary borough) has a population of 423,801 and a park area of 165 acres, including open spaces and recreation grounds, equivalent to 2-5ths of an acre per 1,000, while the death-rate is 28.2.

METROPOLITAN PROVIDENT DISPENSARIES.

A MEETING was held at No. 1, Old Serjeant's Inn, on February 3rd, to discuss the above scheme; Dr. Paramore in the chair. Drs. Carpenter, Hentsch, Kisch, Smith, Sargent, Thomas, Wainwright, Maunsell, and Corbyn, were present. The chairman stated the object of the meeting, and referred to the scheme as one more attempt to starve out the medical profession. The scheme was not a provident one, as patients were admitted when ill, and the scale of charges was so ridiculously low that under the scheme human beings were treated at one-twentieth the sum charged by similar institutions in the veterinary profession where the patients were dogs and horses. During the discussion the chief arguments in opposition to the scheme were: 1. That as an advertising concern it is repugnant to the ethics of the profession. 2. That it is not needed, because those who are too poor to pay are amply provided for by hospitals and parish relief. 3. That the intermediate class are amply provided for by the different clubs of general practitioners. 4. That its scale of remuneration is such as to degrade those practitioners who consider its fees as "generally acceptable to the profession," in the eyes of the public. The following motion was then proposed by Dr. Maunsell, and carried unanimously: "That a committee be formed, with power to add to their number, for the purpose of taking into consideration the scheme of the Metropolitan Provi-

dent Association, and that they be requested to report to a subsequent meeting of general practitioners the objections to be taken to such scheme, and the steps which it may be desirable to adopt for the improvement of the position of the profession. A committee was then formed, consisting of those present; Dr. Paramore being elected Chairman; Dr. Maunsell, Vice-Chairman; Dr. Thomas, Treasurer; and Dr. Corbyn, Secretary. The Secretary to the Committee would be obliged if all opposed to the scheme would forward him their names and addresses on a post card, addressed, T. H. Corbyn, 18, Abercorn Place, N.W.

THE OPPOSITION OF CAMBRIDGE UNIVERSITY TO THE SCHEME OF THE LONDON COLLEGES.

WE published last week the petition drawn up by the Special Board for Medicine of the University of Cambridge, setting forth the grounds upon which the University opposes the grant to a Senate formed by a combination of the two Royal Colleges in London of the power to grant degrees in medicine. At the debate which took place on Saturday last on the question of adopting the petition, the scheme of the two Colleges was defended by Professor Humphry, while Sir George Paget, Dr. Donald MacAlister, Dr. Octavius Sturges, Professor Alexander Macalister and others spoke in favour of the proposition to present the petition in opposition. Letters were read from the Universities of Edinburgh, Glasgow, Durham, Victoria, and London approving of the Cambridge petition. The general result of the debate was, our Cambridge correspondent states, decidedly in favour of the petition. The Council of the Senate accordingly has proposed to affix the Common Seal of the University, and on February 16th a vote will be taken on the question. No notice of *non placet* has yet been issued.

THE NATIONAL PENSION FUND FOR NURSES.

THIS Society has now been incorporated, and its memorandum of association has been registered. The memorandum of articles is signed by Lord Rothschild, Mr. Henry Hucks Gibbs, Mr. E. A. Hambro, and Mr. Junius S. Morgan, the four merchants who have contributed each £5,000 towards the £20,000 which had to be deposited with the Court of Chancery as a security for the proper working of the fund. It is further signed by Mr. F. C. Carr Gomm, Chairman of the London Hospital; Mr. Percival A. Nairne, Deputy Chairman of the Seamen's Hospital; Dr. Bristowe, F.R.S., Senior Physician of St. Thomas's Hospital; Mr. Thomas Bryant, Senior Surgeon of Guy's Hospital; and Mr. Henry C. Burdett, the founder of the fund. The Council includes Mr. John Watney, of the Mercers' Company; Mr. Brudenell Carter, Ophthalmic Surgeon to St. George's Hospital; Dr. J. C. Steele, Medical Superintendent of Guy's Hospital; Mr. Alfred de Rothschild, Mr. Clifford Wigram, Mr. W. H. Burns, Mr. Charles Rawlings, and others.

GOOD MEALS FOR SCHOOL TEACHERS.

It is proverbial that to keep an Englishman in good temper he must be well fed, and the teachers in some primary schools appear to find it hard to work in the afternoon when unable to get any mid-day meal. The new schools must be built where they are wanted, and where space can be obtained at reasonable cost. This has led to schools existing in poor and densely populated neighbourhoods, without necessarily having any adjacent coffee-house or restaurant giving facility to the teachers for obtaining a good mid-day meal. Whenever there are cooking centres in connection with Board schools, no difficulties are experienced by the teachers and pupil teachers in buying well-cooked food for their dinners at a reasonable cost, but there is no systematic arrangement by which provision of this kind is made. In very poor neighbourhoods there is, but little choice for the teachers: they must either live near the schools, so as to get something to eat at their lodgings in the middle of the day, or dine off

sandwiches, buns, etc., as some young teachers do. Teachers preferring to live at a distance would not get home till six in the evening, or later. There is a "teacher's common room" at each school, but it is not possible for teachers to cook food there, and in summer there is no fire. In every school a woman is placed as caretaker; it might reasonably be arranged as a part of her duty that she should cook a plain mid-day meal for the teachers, say a joint and vegetables with pudding, the teachers themselves paying the cost. To become a teacher in a Board school is to undertake important and onerous duties, and it is very important that the health and strength of teachers and pupil teachers should not suffer from want of properly prepared food. When food is wanted in schools, the means of providing it are at hand, and we trust that School Boards will see that the necessary arrangements are made in cases where local circumstances show that they are needed, especially as no question of expense would be involved thereby.

BURIAL REFORM.

A MEETING was recently held at Margate under the auspices of the Burial Reform Association, to which Dr. Rowe addressed some very timely remarks upon the desirability of an alteration in the present system of burial. Dr. Rowe once more pointed out that the decomposition of the body after death is, when viewed from the chemical standpoint, always a combustion, and he admitted the logical consequence—namely, that the most perfect, rapid, and elegant form of combustion was cremation. The "earth-to-earth" system advocated by Mr. Seymour Haden, where the body is placed in a coffin of stout millboard, which rapidly decays, and permits the products of animal decomposition to pass directly into the surrounding earth, is undoubtedly a distinct advance upon the system still prevalent of burying in leaden or stout wooden coffins of many casings, which have the effect of retarding disintegration, and lead consequently to a storing up of huge aggregations of human remains in every stage of decay. Such a system is not consonant with reason, and the Bishop of London has declared it to be "inconsistent with the principles of the Christian faith;" it cannot therefore be defended upon any other ground than an unreasoning acquiescence in a comparatively modern and most unhygienic custom. The Burial Reform Association, of which the Rev. F. Lawrence, Westow Vicarage, York, is the Honorary Secretary, advocates early interment, and the use of perishable coffins to permit rapid disintegration after burial in the earth. As to the first, there can be no room for difference of opinion; and as to the second, those who are unwilling to carry the matter to its logical conclusion may fairly be asked to resort to this system, to which the term "Eremaeusis" has been applied. A conference will be held by the Society in the Portman Rooms, Baker Street, on February 23rd, at 3.15 P.M., in which Sir Edward Sieveking, Dr. B. W. Richardson, F.R.S., the Hon. Dudley Fortescue, and Dr. Danford Thomas will take part. Medical officers of health and other persons interested in burial, funeral, and mourning reform are invited to be present.

THE DIET OF NURSING MOTHERS.

THE influence of the diet upon the function of lactation is a subject of such importance for the rising generation as to warrant frequent investigations by scientific authorities. It seems to be one of the evils inherent in a high degree (so-called) of civilisation that women, in a large proportion, especially among the upper and middle classes, should suppress and ignore the physiological function of the secretion of milk, and abandon the privilege of nursing their children in the natural way. But this being the case, it is desirable that the best substitute be provided. The feeding-bottle is but a poor substitute for the mother's breast, and of late there is a tendency to give too diluted a milk. A wet-nurse

is the best substitute for the mother herself, and a knowledge of the influence of the food upon the composition of milk ought to be widely circulated, at least in its chief features. Dr. Zaleski, Docent in the University of Dorpat, is the latest worker (*Berl. Klin. Wochenschr.*, Nos. 4, 5, 1888) in this subject. He has made careful analyses of the proximate constituents of milk, both in the lower animals and in women, under various conditions of diet, and his chief conclusions are: 1. Milk which contains an undue proportion of fat may have a very injurious effect upon the child. 2. A highly nitrogenous diet causes a great increase of fat in milk; the same kind of diet lowers the proportion of milk-sugar, but has very little influence over the other constituents. Alcohol exerts the same influence as a nitrogenous diet. 3. A proper composition of the milk may be attained, speaking generally, by the use of a proper dietary. 4. The lower animals are subject to the same laws as human beings in the above respects. 5. A large proportion of milk is derived, directly or indirectly (that is, by changes in the blood itself or in glands), from albuminous sources. The above conclusions are directly opposed to the views of the laity on the subject. The wet-nurse, as a rule, is a highly privileged being, who must be allowed an unlimited quantity of butcher's meat and a good supply of stout. The amount of exercise usually taken is a gentle saunter at her own sweet will; active exertion is out of the question. Probably the diet has been previously very plain, and too often the sudden change influences the composition of the milk to the detriment of the child. Diarrhoea, of a more or less fatty character, is often the consequence, and Dr. Zaleski instances a case in point. Chemical analysis of a specimen of the milk of a wet-nurse revealed over 6 per cent. of fat, and inquiry was made as to the condition of the child. It appeared that the child was ailing ever since the services of the wet-nurse had been called into requisition. The latter was a poor girl, whose diet and whole course of life was changed when she became a wet-nurse, and that this injuriously affected the lacteal secretion was proved by the fact that her own child had been far from well since then. An immediate return to the previous mode of life was ordered for the nurse, with the best results.

ANOTHER ANTIVIVISECTIONIST MARE'S NEST.

IF we may judge by the straits to which the agitators are put for materials, and the admission that there prevails "too great optimism in regard to what goes on in England in the matter of vivisection," it would seem that the public mind has become aware of the absurdity of the distorted and often unfounded statements put forward as ground for imposing still further restrictions beyond those which have more than attained the desired end. At the last meeting of the Pathological Society in 1887 some very uncommon kinds of fracture were discussed, and Sir James Paget referred to some experiments made by him years ago which had impressed him with an idea of the enormous force which must be suddenly applied in order to fracture a bone in an adult, and suggested that it would be useful to make fresh experiments in this direction. A correspondent of a contemporary reproduces our report of Sir James Paget's remarks (*JOURNAL*, December 24th, p. 1384), and adds:—"Remark from me is needless. The fact that Sir James Paget expresses this wish, and that Mr. Stephen Paget is secretary of a society which holds vivisection to be an allowable and laudable method of research, is sufficiently ominous without any further words of mine." This reminds us of a story about Bishop Berkeley and his tar water, a remarkable fluid which was believed by him to possess the most wonderful curative properties. A committee, of the Royal Society, if we remember rightly, was appointed to investigate the remedy and collect cases. At one of its meetings it received a letter from a gentleman, who said that he had fallen and broken his leg, but that, by the use of suitable bandages and tar water it was so rapidly and soundly cured that he

was able to walk about on it the next day. The committee was overjoyed, and began to noise abroad this marvellous cure, until, at its next meeting it received another letter from the same gentleman, who said that he had omitted to mention, in his previous communication that the leg was a wooden one. Bishop Berkeley fell into a trap which was laid for him, but the antivivisectionists dig pitfalls into which to tumble. The experiment suggested by Sir James Paget would be performed on a dead body, as was evident to any medical reader of our report from the context, and our reports are addressed to medical readers only. To adopt the phraseology of our opponents, "Remark from us is needless."

PARASITIC FÆTUS.

IN the discussion which followed the exhibition of Mr. Owen's specimen of an anomalous sacral appendage, at the Pathological Society on Tuesday, Mr. Baker and Mr. Bland Sutton expressed their opinion that the appendage ought to be considered as a parasitic fœtus. Mr. Sutton also referred to an example of this monstrosity which is at present being exhibited in London. The subject, "Laloo," is a lad from Oudh, aged 17, about five feet two inches in height, and of a very dark complexion. His expression is pleasing and intelligent, and his disposition very cheerful. There is no family history of any monstrosity. The mass, which appears to be of, at the most, very limited sensibility, is attached chiefly to the epigastric region. It consists of the structures forming the shoulder-girdle, including the integuments, which bear a pair of nipples; and of a second part, including the buttocks and lower extremities. The pubes is hairy, the penis well-formed and its glans uncovered, urine occasionally passing from it. The anus appears to be imperforate. The arms are very long, like those of an American spider-monkey (*Ateles*); the buttocks form a projection rather bulkier than a cocoa-nut; the left foot hangs down nearly as low as the knee. Both extremities present numerous deformities, which cannot be satisfactorily described in this paragraph. Next to the fact that there is a large parasitic fœtus dependent from the epigastrium, the most singular feature of the case is the complete separation of the shoulder-girdle from the lower parts of the parasite. The two parts appear to be separately united to the boy's trunk by freely movable joints; they are invested by a common integument, and divided from each other by a deep groove. We understand that Mr. Sutton and Mr. Shattock examined "Laloo" on Wednesday, for the purpose of furnishing the Pathological Society with a full report of the case.

THE HISTORY OF THE GERM THEORY.

PROFESSOR EDGAR CROOKSHANK gave an interesting lecture at the Parkes Museum of Hygiene on February 2nd. After some preliminary observations he referred to the writing of Kircher, and to the discovery of micro-organisms by Lœwenhoek, whose researches were eagerly caught up by some physicians. Nicolas Andry and his school regarded these minute organisms as worms, and attributed small-pox and other diseases to their action. Lancisi believed that the deleterious effects of marshes were due to such minute creatures, and the rapid extension of the theory to account for all sorts of diseases brought it into ridicule. The micro-organisms themselves, however, continued to be studied, notably by Gleichen, Hill, and Müller; and subsequently the discussion which arose with reference to spontaneous generation invested the investigation with profound interest. After giving an account of the scientific controversy which raged on this subject for so many years, Professor Crookshank mentioned the discovery by Cagnard de la Tour and Schwann of the dependence of alcoholic fermentation on the yeast plant, and pointed out that, owing to relations which were believed on theoretical grounds to exist between the process of fermentation and that of certain dis-

eases, again brought the germ theory of disease into prominence. The discovery by Bassi of a fungus in the silkworm disease encouraged the theory, which was adopted and ably defended by Henle. Pasteur took up the study of the yeast plant, and in 1850 Davaine discovered the bacillus of splenic fever. Then followed Pasteur's researches on the diseases of wine, and the silkworm disease. Davaine, again, studied the anthrax bacillus in 1863; but it was Koch who first published its whole life history, and, by his subsequent observations, placed the existence in some diseases of *contagium vivum* beyond a doubt. The new field thus opened up was soon crowded by investigators, and the results were liable to be received either with incredulity or with too enthusiastic belief. The lecturer concluded by pointing out that we as yet had no adequate proof of the existence of *contagium vivum* in hydrophobia, small-pox, vaccinia, typhoid fever, scarlet fever, and measles. The lecture was illustrated by numerous diagrams, by copies of the works of writers mentioned, and by microphotographs of bacteria, projected by an oxyhydrogen light.

NEW CLINICAL INSTITUTION IN ROME.

THE *Riforma Medica* of January 20 states that the foundation stone of the Policlinico Umberto I was laid on January 19th by the King of Italy. The Queen and the Prince of Naples were also present, together with the Ministers of State and a large number of Deputies, Professors, and public functionaries. An address was delivered by Professor Guido Baccelli, President of the Roman Academy of Medicine, to which the King made a suitable reply, in the course of which he said that, gratifying as the present occasion was, it would be a happier day for him when the building was completed and he could visit the sick in it. The site is outside the Porta Pia, and the plans have been prepared by Cav. Giulio Podesti. The buildings will cover an area of 160,000 metres, and will be constructed in accordance with the most advanced hygienic principles. The new institution is intended not only for the treatment of disease, but as a school of medicine, on which great hopes are founded for the restoration of Italy to the leading position which she formerly held in science. The arrangements for clinical study and pathological research are designed on a scale of the utmost completeness. The foundation of the Policlinico Umberto I is the work of Professor Baccelli, and is only a small part of a comprehensive scheme for the reform of university teaching throughout Italy which he brought forward some years ago when Minister of Public Instruction. His enlightened efforts failed owing to causes which we in this country have no difficulty in understanding. It was the old story of hesitation and delay on the part of the powers that be, and excessive tenderness for vested interests and traditional abuses, complicated with the usual personal and corporate jealousies.

INOCULATION FOR SMALL-POX IN ALGERIA.

DR. PRENGRUEBER has recently written a pamphlet on variolous inoculation as practised by the natives of Algeria. Sometimes the inoculation is made by a linear incision between the thumb and forefinger, and this may cause an indolent local ulcer, lymphangitis, or phlegmonous erysipelas. The practice is one of many employed to procure abortion. The most serious result of inoculation is the frequent artificial production of very severe epidemics, which it undoubtedly effects. Dr. Prengrueber witnessed an epidemic in 1878. In the midst of a population of 13,763 inhabitants, he noted 710 cases of severe and confluent small-pox, with 94 deaths. The origin of the epidemic was satisfactorily traced. A soap merchant of the tribe of Amon-Alls was found, on his return from the city of Algiers, to be suffering from confluent small-pox. The entire tribe, including the children, rushed to his abode and inoculated themselves. The epidemic soon developed, and spread to the Krachnas, Boulderballahs, Mosbahas, and Senhadjis, apparently in

the same manner as caused its outbreak amongst the Amon-Alls. It only ceased when there was nobody left to inoculate. Dr. Prengrueber observes that these Kabyle tribes form an endemic focus of small-pox which spreads to the Europeans and Arabs. Inoculation should be suppressed and vaccination enforced by law, supported, on account of the obstinacy of the Kabyles, by Lebel guns and rifled cannon. He advocated the establishment of stables for calves all over Kabylia; this would avoid vaccination from vaccinated infants, to which the native mothers strongly object. The *keikh* might readily be made an ally, which would encourage vaccination from the calf. British sportsmen often select Algeria for hunting large game; they should not overlook the prevalence of small-pox in country.

INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

AT the meeting of the International Congress of Hygiene and Demography in Vienna last autumn, a permanent committee was appointed to perpetuate the organisation of the Congress, and to initiate the necessary steps for holding the next Congress in London in 1891. A preliminary meeting of persons nominated by societies interested in hygiene was held this week, at which the English members of the permanent committee—Sir Douglas Galton, Professor W. H. Corfield, and Mr. Shirley Murphy—were requested to take steps to bring the subject before the universities, medical corporations, and engineering, architectural, and statistical societies of the United Kingdom.

PIRONITRATE OF AMMONIA IN MALARIAL FEVER.

IN the Bulgarian *Meditzinsko Spisanie*, Nos. 31 and 33, 1887, Dr. A. Golovina, lady physician to the Varna Town Hospital, writes that, at the suggestion of Professor Fr. Goll, of Zürich, she tried pironitrate of ammonia, in 3-centigramme pills, four times a day, in seven cases of malarial fever of quotidian type. In five the paroxysm ceased to recur (in one case from the second day of the pironitrate treatment, in three cases from the third day, and in one from the sixth). Three of the successful cases were of recent origin, and two fairly old. The quinine treatment had been previously tried in three of them (including the inveterate ones) without result. In a sixth patient, however—a lad with quotidian fever of two and a half months' standing—a seven days' course of the pironitrate utterly failed to arrest the paroxysms, the latter subsequently disappearing in two days under quinine (50 centigrammes twice daily). The pironitrate apparently gave negative results also in Dr. Golovina's seventh case. No unpleasant secondary effects were ever observed.

THE ILLNESS OF THE CROWN PRINCE.

WE learn by special telegram from San Remo that the Crown Prince's symptoms had become so urgent that tracheotomy had to be done on Thursday morning. We are pleased to say that the operation was performed with complete success. It is natural enough that some alarm should be felt by the public that this procedure should have become necessary. Our readers, however, will no doubt remember that we have more than once hinted that such a contingency was not unlikely to arise, and last week we intimated, as plainly as was possible under the circumstances, that the time was not far off when the operation would be imperatively required. It is quite inaccurate to speak of the Prince's present condition as a "relapse"; the local symptoms have simply become rather suddenly intensified without any substantial change in their character. The possibility of such an event has been clearly foreseen all along, and it has been obvious for some months past to those

acquainted with the facts of the case that tracheotomy, sooner or later, was inevitable. We are in a position to state that all these points were fully explained, a considerable time ago, to the illustrious patient himself, and to his relatives both in Germany and in this country. It may be well to emphasise the fact that the necessity for surgical interference which has arisen does not in the least degree contradict the more favourable reports as to His Imperial Highness's condition and prospects which we have lately been able to give. It is still highly probable that the disease is not cancerous, but obstruction of the larynx, however "innocent" in itself, is a complication that can only be dealt with effectively by the surgeon's knife. It should be distinctly understood that the operation, when done as in the present instance merely as a security against possible accidents in the future, is not only very slightly dangerous in itself, but is one of the most successful in surgery. There is no reason why a man suffering from a disease which obstructs the upper orifice of the windpipe, but does not spread to neighbouring parts, should not, if tracheotomy is performed in time, live out his full natural lease of life. If at any subsequent period the passage becomes clear again, the tube can be removed; if not, it may continue to be worn with comparatively little inconvenience or discomfort. With a properly constructed instrument the patient is not only free from all risk of suffocation, but is able to speak with perfect ease and distinctness, and can discharge the duties of life, and take part in most of its pleasures, without trouble to himself or distress to others.

SCOTLAND.

ROYAL INFIRMARY, ABERDEEN.

At a special meeting of the Aberdeen Royal Infirmary Corporation recently held, regulations were adopted for the joint management of the infirmary and the asylum.

LIGHTING A LUNATIC ASYLUM BY ELECTRICITY.

At a meeting of the Fife and Kinross Lunacy Board, the question of lighting the asylum by electricity was brought up, and it was agreed to apply for estimates from some of the leading electric lighting companies. A committee was formed for the purpose.

EDINBURGH ROYAL INFIRMARY SAMARITAN SOCIETY.

THE Samaritan Society in connection with the Edinburgh Royal Infirmary continues to do much real good work. At the ninth annual meeting, presided over by Sir Alexander Christison, the Secretary stated that they had every reason to be grateful for the work done during the past year, and for the generous support they had received from the public. The finances of the Society were good. During the year, 895 weekly allowances had been paid to the families of 110 patients, giving an average of eight payments to each family. A number of gentlemen spoke of the great work done by this Society as a supplement to that of the infirmary.

EDINBURGH ASSOCIATION FOR INCURABLES.

THE committee of the Edinburgh Association for Incurables report that, had the accommodation at their disposal been much larger than it is, it could have been fully utilised during the past year, during which time they have admitted 21 males and 23 females, which, added to 33 males and 33 females who were in the home on December 31st, 1886, gave a total of 54 males and 56 females who had received the benefit of the institution. During 1887 32 inmates died, while 15 left of their own accord or were discharged, leaving 31 male and 32 female

patients resident on December 31st, 1887. The wards were fully occupied during the past year, and the committee had dealt with 128 applications, of which 4 were declared unsuitable, 37 were withdrawn or held as withdrawn, 13 died before vacancies occurred, 44 were admitted, and now 30 were standing over for consideration and opportunity. We regret to observe a very considerable falling off during 1887, both of subscriptions and of legacies, the former having fallen off by £197 and the latter by £599; donations, however, showed an increase of £68. The meeting of subscribers, presided over by Lord Trayner, at which these details were made known, was addressed by a number of leading members of the community, who spoke strongly in favour of renewed efforts being made to increase the usefulness of the institution.

GLASGOW UNIVERSITY EXTENSION SCHEME.

AFTER considerable delay the Senate of Glasgow University has constituted a Board for the extension of university teaching by local lectures and classes similar to the Boards already established in Oxford and Cambridge. The Board consists of the Senate and of a large number of the most eminent citizens of Glasgow, such as the Hon. the Lord Provost, Sir John Cuthbertson (of the School Board), Mr. Cochran Patrick, Dr. A. B. McGrigor, and Dr. W. G. Blackie. Professor McKendrick is one of the honorary secretaries. A scheme has been prepared, of which the most important points are as follows. Courses of lectures will be arranged for in Glasgow and the surrounding districts. The Board will determine the subjects and appoint the lecturers. Each course will consist of twelve lectures, delivered once each week during a period of three months. An examination will be conducted at the termination of each course by an examiner appointed by the Board, and to those who pass certificates will be granted in the name of the University. The local arrangements will be undertaken by special local committees, who will pay the fees required by the Board and other expenses. At a large meeting of the Board held in Glasgow on February 1st the proposed constitution was adopted, and a committee was appointed to take steps for carrying the scheme into immediate effect.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

At the last meeting of this Society on February 3rd, Dr. H. C. Cameron made remarks on a case of extra-uterine pregnancy, on which he had successfully operated. Full term was considerably past, and the death of the child before the woman came into hospital had made the diagnosis unusually difficult. After removing the child, which was a well-grown fetus at full term, Dr. Cameron stitched the cyst to the abdominal wall, leaving the placenta in its position. Thorough cleansing of the cyst was performed twice daily. After some days fragments of the placenta began to come away, and finally the remaining mass, considerably shrunken, presented at the wound, and was easily removed. Recovery was throughout uninterrupted, the cyst gradually becoming contracted to a very small size. The fetus and placenta were shown to the Society.

ROYAL HOSPITAL FOR SICK CHILDREN.

THERE were treated by the staff of the Royal Hospital for Sick Children, Edinburgh, during the month of January, 529 patients, of whom 52 were in the wards at the beginning of the month while 51 were admitted during it, 20 were discharged as cured or recovered, and 8 were relieved; the average number daily resident in the wards was 43. In the dispensary department 421 out-patients were treated, and 5 children were vaccinated. The majority of the new cases were from Edinburgh and Leith, only 13 being from the country.

THE NATIONAL REGISTRATION OF PLUMBERS,

A PUBLIC meeting of those interested in the expediency of registering plumbers and providing for their special training, in view of the important bearing which the plumbers' craft has upon public health, was held at Aberdeen on February 6th. The meeting was called by Mr. R. E. Coles, clerk to the Worshipful Company of Plumbers of London, and there was a large attendance of plumbers from the city and representing Aberdeen, Banff, and Kincardine. Lord Provost Henderson occupied the chair. Professor Matthew Hay, who addressed the meeting at considerable length, expressed the opinion that the decrease in mortality in Aberdeen and other cities had been more largely due to improvement in plumbing and in architecture than to any improvement in medical treatment. He concluded by moving that the following gentlemen should be elected as representing the public, and adding to those representing the masters and operatives: William Henderson, Lord Provost of Aberdeen; Dr. Maitland Moir, chairman of the Public Health Committee; Dr. Matthew Hay, ex-Provost; James Matthews, architect; William Smith, city architect; George Rose, convener of the Incorporate Trades; Dr. Alexander Ogilvie, head master Gordon's College; John Miller, Sandilands; William Boulton, burgh surveyor; Kenneth Cameron, sanitary inspector; with Mr. A. M. Byres as secretary. This was unanimously agreed to.

IRELAND.

DEATH OF DR. D. D. TATE.

DR. D. D. TATE, lately resident medical officer, North Dublin Union, died on Tuesday. He had recently retired on pension, owing to severe illness, from which he never thoroughly recovered.

DR. CROKER KING.

WE regret to learn that Dr. Croker King does not make the satisfactory progress which was hoped for, and that it is unlikely that he will be able to resume his duties as medical member of the Local Government Board.

THE CAVENDISH LECTURE.

SIR W. STOKES, Professor of Surgery, Royal College of Surgeons, Ireland, has been invited by the West London Medico-Chirurgical Society to deliver the Cavendish Lecture.

THE ROYAL UNIVERSITY IN IRELAND.

THE Senate of the Royal University has determined that in future the degrees of B.Ch. and B.A.O. shall be conferred in addition to the M.B. upon all candidates who pass the examination for qualification as required by the new Act of Parliament. Candidates will not be required to pay any extra fee. The higher degrees of M.D., M.Ch., and M.A.O. may be taken in three years subsequent to the primary degrees. The privilege now given to old students of the Queen's University of proceeding to the degree of M.D. on the course recognised in that university will be withdrawn at the close of the year 1891.

RELIGIOUS MANIA.

A VERY singular occurrence has recently taken place at Gortley, a village not far distant from the famous Gap of Dunloe. On Saturday, February 4th, six members of one family, in a fit of madness, murdered an idiotic boy aged 13, and threw his body into the yard adjoining the house. The perpetrators of the deed are now inmates of Killarney Lunatic Asylum, but the mother of the lad has confessed to have had some hallucination that so long as he lived the family would be subject to evil influences. On this account she acknowledged having killed her son with a hatchet.

DR. MAGNER.

DR. MAGNER, of Cork, having been sentenced to two months' imprisonment for having taken part in a National League meeting contrary to law, the Local Government Board issued a sealed order dismissing him from his position as dispensary medical officer. At the annual meeting of the Cork Medical Association a resolution in reference to the matter, but the terms of which have not been made public, was passed unanimously, and ordered to be sent to the Local Government Board.

BRITISH MEDICAL TEMPERANCE ASSOCIATION:
NORTH OF IRELAND BRANCH.

THE annual meeting of this Branch was held in the rooms of the Irish Temperance League, Belfast, on January 26th. The President (Brigade-Surgeon M'Farland) occupied the chair. Brigade-Surgeon M'Farland was re-elected President, and Dr. Wm. G. Mackenzie Honorary Secretary and Treasurer for the ensuing year. Dr. Thompson, J.P., Anahilt; Dr. J. Dysart M'Caw, Portglenone; Dr. Dickson, J.P., Ballynahinch; Dr. Taggart, Antrim; Dr. Elliott, Derry; Dr. H. M. Johnston, Stranorlar, Donegal, were elected Vice-Presidents. After a discussion as to the best means of securing the interest and co-operation of those members of the profession who do not now sympathise with the principles of personal abstinence, in which Drs. Barnett (late H.M. Indian Army), Arnold, Osborne, Scott, Sinclair, and the President took part, it was resolved that the Secretary be instructed to send a circular to all the members urging upon them to bring the claims of the association before the medical brethren in their various districts.

THE LATE DR. DAVID J. HAMILTON, OF COOKSTOWN.

AT a meeting of the Cookstown Board of Guardians, held last week, the following resolution was adopted:—"That this board desire to express their sense of the loss they have sustained in the death of Dr. Hamilton, who had been for forty-six years medical officer of the workhouse, and their deep sympathy with his daughter and other relatives." The board have appointed Dr. C. Graves as *locum tenens* in Dr. Hamilton's place, and will elect his successor on February 11th.

THE ROYAL BARRACKS, DUBLIN.

WE publish elsewhere some particulars, which will be found very interesting. The report of the commissioners appointed by Government to inquire into the outbreak of typhoid fever has not yet been made public; but we believe we have been able to collect and present as full a history of the case as is so far available. It is quite plain that there is a fever nest in the Royal Barracks. We think the starting-point has been clearly traced to the ventilating shaft of a sewer at the cavalry mess, and we do not doubt that fresh centres have been established through the impure latrines and the adulterated milk. The ventilating shaft has been removed, and already all improvements that can be rapidly made are being carried out. The pulling down of buildings as recommended will get rid of the narrow lane ways, and the erection of a proposed new cavalry barracks nearer to the Phoenix Park will remove another source of mischief. We are sure that the report will prove a valuable one, and it is to be hoped that, with the changes which must be carried out, the plague spot will disappear.

ANGER OF ENTERING A TRAIN IN MOTION.—Mr. Mortimore Smith, L.R.C.P., of Southport, met with a very serious accident on Tuesday night, whilst attempting to enter the train at Formby, when in motion. Having stepped between the footboard and the platform, he was dragged for some distance, and sustained a compound fracture of the thigh in the lower third, complicated by extensive crushing of the knee-joint. He was immediately removed to the Southport Infirmary, where the thigh was amputated by Dr. Arthur Jones. The patient sank and died on Thursday morning. Dr. Smith had only been in practice at Southport for about two years.

THE NEUROLOGICAL SOCIETY OF LONDON.

THE general annual meeting of this Society took place at the Holborn Restaurant on the evening of February 2nd. The following office-bearers, nominated by the Council, were unanimously elected:

—*President*: Sir J. Crichton Browne, M.D., F.R.S. *Vice-Presidents*: J. Hutchinson, F.R.C.S., F.R.S.; Thomas Buzzard, M.D., F.R.C.P. *Council*: H. Charlton Bastian, M.D., F.R.S.; A. Hughes Bennett, M.D., F.R.C.P.; D. Ferrier, M.D., F.R.S.; J. Hughlings Jackson, M.D., F.R.S.; G. J. Romanes, F.R.S.; G. H. Savage, M.D., F.R.C.P.; E. A. Schäfer, F.R.S.; James Sully, M.A.; D. Hack Tuke, M.D., F.R.C.P.; Samuel Wilks, M.D., F.R.S. *Treasurer*: J. S. Bristowe, M.D., F.R.S. *Honorary Secretaries*: James Anderson, M.D., F.R.C.P.; A. de Watteville, M.D., M.A., B.Sc.

After the business meeting the members of the Society dined together; Sir JAMES CRICHTON BROWNE, President, in the chair. About forty members and a number of guests were present, and amongst the latter was the President of the Royal Society, Mr. Joseph Thomson (the African explorer), and Professor Mivart.

After the loyal toasts, the CHAIRMAN, in proposing the toast of the evening, "The Neurological Society," said that division of labour, it seemed to him, was ever characteristic of advancing civilisation, and that localisation of function might be observed, not less in the community than in the individual. The manufacture of cotton had its centre in Lancashire, that of woollens in Yorkshire, that of gloves in Worcestershire; and in every great hive of industry in these days, like Birmingham, they found that various operations were carried on in different establishments and by different artisans, which in more primitive times would have been conducted in one workshop and by one pair of hands. In science, he ventured to think, as in industry, as that prominent representative of science who had honoured them with his presence there to-night—the President of the Royal Society—would testify, the same kind of division of labour was perpetually going on. It was no longer possible for any one man to emulate Solomon, and talk wisely of beasts and of fowl and of creeping things and of fishes, and to be as encyclopaedic as Aristotle, and every student of science who would be a profitable student must now be content to toil diligently, after a comprehensive general training, of course, in some allotment of one of the fields into which the great domain of science had been broken up. The growth of the tree of knowledge implied the multiplication of branches, and the law would seem to be that in proportion as any branch of science became less abstract and more practical, so the division of labour must be pushed further and further in order that those who followed it might be endowed with due skill and insight. Biology had been broken up into botany, zoology, anatomy, physiology, and so forth; and medical science, which was a branch of applied biology, had been specialised to an extent which was almost a reproach, for they had been told that there was no organ in the human body except the umbilicus, which had not a group of physicians exclusively devoted to the treatment of its diseases. Well, perhaps specialism had been carried a little too far, and they might in some instances have sacrificed breadth to insight, but specialism in medicine was to some extent inevitable, and, in certain directions, it was not only inevitable, but desirable, as in the case of the diseases of an organ, or a system of diseases which were peculiarly complex and varied, that required to be investigated by special methods and special instruments needing special dexterity in their use, and that required to be reviewed from time to time in connection with the development of certain rapidly progressive branches of pure science. And on these grounds he ventured to claim that the diseases of the nervous system, which were certainly very complex, very obscure, and very varied, which required to be investigated by special methods and special instruments, and which had constantly light thrown upon them by physiology on the one hand and psychology on the other, constituted a natural and real speciality in medicine which well might demand the undivided attention of a group of physicians as well as the collateral assistance of other physicians, who, though not making nervous diseases their special study, were particularly interested in them. If nervous diseases constituted, as he claimed, a natural and a real speciality in medicine, they were entitled, he thought, to a Society of their own, in which those that studied them might meet and compare notes—a sort of thought exchange

to which the workers might bring their products to be sampled by those who understood them, to have the actual value attached to them by debate or the haggling of the market, as it might be called. It had thus come about that a few psychologists, who had been accustomed to study mind in connection with its anatomical substrata, a few ardent physiologists who had made a special and particular study of the functions of the nervous system, and a large number of physicians who were engaged in grappling with the disorders and diseases of that system, had found it convenient to band themselves together for mutual encouragement and support into the Neurological Society, the second anniversary of the birth of which they were met to celebrate that evening. Having survived the perils of infancy the Neurological Society had now attained to the enjoyment of solid food and its first dinner, and seeing that the rudimentary brain was a supra-oesophageal ganglion, it seemed to him but right and expedient that the Neurological Society should not altogether overlook the great function of deglutition, and hence their dinner. A number of those who were there that evening had been at the making of the Neurological Society, and it was not necessary to rehearse its origin or progress, but he might merely say that, thanks in a great degree to their indefatigable secretaries—Dr. de Watteville, who was fondly thinking of them on a peak of the Engadine, and Dr. Hughes Bennett, who was blandly smiling upon them at that board—thanks to their exertions, the Society was already in a flourishing condition. Its roll of members was long and lengthening; its meetings had been well attended, and had given rise to discussions of the most thorough, searching, and practical description; and not only had it reached, as he (Sir Crichton Browne) had pointed out, to the enjoyment of solid food, but obtained the command of an organ of articulate speech, for the journal *Brain* had passed into their hands—a journal which, he ventured to say, had already obtained some scientific standing, not only in this country, but on the Continent and in America. He ventured to augur well for the future of the Neurological Society which they inaugurated, and he founded his favourable prognostications upon the knowledge of the stuff of which the members were made, and of the spirit which animated them, of the significance to the community of much of the work in which they were engaged, and of the high and abounding interest of some of the subjects which occupied their attention. As to the stuff of which the members were made, he was quite sure there was no medical society which included a larger number of members devoted to scientific work for scientific work's sake. Happily they had amongst them a large number of practical physicians, whose skill and experience were at the service of the public whenever those silver cords, the nerves, were loosed, and whenever that golden bowl, the brain, was broken, and who obtained substantial rewards. But the neurological work of these practical physicians, like Hughlings Jackson, Buzzard, Ferrier, and Bastian, if looked into, would be found to be of the most thorough and laborious and patient character, with no facile element of display in it; and besides these practical physicians, they had some students of pure science: a number of gentlemen who were 'devoting' themselves to neurological inquiry, animated only by intellectual zeal. The members of the Neurological Society, as a body, seemed to him to be made of the true scientific material, which was likely to give strength and durability to its organisation. With regard to the spirit which animated the members, he might say that it was one of sanguine expectation. Remarkable discoveries on the structure of the brain and nervous system had been made of recent years, striking advances had been achieved in their knowledge of nervous diseases, and those discoveries and those advances had stirred up a spirit of enterprise and of curiosity, which, if he might compare small things with great, he would compare to that spirit which moved this country after the discovery of the New World, and which filled "the spacious times of great Elizabeth with sounds that echoed still." Neurologists had two hemispheres to explore, and the promise of rich treasures of discovery to those scientific adventurers who would embark on the voyage of research. He thought he might say that, stirred by those discoveries and advances that had been made, the members of the Neurological Society were now moved by fervid expectation and anticipation. He was well aware that such fervid anticipations were sometimes fallacious and disappointing, and perhaps some of them would recollect what Oliver Wendell Holmes had told them of his fervid anticipation when he was, as he thought, about to read the riddle of the universe. Having observed that when unconsciousness is consciously approached, as during the

inhalation of an anæsthetic—when the mind is on the confines of two worlds—there arise sublime and voluminous, but fugacious thoughts, and having satisfied himself that in these thoughts, if they could only be caught and transcribed, there lay enshrined the secret of the universe, he determined that by a supreme effort of the will he would catch and transcribe them; so, placing himself in his armchair, with pen, ink, and paper at hand, he inhaled the vapour of chloroform. As drowsiness stole over him and just as unconsciousness was impending, those sublime and marvellous thoughts arose, and by a vigorous effort he seized his pen and wrote, he knew not what, for before he had finished he fell back unconscious. When he awoke, with trembling anxiety he turned to the sheet of paper, on which he could read, in scrawling characters but quite legible, the secret of the universe written in the words: "A strong smell of turpentine pervades the whole." Now that anecdote, he thought, taught that mere fervid anticipations were not to be built upon, but neurologists had momentous discoveries already made to found on. Touching upon the significance to the general community of the work in which the Neurological Society is engaged, he would remind them that the present was a nervous age. The nervous temperament was in the ascendant. The burden of the world's work, which used formerly to be borne by muscle, had been transferred to nerve in devising, guiding, and superintending machinery. Education, which had been so diffuse, had a nervous tendency, and their greatest neurological philosopher, Dr. Ross (of Manchester) had told them that those mental disturbances which were so prolific a source of disease must inevitably exercise a more and more predominant influence in their production as civilisation went on. Then they must remember that the nervous element in our population was constantly being increased by the preservation of sickly lives, which they owed to modern sanitary science. Those epidemics which used to devastate the country carried off a number of those of the least nervous resistance, and now that these epidemics had been restricted in their ravages, a large number of persons of weakly nervous organisation and unstable equilibrium, who would formerly have been cut off, were allowed to grow up and to suffer from every variety of nervous disease. "Take," he said, "infantile convulsions as an example. Within a period of twenty years the mortality fell from 26,000 to 22,000, and that notwithstanding an enormous increase in the population. Now, it was quite certain that under infantile convulsions there used to be classed a large number of maladies which were now recognised of a different nature. But, allowing for this, it was incontestable that a large number of infants, owing to improved methods of feeding and nursing, who would formerly have died of convulsions, were now reared to swell the nervous element in our population." The tide of nervous diseases thus rolled on, and that it did so might, he thought, be inferred from the fact that in the very same period in which the mortality from infantile convulsions diminished so notably the mortality from other nervous diseases rose from thirty to forty-nine per thousand per annum. Nervous disease being the disease of the future, the Neurological Society might, he thought, render important services in safeguarding the public health. It had an important mission, and affecting the general community in connection with mental and nervous hygiene. To bestow just one word on the lofty and absorbing interest of some of the questions which must be deliberated on from time to time by the Neurological Society, he would point out that those questions lay on the margin of that great unbridged gulf which separates the psychical from the physical, that unbridged gulf which was as alluring to the speculative philosopher as the lamp was to the moth. Not, perhaps, until the veil of Life's temple was rent in twain would they rightly comprehend the incarnation of mind in matter, but it was a law of our being to press as closely as may be upon that great mystery and to read with eager interest such fragments as were decipherable of the cryptic records of the brain.

DONATIONS.—Mr. T. Dyer Edwards has given £1,500 to the Chelsea Hospital for Women, to be applied in reduction of the mortgage debt.—Mr. Matthew Whiting, of Lavender Hill, lately paid a visit to the Royal Free Hospital, and on leaving handed to the Secretary a cheque for £1,000.—Mr. James Simcox has given £400 to University College Hospital.—The Mercers' Company have given 100 guineas to the building fund of the Great Northern Central Hospital.—Mr. Matthew Dobson has given £50 to University College Hospital.—"A.B." has given £50 to the Metropolitan Seaside Convalescent Cottage Association at Bognor.

THE HAYA POISON: ITS LOCAL ANÆSTHETIC PROPERTIES.

DR. L. LEWIN, of Berlin, who has already enriched our knowledge of the kava-kava and sassy bark, has, the *British and Colonial Druggist* reports, just coucluded an interesting research upon a new arrow poison, called haya poison, that Messrs. Thomas Christy and Co. sent to him, and which they had received from Africa.

The statement of our contemporary runs as follows; Dr. Lewin, in his report states that he received from Messrs. Christy a box, containing some shapeless fragments of an average length of one centimètre. A superficial examination of the poison showed it to consist of pieces of two different shapes. The first to be examined were amorphous; dark brown, but lighter in the fracture, where the colour was more of a brownish green; easily broken up and showing a smooth section when cut; when squeezed it became flat, and could only be reduced to a fine powder with difficulty. In this powder, as well as in the fracture of the pieces, numerous glistening particles were observed. The other pieces were almost black, somewhat of the colour of the aloe, and presented when splintered the translucency of the latter; the pieces had mostly a decided shape, being convex externally, and having on the inner surface a sharp-edged furrow, suggesting almost that it was occasioned by a narrow angular instrument having been pressed on the surface.

Dr. Lewin is of opinion that the mass had been attached to the barb of an arrow, and this, he says, is all the more probable, as in some of the furrows he noticed a good deal of iron-mould. The pieces which could not be cut up were brittle, fractured, and splintered, like the aloe, and were easily reduced to powder, which, unlike that of the pieces first described, was not sticky. In the powder similar glistening particles to those observed in the first were seen. Upon carefully examining these particles, which were freed from the powder of both the amorphous and the shaped pieces by an aqueous solution, Dr. Lewin found them to consist of gold spangles.

Both powders were odourless and tasteless, readily absorbed moisture from the atmosphere, the amorphous powder doing so to a much higher percentage. Both were soluble in water, especially boiling water, the solution of the amorphous powder varying from a straw to a brown colour, and that of the second powder being of a blackish colour, reminding him of a solution of apomorphine; both solutions, in a minor concentration, showed a distinct opalescence. Upon filtering the solutions there remained a residue containing flint and mica, and having a shimmer like mother of pearl.

Twice did Dr. Lewin separate from the residue some seed husk, which, however, could not be defined even by an expert. The epidermis of a bark was also obtained which, by careful and close examination with specimens in Dr. Lewin's collection, led him to suppose that they consisted of pieces of sassy bark, the ordeal poison of the Africans (*erythrophloeum judiciale*). This supposition was confirmed by Mr. Hemings, of the Botanical Museum of the University of Berlin, and by Dr. K. Schumann, who kindly compared it with specimens of sassy in their possession.

From the amorphous poison about 60 per cent. of the solid substance was extracted by water. The reactions of the aqueous solution were alkaloidal, and remained unaltered when heated in Fehling's solution. The solution of even the smallest particles, when boiled with mineral salts, became yellow, and when treated similarly with Fehling's solution, a bulky mass of oxide of copper was separated. A glucoside was also found. Phosphoric acid, picric acid, and tannic acid yielded from a strongly acidulated aqueous solution of the poison a flaky precipitate. The precipitate from phosphoric acid, when treated with baryta, yielded a minute quantity of golden-brown substance, having a decided effect upon animals' eyes, and which gave certain reactions with a sulphuric acid.

By repeatedly testing the poison with alcohol, a pale yellowish, active principle was obtained, which, in the case of the dark-brown pieces of the poison, was colourless. By adding water to this alcoholic solution, it became opalescent, and after a short time a colourless, flaky, and amorphous substance was precipitated, which does not affect the eye when applied to it. With a view of ascertaining the quantity of soluble matter in alcohol, two grammes of the amorphous poison were well soaked in a little cold alcohol, and then in a little hot alcohol; and, after exhausting the alcohol, 0.35 gramme of a yellowish residue were obtained.

This residue was repeatedly washed, and finally a micro-crystalline mass was yielded, whose crystals melted when heated, and re-crystallised on cooling; these crystals were dissolved by ether and alcohol, produced no effect upon animals, and were separated from the alcoholic residue by treating it with a little water, and then filtering.

After distilling off the water, there remained a substance which, by Lassaigne's process, showed glucoside reactions, which, though not very marked, were capable of being ascertained; this substance had an energetic local and general action on animals.

Dr. Lewin calls particular attention to the fact that the residue, its solution, and one of the whole poison, placed on a porcelain palette with concentrated sulphuric acid, afterwards cautiously and perseveringly manipulated until dry and then heated, gave when warmed a clear pink colour. After the addition of a dilute acid to the aqueous solution of the alcoholic residue, microscopical crystals, mostly rhomboid, were isolated.

After a careful treatment of the poison by alcohol there still remained a substance soluble in water, which seemed to possess a toxic effect unlike that of the alcoholic extract. Treatment with ether yielded no active principle; after passing off the ether, the residue was micro-crystalline, and showed fine needle-shaped crystals. Want of more materials prevented a more ample chemical examination of the poison.

Having often heard of an arrow poison which produced insensibility, Dr. Lewin made experiments to ascertain whether the haya poison produced anaesthesia of the cornea, and he was not a little surprised to find this effect to be obtained with all the animals upon which he tried it. Anaesthesia took place later than by cocaine, but lasted for eight or ten hours, gradually diminishing in its strength during that period. The application produced a passing irritation on the eye.

The action of $\frac{1}{4}$ to $\frac{2}{3}$ concentrated aqueous solution, injected with Pravaz's syringe, on the frog's heart was to diminish the pulsations from 30 to 8 per minute, with paralysis of the extremities. These effects were also noticed in warm-blooded animals. The after-effects were most remarkable, especially in small dogs, in which the respirations, after about twenty or thirty minutes, became arrhythmical, very rapid, with pauses of short duration, becoming, later on, protracted with dyspnoea and langoor; the head drooping, while the position of the body remained normal; there was free salivation. Then the head began to tremble, the animal lay on its side, and the extremities became paralysed; dyspnoea set in, and with it peculiar convulsions, during which the head was drawn close up to the body, the eyes were convulsively closed, and an undulating spasm passed over the whole length of the muscles of the body, and which appeared also to affect the intestines; the almost paralysed limbs were not subject to these convulsions. Decreasing sensitiveness of the surface of the body followed, and death ensued without convulsive effort. The convulsions were noticed to be more severe when using the poison extracted by alcohol and diluting it with water.

The aqueous or alcoholic solutions, injected subcutaneously into a pigeon, produced constant vomiting and frequent evacuations, protracted breathing, as noticed in the previous case; dyspnoea then appeared, and death took place, with convulsions of short duration. Administered to pigeons by the beak large doses only produced constant vomiting and diarrhoea, while small dogs and pigeons, when even so small a quantity as 0.3 gramme was injected subcutaneously, died from the effects. Pigeons remained healthy when even as much as 0.22 gramme was given through the beak.

Dr. Lewin concluded from his experiments that the haya poison may safely be classified with the African poisons already known, or perhaps is identical with them. The effects of the haya poison reminded him very much of those he had noticed with the poison of the Somali, the so-called Ouabaïo, and the effects of the latter resembled the intoxication produced by the erythrophloeum. Besides these coincidences his suspicions were more or less confirmed by the fragments of epidermis which he had found in the poison, and which so strongly reminded him of the erythrophloeum bark, which 13 years previously he worked upon. It was not, however, known that the erythrophloeum contained a principle having a local anaesthetic action, neither was the sulphuric acid reaction which he discovered in the haya poison known.

His suppositions were found to be correct, for a 2 per cent. concentrated solution of hydrochlorate of erythrophloeine obtained from Merck, immediately produced, with contraction of the pupils, insensibility of the eye, lasting from 10 to 24 hours; but

the irritating principle the erythrophloeine contains is present in too great a quantity for it to be neutralised in the concentrated solution; and this was proved by it producing in cats irritation in the cornea, much salivation, running at the nose, and violent sneezing.

It is worthy of notice that solutions of 0.25 per cent., or even 0.10 per cent. of erythrophloeine produced, without apparent irritation, in cats, dogs, guinea-pigs, etc., anaesthesia of the cornea after about 15 to 20 minutes, as was the case with the haya poison, the pupil remaining unchanged for many hours.

A solution of the haya poison was injected subcutaneously into a guinea-pig, and produced an insensibility of the part treated so great that he was able to cut down as far as the muscles without any discomfort to this most sensitive animal. Frogs in which tetanus was produced by injecting erythrophloeine into the leg showed no reaction of that limb when pricked, and the tetanus could not be removed.

Dr. Lewin said he was able to obtain, with the salts of erythrophloeine, that wonderful reaction with sulphuric acid which he is surprised has so long been overlooked. In conclusion, Dr. Lewin says, he has shown that erythrophloeine is contained in the haya poison, if only in minute quantities, and that the action of the poison is partly due to its presence. As soon as he was able to obtain more materials he intended to go further into these matters, and he expresses his satisfaction at the discovery he was able to make of a new anaesthetic.

THE OUTBREAK OF TYPHOID FEVER AT THE ROYAL BARRACKS, DUBLIN.

THE Royal Barracks, Dublin, has gained an unenviable notoriety on the score of its insanitary condition. It has figured in the House of Commons from time to time when some new case of typhoid has occurred, but for some years the authorities have been unable to discover or cope with the cause. Sufficient has now been revealed to show that there are probably several causes in operation.

So long ago as May, 1887, Sir Charles Cameron, medical officer of health for Dublin, and Dr. T. W. Grimshaw, the Registrar-General for Ireland, were appointed to report upon the state of the building and to endeavour to determine the circumstances connected with the prevalence of enteric fever among the troops stationed in the barracks. No one could have been selected better suited for such an investigation. The work was of a most laborious character, and the Blue Book, which will come before Parliament, will show how thorough has been the inquiry.

The geological structure of the site upon which the barracks stand possesses some peculiarities which are of considerable importance. The Dublin district generally stands on the "boulder clay" of the "glacial drift," which is one impervious stratum. There is, however, in the centre of the city of Dublin, extending along the valley of the Liffey, a gravel bed formed by an old raised sea beach. This gravel lies on the "boulder clay" before mentioned—the latter clay being an impervious stratum—the gravel a very pervious one. As the ground rises on each side of the Liffey, the gravel is found at the bottom and the clay on the higher sides of the valley. The result is that the drainage on the higher levels of the valley tends to run off the clay and accumulate in the gravel bed at the lower level. It necessarily follows that the gravel receives not only the sewage and drainage proper to its own area, but also that of the clay above. It so happens that the Royal Barracks are partly situated on the clay and on the gravel, and therefore all drainage not carried off by proper sewers and drains for that part situated on the clay tends to flow down towards the south and accumulates in the gravel. In terracing the ground to accommodate the buildings of the barracks, retaining walls had to be constructed; the dampness of these walls shows that a considerable amount of water is always passing from the higher to the lower ground, and this must ultimately find its way into the gravel bed below. Thus, while the aspect of the barracks is good, its site, from a geological point of view, is defective, and therefore the drainage arrangements require special attention to make the site a healthy one.

The period over which the statistics of typhoid fever in these barracks may be considered extends from 1879 to the latter part of 1887. During that time 59 cases occurred, with a mortality of about 20 per cent. But in 1879, while there were 218 cases in

Dublin with 3 in the barracks, in the first three quarters of 1887; with 90 cases recorded for Dublin, 27 occurred in the barracks. The record of cases in the several military centres is important. Dublin district, which extends right across Ireland to the west coast, shows 2.5 per 1,000; Dublin garrison, 3.5; Belfast, 0.7; Cork, 1.8; Woolwich and Home, 2.5. Deaths from all causes were, in the garrisons of the United Kingdom, 6.55; Dublin district, 6.82; Dublin garrison, 6.63; Home and Woolwich, 6.7. The death-rate in typhoid fever was, in Dublin garrison, 22.6; in the United Kingdom, 23.1.

That the geological structure on which the barracks stand has some influence is shown by the comparative death-rate. In the five years from 1882-7 the death-rate was 1 in 365 on the gravel bed, as compared with 1 in 531 in the rest of the city.

THE PLAN AND STRUCTURE OF THE BUILDINGS.

The distribution of the buildings of the Royal Barracks over the site is somewhat peculiar, and by no means conducive to the health of the inmates. The eastern group of buildings consists of Palatine Square, closed in on all sides, entered by archways, one of which is situated in the centre of each side of the square. To the south of this square is Brunswick Square, which has buildings on three sides only, the fourth side being open to the south. On the north side, and to the rear of Palatine Square, is a terrace rising to the level of the first floor of the buildings. At the eastern end of this terrace stand a number of buildings, which still further intercept the air and light from the windows of the north side of Palatine Square. At the other extremity of the terrace the boundary wall of the barracks is so close to the buildings as to produce the same injurious effect. In fact, all the north structures of the square on the lower storeys have their light and air interfered with. On the eastern side of this eastern group of buildings runs a roadway, with some low buildings on the public side. On the western side there is a totally different state of things. About half of the western side of Palatine Square, and the whole of the western side of Brunswick Square, have their western windows looking into a narrow lane, the opposite side of which is formed of a row of buildings. The lane is but twenty feet wide; the buildings on the Palatine side are four storeys high, and on the other side three storeys. The lane itself contains cook-houses, ablution rooms, washhouses, etc. Thus, the space between the eastern group of buildings, comprising Palatine and Brunswick Squares, and the middle group, is confined by a narrow lane closed at one end, and partly occupied by small buildings scattered irregularly through it—a state of things found in old and overcrowded towns, but not now to be expected in a barrack. An arrangement more calculated to lower the health of the occupants and to spread disease could scarcely be contrived. Similar unhealthy conditions prevail along the western as along the eastern side of this lane. The state of affairs on the western side of Royal Square is almost as bad as on the eastern. The occupants of the buildings cannot ever be expected to be healthy until the insanitary conditions are mitigated. The western group of buildings comprises Cavalry Square, the Horse Square, certain buildings to the north of the Horse Square, consisting of stables, with cavalry soldiers' quarters and recreation rooms over them. To the west of the group of buildings runs another lane, but in this case there are no high buildings; but, on the other hand, there are latrines, cook-houses, stables, and other obstructions. On the eastern side of the western group there is a long narrow lane separating this group from the central group of buildings, with all its unhealthy conditions. The air in these lanes was found to be decidedly bad, and abounding with micro-organisms.

PROBABLE CAUSES.

The cases appear to have first appeared in the Cavalry Square occupied by about fifty persons. Here are the cavalry mess and the cavalry officers' quarters. There were four cases among the officers, one of an officer's servant, and some amongst the sergeants and troopers on the opposite side of the square. A servant's water-closet near the mess room was found to be in a very bad condition. Running up outside the wall of the mess room was a ventilating shaft from the main sewer, not from the closet. When this was tested, it was found that the smoke, as soon as it became cool, began to fall, and then passed into the mess room windows. In summer this room became hot at night, and the windows were always open, so that the gases from the sewer below were constantly passing into the chamber occupied by the officers. A further examination showed that this sewer comes direct from the hospital at Arbour Hill, where infectious cases are treated.

The Palatine Square is occupied by infantry, and is separated from the Cavalry by another square (the Royal), also for infantry. In the Palatine Square two officers were attacked, but they had been in the cavalry mess. The men in this square were soon attacked also, and some cases followed in the Royal Square. It was found that the latrine is common to the infantry of both these squares; but sometimes cavalry men use it also, although that is against orders. Here the poison was probably deposited by the troopers, and in due time spread to the infantry. It was found impossible to flush this latrine effectually. With an enormous force of water only the sides were washed, and there still remained a quantity of decomposing filth. Thus when enteric fever poison got there, it remained there, and was propagated from man to man. The latrine became in turn a regular nursery for typhoid fever.

It is a point of much interest to note that typhoid fever prevails to a greater extent in the army at home than in the troops abroad, and it may be that it is propagated in the way here indicated by the change of regiments from station to station, where the system of drainage is on the same plan. A further interesting point is that in Dublin the death-rate from typhoid is much higher than among the civilian population, the proportion being 11 in civilian males to 22.6 in soldiers.

MILK.

On a particular day, all the milk supplied to the several barracks in Dublin was seized at the request of Sir C. Cameron and Dr. Grimshaw, and it was found that while in several cases the supply was bad, in the Royal Barracks 12 supplies showed 11 to be adulterated with from 13 to 56 per cent. of water. In the total amount of 29 supplies, only 5 were noted as good. Now, this was in the summer, when the cattle were in the fields. The milk was adulterated no doubt from the small streams in the neighbourhood, which were probably impure with cattle droppings. At all events it was from this period that the cases began to increase.

STRUCTURE OF BUILDINGS.

All the buildings are old, many of them very old. The age of the buildings is in itself a source of great difficulty in providing healthy conditions for the inmates. There is a considerable amount of old timber in the floors and elsewhere, which is somewhat detrimental to health.

SEWERS AND DRAINS.

The questions connected with old drains are necessarily very difficult of investigation in such a building as the Royal Barracks. In the many cases in which we have examined the connection between the main sewers we only met with the remains of a very few old drains, none of which contained any recent sewage matter, and must have been completely disused many years ago. In connection with the subject of old drains, it should be mentioned that in some places these drains still exist, and are in use. Such drains are probably harmless when they only carry complete surface drainage, but under all these circumstances they may become sources of danger, and therefore pipes should be substituted. There are no plans of the old drains in existence. We are distinctly of opinion that there are no grounds for believing that the health of the inhabitants of the barracks can be affected by neglected old drains. Important drainage works have recently been carried out by the Royal Engineers, and others are in progress, and cannot fail to have a beneficial influence upon the health of the troops quartered in the Royal Barracks. The latrines are of an unsatisfactory pattern, as are also the arrangements.

RECOMMENDATIONS.

A thorough subsoil drainage of the whole site of barracks, and an extension of the dry-earth system; removal of all irregularities and rendering surface of ground impervious—covering polluted ground with some such material as hygienic cement; removal of considerable portions of the present buildings; complete destruction of the narrow lanes. Buildings to be removed—the whole of the eastern side of Royal Square; the whole of the eastern side of the Horse Square, of the Cavalry Square, the eastern end of the block of buildings separating Cavalry Square from the Horse Square, the riding school north of Royal Square, the cook-houses near the riding school, and several small buildings; removal of boundary wall along Arbour Hill; removal of the magazines on the terrace to the north; the terrace to be sloped down; terrace to the eastern side of barracks in front of officers' stables to be sloped

down; removal of all the small buildings at present in the lanes and yards; ground floor of north side of Palatine Square to be disused for habitation; removal of all very old timber; ventilation of barrack rooms by "Tobin's tubes." Drainage from hospital to be so arranged that sewerage containing discharges from patients with infectious diseases should not be admitted to any of the general sewers of the barrack, and should be disinfected before admission into any sewer. A few other recommendations are made.

Concluding opinion:—That if the foregoing recommendations are adopted the health of the troops in the Royal Barracks will be much improved, and the predisposing causes of enteric fever in the barracks mitigated as far as possible.

ASSOCIATION INTELLIGENCE.

NOTICE OF QUARTERLY MEETINGS FOR 1888.

Meetings of the Council will be held on April 18th, July 18th, and October 17th, 1888. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before each meeting, namely, March 28th, June 27th, September 26th, and December 28th, 1888.

ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member *by the Council* or by any recognised *Branch Council*.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No member can be elected by a Branch Council unless his name has been inserted in the circular summoning the meeting at which he seeks election.

FRANCIS FOWKE, *General Secretary*.

COLLECTIVE INVESTIGATION OF DISEASE.

THE Report upon the CONNECTION OF DISEASE WITH HABITS OF INTEMPERANCE, which was presented to the Section of Medicine in the Annual Meeting of 1887, and a further portion of the Report upon OLD AGE have been completed, and will shortly be published in the JOURNAL.

Reports upon the two remaining inquiries, namely, that into DIPHTHERIA, and that into the GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES, are in preparation, and will be published as soon as ready.

The following inquiry only of the first series remains open, namely, that on THE ETIOLOGY OF PHTHISIS.

A fresh inquiry into the ORIGIN AND MODE OF PROPAGATION OF EPIDEMICS OF DIPHTHERIA has just been issued.

Memoranda upon these subjects, and forms for recording observations, may be had on application to the Secretary of the Collective Investigation Committee, 429, Strand, W.C.

BRANCH MEETINGS TO BE HELD.

METROPOLITAN COUNTIES BRANCH: EAST LONDON AND SOUTH ESSEX DISTRICT.—The next meeting will be held at the Town Hall, Walthamstow, on Thursday, February 18th, at 8.45 P.M. (sharp). The chair will be taken by A. Durham, Esq., President of the Branch. A paper on Pernicious Anæmia, and the Diseases liable to be Confounded with it, will be read by Dr. Bristowe, F.R.S. Visitors will be welcomed.—J. W. HUNT, 101, Queen's Road, Dalston, Honorary Secretary.

METROPOLITAN COUNTIES BRANCH: SOUTH LONDON DISTRICT.—A meeting will be held in the Queen's House, Greenwich Hospital School, on Tuesday, February 14th, 1888, at 8 P.M. The chair will be taken by Dr. Frederick Taylor (Vice-President of the District). Business:—1. To read the minutes of the last meeting. 2. Introductory Address by Dr. Frederick Taylor, as the first Vice-President of the District. 3. Mr. W. Johnson Smith (Resident Surgeon to the Seaman's Hospital) will read a paper on the Radical Cure of Hernia. 4. Cases of interest from the Seaman's Hospital will be shown by Dr. Curnow. Gentlemen desirous of reading papers, exhibiting specimens, etc., at future meetings, are requested to communicate with the Honorary Secretary. All medical practitioners will be welcomed. There will be a meeting of the Committee at the same place at 7.30 P.M.—R. PERCY SMITH, Honorary Secretary, Bethlem Royal Hospital, S.E.

YORKSHIRE BRANCH.—A meeting of the members of this Branch will be held at the Clayton Hospital, Wakefield, on Wednesday, February 22nd, at 3 P.M. Members intending to read papers are requested to communicate at once with ARTHUR JACKSON, Secretary, Sheffield.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.—A meeting of this Branch will be held at 198, Union Street, Aberdeen, on Wednesday, February 15th, at 8 P.M., the President, Dr. Smith, of Kinnairdy, in the chair. Business: 1. Minutes, nomination of new members, etc. 2. Ballot for the admission of Dr. J. Marshall Lamb, Borneo. 3. Motion of Dr. Wight to memorialise the Town Council of Aberdeen that the appointment of medical officer of health at present vacant be filled up by a qualified medical practitioner, who shall be excluded from private practice, and whose whole time shall be devoted to the duties of the office, in terms of the memorandum of the duties of the medical officer of health of the city of Aberdeen, of date March 15th, 1888. 4. Case of Pyloric Obstruction, with great Hypertrophy of the Stomach, by Dr. Blaikie Smith. 5. Exhibition of Specimens: (1) Ram's-horn Toe-nail, by Dr. Garden; (2) Specimen of Compound Dislocation of Ankle-joint, by Dr. Garden. 6. Communication by Dr. Barclay, Banff.—ROBERT JOHN GARDEN and J. MACKENZIE BOOTH, Honorary Secretaries.

STAFFORDSHIRE BRANCH.—The second general meeting of the present session will be held at the Railway Hotel, Stafford, on Thursday, February 23rd. Mr. W. D. Spanton, the President, will take the chair at 3.30 P.M.—VINCENT JACKSON, General Secretary.

GLOUCESTERSHIRE BRANCH.—The next ordinary meeting will be held on Tuesday, February 21st, 1888, at 7.30 P.M., at the Infirmary, Gloucester, under the presidency of Dr. Currie. Agenda: 1. A petition will be laid on the table for signature by members in support of the Architects and Engineers Bill, a Bill to be presented in Parliament next session by Colonel Duncan, R.A., C.B., M.P. 2. A discussion will be opened by Dr. Currie on the Present Position of Homœopathy in Relation to Regular Medicine. 3. Cases of interest in the Infirmary.—G. ARTHUR CARDEN, Honorary Secretary.

BORDER COUNTIES BRANCH.—A meeting of this Branch will be held at the County Hotel, Carlisle, on Friday, February 24th, at 6 P.M. Dr. Byrom Bramwell, of Edinburgh, will read a paper and introduce a discussion on the Process of Compensation and Its Bearing on Prognosis and Treatment. The Secretary will be glad to receive notices of papers for reading, and patients or morbid specimens for exhibition. Supper in the hotel at 9 P.M.—H. A. LEDIARD, Honorary Secretary, 41, Lowther Street, Carlisle.

METROPOLITAN COUNTIES BRANCH; NORTH LONDON DISTRICT.

A MEETING of this district was held on Thursday evening, February 2nd, 1888, at the Training Hospital, Tottenham, Dr. E. HOOPER MAY in the chair. Several interesting cases from the wards were exhibited.

New Instruments.—Messrs. KROHNE and SRESEMANN showed many new instruments, the most important being a modification of Thomas's splint for spinal disease, and the electric light applied to the laryngoscope.

Massage.—Dr. STRETCH DOWSE then read a paper on Massage, demonstrating its practice on a male patient lying on a bed by an assistant "masseuse." The paper and illustrations gave great satisfaction to the many gentlemen present (thirty in number), and was witnessed also by all the sisters of the hospital.

Votes of Thanks.—Votes of thanks were duly recorded to the President, Dr. Dowse, and the other gentlemen.

SPECIAL CORRESPONDENCE.

VIENNA.

[FROM OUR OWN CORRESPONDENT.]

Magneto-therapy.—Calomel Injections in Syphilis.—Influence of Erysipelas on Syphilis.

PROFESSOR BENEDIKT, in a lecture which he recently delivered at the Vienna Policlinic, made some interesting remarks as to the value of magneto-therapy. The opportunity was offered by a girl, aged 18, who had suffered for several months from very frequent convulsions, which, owing to their being complicated with laughing and weeping, showed that the case was one of hysteria. The expression of the patient's face was very timid, and her complexion continually changed, presenting at one time an excessive pallor, and at others a glowing redness. The dorsal vertebrae, the left intercostal spaces, both ovaries, but particularly the left one, were very tender on pressure, and pressure on the ovary during internal examination brought on a fit of weeping. Professor Benedikt pointed out that such irritable forms of hysteria were particularly suitable for magneto-therapy, whereas most of the other methods, such as electricity, hydrotherapy, etc., might aggravate the disease, and the suppression of such attacks by means of narcotics frequently rendered the malady incurable. He applied the metallic magnet over the sensitive dorsal vertebrae without having the patient undressed, as the magnet could act at a distance, and the dress presented no obstacle to its action.

After some applications the patient became quasi-paralysed; she could only with great difficulty and very slowly execute the movements which she was ordered to perform. It thus became evident how the magnet influenced the nervous system; it increased the resistance of conduction in the motor nerves, and this resistance could easily become absolute. During the general relaxation of the muscles, the respiration became sighing, and consciousness gradually disappeared. This became evident, not only from the complete want of reaction to external impressions, but also in part from the absence of recollection when the magnet was removed, and the patient aroused from the hypnotic state by slight irritations. This was the usual form of hypnosis which was observed after the application of the magnet. The direct therapeutic effect in the case under consideration was that the sensibility of the vertebral column disappeared after the application of the magnet, while that of the intercostal nerves became diminished. The ovarian hyperæsthesia, however, in contrast with many other similar cases, did not show any decrease. On the following day the patient stated that her attacks had become less frequent and less severe. As the ovarian sensibility could not be removed by the application of the magnet to the vertebral column, the patient was directed to lie down on the abdomen, and the magnet, wrapped in a cloth, was first applied with one of its poles to the left ovary, and then to the right one. A few of these applications were sufficient to cure the patient. The chief indication for the application of the metallic magnet was a condition of increased irritability and active symptoms of irritation. With regard to the question, how, in a case like this—which was due to disappointed love—the treatment could remove the consequences of a psychical alteration, Professor Benedikt gave the following explanation: the irritability of the nervous system becomes increased by the psychical irritation, and though the primary effect loses much of its intensity later on, a slight irritation is nevertheless sufficient to produce pathological phenomena. When, however, the irritability is diminished by an adequate course of treatment, the pathological condition is liable to disappear, when the cause of the affection has lost somewhat of its primary intensity. This is, of course, true of all therapeutic effects on neuropathic conditions, including the psychical ones, and, for this reason, we cannot expect to influence such patients before the primary irritation has diminished in intensity. Professor Benedikt went on to say that he had no doubt that we could also injure the patients with the magnet; he himself had, however, only once had the opportunity of observing permanent bad effects from this treatment. We had to take into consideration the peculiarities of each case. When the magnetic treatment did not produce a favourable effect at the very outset, he discontinued treatment, and in the same way he took care not to prolong the experiment, when he saw that the patient's readiness to fall into the hypnotic state considerably increased. Professor Benedikt remarked, at the conclusion of his lecture, that since he had employed the treatment with the metallic magnet, he found hardly any further indication for hypnoto-therapeutical attempts. There was no doubt that the hypnotisations and suggestions augmented, in a rapid and progressive manner, the paradoxical behaviour of the nervous system, and particularly the psychical function. More hysteria was thus produced than had been present before, and strange to say the mind ("psyche") of the experimenters was so easily brought into a condition of exalted confusion, that they allowed themselves to be more influenced in the way suggested by the patients than the latter were by them.

At a recent meeting of the Imperial Royal Society of Physicians of Vienna, Professor Neumann discussed the value of the calomel treatment in syphilis. This method had been recommended in 1864 by Scarenzio, who stated that calomel was to be preferred in the treatment of syphilis before any other preparation, owing to the fact that it was first converted into sublimate and slowly absorbed, and that toxic symptoms were thus avoided. In modern times calomel had repeatedly been tried in Germany and Austria and several observers, among whom might be named Professor Neisser, professed to have obtained admirable results with it. They said that a few injections were often sufficient to make the secondary symptoms of syphilis disappear. Professor Neumann had for some time past experimented with calomel, using a solution prepared according to the following formula:—R. calomelanos, sodii chloratis, aa. 5.0 (five grammes). Aq. distill. 50.0, M. Sig. for injections. A Pravaz-syringeful, containing 0.10 (ten centigrammes) of calomel to be injected at once. With this

solution he had treated thirty-six patients suffering from macular, papular, pustular, and tubercular syphilides. The injections were made in the region of the buttocks, and not, as was formerly the case, into the affected parts, the "materia peccans," according to the expression of Lewin. The results which Professor Neumann had obtained were not, however, so favourable as those claimed by other authors. According to his observations more injections were required in order to produce the effect, and in one case he had even to make eighteen injections. To appreciate the value of an anti-syphilitic method of treatment, its action as a preventive had to be taken into account. Latterly the experiments which had already been recommended by Hutchinson, namely, to delay the outbreak of the syphilis, in spite of the presence of the primary affection, by means of inunction, had been taken up by several authors, and Professor Neumann, who had also tried this plan, found the appearance of the eruption could indeed be thus delayed, in one case even for 160 days, but that no advantage was obtained by it; the course of the disease only became irregular, and moreover a greater number of inunctions were required than in other cases in order to cure the disease. As to injections of calomel, he observed that their effect was in this respect still less intense; and according to his own experience the calomel treatment was indeed a new, and in some cases valuable, method, but in general its effect was inferior to that of inunction.

Professor Neumann also communicated to the same Society some important facts relative to the influence of erysipelas on the course of syphilis. It had recently been stated that erysipelas had not only a favourable influence on the course of the disease, but that it also cured the whole process. Dr. Schuster, at the Congress of German Naturalists, at Berlin, opposed this view, maintaining that the influence of erysipelas in these cases was only local. Professor Neumann had an opportunity of observing two cases. One of these was that of a woman with tubercular syphilide, who had three attacks of erysipelas while she was under Professor Neumann's observation. After the first of these the knobs became quite flattened, and after the third the exanthem completely disappeared. A patient affected with recent induration in the "sulcus coronarius" was attacked with erysipelas, which lasted for fourteen days. The induration was not influenced by it in any way, but the outbreak of the exanthem was delayed, supervening only eleven weeks from the date of infection. These facts proved that erysipelas, whilst having a certain influence on the course of the syphilis, did not produce any alteration in the syphilitic process itself; it did not even make the attack milder. Erysipelas was not the sole instance of this kind; it was known, from inoculating experiments, that inoculations with the syphilitic virus in persons who were at the same time affected with acute infectious diseases were not attended with success, and it was also known that syphilitic exanthems disappeared in persons suffering from such diseases though only for a time. In cases of small-pox, the maculous syphilides, indeed, disappeared, but the ulcerous forms became more severe, and covered with purulent exudation.

SAN REMO.

[FROM OUR OWN CORRESPONDENT.]

THE Crown Prince's general health has not been so satisfactory during the past week; he has suffered a good deal from headache, his nights having been somewhat disturbed. This is probably due to the confinement to the house, which was necessary owing to the weather, and the catarrhal attack which he had, and it is hoped that it is due to no other cause. The weather is now very fine and mild, and His Imperial Highness is out daily, driving and walking. The last few days there has been some slight dyspnoea, which has caused a good deal of anxiety to those who have observed it. There has been no question of his leaving San Remo for any other place, and he continues perfectly satisfied with his surroundings here. Sir Morell Mackenzie left on Friday to see a patient at Barcelona, and returns here on Tuesday: every minute of his time is occupied whilst here, patients of all nationalities with throat affections being anxious to secure his opinion. The social event of the week has been an art exhibition, which is held annually at San Remo, and enables artists, amateur and otherwise (of whom a great number congregate on this coast) to exhibit their works, the same being sold either for their own benefit or that of some charitable object. On this occasion the Crown Princess, at the request of Dr. Freeman, graciously con-

sented to be Patroness of the exhibition, with the understanding that any profits arising should be devoted to the Home for Invalid Ladies, which, owing to the bad season of last year, is much in want of funds. To aid this object, Her Imperial Highness contributed a water-colour sketch, the subject being the head and bust of a San Remese girl. The Crown Princess's talent as an artist is well known, and great interest has been excited about this sketch. An offer of £50 was made for it immediately the exhibition opened, and it is expected it will realise considerably over this sum. Prince Henry, Count Seekendorff, and many others also contributed sketches, and a goodly amount will be realised for the institution. The Crown Princess, with the Princesses and suite, arrived at the exhibition at the hour of opening, and were received by the Syndic and Dr. Freeman. She took a great interest in the collection, and expressed herself much pleased with it. The ball in aid of the Ophthalmic Institute, given last week, was a great success, the Royal party watching it for the greater part of the evening from a balcony.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

Carbolic Acid in the Treatment of Carbuncle.—"Chemical Vaccine."—Anæsthesia and Respiration.—Antipyrin in Epilepsy.—Pelletierine as a Vermifuge.—Adulteration of Wine.—Meeting of the Conseil d'Hygiène.—Laicisation of the Paris Hospitals.—Case of Trance.—The Pasteur Institute.

At the Académie de Médecine, M. Verneuil lately described the excellent results he had obtained with carbolic acid spray in cases of boils and carbuncle. He employs a 2 per cent. solution of carbolic acid. The spray producer is placed at a distance of twenty-five to thirty centimètres from the skin. In the case of small or medium-sized tumours, Collin's small spray-producer may be used, but a large one is more efficient in the case of tumours of considerable size. The tumour is surrounded with a roll of linen, in order to protect the adjoining region from the irritating action of the acid. The spray is applied three or four times a day for twenty or thirty minutes at a time. In the intervals the carbuncle is covered with a carbolic acid compress. This method is infallible in arresting the development of small or moderate-sized tumours. In the case of large tumours, it often renders surgical interference unnecessary. In every instance it soothes the pain which accompanies the development of boils and carbuncles.

MM. Roux and Chamberland are engaged on a series of researches to determine whether immunity from certain diseases may not be obtained by introducing soluble substances into the organism, without introducing the actual virus of the disease. The first attempt in this direction was made by M. Pasteur in the case of chicken-cholera. The microbe, placed in chicken-broth, developed during a certain time, but then ceased to do so. The medium, however, retained sufficient organic substances to nourish other kinds of micro-organisms. The development of the microbe ceased, either because it had exhausted certain substances indispensable to its existence, or because it had produced substances which arrested its development. M. Pasteur concluded that broth in which the cholera microbe had existed, injected into a fowl, would preserve the bird from contracting the disease. The notion that immunity from a disease may be obtained by inoculations with substances in which the virus has existed, without the introduction of the virus itself, although not actually demonstrated in this instance, was favourably regarded by many biologists. This artificial attenuation of the virus in the case of septiciæmia of rabbits has been the object of MM. Roux and Chamberland's researches. MM. Pasteur, Joubert, and Chamberland have called attention to a micro-organism the germ of which is found in the earth, and in the intestines of sheep, cattle, and horses. This active organism was termed the "septic vibrio," because it produces a special kind of septiciæmia in guinea-pigs, rabbits, and sheep, rapidly followed by death. MM. Koch and Gaffky described this microbe as the bacillus of malignant œdema. Guinea-pigs inoculated with this microbe presented the following symptoms: the hair stands erect; the animals scream if they are touched, and are attacked with convulsive jerks from time to time. Death occurs within twelve hours. The necropsy reveals sanguinolent œdema in the subareolar tissue of the axillæ and groins; the muscles at the spots where the injections have been made are red; the intestines are red; the liver is discoloured. The septic vibrio swarms in the œdematous area, the muscle

juice, and the peritoneal serosity; it emits gases which make the connective tissue in the axillæ and groins yield a crackling sound when they are pressed. The microbe develops in veal broth to which an alkaline substance has been added, in serum, and in nutrient gelatine, but the cultivation must be protected from the air. In these mediums it produces germs which, when subjected to a temperature of 80° C. (176° F.), die in ten minutes; and in less than five minutes at a temperature of 95° to 100° C. (203° to 212° F.). By placing the serosity from the œdema or the blood from the heart of a guinea-pig which has died from septiciæmia in veal broth, as above described, a cultivation liberating equal quantities of hydrogen and carbonic acid gas is obtained in twenty-four hours. At the end of three or four days the gases are no longer evolved; the microbes, though very small, cease to develop; the medium retains a certain quantity of nutritive substance. The liquid of the cultivation is no longer capable of nourishing the microbe; if, after being passed through a porcelain filter, some fresh septic vibrios are placed in this liquid, it still remains sterile. If a portion of this liquid is added to some fresh broth, it has the effect of checking the development of the vibrio. This fact proves that the vibrio produces substances in the medium in which it develops, which act as an antiseptic and arrest its further development. MM. Roux and Chamberland inoculated some guinea-pigs with sterile cultivation liquid, and by this means the animals were preserved from septiciæmia. The following experiment was made, amongst others: injections with cultivations of septic vibrio, rendered sterile by exposure to a temperature of 105° C. (221° F.), were made in the peritoneum of some guinea-pigs. The doses were gradually increased; 10, 20, 40, 60 cubic centimètres were successively employed. Two other guinea-pigs were inoculated twice in two days with 40 cubic centimètres of the same cultivation. Forty-eight hours after the last injection, all the guinea-pigs were subcutaneously inoculated under the skin with diluted septic blood. This last operation was repeated on three fresh guinea-pigs, and on the two guinea-pigs which had been twice inoculated through the peritoneum with 40 cubic centimètres of pure broth. The guinea-pigs which were inoculated with the septic blood only died in twelve and sixteen hours respectively. Those inoculated with pure broth died within eighteen hours. Those inoculated with the sterile cultivation died in the following order: Those to which 20 cubic centimètres were administered died in 19 hours; 30 cubic centimètres killed the animals in 48 hours; and 60 cubic centimètres killed them in 144 hours. The guinea-pig which was inoculated with 40 cubic centimètres was ill, but ultimately recovered, and was completely protected against septiciæmia. A small eschar was formed at the spot where the inoculation was made; this disappeared in a few days. The two guinea-pigs which were twice inoculated with 40 cubic centimètres of the cultivation appeared to feel no ill effects; the virus evidently did not develop in this case. These experiments show that every degree of immunity from septiciæmia may be obtained without introducing the actual virus into the organism, and demonstrate the influence exercised by the different cultivation media. The serosity removed from the œdematous tissues of a guinea-pig which has succumbed to septiciæmia is a more active medium than broth in which the septic vibrio has developed. MM. Roux and Chamberland conclude that, in a given medium, the microbe may produce certain vaccinal substances which it cannot produce in others, and that the conditions under which a cultivation is prepared have an important influence on the substances which are formed in it by the microbe. The authors believe that a means will be found by which "chemical vaccine" for recurrent diseases will be obtained. The present method of preventive inoculation has so far proved inefficient, because the microbe which causes a recurrent affection develops indefinitely in the body of an animal; it is unable to produce ptomaines (which check its development) with the materials it finds in the organism. In different conditions this pathogenic microbe might form substances which, inoculated in the organism, would prevent the development of microbes of its own kind, or render the organism impervious to their action. It is probable that these substances would be found in cultivations in which the development of the microbe has ceased rapidly. MM. Chantemesse and Widal lately succeeded in rendering some mice refractory to the action of the typhoid bacillus, by inoculating a few cubic centimètres of a cultivation in which typhoid bacilli had been destroyed by the action of heat. When the active substance of these cultivations can be isolated and prepared in sufficient quantities, it will serve to inoculate human beings

attacked by typhoid fever. M. Metchnikoff has shown how the cells of the living organism resist the microbes which are introduced into the body. The influence of the phagocytes in conferring immunity from disease is considerable. This influence is only ineffectual when the microbe finds a peculiarly favourable medium for development in the tissues of the body. When these tissues do not offer such favourable conditions (as is the case when inoculations of attenuated virus have been made) the microbe falls a prey to the phagocytes. During the attacks of intermittent affections, such as recurrent fever, the body acts as a favourable cultivation medium for small spirilla which are found in the blood. During the intervals between the attacks, these spirilla are not observed; they are imprisoned in the cells of the spleen. The substances produced by the parasite during the attacks check their development, and they become a prey to the phagocytes. When the blood has eliminated or destroyed these antiseptic substances, the spirilla reappear. This process would explain the intermittent nature of the disease. MM. Roux and Chamberland believe that the action of the phagocytes is regulated by the chemical changes which occur in the body, and which confer immunity from disease.

At a recent meeting of the Académie des Sciences, M. de Saint Martin communicated the results of his observations on the influence of anæsthetic sleep on the activity of respiratory combustion. M. de Saint Martin stated that these results were directly opposed to those obtained by Paul Bert, who, in his *Lectures on Respiration*, published in 1870, maintained that during sleep produced by chloroform, the quantity of oxygen in the blood is increased. M. de Saint Martin, by his recent experiments, showed that during anæsthesia the proportion of oxygen in the blood diminishes, while the proportion of carbonic acid increases. M. de Saint Martin is evidently not aware that Paul Bert arrived at a similar conclusion in his later researches in 1885, and that he then affirmed that the oxygen in the arterial blood diminishes progressively while the carbonic acid increases during sleep produced by chloroform. M. de Saint Martin also described the different variations which occur in the quantity of carbonic acid expelled from the lungs during anæsthesia. Paul Bert likewise gave a description of these variations in 1885, in which he showed that the quantity of carbonic acid produced diminishes progressively during anæsthesia, while the quantity of oxygen absorbed decreases in the same manner. He proved that the proportion of $\frac{\text{CO}_2}{\text{O}}$ gradually diminishes.

M. Geo. Lemoine, Professor *agrégé* at the Faculty of Medicine at Lille has studied the effects of antipyrin in epilepsy. He concludes that antipyrin diminishes the number of epileptic attacks, and even causes them to disappear under the following circumstances:—(1) When the attacks occur at the menstrual period, and are apparently provoked by menstruation; (2) when the patients are subject to neuralgia and migraine. In every other instance M. Geo. Lemoine believes that antipyrin produces merely transient effects.

M. E. Labbé recommends the following as an excellent tæniacuge: For adults, 40 or 50 centigrammes of sulphate of pelletierine are dissolved in ordinary syrup; for children 8 years of age and upwards, this quantity is reduced to 25 or 30 centigrammes. This remedy should not be administered to children below the age of 8. It is well to add 50 centigrammes of powdered tannin to the mixture above prescribed. The evening before taking this remedy the patient should take only a little milk. An enema should be given at bedtime, and early next morning the mixture is administered. The patient should remain in the horizontal position, in order to avoid vertigo. A quarter of an hour after taking the mixture he should take 30 grammes of German brandy, or an infusion containing 10 to 15 grains of senna. Castor-oil (30 grammes) and sulphate of soda have proved equally efficacious. The tape-worm is usually expelled in three or four hours.

A French publican was lately charged with selling wines composed of the dregs of different white and red wines, filtered through felt. The liquid was analysed at the Municipal Laboratory; it contained 9 per cent. of alcohol, 23 grammes of dry extract, and over 4 grains of reducing sugar. The defendant was acquitted.

At a recent meeting of the Conseil d'Hygiène du Département de la Seine M. Lancereaux reported a fatal case of leprosy which occurred at the Hôpital St. Louis in November.—M. Riche presented a report on the system employed by all the fishmongers at the Halles of preserving fish which they have not succeeded in selling in ice chests lined with zinc or lead. M. Riche considers

that this plan should be prohibited, on account of the toxic properties which may be communicated by the lead to stale fish.—M. Léon Collin presented a report on the epidemic of typhoid fever which has recently appeared at the Duplex barracks and in the neighbouring streets. M. Collin believes that in the second case the epidemic was independent of its appearance in the barracks, and merely resulted from the unhealthy condition of this particular quarter of Paris. He accounts for its appearance in the barracks by the arrival of a regiment of recruits from the provinces, who, by their youth and the fact that they were not acclimatised to Paris, were specially liable to contract typhoid fever, from which Paris is never free. M. Collin suggested that the regiment which suffered from the epidemic should be sent away from the barracks. This measure was adopted, and the regiment was sent to Saint Germain. Only two cases of typhoid fever were recorded in fifteen days in this regiment after leaving Paris.

The laicisation of the Paris hospitals will shortly be complete. The religious staff at the Charité was dismissed a short time ago. The laicisation of the Hôtel Dieu and the Hôpital St. Louis will follow in the course of the year. The laicisation of the hospitals was begun in 1878, with the Hôpital Laënnec. Since that time the Administration of the Assistance Publique has organised a training school for nurses at the Hôpital de la Pitié. The nurses are taken from there to replace the religious nurses, whenever a fresh hospital is laicised. The post of superintendent of a ward is only confided to those who have obtained a certificate at the examinations, proving them competent to undertake such an office. The contract made between the Administration of the Assistance Publique and the religious orders which have hitherto supplied the hospital nurses gave the option to either side to annul the engagement if it appeared advisable.

A curious case of trance is reported from Bordeaux. A woman, aged 57, who had been ailing for many years, fell asleep after an attack of the affection from which she was suffering. Several days passed, and the patient still remained asleep. She was perfectly still, and her breathing was regular. According to a wish previously expressed by her, she was conveyed to a village at some distance from Bordeaux. Shortly after her removal from that city she expired without any apparent suffering, and without waking from her state of torpor.

The Institut Pasteur is being constructed in the Rue Dutot, at Vaugirard, on a piece of ground measuring 11,030 mètres, purchased by the Conseil Municipal for the purpose. The whole cost of the building will amount to over 1,500,000 francs.

SHEFFIELD.

[FROM OUR OWN CORRESPONDENT.]

The Water Supply of Sheffield.—Hospital Sunday.—Revaccination.

THE Water Committee of the Sheffield Corporation has lost no time in trying the effect of placing limestone in the conduits and elsewhere to mitigate the action of the water on the lead piping. The amount of water stored is small, and does not amount to one-half of the total capacity of the reservoirs. The drought of last year told seriously on the storage supply. The autumn rains, usually those of October and November, are relied upon, under ordinary circumstances, to fill the storage reservoirs and provide for the coming year. The rainfall during those months last year was, however, abnormally low; the water in the reservoirs continued to descend, and it was not until the early part of December that any substantial increase was made in the quantity in stock. No restriction has been placed on the water supply since 1870.

Hospital Sunday collections were taken at the different churches and chapels on January 29th. It is anticipated that the amount collected this year will be a little below the sum obtained last year.

Arrangements have been made for the public vaccinators to revaccinate every evening and to attend two days weekly for primary vaccinations. Large numbers are being revaccinated. Dr. Barry, Local Government Board Inspector, who has visited the town, has been successful in giving an impetus to the revaccination movement. He may be congratulated on the way in which he has succeeded in getting the different authorities to work together in taking steps to encourage revaccination.

CORRESPONDENCE.

TO CORRESPONDENTS.

Our correspondents are reminded that prolixity is a great bar to publication and, with the constant pressure upon every department of the JOURNAL, brevity of style and conciseness of statement greatly facilitate early insertion. We are compelled to return and hold over a great number of communications chiefly by reason of their unnecessary length.

CIRRHOSIS OF THE LIVER.

SIR.—The case of cirrhosis of the liver in which the portal blood ran directly into the systemic circulation, read at the annual meeting of the Association, and described in the JOURNAL of February 4th by Dr. Drummond, is full of interest. In this case the conservative formation of compensatory vessels to relieve the portal system led to the patient's death by bile-poisoning. I had for many years been perfectly sure of the fact that the portal blood did take the course more recently demonstrated by Sappey, judging from the great enlargement of the superficial veins of the abdomen seen during life, and the extreme vascularity of the ligaments and tissues around the liver as observed after death. Sappey proved that the umbilical vein, or other veins near it, enlarge sufficiently to carry off the portal blood into the epigastric vessels and general circulation. It is rare that the new vein is so large as that in Dr. Drummond's case, although Dr. Goodhart put up in Guy's Museum a specimen, where, possibly, the vessel was as large. This new channel of relief explains why, in many cases of cirrhosis, dropsy does not occur, or, if fluid has formed, why it sometimes disappears; and also why, after its removal by medicine or by tapping, it may not recur. This subject was not, I think, referred to in the discussion on Dr. Gooding's paper at the Brighton meeting. This gentleman brought forward several cases where ascites had not returned after the removal of the fluid. I have met with a large number of such instances, and never been able satisfactorily to explain the cause of the occurrence. It would appear that, after cirrhosis has advanced a certain stage, some little extra disturbance in the secreting organs will determine a dropsy; but, after these have righted themselves and an equilibrium restored, that the dropsy will depart, although the cirrhosis remains. A better explanation is now forthcoming in the production of collateral or compensatory circulation. Meeting constantly with these cases of temporary recovery, it is interesting to note the value put upon the treatment by the medical man in charge of each patient. One repeats to me the case where jaborandi has cured a man who had been previously tapped ten times; another vaunts the value of copaiba, which has got rid of the fluid, of which there is no return. A well-known shopkeeper in a suburb of London never ceases to praise his neighbour, the homo-opath, who cured him of the dropsy after many other regular practitioners had failed. But lately, I have had a patient die of dropsy which did not return until three years after paracentesis; and I had a hospital patient who went on the same number of years. Neither of these patients, I am sorry to say, profited by their narrow escape, for they both continued to drink, though in less amounts than before. I can, therefore, scarcely encourage the hope which Dr. Gooding clings to, that a total abstinence may be the means of promoting a cure. It is, no doubt, to be recommended, but I fear that no conclusions can be arrived at from the observation of one or two cases, seeing that the symptoms may for a time subside in those who continue to live intemperate lives, or at least do not desist from the use of alcohol either in the form of wine or spirits.—I am, etc.,

SAMUEL WILKS.

Grosvenor Street, February 4th, 1888.

VENTRAL NEPHRECTOMY FOR HYDRONEPHROSIS.

SIR.—Although one can but admire Mr. Hunter's courage in undertaking the formidable operation published in last week's JOURNAL, it would seem right that one with experience in such cases should offer some criticism on the method of treatment adopted. In the treatment of hydrocele it is always laid down that it is first advisable to give the patient the rare chance that the fluid may not re-collect after tapping, and I think such a rule applies with increased force in cases of hydronephrosis, especially as there are well authenticated cases in which the fluid has not re-collected after simple aspiration. Supposing the cyst to have refilled, it might be then advisable, after ascertaining the secreting power of the other kidney, to explore the tumour through the loin, and then

drain or perform nephrectomy according to the conditions found; but to commence with Lauenbuch's incision through the peritoneum appears to me to be rather heroic treatment, and of a kind which exposes the patient to unnecessary risk, especially, as in the case in point, when the peritoneum is adherent to the capsule of the kidney. The case, however, reads as though it might have been successful had free drainage through the loin been secured in the first instance. Still, even had the case been conducted to a successful issue, I should have maintained that the means employed were unnecessarily severe.—I am, etc.,

R. CLEMENT LUCAS, B.S., F.R.C.S.,
Senior Assistant Surgeon to Guy's Hospital.

INTRACAPSULAR INJECTION IN THE EXTRACTION OF CATARACT.

SIR.—Mr. Swanzy is aggrieved because I quoted statistics of the National Eye and Ear Infirmary for 1875-76, and he suggests that the results of operations have been better of late years through certain improvements, and therefore that I should have chosen only "results of to-day" to compare with my own.

I now invite Mr. Swanzy to give (1) details of the extraction of cataract, ripe and unripe, in the National Eye and Ear Infirmary, since he had at his service those improvements to which he refers; (2) like details of other public institutions. When he has supplied these he will have made his first contribution to reasonable criticism. Of assertions and questions suggestive of erroneous inference he has not been sparing; but of material facts he has been parsimonious if not miserly. The "cleansing fire" of fair and reasonable criticism is what I desire.

The improvements Mr. Swanzy indicates are (1) antisepticism, (2) modification in the section, (3) Forster's maturation operation. It is not proved that antisepticism, as carried out by sprays, lotions, dressings, has accomplished anything for cataract operations in any hospital in a good sanitary condition, and in which cleanliness has been strictly enforced.

Let us note what has happened in abdominal surgery. 2. Antiseptic spray and antiseptic solutions are completely discarded by some of the most successful operators. 2. Recent modifications of the section. I suppose Mr. Swanzy refers to the 3-mm. flap of M. de Wecker. I see, however, from the reports of the Moorfields and other large hospitals for last year that Graefe's method was almost exclusively practised. So far from this method being obsolete, it is probably more largely practised than any other; and from long before 1875 till the present time, it has for statistical purposes held its own. 3. Forster's artificial maturation. This is very little practised, and if Mr. Swanzy have any considerable experience of it, it would be well to let us know it.

I have not desired to limit the statistical inquiry. The letter which appeared in the JOURNAL of September 3rd last dealt with all the reports I then had; and when Mr. Swanzy's first letter was published, I endeavoured to ascertain particulars of the operations for cataract in the United Kingdom. I wrote to all the chief hospitals, I examined the special medical and surgical reports of London hospitals, and I only found in addition to what I have already summarised, the reports of Mr. Nettleship for the years 1882, 1883, 1884, and 1885. In the four years Mr. Nettleship operated on 162 senile cataracts; there were 21 (14 per cent.) escapes of vitreous, 36 cases (22 per cent.) in which cortex was not completely removed, 20 cases (12 per cent.) severe iritis, 32 cases (19 per cent.) mild iritis, 40 cases (24 per cent.) of secondary operation, and 17 cases (10.5 per cent.) absolute loss. I must qualify the above statistics by stating that when Mr. Nettleship used M. de Wecker's section, he had fewer escape of vitreous, and that some of the losses in 1885 were due to an untoward and exceptional influence independent of the mere operation. Do these details of the operative work of a reliable and painstaking surgeon support the statement that by the ordinary method of friction cortex can be easily removed, and that iritis, etc., are very rare nowadays?

The only statistics which are of value for analysis and comparison are those which give details regarding (1) the degree of maturation of the cataract, (2) accidents and incidents during operation, (3) the course of all unfavourable cases.

My method, namely, the removal of the cortex by the force and influence of a fluid, is employed by M. Panas and M. de Wecker. Mr. Swanzy gave quotations from MM. Panas and de Wecker, and these I will supplement. M. Panas says:—

"Procéder le plus complètement possible à la toilette du champ pupillaire, couches corticales du cristallin, sang, pigment noir,

bulles d'air, tout doit sortir quelle que soit la peine qu'on se donne pour atteindre le but."

There may be no germs within the eye to be killed, but the antiseptic liquid which is to be forced "jusque dans les profondeurs de l'œil" will often enough find these "couches corticales," etc., and M. Panas is very exacting as to the completeness of their removal. M. de Wecker proves that M. Panas's solution is useless as a germicide, and he writes:—

"Je suis donc absolument partisan des lavages de la chambre antérieure, mais je pense qu'on doit leur laisser cette désignation et ne pas y substituer le mot de désinfection." This is surely plain enough.

Mr. Swanzy should have given a more clear account of the essence of M. de Wecker's practice. There are two preliminary points. 1. In "la pratique usuelle," that is, in ordinary operations for ripe cataract, he says: "Le nettoyage ou lavage de la chambre antérieure n'est pas ce qui nous préoccupe le plus." The pupil being clear and black, he injects a few drops of solution of eserine to contract the pupil, but mark well what he says about this simple injection primarily used for its myotic effect: "S'aperçoit-on que, pendant l'injection, la pupille s'obscurcit par l'apparition de masses corticales rendues opaques par le liquide injecté, on prolonge quelque peu l'injection et l'on reprend la toilette, en répétant cette manœuvre jusqu'à ce qu'une dernière injection laisse une pupille absolument noire et libre d'opacités, même à l'inspection à la lumière électrique. A cet effet on peut promener, pendant l'injection, la canule en argent dans le sac capsulaire et même sous le bord pupillaire opposé à la section."

Leaving aside the evidence afforded of the use of force, we have a striking testimony to the remarkable fact that the cautious introduction of a few drops of eserine solution may, by causing the appearance of unsuspected cortex, reveal the fact that the operation had been imperfectly performed.

2. In unripe cataracts M. de Wecker is of opinion that the mere washing is the prime consideration. He writes: Ici l'on peut faire un véritable lavage des masses corticales opacifiées ou non opaques, mais rendues opaques au moment de l'injection. Dans ce cas encore je préfère l'injection à deux ou trois reprises et reprendre après chaque injection les nettoyages de la toilette, plutôt que de faire un lavage par injection violente." But nobody makes violent injections so far as I know. My injections are gentle and more effectual than pressure. I think I have quoted enough to show that both MM. Panas and de Wecker use the injection for the same purpose as I do myself. M. de Wecker may not go quite so far as I do, but we cannot expect perfect uniformity in views and practice.

The antiseptic treatment of M. Panas and the myotic treatment of M. de Wecker are simple additions which are to be judged from a totally different standpoint from that of intraocular injection to remove cortex. If only an intraocular antisepticism is desired, or if only a myotic influence is sought, then it is necessary only to inject a drop or two of the antiseptic or myotic liquid, as the case may be, and not to practise the prolonged and repeated washings, as MM. Panas and de Wecker have done.—I am, etc.,

WILLIAM A. McKEOWN.

Belfast.

SIR,—On January 22nd, 1884, after extracting the nucleus of a senile cataract, I washed the remaining cortex out of the anterior chamber. I used a new Teale's syringe as a siphon, with distilled water, previously boiled, at a temperature of 97° F., the temperature of the anterior chamber. I was very careful that the conjunctiva, the instruments, the water, the air, and everything which came in contact with the eye was as free as possible from germs. The result was encouraging, with + 12 D. V. = $\frac{1}{8}$. The eye had been blind forty-seven years; therefore I ventured on a new proceeding not expecting such success. Since then I have frequently had recourse to this method of removing lens cortex, and generally with favourable, sometimes with brilliant, results.

In one of my early cases, before cocaine came into use, the patient was very restless, and there was some escape of vitreous immediately on the introduction of the water. The eye did fairly well, V. = $\frac{1}{16}$.

In another early case the operation was followed by severe pain, which kept the patient awake most of the following night I expected the eye would be lost, but the pain gradually subsided, and I was surprised to find the pupil clear. The subsequent progress was good, V. = $\frac{1}{4}$. All my other cases have done

well. I have therefore never had occasion to regret having injected water into the eye; on the other hand, several times when I have left apparently only a little cortex, I have afterwards regretted that I had not washed it out.

My practice is to wash out only when a considerable quantity of lens matter remains which cannot be removed by simpler means without much risk. In such cases it is pleasing to see how readily and gently the water removes the opacity, and the pupil is left beautifully black.

In some cases of traumatic cataract, at the proper time, the anterior chamber may be irrigated, the softened lens matter removed, and the eye saved, when no other method would have been successful.

In cases of unripe cataract I believe with Dr. McKeown that intra-ocular injection will give "results such as have never been otherwise obtained;" but I am sure that "a preliminary iridectomy, combined with Förster's artificial maturation," and after a few weeks extraction under antiseptic precautions and washing out of cortex, will give still better results.

For three years I used the siphon as mentioned; during the last year I have used Dr. McKeown's syringe, but I do not like it because (1) it cannot be used with that delicacy which is desirable when the nozzle is within the eye; (2) the force is uncertain; (3) the action is not sufficiently continuous for some cases.

To my mind the main objection to its more ready adoption is the length of time which is required to have everything exact, and free from germ contamination. The success of cataract extractions depends very much upon the absolute purity of everything which comes in contact with the eye.

I am at a loss to understand the hostile—shall I say unscientific—attitude which has been taken by many eminent specialists with regard to this simple procedure. I suppose it is to be expected that some will commend it unduly, and that others will condemn it unjustly, but whatever may be said I am convinced from experience that it will make its way and will hold its place as a useful addition to our resources in the extraction of cataract.

In conclusion, allow me to state that I think the profession is under great obligations to Dr. McKeown for his distinguished services to ophthalmology, and that, in my opinion, they have not yet been sufficiently acknowledged.—I am, etc.,

J. H. BELL.

Bradford, January 30th.

SIR,—It affords me gratification to see that you have deemed the above subject of sufficient importance to devote an editorial note and also a leading article to its discussion.

In the note referred to, you allude to my paper published in January, 1887, and contend that "the experience given is as meagre as that of the hostile critics." If you will do me the kindness to refer again to my paper, you will see that the desire that actuated me in reading it before the Ophthalmic Section at Brighton was simply to invite other ophthalmic surgeons to make experiments of McKeown's process; and I also took the opportunity to recommend that the water should be introduced by means of an irrigating apparatus rather than by a syringe; the length of time during which I had employed it was obviously too short to afford opportunity for a large number of cases to be operated on.

Lest my experience should again be analogous to that of the "hostile critics," some little time may have to elapse before I fulfil your anticipations, to furnish my "further experiences;" it may, however, happen that, by the time the Glasgow meeting is held, I shall be prepared with a table so strong, numerically, that even your apparently prejudiced contributor will not venture to stigmatise it as meagre.

Meantime I need only add that I continue to adopt the practice with increasing appreciation of its value, as I see more of the beneficial effects it is capable of conferring on those patients in whose cases it is necessary to employ it.—I am, etc.,

73, Rodney Street, Liverpool.

CHARLES G. LEE.

** Our application of the epithet "meagre" to Mr. Lee's statistics in the foot-note to Dr. McKeown's letter on p. 159 was intended solely as an answer to the insinuation that we had suppressed important evidence. We quite admit that Mr. Lee's paper was as full as was possible or desirable at the time it was read, and shall be very glad to hear his further experience.

EARLY OVARIOTOMIES.

SIR.—My old friend and teacher Mr. T. W. Nunn has called my attention to an error in the address you published in the JOURNAL of January 28th, where it is stated that the first ovariectomy at Middlesex Hospital was performed by Mr. Mitchell Henry. The operation had twice previously been performed there by Mr. Nunn, the first being on July 30th, 1860; and in referring to it in a paper read before the Middlesex Hospital Medical Society Mr. Nunn expresses his belief that in one of these cases also death took place from hæmorrhage from the omentum. This only serves to show that such an occurrence may have been more frequent than my statement would infer in the hands of the best operators of that day.—I am, etc.,

W. D. SPANTON.

Hanley, January 31st, 1888.

APPOINTMENT TO HAYWARD'S HEALTH ASYLUM.

SIR.—It is perhaps of little service to complain of things which cannot be altered, yet, though the past may be irrevocable, the future is in some way in our hands, so I write. The valuable appointment as Superintendent of the Sussex County Asylum became vacant by the resignation of Dr. J. W. D. Williams. The advertisement appeared in due course, and the requirements were at once seen to be higher than is in any way usual in a county asylum. This made the candidates question whether these were not specially arranged to suit some one man. Candidates who were eligible sent in their applications, and though the requirements had greatly reduced the number of good and suitable men, yet some very representative men who had gone through the apprenticeship of county asylums contended, but the result was that a gentleman with absolutely no practical training by residence in asylums was selected. Because a man happens to be a friend of the representatives of the Court of Chancery it seems shameful that his deficiencies should be overlooked, and men who have wrought for the good of the speciality should be passed over. I should have thought that it would have been in better taste if the representatives of the law refrained from giving testimonials and using influence in such cases. No one has a word to say against the successful candidate as a man, but he is simply unknown in lunacy.

I trust this miscarriage of justice may not disgust rising men and prevent them from continuing to work for this honourable but badly-used speciality.—I am, etc.,

G.

NAVAL AND MILITARY MEDICAL SERVICES.

THE ARMY MEDICAL SCHOOL AT NETLEY.

THE distribution of prizes to the successful students in the Indian Medical Service, at the close of the fifty-fifth session of the Army Medical School, took place at noon on Friday, February 3rd, in the lecture hall of the Royal Victoria Hospital at Netley. Mr. George Pollock, Consulting Surgeon to St. George's Hospital, London, and examiner in surgery for Her Majesty's Army, Navy, and East India Medical Services, presented the prizes.

The following is the list of surgeons on probation in Her Majesty's Indian Medical Service, who were successful at both the London and Netley examinations. The prizes are awarded for marks gained in the special subjects taught at the Army Medical School. The final positions of these gentlemen are determined by the marks gained in London added to those gained at Netley, and the combined numbers are accordingly shown in the list which follows:

21. A. F. Roberts	6,410	13. J. L. T. Jones	5,110
22. D. M. Davidson	6,055	14. W. J. Buchanan	5,030
23. P. P. Maynard	5,895	15. J. K. Close	4,995
4. J. C. Lamont	5,869	16. J. M. Macnamara	4,915
5. A. H. Nott	5,715	17. W. E. Jennings	4,900
16. J. Holt	5,675	18. H. M. Brazazon	4,885
7. A. Coleman	5,495	19. W. H. M. Ingham	4,860
8. W. W. White	5,390	20. F. J. Dewes	4,845
9. D. T. Lane	5,380	21. J. O. Pinto	4,805
10. R. C. Macswat	5,330	22. P. C. H. Strickland	4,790
11. W. H. F. Woodwright	5,290	23. T. W. Stewart	4,575
12. T. H. Griffith	5,130		

* Gained the Martin Memorial Gold Medal and the Prize in Clinical Medicine presented by Surgeon-General W. C. Maclean, C.B.

† Gained the Herbert Prize of £20, the Montefiore Medal and prize of 20 guineas, with the Parkes Memorial Bronze Medal.

‡ Gained the Montefiore Second Prize.

§ Gained the Prize in Pathology presented by Sir Thomas Crawford, K.C.B.

At the close of the distribution, Mr. Pollock delivered an address, taking for his text the imperative necessity for continuous research and labour in the medical profession, and the almost unlimited opportunities for useful medical and sanitary work offered in the vast territories of India, where the surgeons on probation were destined to pass a great portion of their future professional careers. The only surgeons on probation who had passed through the courses of instruction during the session were candidates for commissions in the Indian Medical Service. At the close of Mr. Pollock's address, Sir Joseph Fayrer, speaking from his Indian experience, made some encouraging remarks to the young surgeons, saying that in spite of certain changes he regarded the Indian as still, without exception, the finest medical service in the world; and Sir Thomas Crawford, in conveying thanks to Mr. Pollock for his attendance at Netley, as well as for his admirable address, mentioned the gratification he had derived from the very favourable reports which had reached him not only as to the conduct and diligence of the surgeons on probation, but also regarding the manner in which the class of surgeons who had been at Netley during the session had taken advantage of the opportunities of study presented to them.

THE PARKES MEMORIAL PRIZE.

IT may be useful to remind our naval and military readers that the triennial Parkes Memorial Prize of £100 in money and a gold medal, value fifteen guineas, is to be awarded at the close of the present year. The competition for the prize is open to all medical officers of the Army, Navy, and Indian Services of executive rank. The subject, as previously announced, is the "Etiology and Prevention of Yellow Fever, to be illustrated, as far as practicable, from the personal experience of the writer," and the essays, each bearing a motto and accompanied by a sealed envelope with the same motto and containing the name of the competitor, are to be sent to the Secretary of the Parkes Memorial Fund, Royal Victoria Hospital, Netley, on or before December 31st, 1888.

THE NAVY.

THE following appointments have been made at the Admiralty:—R. H. NICHOLSON, Surgeon, to the Plymouth Division, Royal Marines; G. F. WALES, Surgeon, to the *Cambridge*; G. D. T. ROBER, Surgeon, to the *Stork*; F. J. BURNS, Surgeon, to the *Jackal*; E. H. SAUNDERS, Staff-Surgeon, to the *Porpoise*.

THE MEDICAL STAFF.

SURGEON-GENERAL JAMES MOUAT, V.C., C.B., half-pay, has been appointed Honorary Surgeon to the Queen, *vice* Deputy Inspector-General E. Bradford, deceased. Surgeon-General Mouat's career in the army has been long and distinguished. Entering as Assistant-Surgeon in 1838, he passed through the intermediate ranks till, in 1864, he became Surgeon-General, and retired on half-pay in 1876. From Hart's *Army List* we learn that he served in the Eastern campaign of 1854-55 with the 6th Dragoons, and on the Medical Staff, and was in medical charge of the General Field Hospital of the 3rd Division throughout the siege operations until the fall of Sebastopol, and subsequently as Principal Medical Officer of Balaklava until the final evacuation of the Crimea, June 12th, 1856, having been present at the battles of Balaklava, Inkerman, and Tehermaya, and the night reconnaissance and attack on Russian outposts February 19th, 1855 (C.B., Victoria Cross, medal with three clasps, Knight of the Legion of Honour, and Turkish medal); he was awarded the Victoria Cross "for having voluntarily proceeded to the assistance of Lieutenant-Colonel Morris, 17th Lancers, who was lying dangerously wounded in an exposed situation after the retreat of the Light Cavalry at the battle of Balaklava on October 26th, 1854, and having dressed that officer's wounds in the presence of the enemy. Thus, by stopping a serious hæmorrhage, he assisted in saving that officer's life." Served during the New Zealand war of 1860-61 throughout the operations under General Pratt (twice mentioned in despatches "for valuable services rendered at all times and in all positions"). Present in the field as Principal Medical Officer throughout the operations in Waikato, Taranaki, and Tauranga districts in 1863-65 under Sir D. Cameron, and repeatedly mentioned in despatches (medal). Received the thanks of the New Zealand Government for "special and valuable services rendered to the Colony." He is in receipt of a reward for distinguished service.

Surgeon-Major P. LAVERY, of the 3rd Battalion Irish Fusiliers (late the Armagh Militia), has resigned his commission, which was dated May 22nd, 1873; he is permitted to retain his rank and uniform.

Surgeon-Major W. P. BRIDGES, serving in the Bombay command, is transferred from the medical charge of the Station Hospital, Deesa, to the medical charge of the Station Hospital, Purandhar.

Surgeon R. HOLYOAKE, serving in the Bombay command, is placed on general duty, Presidency district.

Surgeon-Major J. PRENDERGAST, serving in the Bombay command, is transferred from the medical charge, Station Hospital, Purandhar, to general duty, Poona division.

Surgeon R. H. HALL, M.D., serving in the Bombay command, is granted leave to England, on private affairs, with the necessary subsidiary leave.

Surgeon-Major J. E. V. FOSS, M.D., has been brought on the strength of the British forces in the Bombay command.

THE INDIAN MEDICAL SERVICE.

BRIGADE-SURGEON G. C. CHESNAYE, Bengal Establishment, officiating examiner of medical and fund accounts, Bengal, is confirmed in that appointment, *vice* Brigade-Surgeon G. S. Sutherland, M.D., who has vacated the appointment.

The services of Surgeon-Major G. BOMFORD, M.D., Bengal Establishment, officiating Professor of Physiology, Calcutta Medical College, now on leave, are temporarily placed at the disposal of the Government of India in the Home Department.

Surgeon R. PEMBERTON, Madras Establishment, Civil Surgeon, Guntoor, and now Acting Civil Surgeon, Chittoor, is appointed to act as Civil Surgeon at Berhampore, during the absence of Surgeon D. Elcum on other duty.

Surgeon-Major G. F. BEVAN, Madras Establishment, is appointed to act as Secretary and Statistical Officer to the Surgeon-General Her Majesty's Forces, Madras, during the absence on leave of Surgeon-Major W. E. Johnston.

Surgeon W. G. M'EVOT, Madras Establishment, doing duty in the Eastern district, is directed to do duty at Bellary.

Surgeon-Major S. O'B. BANKS, Bombay Establishment, is appointed to act as Professor of Surgery and Clinical Surgeon in the Grant Medical College, during the absence of Surgeon-Major W. Gray, M.B.

Surgeon-Major J. LUCAS, Bombay Establishment, having returned from leave, is placed on general duty in the Presidency district.

Surgeon-Major A. H. C. DANE, Bombay Establishment, in medical charge of the Bhopal Battalion, is allowed furlough to Enrope for eighteen months, on private affairs.

The undermentioned gentlemen, all of the Bengal Establishment, have leave of absence on private affairs for the periods specified:—Brigade-Surgeon E. O. TANDY, 8th Native Cavalry, for 315 days; Surgeon-Major C. CAMERON, for one year; Surgeon-Major G. R. DAPHTARY, M.D., for two years; Surgeon-Major H. K. MCKAY, for 205 days; Surgeon-Major W. A. SIMMONDS, 12th Native Cavalry, for one year and 212 days; Surgeon-Major W. M. COURTNEY, 83th Native Infantry, for one year; Surgeon-Major F. A. SMYTH, 2nd Battalion, 3rd Goorkhas, for one year; Surgeon A. DUNCAN, M.D., 14th Native Infantry, for one year.

THE VOLUNTEERS.

MR. R. H. WRIGHTSON, M.D., is appointed Acting-Surgeon to the 1st Volunteer (Norfolk) Brigade Eastern Division Royal Artillery (late the 1st Norfolk Artillery).

Acting-Surgeons J. F. MERRISON, M.B., and H. MARTIN, M.B., of the 1st Dunbarton Rifles, have resigned their appointments; that of the former was dated March 10th, 1883; that of the latter March 25th, 1885.

Surgeon P. YOUNG, of the 3rd Volunteer Battalion Royal Highlanders (formerly the 3rd Forfar), has also resigned his commission, which bore date June 23rd, 1882.

We thank a "Surgeon," Medical Staff, for his communication on the duties and pay of army medical officers, the substance of which we hope to be able to place before our readers on an early date.

MEDICO-LEGAL AND MEDICO-ETHICAL.

"ANOTHER MEAN FRIEND."

F. H. D. writes: F. H. D. and C. B. H. S. are surgeons in the same town, who have always been upon the most friendly terms until about six months ago. Five years ago F. H. D. had a very good offer made to him of practice in another town, which he then declined. Within the last few months this offer has been repeated, and F. H. D. had nearly made up his mind to accept it, because of the bad state of trade, sbnting up of ironworks, etc., in his own district. F. H. D. offered his practice to S. In the meantime, C. B. H. S. had heard that F. H. D. had an idea of leaving, and wrote to S. informing him that "all F. H. D.'s patients had been his (F. H. D.'s) father's, who, out of respect for his father, stuck to F. H. D., but that if the practice changed hands, the patients would go to him" (C. B. H. S.). This seems to be a deliberate attempt to spoil any sale between F. H. D. and S. F. H. D.'s father has been dead eighteen years, and F. H. D. has been in practice twelve years, and very many of his patients have been C. B. H. S.'s, and have called in F. H. D. for reasons of their own. C. B. H. S. next writes to the secretaries of F. H. D.'s clubs before he has resigned or intimated in any way to the members that he is leaving, informing them that F. H. D. is leaving for practice in another town, and asking to be appointed surgeon in F. H. D.'s place.

Regrettable as is such an incident, the question involved has especially relation to the general moral obligation of man to do unto others as he would be done by, rather than to medical ethics proper; and, therefore, however morally indefensible "C. B. H. S.'s" alleged conduct may be held to be, we are not in a position to express other than regretful surprise that our correspondent should have experienced such unfriendly treatment from an assumed friend of so many years' standing. Possibly, however, four remarks on the case may lead to reflection, and at the same time promote a healthy reaction in the mind of the practitioner alluded to.

CERTIFICATION OF STILLBORN CHILDREN.

L.R.C.P. Etc. writes: A woman takes to a medical man the body of a child, and asks him to certify that it was stillborn. Can he legally do so without having seen the mother, and without making a *post-mortem* examination of the body?

By the Registration of Births and Deaths Act, 1874 (38 and 39 Vic. c. 89, s. 18), it is enacted that the body of a stillborn child shall not be buried unless at the time of burial there is produced (a) "a written certificate that such child was not born alive, signed by a registered medical practitioner who was in attendance at the birth, or has examined the body of such child;" or (b) a declaration that no registered medical practitioner was present at the birth, or that his certificate cannot be obtained, and that the child was not born alive. This declaration is to be made not by a medical practitioner, but by a person who would by law have to give information concerning the birth. By Section 40 it is made an offence, punishable in certain cases with penal servitude, "wilfully to make any false certificate or declaration" under the Act. Our correspondent will therefore see that to give a certificate under

the circumstances stated would be clearly contrary to law, and might entail very serious consequences.

M.D. YEOVILL.—Inasmuch as we have, after a careful and unbiassed but wearisome consideration of the lengthy correspondence relating to the dispute in question, twice expressed our deliberate opinion on the points submitted for our judgement; and believing, moreover, that no practical good, personal or otherwise, can accrue from its further discussion, we cannot, in justice to other correspondents, and the ever increasing demand on our limited space, accede to "M.D.'s" request for a further exposition of our views upon the latter statement. We are constrained, therefore, to close the discussion in so far as relates to the JOURNAL.

AGREEMENTS WITH ASSISTANTS.

MR. PERCIVAL TURNER (Adolph) writes: With regard to the discussion going on as regards "the usual bond" permit me to remark that this term as was applied does in fact mean an agreement somewhat similar to that indicated by your correspondent "A. W. B.," and not what used to be understood as a bond, a formidable looking document, naming a heavy penalty, but practically a much less serviceable document than the "usual agreement" now in vogue, which is equally applicable and binding on qualified or unqualified assistants, and effects the principal object with less chances of dispute and difficulty than any bond can do, and which, as you remark, if properly drawn and impressed with a sixpenny stamp, will hold good in any court.

CANVASSING FOR PATIENTS.

A CORRESPONDENT has forwarded the following advertisement, cut from a Leeds paper:

"LARGE BONUS.—Wanted, influential Persons to obtain Clubs, Friendly Societies, etc., for medical attendance by a Doctor; also to Canvass."

"A doctor" who seeks to acquire practice by such exceptional and professionally reprehensible means as those indicated in the above advertisement must, we apprehend, have mistaken his true vocation. Such practitioners are untrue to themselves and alike insensible to the honour and dignity of the profession, and of their relative duty to it. In reality they are a law unto themselves, and pursue their own course, regardless of the rules (*leges scriptae et non scriptae*), by which the profession of medicine has been ethically governed from time immemorial.

CHARGING FOR MEDICINE.

A SUBSCRIBER asks whether a general practitioner holding the M.R.C.S. Eng. and L.R.C.P. Edin. has a right to charge for medicines supplied to his patients.

Although Section 6 of the Medical Act, 1858, is not so clear as Section 31 of the Medical Act, 1853; it is, we think, quite clear that "A Subscriber's" qualifications entitle him to charge for medicines supplied to his patients in addition to his fees, and that his charges are made out in the proper way.

SIGNATURE OF LUNACY CERTIFICATES BY PARTNERS.

M.D. (Scotland) writes: A. and B. are in partnership. A. grants a certificate of insanity in the case of C. Does the fact of a partnership existing between A. and B. disqualify B. from giving the second certificate requisite for C.'s admission to an asylum? I always understood it did; but I can find nothing in the Lunacy Act under Section "Disqualifications," which confirms my belief.

In England and Wales medical men in partnership cannot sign the certificates of insanity under which a patient shall be sent to an asylum, for the same patient on the same occasion. 16 and 17 Vict., cap. 96, Sec. 4.

QUACKS AND PRACTITIONERS.

M.D. writes: I should like the opinion of the medical profession on the following case, as it appears to me to be very contrary to etiquette, and extraordinary.

A is asked to call to see B. B. states that she is taking medicine ("cancerura"), amongst others, from a quack in London, and that he will not, or does not care to, send more medicine unless she is under the supervision of a medical man in the place whom she wished to correspond with the quack, and still to treat her with the quack remedies. A. refuses to attend under such conditions, considering them unprofessional. B. then calls in C., an M.D. practising in the place; he attends, takes up the case, corresponds with the professor or quack, and gives or allows the patient B. the quack remedies, and, therefore, is really acting as the quack's assistant, and, if anything goes wrong, of course would be convenient to sign a death certificate, and, therefore, avoid an inquest. If qualified medical men are allowed to do these things, one cannot wonder that quacks get on; and surely such men cannot be met in consultation or treated as brother practitioners.

The course described is so unusual as to be almost incredible, and certainly contrary to all professional rule. It seems possible, however, that there may be some errors in the facts of the case as stated. We only hope that this may be so.

FEES TO WITNESSES.

F. W. D. McC. E. asks what fees he is entitled to in the following case: He has received a subpoena to appear as witness in an action brought by a patient whom he attended against a railway company. He is district surgeon to the company, and has received a subpoena from the plaintiff.

According to the authorised scale, the allowance to professional men for attendance as witnesses in a common law action is £1 ls. per diem, if resident in the town in which the action is tried; and £2 2s. to £3 3s. per diem, inclusive of all except travelling expenses, if resident at a distance from the place of trial. If the action is in the county court the scale is lower.

LIABILITY FOR SCHOOL FEES IN CASES OF INFECTIOUS DISEASE.

A MEMBER asks: Am I liable for school fees when children have been prevented returning to school at the commencement of a new term, owing to the risk of their communicating an infectious disease to others?

. Unless there is an express contract on the point, the ordinary contract for schooling is for a term's notice or a term's pay; the master could, therefore, claim payment for the term, although the child last part of the term through illness. In one case, in 1877, Mr. Justice Denman held that, where the master sent a boy home on account of illness, and he was too unwell to return the next term, payment could not be enforced; but the circumstances there were exceptional. As a rule, the illness of the child is no reason for depriving the schoolmaster of his fees.

ACTIONS TO RESTRAIN NUISANCES.

R. C. asks where he can obtain a full report of the case of Wallacey Local Board v. Gracey, under the Public Health Act, reported in the JOURNAL on November 25th, p. 1190.

. The case, having been tried at Nisi Prius, does not appear in any of the regular reports. The only way to get at the facts would be to apply to the solicitor of one of the parties, who could say whether a shorthand note was taken. Actions to restrain nuisances should not be undertaken without good legal advice.

MEDICAL MEN AS TRADERS.

NEMO writes: I have noticed by the reports of cases at County Courts, etc., in your paper that a medical man who supplies medicines and charges for them to his patients is a "trader." May I ask in what position a man is who arranges with a chemist to supply them by making up his prescriptions and charging the patient and giving the doctor a commission on amount paid, or if the doctor, making up his book from the chemist, charges for medicines himself? Both of these things are done by men who would be very indignant at being termed "traders." Are they not so really?

. Under the circumstances stated, the medical man would certainly be interested in trade, and might fairly be termed a trader, just like any other partner in a trading business.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

THE REGISTRAR-GENERAL'S QUARTERLY RETURN.

THE Registrar-General has just issued his quarterly return relating to the births and deaths registered in England and Wales during the fourth or autumn quarter of last year, and to the marriages in the three months ending September last. The marriage-rate, although it showed a slight recovery from the exceptionally low rate in the third quarter of 1886, was considerably below the mean rate in the corresponding quarters of the ten years 1877-86. The birth-rate and the death-rate were also below their respective averages. The mean temperature of the air during the quarter was considerably below the average, but the weather was, on the whole, favourable to the public health.

The births registered in England and Wales during the three months ending December last were 217,749, equal to an annual rate of 30.6 per 1,000 of the population, estimated by the Registrar-General to be about twenty-eight and a quarter millions of persons. This birth-rate showed a further decline from the rates recorded in the corresponding quarters of recent years; it was as much as 2.4 per 1,000 below the mean rate in the fourth quarters of the ten years 1877-86, and was actually lower than that recorded in the last quarter of any year since 1849, when the registration of births was admittedly defective. The birth-rate in the quarter under notice in the several counties ranged from 26.1 in Shropshire and 26.2 in Sussex, to 33.9 in Northumberland, 35.4 in Monmouthshire, and 35.6 in Essex. In the twenty-eight large towns for which the Registrar-General publishes weekly returns, the birth-rate last quarter averaged 31.8 per 1,000, ranging from 25.5 in Brighton and 26.2 in Bradford, to 38.0 in Portsmouth, 40.2 in Newcastle-upon-Tyne, and 40.5 in Cardiff. The births registered in England and Wales during the quarter under notice exceeded the deaths by 83,957; this represents the natural increase of the population during that period. From the Board of Trade returns it appears that 70,735 emigrants sailed from the various ports at the United Kingdom at which emigration officers are stationed; of these, 36,030 were English, 6,691 Scotch, and 9,286 Irish. The proportion of British emigrants to a million of the respective populations of the three divisions of the United Kingdom were 1,276 from England, 1,676 from Scotland, and 1,913 from Ireland.

During the last quarter of 1887 the deaths of 133,792 persons

were registered in England and Wales, equal to an annual rate of 18.8 per 1,000 of the estimated population. This death-rate, although it slightly exceeded the very low rates recorded in the last quarter both of 1885 and 1886, was 1.0 per 1,000 below the mean rate in the fourth quarters of the ten preceding years, 1877-86. Among the urban population of the country, estimated at about eighteen millions of persons, the rate of mortality during the quarter under notice was equal to 19.8 per 1,000; in the remaining or chiefly rural population of little more than ten millions the rate did not exceed 16.9 per 1,000. These urban and rural rates were both below their respective averages for the six preceding corresponding quarters. The rate of mortality among infants under one year of age, and of persons aged between one and sixty years, was below the average; while the death-rate of persons aged upwards of sixty years exceeded the average of the ten preceding corresponding quarters.

The 133,792 deaths registered in England and Wales during the three months ending December last included 3,104 which were referred to measles, 2,921 to scarlet fever, 2,464 to whooping-cough, 1,914 to diarrhoea, 1,835 to "fever" (including typhus, typhoid, and simple fever), 1,563 to diphtheria, and 358 to small-pox; in all, 14,159 deaths resulted from these principal zymotic diseases, equal to an annual rate of 1.99 per 1,000, the average annual rate in the ten preceding corresponding quarters having been 2.44 per 1,000. The mortality from measles, diphtheria, and small-pox showed a slight excess; while that from each of the other zymotic diseases was below the average. The deaths referred to small-pox, which had been 30, 47, and 70 in the first three quarters of last year, increased to 358 during the quarter under notice, of which no fewer than 230 occurred in Sheffield, 50 in other parts of Yorkshire, 35 in or around Bristol, and only 43 in the remainder of England and Wales. In London only 3 fatal cases of small-pox were recorded during the quarter.

The rate of infant mortality, or the proportion of deaths under one year of age to registered births, was last quarter 136 per 1,000, and was slightly below the average proportion in the ten preceding corresponding quarters. While the rate of infant mortality in London during the last three months of 1887 did not exceed 145 per 1,000, it averaged 162 in the twenty-seven provincial towns, among which it ranged from 111 in Brighton and 123 in Norwich, to 198 in Oldham, 217 in Bolton, and 233 in Blackburn.

SANITARY REGISTRATION OF BUILDINGS.

A CONFERENCE convened by the Sanitary Assurance Association was held on Saturday, February 4th, at the Society of Arts, Adelphi, for the purpose of considering the proposed Sanitary Registration of Buildings Bill. Sir Joseph Payter, who presided, said he knew by sad experience what an immense amount of disease and impaired health was entailed on the populations of great cities by insanitary dwelling houses, and they also knew that those evils being preventable, it was their duty to do all they could to prevent them. It was their wish that all public buildings and dwelling houses should be registered by law, the registration to be optional in the case of private dwellings and compulsory in that of public buildings, such a course to be taken after they had been examined and certified as being in a satisfactory sanitary condition, and this was what the Sanitary Registration of Buildings Bill proposed to do in the interests of the public.

Mr. Mark H. Judge read a paper explaining the provisions of the Bill, and moved a resolution approving them. It was further resolved that all dwelling houses erected after January, 1890, should come under the compulsory clause of the Bill.

THE PRESIDENT OF THE LOCAL GOVERNMENT BOARD, AND THE VALUE OF VACCINATION AT SHEFFIELD.

MR. C. T. RICHIE, the President of the Local Government Board, in addressing a political meeting at Sheffield, on January 30th, took the opportunity of, in the first place, making public the lessons as to the value of vaccination to be learnt from the epidemic of small-pox at present afflicting that town. "Overwhelming evidence," he said, "had been given during the course of the epidemic of the enormous value and protection of vaccination. It was estimated from clear evidence that the number of unvaccinated children under 10 years of age in Sheffield is about 5,000, and the number of vaccinated about 95,000. Out of the 95,000 children who have been vaccinated, there have been 189 attacks and two deaths. Out of the 5,000 unvaccinated children, there

have been 172 attacks and 70 deaths. This is the position of affairs. If we were to assume for a moment that all the children of Sheffield under 10 were vaccinated, you would have had 200 attacks, and two and a fraction deaths. But if all the children of Sheffield, under 10, had been unvaccinated, you would have had 3,277 attacks, and 1,330 deaths, or just exactly 600 times greater mortality. Now, gentlemen, it is almost an established fact that, after the age of 10, vaccination loses a great deal of its effect, so that the moral of this visitation is, as far as I can see, that all those above 10 should get revaccinated, and by that means there is little doubt that in a limited space of time Sheffield will be free of the disease. It gives almost entire and absolute protection to those who are revaccinated, and as an illustration I may tell you that during the whole time that the Hampstead Small-pox Hospital was open, only one person out of the numerous *employés* engaged at that hospital took small-pox, and he was the under gardener, who by some mistake had escaped revaccination, and I am informed by the medical inspector of the Local Government Board who has been down here, that out of more than 290 men and boys employed in the Sheffield Post Office, not a single case of attack has occurred. Well now, gentlemen, I think after such evidence it is impossible for even the most rabid antivaccinationist to gainsay the beneficial results following from revaccination."

RECORDS OF VACCINATION IN THE HOSPITALS OF THE METROPOLITAN ASYLUMS BOARD.

ON the suggestion of the Local Government Board the Metropolitan Asylums Board have recently adopted a new form of "bed card" for the small-pox patients in their hospitals, in which fuller information than has hitherto been given will be required to be recorded. The general character of the disease and the position of the eruption are to be stated amongst other particulars; but the most important alteration is that which relates to vaccination. Hitherto the efficiency or otherwise of the previous vaccination of the patient, as shown in the character of the cicatrices, has not as a rule been recorded, and patients have simply been classified under the general headings of "vaccinated," "unvaccinated," "doubtful." In future the "bed card" is to show; (1) the statement of the patient or his friends as to primary vaccination, (2) the number of vaccination cicatrices, (3) their collective area, (4) the fraction of cicatricial area that can be described as foveated; (5) the number of cicatrices noted as (a) depressed, (b) not depressed, (c) puckered, (d) glazed, (e) not defined in margin. It is also to state the date in case of revaccination, and the character of the cicatrices. Where a child is presented for admission by a person who can give no account of the primary vaccination, means are to be taken to obtain the needed evidence from the nearest relative. In calculating the collective area of the cicatrices it is suggested that the diameter of each should be measured and the area calculated in hundredth parts of a superficial inch. Eventually these "bed cards" may be bound together, and form a convenient "case book." Careful record of the vaccination of officers and of visitors is also to be kept.

Obviously it is important, in view of the existence of much imperfect vaccination amongst us, that efficient and inefficient vaccination should be separated wherever possible. In 1876, the late Mr. Marson, surgeon of the London Small-pox Hospital, prepared a table, summarising his observations during twenty-five years in nearly 6,000 cases of post-vaccinal small-pox, and showing the different degrees in which persons vaccinated in different ways had been safe against death by small-pox. He showed that amongst those stated to have been vaccinated, but having no cicatrix, 21½ per cent. died; of those having one cicatrix, 7½ per cent.; of those having two cicatrices, 4½ per cent.; of those having three cicatrices, 1½ per cent.; and of those having four or more cicatrices, only ¾ per cent. died; whilst 35½ per cent. of the unvaccinated perished. The new arrangement in the metropolitan hospitals will involve some additional trouble and expense; but, from a scientific point of view, the advantages of being able before long to issue an authorised and revised version of Mr. Marson's valuable statistics outweighs other considerations.

MARGARINE AND BUTTER.

THE effect of the Margarine Act has hitherto not been to diminish the supply of imitation butter, the demand for which seems to be largely on the increase. It has been pointed out that, rigorous as are the provisions of the Act, the keepers of refreshment and boarding houses, coffee-shops, and the like, are still allowed to

foist on their patrons an article as butter which costs less than tallow, and which has little or none of the ingredients of the genuine commodity, and that in this respect we might well follow the example of the American margarine inspectors, who have begun to summon the keepers of refreshment and boarding houses for palming the counterfeit articles off on their customers for genuine butter.

COMPULSORY CLOSING OF A SCHOOL.

IN the Queen's Bench Division, the case of Roberts v. Falmouth Urban Sanitary Authority came before Justices Mathew and Smith, on appeal under the Summary Jurisdiction Act, 1879. The action was brought by the head master of the Falmouth British Schools for Boys to recover compensation for loss of emoluments suffered by the appellant from the compulsory closing of the schools for about three weeks during an epidemic of measles. The schools were closed by the managers after receiving a warning from the respondent authority that they would communicate with the Local Government Board on the subject. The Falmouth magistrates held the view that the schools were closed by the managers by reason of the obligations imposed on them, and the Judges, endorsing that view, dismissed the appeal with costs.

HEALTH OF ENGLISH TOWNS.—During the week ending Saturday, February 4th, 5,739 births and 3,945 deaths were registered in the twenty-eight large English towns, including London, which have an estimated population of 9,398,273 persons. The annual rate of mortality per 1,000 persons living in these towns, which had steadily declined in the four preceding weeks from 23.8 to 22.5, further fell during the week under notice to 21.9. The rates in the several towns ranged from 13.4 in Bradford, 17.9 in Bolton, 18.1 in Hull, and 18.2 in Birkenhead to 25.9 in Blackburn, 27.3 in Manchester, 31.8 in Preston, and 32.2 in Plymouth. The mean death-rate in the twenty-seven provincial towns was 20.9 per 1,000, and as much as 2.2 below the rate recorded in London, which was 23.1 per 1,000. The 3,945 deaths registered during the week under notice in the twenty-eight towns included 506 which were referred to the principal zymotic diseases, against 481 and 478 in the two preceding weeks; of these, 248 resulted from whooping-cough, 75 from scarlet fever, 52 from "fever" (principally enteric), 42 from diphtheria, 35 from measles, 35 from diarrhoea, and 19 from small-pox. These 506 deaths were equal to an annual rate of 2.8 per 1,000; in London the zymotic death-rate was as high as 3.7, while it averaged only 2.0 in the twenty-seven provincial towns, among which it ranged from 0.3 and 0.5 in Newcastle-upon-Tyne and Cardiff to 3.9 in Blackburn, 4.5 in Sheffield, and 4.9 in Derby. Whooping-cough caused the highest proportional fatality in Brighton, Salford, Bristol, London, and Leicester; measles in Birmingham and Derby; scarlet fever in Manchester, Oldham, Huddersfield, and Blackburn; and "fever" in Nottingham and Derby. The 42 deaths from diphtheria in the twenty-eight towns included 29 in London, 3 in Birmingham, and 3 in Manchester. Of the 19 fatal cases of small-pox recorded during the week under notice, 17 occurred in Sheffield, 1 in Leeds, and 1 in Bristol. The Metropolitan Asylums Hospitals contained 7 small-pox patients on Saturday, February 4th, of which 2 were admitted during the week. These hospitals also contained 1,558 scarlet fever patients on the same date, against numbers steadily declining from 2,602 to 1,641 in the nine preceding weeks; there were 95 admissions during the week. The death-rate from diseases of the respiratory organs in London was equal to 6.3 per 1,000, and was considerably below the average.

WANTED: A MODEL SMALL-POX HOSPITAL.

DR. BROWN.—There is no small-pox hospital which gives security against infection aerially conveyed. Of fever hospitals, none are without some faults, but lessons could be learnt from the Liverpool (Grafton Street) Hospital, Aston Manor Hospital, Bromley Hospital, Guildford Urban Hospital, and that which is now being erected for Leamington and Warwick is especially deserving of notice.

E. E. P.—We consider that the expression "a perpetual or perennial endemic of typhoid fever" means that the disease is peculiar to a locality, and dependent upon some cases special to it, and that this disease is always existent.

It is satisfactory to learn that small-pox is on the decrease at Leeds, no fresh cases having been reported to the sanitary authorities. The hospital now contains only thirty inmates, compared with forty-nine a fortnight ago.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the necessary Examinations, were, at a meeting of the Council on January 10th, admitted Members of the College, namely:—

*L. W. Andrews, L.R.C.P.L., St. Bartholomew's Hospital; A. B. Avarne, L.S.A., 46, King Henry's Road, N.W.; A. Badoock, L.K.Q.C.P.L., 1, Hillary Street, Leeds; J. Bamfylde, L.S.A., 43, Endwell Road, Brockley, S.E.; J. T. Bayes, L.S.A., Queen Street, Peterborough; *R. O. Bowman, L.R.C.P.L., Spring Bank, Woodley, Cheshire; *G. A. T. Bray, L.R.C.P.L., 41, Great Russell Street, Bloomsbury; *F. H. Bronhugh, L.R.C.P.L., "West Leigh," Loughborough, Leicestershire; *W. G. S. Brown, L.R.C.P.L., 45, Tollington Park, N.; A. J. Bulger, L.S.A., Wellington Road, Dudley; *F. Calder, L.R.C.P.L., Highland Villa, Bristol; *W. J. H. Carter, L.R.C.P.L., 8, Thistle Grove Lane, South Kensington; *B. Cartley, L.R.C.P.L., Bramley, Leeds; *C. M. Clark, L.R.C.P.L., Dorking, Surrey; G. S. Clarke, L.R.C.P.L., 63, Grosvenor Rd., S.W.; H. F. Cleveland, L.R.C.P.L., 26, Kiddbrook Grove, Blackheath; *H. S. Collier, L.R.C.P.L., Infirmary, Leicester; *W. M. Cotton, L.R.C.P.L., 37, Marquis Road, Camden Square, N.W.; C. A. S. Cox, L.R.C.P.L., Fordwick House, Fordwick, Canterbury; J. D. Cree, L.R.C.P.L., 2, Pemberton Villas, Upper Holloway; W. H. Cundell, L.S.A., 1, The Avenue, Kew; *F. X. Da Costa, L.R.C.P.L., 7, Delvine Road, Fulham; *E. P. Daniell, L.R.C.P.L., 5, College Street, Islington; *B. W. Darroll, L.R.C.P.L., Clun, Shropshire; *W. H. C. Davey, L.R.C.P.L., Norwood House, Elder Road, West Norwood; A. O. Davies, L.R.C.P.L., Compton House, Barmouth, North Wales; *H. P. Devis, L.R.C.P.L., 85, Clarence Road, New Cut, Bristol; C. J. Devins, L.S.A., 29, Palace Road, Upper Norwood, S.E.; C. A. Duckett, L.R.C.P.L., Great Yarmouth; *T. A. Durrant, L.R.C.P.L., "Avondale," Crescent Road, Kingston Hill; C. H. Eccles, L.R.C.P.L., Brigg, Lincolnshire; *C. S. Edward, L.R.C.P.L., Lindfield, Sussex; *H. W. Elphick, L.R.C.P.L., 3, Mecklenburgh Street, W.C.; A. M. Ewing, M.D. Toronto, 50, Avenue Road, Toronto; G. A. Ferraby, L.R.C.P.L., 381, Summer Lane, Birmingham; *J. E. Forster, L.R.C.P.L., Blue House Farm, Milden, Surrey; *T. W. Francis, L.R.C.P.L., 145, Isledon Road, Finsbury Park, N.; J. Good, L.S.A., Aston Court, Tenbury, Worcestershire; W. Ap S. J. Graham, L.R.C.P.L., Wenlock House, Burton Road, Kilburn; *W. T. Grenfell, L.R.C.P.L., 23, St. Stephen's Square, Bayswater; *F. W. Guisclair, L.R.C.P.L., 13, Messina Avenue, West Hampstead; *W. E. Hardy, L.R.C.P.L., Wellington, Salop; N. C. Harding, L.S.A., 334, Upper Brook Street, Manchester; E. M. Harnden, L.S.A., Down House, Sutton, Surrey; *G. Heaton, L.R.C.P.L., Church Hill, Handsworth, Birmingham; H. H. Heffernan, L.R.C.P.L., Alma, Victoria Road, North Sutherland; *C. T. Holland, L.R.C.P.L., Stanhope House, Mornington Road, N.W.; A. K. Holt, L.R.C.P.L., Tuttand, Perry Vale, Forest Hill, S.E.; *P. M. House, L.R.C.P.L., 3, Cowley Street, Westminster; F. Jeeves, L.R.C.P.L., 59, Esplanade, Scarborough; *F. S. Jermaine-Lulham, L.R.C.P.L., 70, Castle Street, Farnham; C. S. Johnston, L.S.A., 9, Easy Row, Birmingham; J. Jones, L.R.C.P.L., Northcote, Lermard Road, Penge; B. E. Kershaw, L.R.C.P.L., Pitton House, Shepton Mallet, Somerset; *H. Laving, L.R.C.P.L., 52, Alderney Street, S.W.; *R. J. Langley, L.R.C.P.L., Park Cottage, Tielhurst, Reading; P. Lisboa, L.M. and S. B. Bombay, 21, Woburn Place; T. Lissaman, L.R.C.P.L., 30, Millman Street, Bedford Row; C. E. Lister, L.K.Q.C.P.L., Shildben Hall, Halifax, Yorks; A. Lucas, L.R.C.P.L., 7, Leonfield Road, Highbury, N.; J. Maberly, L.R.C.P.L., 19, Devonshire Buildings, Bath; J. B. Melroy, L.R.C.P.L., Derwent Villa, Eglinton Road, Shooter's Hill, S.E.; J. Magauran, L.K.Q.C.P.L., Creehan, Cavan, Ireland; *C. T. B. Maisey, L.R.C.P.L., Charlbury, Oxon.; *H. B. Marriott, L.R.C.P.L., Malton, Ipswich; *A. D. Miller, L.R.C.P.L., 336, Dudley Road, Birmingham; *R. D. Mothersole, L.R.C.P.L., The Infirmary, East Dulwich Grove, S.E.; *G. T. Mould, L.R.C.P.L., 4, Tavistock Crescent, Westbourne Park; F. M. Ogilvie, L.R.C.P.L., 12, Park Lane, W.; W. T. Ord, L.R.C.P.L., Cardos, Bourne-mouth; J. W. Peaker, M.B. Toronto, Brampton, Ontario, Canada; J. N. Phillips, L.R.C.P.L., Goginan, Aberystwith; H. P. Pranker, M.B. Ed., 40, Queen's Road, Bayswater; *E. B. Randall, L.R.C.P.L., Basset, Southampton; J. Rees, L.R.C.P.L., Penyffoes, Rhydlwies, R.S.O., S. Wales; *J. L. Rees, L.R.C.P.L., 45, St. Peter's Street, Mile End, E.; J. K. Reeves, L.R.C.P.L., Heathfield, The Avenue, Beckenham, Kent; A. C. Roberts, L.R.C.P.L., Badlesmen, Eastbourne; A. H. Robinson, L.S.A., Low Moor, near Bradford; *T. Robinson, L.R.C.P.L., Station Street, Burton-on-Trent; J. O. Rossall, L.R.C.P.L., 20, Aberdeen Place, Maida Vale; *O. R. Salisbury, L.R.C.P.L., Care of Mr. Crossley, Scatliffe House, New Walk, Leicester; *J. G. V. Sapp, L.R.C.P.L., Palmerston Road, Southsea; *A. Scott, L.R.C.P.L., North End House, North End Road, West Kensington; H. J. H. Scott, L.R.C.P.L., 2, Heathcote Street, Mecklenburgh Square; *H. Shipton, L.R.C.P.L., Buxton, Derbyshire; *C. W. Smeeton, L.R.C.P.L., 15, Reginald Terrace, Leeds; T. M. Smith, A.M. and M., 8, Brunswick Walk, Cambridge; F. W. B. South, L.S.A., Downham Market, Norfolk; H. A. Spence, L.R.C.P.L., 5, Lansdown Place, Clifton, Bristol; *C. P. Spink, L.R.C.P.L., 1, Cavendish Terrace, Leeds; *E. H. Starling, L.R.C.P.L., 146, Alexander Road, N.W.; *P. W. Strenfield, L.R.C.P.L., College Road, Maldstone; *H. Symonds, L.R.C.P.L., 15, John Street, Hampstead; E. Telchelmano, L.K.Q.C.P.L., 245, Great Vincent Street, Birmingham; *R. Thompson, L.R.C.P.L., 10, Dartmouth Terrace, Lewisham; N. Tyacke, L.R.C.P.L., Kermick, Penryn, Cornwall; A. F. Tyrrell, L.R.C.P.L., 16, Colloct, Road, Putney; F. J. Wallham, L.R.C.P.L., Walton Lodge, New Hampton, Middlesex; J. H. Walker, L.R.C.P.L., 22, Albert Street, Regent's Park; *J. Wayte, L.R.C.P.L., 13, Sloane Terrace, S.W.; A. J. Weatherly, L.R.C.P.L., Seven Springs, Oxford; *C. J. Weekes, L.R.C.P.L., 51, Harrington Street, Hampstead Road, N.W.; A. S. Wilson, M.B. Cantab., 7, Warrlor Square, St. Leonards-on-Sea; H. E. Winter, L.R.C.P.L., 6, Elliott Place, Blackheath; *H. W. Wise, L.R.C.P.L., 15, Lyndock Place, Edinburgh; J. F. Woodhurrat, L.R.C.P.L., 10, Market Place, Macclesfield; W. L. Wyatt, L.R.C.P.L., Corse Vicarage, Gloucester; T. B. Young, L.R.C.P.L., The Laurels, Haldenowen.

*Candidates under the regulations of the Examining Board in England.

UNIVERSITY OF LONDON.—Preliminary Scientific (M.B.) Examination, January, 1888. Pass list. Entire Examination.

First Division.—J. H. Griffiths, University College, Aberystwith, and St. Bartholomew's Hospital; W. N. Soden, St. Bartholomew's Hospital; P. W. Wesley, University College.

Second Division.—Fanny Armitage, Yorkshire College; J. Hall, B.A., private study and University Correspondence Cl.; W. J. Johnson, Guy's Hospital; A. B. Jones, Epsom and University Colleges; C. H. Mott, University College and University Correspondence Cl.

Two Subjects of the Examination.¶

V. J. Battenon (c. n.), University College and private study; C. Butcher (c. p.), Guy's Hospital; B. Collyer (c. p.), St. Bartholomew's Hospital; P. S. Eves (c. p.), University College and School; H. W. Jacob (c. p.), Trinity College, Dublin; H. M. Moore (p. n.), private study; H. S. Revell (c. p.), University College and School; L. Rogers (c. p.), St. Mary's Hospital; W. Turner (c. p.), King's College and School; J. E. B. Wells (c. n.), St. Mary's Hospital and private tuition.

One Subject of the Examination.¶

G. J. Arnold (c.), St. Thomas's Hospital; L. W. Bathurst (p.), St. Bartholomew's Hospital and private tuition; Alice McW. Budgett (c.), University College; F. J. Carter (p.), St. Bartholomew's Hospital; T. Cartwright (p.), University College and Middlesex Hospital; J. H. Crawshaw (p.), Archbishop Holgate's School, York, and private tuition; W. E. de Korté (p.), University College; H. J. Jäger (c.), King's College; H. W. Lane (c.), University College; H. B. Pace (p.), University College and London Hospital; C. S. Pantin (p.), Blackheath Proprietary School and University College; A. W. Peake (p.), University College, Bristol; A. F. Percy (p.), Queenswood School, Birkbeck Institute, and private study; F. R. Rowland (n.), University College; W. Stokes (c.), Trinity Hall, Cambridge, and King's College; H. S. Taylor (c.), University College; J. P. Tildesley (p.), Mason College, Birmingham; K. B. J. Vickers (c.), Westminster School and St. Thomas's Hospital.

¶The subjects taken up by these Candidates are indicated by initials after the name—C.=Chemistry; P.=Physics; B.=Biology.

‡These Candidates have now completed the Examination.

MEDICAL VACANCIES.

The following Vacancies are announced:

ATHLONE UNION.—Medical Officer, Moate Dispensary. Salary, £140 per annum and fees. Applications to Mr. Luke Egan, Honorary Secretary. Election on February 21st.

BALLYSHANNON UNION.—Medical Officer, Kinlough Dispensary. Salary, £120 per annum and fees. Applications to Mr. M. Clancy, Honorary Secretary, Stracomer. Election on February 13th.

BIRMINGHAM CHILDREN'S HOSPITAL.—Assistant Resident Medical Officer. Salary, £40 per annum, with board, etc. Applications by February 21st to the Secretary.

BIRMINGHAM GENERAL HOSPITAL.—Assistant House-Surgeon. Applications by February 25th to the House Governor.

BRISTOL ROYAL INFIRMARY.—Dental Surgeon. Applications by February 13th to the Secretary.

CANCER HOSPITAL, Brompton.—Pathologist. Honorarium of £80 for twelve-months. Applications by February 21st to the Secretary.

EARLSWOOD ASYLUM FOR IDIOTS, Redhill.—Medical Superintendent. Salary, £500 per annum, with apartments, etc. Application by February 21st to the Board of Management, 38, King William Street, E.C.

EAST SUFFOLK HOSPITAL, Ipswich.—Assistant House-Surgeon. Applications by February 21st to the Secretary.

FOREST HILL PREVENTIVE DISPENSARY.—Medical Officer. Applications by February 15th to F. J. Marriott, Esq., 2, Perry Villas, Perry Vale, Forest Hill, S.E.

LIVERPOOL NORTHERN HOSPITAL.—Assistant House-Surgeon. Salary, £70 per annum, with board and residence. Applications by February 22nd to the Chairman of the Committee.

MEPSTON ASYLUM, near Leeds.—Medical Superintendent. Salary, £400 per annum, with board and residence. Applications by February 15th to W. L. Williams, Esq., West Riding solicitor, Wakefield.

METROPOLITAN HOSPITAL, Kingsland Road, E.—Ophthalmic Surgeon. Applications by February 20th to the Secretary.

NATIONAL ORTHOPÆDIC HOSPITAL.—Surgical Registrar and Anæsthetist. Honorarium, £20. Applications by February 21st to the Secretary, Great Portland Street, W.

NENAGH UNION.—Medical Officer, Silvermines Dispensary. Salary, £100 per annum and fees. Application to Mr. Joseph Ryan, Honorary Secretary. Election on February 17th.

OLDCASTLE UNION.—Medical Officer, Oldcastle Dispensary District. Salary, £135 per annum and the usual fees. Applications to William Harman, J.P., Honorary Secretary, Crossdrum. Election on February 13th.

OUGHTERARD UNION.—Medical Officer, Oughterard Dispensary. Salary, £112 per annum and fees. Applications to Mr. Robert Mons, Honorary Secretary, Drumakill Lodge. Election on March 7th.

ROXBURGH DISTRICT ASYLUM, Melrose.—Assistant Medical Officer. Salary, £80 per annum, with board and residence. Applications to Dr. Johnstone.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road.—Assistant Physician. Application by February 11th to the Secretary.

ROYAL SURREY COUNTY HOSPITAL, Guildford.—House-Surgeon. Salary, £40 per annum, with board, etc. Applications by February 15th to the Assistant Secretary.

STAFFORDSHIRE GENERAL INFIRMARY.—Assistant House-Surgeon. Applications by February 18th to the House-Surgeon.

TUNBRIDGE WELLS BENEFIT SOCIETIES' MEDICAL ASSOCIATION.—Assistant Medical Officer. Salary, £120 per annum. Applications by February 13th to Mr. J. Wallis, 25, Newcomen Road, Tunbridge Wells.

YORK COUNTY HOSPITAL.—Senior House-Surgeon. Salary, £100 per annum, with board, etc. Applications by March 1st to the Secretary.

YORK DISPENSARY.—Three Resident Medical Officers. Salary, £130 per annum, with furnished apartments, etc. Applications by February 29th to S. W. North, Esq., 84, Micklegate, York.

MEDICAL APPOINTMENTS.

BLONFIELD, A. G., M.D., A.K.C.Lond., Physician to the Exeter Dispensary, elected Physician to the Devon and Exeter Hospital.

CARTER, Rowland Wimburn, M.D., M.R.C.S., L.S.A., appointed Surgeon Weymouth Royal Hospital and Dispensary, *vice* F. C. G. Griffin, M.A., M.B., M.R.C.S., resigned.

CLARK, C., M.D., appointed Superintendent of the Rosewell Asylum, Midlothian, *vice* R. W. Cameron, M.D., resigned.

HANLY, Edward, M.D., appointed Visiting Physician to the British Hospital, Buenos Ayres.

HAWKES, L.A., M.B., C.M., appointed Assistant Resident Medical Officer to the Royal National Hospital for Consumption, Ventnor.

HINDE, F. R. Borthon, M.B., C.M. Edin., M.R.C.S.Lond., appointed Junior House-Surgeon to the Macclesfield General Infirmary, *vice* J. M. Gell, M.B., C.M., M.R.C.S., resigned.

LEWIS, C. M., M.R.C.S., L.R.C.P., appointed House-Surgeon to the Western Branch of the Brighton, Hove, and Preston Dispensary, *vice* L. Phillips, M.R.C.S., L.R.C.P., resigned.

LIVINGSTON, J. Lockhart, M.D., M.S., M.A.O. Roy. Univ. Irel., appointed House-Surgeon to the Bristol Hospital for Sick Children and Women, *vice* H. F. Semple, M.R.C.S., L.R.C.P., resigned.

MAUGHAN, James, M.D. Brux., M.R.C.S., L.R.C.P.Lond., appointed Lecturer on Histology to National Dental College, *vice* Thomas Gaddes, L.D.S. Eng. and Edin., resigned.

MILLS-ROBERTS, R. H., M.R.C.S., L.R.C.P., appointed Assistant House-Surgeon to the Birmingham General Hospital, *vice* J. Errington Ker, M.R.C.S., resigned.

PEAKE, W. Pemberton, Esq., M.R.C.S., L.R.C.P.Lond., appointed Assistant Medical Officer to the St. Marylebone Infirmary, *vice* Raymond Courteen, M.B., resigned.

SPOULE, R. H., M.D., M.Ch., L.M., appointed Medical Officer to the Killyleagh Dispensary of the Downpatrick Union, *vice* R. G. Shiel, M.D., resigned.

WATSON, W. J., M.B., M.R.C.S., appointed House-Surgeon to the Northern Branch of the Brighton, Hove, and Preston Dispensary, *vice* E. S. Hasell, M.R.C.S., L.S.A., resigned.

WOODHALL SPA, LINCOLNSHIRE.—Among recent considerable additions and improvements made for the accommodation and convenience of visitors to the Woodhall Spa, there has, we learn, just been completed, from the designs of Major Davis, F.S.A., of Bath, who, two years ago, made a tour of the chief European Spas at the request of the Corporation of Bath, a splendid series of baths and pump-room fitted up with every modern appliance and convenience, including shower, vapour, douche, inhalation, and local baths. In the pump-room accommodation is provided for a first-class orchestral band. Plans of a new hospital have been prepared, and in addition to the valuable site given by the present proprietors, subscriptions to the extent of £1,000 have been raised towards this object. Several new villas have been erected, and others are in course of building. The hotel to which a new wing has been added has been entirely remodelled and furnished to meet all the requirements of patients and guests, and the gardens, which have been newly laid out, are surrounded by a charming park of seventy acres. Messrs. Robey and Co., of Lincoln, are, we learn, putting down new machinery for the elevation of the water, which, when completed, will deliver about 20,000 gallons a day; and new tanks have also been constructed to hold some 60,000 gallons of water. It is anticipated that this spa, which was largely attended by rheumatic and other patients during the past year, will, in consequence of the greater conveniences provided, be more generally resorted to.

THE INTER-HOSPITAL (RUGBY) FOOTBALL CUP TIES.—The following are the results of the first round:—The matches are played on the Richmond Athletic Association Ground. St. Mary's a bye, Westminster scratched; Middlesex a bye, King's scratched. St. George's beat Charing Cross on January 23rd, a somewhat easy victory, 2 goals, 2 tries, and 5 minors (75 points) to 1 try and 1 minor (11 points). St. Thomas' beat Guy's on January 27th. Contrary to expectation, Guy's was defeated, the Lambeth forwards so penning their rivals as to prevent their three-quarters getting off. After a most stubbornly contested game the score was 1 goal to 2 minors (27 points) to one try (10 points). London v. St. Bartholomew's resulted in a draw, both sides scoring two points. London, though unable to score, had slightly the best of the game. University a bye. The draw for the second round is as follows:—Monday, February 13th, University v. St. Thomas's; Tuesday, February 14th, St. Bartholomew's v. St. George's; Thursday, February 16th, London v. St. Mary's, Middlesex a bye. ...

THE HEXTHORPE ACCIDENT.—At the meeting of directors of the Manchester, Sheffield, and Lincolnshire Railway Company, held at Manchester on the 25th January, Sir Edward Watkin, Bart., in the chair, the following resolutions were passed:—"That the best thanks of the Board be given to the governors and committee of the Doncaster Infirmary for the valuable aid they had rendered to the parties injured in the Hexthorpe accident, and for the care and attention bestowed upon them during the time they were in-patients in the infirmary. Further, that a sum of 250 guineas be handed to the funds of the hospital towards meeting the additional expenses incurred in consequence of the accident." "That a sum of fifty guineas be voted to Mr. Penny, the house surgeon of the Doncaster Infirmary, in recognition of the additional labour imposed upon him in connection with the accident at Hexthorpe, with the best thanks of the Board."

SMALL-POX AT NOTTINGHAM.—At a meeting of the Nottingham Town Council on Monday, a report was submitted to the Health Committee of the Corporation recommending the erection of a permanent small-pox hospital at Bagthorpe at a cost of £26,000. The matter was deferred for two months. It has, we believe, already been under consideration for four years. There are still eighteen patients in the temporary hospital. Another death from small-pox is reported. Nearly three weeks ago a man was removed from a house to the temporary hospital. All the inmates of the house consented to be vaccinated, except a young woman, who resolutely refused to adopt this precaution. She alone caught the disease, was conveyed to the hospital, but never rallied, and died on February 6th.

LURGAN UNION.—A special meeting of the Lurgan Guardians was convened recently in order to consider the liability of the Board to pay the salary of a substitute for one of the dispensary officers of the union. It appears that on September 15th last, the Lurgan Dispensary Committee allowed Dr. Agnew, medical officer of No. 1 District, three weeks' leave of absence on the occasion of his marriage, and the Committee appointed Dr. Magennis, J.P., as *locum tenens* at a salary of £2 2s. per week. The Board of Guardians, while confirming the grant of leave of absence to Dr. Agnew, declined to pay his substitute, on the ground that, all things considered, Dr. Agnew was liable. A resolution reaffirming their decision refusing to pay the amount was unanimously agreed to.

PASTEURISM IN POLAND.—Dr. Monin furnishes the following statistics concerning the number of preventive inoculations for rabies practised in Warsaw by Dr. Bujwid, and the results obtained. From the beginning of 1887 to July 1st, 220 persons were inoculated; in 85 per cent. of the cases the bites were inflicted by animals proved to be suffering from rabies. In 15 per cent. of the cases this fact was not certified; thirty-five persons who were bitten were not inoculated, owing to the insignificant nature of the bites. Two of the patients inoculated died; the mortality was therefore 1.06 per cent. This proportion is much the same as that shown by the results of similar experiments at the Institut Pasteur.

CREMATION IN FRANCE.—At a meeting of the French Cremation Society held in Paris on January 29th, the President announced that he had received from the Ministry the assurance that an edict rendering cremation legal would very soon be promulgated. A requisition to the general commanding the army in Tonquin that French soldiers dying there might be burnt and their ashes sent to France for burial had been answered by the usual official formula, "It is not the custom."

THE Leeds Trained Nurses' Institution seems to be doing a good and useful work. The staff consists of eighty engaged in private nursing; seven engaged in district nursing; and sixteen probationers in training at the hospitals, giving a total of one hundred and three. The number of cases attended during the year was eight hundred and seven; and one hundred and seventeen cases had to be declined, owing to inability to supply a nurse at the time she was needed. The Honorary Secretary is Mrs. Edward Walker.

ADULTERATION OF PEPPER.—A number of Liverpool grocers have recently been convicted for selling adulterated pepper. The fines and costs, however, we are informed, are in each case paid by the grinders, who are the real offenders, and whose names are, by this means, not disclosed. If the same attention were given to the detection of fraud among manufacturers as is now given to its detection among the retail dealers, such instances of evasion of the law would be less frequent.

THE Committee of Management of the City of London Hospital, in presenting the 137th annual report, expressed their gratification in the satisfactory character of the year's working, both as regards the sanitary condition of the hospital and its financial position. During the year, 356 women have been delivered in the hospital, as against 283 in 1886; 338 children were born, namely, 177 boys and 161 girls; 7 children were stillborn, and one woman has died, the death of the mother, from extraneous causes) being the only one since May, 1886, out of 506 deliveries, the mortality being under 2 per 1,000.

EDINBURGH DENTAL HOSPITAL.—The necessity for the erection of a specially designed and enlarged hospital on a suitable site for the reception of the staff and patients of the present Edinburgh Dental Hospital becomes more apparent every year. During 1887 there was an increase of 785 patients registered as compared with 1886. The staff of the hospital devotes a considerable amount of time to the stopping and preservation, as well as the extraction, of teeth.

MR. THOMAS MONK, surgeon, of Preston, has died at the venerable age of 90 years. The deceased gentleman was for many years a member of the Town Council, was made alderman in 1845, and served the office of mayor during the year 1851-52. Up to about a year ago Mr. Monk continued in active practice.

A TRAMP'S PARADISE.—Orders have been issued by the Chief Constable of Derbyshire for the revaccination of the members of the police force as a precaution against the small-pox epidemic prevailing in the adjoining county. No vagrants or merely suspicious characters are to be apprehended until this order has been carried out.

TRALEE UNION.—The guardians recently passed a resolution increasing the salary of Dr. Hayes from £100 to £120 per annum. As, however, Dr. Hayes had only lately been appointed a medical officer of the union, the Local Government Board have refused to sanction the proposed increase.

GLASGOW SAMARITAN HOSPITAL.—This is one of the youngest of the medical charities of Glasgow, being established for the treatment of diseases of women. During the past year the total number of patients was 203, and the number of operations 93. No deaths occurred.

ACCORDING to M. Leroy-Beaulieu, the medical profession in France pay to the Treasury an annual sum of 12,384,930 francs for their "patentes," a tax levied on the exercise of every trade, profession, and occupation in that country.

GLASGOW DENTAL HOSPITAL.—The annual report of this hospital shows an increase of 1,416 cases treated, the total being 8,212, which included 62 special operations performed under anaesthetics.

A NEW medical journal, called *Electrotherapie*, has recently appeared in France under the editorship of Dr. Léon Danion, who has given much attention to electricity as applied to medicine.

FROM Dr. Diplock's annual report it is seen that considerably over one-fourth of the inquests held in West Middlesex last year were upon children under the age of 12 months.

A "FIRST AID" class of the St. John Ambulance Association has been formed by the Duchess of Albany at Esher, Her Royal Highness herself attending the lectures.

OBITUARY.

WM. BOYD MUSHET, M.B. LOND., M.R.C.P. Dr. MUSHET, whose death occurred at Aldershot towards the end of last year, was a man of varied accomplishments, and highly esteemed by a large circle of personal friends. His educational career was a promising one. He took the degree of M.B. Lond. in 1855, and became Member of the Royal College of Physicians of London in 1863. He was University Medallist in Medicine, and took Honours in Surgery, Midwifery, and Materia Medica. He was late Honorary Consulting Physician to the Mariners' Home, Egremond; Physician to the London Hospital, Norwood; and Resident Physician to the St. Marylebone Infirmary. He was also a member of the Haryeian Society. He was the author of many works on a variety of subjects. In 1864 he published *Man and Apex*. He was also the author of a *Practical Treatise on Apoplexy*, *The Pathology of Angina Pectoris* (contributed), to the *JOURNAL* (1859); *Cholera; its Pathology, Contagiousness, and Treatment* (He

was also the author of a satire entitled *Hyde Park*, and a contributor to the medical journals and *Morning Star*.

MICHAEL LEAHY, M.D. ED.

DR. LEAHY, the oldest practitioner in Bridgend, died on January 29th, aged 76, from a cold contracted when out attending his patients. Dr. Leahy studied at Dublin and Paris, as well as at the University of Edinburgh, where he was a distinguished student in the class of the late Sir James Simpson, and afterwards his class assistant. He obtained the qualification of L.R.C.S. Edin. in 1839, and that of M.D. Edin. in the following year. He was a good French scholar, and well versed in French medical literature. He acted as chief surgeon to the workmen in the Tondou iron-works for upwards of forty years, and he and his valued friend, Dr. Pritchard, who attended him during his illness, have been the two leading practitioners at Bridgend for nearly half a century. His unselfish devotion to duty, his invariable kindness and charitable dealing, and honourable and straightforward action under all circumstances, won for him deservedly the respect of all and the affection of a wide circle to whom he was more intimately known.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 P.M.—Professor John Bland Sutton: Lecture on Evolution in Pathology. I. Coalescence.

MEDICAL SOCIETY OF LONDON.—Dr. Donald Hood: The Treatment of Rheumatic Fever, with especial reference to the Use of the Salicylates.—Dr. Kent Spender: Some hitherto Undescribed Symptoms in the Early History of Osteo-arthritis.

WEDNESDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 P.M.—Professor John Bland Sutton: Lecture on Evolution in Pathology. II. Coalescence (continued).

ROYAL METEOROLOGICAL SOCIETY, 7 P.M.—Hon. Ralph Abercromby, F.R.M.S.: Electrical and Meteorological Observations on the Peak of Teneriffe. W. B. Tripp, M.I.C.E., F.R.M.S.: Rainfall of South Africa, 1843-1886. Nils Ekholm: Some Methods of Cloud Measurements.

THURSDAY.

HARVEIAN SOCIETY.—Dr. Stephen Mackenzie: Some Cases of Hysteria. Dr. Lees: Case of Hysteria. Mr. Silcock and Dr. Maguire: Death, with Symptoms of Hysteria.

PARKS MUSEUM OF HYGIENE, 5 P.M.—Dr. J. F. Payne: Plagues, Ancient and Modern.

FRIDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 P.M.—Professor John Bland Sutton: Lecture on Evolution in Pathology. III. Anatomical Peculiarities and Their Mediating Effects upon Disease.

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 7.30 P.M.—H. E. Armstrong, M.R.C.S.: Port Sanitary Administration on the Tyne; a Seven Years' Retrospect. Campbell Muir, M.B.: Sanitary Administration in the United States.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the announcement.

BIRTH.

FENWICK.—At 5, Old Burlington Street, W., on the 2nd February, the wife of E. Hurry Fenwick, of a daughter.

MARRIAGES.

JAMES—CORMACK.—Tuesday, the 7th February, at the Cathedral, Bombay, William, third son of Edward James, J.P., Greenbank House, Plymouth, to Caroline, youngest daughter of the late Sir John Rose Cormack, M.D., Edin. and Paris.

OGSTON—RODINGS.—On 7th December, 1887, at Bishop's Court, Auckland, New Zealand, by the Right Rev. the Bishop of Auckland, assisted by the Ven. Archdeacon Dudley, Frank Ogston, M.D., Lecturer on Medical Jurisprudence, Otago University, Dunedin, to Kate Mary, eldest daughter of the late George Rodings, Esq., of the same place.

WADE—WILSON.—February 1st, at St. Peter's, Southampton, by the Rev. A. G. Wade, Vicar of Trinity Church, Ryde, father of the bridegroom, and the Rev. C. T. Steward, Vicar of the parish, Arthur Brecon Wade, M.B., Southampton, to Annie, eldest daughter of the late Col. Wilson, B.N.F., of the Polygon, Southampton.

DEATH.

ADBY.—On the 2nd February, at St. Leonard's-on-Sea, Charles Augustus Ader, M.D., F.R.C.P., Consulting Physician to the Hastings, St. Leonard's, and East Sussex Hospital, aged 65 years.

THE HUNTERIAN ORATION

ON THE

LIFE-WORK OF JOHN HUNTER, AND HIS INFLUENCE ON SURGERY.

Delivered before the Hunterian Society on February 8th, 1888.

By R. CLEMENT LUCAS, B.S., F.R.C.S.,

President of the Society.

THE biographies of great men form conspicuous landmarks in the histories of nations like the mountains to our plains and the capes and promontories to our ocean shores. Without them the records of time would be as uninteresting in their monotony as the tedious columns of a banker's ledger, where every figure must fall with wearying regularity into one of the three spaces devoted to pounds, shillings, and pence. There would be reiterated repetition without relief, and a dull monotone would be the only sound heard in a chorus of universal platitudes. But, happily, high above the hum of the multitude, back from infinite space which time overshadows, come the voices of the great, ever calling to us to follow in their footsteps, and to search out the labyrinths of Nature by the aid of the lamp of truth. First among surgeons of immortal renown will ever remain the name of him in whose honour we have met together to-night, and after whom this Society takes its name, the illustrious John Hunter. By his beacon light the reputations of all future generations of surgeons will be tested; and whereas it may be safely predicted that the flickering light of many will disappear like the light of the stars before the rising sun, yet it may still be hoped that the world may create and this nation produce surgeons whose genius will in after years shine with as steady a light as that of the planets in the universal ether. Let us turn to the history of this great man's life, to see if we can discover in it the secret of his power, or learn how to train ourselves, in however distant a way, in the direction of this ideal. Was it by birthright, by the aid of parental wealth, that he gained a start over his fellows in the race of life? Anything but this. Was it by early mental culture, by the careful and exact training of cultivated minds in his early childhood, that he learnt the lesson of his life? No, far from this. The youngest son of a Scotch laird, his home was in the wilds of rugged Scotland, and his early education only that of a village school. Till early manhood his mind lay fallow, like his father's acres under the leaden sky of winter. True, his parents were persons of keen intelligence, if not of the highest culture, and under their roof his mind would be steadied in virtue and guarded from vice. But the records of his boyhood show no promise of pre-eminence. The time was idly spent and uneventful. We cannot even discover that he displayed any inquisitive interest in the structure of the birds or reptiles that in boyish mischief he may have captured. There is no indication of the future biologist in the boy, and nothing whatever to indicate the great scientific mind that lay in him as yet undeveloped. But, mark you, he comes of that sturdy yeoman stock that in the previous century had produced a Newton, and his two elder brothers had already shown signs of high intellectual power. These two, migrating to London, were becoming distinguished in the medical profession. The eldest dies young, but the second son, William, is destined to be the magnet that attracts the youngest towards intellectual pursuits, and through him John Hunter derived that inspiration which roused his hitherto chrysalid mind to the mighty exertions of after years. Little can we learn from such a boyhood. It is devoid of those little incidents upon which biographers delight to lay so much stress as indicating the bent of the developing mind. There is nothing corresponding to the boyhood of the great general who loved more than other boys to play with cannon, or to that of the great engineer who delighted in mechanical contrivances. All we have to contemplate is a wide uncultivated field, but the adjoining acres indicate that the soil is fertile if sown with the appropriate seed. The first venture is unsuccessful. At the age of 17, John Hunter is sent to assist a failing brother-in-law, who is a cabinet maker in Glasgow. As well might his friends have attempted to grow a succulent water-lily on the Surrey sand hills as to force such a calling upon the unwilling youth. The result is failure, and he returns again to home and idleness. Thus the first twenty years of his short life of sixty-five are, as we now judge, lost—or, at least, unproductive. Whether years that in their own time prove

unproductive are, when added to the human cycle, to be regarded as lost is an interesting problem. If so, then hours spent in healthy exercise—inasmuch as they seldom lead to immediate intellectual results—may be regarded as lost also. And sleep, even, that “foster-nurse of Nature,” may be blamed for her apparently unproductive hours. But if those twenty years of mental repose led to the storing up of energies which in after years produced such magnificent results, then must they not be regarded as lost, but as potential. It is possible even that this storing up of energies by lack of opportunity had been present in the family of Hunters prior to the generation in which John was born. It is certain that the strain of blood derived from Hunter's parents was capable of supporting the highest intellectual attainments, as evidenced not only in Hunter and his brothers, but afterwards in the family of Baillies, one of whom married his sister.

John Hunter was the youngest and tenth child, but only five of the family lived to adult age. It may be interesting to those in search of the origin of genius to note that there was a great difference between the ages of Hunter's parents, and that the father was verging on his seventieth year when John was born. He lost his father when 10 years of age; to this circumstance and to his mother's indulgence is attributed the neglect of his early education. This defect followed him throughout life. His grammar is often incorrect, his sentences clumsy and obscure, and his expressions coarse, or at least inelegant. But a vigorous intellect and irrepressible will struggle through all the difficulties resulting from his defective tuition, and in this we recognise the impulsive force of true genius. To how many would such an education have proved an impassable barrier to higher intellectual attainments! Ignorant of any language but that of his birth, and but little skilled in using even this, we find him twenty years of age before his mind commences to unfold. Then comes the turning-point of his whole life, that

Tide in the affairs of men,
Which, taken at the flood, leads on to fortune;
Omitted, all the voyage of their life
Is bound in shallows and in miseries.

This turning-point is a letter which he addressed to his distinguished brother William, “requesting to be allowed to join him in London, and offering his services as an assistant in the dissecting-room.” The reply was favourable, and contained a kind invitation to visit London. Now, mark you, this is apparently the first time that Hunter attempts to direct his own path in life. It is his own initiative. Before, he shows no liking for the parental acres. He is said to be attached to country sports but negligent of farming. His fond living parent, having neglected his education, thinks that he may earn an easy living by falling into the business of a dissipated brother-in-law. From this he returns in disgust and failure.

The tendency of parents generally is to place their sons as soon as possible into positions of ease, regardless of their inclinations; but there is this consolation, that men of genius commonly break through all restraint, and eventually determine for themselves their paths in life. It was so with the Hunters. Why parents too often fail to direct aright their children's futures if it is not difficult to understand; for youth strives for distinction, age for affluence. Having arrived at a time in life when they begin to feel the burden of work and the luxury of rest, when they desire to defend their sons from the toils and dangers by which alone distinction can be secured. Happily for the world, the two Hunters broke loose from parental guidance, and found in the medical profession that scope for intellectual activity to which their minds were best adapted.

Let us rest for awhile from the contemplation of John Hunter's life to study the character of that elder brother, William, who henceforth is destined to exert so powerful an influence on his career. William is ten years his senior, and was sent to Glasgow University at the age of 14 to read for the clerical profession. After five years of study his tastes lead him in another direction, so that at the age of 19 we find him at Hamilton, with a young doctor named Cullen. Three years with Cullen intensify his love for the medical profession, and he proceeds first to Edinburgh, then to London, to study, with the object of becoming Cullen's partner. At the age of 23 he is in London, residing with Dr. Douglas, a celebrated anatomist of that day, whose house he enters in the double function of anatomical assistant and preceptor to his children. Here wider fields are opened for his talents, and once more we find him asserting his own judgment. His father doubts the wisdom of this step, and writes strongly urging him to adhere,

to his original intention of returning to Hamilton to be Dr. Cullen's partner, "where," he writes, "you may be very comfortably settled and make money; and if you miss this opportunity now you cannot be sure of it at another time." This parental advice, tinged as it is with Gaelic prudence, is not followed by William Hunter, who, continuing to pursue his studies in London, rapidly rises to be the most distinguished anatomist and most brilliant lecturer of his time. Later in life he directed his attention specially to midwifery, and published, nine years before his death, his great work on the gravid uterus. He collected a large museum, the materials of which cost him £100,000, and this collection, together with £8,000 for its maintenance, he bequeathed to the University of Glasgow. Adams thus describes him: "His person, though small, was graceful; his cast of features regular and interesting; his voice musical; his manners attentive and flattering. In short, Dr. Hunter was a polite scholar, an accomplished gentleman, a complete anatomist, and probably the most perfect demonstrator as well as lecturer the world had ever seen."

One sentence from a letter to his old friend Cullen, who rose to be Professor of Medicine in the University of Edinburgh, will show at once the manner and character of this truly distinguished physician. "Since I began to think for myself," he writes, "Nature, where I am best disposed to mark her, beams so strongly upon me, that I am lost in wonder, and count it sacrilege to measure her meanest features by my largest conceptions." In that one sentence we note the humility of scientific thought, associated with breadth of view and beauty of expression, which were characteristics of William Hunter. Had the whole world been searched over to find an appropriate teacher for a young developing genius, it would have been difficult to discover a more able and accomplished guide and instructor. For not only was William Hunter recognised as a scientific physician and anatomist of the greatest eminence, but he possessed in the highest degree the power of communicating knowledge. John Hunter rode from Scotland on horseback in 1748 to join his brother in London. What a new world for the uncouth Scotch lad! Picture the indifferently educated, awkward, ungainly youth, now suddenly imported into the centre of intellectual activity. How keenly must he have felt the distance between his limited knowledge and that of the circle in which his elder brother was already distinguished. At first it would seem he displayed little love for refinement, and became a leader among his brother's more noisy pupils. The higher civilisation acted slowly upon him, and came too late to remove all the angularities of thought and expression which had become deeply rooted in his northern home; but he brings a robust constitution and a determined will to carry him through his future studies, and in his brother's dissecting room he finds that new interest which supplies the requisite stimulus to excite his dormant energies into activity. His brother starts him in the usual way by giving him an upper extremity to dissect, and the pupil acquits himself so well that the master predicts for him a distinguished future in anatomy.

Thus is Hunter's mind inoculated by his brother towards the study of life through death, and henceforth the feverish thirst for knowledge, thus excited, grows more and more intense with increased acquirement. But for this one sphere of knowledge only is his mind adapted, and that the widest sphere of all; every creature or thing that may be accounted to have life will, in future years, when brought within his ken, command his earnest attention and study. As yet he treads but the lowest steps in the study of life, but his interest is awakened, and he is, thus encouraged to labour on without sense of weariness.

The following summer, again through his brother's influence, he is enabled to study surgery at the Chelsea Hospital under Cheselden, the famous lithotomist, and he returns to assist his brother when the autumn session of anatomy commences. After Cheselden's retirement he studies under Percival Pott, and thus five years are spent between anatomy and surgery. Then, in 1753, a new departure is made, and we find John Hunter entered as a gentleman commoner at St. Mary's Hall, Oxford. This change is attributed to the desire of his brother William to see him better trained in classic lore, but the experiment is a failure. Hunter's mind is one strong in its own lines, but showing little adaptability to the teaching of others, and at the age of 25, after five years spent in anatomy and surgery, he cannot be persuaded as he says "to stuff Latin and Greek at the university," so he returns again to London to enter as a pupil at St. George's Hospital, where, in 1756, he is appointed house surgeon. In the same year he joins his brother as a partner and joint lecturer in his

anatomical school, and this must therefore be regarded as the termination of his student's career. He is now 23 years of age, well trained in surgery, and an able and laborious anatomist; but as a lecturer we find him, when brought into contrast with his brother, a comparative failure. This is due in no way to a lack of knowledge, but to the difficulty he experienced in expressing his thoughts in words ready for immediate service. Perhaps it may be regarded in some degree as fortunate that he was not possessed of natural eloquence, inasmuch as a popular teacher is apt to be diverted by his popularity from those close studies and laborious investigations with which Hunter's name is henceforth to be associated.

Thus he labours on with scalpel and forceps in the dissecting-room, and now begins to widen his views by original researches in conjunction with his brother William, or independently of him. He works at the descent of the testis, and employs himself in a series of observations on the anatomy and uses of the lymphatics. But this close and continuous anatomical work begins to tell on his health, and in the spring of 1759 he is seized with inflammation of the lungs. The effects are slow in clearing, and as his elder brother James died of consumption, he is strongly advised to leave London, and seek change in a warmer climate. With this object he applies for an appointment in the army, and is soon on his way as staff-surgeon with the expedition sent in 1761 to lay siege to Belleisle. The army has proved destructive of many an early reputation, and there might have been a danger to Hunter of a renewal of those dissipations to which he appeared to have some inclination when he first came to London. But the love of science has taken too strong a hold upon him to allow him to break away from her influence. Although engaged in practical surgical duties and the study of gunshot wounds, we find him employing his leisure hours in observations on the hearing of fishes and the digestion of hibernating animals during the torpid state. The following year he is sent with an expedition to support the Portuguese against the Spaniards, and peace being proclaimed in the spring of 1763 he returns once more to London.

John Hunter's second entry into the metropolis at the age of 35 may be contrasted with that he made fifteen years before under his brother's guidance. Then he was ignorant, uncultured, and without prospect in life. Now, thanks largely to that brother's influence and training, he is recognised as an accomplished anatomist and able surgeon. He still displays some roughness of manner, some ungoverned impulses of temper, and perhaps a little tendency to quarrel with other workers in the same field, but he is thoroughly imbued with a love of scientific inquiry, and has shown an industry, perseverance, and originality of thought which in future years will raise him to the highest pinnacle of surgical fame.

The position he held as demonstrator in his brother's dissecting room has been worthily filled by a Mr. Hewson in his absence, and the independence of thought which was one of John Hunter's characteristics may have rendered a reunion with his brother inadvisable even if again possible. He is still poor, but possessed of resources which may command wealth, and he has his half-pay from the army to contribute to his support. He starts in practice in Golden Square, but the public are slow to discover his talents, and thus he is left with plenty of time in which to pursue his biological studies. In order to increase his income he gives a course of lectures on anatomy and surgery, but these are not largely attended. Thus his two chief defects, roughness of manner and lack of fluency in speech, debar him at the commencement both from public and professional favour.

About this time he purchased a piece of ground at Earl's Court, then two miles from London, and built there a small house, which he converted into a kind of menagerie for the study of animals and for the carrying out of experiments. There bulls and leopards, eagles, dogs, pigs, poultry, bees—indeed, almost every living creature he could collect around him—were subjected to his critical examination and study. This house came under the auctioneer's hammer on February 16th, 1886, only two years ago, and it may be interesting to hear a last description of it, which I take from the BRITISH MEDICAL JOURNAL of February 20th: "Behind a large brown brick house stood a fine lawn, at the right extremity of which was a grassy mound, in form like a small brick kiln. This mound was surmounted by a low machicolated brickwork turret, for which various explanations have been advanced. Indeed, this tower has been made the basis of Hunterian legends; but it was most probably erected before Hunter's time, and meant for ornament, after ideas due to influences derived from Versailles and Holland. Three dens were excavated in the mound, the

central den being fairly capacious; but, according to modern ideas, they were ill-adapted for the reception of live carnivora. The story of the escape of two leopards from the den is probably well known. Close to the dens grew some fine trees, including a fine mulberry, in the bark of which the late Mr. Frank Buckland believed that he could trace old incisions, made by Hunter, for the introduction of a thermometer in his experiments on the physiology of the circulation of the sap. At the left hand corner of the grounds, beyond the lawn, was a small workshop, with a loft, evidently as old or older than Hunter, but what use he made of it remains unknown. Turning back to the house, a long, low, subterranean passage led from the grounds under the building to the yard in the front part of the premises. It was hardly six feet in height, and midway it led to two small chambers well bricked, the one was used for the famous madder-refuse experiments on swine, the opposite chamber contained two copper furnaces. It was in the larger copper, concealed in this little apartment, that the skeleton of the Irish giant, Byrne O'Brian, and many other specimens, were prepared. Doubtful as may be the original meaning of the passage under the house, it cannot be doubted that Hunter found it very useful for the introduction of 'subjects' and the prosecution of work away from the dangers of popular prejudices and inquisitiveness."

But to return to Hunter's life. Although as yet he has found little favour with the public, in the scientific world his eminent abilities now command respect, and it is to the credit of the Royal Society that he was elected a Fellow in 1767, at a time when he was poor and little known apart from anatomical work. The following year, again through his brother's influence, he is elected surgeon to St. George's Hospital. One last benefit he obtains from that elder brother, when Dr. Hunter gives up to him his house in Jernyn Street, after moving his museum and school to a more spacious house in Great Windmill Street. This change was made in 1770. Thus we find John Hunter, at the age of 42, acquiring that success in life which he so well deserved, living in a large house in a situation favourable for practice, surgeon to a hospital, and a Fellow of the Royal Society. His income is further increased by taking resident pupils (of whom the afterwards celebrated Edward Jenner is the first), and in 1771 he marries Miss Home, to whom he had been engaged for some years.

From the time he left the army till this year, when he published a treatise on the teeth, there has survived no paper from his pen; but he doubtless was, by his laborious dissections, laying the foundations of many of his future researches into the study of life.

When 40 years of age he began to suffer from gout; and at the age of 45 he had his first attack of angina pectoris, during which his pulse could not be felt at the wrist, and his respiration was, according to his own account, only carried on by voluntary effort. This was the first indication of ossified coronary arteries, to which he succumbed twenty years later during a fit of excitement.

John Hunter's first paper before the Royal Society was communicated five years after election, on the suggestion of the President, Sir John Pringle. It was on *Post-mortem Digestion of the Stomach*, a subject that brought him into court some nine years later as an expert in the trial of Captain Donellan for the murder of Sir Theodosius Broughton. To the legal mind, which requires a positive affirmation or denial of every question, Hunter's evidence appeared worse than useless. He could not be induced to give any opinion that his knowledge of facts would not warrant, and this caution (which is characteristic of a philosophical mind) brought down upon him some severe and sarcastic remarks from Mr. Justice Buller, who presided at the trial. It would be impossible for me to notice the many different contributions to biology, physiology, and pathology from Hunter's pen; but this may be said of all, that they invariably indicate a mind trained to exact observation, ever on the search for truth; and, where possible, observation is always supplemented by experiment. Over what a wide field he travelled will be sufficiently indicated by naming a few of them: *Observations on Animals and Vegetables with respect to the Power of Producing Heat; An Account of Certain Receptacles for Air in Birds; Proposals for the Recovery of People apparently drowned; Observations tending to show the Wolf, Jackal, and Dog are all of the same Species; Some Observations on Loose Cartilages found in Joints; Observations on the Structure and Economy of Whales; Observations on Bees; Observations on Fossil Bones*. These and many other scientific papers were written whilst he was a surgeon and lecturer at a hospital and occupied more or less with private practice.

As a lecturer he appears never to have been a great success, not simply on account of his difficulty in finding words to express his views, but because he dared never make any statement beyond what his facts would warrant, and consequently never spoke with dogmatic emphasis. The difficulty appears to have been felt as much by the teacher as by the students, for one biographer states that "the task was so formidable to him that he was obliged to take thirty drops of laudanum before he entered the theatre at the beginning of each course," and, as a result, I imagine the lecturer and class must have gone to sleep together.

His friend and pupil, Edward Jenner, had now settled at Berkeley in Gloucestershire, and Hunter enters into a correspondence with him, which is full of the ideas which are occupying his mind. He thus stimulates his friend to exert himself in original inquiry, and asks his assistance in obtaining specimens for himself. The following is a typical sentence from one of these letters: "I want you to pursue the experiments on the heat of the hedgehog this winter; and if you could send me a colony of them I should be glad, as I expended all I had except two—one an eagle ate, and a ferret caught the other."

Hunter's fame as a surgeon is now rapidly on the increase. In 1776 he is appointed Surgeon Extraordinary to the King, and his pathological labours begin to excite a mixture of admiration and envy. He commenced to erect his museum in Leicester Square in 1783, as the house he lived in would no longer hold his numerous specimens, and the new premises were completed in 1785, the year which is rendered noteworthy in the annals of surgery by the first performance of his operation for aneurysm.

In the spring of this year he is seized with a very severe illness, accompanied by cerebral symptoms and a number of curious secondary sensations, from which he imperfectly recovered. After this date any exercise or mental emotion was apt to bring on acute spasmodic agony, but his work was by no means finished, and he laboured on.

In 1786 he was appointed Deputy Surgeon-General to the Army, and he soon after published his work on the *Lues Venerea*. This work shows much philosophical reasoning, but he falls into two serious errors: one that two diseases cannot exist in the body at the same time, and the other (well known as the result of sacrificing his own bodily health to experimental inoculation) that gonorrhoea, chancre, and soft sore were all the result of one poison. In spite of these errors, his description of the hard, or, as it is still called, the Hunterian chancre, is as true now as then, and with its signs well developed secondary symptoms invariably follow. I will quote from this work to show how wide was Hunter's reasoning: "Nature," he says, "has not been able to apply any one part to two uses with advantage, as might be illustrated in many instances in different animals. The animals whose legs are contrived both for swimming and walking are not good at either, as seals, otters, ducks, and geese. The animals, also, whose legs are intended both for walking and flying, are but badly formed for either, as the bat. The same observations are applicable to fish, for the flying fish neither swims nor flies well, and whenever parts intended for such double functions are diseased, both are performed imperfectly. This is immediately applicable to the urethra, for it is intended as a canal or passage, both for the urine and the semen. The urine requires the simplest of all canals, and of no greater length than the distance from the bladder to the external surface, as we find the urethra in women, birds, the amphibia, and fish; but the passage for the semen in the quadruped requires to be a complicated canal, and of a length capable of conveying the semen to the female, provided with many additional and necessary parts, as the corpus spongiosum urethrae, muscoli acceleratores, Cowper's glands, prostatic gland, and vesiculae seminales. As all these parts are to serve the purpose of generation, and as the diseases of the canal are principally seated in them, we at once see how much the urinary organs must suffer from a connection with parts so numerous and so liable to disease; and what adds to the evil is that the actions of the urinary organs are constant and absolutely necessary for the well-being of the machine, whereas the evacuation of the semen takes place only during a certain portion of life, is then only occasional, and never essentially necessary to the existence of the individual."

In another place we find him, with philosophical fairness, framing an apology for the exaggerated praise with which Daran introduced the use of the bougie: "Such extravagant recommendations of particular remedies," he says, "are not at all times without their use. Inoculation would still have been practised with caution, had it not been for the enthusiasm of the Suttons. Pre-

parations of lead would not have been so universally applied, if they had not been recommended by Goulard in the most extravagant terms; nor would the hemlock have come into such general use, if its true merits only had been held forth. Improvements are often over-rated; but they come to their true value at last. Sutton has told us that the cold regimen in extreme is infinitely better than the old method; but from general practice we have learned that moderation is best, which is all we yet know. When Daran published his observations on the bougie, every surgeon set to work to discover the composition, and each conceived that he had found it out, from the bougies he had made producing the effect described by Daran. It never occurred to them that any extraneous body of the same shape and consistence would do the same thing."

In spite of the errors to which I have alluded, this work did much good service, for it was an honest endeavour to free an uninviting branch of surgery from the monstrous quackery with which it was then associated, and from which, even in our day, it cannot be considered to be absolutely disentangled. The same year that he published this work, he received the Copley Medal of the Royal Society, and he opened his museum in Leicester Square. In 1789, he is appointed Surgeon-General and Inspector of the Army, and he has a rather severe illness, accompanied with cerebral symptoms. The attacks of angina now become frequent; yet, in the year before he died, we find him printing his great work on the blood and inflammation; and he is at work framing a catalogue for his museum. So well did he know his dangers, that he used frequently to say "his life was in the hands of any scoundrel who chose to put him in a passion." The sudden death he had so truly predicted actually took place in St. George's Hospital, in 1793, when he retired from a meeting at which he had been opposed to die in an adjoining room.

Such was the life of Hunter, a life of infinite labour. Yet, what surprises us most is the immense amount accomplished in so limited a space of time. For the first twenty years cannot be counted as part of his mental life. This was a period of mental quiescence. Then followed ten years of arduous preparation, resulting in illness, and the rest of his days he works on with heroic fortitude, under conditions of health that would have determined any other man to have relinquished all ideas of fame and fortune, and to have retired to a life of rest and obscurity. During the last twenty years of his life he was subject to attacks of agonising angina, and no one knew better than he what dangers to life these symptoms foreshadowed. Yet, with a perfect knowledge that any sudden emotion might result in immediate dissolution, he labours on to the very end. Truly this was a courageous life, ending, like the soldier's on the battle-field, in heroic death. He might well have said, with Cæsar:

Cowards die many times before their deaths;
The valiant never taste of death but once.
Of all the wonders that I yet have heard,
It seems to me more strange that men should fear,
Seeing that death, a necessary end,
Will come when it will come.

Let us endeavour now to trace some of the distinguishing faculties of this master mind. In many qualities John Hunter resembled his elder brother, whilst in most he surpassed him. In both there was the same insatiable love of collecting, which was not confined to objects of professional or even biological interest, but extended to coins, pictures, armour, or indeed anything out of the common. In both there was the same industry, perseverance, and love of original research. In both we trace the same self-will and integrity, combined with a jealous determination to defend any encroachment upon supposed or actual rights. This jealous care over the fruits of their labours ends eventually in an estrangement between the two brothers, which is only healed when the elder is on the point of death. Much as it was to be regretted, it probably arose from the natural antagonism of the same qualities in each, rather than from any actual rivalry. Lastly, we find that the study of life and of death, with a view of benefiting their fellows, was the one overruling passion in the mind of each.

It may be an interesting speculation how much of John Hunter's genius was transmitted to him by his parents, and how much was due to the influence of his elder brother. I think we must recognise both these factors as contributing to his success. The close resemblance we have traced in many of the mental attributes of the two brothers indicates their origin from a common stock, as clearly, perhaps, as any resemblance in their features. It was the elder brother, William, who first discovered for himself

that the study of life was the direction in which his mind felt the greatest pleasure, and he had advanced far along the road of science before John attempts to follow him. But when once John is brought under his influence, he suddenly develops a thirst for knowledge which is in extraordinary contrast to his former indifference. It can only be compared with the inoculation of virgin tissue with some virulent poison, or, what we now begin to regard as a similar process, the fermentation of some minute fungus in its appropriate nidus. His love for scientific research grows into a raging lust, which governs his whole future, and causes him to sacrifice both wealth and health in its pursuit.

All here will easily bring to mind a parallel between two brothers now living and the two Hunters. I need not mention names, to remind you of an elder brother, distinguished in medicine, who has been more than equalled by a younger brother who has devoted his life to the science and art of surgery.

John Hunter married about the middle period of life, and had four children, two of whom grew to adult age, but neither of these left issue. Although Galton has attempted to trace hereditary genius, his observations would tend to show that it is more likely to make its reappearance in side-heirs than in the immediate offspring of great men. I have often thought it, a pity we cannot slip geniuses as they do rare plants and shrubs. The children of highly intellectual parents are too often the outcome of mental and physical exhaustion, and the race becomes weak, erratic, or extinct. Doubtless great cities, which are the hotbeds of intellect as well as of vice, are largely responsible for this degeneration. As Emerson puts it: "The city would have died out, rotted and exploded, long ago, but that it was reinforced from the fields. It is only country which came to town the day before yesterday that is city and court to-day." The proper children of great intellects are the intellects of their pupils rather than those of their flesh-begotten offspring. Traced in this way Hunter left many children, and his race has spread far and wide. It must never be forgotten that Edward Jenner was his most intimate friend and pupil, and the Hunterian mode of thought developed in Jenner led to the immortal discovery of vaccination. What inestimable benefits have accrued from this discovery by a child of Hunter may be gauged by the foolish opposition that immunity from small-pox has enabled agitators to develop against the Vaccination Act. I would the antivaccinators would take to heart *Punch's* parody on Hamlet:

To vaccinate or not?—that is the question;
Whether 'tis better for a man to suffer
The painful pangs and lasting marks of small-pox,
Or to bare arms before the surgeon's lancet,
And, by being vaccinated, end them? Yes,
To feel the tiny point, and say we end
The chance of many a thousand awful scars
That flesh is heir to, 'tis a consummation
Devoutly to be wished. Ah! soft you now—
The vaccinator! Sir, upon your rounds,
Be my poor arms remembered.

But not Jenner only, but Home, Cline, Astley Cooper, Abernethy, Travers, and Blizard were Hunter's intellectual descendants by direct contact, and they have handed on his teachings to those known in our own day.

What was there in Hunter's mind that made such great men his apostles, and led all subsequent generations of surgeons to regard him as a guiding star in surgery? If we inquire what improvement, that might be regarded as an invention, he added to the art of surgery? the answer comes at once: the Hunterian operation for aneurysm. Nearly every great surgeon devises one new operation, to which his name is apt to become attached; but if his reputation depended on this alone, how little would be his worth.

Hunter was the first to perform the operation for the cure of aneurysm by ligaturing the artery, on the proximal side, at a distance from the sac. Astley Cooper's name is associated with a bold attempt to ligature the aorta, but his reputation rests mainly on his philosophical work *On Fractures and Dislocations*. Lister's name is associated with a not very successful method of excising the wrist-joint, but his fame will be handed down by his scientific investigations for the protection of wounds from external influence, which resulted in the "antiseptic system." Even I, who do not deserve to be mentioned in the same hemisphere with such men, have performed one operation of which a small mind might be proud. I allude to a case of total suppression of urine lasting five days, which I relieved when the patient was *in extremis* by cutting down on the one remaining kidney, and removing a stone, which was plugging its outlet. This patient, two years and a half

after the operation, remains in perfect health. But such advances in operative surgery, though of importance to the world as tending to preserve life, will never alone serve to support a great reputation. Hunter was far more than a mere operation-inventor; though this, when it can be shown, to have been deduced from previous observations, is not a thing altogether to be despised. He was far greater than this. He was above all the greatest surgical philosopher that every lived. He was constantly searching for new facts, and adding to his museum preparations which acted as a kind of index to those facts; and from these facts, when accumulated in sufficient numbers, he deduced general laws. Thus he worked a revolution in surgical pathology, and he raised the science of surgery, from the doubtful position that it occupied before his time to a level with the sister science of medicine. Over what a desert the river of his thoughts has since flowed! How many diseases and deformities, then thought to be incurable, have since been brought within the range of surgical relief! The old lumber room filled with incurable diseases and misunderstood pathology, that was left to the care of medicine, has since been ransacked over and found to contain much that surgery could relieve or cure. Within our own time the kidney has become a surgical organ, the gall-bladder has had to yield up its obnoxious stones to the captivating influence of the surgeon's knife, the stomach and intestines, the lung, and even the brain itself, have in turn been brought within the range of surgery.

To aid us in our labours, two great discoveries have been made since Hunter's time; the introduction of chloroform, which makes operations painless, and the use of antiseptics, which renders them safe. But in spite of all the great advances made since his time, Hunter's name and Hunter's fame shine through them all. So far from detracting from the merits of his labours, they simply add lustre to his achievements. But we must not be deterred by the contemplation of his greatness from exerting such talents as we may possess in the humble sphere that we may occupy. Though it is allowed to few like Hunter to touch immortality on this side of eternity, yet let us take courage in the thought that there is nothing in Nature, however minute or obscure, that has not some power over its immediate surroundings. With this thought let me close my address in the words of a philosopher I have already quoted: "All things are engaged in writing their history. The planet, the pebble, goes attended by its shadow. The rolling rock leaves its scratches on the mountain, the river its channel in the soil, the animal its bones in the stratum, the fern and leaf their modest epitaph in the coal. The falling drop makes its sculpture in the sand or stone. Not a foot steps into the snow, or along the ground, but prints in characters more or less lasting a map of his march. Every act of the man inscribes itself in the memory of its fellows, and in his own manners and face. The air is full of sounds, the sky of tokens, the ground is all memoranda and signatures, and every object covered over with hints which speak to the intelligent."

CLINICAL LECTURES

DISEASES OF THE NERVOUS SYSTEM.

BY A. HUGHES BENNETT, M.D., F.R.C.P.

Physician to the Westminster Hospital; and to the Hospital for Epilepsy and Paralysis.

LECTURE IX.—SENSORY APHASIA.

THE manifold forms of aphasia have been variously classified by different authorities. The comparative claims of the diverse divisions of the subject it is at present unnecessary to discuss. It will be convenient in this lecture to regard the disorder simply from a dual aspect—namely, from the influence the sensory or motor elements of the nervous system have in its production. Intellectual language, taken in its broad sense, is the medium through which individuals intercommunicate. This may be effected in a variety of ways, but is chiefly carried on by means of speech, writing, and gesture. For the successful performance of these, a double attribute must exist: first, we have to appreciate and understand the indications given by our neighbours; and, secondly, we have in turn to convey our thoughts and purposes to them. As a knowledge of the former is derived through our senses, the collective phenomena involved in its production

may be called the ingoing, impressive, centripetal, or, in simpler terms, the sensory function of intellectual language. On the other hand, the latter, which, as a rule, is accompanied by the performance of a muscular act, may be named the outgoing, expressive, centrifugal, or the motor function of speech. Each of these sensory and motor functions is represented by a corresponding special nervous mechanism, which may become diseased and give rise to a characteristic disorder of speech, and which may, for convenience, be termed respectively sensory or motor aphasia. That form of aphasia which results from interrupted functional activity of the motor nervous elements includes disorder, not only of speech, but of writing and gesture; in short, of all those means by which an individual attempts to convey his wishes or thoughts to another. Each of these modes of expression is presided over by a complex system consisting of muscles, nerves, and centres in the cord, medulla, and cortex, which may be independently deranged, or lost, and, in consequence, aphonia, agraphia, or amimia, is induced. These varieties of so-called aphasia are of tolerably frequent occurrence; they are, as a rule, capable of easy recognition, and so many instances have been recorded in medical literature that their existence has been amply established.

The condition of what has been termed sensory aphasia is much more complex, and uncomplicated examples are of much less frequent occurrence. It is through the senses, and especially through those of hearing and sight, that the faculty of intellectual language is acquired, and by which it is organised in the individual. The association of the senses with the acquisition of speech is effected by certain nervous elements, including the organs of sense, various conducting media, and centres in the medulla and cortex cerebri. By sensory aphasia, therefore, is understood the results of interruption or disease of any of these centripetal paths or centres which induce an imperfect appreciation of language or its symbols, and which, as a consequence, may indirectly lead to disorder of the faculty of expression. In addition to the sensory organs themselves, and the complex nervous arrangements which connect them with the surface of the brain, there must be other and more extensive cerebral structures engaged in the acquisition or formation of speech. These supply what has been termed the apprehensive faculties, or the mental attributes involved in the process of human intercourse or communication, the exact nature and locality of which is not accurately determined. Therefore, on the sensory side aphasia may arise either from disease of the centres associated with the senses, themselves, and especially those of hearing and sight, or with a derangement of the nerve elements, whichever and wherever they may be, which preside over the so-called apprehensive faculty. This results in what has been termed respectively word deafness, word blindness, and word forgetfulness, or verbal amnesia, each being due to disorder of the special nervous mechanism which originates and regulates the corresponding function. Uncomplicated examples of these forms of sensory aphasia are rare; accordingly, I now demonstrate an illustrative case of each.

1. *Case of Word Blindness.*—G. L., aged 52, a shipwright. This patient complains of blindness to the right side of both eyes, and although on the left he can see fairly well, of inability to read or understand written or printed words. He states that his family history was unimportant, that he never had suffered from syphilis, and that he had always been a temperate man. For some years before he came under observation he had complained of indefinite pains in his lower extremities, accompanied with general malaise, neither of which, however, had incapacitated him from work. With these exceptions he was in all respects a healthy man till some twenty months before examination, when one day he suddenly fell down, unconscious, and remained so for about an hour. He did not know whether or not he was convulsed. Soon after this attack he regained his former condition and returned to work, but he fancied that his right side was weaker than before, and that his eyesight was not so good as formerly. He, however, continued at his ordinary occupation till five months before coming under observation, when he gradually became incapacitated from giddiness and slowly increasing inability to read.

On examination he is found to be a robust and healthy-looking man. The organs and functions are normal, except those about to be mentioned. There is nowhere any sign of paralysis or tremor, but there is a suspicion that the power of the right side is slightly impaired; but if this is so it is scarcely noticeable. Both knee-jerks are somewhat exaggerated, especially on the right side, and here also there is imperfect ankle clonus. Sensibility is everywhere normal. The vessels throughout are somewhat hard and

ortuous. Vision is stated to be defective. The pupils are equal and normal; there is well marked arcus senilis; the movements of the eyeballs are natural. Investigation shows the presence of well marked hemiopia in both eyes on the left side, and especially in the right eye, thus inducing right homonymous hemianopsia. (Circumstances unfortunately prevented a complete perimetric examination.) The discs of both eyes are somewhat grey and ill-defined, but the fundi are otherwise normal. The patient is very intelligent, and gives an accurate account of himself and his illness. He says that he thinks his memory is not so retentive as formerly, but of this there is no definite proof, as he seems to remember all the circumstances of his life, and to intelligently describe them. The articulation is distinct and natural, and there is no trace of thickness or hesitation in speaking. The patient expresses himself in language unusually apt for his station in life, his choice of words is that of a man of education, and his words are delivered with ease and facility. He is somewhat deaf on both sides, but this is due to a chronic catarrhal condition of the ears. When spoken to loudly he understands everything that is said, and responds by appropriate answers in a perfectly rational manner. The patient cannot read a single word of written or printed matter. This is not from inability to see, as he names all individual letters correctly, the vision on the left side of both eyes being fairly good. Although he names every letter without mistake, he is unable to tell or understand a single word, no matter how short, unless he spells it out aloud like a child learning its first lesson. For example, when shown the word "cat," he cannot read it, and does not understand what it means. When, however, he spells it out c a t aloud, he at once says "cat," and recognises the meaning of the word. The same occurs with all words of two, three, or even four letters. With longer words, when they are spelt out, he is doubtful and uncertain, and frequently makes mistakes in naming them. With very long words, such as "Constantinople" and "hippopotamus," although all the letters are read in turn, the patient gets confused, and either miscalls them, or altogether asserts his inability to name them. It may also be mentioned that he cannot even read his own name. This difficulty in reading applies equally to writing and print. The patient, although he cannot read a single word, can write a letter like any educated man, and his handwriting is excellent. He can spontaneously indite and write anything he desires with as much ease and facility as formerly. I asked him for example to write out for me an account of his case. He did so in a very intelligent manner, giving a fair history and description of his complaint, and did not make a single mistake. On showing him his own letter he is unable to read a single word of it, and can only make out the shorter words by spelling them over as he does with print. When asked to copy writing or print he does so with perfect accuracy, but very slowly, letter by letter. Printed letters he transcribes into written characters. He does not understand what he is copying unless he spells the word out loud. His writing to dictation is without fault. He can read figures correctly, and his powers of arithmetic are seemingly intact.

REMARKS.—This case is an example of pure word blindness, as, with the exception of the homonymous hemianopsia, the man may be said to have little else the matter with him. On the left side of both eyes vision is practically normal, so that the inability to read is not due to an ordinary defect in sight. The patient recognises and names individual letters with facility, but cannot understand or pronounce even the shortest words except by spelling them out aloud. While totally unable to comprehend written or printed language the remarkable fact remains that he can put his thoughts into writing without any difficulty, but immediately after he is unable to read a word of his own composition. In short, his intelligence is normal; he can express his ideas in speech and writing, and he retains the power of understanding spoken language and of recognising individual written characters, but he has lost the faculty of appreciating the meaning of composite symbols, and the visible signs of words fail to revive in consciousness ideas previously connected with them. As regards reading, he is in the position of a child who can speak and who can understand all that is said to him, who, while he knows his letters, has not yet learnt to recognise the smallest words, until he laboriously spells them out aloud so as to appeal to his sense of hearing. He is also like an ordinary individual in regard to a piece of music, who, while he may be able to see or recognise the name of each printed note, is unable, like a practical musician, to feel and appreciate the harmony at which he looks. The resemblance to the child and musician

is not, of course, in all respects complete, because this patient can express himself in writing, which neither of these could do. This case constitutes an interesting example of dissolution of the faculty of reading by disease, in which the most early acquired, and, therefore, the most highly organised, functions remain, while the later and less stably organised have been destroyed. As Dr. Ross aptly puts it, "In partial diseases of the nerve centres the latest evolved structure is the most liable to injury. The intruders to disease conform, both as regards structure and function, to the law of dissolution, the mode of invasion being from the complex to the simple, from the special to the general." This man recognises and names letters, the most highly organised symbols, while he does not know words, a faculty of later development, and, therefore, of lower organisation. While unable to comprehend the meaning of words by sight, he can, by spelling them out aloud, name and understand them, showing that he arrives at this result through his auditory and not through his visual faculties, probably translating the latter into the former. In many cases of word blindness, the power of recognising even letters is lost. Between this extreme and the case under observation are various degrees, still further illustrating the law of dissolution. I have a man at present under observation, who, in addition to other ailments, is completely word blind, with the exception that he can read only his own name and the letters which compose it. When a heap of letters are placed on the table he can pick out all the g's, e's, o's, etc., composing George Smith, and leaves the a's, b's, c's, and other letters of the alphabet untouched. In short, his name and the letters of which it consists are those which have become most automatic and most highly organised, and these are retained in his memory, all the others having been forgotten. The original patient under observation can express his ideas in speech and writing, and can write from dictation. When, however, he copies he does so letter by letter, without understanding what he writes. If, however, he spells out a short word aloud, he can then write it down with a full comprehension of its meaning. This further shows that he translates visual into auditory impressions; otherwise he only mechanically copies such letters, without having any idea of the meaning of the words which they compose. No better example could be given of the remarkable phenomena of an individual who, while able spontaneously to indite and execute a well-written epistle, a few minutes afterwards is unable to read or understand a single word of his own performance. In this case there is an absence of paralysis and all other objective symptoms except the homonymous hemianopsia. It is probable that the condition is due to interference in the function of the angular gyrus and its neighbourhood on the left side, or to that portion of the cortex in which reside the elements concerned in the acquisition of written characters. This has been partially interrupted, and hence, according to the principles of dissolution, while the knowledge of individual symbols in the form of letters is retained, the memory of their combination into words is lost. All the other faculties of intellectual language remain intact, which seems to show that the lesion is limited to this special centre. If the disorder was the result of a more diffuse partial disease, by the same law we should expect that writing, which is acquired later than reading, would have been affected the first.

2. Case of Word Deafness.—Sarah G., aged 55, complains of inability to comprehend spoken language and to make herself understood by speech. Her friends state that until seven weeks ago she had enjoyed excellent health, never having had a day's illness in her life, and that her family history was unimportant. One day about this time she slipped off the step of a tramway car in motion, and fell somewhat heavily on the ground. She was raised up, felt stunned and confused, but gave her name and address, and was carried home in a cab. An hour afterwards she could not understand what was said to her, although perfectly conscious of what was going on around, and her speech also was noticed to be unintelligible; otherwise she did not appear to be any the worse for the accident. Next day she got up, physically apparently quite well; but the inability to understand spoken language and to make others comprehend what she wanted by speech continued, and has remained so ever since.

On examination the patient is found to be in every respect a healthy person, with the exception about to be described. All the organs and functions of the body are normal, and there is nowhere any trace of paralysis. The superficial and deep reflexes are normal, so also is cutaneous sensibility. The special senses are as in health, and hearing especially is acute for all ordinary sounds. The patient cannot understand a single word of spoken language.

Her friends assert that they cannot get her to comprehend anything they say, but that she is very intelligent in anything which does not require language, and quick at giving and understanding signs. Since her accident, she has performed all her household duties as before, with the exception of being unable to comprehend what is said to her, and to make herself understood. If she wishes an article, she makes signs which are sufficient to indicate her wants. For example, if she requires an egg she produces an egg cup, and points interrogatively to its inside, and so on with everything else, and she is especially ingenious in making her desires known by pantomimic demonstrations. Her friends say that they cannot discover that she understands any single word spoken in her presence, not even her own name. On examination, I cannot satisfy myself that she comprehends any word. When told to do the simplest act, if not accompanied by any clue in the way of signs, the patient does nothing, looks puzzled, evidently understands that she is being asked to do something, and although anxious to oblige, fails to comply. The slightest hint in the shape of a sign is quickly interpreted. So great is her anxiety to succeed that she often does wrong things, simply because she fancies they are required. For example: asked to put out her tongue, she does nothing and looks puzzled; question repeated, the observer looking at the patient's mouth, the tongue is at once protruded. Asked to shut her eyes, the observer as before looking at the patient's mouth, the tongue is promptly put out, and so on with all other actions, proving that the patient does not comprehend words if they are not accompanied by gesture or some visual indication, which latter she is very quick to translate. If several objects are placed on the table, and the patient given to understand that she is to give me what I call for, she never, except occasionally by chance, hands the right one, if my back is turned to the articles. If I look at them, she often selects the right one, being, like the so-called thought reader, ready to interpret my glance towards the right object. In short, various tests all combine to show that the patient is incapable of understanding the meaning of any word spoken in her presence. The powers of reading and writing cannot be ascertained, as, unfortunately, this woman is uneducated, and has never been able to do either. The patient has no affection of her vocal or articulatory organs. She talks with the greatest distinctness and volubility, all the words themselves being properly pronounced and enunciated without the slightest hesitation or error. None of these, however, are *à propos*, but constitute an unintelligible jargon of meaningless strings of words, all rightly pronounced, but, taken together, signifying nothing. She is always ready with this voluble and purposeless torrent of conversation, and is constantly making attempts apparently to explain her wants, or to reply to questions which she does not understand. The following is an attempt to describe what takes place. Doctor: "How are you to-day, Mrs. G.?" Patient (with the greatest readiness, rapidity, and distinctness of articulation): "Yes, why should I not do, for really, you know, it could be." Doctor: "Are you a hundred years old?" Patient (with the utmost gravity): "Well but then I will so, for why it is. No. Yes." And this goes on *ad infinitum*. She also bursts out into long spontaneous floods of the same incongruous speech, in which she is evidently trying to explain something, and which often end by the woman bursting into tears. Although she does not know that the words she uses are wrong, she evidently appreciates the fact that she is incapable of making others understand her explanations, and is distressed in consequence. Not only is spontaneous speech lost, but the patient is unable to repeat a single word correctly when prompted to do so. As far as can be judged from the general demeanour, the patient seems to be intelligent, and she continues to perform all her household duties as well as formerly. Her friends say that, with the exception of not understanding spoken language, and inability to express herself in words, the woman is precisely in the same condition as before her illness, and my own observations coincide with this opinion.

REMARKS.—This woman, although retaining natural hearing for all ordinary purposes, seems to be a case of pure word deafness, the accompanying paraphasia, or inability to express herself intelligently, being the result, not of any impairment of the motor functions of speech, but the secondary consequence of incapacity to associate the sounds of words with their proper execution. The motor mechanism of speech is intact, as evidenced by articulation being in every respect normal, and because a large vocabulary of words is pronounced in a natural manner. These utterances, however, are not properly applied, and, therefore, constitute mere jargon. The patient evidently knows exactly what she

wishes to say, and in response to this desire articulates a copious flow of words, but she is incapable of applying them properly, and is ignorant of the fact that they are misapplied. Notwithstanding, as far as can be determined, the intellect is not affected, for although she cannot express her desires, and does not know whether her uttered words are right or wrong, she thoroughly appreciates the fact that she does not succeed in making herself understood, and shows corresponding signs of annoyance. A suitable idea is apparent to her mind, but, when spoken, it is replaced by unfitting words unknown to the speaker; the connection of thoughts with word images is so disordered, that, instead of appropriate terms, those of a totally different meaning are used. There is ample evidence to show that not a single word is understood by the patient, who, however, is very quick to appreciate and express herself by gesture. In pure motor aphasia the sensory side may remain intact, so that a person who cannot speak is able to comprehend what is said to him. On the other hand, when sensory aphasia exists, the motor side is, as a rule, secondarily involved, although in itself unimpaired, and paraphasia results, as in the present case. An individual who cannot understand spoken language must, as a consequence, be unable to speak it, because he is incapable of mentally recognising whether or not his efforts to do so are correct; hence the volley of words in response to a desire to speak, all of which are in themselves perfectly articulated, and constituting an extensive vocabulary, but in no way expressing the meaning they are intended to convey, the patient all the time being ignorant of her failure to succeed. Hence the inability to express thoughts in intelligible spoken language, and even to repeat words when required to do so. It is a disputed point whether in such a case as the present intelligence can remain intact. Abstract thought, it is maintained, is the outcome of language; and as this has usually been acquired through the auditory perceptions, if the organs of these are destroyed, internal as well as external speech must be impaired, and the faculty of thought interfered with. The congenital deaf mute possesses his faculties of thinking intact, because he has cultivated ideas and powers of reasoning through other sensory channels. With an ordinary person, however, when the auditory centres are suddenly destroyed, there have been no such opportunities for developing these accessory paths; hence the belief that abstract thought must in consequence be disordered. A decision on this point is one of great difficulty, especially in uneducated persons, as in the case of Sarah G. It can only be said that no evidence could be produced to show that the mental powers, so far as they existed, were in any way affected, and that, with the exception of her inability to understand and be understood, she performed all the duties of life as well as before her illness. As a person who is word deaf is sometimes able to understand printed or written language, there seems to be no reason why the reasoning faculties should not be exercised without the aid of internal auditory impressions, and be translated into some other sensory channels. It is also possible that the power of abstract thought having once been acquired may be retained, even without the use of words. In this case there is no paralysis or other objective complications, and, therefore, the lesion is probably a local one, involving those centres presiding over the faculties for the appreciating of the auditory perception of speech. These are believed to reside in the superior temporal convolution on the left side.

3. *Case of Word Forgetfulness.*—William H., aged 70, a distinguished divine and author. This gentleman belongs to a gentry family, and has himself had occasional slight attacks of that disorder. With this exception he has been in every respect healthy all his life. He has led a very active life, both physically and intellectually, and has been well known as a man of exceptional mental capacity. For some years past he has been supposed by his friends to have gradually become very "absent-minded" and "forgetful," and latterly this has reached a high degree, in the manner about to be described. His general health remains good, and his intellectual faculties are said to be in no way affected.

On examination the gentleman (for he is not a patient) is remarkably good health and vigour for his years. All his organs and functions are normal. His vessels are somewhat rigid and tortuous, but not to any great extent. Mr. H. is a highly-educated and intellectual man, and takes the greatest interest in his own case; and thus, although his powers of verbally describing his condition are limited, the main facts can be easily elicited by means of cross-examination. His chief, and indeed only, complaint is that he has forgotten the use of most words, and especially of nouns, places, persons, etc. From him it is elicited that

he considers his intellectual faculties to be as good as ever they were, and his reasoning powers to be intact. He can recall every object in his mind, but has simply forgotten the name of it, and of voluntarily reproducing it either in speaking or writing. Efforts, therefore, at spontaneous conversation or expressing his thoughts on paper are seriously impaired. Hearing and sight are as good as in most men of his age, and he understands spoken language and printed or written matter as well as ever he did. Although spontaneous writing is impaired, that to dictation is natural, and he copies with perfect ease; and his articulation and handwriting are perfectly normal. On attempting to read aloud his efforts are very imperfect, and words are mispronounced. The meaning of the text is understood, and he knows when mistakes are made. His difficulty consists in having forgotten his own language to a great extent, and he is exactly in the condition of a man who, having formerly been a proficient in a foreign language, has lost the art of speaking or writing it, although retaining the power of understanding it when reminded of it either by conversation or literature. In this way he cannot voluntarily repeat or write hardly any noun and many other words. He generally cannot tell his own name and age; not that he has forgotten them, but that he cannot recollect their verbal representatives. He has forgotten, as a rule, the names of his wife and children, and therefore, it need scarcely be said, of everything belonging to him. Many verbs and other parts of speech are also not remembered, and it may, therefore, easily be supposed that his powers of expressing his thoughts are very imperfect. This failure to express himself is always most marked when he makes the greatest efforts to remember anything, or when he is especially anxious to make himself understood. At other times, when listening to general conversation which he understands perfectly, he frequently joins in quite *à propos*, using appropriate language, in short sentences, as it were automatically, for, if asked to repeat what he has just said, he is unable to do so. For example, at dinner, the conversation being on politics, of which he is a keen follower, and to which he had been paying intelligent attention, he suddenly exclaimed, "We will never have peace till these wretched Radicals are kicked out." When pointedly asked what he had just said, he was totally unable to repeat it, although he perfectly recollected the nature of his remark, as evidenced by the fact that, when it was repeated to him, he acknowledged it to have been correct. In short, conversation with him is a slow, laborious, and roundabout effort to try and express himself, in which nearly every substantive and many adjectives and other parts of speech are left out. Not only are words not forthcoming at will, but, when produced involuntarily, they are often distorted, very much after the fashion of Mrs. Malaprop; of which mistakes, however, as soon as they are made, he is perfectly conscious. He might say, for example, "constitution" for "constituency," "illiterate" for "literary," and "phosphorescent" for "philosopher," and so on. Voluntary attempts to express his ideas are, therefore, so imperfect, either in speaking or writing, that the effort only makes Mr. H. annoyed and depressed, as he is perfectly conscious of his failure. For the most part he remains silent, and passes his time either in listening to the conversation of others, which he perfectly understands, or in reading books, of which he is an inordinate lover.

REMARKS.—This example of sensory aphasia is unlike the two others, inasmuch as the individual comprehends both spoken and written language, and has forgotten neither ideas nor things, but only fails to remember their names and the words which represented them. He is, in short, incapable of spontaneously reviving and reproducing by means of speech the thoughts which exist in his mind, but he recognises these when they are reproduced to him through his ear or eye. It is not an instance of mere loss of memory, because there is no evidence that either events or things are forgotten. All that is wanting is the spontaneous power of putting them into words. Although this exists to such a degree as to render voluntary conversation almost impossible, connected sentences and appropriate observations are often made involuntarily in conversation or under emotion, which same remarks immediately afterwards cannot be reproduced at the wish of the patient. If these are supplied by another person he can at once repeat them. Here the centres associated with the auditory and visual verbal mechanisms are apparently intact. There is a disorder of some higher structures in the cerebral organism, the failure of which prevents a spontaneous revival of names or words, although the ideas they represent remain. Here again it may be questioned whether an individual who cannot voluntarily

recall the names of things even in internal speech, can retain his full intellectual vigour and his power of abstract thought. In this case there is no positive evidence that either of these is in any way affected, and the patient himself, while perfectly conscious of his peculiar failing, maintains that his reasoning faculties are unimpaired, although the power of expressing them is so imperfect. As has been already stated, it would appear that ideas once acquired may remain independent of words, although, doubtless, without them, or some other form of sensory impression, they never would have been obtained. If not produced spontaneously, they can be revived both by spoken and written signs from without. The patient cannot think aloud, but silent thought remains. If any impairment of intellect or memory for things exists which is always difficult to determine, in such cases, it certainly is in no proportion to the loss of memory for words. Whether verbal amnesia can be localised is a matter of speculation, and we have as yet no positive information on the subject. The perceptive centre is probably a union of all the sensory centres. Perceptive conceptions and abstract thinking have all probably different levels of development, and degrees of directness, one or more of which may be specially affected. It might of course be maintained that the loss of memory for certain words is only the symptom of an incipient general mental failure. A study of these cases, however, suggests that the faculty of memory for words has some more or less special position in the cerebral hemisphere, and there is no necessary relation between its loss and that of intelligence.

WHAT IS A STONE IN THE BLADDER?

By SIR HENRY THOMPSON, F.R.C.S., M.B. LOND.,

Consulting Surgeon to His Majesty the King of the Belgians; Consulting Surgeon and Professor of Clinical Surgery to University College Hospital, etc.

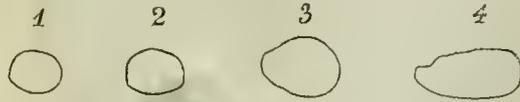

At a lecture which I gave at University College Hospital in November last on the subject of vesical calculus, embracing a sketch of the physical and chemical characters, frequency of appearance in regard of age, etc., I observed that it was becoming desirable to consider the question, "What is a stone in the bladder?" When there was only one method of removing it, and that by the knife, there was rarely any doubt in offering a reply; but with our present facility for removing small formations, the term is sometimes loosely employed. By way of endeavouring to define it in a sense which may commend itself to the judgment of surgeons generally, I suggested that we might still retain a practice followed by our predecessors, which may be thus expressed. Any calculus which can be by any means removed entire through the urethra, including one impacted therein and removed thence by the knife, cannot be admitted to rank as a vesical stone, nor can such an operation be regarded as one for stone in the bladder. And I added that for those which are crushed, only formations of a certain weight can be fairly described by the word "stone."

It was indeed for the express purpose of distinguishing the various small formations from "stone" that the terms "gravel" and "concretion" have been long employed.

I little thought, however, that so apt an illustration of my remarks would appear as that presented by a paper entitled "A Hundred Cases of Stone in the Bladder," by Surgeon-Major P. J. Frey, published in the *JOURNAL* of December 24th. I have purposely waited some weeks in the hope that someone else might raise this question, and I now write with much reluctance as a matter of duty, lest a precedent should be established which I think it is very undesirable to follow.

Among the hundred cases of stone thus reported, I observe no fewer than a dozen cases, the largest of which does not exceed 12 grains, and this not merely in children, for ten of them are adults. But what is more remarkable still is that a tiny concretion weighing only 2 grains is twice reported as "a stone" in the adult bladder, as are also two of 3 grains each, besides others of 4 and 5 grains respectively. Indeed, the total weight of the "stones in the bladder" for which in eight adult cases "the operation of lithotripsy" has been performed amounts to no more than 37 grains, an average of about 4 grains each, the total weight of the eight being only that of quite a small stone. Such tiny pro-

ducts are easily removed for the most part by washing out the bladder, from which indeed they usually escape spontaneously. I append outlines of the exact size of such concretions, scores of which now in my possession have been so removed, and which it has never occurred to me to regard or to report as cases of stone in the bladder. I may add that exact outlines present to the eye an idea of magnitude exceeding that conveyed by the body itself, as anyone may observe by placing one within the outlines given.

1. A concretion weighing 2 grains.
 2. " " " 3 " "
 3. " " " 5½ " (this is a rather flat one).
 4. " " " 7½ " (this is cylindrical, or nearly so).
 The largest measurement is of course given in every case.

Thus in my cabinet of calculi, now numbering about 950 cases removed by operation, with the history of each appended, there is not one weighing less than 20 grains, and I have never accepted or reported an example beneath that weight as a "stone." I have crushed many from that weight downwards to 5 or 6 grains, and had I so regarded them could report at least 1,100 cases instead of 950. I still venture to think that most of my brethren will agree with me that 20 grains is the very lowest weight, in the adult, the removal of which should be esteemed an operation for stone in the bladder. And in chronic prostatic retention cases, where the phosphatic concretions so frequently and so rapidly form, I have never recorded anything as a stone which has not reached at least half a drachm.

There is another aspect of the matter, too, which cannot be lost sight of. I think that it is very undesirable, from more than one point of view, to convey an impression to any patient from whom a bit of gravel weighing 2 or 4 grains has been removed that he has undergone an operation for stone in the bladder, and that the custom might give support to objectionable practice.

I beg to submit these remarks to the consideration of my professional brethren, in the belief that it is desirable to have some general understanding as to the meaning of the term in question, and to adopt, if possible, a uniform method in the employment of it in future.

CASE OF RAYNAUD'S DISEASE, OR SYMMETRICAL GANGRENE.¹

By J. W. F. SMITH-SHAND, M.D.,

Professor of Practice of Medicine, Aberdeen University; Senior Physician to the Royal Infirmary.

GENTLEMEN,—I must premise that the case I am going to bring under your notice to-night is that of a girl of excitable nervous temperament, of but moderate intelligence, and of questionable habits. Great difficulty has been experienced in getting an accurate account of the previous history, more especially with reference to the occurrence of "chilblains" and other points, for what she affirmed to-day she would contradict to-morrow. My examination of her always seemed to make her very nervous, particularly in the presence of students; and thus I asked Mr. Shirras, the house-physician, to undertake the narrative of the case, as I supposed she would be more at her ease with him. Consequently it is mainly to him that we are indebted for the following history.

J. A., aged 20, a servant, was admitted into the Royal Infirmary on May 24th, 1887, complaining of pain in the hypogastric and lumbar regions, with frequency of micturition, which symptoms, she stated, had been present for the last four days. Her appearance was striking, as the face was much flushed, the lips swollen, with the mucous surfaces of a purplish colour, and a general erythematous redness all over the body. The skin was moist, and the patient said her body felt hot. Her face was heavy and dull in expression.

Three hours after admission her temperature was 104°, respirations 40, pulse 125 per minute. On physical examination, heart

sounds normal, pulmonary percussion normal. On auscultation, breath sounds harsh. No cough or expectoration. Liver normal; spleen slightly enlarged; tongue dry and coated with white fur; great thirst; appetite bad; bowels confined. There was marked tenderness on pressure over the lumbar regions. Urine scanty, specific gravity 1030, acid reaction, dark yellow in colour, with sediment composed of lithates and pus; upper portion showed trace of albumen.

On the 25th the temperature was 104.4°, but, under the use of antipyrin, fell to 101.6° in the evening. As she said she was unable to pass urine, the ward sister used the catheter and drew off 42 ounces.

Twenty-four hours after admission she complained of great pain in the ears, and shortly afterwards symmetrical black patches appeared on the lobes, and after some time became filled with dark serum. Soon after this other black patches appeared symmetrically on each cheek and on the point of the nose. Still later, on the following day (26th), other symmetrical spots were seen on the face and neck, on the arms, hands, and legs above each knee. No patches appeared on the trunk, fingers, or feet. The largest patches were on the arms. The one on the right measured seven inches in length and three and a half in breadth; the patch on the left arm measuring five and a half in length and three in breadth. Before these patches appeared the patient complained of a severe burning sensation in the parts, which was greatly intensified on pressure. They appeared suddenly, and were of a very black colour; the margins were distinctly marked, there being no shading of colour. The surface of the patches was covered with moisture. After the patches appeared the general erythematous condition diminished very considerably.

For eight days the patches remained as described, but after that a reddish border appeared around them, and by the tenth day they began to shrink in length and breadth, and by the thirteenth day sloughing sores had formed on the arms, and were dressed with carbolic oil and enveloped in cotton wadding. The ulceration was quite superficial. The patches on the ears, cheeks, and neck shrank and disappeared, leaving a small thick crust, which gradually got smaller and dropped off, leaving on the left ear a certain amount of atrophy of the tissue. On the ninth day after admission the lumbar pain and frequency of micturition began to abate, the pus and albuminuria diminished, and by the eleventh day these symptoms had completely disappeared. Since then her only complaint has been of thirst, and pain when the arms were being dressed. The temperature ranged high for over three weeks, the maximum being marked on May 28th, when it was 104.6°. During the second week of her illness she had diarrhoea for several days, having five stools on June 3rd. The treatment consisted in giving ten-grain doses of antipyrin for the first three days every six hours, and afterwards a mixture containing arsenic and strychnine every six hours.

Previous History.—Patient, up to the age of 16 years, enjoyed good health, but since she first menstruated (when 17 years old) she has always suffered more or less from dysmenorrhœa and irregular menstruation; she menstruated last on May 7th. She told Mr. Shirras that she often complained of chilblains in the winter time, and suffered more or less from cold hands and feet. She denied this to me, but said that four years ago, when she was in the House of Nazareth, she, along with many others, had little red lumps about the size of pins' heads on her fingers, and that the nails cracked and came off, and at present the nail of the forefinger of the left hand is fissured. This winter she told me she suffered from cold hands and feet, and her hands were blue and swollen, but "not like chilblains."

On April 28th of this year she was admitted into the Infirmary under me, but during my absence from home, complaining of severe pain in the lumbar and iliac regions, and retention of urine. Mr. Williamson, then house-physician, considered this last symptom as hysterical, and refused to draw off her urine, and in a short time she passed it all right. At this time a bulla, about the size of a five shilling piece, developed on her left hand. It was very painful, containing at first clear serum, but rapidly becoming purulent. It was punctured, and in three days had quite healed; she was dismissed on May 7th "cured."

Under the date of July 4th I have to report that the patient says she is quite well, that the ulcerated surface on the left arm has been perfectly healed for the last three days, and that on the right arm there are now two ulcerated spots, one about the size of a sixpence, and the other being half an inch in length and half an inch in breadth.

RIGHT SIDE.

LEFT SIDE

REMARKS.—This is the first case of Raynaud's disease which I have observed, so-called after Raynaud, who made it the subject of a thesis in Paris in 1862, and who then brought together twenty-eight examples of this morbid condition. It has, as a result of this and of an article written by him in the *Dictionnaire de Médecine et de Chirurgie*, of late years been brought more prominently before the profession. But for many years previous to this isolated instances of this disease have been recorded in the medical journals.

From the special character of the symptoms it has also received the names of symmetrical gangrene and local asphyxia, and the opinion now held of its nature is that it is a neurosis due to vasomotor disturbance. At my first visit this was the view I took of the case before us, but I was at first inclined to believe that it had been brought about by some toxic influence—that the patient had been taking some drug such as belladonna, which had produced the great dilatation of the cutaneous capillaries; but she stated that she had been getting no medicine before admission, and when the gangrenous patches made their appearance, the nature of the disease then became apparent.

Notices of this affection are singularly rare in systematic works of medicine. Quain's *Dictionary of Medicine* gives three lines to it. It is not mentioned in Ziemssen's *Cyclopædia of Medicine*, beyond a short reference to gangrene from ergotism, a condition which it somewhat resembles, but in this case the nature of the patient's food did not allow of such an explanation of the symptoms. A good description of the disease is given by Dr. Allen Starr, in Pepper's *System of Practical Medicine*, an American work of great value. My case, however, differs in certain important respects from the picture there drawn.

It is there stated that while the disease commences suddenly in all cases, the local symptoms as a rule are more marked than the constitutional, and that these local symptoms begin with pains usually limited to the tips of the fingers and toes. These pains are commonly followed, and rarely preceded, by a condition of (1) ischæmia, (2) cyanosis, or (3) erythema.

1. Ischæmia. This first stage Raynaud described as the condition of local syncope, in which the fingers more frequently, and the toes more rarely, are involved, and look pale, shrunken, and dead, owing to the diminished quantity of blood flowing through the contracted arterioles. This condition may pass off in a short time, in which case the arterial spasm relaxes, and the parts resume their normal appearance; this change, however, being generally accompanied by a feeling of burning pain. But if this arterial spasm be of long duration, then the second stage of cyanosis is certain to be reached.

2. Cyanosis. This stage, Starr says, must result from one of two conditions; "either the arterial spasm is so complete that no blood passes into the part, in which case venous blood from lack of *vis a tergo*, or in response to gravitation, regurgitates into the capillaries, distending them and producing a state of blueness; or a venous spasm occurs, preventing the exit of blood from the part, which then becomes actively congested, and the blood in the capillaries, from want of renewal, soon becomes venous and produces the cyanotic appearance. This stage of local asphyxia may be of variable duration, from hours to days, and may terminate in a gradual return to the normal condition, but more usually it is followed by gangrene.

3. Erythema. Some doubts have been expressed by various observers as to this being a true stage, because it has sometimes been found to be of a more permanent character, while at the same time it is seldom followed by the death of the part.

The experience of my case, however, I consider warrants us in the conclusion that it is a true stage. This condition of erythema may be ascribed to a paralysis of the vaso-constrictors, or to an irritation of the vaso-dilators.

When the stasis of blood in the vessels has been extreme, this is followed by gangrene and death of the part, and the symmetrical manner in which this is brought about constitutes the special character of the disease. The most frequent site, as I have said, is in the tips of the fingers, the least frequent the arms. As a rule the gangrene is limited and superficial, although in rare cases the terminal phalanx of the fingers may be entirely lost. This gangrene, it has to be observed, is not dependent upon embolism or upon any diseased condition of the coats of the vessels, and as a rule is only noticed in the tips of the extremities, so in this respect also my patient forms an exception to the rule.

The constitutional symptoms consist of headache, mental depression or irritability, disturbed sleep and loss of appetite. Tem-

porary albuminuria, hæmaturia and glycosuria, have also been observed. Starr says that "fever never occurs as a symptom of the disease, and if present, must be ascribed to some other condition." Now, in my patient I could find no other condition to account for the quick pulse and high temperature, and I looked upon the latter symptom as being purely nervous, and solely due to irritation of the heat-regulating apparatus.

This brings us to a consideration of the nature of the disease. Raynaud believed it to be of central origin, while Weiss, a recent writer, considers it to be a reflex neurosis dependent upon any peripheral irritation. Certain it is that it is most common in young adults, in females rather than males, and that menstrual disorders have been observed in a large number of the female cases, while in one third of all the cases a recurrence of the disease has been found to take place within a year of the first attack.

Fearful as the appearance of my patient was at the height of the disease, so much so that the ward sister thought it impossible that she could recover, I yet gave a favourable prognosis, as no fatal result has yet been recorded, so far as I know, of a genuine case of the disease.

No special plan of treatment has been found beneficial, beyond general tonics, the occasional use of sedatives when pain is severe and when gangrene is present, using some antiseptic dressing, and raising the affected limbs well on pillows, while they are kept warm and enveloped in layers of cotton wadding.

ABSTRACT OF A LECTURE

ON

AMBULANCE WORK IN CIVIL

PRACTICE.

By RICHARD DAVY, M.B., F.R.S.E.

Surgeon to the Westminster Hospital.

GENTLEMEN,—There is scarcely a day passes in hospital or private practice without some special form of conveyance being required for our patients, either for convalescent or urgent necessity. Conveyance of a patient may be a very simple matter, as, for instance, the use of a stretcher or chair to carry him from one room to another, or a really complex undertaking, such as the transport of an enfeebled or injured man from one point of the kingdom to another, or from Great Britain to the Continent. I have endeavoured to practically overcome many of these difficulties, and have now the pleasure of explaining to you the construction of our hospital ambulance, which is the generous gift of one of our governors, the Rev. T. S. Echalaz, M.A., and which has been designed throughout by myself.

The woodcut will give you a good general impression of the carriage and a patient placed in it ready for transport. The carriage part of the mechanism, the stretcher, the cradle, and hood are all portable and easily detached, and will be described separately. The carriage part consists of four 26-inch iron wheels, supporting on springs two grooved bars firmly braced together on either side for the stretcher poles to fall into; these poles are fixed at any point by means of two clips, so that there is no danger of tilting, and the weight trimming is adjusted to a nicety. Four wheels have been used in this hospital ambulance, for the general advantage of the stretcher being ever safely on the wheels, and for the whole arrangement being used as a convalescent couch or airing vehicle. For my own use (and I have now superintended many hundreds of journeys) I have two wheels only; but, for careless or nervous hands, four wheels are safer than two; this, moreover, is the common experience of carriages in general. Remember that by proper adjustment this ambulance can be driven on two or four wheels, so the wheeled framework consists only of a sort of perambulator pattern, receiving the poles of the stretcher instead of the carriage body. The stretcher itself is so well known now as not to call for any full description; it consists of two hickory poles, two cross bars, and a sheet of red duck canvas; the two cross bars are of iron, and at either end have forged on

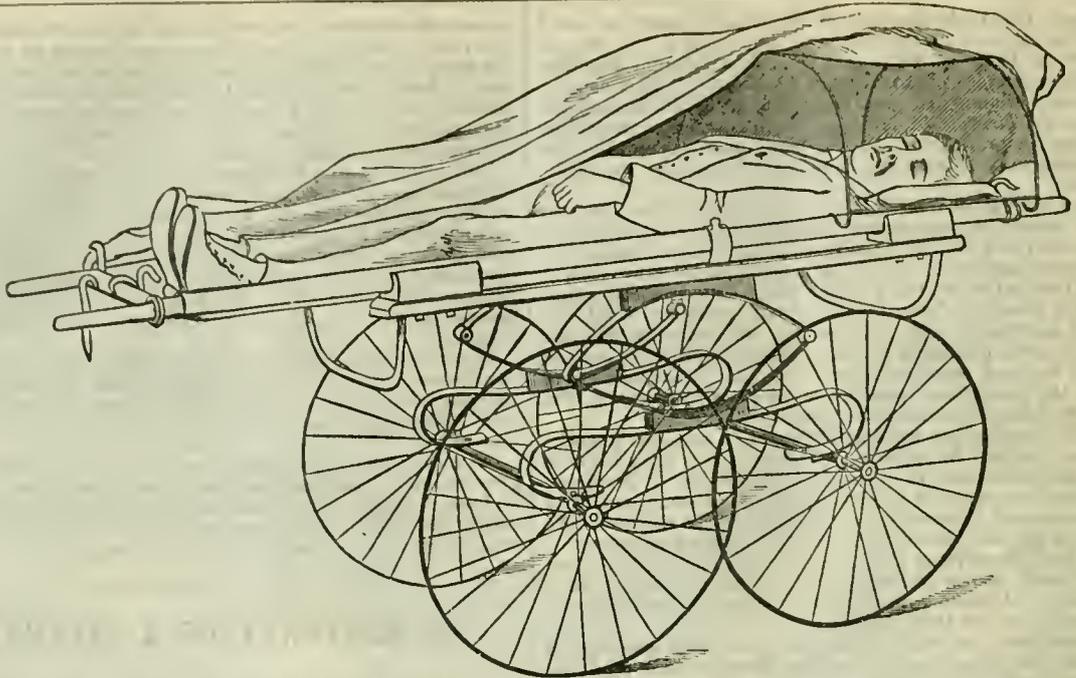

Fig. 1.

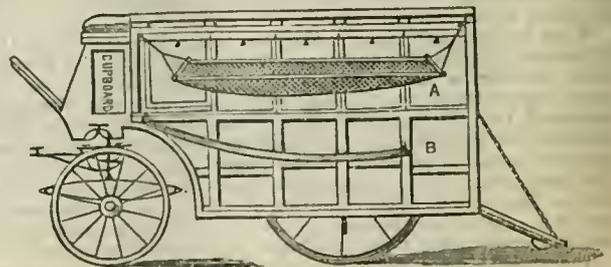

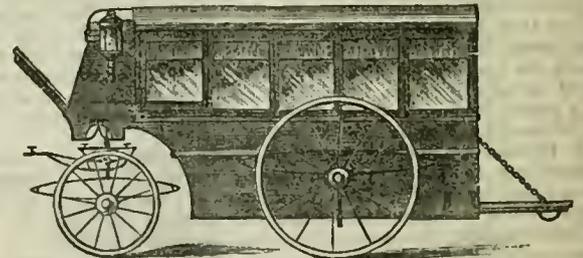

the suspending hooks. I have used this, my own form of stretcher, for fifteen years, and have never yet had any reason to distrust it; on the contrary, it has done hard work and very good service. The form of cradle here used is quite new, and answers well. It

fits on and upon the stretcher poles, and may be used either at the head or foot of the stretcher, thus giving support to the hood, and playing also the part of a surgical cradle in the event of a smashed head or broken leg. It is a wrought iron framework, and is well shown in the woodcut. The hood is made of canvas or waterproof; it rests upon the poles and cradle: its presence or not depends upon the state of the weather and the wishes of the patient. Its fashion also varies according to the taste of the surgeon.

Let me now suppose that a patient has to be shifted from our accident ward to Margate; and we will assume him to be the subject of a compound fractured thigh, knit, yet sinuses refusing to heal. Having seen that the whole machinery is in order, wheel the ambulance to the patient's bed; place him on the stretcher by rolling him on to it; then fix the stretcher poles to the framework of the wheels; put on the cradle and hood; then one porter can drive him to Victoria Station, another porter walking at his

Fig. 2.

side. On reaching Victoria, a guard's van—having had two hooks

driven by screw into the roof of the car—receives the stretcher carried by the two porters, and it is immediately slung up by two elastic cords, the patient himself being absolutely free from possibility of harm. Next wheel your four wheels into the same van, and let the porters go down with the man to Margate—the faster the better. At Margate the procedure at Victoria is reversed, the patient being driven from the station to his own home on the ambulance; the porters roll him off the stretcher on to his new bed; then pack up stores and return to Westminster with them.

But at this point let me put you up to a valuable hint. Many of our English houses are extremely small, especially about the staircase, which is frequently crooked and angular; no stretcher carried by two porters can pass—no chair of ordinary dimensions can pass, either. The means that I have successfully adopted is to make use of a good strong jaek-towel as a support to the patient in getting up these defiles, and its method of usage is shown in the woodcut. The carriage upstairs must be done with care; but the jaek-towel will twist a little, and that little makes all the difference.

By passing the loop of a towel across the patient's chest, beneath his arm-pits, he can be securely bound to the back of the leading porter; generally speaking there is no fear of falling, but far more of any blow or injury to the leg in passing corners.

This woodcut shows my hammock van and stretcher slung within; it has now run over most of our lines of railway—the wheeled ambulance can easily go inside the horse ambulance.

At the present time much inconvenience results from the surgeon having to make special arrangements with each railway company over which the van has to pass. I look forward with pleasure to the time when all our public railways will be handled by one superintending power; and that power should be the Government.

I have every reason to speak in praise of the principle of suspension as applied to the transit of invalids, and I entirely disagree with what Mr. John Furley stated at the meeting of the St. John Ambulance Association, that the patient's bed should be a fixture, for though there may be individuals who object to any swinging motion, yet in cases of necessity this objection ought to be overruled by considerations of far higher moment, namely, the actual safety of the patient and the prevention of further injury to a part already injured. An attendant by the side of the suspended patient during a railway journey is the best agent for overcoming any undue oscillation, the touch of a gentle hand being lighter than the restraint of fixed elastic cords.

It is a humiliating reflection that in civilised Great Britain property receives more consideration than human life. There is no court of criminal appeal, although trivial disputes may be carried from court to court. Ship cargoes are heavily insured, but not the crew who man the ship. Furniture is most carefully removed, but, until lately, no regard was given to the removal of an invalid. I have endeavoured to practically refute this last accusation, and commend ambulance work to your notice, as being one worthy object of your high professional training.

ABSTRACT OF

A PAPER ON THE RELATION OF THE MEDICAL SCHOOL TO THE HOSPITAL.

Read before the Hospital's Association at their meeting in the Board-room of St. George's Hospital, February 8th, 1888.

By TIMOTHY HOLMES, F.R.C.S.,

Consulting Surgeon to St. George's Hospital.

AFTER apologising for appearing on a short notice to fill a vacancy left by Dr. Gilbert Smith, who was to have treated this subject, but had been prevented by illness, Mr. Holmes went on to observe that a hospital might be regarded in various aspects:

1. As a body of governors, to regulate and administer the whole institution; and he endeavoured in this connection to show how great assistance the authorities of a school can give, from their intimate knowledge of all the arrangements and their direct per-

sonal interest in their success, and consequently how important it is that teachers and other qualified members of the school should be admitted on terms of equality to a voice in the management of the hospital, and showed from the experience of St. George's what good results follow from this plan.

2. Looking at the hospital in its financial aspect, he insisted on the great aid which a good medical school gives in the way of providing subscribers and procuring donations and legacies, instancing on the latter head the splendid bequest made to St. George's by Mr. Atkinson Morley on account of his old connection as a pupil of the school. On the other hand, the medical school assists the hospital materially in obtaining efficiency by well-considered expenditure in all departments. This does not necessarily mean saving money. It may involve increased expense, as in the recent great increase in the cost of surgical dressings; but if this increase is accompanied (as has been the case in that instance) by a diminished mortality, it is true economy.

3. Regarded as a body of medical officers engaged in treating the sick, the hospital derives the greatest benefit from the medical school. The school keeps alive the *esprit de corps* by which one hospital is stimulated to surpass its rivals, if possible, in medical progress, and one part of the country to try and outstrip another, and to this healthy competition much of the extraordinary activity and success of the British school is due. The intimate acquaintance between members of a staff who know each other as teachers, fellow-students, and pupils is also a great advantage to the patients; and, again, the necessity for clinical instruction is a great benefit to the sick. The idea sometimes entertained that the presence of students in the wards is one of the drawbacks of a hospital was combated, and it was, on the contrary, contended that the need for clinical instruction, by compelling the attention of the physicians and surgeons to the patients, greatly improves their prospect of recovery.

But though a school ought to be able to supply to the hospital the great bulk of its medical staff, yet it ought not to be a "close borough," but should be ready on proper occasions to recommend to the governors persons from outside if their election would promote the good of the hospital.

4. Looked at as a place for the study of the medical art, the hospital derives still more important aid from the school. The great advances which have been made of late years both in medicine and surgery have been secured for the most part by the co-operation of many men working together in the same school, and many schools working together in testing theories by practice, and this is especially true of the progress of pathology, which is the basis of all improvement in medicine, and which promises such brilliant results in the near future.

5. A hospital ought also to be the centre of the medical charities of its district, to which such institutions as poor-law infirmaries, dispensaries, fever hospitals, and lunatic asylums should be affiliated or connected; but this idea has not yet been realised. If it were, the aid of the junior practitioners and students of the school would be most important, and they would in return obtain experience of kinds of practice not at present well illustrated in hospitals.

Again, the out-patient department is most important to the school and the hospital to it. The main object of the reforms proposed in this department is to make it more efficient both for the use of patients and the teaching of medicine; and, on the other hand, the need for teaching is a great stimulus and assistance to the medical officers in charge of out-patients. And here also a medical school, so far from being a nuisance or a disadvantage, is a very great benefit to the patients.

These being some of the advantages of the school to the hospital, they are required on behalf of the hospital by the indispensable service of providing the school with its whole material for clinical teaching, and this should be provided as freely as possible; that is, no class of disease should be excluded which can be admitted with safety to the patients, and the pupils should have the freest possible admission to the wards consistently with the regular service of the hospital and the comfort of the patients. But it seems doubtful whether the hospital is justified in undertaking any expenditure on behalf of the school, such as is involved in the erection of premises. The great principle seems to be that the governing body of a hospital should accept the teaching of medicine and the presence of students working in the wards as a great benefit both to the institution and to the individual patients, and endeavour in all legitimate ways to encourage both the one and the other.

THE BEARING OF ALBUMINURIA ON LIFE ASSURANCE.

By F. DE HAVILLAND HALL, M.D., F.R.C.P.,
Physician for Out-patients, Westminster Hospital.

SINCE Dr. Grainger Stewart read a paper before the Royal Society of Edinburgh, in June last, on the discharge of albumen from the kidneys of healthy people, the attention of the profession has been directed to this important subject. I would suggest that before the word "healthy" be inserted "apparently," so that the sentence would run: "the discharge of albumen from the kidneys of apparently healthy persons." It is, I think, begging the question to call persons healthy who are passing albumen; and I gather that this is also the view of Dr. Stewart, as in the report of the meeting in the JOURNAL for June 11th, from which I get my information, he is said to have arrived at the following conclusion, amongst others: "That there is no sufficient proof that albumen is normally discharged from the human kidneys."

The point, however, to which I wish to direct attention is the bearing of albuminuria on life assurance. The question at once arises, Are medical officers to life assurance companies justified in rejecting or referring all applicants found to be passing albumen? I am distinctly of opinion that at the present time there is not sufficient evidence before the profession to allow of any answer except an affirmative being given to this question. If Dr. Saundby could give us the result of his experience of the last ten years a little more definitely, it would make a good commencement.

The only attempt with which I am acquainted to follow up in a systematic manner the after-history of cases of albuminuria is that made by the medical staff of the United States Life Insurance Company in their annual reports to the board of directors. Struck by the fact that nearly 10 per cent. of all the deaths of policy holders in their company occurred from Bright's disease, an examination of the urine was required in the case of each applicant. In the first year, twenty-four cases of albuminuria were detected. "In each the heart and lungs were found to be normal, and nothing could be learned from the past history to lead to the suspicion that albuminuria existed; furthermore, the physical appearance in every case (with, perhaps, two exceptions) indicated a healthy condition. Each one considered himself in perfect health, and really appeared as if he were. They were all excluded solely on account of albuminuria, and formed 11 per cent. of those presenting themselves to me for examination. In nearly every case two or more specimens taken at different times were examined and albumen found in each." A similar procedure was adopted in 1879, with the result that nineteen cases, or 12 per cent., and in 1880 twenty-six cases, or 10 per cent., were found to be suffering from albuminuria.

In his concluding report Dr. Munn sums up his experience of the 69 cases as follows: "In view of the fact that four of the number have died, and that the general appearance of the majority of those who have been under observation for more than one year is gradually deteriorating, I am led to believe that albuminuria should be regarded as of grave significance. In some cases, however, it may be of slight importance, and further research may possibly enable us to discriminate between them."

The reports are accompanied by tables recording the occupation, age, weight, height, frequency of pulse, amount of albumen, presence or absence of casts in each case.

In favour of the line of action that I am recommending, namely, that persons suffering from albuminuria should not be accepted, is the fact that the vast majority of applicants for assurance are examined some hours after breakfast, so that those cases in which albumen is only found immediately after that meal would not be excluded from the benefit of life assurance.

In analysing Dr. Stewart's tables contained in your issue of October 15th—and I only take into consideration Tables II, III, and IV, the other tables, embracing children and scarlet fever patients, having no practical bearing on the assurance aspect of the question—I find that, of cases of Bright's disease (including those probably due to Bright's disease), in forty-nine instances the albumen was detected by nitric acid, and in five instances by picric acid only; grouping all the other conditions giving rise to albuminuria together, in forty-seven instances albumen was detected by nitric acid, and in twenty-eight instances by picric acid only;

therefore if picric acid had been dispensed with, five cases of Bright's disease would have been overlooked; but on the other hand, twenty-eight instances where there was no evidence of organic disease of the kidneys would not have been included in the category of persons unsuitable for assurance purposes on account of renal disease. Using nitric acid only, forty-nine cases were referred to Bright's disease and forty-seven to other causes. The outcome of this analysis is that in more than half the cases, in which albumen was detected by cold nitric acid Bright's disease was the cause. I am therefore of opinion, as I have already stated, that medical officers to assurance companies should not recommend cases of albuminuria for acceptance where the albumen has been detected at mid-day or in the afternoon, on boiling the urine, or by means of cold nitric acid. From an assurance point of view I think it would perhaps be better not to employ picric acid, as otherwise fairly good lives might be excluded.

Before concluding, I must express my admiration of the able manner in which Dr. John Munn, one of the medical officers to the United States Life Insurance Company, has drawn up his tables, and of the very careful directions he gives for examining the urine.

CLINICAL MEMORANDA.

A CASE OF "QUINTAN" AGUE.

Mrs. B. M., a widow, aged 46, consulted me in October last. She was suffering from an attack of ague, which had commenced in the preceding June. The symptoms were very typical, the cold, hot, and sweating stages being well marked. The temperature rose during the cold and hot stages, reaching 105° F., and fell during the sweating stage, being normal during the intervals. The spleen was slightly enlarged, the other organs normal.

The most interesting feature of the case which leads me to record it was the rare interval between the attacks, namely, four days. I have consulted most of the books dealing with malarial diseases, but find that, while they all mention the ordinary types—quotidian, tertian, quartan, and the double varieties of these—none of them mention what may be called a "quintan" type, in which the interval was four days. Another interesting point was that a spot about the size of a shilling, near the tip of the tongue, became pale, cold, and anæsthetic during the height of each attack, and was accompanied by an eruption of herpes on the inside of the lips and cheeks. Those symptoms subsided during the interval, to return afresh on the fourth day, with the next paroxysm of ague.

At the Plymouth and Devonport Medical Society, on December 12th, Dr. W. H. Pearse said that in India herpes and ague sometimes alternate, but in this case they occurred concurrently. The patient had been in Massachusetts, U.S.A., in her youth, but does not remember having had ague there, but may possibly have forgotten, as it is twenty-six years since she returned from that country. There is a large swamp adjacent to her residence, which was lately in process of drainage, and the drying of this under the intense heat of last summer was probably responsible for the malarial infection.

I put the patient on treatment by quinine, which produced an immediate improvement. The next attack was much reduced in severity, while the one following that was only represented by a slight rise of temperature, headache, and malaria. After this all the symptoms disappeared; the spleen decreased in size; she had no return of the herpes or anæsthesia of the tongue. Her general health also rapidly improved, and I had a letter from her shortly before Christmas, in which she stated that she felt in better health than she had done for several years.

Dublin.

JOHN P. HENRY, M.B., B.Ch., T.C.D.

A CASE OF MELANCHOLIA PRESENTING SOME EXCEPTIONAL FEATURES, PROLONGED REFUSAL OF FOOD, AND FORCED ALIMENTATION.

INTEREST attaches to cases of melancholia of the kind here reported owing to the relation which they bear to, and the light which they tend to throw upon, the cause or causes in operation which sometimes lead to prolonged fasting in so-called "fasting girls" and others; for I may at once say with regard to this case, before entering upon any details, that, as a result of delusion, no less than 123 days have elapsed since food or nourishment of any

kind has been partaken of voluntarily, or without resistance; forced alimentation has been necessary to sustain life during the whole of that period, and the determination to refuse all sustenance remains to-day as firm as it was 123 days ago.

The patient in question is a young lady, aged 25, unmarried; she was pale, thin, exhausted, sad, and taciturn when she came under my care in August, 1887; at that time, when asked to take food or nourishment, she placed her hand firmly upon her mouth, clenched her teeth, and tightly compressed her lips, thus clearly indicating her very fixed resolve not to do so; the pupils were dilated, there was hysterical quivering of the upper eyelids, the pulse could scarcely be felt at the wrist; the tongue, teeth, and lips were dry, and thickly coated with sordes; the breath was very offensive, and of that peculiar odour which indicates prolonged abstinence from food.

The attack of mental disease was described as the first, and was of sixteen days' duration. Suicidal and dangerous propensities existed, and no food had been partaken of for eight days. The reasons for this abstinence were found to be beliefs on her part that she had been directed by God to abstain from taking all food. Finding that it was quite useless to try to induce her to take food, and it being absolutely necessary that the process of nutrition should be recommenced without further delay, forced alimentation was resorted to, and, as already stated, it has been continued daily since, the three hundred and forty-fifth feeding in succession having been performed this day. Exhaustion had, however, already proceeded so far, and the strength was already so much reduced when this was begun, that it was feared for some time that she would sink; the pulse rose to 120 or more; the temperature also rose to 102°. She lay motionless and torpid, and as if in a trance; respiration, however, continued normal; there were marked pallor and prostration, also a staturesque condition, but without the muscular rigidity or catalepsy so often observable in such cases; neither was there the usual stupor accompanying melancholia of this description; the intellectual faculties were apparently perfectly clear.

During the progress of the disorder menstruation has been altogether absent; the calls of nature were not attended to, diarrhoea also was persistent for a time, but was relieved by the usual medicaments, and alteration in the diet as forcibly administered.

The present physical condition may be described in a few words. The strength is well maintained, the patient has gained in weight, the pharynx and œsophagus are free from congestion or tumefaction, the tongue is clean and moist, the mucous membranes are generally quite healthy in appearance, the breath is free from offensive odour; the delusions still continue, but I am disposed to form a not altogether unfavourable prognosis; with improving nutrition and brain-rest a change of ideas will come, it may be suddenly, but more probably there will gradually be a return to mental health.

THERAPEUTIC MEMORANDA.

ALARMING SYMPTOMS PRODUCED BY SPRAYING THE THROAT WITH COCAINE.

DR. MCNEILL WHISTLER'S note on cocaine reminds me of the following history which I lately had from the patient and her husband, both persons of great intelligence. The lady, middle-aged and stout, but otherwise healthy, had been prescribed a spray of cocaine (2 per cent.) for "irritability of the windpipe and cough." The solution was made up abroad, and there is some doubt as to the strength actually used. She sprayed heavily for the first time about 5 P.M. for about a quarter of an hour. The symptoms then commenced, with coldness and numbness of the tongue, weakness of the lower limbs and staggering, mental distress and great depression from the very first. Her husband states that she was unconscious before 9 P.M., and remained so more or less until 2 A.M., but she says that she had glimmerings of consciousness most of this time, although she could not articulate, thought there were strange objects in the room, and feared lest anyone should speak to her. Great prostration followed, and I am told it was some weeks before this lady regained her usual strength.

Strathpeffer Spa, N.B.

OPHTHALMOLOGICAL MEMORANDA.

ANÆSTHESIA DURING STRABISMUS OPERATIONS.

MR. EDGAR BROWNE, in the JOURNAL of December 10th, describing an ingenious irrigating strabismus hook for producing local anaesthesia in strabotomy, says, "squint operation, even in nervous, frightened children, can be done painlessly."

Mr. Lloyd Owen, in the JOURNAL for December 24th, described a method by which the same effect can be accomplished very well without this special instrument, saying that by this means "the operation can be completed painlessly"; while Mr. Priestley Smith, in the JOURNAL for January 14th, explaining another very good means by which local anaesthesia by cocaine can be induced, says with a nearer approach to accuracy that the operation can, thereby be performed "in most cases without pain."

In my experience, while cocaine does abolish the pain caused by cutting the conjunctiva, and even the actual division of the tendon, I have not found it suffice to annihilate the very unpleasant sensation, I might say pain, occasioned by stretching the tendon with the hook, which, if the patient is unruly, may be considerable, and become very inconvenient to both the surgeon and the patient. I have, therefore, since cocaine was introduced, in addition to using it, administered nitrous oxide gas as well for this operation; by this means all the early steps of the operation, rendered painless by the cocaine, can be performed before complete anaesthesia by the gas is reached, the drawing forward of the tendon on the hook, and its division, being reserved for the stage of complete nitrous oxide anaesthesia which lasts long enough to complete this part of the procedure in comfort.

Having employed this plan frequently for the last three years, or so, I can strongly recommend it for this operation, the patients requiring which are so many of them of tender age. My chief object in writing is to draw the attention of my colleagues to the use of an anaesthetic which, I fear, is not generally sufficiently appreciated except by dentists, and which I have found valuable for many short operations, especially when assisted in this way by the local effects of cocaine.

In conclusion, I would say that I hardly think any plan of applying cocaine locally will be found to anaesthetise the whole of the internal rectus, running back as it does to the apex of the orbit—I am, etc.,

REPORTS

OF

HOSPITAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN, IRELAND, AND THE COLONIES.

GENERAL HOSPITAL, MADRAS.

(Cases under the care of Brigade-Surgeon SIBTHORPE.¹)

CASE I.—*Large Collection of Urethral Calculi; Operation: Recovery.*—A thin, slightly anæmic native Christian, domestic servant, of intemperate habits, aged 35, was admitted into the General Hospital on May 24th, 1887. He stated that twenty-one years before admission he had gonorrhœa, which was cured in the course of about six weeks; that he enjoyed fairly good health till about six years before admission, when he contracted a second attack of gonorrhœa, which was followed in twenty days by a bubo in each groin, together with a sore in the meatus urinarius externus. This sore gradually affected the whole margin of the opening, and was followed by some cicatricial contraction of the orifice, which steadily went on to complete closure, and led to formation of a urinary fistula just behind the meatus, through which he had since been passing urine with great difficulty. Five years before admission he began to pass gravel in his urine, accompanied by severe pain over the region of the bladder, and feverishness; he continued to do so for a month; during this time he suffered occasionally from symptoms of cystitis and renal colic. He had never since passed gravel; but, on the other hand, he had noticed a swelling near the root of his penis, which had gradually enlarged. Ever since the appearance of this swelling the act

¹ These three cases were reported at the meeting of the South Indian Branch, on September 2nd, 1887.

of micturition had been attended with great difficulty and straining, to overcome which he had been in the habit of pressing the swelling downwards and backwards with his fingers during micturition.

During the five years before admission, after any unusual exertion or excess in eating or drinking he had been subject to slight febrile disturbances, attended with pain in the hypogastric region, pain during micturition, passage of blood and mucus in the urine, and occasional attacks of renal colic. When admitted he was passing urine seven or eight times in the twenty-four hours; there was pain and tenderness on pressure over the hypogastrium, and scalding during micturition; blood was not then passed in the urine, which was opaque-yellowish, slightly turbid, the turbidity being unaffected by heat; reaction was alkaline; there was no albumen. The deposit under the microscope showed amorphous and crystalline phosphates and mucus cells. The size of the stream of urine was narrowed, the urine sometimes coming away in drops. There was a pyriform tumour, the size of a lime, underneath the root of the penis, situated a little to the left side; it had the peculiar feel of the crop of a bird, due to small calculi having collected and distended the lower urethral wall into a sac; there was some degree of tenderness on pressure over this sac. On sounding the urethra, two strictures were detected, one at the false meatus and the other two inches and a half from it, the former admitting a No. 6 silver catheter and the latter a No. 1. No instrument could be passed beyond the seat of the gravel sac.

May 27th. The patient having been placed under the influence of chloroform, both strictures were divided by means of a *bistouri caché*, and a No. 8 silver catheter was passed into the bladder. An incision two inches and a half long was then made over the gravel sac antero-posteriorly; the sac was opened and the gravel removed. The superabundant portion of the sac wall was removed by scissors, and the bladder was washed out. The edges of the wound were brought together with four harelip pins, with silk sutures twisted over them in a figure of eight. The parts were dressed with lint soaked in perchloride lotion. The sac wall was about one-eighth of an inch thick; the opening by which the sac communicated with the urethra was a large one. The calculi, numbering about eighty, varied in size from a pin's head to that of a tamarind seed. They were sharply angular, and finely polished, of hard consistence; on analysis, they were found to consist of uric acid, phosphates, and organic matter.

He recovered well from the effects of the chloroform, and was quiet during the day. In the evening the temperature rose to 101° F. At 5 P.M. he passed his urine in the knee-elbow position. Some urine escaped through the wound; the bladder was washed out with warm perchloride lotion at 5 P.M.

May 28th. He felt better; the temperature had come down to normal. The bladder was washed out.

June 5th. He passed fifty-six stones similar to those which had been removed through the wound.

June 6th. The temperature had been keeping normal; the wound was looking clean and granulating; there was some dribbling of urine through it; there was no discharge from the wound. Urine was slightly cloudy.

June 10th. The wound was healing; there was dribbling of urine still through it; he passed urine four or six times in the twenty-four hours.

June 11th. The urine was almost clear, with only a slight deposit of mucus at the bottom of the glass. There was no difficulty or pain during micturition. Some urine still dribbled through the wound, especially when he micturated in the sitting or in the erect posture. The silver catheter which was tied in since May 27th was removed, and the bladder washing stopped.

June 14th. For the last three days the urine had been turbid with a heavy deposit. He passed his urine four or six times in the twenty-four hours. The wound was contracting.

June 12th. He had passed about 100 pieces of gravel of varying sizes, similar to those he had passed on June 5th; he passed ten more on June 10th and five on June 14th. These came away mostly at night through the scrotal wound, unaccompanied by any symptoms.

On June 25th a No. 7 silver catheter was passed, and on June 30th there was no dribbling through the scrotal wound, which was contracting. He retained the catheter without any trouble.

August 23rd. The urine continued quite clear. No calculi had been passed since June 14th. The urine occasionally dribbled through the scrotal wound, especially when he strained in defæca-

tion. The wound had contracted to about a quarter of an inch, but showed no further tendency to contract, and seemed to be unaffected by stimulating injections.

A No. 8 gum-elastic catheter had been retained and renewed every week, to prevent the contact of urine with the wound, but without any effect.

August 24th. An attempt was made to close the opening by the following operation: he was chloroformed; a No. 10 silver catheter was passed, but met with some obstruction at the seat of the second old stricture; this was divided with a *bistouri caché*, and the catheter was passed into the bladder. The edges of the wound were freshened with a scalpel and brought together with silk sutures; a No. 10 gum-elastic catheter was tied in. The next day the sutures gave way on account of the impossibility of preventing the contact of urine with the wound. No constitutional disturbance followed the operation, the sutures were removed, and the catheter retained.

September 1st. The edges of the wound had healed, leaving the fistula open. He insisted on going home, as he was satisfied with the result.

REMARKS BY BRIGADE-SURGEON SIBTHORPE.—A very interesting and an unusual case, for the notes of which I have to thank Civil Apothecary Rama Row, L.M.S.; such a collection of gravel in a sac formed from the walls of the urethra behind a stricture is rare. It was difficult to say where the stones came from which he passed subsequently to the operation, for the sac was completely cleared out and its walls removed; he has had no symptoms of calculi in the bladder, nor have any been detected in it, though it has been sounded on several occasions. There is little chance of closing the opening in his urethra, which rendered him impotent. Another attempt would have been made if he had consented.

CASE II. *Congenital Sebaceous Cyst*.—A young, healthy, muscular Hindu (Malayalee), from near Palghaut, was admitted on July 30th, 1887. He stated that the tumour existed at the time of his birth, and had gradually grown till two months before admission, when it had attained the size of an orange; since then it grew more

rapidly. The tumour, which was of the size and shape of a large cocoon, was soft, fluctuating, elastic, and painless; it could not be moved on the cranium, and pressure on it caused no distress; the scalp over it was reddish, shining, and somewhat hot to the touch; two large tortuous arteries could be seen, one on either side of it; it measured fifteen inches in circumference at its roots, and twelve inches from before backwards in the middle line. After exploration it was removed on August 3rd, about a third of the distended skin being taken with it; it was found impos-

sible to take away the sac without opening it, the wall being so thin; it was closely attached to the pericranium; its contents consisted of the usual putty-like substance, full of short hairs and a quantity of dark greasy fluid full of fat cells. The operation was performed under strict aseptic conditions; the hemorrhage gave but little trouble, and the wound, was dressed after the method of Sir Joseph Lister. He made a good recovery, except for a curious attack of inflammation of the glands of the neck attended with fever, which came on suddenly, and without any apparent cause, on August 6th, and left him on the 9th. During this attack the wound was perfectly aseptic, and free from any sign of inflammation. He left the hospital on August 25th with the wound completely healed.

CASE III. Impacted Intracapsular Fracture of the Left Femur.—A young and healthy-looking Hindu horse-keeper, aged 16, was admitted on August 16th, complaining of pain in the left hip-joint. He stated that about a month before he fell from a tree, from a height of about twelve feet, on his left side. He was conscious after the fall, but felt some pain in the left hip-joint; he, however, managed to walk with a limp and reach the stables, about a quarter of a mile distant, where he sat down. After a while, on attempting to rise, his leg became everted, and he felt considerable pain in the hip-joint, with inability to walk. He was taken home in a cart, and fomentations were daily applied. In about a fortnight's time he was able to limp about, and felt only slight pain in doing so. He did not bear any marks of syphilis or other constitutional diseases. In walking he limped a good deal, but did not evince any pain or discomfort in doing so. The left limb was straight, but looked shorter than the other. On measuring, there was a difference, the affected side being about half an inch shorter in the perpendicular line of Bryant's triangle. On manipulation the trochanter major could be felt rotating with the shaft of the femur, and distinct crepitus could be detected in the joint. He refused to remain in hospital after September 2nd. The leg was kept for a fortnight in a long splint, but he found this so irksome that he wished it removed. There was little or no improvement when he left the hospital, but Dr. Sibthorpe thought that as time passed on the leg would doubtless get stronger.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, FEBRUARY 14th, 1888.

W. H. DICKINSON, M.D., Vice-President, in the Chair.

Relapsing Typhlitis treated by Operation.—Mr. FREDERICK TREVES read a paper on this subject, in which he said that in the majority of the cases of so-called typhlitis the appendix was the cause of the trouble, and the perityphlitic abscess was more usually an encysted peritonitis due to perforation of this process, than to disease in the cæcum. The appendix might become the starting point of inflammation, by reason of congenital deformities, of changes that took place in its mesentery, producing bending; of the lodgment of foreign bodies or concretions that were encouraged to remain unmoved, on account of the feeble muscular coat of the tube. This source of manifold disturbance could be destroyed by removal of the appendix, or by correcting any simple deformity of which it was the seat. The question of such interference was only considered in reference to relapsing typhlitis. The statistics of Fitz showed that in 11 per cent. of the examples of this affection the patient was the subject of successive attacks. In one case quoted five attacks occurred in a period of eighteen months. The author was of opinion that relapsing typhlitis was due in a very large proportion of instances to some appendicular trouble, and was, therefore, a condition which might possibly be relieved by operation during the period of quiescence that followed an attack. A case of relapsing typhlitis, in a man aged 34, was reported. After the subsidence of the second attack, and during a period of freedom from all symptoms, the author performed laparotomy, and found a diseased appendix, which was dealt with. The patient made a perfect recovery, and had remained free from further relapses. The mode of dealing with diseased appendices was discussed.—Mr. TIMOTHY HOLMES remarked that Mr. Treves's very interesting paper reminded him of a case that he had treated some years ago which was somewhat similar, but in which his operation, though giving great relief, had not proved such a complete success as in Mr. Treves's case. A man, aged 30, had been

admitted into St. George's Hospital under the care of his late colleague, Dr. Barclay, in 1880, for vomiting, constipation, and pain in the right iliac fossa. He was a worker in lead, and that was supposed to have been the origin of his symptoms. Relief was given by medical treatment, but he returned to St. George's Hospital in 1884, with a more severe attack of the same nature, under Dr. Ewart. Operative treatment was suggested, on the hypothesis that the symptoms were due to a foreign body in the appendix, but was not adopted, as the indications seemed insufficient. There was considerable improvement in two months, and he was discharged, but the day following came back to the hospital in great pain. Examination under ether showed an immovable tumour in the right iliac fossa, which felt more like a foreign body than a mass of faeces. There was much thickening round it, and great pain followed the examination. As constipation was obstinate, and purgation very distressing, he cut down upon the mass by an incision such as would be suited for tying the common iliac artery. He found a mass in the cæcum, and the surrounding tissues much confused, and matted together by old inflammation. An elongated body adherent to the cæcum was recognised as the appendix, was somewhat torn in dissection, and a probe passed up it into the small intestine to ensure its diagnosis; the torn end was removed, and the remaining portion secured by ligature. No accurate sewing of peritoneal and mucous surfaces was possible in such thickened and adherent tissues. The result was satisfactory for the time, for the man lost his pain and vomiting, and could go to work again. His health, however, was not perfect, for whenever he ate too much, he got fresh attacks of pain, and came again under treatment at St. George's and elsewhere. The appendix was lying vertically on the cæcum, and the adherence was so close that it would probably have been impossible to detach it completely without wounding the bowel. The case was one which helped to justify Mr. Treves in saying that the removal of the appendix was sometimes advisable; and he agreed that if the tissues were clearly defined both peritoneal and mucous coats should be sewn together. Many years previously, when house-surgeon to St. George's, he had to deal with a woman in whom the right iliac region had all the appearances of acute cellulitis. On that he had thought it his duty to make several incisions, and to his surprise and dismay faeces came out through them, and continued to do so. Nevertheless the patient lived some three months, and at the *post-mortem* examination it could be shown that the wound was in a very much enlarged appendix. Mr. Treves's paper had contributed to his opinion that there was a field for active surgery in these cases.—Mr. HOWARD MARSH congratulated Mr. Treves on having supplied suggestions that would make the treatment of many cases clearer. He related a case of acute general peritonitis, in which he had opened the abdomen and found the cause in faecal extravasation through a perforation in the appendix. He had amputated the appendix and washed out the abdomen, but the patient died after a few hours. If the case had been brought under treatment a day or two earlier it might have been possible to save life.—Mr. BRYANT cordially agreed to the propriety in some cases of surgical interference, and considered the appendix as the cause of many of them. A surgeon might be quite justified in trying to anticipate the recurrence of them. If he had understood rightly that Mr. Treves had only found an appendix curled up and not perforated, he doubted whether he should have himself operated. He had made oblique incisions to look at the cæcum, and had washed out faecal and other abscesses, but he had not amputated an appendix.—Mr. WALSHAM could hardly regard all cases of typhlitis and perityphlitis as due to the appendix. He related, however, a case of acute abdominal obstruction which he saw with Dr. Andrew at St. Bartholomew's on the fourth day, and, on cutting down, found localised peritonitis around a gangrenous appendix, in which a gall-stone was lodged. He amputated the appendix, which was sealed over with plastic lymph and needed no more than a ligature. Another patient had had many attacks of abdominal pain, for which no surgical treatment had been used at first, but lately the abdomen had been opened, and a pint of fetid pus withdrawn from a localised peritonitis, of which no definite cause had been ascertained, but which was probably to be traced to the appendix. The man was now nearly well.—Dr. HARE admitted that it was hardly his province to speak on a surgical subject, yet remarked with some emphasis that he had never found any need for surgical interference in his own cases of typhlitis or perityphlitis. In cases of acute tenderness, swelling, fever, etc., he advocated the free use of leeches to the part.

and was frequently surprised to find such a sure source of relief neglected nowadays.—Mr. HULKE observed that most of those present must regret to have seen cases in which leeches were freely used, but without avail. In a case of his own, in which he was inclined to operation, a consultation led to abandonment of surgical measures, a resort to leeches, and a termination in death by perforation of the appendix. It might fairly be said of such a case that tentative measures deprived him of his chance of life. Another patient who had had dysentery three times, and had led an irregular life, came under his treatment three weeks ago with acute pain and much swelling of the right iliac fossa. He cut down upon the swelling and found inflamed omentum, which he removed, and as he found no further definite disease, took no further steps. The patient was relieved for a week, but then showed signs of a deep abscess, which was opened, and he was now convalescent. He wished to call attention to a very interesting pamphlet on this subject by Dr. Henry B. Sands, of New York.—Dr. DOUGLAS POWELL regretted that typhilitis and perityphlitis should have been confused in this discussion, as they were in reality as separate as pleurisy and pneumonia, though their diagnosis was often difficult. If a foreign body was present he admitted the use of surgical treatment, but typhilitis was generally the result of errors of diet, and could not be benefited by surgery. He thought "relapsing typhilitis" an unfortunate title for Mr. Treves's paper, which, had, as he understood it, dealt with the treatment of relapsing perityphlitis.—Dr. DICKINSON thought that perityphlitis, as far as we could judge of it accurately from the *post-mortem* table, was chiefly due to diseases of the appendix, more especially to concretions, which were not foreign bodies, but of home manufacture, stratified lumps, looking at first sight like calculi. He considered Dr. Hare had quite established his right to speak on old-fashioned treatment, and agreed with him as to the great use of leeches in the earlier though acute stages of the disease.—Mr. TREVES thanked the Society for much interesting information and discussion. Dr. Powell had opened up again the old difficulty of estimating the distinctions between relapsing typhilitis, typhilitis, and perityphlitis. Of typhilitis properly so called he thought we knew little; museums certainly did not illustrate it, and he was not aware that intestinal inflammations restricted themselves to such narrow boundaries. In the cases of Fitz and Sands the original trouble had been almost always in the appendix; and he felt justified in holding to his opinion that relapsing typhilitis was due chiefly to the diseases of the appendix, and not to a mass of fæces. Mr. Holmes's case might be interpreted as an argument for earlier surgical interference. He thought that Mr. Bryant's disinclination to operation was probably due to his own imperfect description of the circumstances, and would have disappeared if he had seen the curled and rolled up mesentery of the appendix. Dr. Hare's remarks made him hope that earlier treatment might be made more serviceable, but they could hardly influence the conclusions of most surgeons who had not shared his experience.

As the hour of adjournment was nearly reached, Mr. Henry Morris's paper on Hydrocele was postponed till the next meeting.

CLINICAL SOCIETY OF LONDON.

FRIDAY, FEBRUARY 10TH, 1888.

W. H. BROADBENT, M.D., F.R.C.P., President, in the Chair.

The Diagnosis and Treatment of Ruptured Intestine without External Wound.—Mr. MAYO ROBSON, Leeds, read a paper, basing his remarks on six cases which had come under his own observation, or under the care of his colleagues, Mr. E. Atkinson and Mr. Ward. In two of the cases abdominal section and enterorrhaphy had been performed. After a detailed description of the cases, Mr. Robson remarked that in some cases of ruptured intestine, the symptoms were so distinct as to be almost pathognomonic; that other instances of abdominal injury might present most of the signs of ruptured intestine, and yet recover; the shock being due to disturbance of the sympathetic nervous system, and the diminished liver dulness to distended intestine; that the usual symptoms might be entirely absent for a time, only becoming evident after some hours; and that a failure in diagnosis might occur from injury to other regions taking the attention from the abdomen. In discussing the diagnosis, Mr. Robson considered the symptoms and signs separately, and then collectively; remarking on the variability of the cause, the difference in the degree of shock, the usually rapid and feeble pulse, the constant presence of vomiting and of pain, and later, the usual signs of peritonitis;

but especially dwelling on the importance of altered liver dulness, which when normal was almost proof of absence of perforating wound of alimentary canal; when diminished, was suspicious of perforation, but when absent was almost pathognomonic of rupture. He considered the combination of symptoms most to be relied on were shock more or less severe following immediately, or within a short time, on an accident; pain in the abdomen; moderately quick and flabby pulse; vomiting of contents of stomach, followed by bilious vomit; anxious countenance; and diminished or absent liver dulness. After showing that on expectant treatment no reliance could be placed, Mr. Robson remarked that the only hope of success lay in early operation, and consequently that a timely diagnosis was of vital importance, to attain which it would seem necessary that all cases of intra-abdominal injury should be both accurately observed and fully reported. For his own guidance he had adopted the following rule. In cases where there was a reasonable belief that the intestine was wounded, as evidenced by the history, symptoms, and signs, exploration by a small median incision must be made: when, if there were any rupture of the bowel, flatus or serum, tinged with blood or faeculent material, would escape through the small peritoneal opening, which could then be enlarged, and necessary treatment adopted; but should no flatus or fluid appear and the peritoneum prove to be healthy, the small wound could be closed, and no harm would have been done.—Mr. GOLDING-BIRD said that the late Mr. Alfred Poland was wont, in cases of abdominal injury, to ascribe pains radiating from one point of the abdomen to rupture of the bowel; and his treatment in all such cases was very strict. For example, he would not allow the patient to suck ice. He considered that the surgeon knew not how much was taken, and that pounds might be given by the nurse in twenty-four hours. Often at a *post-mortem* examination there might be pints of blood-stained liquid (chiefly the melted ice) found in the abdominal cavity. The speaker asked how Mr. Robson's patients had been treated, *re* food, prior to operation. Some of the cases showed the symptoms early, some late. Was it known in each case how long before the accident the previous meal had been taken?—Mr. BRYANT thought there was room for improvement in the surgical treatment of these cases. Mr. Robson had emphasised the fact that patients might have received a considerable rupture of the bowel, and yet have scarcely any indications in pain, pulse, or even local tenderness. Acting on this knowledge, he himself always instructed his dressers to admit all cases of abdominal injury, and keep them for twenty-four hours in bed, to see what might eventuate. He would give one instance of the value of this plan. A child fell on a sharp pointed piece of wood. When admitted to the ward, she had scarcely any external sign of injury, but she had cried much at the time of the accident. She had no pain on admission. Scarcely any food was given, but in twenty-four hours there was a slight tendency to vomit, and it was thought probable that peritonitis might be coming on. Next day there was acute peritonitis, and on the fifth day the child died. At the necropsy, rupture of the intestine was found. Granting the diagnosis, which was often a matter of difficulty, there could be no doubt about the treatment to be adopted in the way of surgical operation if the diagnosis tended to support the theory of rupture. In a former volume of the *Guy's Hospital Reports*, Mr. Poland had published a valuable paper on these cases. If one could not find therein the materials to support the line of treatment recommended by Mr. Robson, he feared it would be obtained nowhere else.—Sir WILLIAM MAC CORMAC had listened with much pleasure to the paper of Mr. Robson, which endorsed the line of treatment that he himself had recently inculcated. He thought that surgeons should adopt in these cases the same plan as in hernia—namely, "when in doubt, operate." He was glad that Mr. Bryant had also endorsed that plan of treatment. Mr. Robson's case showed that the old idea of collapse was not reliable. He himself had seen patients with ruptured bowel walk to the hospital and have no pain for some little time.—Mr. W. H. BENNETT said that often, in cases of abdominal injury, the symptoms were so slight that he thought Mr. Bryant's proposition to watch them for twenty-four hours was not enough. Thus, in the case of a youth struck by a cricket-ball, who was sent to bed and kept on a spare diet for a week, there were scarcely any symptoms of severe injury; he was then allowed to leave his bed, at once felt faint, and in a short time was dead. Upon inspection there was found to be rupture of the duodenum, extending half round the bowel, allowing extravasation of fæces. The amount of symptoms

might be due to the amount of peritonæum involved in the rupture; for, in the case cited, there was very little peritonitis found at the *post-mortem* examination, and at the first the peritonæum was probably not involved. Perhaps, even if laparotomy had been performed, the rupture might not have been in that case discovered.—Mr. ROSSON, in reply, said that shock due to the injury must be distinguished from that due to its after-effects. When absorption of the extravasated material set in, the symptoms were rapid and violent. It would be rather inconvenient to keep all cases of abdominal bruising in hospital for a week, though he agreed with Mr. BRYANT that detention for twenty-four hours was most advisable. But even the rigorous adoption of this plan would have been of no avail in his first case, as that patient came to the hospital for the injury to his head, and did not mention at the time that his abdomen was at all hurt. In all cases where the injury was indirect the pain was of a general character; it was only radiating from one point when caused by a direct blow. As regarded treatment, he always starved these cases, and allowed no ice in any abdominal case. Even in ovariectomy he only allowed ice in pieces the size of a pea, and if thirst was great, he ordered an injection of one pint of lukewarm water into the bowel, whence a large amount of it was absorbed.

A Case of Intestinal Obstruction, in which the Colon gave way Outside the Peritonæum.—Mr. WILLIAM H. BENNETT brought forward this case. The patient was a gentleman advanced in age, who for many years had been habitually constipated. At frequent intervals he was in the habit of using violent purges, without which the bowels never acted. About the middle of September, 1887, the constipation became more obstinate, and attacks of colic, from which the patient had also often suffered for years, were frequent and most severe. He was able, however, to obtain sufficient relief by means of his usual medicines up to October 17th, when a very small hard motion was the only result of this treatment; the colic, which was very acute, did not completely subside. Gradually the abdomen became distended, and great discomfort ensued in consequence. Further purges were taken without any good effect, although there was a frequent urgent desire to defæcate. On the 21st, whilst stooping over a letter, he felt a sudden acute pain passing down into the left loin. Some nausea and faintness followed, from which he soon rallied. He was seen by Mr. Bennett on the 22nd. His face was pinched and anxious in aspect; the tongue was brown and dry; the pulse very weak. The belly was much distended, especially on the left side, where the loin bulged very prominently. The rectum was empty, but a hard mass could be felt through its walls, situated in the bowel higher up. The distress from the distension was extreme, and the patient begged for an operation. As the case was clearly one of obstruction above the sigmoid flexure, a left lumbar colotomy was performed. On opening the abdominal cavity there rushed out, before any gut was exposed, a large quantity of gas and some liquid feces; on introducing the finger, the intestine could be felt in front of a space, from which the gas, etc., had come; manipulation of the colon, which could be easily made out, caused the air which remained in it to come through an opening in the gut at the lower part of the space mentioned, just below which could be felt a hard mass in the bowel. The distension at once subsided, but the patient became collapsed and did not rally. The case was regarded as a clear instance of rupture of the colon outside the peritonæum, which explained the mildness of the symptoms following immediately upon the giving way of the gut, which it was assumed took place when the acute pain, mentioned in the account of the case, suddenly seized the patient. In the same way the one-sided character of the abdominal distension and the absence of peritonitis could be accounted for, and a curious corroboration afforded to a statement of the patient, to the effect that attempts at defæcation only increased his distress, for it was easy to see how such attempts could force the contents of the loin more and more into the surrounding cellular tissue. The case was considered remarkable for its rarity, and on that account had been thought worthy of record.

Intestinal Obstruction: Nélaton's Operation: Death: Volvulus of the Cæcum; Malposition of the Ascending Colon.—Mr. WALSHAM related the case of a man, aged 63, previously healthy, suddenly seized with severe abdominal pain and vomiting, and the bowels, which were regular up to the time of the seizure, became obstinately confined. On his admission, two days later, into St. Bartholomew's Hospital, under the care of Dr. Gee, nothing could be found to account for the pain, either on palpation of the abdomen or rectal examination, save some slight fulness and tenderness in the right

iliac region. Temperature, tongue, pulse, etc., were fairly normal. On the 18th, two days after being in the hospital, he began to vomit continuously. On the 20th he seemed better, and the vomiting ceased, but the bowels remained obstinately confined. On the 24th, stercoraceous vomiting set in, and he became collapsed. A consultation was held, but no diagnosis could be arrived at, save that the obstruction was probably situated low down, though too high to admit of relief by right colotomy. As the patient's condition was such as to make it appear probable that he would die on the table were exploration of the abdomen attempted, the abdomen was opened in the middle line, and a portion of inflamed and distended intestine—the portion which first presented—was secured by suture to the abdominal wall. Only a small quantity of feces escaped. Though vomiting did not return, the abdomen continued swollen and tender, and the bowels remained unopened. He died on the afternoon of the 23rd. At the necropsy a volvulus of the cæcum was discovered, as shown in the specimen exhibited. There was general peritonitis, but neither extravasation of feces nor collection of fluid in the peritoneal cavity. It was found on tracing the gut backward that the colon, beyond the splenic flexure, instead of passing across the abdomen to form the transverse arch, descended vertically to the left iliac fossa, and thence returned to the lower border of the stomach, forming a U-shaped bend. It then turned to the right, and, having reached the median line of the abdomen, again ran downwards to end in the cæcum, which was situated over the last lumbar vertebra almost in the middle line. There was no ascending colon in the right loin, and the cæcum was absent from the right iliac fossa. The gut that was opened proved to be the cæcum, which was situated at the apex of the volvulus. It was ulcerated in places; but, owing to the surrounding adhesions, no feces had escaped. Mr. WALSHAM remarked that the suddenness and acuteness of the symptoms pointed to some internal strangulation or volvulus; but, after careful watching, no definite diagnosis could be arrived at. Laparotomy was not undertaken, because of the patient's collapsed condition; and Nélaton's operation—varied, however, by making an incision in the middle line—was accordingly performed. As it turned out by this operation, the cæcum, the apex of the volvulus, was secured to the wound, and subsequent untwisting of the gut prevented. Mr. WALSHAM, however, did not believe that the gut could in any case have become untwisted without surgical interference. Some surgeons held that primary enterotomy was not to be advised, while others thought highly of it as being less dangerous than exploration of the abdomen. In the present case, enterotomy was performed as likely to give the patient a better chance. Mr. WALSHAM thought that the consideration that like and similar conditions, though rare, were of occasional occurrence, should influence us to some slight extent in determining whether laparotomy or enterotomy should be performed, and, when taken in connection with the other objections that had been raised by some surgeons, should, he thought, dispose us to reserve enterotomy as a primary operation merely for those desperate cases in which it appeared that laparotomy must inevitably prove fatal.—The PRESIDENT considered both cases unique, each in its own way.—Mr. BRYANT recited the case of a lady, aged 73, liable to attacks of spasm and nausea, with difficulty of defæcation, for which she was constantly taking aperient medicine. She was seized at Folkestone with intestinal obstruction, and was thence brought back to London. Being summoned by Dr. Cumberbatch, Mr. Bryant found the case to be one of chronic obstruction, with acute symptoms superadded. The abdomen was swollen, with large coils of intestine bulging its anterior wall. Nothing could be felt from the rectum. Right colotomy was performed, but the ascending colon was found empty. Nélaton's operation was then performed between the umbilicus and right anterior superior iliac spine, where a large coil of intestine was especially evident. For three days the bowel continued to empty itself; and on the fourth day the stitches were removed. The patient rallied much after the operation, and did well for a time; but unfortunately she remained very feeble, and eventually died on the fourteenth day, from exhaustion. At the necropsy a large distended sac was found in the abdomen; this was the cæcum, which had fallen over a band, so that what should have been its posterior had become its anterior surface, and its lower end was also turned upwards. The volvulus of the cæcum caused obstruction in the ascending colon near the seat of the first operation. Failing to find the distended bowel in the colotomy, it was right to do "the Nélaton." It relieved the patient; and had she been younger, he believed she would have recovered. In cases where constricting bands or in-

ternal hernia were expected, or in other doubtful cases; where colotomy was out of court, laparotomy was called for. He had had three cases; one lived for five months, and another for two months, much relieved by the operation. He might cite another case of colotomy which bore upon Mr. Bennett's case. Upon cutting into the subperitoneal tissue, a puff of faeculent gas escaped. Upon traction being made upon the colon, faeces passed also from behind the bowel. The wound was then thoroughly washed out with iodine water, and a drainage-tube inserted. On the third day the bowel was opened, and the patient went on to recovery. He now thought that the case must have been such a one as that described by Mr. Bennett.—Mr. HOWARD MARSH said that, as regarded Mr. Treves's adverse opinion of Nélaton's operation, there were instances in which the patient was so ill from obstruction that laparotomy could not be done; then to open the abdomen in the middle line, and perform Nélaton's operation, sometimes gave great relief. A patient so operated upon by Mr. Morratt Baker some years ago had recovered. He would ask if there was any considerable resistance under the abdominal wall in Mr. Walsham's case to point to the trouble being at the region operated upon. If so, possibly the patient would have had more chance if the operation had been done farther from the actual site of the trouble. He had lately operated upon a patient by opening the colon in the loin, and so large a quantity of faeces had immediately escaped that he believed if the operation had not been done the bowel would soon have ruptured.—Dr. HENRY HANSEN said that he had recently made a *post-mortem* examination on a man supposed to have malignant disease of the sigmoid flexure. Fourteen days before death he had great pain in the abdomen, but went to his work until two days before death, when peritonitis began. The ascending colon was parallel and close to the descending, and there was cancer of the sigmoid flexure.—Mr. ROBSON asked if any pus was found behind the colon in Mr. Bennett's case. Might it not be that an abscess had broken into the bowel? He had twice performed Nélaton's operation, once successfully, whilst the other patient died two days after the operation. In the first case the patient had cancer, and upon colotomy being done, the bowel was found to be empty. A large coil of intestine was then discovered beneath the anterior abdominal wall; it was brought to the surface, stitched there, and opened, and the patient was probably living now. It was a great comfort to have Nélaton's operation to fall back upon when the abdomen could not be explored.—The PRESIDENT mentioned a case that had perplexed him. Upon an exploratory incision being made the caecum was found distended, and lying in the pelvis, and encircled by a coil of adherent small intestine, which had blocked the passage. The caecum had given way during the operation, and the patient died from peritonitis.—Mr. BENNETT said Mr. Bryant's case was evidently like his own. There was no trace of pus in the cavity behind the bowel, and it was not at all like an abscess cavity.—Mr. WALSHAM said that it was thought that there was some fulness in the left iliac fossa, but nothing definite was made out. An early operation would probably have saved his patient.

Living Specimens.—The following living specimens were exhibited. By Mr. B. ROTH: A Girl with Arrested Growth of Ulna from Exostosis. Dr. Pasteur: A case of Congenital Hypertrophy of One Lower Limb in a Girl. Dr. Fox: A Girl with a Chancre on the Lip. Mr. MARSH: A Successful Case of Laparotomy for Tubercular Peritonitis.

MEDICAL SOCIETY OF LONDON.

MONDAY, FEBRUARY 13TH, 1888.

J. HUGHINGS JACKSON, M.D., F.R.S., President, in the Chair.

The Treatment of Rheumatic Fever.—Dr. DONALD HOOD read a paper on the treatment of rheumatism, with especial reference to the use of the salicylates, an abstract of which we shall publish.—Dr. S. WEST said that the value of statistics such as those drawn up by Dr. Hood, depended, to a very great extent, upon the way that the items were classified and grouped. Probably no disease was so difficult to classify and properly group as rheumatic fever and the different diseases which were closely allied to it and so difficult to distinguish from it. It was very curious, on comparing the statistics of different hospitals, to see how those differences were grouped in so many unexpected ways. He thought that the high percentage in recent statistics of *morbus cordis* was due to the fact that the statisticians were much more careful. They were now gradually approximating to the original

statistics when the connection between the two was first described. He said that a great deal turned upon the anomalous groups of cases which might be termed chronic rheumatism or chronic rheumatic fever, according to the relation which it was supposed they bore to rheumatic fever. He observed that there had only been one or two cases of hyperpyrexia under his notice during the last seven or eight years, whereas when a student they were of comparatively frequent occurrence. Another important point which tended to vitiate the conclusions was that drunkards suffering from acute rheumatism were very liable to get delirium.—Dr. WHIPHAM observed that, when that method of treatment was first introduced in London, they found exactly what Dr. Hood had said—namely, that relapse after relapse occurred. It then became clear that the salicylates were anodynes more than anything else. Since then it had always been the custom to combine alkalies with the salicylates, according to the condition of the urine. With such a mixture, relapses were comparatively rare. He was inclined to attribute the toxic effects to impurity of or imperfections in the drug. He mentioned that in 655 cases of rheumatic fever brought together for the Collective Investigation Committee, only four cases of hyperpyrexia were reported. The best remedy for delirium was alcohol.—Dr. WICKHAM LEGG said he had noticed symptoms resulting from the use of the salicylates respecting which further inquiry was necessary. He said they would have to find out what the cause of these effects was.—Dr. DREWITT observed that the appearance of the artificial acid differed *in toto* from that obtained from the oil of wintergreen; and, moreover, that if one compared samples of the acid at different hospitals or from different chemists, the greatest variety was found of taste, appearance, and effects.—Dr. ARCHIBALD GARROD mentioned several instances of very severe symptoms following the administration of salicylate of soda, and expressed an opinion that differences in the preparations used were responsible for many of these effects. He said he had certainly noticed epidemics, so to speak, of toxic effects in patients during particular periods of time. He added that discrimination was necessary in the administration of the salicylates, and in persons who could not be closely watched their use had probably be better dispensed with.—Dr. ROUTH recommended the employment of cold baths as a means of combating the tendency to hyperpyrexia. He pointed out that the connection had not been made clear between the delirium recorded in Dr. Hood's paper and the hyperpyrexia. He thought that delirium was often due to an impending attack of hyperpyrexia.—Dr. DONALD HOOD, in reply, said he had not intended to convey the idea that hyperpyrexia was more common, but only that it would sometimes occur in spite of antipyretics. He mentioned that hyperpyrexia occurred in cycles of intensity. He wished to contest Dr. Fagge's assertion that hyperpyrexia might be averted if the patient itself took enough salicylate.

Some hitherto Undescribed Symptoms in the Early History of Osteo-Arthritis.—Dr. KENT SPENDER read a paper on this subject.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

MEDICAL SECTION.

FRIDAY, JANUARY 27TH, 1888.

JAMES LITTLE, M.D., President, in the Chair.

Nervous Diseases: Congenital Spastic Paraplegia: Ataxic Paraplegia.—Dr. C. J. NIXON made a communication upon congenital spastic paralysis and ataxic paraplegia, and exhibited two cases illustrating both diseases. He divided cases of congenital paralysis into those which were cerebral and those which were spinal in origin, and dwelt at length upon the various conditions with which both forms were associated. One of the cases exhibited was paraplegia, due to compression of the upper part of the Rolandic area during an instrumental delivery by the forceps. In the case of ataxic paraplegia Dr. Nixon first detailed the evidence which had been afforded by recent investigations as to the probable course taken by the sensory muscle-tracts in the spinal cord—namely, in the columns of Goll, the direct cerebellar tracts, and in the short vertical fibres which connect the posterior horns of grey matter at different levels in the spinal cord. The last was the part in which the comma-shaped degeneration was found. In noting the motor paralysis which existed in ataxic paraplegia, special reference was made to the difficulty of distinguishing a lesion of the delicate fibrillary network which connects the terminations of the pyramidal tracts with the network of Gerlach,

though a slight lesion in the situation, as being the furthest point from the influence of the trophic centres, would most probably be attended with serious disturbance of the motor function. Dr. Nixon also adverted to the different pathological lesions which might be set up in the cord, the results of which, as regards the intensity of the symptoms and their duration might be very different. Many cases of the most profound disturbance of both sensibility and mobility got well, though this result was usually considered as phenomenal. Allusion was made to the effect of treatment in certain affections of the spinal cord.—The PRESIDENT observed that it was evident Dr. Nixon did not share the opinion of a distinguished physician that "all diseases of the nervous system are either syphilitic, or they are not; if they are not, you will do them no good; if they are syphilitic, treat them with iodide of potassium."—The Rev. Dr. HAUGHTON said the distinction drawn by Dr. Nixon between the sensory and muscular nerves was of great importance. There was one thing they had certainly determined, although the difference was exceedingly small—namely, that the rate of transmission of a sensation and the rate of transmission of an order from the brain to use muscular action differed slightly. Everything seemed to show that the mode of communication with the external world, which took place from the sensorial nerves and from the nerves that transmitted orders for muscular action, differed.—Dr. BEWLEY related the symptoms presented by a man suffering from ataxic paraplegia under his care. This man, aged 38, with no history of syphilis or alcoholism, had been in perfect health until April last, when he began to suffer from pain in the lower lumbar region of his spine on going to bed. The case was remarkable for the great rapidity with which the symptoms had come on. Within a fortnight after the first trouble had been noticed in the legs ataxy was extreme; and within two months the man was unable to move his legs, owing to their rigidity. The affection of the sensory nerves was indicated by the anaesthesia and pain attributable to slight isclerosis of the postero-external column in the lumbar region, which was sufficient to cause irritation of the sensory nerve roots, but not sufficient to cause paralysis. Locomotor ataxy and spastic paraplegia were two extremes between which might be found almost any combination of symptoms.—Dr. WALTER SMITH mentioned a case in Sir Patrick Dun's Hospital as illustrating one of the most interesting phenomena of spinal diseases, namely, the different modes of transmission of different sensory impulses. Prying the patient with a pin or twisting the skin he did not perceive; yet in all parts of the limbs, down to the very toes, he could feel and localise accurately the touch of a feather, while he was thoroughly insensible to the most painful impressions, and unable to discriminate between heat and cold. The symptoms pointed to acute destructive inflammation of the lower part of the spinal cord.—Dr. Nixon, in reply, said it was not to be expected that all cases of ataxic paraplegia would be precisely similar. On the contrary they must vary, inasmuch as the pathological changes in any two cases would vary, and accordingly as the disease became more pronounced in the lateral roots in one case or in the posterior.

Heredity in Hemorrhagic Purpura.—Dr. J. F. KNOTT read a paper on this subject.—Mr. FOY, Dr. J. F. POLLOCK, and Dr. C. F. MOORE made some remarks, and Dr. KNOTT replied.

CAMBRIDGE MEDICAL SOCIETY.

FRIDAY, JANUARY 6TH, 1888.

E. CARVER, F.R.C.S., President, in the Chair.

Note on Subcutaneous Nodules in the Hands.—The PRESIDENT read a short paper on subcutaneous nodules in the hands occurring in rheumatic individuals. His remarks were based on two cases which had somewhat recently come under his notice. The patients were gentlemen on the shady side of 50; each was rheumatic, dyspeptic, and somewhat gouty. The nodules were painful only on pressure, and fixed to the deeper textures, but unattached to the skin, which preserved its normal healthy condition. In the one case the nodules disappeared under treatment by alkalies and oleic acid; in the other case the nodules diminished under alkaline treatment. Both cases showed evidence of gout in the contracted finger and enlargement of the phalangeal joint. The fibrous nature of the nodules was alluded to, their microscopic appearance being identical with that of the vegetations on the valves of the heart. The President brought these cases before the Society inasmuch as the behaviour of the nodules was different from that described by others. In the young and up to early adult age the nodules had

been observed to come and go, sometimes in successive crops, disappearing altogether in from a few days to a few months. Where these nodules had appeared later in life, they had been noticed to last for years.

Cases of Abscess in the Tibia.—Professor HUMPHRY related two cases of this disease, which presented the ordinary symptoms of abscess in bone, but were situated rather lower down than usual. He remarked on the length of the previous history of the symptoms in these two cases. Remarks were made by Dr. EASEY and Mr. WHERRY.

Wound of Palmar Arch: Abnormal Blood Supply.—Mr. WHERRY related the history of a middle-aged woman, who broke a glass bottle with great violence into the palm of the hand. The surgeon in attendance had tried all the usual means of stopping hemorrhage, but without lasting success, so that during four weeks there were six considerable and sudden losses of blood. When Mr. Wherry first saw the hand, a month after the accident, the fingers were becoming gangrenous, and the general condition of the patient was feeble and anæmic. Amputation of the hand was followed by a good recovery. A large traumatic aneurysm was found in the palm, full of clot and pieces of glass. A large ulnar artery communicated with the sac, and no deep arch formed by the radial existed. There was no deep or communicating branch from the ulnar artery passing between the little finger muscles. The small representative of the radial appeared to communicate with the wounded palmar arch by a branch passing through the second interosseous space. This absence of the deep arterial arch, with the enlargement of the superficial (ulnar) supply in the hand, was, according to Quain, the most uncommon of abnormalities, and might explain the great difficulty in controlling the hemorrhage, and also the ready tendency to gangrene of the digits in a large flat hand.

Enlargement of the Prostate.—Mr. GRIFFITHS showed this specimen. The patient was an elderly man, whose urine contained a small quantity of albumen; attacks of uræmic convulsions came on, and he died comatose. The heart was hypertrophied, and the ureters and pelvis of the kidneys much dilated. The third lobe of the prostate was remarkably enlarged and prominent, and there was a sacculæ in the bladder. Mr. Griffiths gave a detailed account of the morbid anatomy and histological characters of this form of enlargement of the prostate. It corresponded entirely with the adenomata, and might be well compared with such tumours as adenoma of the mamma.

MIDLAND MEDICAL SOCIETY.

WEDNESDAY, JANUARY 25TH, 1888.

W. ROSS JORDAN, M.R.C.S., President, in the Chair.

Congenital Sacral Tumour.—Mr. WILLIAM THOMAS exhibited a child, aged 11 months, which had a large congenital sacral tumour. The tumour was of a mixed character, containing several cysts, much fatty tissue, and some firm cartilage-like masses continuous with, but movable on, the sacrum. No communication was evident between the tumour and the spinal canal. The tumour projected downwards and backwards, its lower limit reaching the middle third of the thigh. The mother stated that it was relatively as large at birth. Mr. Thomas intended keeping it under observation for a time with a view to removal.

An Undescribed Fallacy in Testing for Albumen in Urine with Nitric Acid.—Dr. CARTER drew attention to the importance of securing complete purity of nitric acid for the purpose of testing for albumen in urine; and showed a specimen of acid which he had obtained from a druggist of good position, and which, evidently from the presence of some impurity, gave reactions indistinguishable from those of albumen. Subsequent analysis of the nitric acid had shown that it contained a trace of nitrate of silver.

Cardiac Thrombosis.—Dr. CARTER also showed a specimen of cardiac thrombosis, taken from a lad of 13 years of age, who about a fortnight previously had been attacked with sore throat of a low type. The lad was very emaciated, had been greatly neglected, and his surroundings had been unhealthy. A few days before his death he had been attacked with acute pneumonia, and was admitted into the Queen's Hospital in a state of collapse, and died shortly afterwards. On *post-mortem* examination adherent clots of various sizes were found in both ventricles, many of which had undergone central softening, and were beginning to break up. The greater part of the right lung was in a state of pneumonic consolidation, and presented two or three recent in-

farcets of considerable size. The left lung was congested, but free from consolidation and infarcts. The other organs were normal. Dr. Carter drew attention to the importance of the nutrition and vitality of the blood as a tissue of the body, as a factor in thrombosis, to which he was inclined to attach even greater pathological significance in these cases, than to such conditions as alteration of the vascular walls, and retardation of the blood-current.

Abscess of Frontal Sinus.—Mr. LLOYD OWEN showed a case of chronic abscess of frontal sinus successfully treated by opening and free drainage.

Tubercular Necrosis of Cranial Bones.—Mr. BARLING showed a case of tubercular necrosis of the cranial bones, causing perforation, in a young girl.

Use of Electricity in Gynecology.—Mr. J. W. TAYLOR read a paper on the Use of Electricity in Gynecology.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY. THURSDAY, FEBRUARY 2ND, 1888.

E. MACKEY, M.D., afterwards J. HARRIS ROSS, M.D.,
in the Chair.

Lupus Erythematosus.—Dr. MACKEY showed a case of this disease in a woman, aged about 43, of three years' duration. Treatment by resorcin, and scarification was just commenced.

Nephrotomy.—Mr. JENNER VERRALL read notes of a case of renal calculus with nephrotomy. The patient, a married woman, aged 47, first noticed pain in the right flank five years ago, after a confinement. At times there was hematuria, but never severe. The pain had steadily increased, and after her last confinement, three years ago, pus first appeared in the urine. The quantity passed had been variable, the urine being at times almost wholly purulent. For some time there had been swelling of the right side of the abdomen, which had more than once disappeared with sudden passing of a quantity of pus, and again reformed. It was present when the patient was admitted into Sussex County Hospital under Dr. Mackey. As she was getting gradually worse, and there was distinct evidence of a calculus, Mr. Verrall, on December 10th, 1887, explored the kidney from the lumbar side, and extracted a large stone, weighing when removed three ounces and a half. The cavity was at first drained, but the tube was removed on December 20th. The wound was closed with the exception of a small sinus, discharging about a drachm of pus in the twenty-four hours. General condition much improved, though there is still some nocturnal rise of temperature, and about one-eighth of pus in the urine.

Tubercular Pyosalpinx.—Dr. CHAFFEY showed a specimen of endometritis and meningitis from a child, aged 12 years, who died with chronic tubercular peritonitis. The body of the uterus was enlarged to the size of a pigeon's egg, its cavity, along with that of the Fallopian tubes, being distended with cream-like material. The os internum was plugged with glairy mucus; cervix natural; no displacement of the organ. Destructive changes had taken place in the walls of the organ, so that no definite tubercular growth could be distinguished.

Clinical Remarks on Resorcin, Antifebrin, Naphthol, and Naphthalin.—Dr. MACKEY read a paper showing the value of resorcin in gastric ulcer and catarrh, as illustrated by fifteen cases; also on the power of moderate doses of antifebrin to lower pyrexial temperatures, of naphthol to relieve pruritis, etc., and of naphthalin to control intestinal catarrh and offensive stools.—Mr. VERRALL mentioned two cases of gastric ulcer without hæmatemesis, which rapidly disappeared under the internal administration of resorcin.—Mr. CRESSWELL BABER had found in a case of epithelioma of the fauces more relief to the pain from a spray of 20 per cent. resorcin combined with cocaine than from a spray of the latter alone, although it had no effect in arresting the disease.

Phosphorus Poisoning.—Mr. LINGARD STOKES gave particulars of a case of phosphorus poisoning in a woman, aged about 20, who was seen to swallow some green-coloured paste five days before she died. The symptoms were vomiting, slight jaundice, coldness of extremities, severe pain in the abdomen, especially in the epigastrium, great thirst, etc. On examination the muscles were found soft and fatty; the pericardium contained some brown serous fluid; heart full, otherwise healthy; lungs healthy; liver greatly enlarged, of the consistence of dough, breaking down on the least pressure, of pale yellow colour, not a trace of liver colour being found. The stomach showed the usual symptoms of gastritis; no ulceration. The intestines were much inflamed, but presented no luminous patches. The kidneys were large, white,

and fatty, the pyramids natural in colour and cortex white. The stomach contained a large quantity of chocolate-coloured grumous fluid, which, on first opening and heating, gave off a slight smell of phosphorus.—Mr. DOUGLAS ROSS referred to a case of phosphorus poisoning he had brought before the Society (see JOURNAL for December 3rd, 1887), and thought that the state of the liver left no doubt as to Mr. Stokes's case being of this character.—Dr. HARRIS ROSS, Dr. CHAFFEY, and Dr. MACKEY also took part in the discussion.

MANCHESTER MEDICAL SOCIETY.

WEDNESDAY, FEBRUARY 1ST, 1888.

JULIUS DRESCHFELD, M.D., F.R.C.P., President, in the Chair.

Bacteria.—The PRESIDENT, on taking the chair, delivered an Inaugural Address on Bacteria.

Plastic Surgery.—Mr. WHITEHEAD showed a patient on whom he had performed a successful plastic operation. The skin had been taken from the arm, and the object of the operation had been to restore the surface of an extensive rodent ulcer which had been excised. During the period of union the arm was fixed to the head by plaster-of-Paris.

Osteitis Deformans.—Mr. SOUTHAM showed a man, aged 70, with osteitis deformans. The bones generally were affected, especially the cranium, spinal column, and shafts of both tibiae. The disease commenced thirty-five years ago, and was apparently induced by exposure to cold and damp. The patient was also affected with contraction of the palmar fascia, and it was suggested that both conditions were of rheumatic origin.—Mr. BISHOP showed a woman suffering from the same disease.

Spina Bifida Occulta.—Mr. STOCKS showed a case of spina bifida occulta, in which the lumbar region for about the space of six inches was covered with a considerable crop of long hair. The arches and spinous processes of several of the lumbar vertebrae were wanting. The patient was a woman in good health, the mother of several children, who had never suffered any inconvenience from the want of development.

Unnoticed Symptoms, and Unrecorded Reflex.—Mr. HENRY COLLEY MARCH communicated an unnoticed symptom in apæticæmia, and an unrecorded cutaneous pain-reflex, producible at will.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, FEBRUARY 3RD, 1888.

EDWARD ATKINSON, M.R.C.S., President, in the Chair.

Intestinal Obstruction.—Mr. MCGILL showed a case of acute intestinal obstruction due to a Meckel's diverticulum successfully treated by laparotomy (see JOURNAL for January 14th).

Ileo-cæcal Growth.—Mr. JESSOP related a case in which obstruction was caused by an ileo-cæcal growth. G. J., aged 33, signalman, was admitted into the Leeds General Infirmary on November 22nd, 1887. Nine weeks previously, there was a gradual onset of abdominal pain, and at the end of twenty-four days he was seized with symptoms of complete obstruction, the vomiting becoming stercoraceous. This lasted for seventeen days, when diarrhoea supervened, and there had been no vomiting for eight days before admission, at which time he was very ill and wasted, the abdomen much distended with constant borborygine and visible peristalsis. On December 1st, the abdomen was opened by the usual median incision, and a hard, fixed, irregular mass was at once felt at the junction of the ileum and cæcum. The colon was collapsed. An incision was made a few inches above the obstruction, and an artificial anus was established, the whole of the small intestines having been passed twice through the fingers in order to empty them and facilitate their reduction within the abdominal cavity. The patient made a good recovery, and was discharged on January 21st, 1888.

Intestinal Diverticulum.—Mr. T. PRIDGIN TEALE narrated the case of a man, aged 28, who had previously suffered from attacks of colic, and who, on December 24th, after a hearty supper was seized with colic, vomiting, and obstruction of bowels. When seen on December 27th by Mr. Teale, there had been no vomiting for twelve hours, and it was decided to wait. On the 28th vomiting came on again, and grew steadily worse; and on the 29th the abdomen was opened by a median incision below the umbilicus. A coil of intestine was seen to be bound down by a slender, though firm band, from the cut ends of which, when divided, a thin fluid

exuded, having a distinctly stercoraceous odour. The ends were secured by ligature. Upon irrigating the peritoneum a clubbed diverticulum was washed up out of the pelvis, where apparently the free end had been impacted, and had in that way been enabled to give rise to symptoms of obstruction. The patient died immediately after the operation.

Rupture of Intestine.—Mr. ATKINSON, related the case of a porter, aged 28, who was admitted into the infirmary at 2 p.m., August 15th, 1887, having shortly before received a severe contusion of the abdomen from falling against the edge of a table. On admission he was somewhat collapsed. The breathing was thoracic; the abdominal walls retracted; there was no pain but there was tenderness over contused spot; the flanks were resonant, the liver dulness normal. A catheter was passed and clear urine drawn off. He shortly afterwards vomited some undigested food free from blood. Intense abdominal pain afterwards came on above the level of the umbilicus, and at 10 p.m. abdominal section was performed by median incision below the umbilicus. Bubbles of gas and some blood-stained fluid escaped. The intestines were deeply injected, and glued together in places by patches of lymph. A perforation about half an inch in length was found close to the duodenum. The mucous membrane was everted close to the mesentery, which, as well as the intestine, was severely contused and echymosed. The wound was closed with six Lembert's sutures of chromicised gut; the peritoneal cavity irrigated with a 2 per cent. solution of boracic acid at a temperature of 96°; a Bantock's tube placed into the recto-vesical pouch, and the abdominal wound closed with wire sutures. He grew steadily worse, with occasional vomiting, hiccough, pain, tympany, and complete obstruction. On August 15th, there being obvious peritonitis, the abdominal wound was reopened at midday, and the peritoneal cavity again irrigated with boracic lotion. Acute peritonitis was found, but no faecal extravasation. He died at 4.30 p.m.

Acute Dilatation of the Stomach.—Mr. JESSOP communicated this case.—The patient, a lady, aged 26, had a month before undergone excision of the hip-joint for disease of seventeen years' duration, originating in distinct traumatism, and which Mr. JESSOP believed to be non-tubercular. Her general health and her family history were remarkably good. At the operation the disease was found to be limited to the head of the femur, the section being made through healthy bone, and the acetabulum intact. The wound was nearly closed, and she was rapidly improving, when one day, in the absence of the nurse, she obtained an apple, the whole of which she ate greedily. She was shortly afterwards seized with severe continuous vomiting. An aperient was administered, and she was put on milk diet. On the following two days the vomiting was intermittent, and was associated with extreme thirst. On the third day it was observed that before vomiting the abdomen was tumid, and the outline of the stomach, much distended, was clearly visible. After vomiting, the abdomen became flaccid, and nothing abnormal could be made out either as regards resonance, resistance, or tumour. There was no tenderness, but the extreme thirst continued, and the patient was obviously rapidly sinking. On the fourth day, as a last resource, the abdominal cavity was explored by the usual median incision, when the stomach, duodenum, and the first six inches of the jejunum were found enormously distended, the whole of the remainder of the intestines being remarkably collapsed and small. The stomach was opened by a small incision near the pyloric end, and a finger introduced. The pylorus could not be distinguished owing to its extreme dilatation, a condition which also affected the duodenum as far as the finger could reach. The patient died in a few hours. At the necropsy nothing more could be made out. There was no mechanical obstruction anywhere. The intestine simply seemed to pass from a condition of extreme dilatation to one of extreme contraction at a point six inches below the duodenum.—In the discussion which followed, Dr. CLIFFORD ALBUTT said it was difficult to account for acute dilatation of the stomach except on the theory of a neuroparesis in patients of feeble constitution or weakened by long illness, in whom an acute condition supervened. In Mr. JESSOP's case the collapse of the intestines was remarkable, and might possibly have allowed of the distension of the stomach; on the other hand, it might be secondary, and due to compression by the stomach.—Mr. TEALE said that in his experience one third of the cases of intestinal obstruction got well without operation, and thought that this consideration was mainly responsible for the unfortunate delays which so often terminated fatally within five days. He had

never seen a life thrown away by operation, but could call to mind four cases where death had resulted from the operation being performed too late, and he thought that it would be better occasionally to risk opening the abdomen unnecessarily, and especially in cases of chronic obstruction, or in acute cases where there was a history of former attack. There were undoubtedly grave intrinsic dangers from the damage done to the intestines by the enormous distension, and he had seen one case of ileo-caecal rupture where the patient had been watched for four weeks before a malignant stricture was discovered high up the rectum.—Mr. JESSOP, in operating upon all cases where there was danger of asphyxia from hæmorrhage or vomiting, had the patient's head brought well down over the edge of the table, so that the upper part of the pharynx became the most dependent.—Dr. JACOB referred these cases of acute dilatation of the stomach to a purely mechanical causation. It usually occurred in invalids in whom, as the result of careful and limited diet for a long period, had supervened an atrophic condition of the intestine. After a meal of indigestible or unsuitable food a large quantity of gas was evolved, and immediately produced a condition of extreme distension and paralysis.

Pathological Specimens.—Mr. E. ATKINSON: Bladder from case of Suprapubic Prostatectomy.—Mr. MAYO ROBSON: Hydrosalpinx.—Dr. JACOB: Microscopic Sections of Laryngeal Papilloma recently removed.

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND.

WEDNESDAY, FEBRUARY 23RD.

Professor HUMPHRY, F.R.S., President, in the Chair.

Sinuses of Valsalva.—Mr. MAYO COLLIER read a paper on the functions of the sinuses of Valsalva and auricular appendices, with some remarks upon the mechanism of the heart and pulse. He began by discussing current views of the formation and action of the sinuses of Valsalva. Those pouches were not pathological formations, but were essential to the action of the heart. Their closure was not sudden but gradual, and the second sound of the heart was due to the sudden distension of the aorta. The force of the ventricular contraction was expended in distending the aorta rather than in propelling the main column of the blood. The auricular appendix was the part of the auricle which forcibly contracted and propelled the blood into the ventricle during its diastole. The current views as to the flapping of the valves of the heart were next refuted, and it was maintained that the first sound of the heart's beat was in no way caused by the closure of the valves. The pulse was afterwards spoken of, and the dicrotic wave was considered not to be due to a back wave, but to other causes.

Ossification of Skull.—Mr. J. BLAND SUTTON showed specimens of the ossification of the superior maxilla, inferior maxilla, and malar bones to illustrate his paper on the morphology of the skull. There was no discussion.

Cranio-Cerebral Topography.—Professor CUNNINGHAM then showed and explained a series of models which illustrated cranio-cerebral topography. The series consisted of plaster casts, made before and after the removal of the skull cap, and comprised specimens of 5, 11, 12, and 15 years, and of adult male and female. The suture lines had been left, and the convolutions placed in relation to them.

Musculus Sternalis.—Professor CUNNINGHAM next read a paper on the musculus sternalis. After reviewing the literature, the results of his own dissections were given, and he maintained that the muscle was not a part of the panniculus carnosus, but a downward dislocated portion of the pectoralis major. This assertion was chiefly based upon its nerve supply, which was exceedingly long, and came from the anterior thoracic nerves, and upon the fact that the anterior branches of the intercostal nerves were recurrent round the inner margin of the sternalis.—Professor HUMPHRY considered the existence of the sternalis due to incomplete segmentation of the great muscular sheet.—Professor MACALISTER discussed the question of the origin of the sternalis, and thought too much stress had been laid upon the last point. The muscle was present in 3 cases out of 115, but this was a low average. He confirmed Professor Cunningham's observations that the muscle was absent in other mammals.—Professor TRANE was inclined to agree with the author of the paper. He discussed the question whether the muscle was vestigial or developing, and, in

the latter case, as Professor Cunningham had remarked, devoted to costal respiration.—Mr. SUTTON also made some remarks.

Morphology of Extensor Muscles.—Professor CUNNINGHAM read a paper by Dr. ST. JOHN BROOKS on the morphology of the muscles on the extensor aspect of the middle and distal segments of the limbs. The paper showed that: 1. The extensor minimi digiti was originally the fifth belly of a short extensor. 2. The anconeus belonged more properly to the extensor carpi ulnaris than to the triceps. 3. That the occasional extensor brevis digitorum manus in man was not homologous with the extensor brevis digitorum pedis, but to the occasional deeper slip of that muscle. Finally, that the nerve to the anconeus was homologous to the branch of the anterior crural, which sometimes supplied the tibialis anticus.

Vestigial Muscles.—Mr. J. BLAND SUTTON then read his paper on vestigial muscles, which, he said, reviewed the subject of Dr. Brooks's communication from an entirely different standpoint. Man, in common with the quadrupeds, originally had a deep as well as a superficial set of extensors for the fingers. The deep set originally arose from the external condyle of the humerus and adjacent olecranon; gradually they migrated down the ulna. As they descended they carried the posterior interosseous nerve with them. By degrees the middle slips regressed into fibrous tissue, and their nerve became imbedded in their remains on the back of the carpus. Gimbernat's ligament and the triangular fascia were then argued to represent a ligament which binds the epipubis to the ilio-pectineal line in the marsupials, and the ilio-femoral ligament was said to represent the gluteus quartus.

Specimens.—The following specimens were also shown: Professor THANE: Obliteration of the Coeliac Axis: Collateral Circulation established through the Pancreatico-duodenal Arteries.—Professor CROFTON: Interparietal Bone; Double Arch of Aorta, enclosing Trachea and Oesophagus; Constricted Arch of Aorta, with enlarged Anastomotic Branches.—Mr. KENNY: Abnormal Relation of Phrenic Nerve to the Subclavian Vessels.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

THURSDAY, FEBRUARY 9TH, 1888.

LAWSON TAIT, F.R.C.S., President, in the Chair.

Ununited Fracture.—Mr. VINCENT JACKSON exhibited a patient, aged 27, who was seen last March on account of an ununited fracture of both bones of the right leg at the lower third, injuries received eight months previously. The operation consisted in most carefully removing by cutting, snipping and scraping all the soft tissues connecting the ends of the bones, then placing these in apposition, and after each fragment had been pierced by a bradawl, they were permanently fixed by being nailed together by two wire nails two inches in length, the heads of which were buried in the soft parts, and at the present time were to be felt subcutaneously. The operation wound healed within a fortnight, and when the plaster-of-Paris case, after being worn for eight months, was permanently removed, it was evident that the most perfect union of the fractured bones had resulted.

Suprapubic Lithotomy.—Mr. VINCENT JACKSON exhibited a man, aged 57, upon whom he had, in December last, performed the operation of suprapubic lithotomy for the removal of a uric acid calculus weighing fifty-one grains, tightly fixed in a diverticulum at the extreme posterior limit of the base of the bladder on the left side. It had previously been attempted to remove the calculus by perineal lithotomy.

Loose Cartilage.—Mr. VINCENT JACKSON showed a loose body recently removed from the right knee-joint of a gentleman, aged 27. The measurements of its longest and shortest diameter, as well as of its thickness, were $2\frac{1}{2}$, $1\frac{1}{2}$, and $\frac{1}{2}$ inches. Within a fortnight the operation wound into the joint had quite healed.

Successful Nephro-lithotomy.—Mr. BENNETT MAY brought to the meeting a young man whose case presented some unusual features. The number of calculi removed from the left kidney was four; they were very small and faceted, the total weight being twelve grains. In spite of the fact that the kidney, when operated on, was enlarged and dilated, the patient was now (four months) perfectly well in every respect. Hematuria occurred eight years ago, and since then he had never been free from symptoms. For the last year the pain after exercise had been unbearable, and he had been in bed for a month. There was much pus in the urine. Remarking on the good fortune which had attended the exploration, Mr. May said he thought these small calculi must together have acted as a ball-valve in the ureter, and that the sudden

recoil and outflow of urine which took place on incising the kidney substance brought them within easy reach of the finger. They were all he could find on a careful and prolonged search. The patient rapidly recovered, had remained perfectly free from pain, though engaged in a laborious occupation, was now in perfect health, and his urine showed no trace of the former deposits.

Specimens.—Mr. JORDAN LLOYD exhibited a typical raspberry-like adenomatous polypus, removed from the rectum of a man nearly 70 years of age. Haemorrhage of between two and three years was the only symptom. He also showed a large sebaceous cyst which he had excised from the abdominal wall of a woman 50 years of age, and which presented all the phenomena of irreducible umbilical hernia.

Cholecystotomy for Gall-Stones.—Mr. LAWSON TAIT exhibited a large solitary gall-stone, from a case of suppurating gall-bladder, which he had operated on about a fortnight previously. At the time of the operation, the gall-bladder was in a condition of suppuration, and was adherent to the surrounding viscera, but not to the parietal peritonium. Its walls were very thick and friable, and it was with great difficulty the stone was brought to the surface. The patient made an easy and rapid recovery. This was the last of a series of forty-one consecutive cases in which Mr. Tait had performed the operation of cholecystotomy, and he had only two fatalities in the series, in both of which the operation did not seem to make any difference as to the progress of the disease, as it was malignant, associated with gall-stone.

Uterine Appendages.—Mr. LAWSON TAIT also showed the uterine appendages of a case recently published, in which the operation was performed for intense hysterio-epilepsy. Professor FORRÉ had made an effort to remove the appendages six weeks before, but had completely failed on account of the dense adhesions, evidences of which were to be seen all over the surfaces of both tubes and ovaries. Both tubes were occluded, and had been occupied by a small amount of serous fluid. The patient had had no return of the symptoms since the operation, now nearly four months.

Modification of Tait's Trocar.—Mr. LAWSON TAIT showed a modification of his trocar which had been forwarded to him by an American surgeon as an improvement. It was made of vulcanite, and consisted of the old-fashioned arrangement of an inside tube and outside slide, and the apertures of the trocar could be closed either by intention or by accident. This, in Mr. Tait's opinion, was the great drawback, because if the trocar was in a cavity and there was any fluid left in the cavity, under no circumstances ought the apertures in the trocar to be closed, for the intention was that the fluid should run out of the cavity. If, on the contrary, there was no fluid in the cavity to run out, no harm was done; but if there was fluid to be extracted, and by an accident the apertures of the trocar were closed, serious mischief might arise. Therefore it could not be necessary, under any conceivable circumstances, to close the apertures of the trocar, and in his opinion the so-called improvement was a mistake.

Gall-stones.—Mr. LAWSON TAIT also showed a preparation of three gall-stones of large size impacted in the common gall-duct. They were so situated that they might have been reached from within the peritoneal cavity and crushed, as Mr. Tait had done in several instances, from outside the duct, the fragments then passing on. The preparation was sent to him by Dr. Forty, of Wotton-under-Edge, and showed clear evidence of the evil results which would have accrued from removal of the gall-bladder—the so-called operation of cholecystectomy. If this had been done with the gall-bladder occluded as it was, all the bile would have flowed into the peritoneal cavity. As it was, the patient lived for many years after a cholecystotomy for the removal of a large number of gall-stones, and these were left in the duct.

Tumours of the Bladder.—Mr. G. BARLING read an exhaustive paper upon this subject.

THE LABOURERS' ACT.—The Clonmel guardians have agreed to pay their medical officers a fee of five shillings for each cottage examined and reported upon under the provisions of this Act.

UNUSUAL DEATH-RATE.—The Medical Officer of Motherwell reports for the month of January a death-rate equal to 50 per 1,000 per annum. During the month, 40 out of the total of 74 deaths were caused by zymotic disease, 22 being due to measles, 12 to whooping-cough, 4 to scarlet fever, and 2 to diphtheria.

The will of Dr. James Cato de Castro, formerly of Ilinde Street, Manchester Square, but latterly of Torquay, has been proved; the personal estate valued at upwards of £22,000.

REVIEWS AND NOTICES.

THE USE OF ELECTRICITY IN GYNÆCOLOGICAL PRACTICE. By GEORGE J. ENGELMANN, M.D., Professor of Obstetrics and Diseases of Women, St. Louis Post-graduate School of Medicine. (Reprinted from the *Transactions of the American Gynæcological Society*, vol. xi, 1886). New York: D. Appleton and Co. 1887.

DR. ENGELMANN, of St. Louis, has earned the right to be considered as an authority in the application of electricity to gynæcology, along with Apostoli, Cutter, and Steavenson. This memoir includes a definite system of electric measure and dosage. The author rightly dwells on the difficulties which attend the use of electrical apparatus. He distinguishes nine radical errors into which practitioners have fallen. These errors are, first, the empirical use of electricity, and the want of proper indications for the use of this powerful agent; secondly, ignorance of the powerful action of the pole direct and use of the interpolar current, inferior as a remedial agent; thirdly, indiscriminate use of the various forms and modifications of galvanic and faradic current; fourthly, indiscriminate use of both poles; fifthly, want of localisation and diffusion of current; sixthly, lack of exactness, if not total absence, of measure and dose; seventhly, the use of currents too weak to be effective, and the too ready limiting of their intensity by the pain which they inflict; eighthly, the long duration of sittings long continued; and ninthly, the lack of proper electrodes and of instruments of precision.

An instructive commentary is given on each of these errors, and the right path is indicated. Some good comparative tables of the effects of galvanic and faradic electricity are placed alongside each other. In the essential part of the memoir are paragraphs on the management of the apparatus and the application of the poles. Dr. Engelmann agrees with M. Apostoli in his theory of the action of the positive and negative poles when the galvanic current is employed. A long series of cases concludes the memoir. We need hardly say that, on the whole, brilliant results are claimed, but the cases are fairly reported. Each demands close scrutiny, and we know the great difficulties which attend any attempt to determine the precise agent which has brought about the cure of any given case. We do not wish to be sceptical about Dr. Engelmann's system; we rather commend his method of teaching it through a literary medium. The matter, at first sight, looks very heavy; but the man who takes to electrical apparatus must work hard, and cannot expect to find his preliminary instruction light. Dr. Engelmann has altogether been merciful to his pupils, that is to say, his readers; he does not terrify them with long scientific tables, loaded with figures, decimal points, and still less familiar mathematical symbols. We regret, however, that, owing no doubt to its publication as part of the archives of a Society, it is not illustrated. Some good diagrams of the parts of a battery and some drawings of the method of application of the poles should have been added. Lastly, we cannot share the author's confidence about the partial cure of a case of ovarian sarcoma with perimetritis by electricity. The most experienced authorities may take many curable abdominal affections for ovarian tumour; and a sarcoma of the ovary is not always easy to recognise, even when exposed by abdominal section, which does not appear to have been done in this case; adhesions, too, are not so readily diagnosed as the author here implies. Electricity may, some day, be made to cure malignant tumours, but first we must be sure both of the electricity and of the tumour.

LIGHT DIET: A HANDBOOK OF DIET AND COOKERY FOR ALL CLASSES OF INVALIDS. By H. W. SEAGER, M.B., etc. London: Simpkin, Marshall and Co. 1887.

SOME acquaintance with, at least, the elements of the art of cooking is a very necessary part of the outfit of a successful practitioner of the art of medicine; Dr. SEAGER's book is intended for the use and information of the lay patient, and the receipts it contains may be handed to any intelligent cook. It is, however, likely to be of great use to the physician; it is a careful compilation of receipts for the preparation of wholesome and palatable dishes from all varieties of food, which are classified in thirteen chapters, each provided with some general introductory observations. There are chapters also on enemata and predigested foods, on the feeding of

infants, and on drinks. Dr. Seager seems to have taken great pains to obtain trustworthy information, and to lay the results of his researches before his readers without prejudice, and the book is quite free from the "fads" which sometimes diminish the value of works intended for the use of invalids. The author has taken the word invalid in a wide sense, as may be gathered from the following quotation: "Sucking-pig is too rich for most people, but is so excellent a dish that it seems a pity to forbid it altogether."

The introductory observations prefixed to the various chapters are short and to the point, giving trustworthy particulars as to the properties of each class of food; but the collection of receipts could only be really judged by experiment in the kitchen, though the majority are fairly well known and approved. The directions for preparing predigested foods ought to have been more precisely given, as the method is unfamiliar to most people, even to many trained nurses; it may be observed in passing that the glycerine extract of pancreas will keep for a longer period than "several days," and the quantity directed to be used for each injection is unnecessarily large. We have noted a few statements which are, to say the least, open to question, and contrary to opinions founded on long experience, as, for instance, that snipe is better than woodcock, and that both are very digestible; that pheasant is "a much over-rated bird; he has little more flavour than a chicken, and is not nearly as digestible." The remarks on wines are on the whole sound, but it is not correct to say that "marsala is an inferior, madeira a superior, sherry;" neither does it seem very judicious to write: "Sweet wines, for example, tokay, malaga, malmsey, port, Lacryma Christi, etc., should only be taken in liqueur glasses with a plain biscuit when the stomach is not full, and are good as a stop-gap between meals." Aside from the danger of inducing habits of intemperance, by advising or permitting such "nips" between meals, the best opinion is that port wine should be taken after dinner, no wine, or very little, being taken during the meal.

MANUAL OF HYPODERMIC MEDICATION. By Drs. BOURNEVILLE and BRICON. Translated from the second edition, with additions, by ANDREW S. CURRIE, M.D. Edin. London: H. K. Lewis. 1887.

THE method of administering drugs by injection of their solutions into the subcutaneous tissue is not much more than thirty years old. It is true that a few physicians had from time to time resorted to the method in an experimental kind of way for some years before the publication of Dr. Wood's treatise in 1855, but the method did not come into general use until after that date. Questions of priority are always rather unsatisfactory topics of discussion, and this is especially so in this instance, for physiologists had used the method since the beginning of the century at least, and the application of the method to the human subject is hardly to be accounted a stroke of genius, though creditable to the adopter, whoever he may be, whether Rynd, Taylor, Washington, or Kurzak. Practically, in this country at least, the method has been used for a very limited number of drugs only, and it will probably be a surprise to many readers to learn that Drs. BOURNEVILLE and BRICON treat of over one hundred drugs which have been (with varying frequency and success it is true) administered hypodermically in disease.

The *Manuel* of these two authors is so well arranged, accurate, and portable, that it is rather surprising that it has never been translated before. It has not been a difficult book to translate or adapt to English measures. Dr. Currie has done his work, so far as we have been able to judge, well, and his notes and additions are, as a rule, judicious. It is a pity that the publisher has not better seconded the translator's efforts by bringing out the volume in a neater and more portable form.

The main body of the *Manual* consists of a series of articles on the various drugs arranged in alphabetical order, after the manner of the *British Pharmacopœia*. The physical properties of the drug are first described, then its physiological effects, and antidotes, next formulæ which have been employed are given, and, finally, the therapeutic uses are indicated. As the authors confess, many of the formulæ given are not good, and it is doubtful whether any useful purpose is served by preserving them in a work so well-known and so highly valued as MM. Bourneville and Bricon's *Manuel*. Many of the drugs also have never come into actual use, and it is hardly probable that they will ever pass beyond the experimental or tentative stage.

Dr. Currie has increased the value of the *Manual* for reference in emergencies by adding a therapeutic index based on those contained in the well-known works of Dr. Ringer and Dr. Lauder Brunton. He has also drawn up a table of antidotes and antagonisms, a posological table, and a general index. He has written several articles, which are well up to the mark, and has throughout the work taken great pains to make the information furnished complete and accurate.

NOTES ON BOOKS.

Longley's Student's Pocket Medical Lexicon. (Edinburgh Young J. Pentland. 1888.)—This is a new edition of a little work which usefully fulfils its purpose. It places in the hands of students a dictionary of over seven thousand words, embracing all the words and terms in most general use in medicine and the collateral sciences, with the pronunciation of each word fully and distinctly indicated by means of the American phonetic alphabet, which requires very little patience to acquire. The meanings are tersely, accurately, and well expressed. Of course such a work as the present is not intended to supersede the larger and more comprehensive works of Thomas, Dunglison, and the like; but as a pocket medical lexicon for students it fulfils in an admirable degree its useful object. An appendix, giving a list of poisons and their antidotes, renders the work additionally valuable. There are also given the abbreviations used in prescriptions and the metric scale of doses. As a compendious pocket guide for medical students, a veritable *multum in parvo*, we can warmly recommend it.

Travels in the Interior, or the Wonderful Adventures of Luke and Belinda. By LUKE THEOPHILUS COURTENEY. Edited by a London Physician. With Illustrations by Harry Furniss, and Original Scientific Drawings by L. T. C. London: Ward and Downey, 1887.—It is rather curious that *Alice in Wonderland* has found so few imitators; other works of imagination and humour, far less successful in catching the popular fancy, have set a fashion followed with a brief period by many writers; in this volume, "edited by a London Physician," we have a sort of *Alice in Wonderland* with a purpose. Alice, whose name however is Belinda, is accompanied by her brother, a new-fledged M.R.C.S., and his friend; like Alice, they incautiously eat a magic sweetmeat, and decrease so rapidly in size, that they are accidentally carried into their uncle's mouth, where two of the party find a temporary refuge in a hollow tooth. The M.R.C.S. is an inventive genius, somewhat ahead of the day perhaps, who is provided with a pocket electric light, a wonderful apparatus for waterproofing clothes, and a still more remarkable respirator; thus armed, the pigmy travellers visit the tympanum and the larynx, travel down the œsophagus, watch the process of digestion in the stomach and duodenum, bore their way into a lacteal, journey through the receptaculum chyli and thoracic duct, gain a cutaneous vein, and finally after many hairbreadth escapes, reach the surface, and regain their natural dimensions. The M.R.C.S. and his friend discourse pleasantly at the various stages of the journey, explaining to the inquisitive Belinda the significance of the various structures and processes observed. The information thus conveyed is always accurate, and we have indeed noted one point, the mode of absorption of fat by the lacteals, where the statements are an advance on these still made, if we mistake not, in the ordinary textbooks. The story is well told, and if young people can be induced to get over a little natural repugnance to the subject, and to being taught under the guise of amusement, they will become sufficiently interested in the fortunes of the adventurous travellers to follow them to the end. Mr. Furniss's illustrations will conduce to this; they are well and gracefully designed, and realise the ideas of the author, without the least suspicion of coarseness.

Dr. WEST asks us to correct the statement in the roll of the Royal College of Physicians, to the effect that he has taken up his residence in Rome; he continues to reside and practise in London, and is merely absent on a short holiday.

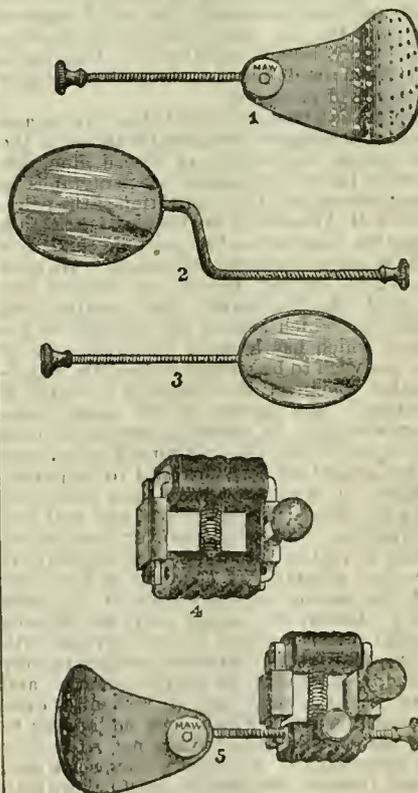

PRESENTATION.—On the occasion of leaving Byers Green, for Whitburn, near Sunderland, Dr. McKane has been presented by some of his late patients and friends, with a handsome microscope as a token of esteem.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS, IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

NEW GAG WITH THROAT GUARD.¹

By JOHN WARD COUSINS, M.D.LOND., F.R.C.S.,
Senior Surgeon to the Royal Portsmouth Hospital, and to the South
Hants Eye and Ear Infirmary.

The instrument exhibited in the engraving consists of a gag in combination with a throat guard, mouth mirror, and tongue depressor. The gag is small and square-shaped (Fig. 4), and it can be opened and closed when placed in position in the mouth. The dental surfaces are made of steel, covered with thick pads of red rubber, and they are supported on either side by sliding bars and a metal collar. The bars are expanded by a central spring, and fixed by a rack and screw adjustment. The lower dental bar is tunnelled for the purpose of carrying the stem of the guard or mirror. By rotating the stem in the gag, the mouth-plate of the

appendage is readily shifted, and then, by turning a binding screw, it is securely fixed. The gag with the throat guard, attached to it is shown in Fig. 5. The plate of the guard is spoon-shaped, and half of its surface is perforated with small openings, so as to permit the passage of air (Fig. 1). It is also flexible, and can be easily bent to fit a shallow mouth. When placed obliquely on the fauces, its posterior edge rests against the anterior pillar, and it thus forms a complete protection to the throat. The guard divides the oral cavity into two parts, at the same time it acts as a very efficient tongue depressor.

The gag is especially designed for the purposes of dental surgery, and for other minor operations on the mouth and gums. It can be used with safety during the administration of chloroform or nitrous oxide gas, and the guard is a great protection against the slipping of a tooth into the throat, an accident which may happen even to a careful and dextrous operator. It, moreover, enables the mouth to be readily cleansed of blood, and prevents it from entering the respiratory passages. The guard is generally very easily adjusted without causing any discomfort to the patient; but, whenever the fauces are extremely sensitive, it must be introduced with care and gentleness. In many cases the irritability is removed at once by the application of a solution of cocaine to the throat. The mirrors serve for tongue depressors, and they are adapted to illuminate the mouth in any direction. They are made in several sizes, and with both straight and angular stems (Figs. 2 and 3). The buccal mirrors are not represented in the engraving; they

¹ Exhibited in the Section of Surgery at the Annual Meeting of the British Medical Association held in Dublin, August, 1887.

consist of narrow reflecting plates, which are fixed at right angles on flexible stems. The right upper buccal mirror can be used for the outer surface of the left lower molars, and the left upper mirror can be fixed on the right side for a similar purpose. When in position the buccal plate gives a complete view of the outer surface of the teeth and gums, and acts also as a cheek distender, and compressor of Steno's duct. All the mirrors can be very conveniently used for dental operations, such as stopping and sealing, and they are intended as substitutes for the ordinary dental mirrors, which are often encumbrances in the hands of the operator. The gag is manufactured by Messrs. Maw, Son, and Thompson, of London.

HARTMANN'S SANITARY WOOD WOOL SHEETS, AND HARTMANN'S SUBLIMATE LOTIFORMS.

THESE new preparations have been submitted to our notice by the Sanitary Wood Wool Company, of 11, Hatton Garden, E.C.

The sheets consist of a good thickness of Hartmann's well-known wood wool enclosed in gauze, and secured so that when used the wool does not shift its position. They are made of various sizes, those of about three feet square being, perhaps, as convenient as any. They can be used in place of mackintosh sheeting in lying-in cases, as well as in other cases where there is a large secretion or discharge from which the bedding requires protection. These sheets possess the advantage of having no odour. They are very soft and absorbent, and, being antiseptic, the secretion and discharges absorbed by them do not tend to decompose.

The lotiforms consist of small pledgets of coloured wool, enclosed in a little gauze bag. They are impregnated with corrosive sublimate to such a degree that one lotiform cut open and placed in two pints of hot or cold water, and stirred, will give a solution of a strength of 1 in 10,000. This strength can, of course, be varied by using a larger or smaller quantity of water. The lotiforms are cheap and portable, and very convenient for making extemporaneously a solution of corrosive sublimate, either for vaginal injection or for general use as a lotion. Owing to the nature of the material of which they are made, there is no danger of their being swallowed by mistake.

CALVERT'S CARBOLIC LOZENGES AND CAMPHORATED CARBOLIC SOAP.

THESE preparations are made by Messrs. Calvert, of Manchester, the well known manufacturers of carbolic acid. The lozenges contain one-fifth of a grain of pure phenol, and are as palatable as any lozenge can be containing such a proportion of carbolic acid.

The camphorated carbolic soap is recommended to prevent chapped hands and insect bites. As a bath soap it will be found useful in destroying the odour of perspiration, and leaving the skin in an agreeable condition. It can also be used generally for those skin diseases in which the application of a mixture of carbolic acid and camphor is indicated. The soap lathers well, and it has a wholesome and pleasant odour.

GLASS STETHOSCOPES.

MR. ALEX. FAULKNER, M.R.C.S. (London), writes: I should like to bring to notice an improved stethoscope which I had made for myself, and which I have used for some time. It is made entirely of glass, and there is no loss of continuity in its construction, its cylindrical portion being either solid or hollow, and its shape is similar to other ordinary stethoscopes in general use. It is an excellent conductor of sound.

TUNBRIDGE WELLS URBAN.—A comparison of the death-rates of this district with those of the twenty-eight large English towns for 1886 elicits from Dr. Stamford the boast that no town of the same population suffered so lightly, judging from the mortality statistics, as Tunbridge Wells. Moreover, he was so satisfied with its condition at the close of the year that he had no further measures of sanitary improvement to recommend. Only 20 deaths resulted from zymotic disease, and half of these were due to diarrhoea. The sufferers from this disease were nearly all infants, and the deaths were in the third quarter of the year, facts which Dr. Stamford remarks upon, and which lead him to doubt whether the deaths were due to zymotic origin. He attributes them rather to fermentative change in the food. Twenty-two cases of scarlet fever were removed to the sanatorium, and all were discharged convalescent. One death from this disease took place in the town. The general death-rate was 14.4 and the zymotic rate 0.7 per 1,000.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1888.

SUBSCRIPTIONS to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the West Central District Office, High Holborn.

The British Medical Journal.

SATURDAY, FEBRUARY 18TH, 1888.

LESSONS FROM SHEFFIELD.

SURELY something must be wrong in the education given to the people, or it would not be possible in a town like Sheffield, at the close of the nineteenth century, to find such an amount of ignorance, prejudice, credulity, and folly as was seen in the Temperance Hall of that town, on the evening of February the 9th.

A Mr. Herring, of Leeds, gives out that he can cure small-pox in two days. At once a memorial is signed by 2,000 persons requesting the Mayor to convene a meeting before which Mr. Herring could explain his plan of treatment. The requisition further stated that, notwithstanding the fact that Mr. Herring could get no recognition from the Corporation, he had come to Sheffield, and already successfully treated a number of cases, particulars of which could be produced at any time. In response to this document the Mayor, very foolishly as we think, called a meeting, at which he himself took the chair. The hall, a large one, was crowded to its utmost capacity, and so great was the attendance that many persons were unable to gain admittance, while the wild enthusiasm shown by the audience was a noteworthy feature of the meeting.

A person named Adams moved the first resolution, which was, like the remaining one, carried by acclamation. It was this: "That, in the opinion of this meeting, the fearful state of small-pox in the town, the damage to shopkeepers and trade in general, the fearful loss of life, and the consequent suffering therefrom, demand that prompt action be taken by the health authorities to extinguish the disease, and so lift the town from its present unenviable position."

Mr. Hill, the seconder of this resolution, made the statement that when a man suffering from small-pox got into Mr. Herring's bath, with the water up to his neck, and had his head sponged, it was "domino" with the disease; he does not explain, however, to what extent it is likewise "domino" with the patient.

The second resolution was, if less grammatical, more definite in its recommendation; it ran as follows: "That this meeting having had produced before it such evidence of Mr. Herring's ability to reduce the disease in an incredibly short time, and having regard to his offer to the town of Sheffield, which he now repeats, we request the Town Council to engage him at once, and

place him in a position for showing the efficiency of his treatment of small-pox cases."

In the course of the discussion, Mr. Herring gave his auditors an account of the *rationale* of this treatment; it was beautifully simple. "The blood was reduced to its natural heat; and as the blood was stopped from being inflamed, the flesh was prevented from being mortified. The disease was stopped in two minutes."

An admirer of Mr. Herring, to whom the latter might justly say "save me from my friends," at this stage asked him how many cases of small-pox he had dealt with before he came to Sheffield, during the twelve years he had been in practice, and what had been the result of his treatment in these cases.

This was Mr. Herring's remarkable reply, reported in his own lucid and elegant language: "He had cured hundreds of people who had been crippled with rheumatism and drawn all shapes." "As regards small-pox," continued he, "I have only had four cases, which was cured direct in a state of fever—no spot on them. One young man that come, he had got into a state while his flesh was beginning to inflame a bit, and under the treatment it simply showed where he would have a spot, and that was gone away when the medicine was dried in. As regards typhoid it is as bad as small-pox, and it is as readily cured by this treatment. Scarlet fever, I have cured hundreds of children and grown-up people—hundreds. Once at Batley I cured twenty-six children in three days."

Mr. Paul Gill asked Mr. Herring if it was true that a person had died under this treatment? But he was promptly extinguished by a woman who cried out from among the audience, "How many have died under doctors?" and by Mr. Herring, who, amid loud and prolonged cheers, said: "The answer is simply this; the man was dead when I went to him." At this the Chairman interposed, and declared himself shocked at Mr. Herring's statement, for that person, in speaking privately to him a few minutes before of this very case, had said that the man was not dead when he was called in to him, but so ill that he dared not give him a bath, but simply bathed his face with the remedy. Mr. Herring, however, was equal to the occasion; he replied: "I did not say he was lifeless, I said he were dead; his flesh were dead; he was simply breathing in and out of his mouth, and that was nearly closed. His flesh were all gone; no life in it. Of course, if there is no life in your flesh you are dead, are you not? I did not mean to say the man were lifeless, I said he were dead."

After this luminous explanation, which, however, drew forth the taunt from one of the audience: "You ain't had a school-board education," the resolution was passed unanimously amid loud cheers. On his way from the meeting Mr. Herring was followed for some distance by an enthusiastic and cheering crowd.

While the people of Berlin press round Prince Bismarck with their enthusiastic applause as he walks from the Reichstag after making a speech which echoes throughout Europe, the inhabitants of Sheffield can find no better object for their hero worship than a mischievous and ignorant pretender. We trust this is no

symptom of a degeneration of our countrymen, but only a passing example of the truth of Carlyle's dictum, "That England is inhabited by thirty millions of people, mostly fools."

Both this meeting and its cause have several lessons even for wise and scientific men. They show that an epidemic, if not prevented by isolation and separation in the first instance, may, in spite of all subsequent efforts, become an endemic plague, throwing the people of the affected district into panie terror, and making them the easy prey of quacks and charlatans of all kinds. They show, too, that without local or general Acts for the compulsory notification of infectious disease, preventive measures are merely a delusion and a snare.

Leicester, with its explosive population and under an Act for compulsory notification, stamps out each case of small-pox as it arises. Sheffield, partly protected, which refuses such a clause, becomes a very pest-house, injurious to its own inhabitants, their trade and life, and a source of danger to the whole country.

Another lesson is the importance of instructing the people in the causation and course of disease by means of classes and lectures and private instruction, in order that they may be protected from such folly as the Sheffield Temperance Hall meeting. Let them learn the etiology and course of this and all kindred diseases, and they will not be prone to believe that what the wisest and most learned of our physicians, from Sydenham to Murchison, have declared to be impossible, an uneducated pretender from Leeds can accomplish with ease.

Let the public also learn from the action of our own body, from our private conduct and our public pretensions, that the days of empiricism and theoretical pathology are passed away—that we are not believers in the possibility of cure by the vague and indiscriminate administration of drugs. That in some few diseases there are specific remedies; that in others we can guide the patient safely through an illness, which we can no more check, or seek to check, than the skilful pilot quiets the raging storm, through which, however, he steers his labouring ship to its desired haven.

Let us also insist, both publicly and in private, that no valuable discovery in healing has ever been made by the compounders of quack medicines, and that they are simply impostors, growing rich on the credulity of silly people. Let us also agitate for some such wise law as that of France; that the composition of every patent medicine shall be declared before it is permitted to be sold. As to Mr. Herring, if the Corporation of Sheffield does not ignore his modest request to treat patients in the Fever Hospital, it should be granted on one condition, that, in case of failure, he submit himself to be publicly whipped at a cart's tail from the hospital to the Temperance Hall, as a detected impostor, a rogue, and a vagabond.

The thanks of the people of Sheffield and of our profession are due to Sir William Leng, the editor of the *Sheffield Telegraph*, for the judicious method in which he has reported this meeting and exposed and ridiculed this nineteenth century repetition of the folly and ignorance of the Middle Ages.

STUDIES IN THERAPEUTICS:

III.—RECENT CARDIAC TONICS.

DIGITALIS still holds its own as the most powerful heart tonic which we as yet possess, and the most permanent in its effects. But its use is more or less contra-indicated in certain forms of disease of the heart; and, on the other hand, it is sometimes found that digitalis is not well tolerated even in cases apparently suitable. In fact, a watchful care is required whenever this drug is given, not only at the beginning of treatment, but as long as it is continued, because alarming symptoms may arise at any time during its use, although its so-called "cumulative" effects are questioned by several recent observers. Of late years ceaseless efforts have been made to find some other means of strengthening the heart's action safely as well as certainly in cases of failure of compensation.

Oertel, dispensing with drugs altogether as far as regards the heart, effects this by muscular exercise, graduated to suit the patients. He finds hill climbing to be the best means of stimulating the heart muscle to increased action, and thereby promoting increased growth of its fibres. The excess of water connected with venous stasis is for the most part previously removed from the blood, and altogether it will be found that the treatment adopted is exactly that calculated to put the patient "in good condition," just as a horse is trained for racing. Grooms are sparing in the amount of water they give to hunters and racers during severe exertion; when cool the animal will not drink too much even with water constantly before him. But man is a very different animal, and there is no doubt that most people imbibe much more liquid, of one sort or another, than is necessary for the physiological requirements of the body. Oertel's work on circulatory disorders is now to be had in English, and it is to be hoped that it will receive the serious attention which it deserves, but which it has not yet obtained in this country. The manner in which the heart muscle grows larger under increased exertion still requires explanation. Stricker is of opinion (*Vorlesungen*, 1883) that together with impulses to the motor muscles of the body during work, impulses are also communicated to the vasomotor nerves of the viscera, causing a rise of blood pressure, which would explain the persistency of the increased blood pressure after the exertion is over. Nothnagel attributes this increased blood pressure to compression of the peripheral vessels during muscular exercise, and, moreover, regards the increase of carbonic acid in the blood caused by work as a stimulant to the heart. Practically speaking, it is of course understood that hill climbing is only suitable in cases of insufficiency of the heart muscle when this condition is not too far advanced; if this be the case, Nothnagel very properly calls the method a "two-edged sword." But Oertel does not advocate sending a patient—for example, with severe valvular derangement, an irregular pulse, and œdema about the ankles—straight to the mountains to be walked up and down. Von Bamberger advocates Oertel's method, but he also would confine its application to commencing in-

sufficiency of the heart muscle, with or without valvular derangement.

The double salts of caffeine, as examined and recommended by Riegel, have attracted some attention as a means of strengthening the heart's action; but their use is not altogether free from danger, and again they sometimes fail wholly in effect. They have not succeeded in coming into general favour.

Sparteine (sulphate) is the next claimant of our attention. Sparteine is a base derived by Stenhouse from *spartium scoparium*, and pronounced by Mills to be a tertiary diamine having the formula $C_{15}H_{26}N_2$. It is a colourless alkaline liquid, boiling at $287^{\circ}C.$, of penetrating, disagreeable odour and very bitter taste. It is heavier than water, and only slightly soluble therein, easily soluble in ether or chloroform. It forms crystalline salts with acids, from which it is precipitated by alkalis. The sulphate is the best salt medicinally. Fick studied the action of sparteine on the animal organism, and Froumüller established its diuretic effect. Recently it has been rescued from oblivion by Germain Sée (*Comptes Rendus*, 1885, No. 21), who recommends it warmly as a cardiac tonic. This observer declared that sparteine had a stronger effect in prolonging systole and increasing the energy of the cardiac contractions than even digitalis or convallamarin; also that rhythmic action was re-established, and that the pulse was rendered fuller and slower. A diuretic effect was not observed. Voigt (*Wiener med. Blätter*, 1886, Nos. 25-27) concluded that sparteine was a valuable drug, worthy to be placed beside digitalis, but that it had not the persistency of the latter in its effects, which, however, were superior to those of caffeine, adonis vernalis, and convallamarin. Increased diuresis frequently resulted, but in this respect sparteine was easily exceeded by other medicines. Voigt recommended sparteine in insufficiency of the heart muscle, with or without valvular disease, in pericarditis, and as an adjunct to digitalis, or rather an occasional substitute. Leo (*Zeitschrift f. klin. Med.*, 1887, p. 143) found that sparteine acted as a powerful diuretic, and was beneficial in exactly those cases in which digitalis failed. The diuretic action Leo ascribes to direct irritation of the renal epithelium, and not to the increased blood pressure from increased cardiac action. Palpitations and cardiac asthma were much relieved, but whether from some narcotic influence or from increased cardiac action is left undecided. The last observer in this department is Dr. Prior, Docent in the University of Bonn (*Berliner klin. Wochenschr.*, 1887, No. 36). According to Prior, sparteine only occasionally acts as a diuretic in health; and this effect is probably due, when it occurs, to increased blood pressure. He found it to act better in valvular failure than in simple insufficiency of the heart muscle from other causes. Its effects were, on the whole, fairly constant, rapid, and marked, but did not persist long. In some cases the heart's action was regulated for a long time by sparteine, the urine being increased, and œdema diminished or removed. Dyspnoea and palpitation were relieved within two hours, often less, in severe cases of heart disease, even when the heart's action was unaltered; but the drug was of no use in bronchial asthma. A grain and a half of

the sulphate was found the best to begin with. No cumulative action was made out. Prior advocates the use of sparteine sulphate in those cases in which digitalis has failed to do any good; also when it is required to relieve severe stenocardiac attacks as speedily as possible, as sparteine often effects this even when the heart's action is unaltered by it. He also regards it as a valuable diuretic.

We have not space for convallamarin and some other drugs, but will conclude with a few words on strophanthin, a powerful rival to digitalis. Fraser first isolated the glycoside strophanthin from *strophanthus hispidus* (Kombé), and has written more than once about its uses. But it is only recently that the plant has been imported from Africa in sufficient bulk to allow of general investigation. At present, *strophanthus*, whether the tincture or strophanthin be used, is the strongest rival against digitalis in the field. Zerner and Löw have recently reported on the new drug in the *Wiener med. Wochenschrift*, No. 36. They support Fraser in his assertion that, unlike digitalis, strophanthus preparations do not cause arterial contraction. As regards the heart, diastole is prolonged, while systole is rendered shorter and more energetic. Irregularity of the pulse usually disappears under the use of strophanthus, but sometimes only a slight improvement in this respect is obtained. They found that for hypodermic injection of strophanthin, a milligramme (a little under a sixtieth of a grain) was a moderate dose, but preferred to give it by the mouth in doses between the thirtieth and the sixteenth of a grain. Experiments showed that in health no appreciable diuretic effect was exerted, while in disease the urine was often considerably increased by the use of strophanthin, and sphygmographic tracings showed that this effect was due to increased cardiac action, causing increased blood pressure. In one case of pleuritic effusion, increased diuresis persisted for some time, the patient taking forty-five minims daily of tincture of strophanthus, and the area of dulness steadily diminished. These observers strongly oppose the statement, often asserted, that strophanthus acts as an irritant to the healthy kidney; and, as above remarked, ascribe its effects solely to increased cardiac action. They are also against Fraser in his assertion that it is able to lower the temperature of the body, as they tried in vain to obtain this effect in bad cases of pneumonia. Indeed, unless in the stage of collapse, when strophanthus is eminently useful from the rapidity of its effect in stimulating the heart, they consider that this medicine is contra-indicated in pneumonia and fevers generally. The tincture is well tolerated if a little syrup of orange peel be added; a slight diarrhoea may follow, often beneficial; but strophanthin causes no discomfort in the proper doses. One case of myocarditis, with pulmonary and hepatic congestion, was cured by strophanthus after digitalis had been tried in vain. Two cases of fatty degeneration of the heart, which were not very far advanced, were also greatly benefited; but in a third extreme case no advantage was obtained from the drug, there being scarcely any heart-muscle left to act upon. But it is in valvular disease with failure of compensation that strophanthus is so useful. In one mitral case the writer was

surprised at the earnestness with which the patient begged for "more of the last medicine." He had been taking digitalis for some time previously without any marked benefit, but felt better after every dose of strophanthus, and his pulse became regular at once. Strophanthus does not appear to possess any "cumulative action," but time is required to show how far its undoubtedly good effects in appropriate cases are persistent.

THE SCHEME OF THE LONDON COLLEGES FOR DEGREE-GIVING POWERS.

As the weeks wear on, the opposition to the scheme promoted by the London Colleges of Surgeons and Physicians for obtaining for themselves exclusive powers for granting medical degrees to their members and licentiates in the future, widens and gathers strength. The University of Oxford has thrown its weight into the balance against the two Colleges, and the University of Cambridge is preparing to take the same course. Moreover, the London medical schools, although largely controlled by councillors of the two Colleges, and therefore slow to move in the matter, are beginning to awaken to the imperfections and dangers of a scheme which, while promising them much, offers the gift in so doubtful a shape that not even a supposed self-interest can blind them to the serious defects by which the scheme is disfigured. We have already pointed these out, and some of them are clearly indicated in the memorial from the Westminster Hospital Medical School. That memorial, which is drawn up with a full recognition of the advantages to London medical schools of reasonable facilities for acquiring the degree of medicine in London for the students whom they train, points out the palpable fact that of all the schemes which are now before the Privy Council, that of the two Colleges is the least satisfactory.

It is unsatisfactory for three main reasons—first, because it fails to give to the body entrusted with this new degree-giving power even a reasonably representative constitution. Neither the teachers as such, nor the competent colleges and medical schools as such, nor the graduates are represented in it. The degree-giving power would be given to a Senate, in which the teaching bodies of London would have no representative voice. The colleges and medical schools would have no power of appointing delegates to express their united opinions on any subject of teaching or examination, nor would the persons who sit on the Senate be in any way responsible to the schools for their votes or acts, or on any occasion be called upon to give an account to them of their proceedings. Again, the graduates of the university, to whom its interests, its reputation, and its development will be at least as dear and as important as to any other persons, would, by the proposed constitution, be totally excluded from any right to representation on the governing body of their own university. This is an anomaly of which we know no other example. The whole constitution of the university is imposed upon it by the self-elected and non-representative Council of the College of Physicians, and by the most inadequately constituted and imperfectly repre-

sentative Council of the College of Surgeons. No security is taken that the University would be administered otherwise than in the corporate interests of those two licensing bodies, and, in fact, every precaution is taken to prevent any interest which can be supposed to conflict with the individual and joint interests of those two bodies from being allowed even to have a voice in the management of the new University.

The spirit in which it is likely to be administered is further indicated by the fact that it is not proposed to constitute this new body as a degree-giving power for the students of the medical schools of London, all educated alike, under the same conditions, with the same curriculum, and with the same clinical and scientific advantages. But it is proposed to take from them the right of choice as to the portals through which they will present themselves for this higher grade, and to confine their selection exclusively to these two particular licensing bodies. In the name and with the object of granting degrees to the London medical students, an effort is made by this proposal for a charter practically to tie them up to selection of the Membership of the College of Surgeons and the licence of the College of Physicians as the sole mode of entrance. Thus, whether it be regarded from the point of view of the relation of the teaching bodies to the examining bodies, or from the point of view of a just and fair constitution of the University, or from the point of view of fairness to the medical students themselves, the proposition stands condemned. Most persons will agree with the memorial of the Westminster School in the opinion that of all the schemes before the Privy Council that of the College of Physicians is the most objectionable.

With the immense body of opposition which has now arisen to that scheme, in the profession at large, as represented by the Society of General Practitioners and the Apothecaries' Society, by the Scotch Universities, by the English Universities, and by the feeling in the medical schools which the Westminster memorial expresses, it is hardly conceivable that the Privy Council can adopt any other course than that which we have from the first advocated, of appointing a Royal Commission fully to inquire into the whole subject, and to arrange a scheme which shall meet all the just requirements of the case.

MR. E. H. BUSK, M.A., LL.B., who had much to do with the throwing open of the London University to women, has been nominated for election to the Senate, in opposition to Mr. James Anstie, Q.C.

DR. STRAUS has been unanimously chosen by the Professors of the Paris Faculty as the successor of Professor Vulpian in the chair of Experimental and Comparative Pathology. The regulations require two names to be submitted to the Minister of Public Instruction, and that of Dr. Hanot was chosen as the second.

MEDICO-PSYCHOLOGICAL ASSOCIATION.

A SPECIAL general meeting of the Medico-Psychological Association will be held at Bethlem Hospital, on Friday, February 24th, 1888, at 5.30 P.M., "To consider the recent appointment at the Hayward's Heath Asylum."

CREMATION.

WE are informed that during the present year already five cremations have taken place at the Woking Crematorium of the Cremation Society. One of them was a child eight months old, and the ashes weighed only eight ounces. Up to the present time thirty-one cremations have taken place at the Society's Crematorium. A gold medal was awarded to the Cremation Society of England at the Yorkshire Jubilee Exhibition lately held at Saltaire.

THE SECTION OF SURGERY AT THE GLASGOW MEETING.

THE President of the Surgical Section (Professor George Buchanan) will take it as a favour, if those gentlemen who propose to bring forward papers or cases in surgery will kindly give early notice of their intention, either to himself at 193, Bath Street, or to Dr. Knox, Local Secretary of the Surgical Section, India Street.

PROFESSOR LANKESTER AND THE VICE-CHANCELLOR.

PROFESSOR RAY LANKESTER has been defeated in his action against the Vice-Chancellor of Oxford University. Professor Lankester had objected to go from London to Oxford to hold a preliminary *vivâ voce* examination in animal morphology on the ground that it was useless, and not required by the statutes. The University authorities held that it was an integral part of the examination as required by the statutes, and dismissed the recalcitrant examiner. The Queen's Bench decided not to issue a *mandamus* requiring the Vice-Chancellor to reinstate Professor Lankester.

THE NATIONAL PENSION FUND FOR NURSES.

THE first meeting of the Council was held at the Offices, 38, Old Jewry, on Friday, February 10th. Mr. Walter H. Burns (Messrs. J. S. Morgan and Co.) was appointed Chairman, and Mr. Burdett Deputy-Chairman of the Council. Mr. Thomas Bryant (Senior Surgeon of Gny's Hospital), Mr. R. Brudenell Carter (the St. George's and National Epileptic Hospitals), and Major Ross, M.P. (Chairman of the Middlesex Hospital), were elected members of the Council. The tables, rates of premium, and other forms which the actuary had prepared were submitted, and arrangements were made for the completion of the necessary prospectuses, etc., for the information of those waiting to join the fund. The Earl of Aberdeen, Lord Rothschild, Messrs. E. A. Hambro, Henry Hucks Gibbs, and Junius S. Morgan were elected Vice-Presidents; and the Countess of Rosebery and Lady Rothschild patronesses. It was reported that several hundred names of those anxious to join the fund had been registered during the last three weeks, in addition to the 1,400 previously announced. Mr. Philip Grove was appointed Secretary, and all names and inquiries should be addressed to him at the offices of the Fund, 38, Old Jewry, E.C.

TREATMENT OF INEBRIETY.

FOLLOWING the example set by the Dalrymple House, Mr. Harrison Branthwaite has tabulated the records of the cases of inebriety treated by him at High Shot House, Twickenham. It would be well if the licensees of other retreats for inebriates followed suit. Mr. Branthwaite reports 50 cases of alcoholic inebriety in 2½ years, morphine cases being excluded. Of these, 27 were under the Habitual Drunkards' Act and 23 were received as private patients. The average age was 39.38 years; 30 were married, 18 single, and 2 widowers; all but 5 had had a good education; 9 were merchants, 7 in the army, 4 clergymen, 2 doctors, 2 artists, 3 hotel proprietors, 2 clerks, 2 gentlemen, 2 wine merchants, 2 timber merchants, besides a barrister, a solicitor, a journalist, an architect, a surveyor, a land agent, a builder, a student, a civil servant, a corn merchant, a linen draper, a grocer, and a boot merchant. There

was a history of heredity in 38 per cent., of insanity in 12 per cent.; 47 used tobacco; 45 were regular and 5 periodical inebriates. The average length of addiction was 9.84 years; 11 used whisky, 6 spirits, 4 brandy, 3 beer and whisky, 1 brandy and whisky, 1 wine, and 1 beer. In all but 6, either company, or occupation, or some other exciting cause, was present; this in one case being accident, and in another sunstroke. Some complicating disease was present in 11 cases. The average time under treatment was 5.5 months. Of the patients, 26 were doing well, 9 had relapsed, 7 were still under treatment, and 1 had died.

MEDICAL AND SURGICAL CONGRESSES IN GERMANY.

The seventh German Medical Congress will take place at Wiesbaden, from April 9th to the 12th, under the presidency of Professor Leube, of Würzburg. The following questions will be discussed:—1. Chronic diseases of the myocardium and their treatment. 2. Alcohol as a medicinal agent. 3. Prophylaxis and treatment of Asiatic cholera.—The seventeenth congress of the German Surgical Society will be held at Berlin, from April 4th to the 7th.—On the evening of April 3rd, the German Surgical Society and the Berlin Medical Society, will hold a special meeting in common for the purpose of celebrating the anniversary of the death of the late Professor von Langenbeck.

THE OFFICIAL REPORTS ON THE ILLNESS OF THE CROWN PRINCE.

The full text of Professor Virchow's last report on the case of the Crown Prince, together with an important statement which Sir Morell Mackenzie has presented to the Emperor of Germany will be found at p. 370. From the former it will be seen that the most careful microscopical examination has failed to detect any conclusive evidence of malignant disease. The substances examined consisted of one large and two smaller pieces of dead tissue, which had spontaneously become detached from the inner surface of the larynx. The larger of these sloughs contained a considerable amount of muscular structure, but no cartilage. The disintegrated tissue was thrown off from the site of the growth on which the diagnosis of cancer was founded. It is, therefore, a fact of the very highest importance that in this material no evidence of any morbid process beyond violent inflammation was detected. The two reports taken together seem fully to justify the best hopes for the future.

THE UNIVERSITY OF LONDON AND THE PROPOSED NEW UNIVERSITY.

The Senate of the University of London at its last meeting appointed a committee to watch the proceedings in the matter of the petition of the University and King's Colleges for the constitution of a Teaching University in London. The members of this committee are, we believe, Lord Herschell, Lord Justice Fry, Sir Julian Goldsmid, Sir John Lubbock, Dr. Quain, Dr. Wood, Mr. Hutton, and Mr. Fitch. At the same meeting a resolution was adopted calling the attention of the Home Secretary and the Lords of the Treasury to the petition, and asking for a full inquiry into the effect of such a charter on academic organisation, and on the interests of learning in the country generally; and without determining (a) whether the independent functions and duties of this University, which have been exercised for more than fifty years by virtue of charters granted by the Crown under regulations sanctioned by the Secretary of State, and with the aid of funds annually voted by Parliament, will not seriously be interfered with if a second University, composed exclusively or essentially of teaching colleges, be established in London; and (b) whether, as the Senate are of opinion, the objects promoted by the petitioning Colleges, so far as consistent with the interest of higher education in London, would not be more effectually ad-

vanced by a well-considered modification of the constitution of this University, such as the Senate have had under consideration, and would be prepared to submit, rather than by the foundation by its side of a new and probably less comprehensive University.

"STONE" OR "GRAVEL."

The short but pregnant paper of Sir Henry Thompson raises the question of nomenclature, which has a real surgical interest in the determination of surgical methods to be adopted in the treatment of stone in the bladder. It is, of course, important to know whether the various authorities are discussing what is really the same thing. We all know the old-fashioned designation of "gravel," and we know also that it has not been customary for surgeons gravely to discuss surgical operations in connection with the evacuation from the bladder of small calculous particles of insignificant size, which can often be washed out or spontaneously expelled. Sir Henry Thompson refers to certain instances in which there appears to have been rather an abuse of the ordinary nomenclature of stone in this relation, and it is, at any rate, of importance—especially for statistical purposes—that some sort of agreement should be general as to the size of a calculous particle, which should be dignified by the name of a "stone," otherwise statistics of the kind would soon come to have very little or no value.

SMOKE ABATEMENT.

The National Smoke Abatement Institution, on Saturday, February 11th, inaugurated a series of lectures at the Society of Arts, John Street, Adelphi, W.C. The chair was taken by Sir W. Aitkin, F.R.S., and a lecture on "Town Smoke and House Warming" was delivered by Mr. A. E. Fletcher, chief inspector under the Alkali, etc., Works Regulation Act. In his official capacity the lecturer has had great experience of factories and districts where black smoke was produced in much larger volumes than in the Metropolis, and he congratulated Londoners that in the absence of smoking manufactories they had really far from the worst conditions to deal with. The chief source of smoke in London was the domestic fires. The factories were admirably dealt with under the Smoke Prevention Act, which was well carried out under the Commissioners of Police, who were independent of personal interests. Although London had, during recent years, greatly improved, there was every reason for getting rid of the very considerable residue of black smoke which still affected its atmosphere and its fogs. Primarily, he laid great stress on the use of gaseous fuel; secondly, on the more perfect combustion of the coal itself when used direct as fuel. A discussion followed, in which it was stated that 600 tons of coal are daily burnt in the bakeries of London in the early hours of the morning.

REVACCINATION.

The Local Government Board have adopted the advice that the limit of age prescribed by the regulations of February 18th, 1868, respecting revaccination at the public expense, should be reduced, and they have issued an order, dated February 3rd, 1888, providing that in future revaccination may be performed by a public vaccinator under contract when the applicant has attained the age of 12 years (instead of 15 years as heretofore), or, in case there is any immediate danger of small-pox, the age of 10 years (instead of 12 years as heretofore), and has not before been successfully revaccinated. The term "public vaccinator" includes the medical officer of a workhouse, separate workhouse school, or infirmary; and, as regards children in those institutions, the order very wisely leaves a discretion in the hands of the medical officer by providing that he may, in any case in which he deems the primary vaccination to have been inadequate, revaccinate any child under the prescribed age who has not before been successfully revaccinated. The experience which is accumulating day

by day as to the great value of revaccination in mitigating the severity of small-pox epidemics, should stimulate local vaccination authorities to promote revaccination as well as primary vaccination in their districts. The step which has been taken by the Local Government Board will greatly facilitate any such action by enabling the revaccination to be performed whilst children are still at school, and before they have actually entered upon the serious battle of life. We trust that boards of guardians will, as we have often urged, take more special measures in the future than has been the rule in the past, to encourage the revaccination of young persons immediately the age of 12 years has been reached.

LORETA'S OPERATION ON THE STOMACH.

SOME two months ago Mr. Treves performed this operation at the London Hospital upon a man suffering from fibrous stricture of the pylorus. At the time of the operation the patient was very much reduced by pain and constant vomiting, and had been for some time unable to take food by the mouth. The abdomen and stomach were opened, and through the incision made in the viscus the pylorus was dilated with the fingers. The man made a rapid recovery, and has not vomited since the operation. He can now take any food well. The case will be shown at the next meeting of the Clinical Society.

DEATH OF MR. J. H. WALSH.

WE regret to see the announcement of the death of Mr. J. H. Walsh, who, though a medical man, was best known as the author (under the *nom de plume* of "Stonehenge") of a number of very popular works on British sport, and who since 1857 was the editor of the *Field*. Mr. Walsh was born in 1810, and became a Fellow of the Royal College of Surgeons. He practised as a medical man in Worcestershire until 1852, when he quitted the provinces for the metropolis, and subsequently spent some time abroad. He ultimately settled in London, and devoted himself to literature as a profession. He was an acknowledged authority on sport of all kinds, and published the following works: *Horse in the Stable and the Field*, *Shot Gun v. Rifle*, but he was best known perhaps as the author of *British Rural Sports*, a work which went through many editions. He also published *Domestic Economy*, and *Domestic Medicine*, and in 1858 the *Dog in Health and Disease*. Some years later he wrote the *Dogs of the British Islands*, which passed through several editions, and in 1882 he produced the first volume of the *Modern Sportsman's Gun and Rifle*, the second following in 1884.

A CONTRADICTION.

A STATEMENT has been going the round of the public press which has caused a good deal of severe comment, to the effect that a poor woman, in a condition which demanded immediate care and succour, was carried by a policeman and some women to the Lying-in Hospital, Endell Street, which was near at hand, and that the authorities refused to admit her; that, suffering as she was, she was taken from there to the workhouse, though she piteously begged to be taken "anywhere but there." As might have been anticipated, we find on inquiry that the facts as stated, with respect to the Endell Street Hospital, are a pure invention. No application, we are informed, was made to admit the woman at that institution. She was, it appears, delivered of her child in the street close by, without any attempt being made either to summon one of the staff or to take her to that hospital. She was, as a matter of fact, on her way to the lying-in ward of the workhouse next door, and had not thought of going to the hospital. Had the incident been known to the medical staff, no question would have been asked as to whether she was married or single, but the woman would have been taken in and kept for at least eighteen days.

MEMORIAL TO THE LATE SURGEON-MAJOR

T. R. LEWIS.

THE subscribers to the above memorial will be glad to learn that the reprinting of Dr. Lewis's collected scientific works has now nearly approached completion, much delay having been occasioned by the reproduction of numerous maps and lithographs. The volume, in crown 4to., when completed will contain about 800 pages illustrated by 5 maps, 24 copperplate engravings, 15 chromolithographs, and numerous woodcuts, with a portrait of the author, in autotype, forming a fitting memorial of one who devoted his life to scientific medical research. It is hoped that intending subscribers will give in their names as soon as possible to the Honorary Secretaries, care of Messrs. Holt, Laurie and Co., 17, Whitehall Place, S.W., as it is especially wished that the names of all supporters of the memorial (each subscriber of £1 receiving a copy of the reprinted works) should appear in the list of subscribers, which will appear as an appendix to the volume.

ZOOPLASTIC GRAFTS.

SURGEONS are familiar with skin grafting in the human subject, but it is rather a novel procedure to substitute the skin of birds and poultry for snips from the patient's own healthy skin. Wiesmann twice transplanted skin from pigeon to pigeon with success, and three times from fowl to fowl. Under the title of *Dermepenthesis*, Mr. G. F. Cadogan-Masterman published some interesting cases a few weeks since in our columns, in which he had succeeded in utilising the skin of young wild rabbits for the purpose of bringing about the cicatrisation of raw and ulcerating surfaces. Several others have repeated and varied Wiesmann's experiments, but before Mr. Masterman none of them seem to have been enterprising enough to spare their patients the disagreeable snipping incidental to the operation as it is usually practised. At about the same time Dr. Redard communicated to the Paris Academy of Medicine some observations of his own with animal grafts on wounds in human beings. In a case of severe burn of the scalp of eight months' standing, in a child 2 years of age, he obtained a rapid cicatrisation by means of grafts from a fowl. He first tried grafts of frog's skin, but as these proved to be repulsive to patients, and did not give very good results, he substituted others from the fowl, and the wound, which measured three inches by two and a half, had completely healed in two months. He had been equally successful in other and subsequent cases. He takes the skin from beneath the wing of a chicken, carefully securing the subjacent cellular tissue, but avoiding adipose tissue. The transplanted pieces varied from a sixth to a third of an inch in size, and they were maintained in position by means of a little cotton-wool and iodoform gauze. The skin of birds and fowls has the advantage of being supple, delicate, and vascular; it adapts itself readily to the surface of the wound, and adheres without undergoing absorption.

THE HUNTERIAN SOCIETY.

THE annual dinner of the Hunterian Society was held on Friday evening last; Dr. Gervis, President, in the chair. There was a large attendance, including Dr. Robert Barnes, Mr. Clement Lucas (President-elect), Dr. Holman (Reigate), Mr. Ernest Hart, Dr. Savage, Dr. Galabin, Mr. de Berdt Hovell, Dr. F. Charlewood Turner, Mr. Bland Sutton, Mr. Stewart (Conservator of the Hunterian Museum), and other guests and members of the Society. After proposing the usual loyal toasts, the Chairman referred to the long-standing prosperity of the Society, and the valuable contributions which its members had made to clinical and scientific medicine, enumerating a long list of eminent surgeons and physicians—Buzzard, Curling, Bright, Herbert Davies, and others—who had taken a deep interest in the work of the Society. It was one of the specialities of the Society that it had hitherto pursued

its course without seeking publicity for its work, and in the belief that conference without publication was a valuable means for promoting scientific progress. Dr. Holman responded for the British Medical Association, Mr. Stewart for the Hunterian Museum, and Mr. Ernest Hart for the visitors. In proposing the health of the Chairman, it was mentioned that after thirty-seven years of active service at St. Thomas's Hospital, he was now proposing to lessen the work attached to his public appointments, in view of the heavy occupations of private engagements, and after having made a contribution of the best work of the best years of his life to the service of his hospital, and to the furtherance of systematic and clinical teaching. The toast was received with much enthusiasm, and duly acknowledged. In the course of the meeting it was mentioned that an important announcement was shortly about to be made, of a character gratifying to the members of the British Medical Association, on the unanimous recommendation of the Council of the Hunterian Society, with reference to the disposal of its valuable library. Mr. Hart, in referring to this, gave a brief sketch of the present promising position of the newly founded library of the British Medical Association, and of its probable development. The dinner was enlivened with admirable music, and broke up at a late hour.

ELECTRICAL THERAPEUTICS.

THE gullibility of the public has seldom been rendered more evident than in the case with which they are fleeced by empirics who trade on the unknown potentialities of electricity. A few pieces of feebly magnetised clock spring sewn into flannel or leather constitute a magnetic appliance which is advertised to cure most of the ills of suffering humanity. Pieces of metal welded together in defiance of the most elementary laws of electric science are credited with powers for good beside which the elixir of life itself would pale. As the prices asked and received for such articles from a confiding public are calculated, not on the cost of production, but on the claims of their introducers, this department of industry is about the most remunerative yet discovered, and success has brought numerous rival magneticians and electricians into the market, who vie with each other in the audacity of their assertions. What one regrets is, perhaps, less the fact that the public are induced to part with their money—*populus vult decipi*—but that discredit is thereby brought on what promises in the future to be a very useful branch of therapeutics. The absence of any organised means of providing for the electrical treatment of disease, and the scanty supply of apparatus too often found in hospitals, are responsible for much of the public gullibility. This deficiency may, if the undertaking is properly managed, be remedied by the Institute of Medical Electricity, which has just been organised with the approval and under the control of a number of distinguished hospital physicians for the express purpose of providing a place at which, or in connection with which, people of limited means may obtain electrical treatment under the direction of their own medical attendants at moderate fees. There is no reason why such an institution should not fulfil a useful purpose in the treatment of disease, the names of the hospital physicians and men of science connected with it affording a guarantee of its being restricted to its proper functions.

REMOVAL OF A HAIRPIN FROM THE PERITONEUM.

DR. FREUND, of Strasburg, describes in the *Centralblatt für Gynäkologie* (December 17th), a case where a hairpin was found in the peritoneal cavity in the course of an exploratory operation for suspected disease of the uterine appendages. The patient was a sickly and emaciated woman, aged 41, who had symptoms of tertiary syphilis. Her period had been regular till about four months before she first applied for hospital relief; then it did not

appear for two months; at the end of that period metrorrhagia set in, with the discharge of small shreds, and spasmodic pains in the sacral region and the hypogastrium. The discharge of blood continued for five weeks, then epileptiform fits occurred. The uterus was found anteverted, and a small oval tumour lay to its left side, connected by a tough cord with the pelvic wall. Tubal pregnancy was suspected. On March 2nd, 1887, an exploratory incision was made; the adhesions, which bled freely, had to be broken down, and a cyst of the left tube, "the size of an apple," was removed. It was universally adherent to surrounding structures; and, in securing some bleeding vessels to the great omentum, a piece of hairpin, an inch long, and consisting of part of the two shanks pressed close together just below their point of union, was discovered and extracted. A drainage-tube was left for twenty hours in the wound. The patient did well for a fortnight, then the stump of the tubal pedicle suppurated, and the pus which escaped contained ligature-threads. The first period after operation was attended with attacks of convulsions, which lasted eight days; but the second was only represented by the molimen without show, and by slight convulsive attacks. Ten days later a hard substance was detached, on vaginal examination, to the left of the cervix. The woman was in good health when last seen by Dr. Freund; but there were slight convulsions at every menstrual period. Should a portion of the hairpin yet remain in the pelvis, the persistence of the neurosis is readily comprehensible; should the hard body be simply an inflammatory deposit, the persistence of the symptoms would be a feature already observed in other cases, where self-evident causes of nerve irritation have been removed, the neurotic condition remaining for a long time after their removal. It appears that in this case the shanks of the hairpin had been pressed together, and introduced into the uterus for the destruction of the imaginary fœtus, amenorrhœa having followed cohabitation. The pin had broken, found its way into the left tube, set up salpingitis, perforated the tube, and reached the omentum. Dr. Freund shows, on carefully considered evidence, that the prevalent theory that hairpins are introduced into the genito-urinary tract, either in the belief that the practice may produce abortion, or for another repulsive purpose, is perfectly correct.

SCOTLAND.

INCREASE OF MORTALITY IN EDINBURGH.

THE mortality for January in Edinburgh this year shows a very considerable increase when compared with the two preceding years. There were 529 deaths, equal to a death-rate of 24.16 per 1,000 of the estimated population; in January, 1887, there were 446 deaths, equal to 20.69 per 1,000; while in 1886 there were 362 deaths, and the average death-rate for five years was 20.13. Diseases of the chest accounted for 166 deaths, while zymotic diseases caused 72 deaths, of which no fewer than 44 were from measles. The above death-rate for January, 1888, is the highest that has been recorded since 1872.

INNOVATION AS TO MORTALITY STATISTICS.

THE Public Health Committee of Edinburgh Town Council discussed at length and unanimously adopted a motion by the Dean of Guild (Sir James Gowans), which is a decided innovation as regards the publication of mortality statistics in Edinburgh, and which will likely yield abundant material for generalisation as to the effect of house environment in the death-rate of the dwellers in that city. The motion proposed was that, instead of the present system, Dr. Littlejohn, the medical officer of health, should make a return of the deaths in the city, with the rental of the houses in which they occur, the necessary information regarding

rental to be supplied by Mr. Paterson, the assessor. This statement would be prepared every four weeks and submitted to the Council, the convener of the committee giving at the end of each year a summary showing the results of the preceding months. This scheme of Sir James Gowans was thoroughly gone into by a subcommittee, and by it unanimously recommended for adoption. It was agreed to classify the rental as follows: Under £5, from £5 to £10, £10 to £15, and so on up to £50, all above that being classed the same.

ROSEWELL ASYLUM.

THE appointment of Dr. Campbell Clark as Medical Superintendent to Rosewell Asylum is not to be carried out, Dr. Clark having elected to remain at Bothwell Asylum. The directors have now appointed to Rosewell Asylum, as Medical Superintendent, Dr. Mitchell, at present senior resident in Morningside Asylum.

CASE OF LONGEVITY.

A REMARKABLE case of longevity, the circumstances of which have been carefully looked into, is that of Mr. Michael Smith, of Larkhall, who has reached the age of 111 years. Smith was born at Auchnagrgan, and baptised at Ballymacnab in the month of October, 1776. He was married in 1818, at 42 years of age, and had eleven children, the eldest of whom would have been 69 years of age had he been alive. A movement is on foot at Larkhall to present Mr. Smith with a testimonial.

GLASGOW PHILOSOPHICAL SOCIETY.

AT the last meeting of this Society, on February 8th, Professor McKendrick exhibited and described E. von Fleischl's spectropolarimeter for the estimation of grape sugar, a centrifugal apparatus for separation of blood into corpuscles and plasma, and Kronecker's electromyographion. Sir William Thomson exhibited various new electrical measuring instruments, ampèremeters, etc.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

AT the last meeting of this Society, on February 10th, a variety of specimens were shown by Dr. Samsen Gemmill, Mr. A. E. Maylard, Dr. C. F. Pollock, and Dr. Parry. The specimens included

lung with bean impacted in bronchus, a larynx with papillomata, cultivations of the organisms of pus, and microscopical specimens of meibomian glands and cysts of eyelids. Dr. Macewen showed the parts in left inguinal hernia, removed *post-mortem* from a man who had undergone Dr. Macewen's operation by "internal abdominal peritoneal pad, and the restoration of the valved form of the inguinal canal," and who had been able afterwards to carry on his work as a carter without any external support.

ST. MUNGO'S COLLEGE, GLASGOW.

THE agitation for the erection of the Glasgow Royal Infirmary Medical School into a College of the University of Glasgow has been brought to a head by the introduction into Parliament by some of the members for Glasgow of a Bill for this purpose. It proposes to establish in the East End of Glasgow a College of the University, to be called "St. Mungo's College," with which the medical school of the University shall be incorporated, and to which all the premises and effects, etc., of the infirmary school shall be conveyed. The Bill provides for the management of the affairs of the College by a body of governors, who shall appoint the professors and lecturers. The teaching at the College is not limited in the Bill to medicine, but includes the sciences and arts and other branches of learning as the governors may deem fit. The status, rights, and privileges of the professors, are to be the same as those pertaining to the University professors, and each faculty of the new College is to be adequately represented in the University Court. It will thus be seen that the Bill has been

drafted in a bold spirit, and that it will commend itself to the public mind is obvious. None the less it is certain to meet with stubborn opposition from the Senate of the University. But so many guarantees for the proper management of the College have been introduced into the Bill, so full is the University representation on its board of governors, that it will be difficult for the University authorities to convince the public that it is not a Bill worthy of becoming law. The board of governors, it is proposed, shall consist of nineteen persons, of whom six are University representatives and five representatives of the Royal Infirmary. The Faculty of Physicians and Surgeons is accorded one representative. The Lord Provost of the city is named one of the board, and the Town Council names a representative. The other representatives are sent by various other important public bodies. The six University representatives are the Chancellor, Vice-Chancellor, two elected by the Senate, and two by the General Council. The proceedings of the governors are to be subject to the review of the University Court. The details of the Bill thus bear out its profession that it is drawn in "the interests of learning, and more especially of medical education and science." Even though it does not succeed in passing into law, it will not fail to have a stimulating effect upon the authorities of the University.

IRELAND.

ST. JOHN AMBULANCE ASSOCIATION, BELFAST CENTRE.

COURSES of ambulance instruction have recently been given in Belfast by Professor Sinclair, Dr. W. G. Mackenzie, and Dr. Strahan. They have been very largely attended; the utmost interest being shown in the work, and the excellence of the instruction given has been attested by the very satisfactory results of the examinations, conducted by Surgeon Fagan, Dr. Walton Browne, and Brigade-Surgeon McFarland.

EPIDEMIC OF MEASLES AT SCHULL.

ANOTHER epidemic of measles has broken out in Schull and district, near Skibbereen, County Cork. The disease first made its appearance in the coastguard station among the children. The schools have been closed, and steps taken to prohibit the holding of "wakes." Up to last week there were about fifty cases, with only one death.

DUBLIN HOSPITAL FUND.

AT the annual meeting of the Dublin Hospital Fund, held last week, it was stated that the amount received was less by £200 than in 1886. The total received was £3,957 9s. 3d. The following is the result of the distribution for the year:—Sir Patrick Dunn's, £238 12s.; City of Dublin, £587 18s. 9d.; Doctor Steevens's, £99 18s. 7d.; Meath, £483 2s.; Mercer's, £106 4s. 6d.; Whitworth (Drumcondra), £40 0s. 10d.; Coombe (Lying-in), £118 5s. 7d.; Rotunda (Lying-in), £114 5s. 3d.; St. Mark's (Ophthalmic), £184 3s. 5d.; National Eye and Ear Infirmary, £102 0s. 9d.; Convalescent Home, £233 12s. 8d.; Cork Street (Fever), £111 1s. 8d.; Adelaide, £847 16s. 6d.; Monkstown, £154 6s. 5d.; Orthopaedic (Great Brunswick Street), £160 18s. 9d.; National Children's, £99 5s. 7d.—total, £3,681 13s. 3d. The Committee felt bound to inquire whether any of the ordinary funds would be employed to defray the expenditure of the investigation at Mercer's Hospital. They were informed that the "only expenses which would fall on the hospital would be the assessors' fees, and the costs of reports and printed evidence, and the charge for the inquiry in the room at the Four Courts." The grant to the hospital will therefore be paid.

THE CASE OF HIS IMPERIAL HIGHNESS THE CROWN PRINCE OF GERMANY.

By SIR MORELL MACKENZIE, M.D.

His Imperial Highness the Crown Prince of Germany having expressed his wish that I should now place on record my opinion of his case, the opportunity is afforded of correcting some of the statements which from time to time have been inaccurately attributed to me.

The general idea is that I am of opinion that the disease from which His Imperial Highness is suffering is not cancer; the view on the other hand, which I have consistently maintained is, that there never has been any proof of the existence of cancer.

To enter more into detail: When I arrived in Berlin, last May, I stated to my colleagues that, in my opinion the appearances seen in the throat were of a negative character, that is to say, that the disease might be either benign or malignant, and that its nature could only be determined by microscopical examination. A portion of the diseased tissue having been taken away by me from the throat of His Imperial Highness, it was submitted to Professor Virchow, who could not detect in it anything of a malignant nature. Repeated examinations by Professor Virchow of other portions removed by me yielded similar results.

In the month of July, whilst His Imperial Highness was staying in the Isle of Wight, I pointed out to more than one of his august relatives that the danger that I most dreaded was the occurrence of perichondritis at a future date, and three months later this fear was proved to be well grounded. At the end of October and early part of November entirely fresh symptoms appeared, and at that time the local disease presented an appearance which was consistent with the diagnosis of cancer. It was then impossible to obtain any fresh microscopical evidence in the matter, and I considered it safer accordingly to treat the case as one of a malignant nature; at the same time, however, I drew up and submitted to my colleagues a *protocol*, in which I stated that although the disease at that moment looked like cancer, I could not agree that the malady was proved to be malignant until a further microscopical examination had been made. The document in which I set forth my views was forwarded to Berlin to be placed in the State Archives. Although the unfavourable symptoms then present were explicable on the ground of the existence of cancer, yet it was clear to the majority of the physicians at that time in attendance that perichondritis had supervened.

In the middle of December, however, the unfavourable signs had passed away, and there were no longer any clinical symptoms of cancer. Microscopical evidence on the subject was, however, still wanting. This was furnished at the end of January, when a slough was expectorated from the very spot which had presented such a highly suspicious appearance in November. This slough was most carefully and repeatedly examined by Professor Virchow, and the result (which is now published) again shows that cancer could not be detected.

To recapitulate: In my opinion the clinical symptoms have always been entirely compatible with non-malignant disease, and the microscopical signs have been in harmony with this view. I need only add that although in nearly every case of laryngeal disease it is possible at the first inspection to form an accurate opinion as to the nature of the disease presenting itself, yet, in a few rare instances, the progress of the complaint alone permits its character to be determined. Unfortunately, the case of His Imperial Highness is among the latter number, and at this

moment medical science does not permit me to affirm that any other disease is present than chronic interstitial inflammation of the larynx combined with perichondritis.

San Remo, February 12th, 1888.

REPORT OF EXAMINATION OF THE SLOUGH FROM THE LARYNX OF HIS IMPERIAL HIGHNESS THE CROWN PRINCE OF GERMANY.

On the morning of the 26th of January, 1888, Dr. Wegener brought me a sealed box with a letter dated 23rd from Dr. Schrader from San Remo. It was accompanied by a report, dated January 17th, from Dr. Krause respecting a large piece of tissue which had been expectorated on the same day from the larynx of H. I. H. The Crown Prince.

The portion sent was the whole of the matter expectorated, with the exception of six small particles removed by Dr. Krause for examination in the fresh state. The piece of tissue was in a sealed bottle containing absolute alcohol. In addition to the large portion referred to, there were also two other separate and somewhat harder pieces—a larger and a smaller. The former, according to Dr. Krause, was originally a part of the principal mass. The examination offered great difficulties, the nature of which could not have been anticipated, either from the form or the appearance of the pieces submitted for investigation.

The large mass greatly resembled certain portions of imperfectly masticated pieces of meat, which are sometimes rejected in vomiting after being swallowed. This view seemed to derive support from the presence here and there of small yellow and brownish particles of fine cellular vegetable structure, and from the existence in the innermost portion of the large piece (expectorated) of an abundance of elastic fibres.

In consideration, however, of the very precise information conveyed by Dr. Krause to the effect that the substance had been observed before its separation (from the larynx) extending from beneath the left ventricular band from the middle to the anterior angle, and also below the glottis, and even extending round below the anterior part of the right vocal cord, there could be no doubt, on further examination, that we had to deal with a large slough spontaneously separated from the inner surface of the larynx, and not with a purely exudative (fibrinous) mass.

In the substance which, according to the report of Dr. Krause, when first expectorated, measured $3\frac{1}{2}$ centimètres in length, whilst at the thinner end it was half a centimètre in width (its thickness being 4 millimètres), and at the thicker end one centimètre wide, a small smooth semicircular spot in the long diameter of the substance could be seen. All the rest of the surface was occupied by long and very closely arranged fibres. Although there was no epithelium on the smooth spot, and no glands beneath it, it cannot be doubted that this was the free surface of the mucous membrane. For beneath it could be seen microscopically a thin layer of almost homogeneous connective tissue, and a great mass of elastic fibres. Beneath this, there was, deeper down, a very thick layer, consisting especially of tubules with granular amorphous contents. From this thick layer originated the long fibres observed with the naked eye. It was not once possible to recognise in these tubular layers any transverse stripes, but they seemed to contain only amorphous matter, in which, on more minute examination, numerous micrococci were found. Here and there numerous but very small clear brown bodies, or crystal-like deposits, were observed. Nevertheless, I have no doubt that these tubular layers and fibres are primitive muscular fasciculi which, through a necrotic process, have been destroyed.

The slough must therefore be regarded as a necrotic and decomposed part of the larynx, which in parts has been separated from the surface to a depth of 4 millimètres. The very rich muscular structure could only be attributed to the thyro-arytenoid muscle.

I could not determine what kind of morbid process had caused the gangrene, nor what kind of process had produced the demarcation and exfoliation of the substance. Neither pus-corpuscles nor granulation-cells could be distinguished; and, in fact, in most places there was nothing of a heterogenous nature to be discovered. Only in the larger (of the two smaller pieces) which had been cut off the main mass by Dr. Krause from a somewhat hard spot, and which had the form of a flat wart on section, with the

¹ In this statement the words "cancer," "cancerous," and "malignant," are used synonymously.

naked eye a central whiter and an external and opaque rather thick covering could be distinguished.

In every microscopic section so-called nests (*zwiebeln*) of epidermoidal cells, for the most part of homogeneous character, were seen. As a rule these nest-cells were in the most external layer, or in that lying immediately beneath it. The external layer had also most likely consisted of an epidermoidal formation, though these cells could only be here and there partially distinguished.

I could not find epidermoidal cells in the deep parts, and distinctly isolated alveoli were nowhere to be discovered, in spite of assiduous researches.

These examinations will be continued, and if any further result is obtained I will send a report instantly.

(Signed) **RUDOLF VIRCHOW,**
Director of the Pathological Institute, Berlin.

January 29th, 1888.

We are informed by Sir Morell Mackenzie, who has forwarded the above translation to us, that Professor Virchow has since sent several private letters, in which, however, he has not been able to add anything to his original report. Nevertheless, he remarks that he has not found any cartilage in any portion of the slough.

THE BRITISH NURSES ASSOCIATION.

A MEETING in furtherance of the aims and objects of the British Nurses Association, was held on Monday last, at St. George's Hall, Langham Place, at which the Princess Christian, of Schlesweg-Holstein, the President of the Association, was present. The chair was taken by Mr. Savery, President of the Royal College of Surgeons, who was supported by Sir Henry Acland, Dr. Quain, Sir Joseph Lister, Sir Dyce Duckworth, Mr. John Marshall, Sir Douglas Powell, Mr. Brudenell Carter, Sir Joseph Fayrer, Mr. Gant, Dr. Norman Moore, Miss Mollett, Miss Stewart (St. Bartholomew's), and other matrons of metropolitan hospitals, together with a large gathering of representatives of the nursing profession.

PRINCESS CHRISTIAN, in opening the proceedings, said: I have been asked to say a few words to open this meeting, a meeting of which the importance and interest cannot be overrated. We are met together to-day to lay the foundation stone of an Association, which should not be inferior to any other great institution of this kingdom. I said lay the foundation stone, but that is already laid. We have, rather, come together to enlist the public sympathy and support in furthering it, in building it up. The British Nurses Association seeks to unite in common action all who are engaged in doing woman's highest and noblest work, namely, that of nursing the sick. The first object of the Association is to obtain for the calling of nursing the recognised position and legal constitution of a profession which shall from henceforth be inseparable from the noble profession of medicine. It will follow from this, that in the future every member of the nursing profession must have been educated up to a definite standard of knowledge and efficiency. The importance of this guarantee to the public cannot be overestimated. Another object is to enable the members of the Association to assist each other in illness or old age. But the British Nurses Association has also a deeper, a wider, and a grander meaning. I believe it is the first example of a large number of women combining together, not only to help their overworked or weaker sisters, but also to further and advance their calling, and to raise their work to a higher level than it has hitherto held. If the Association be successful—and its success now depends mainly on the united efforts of the nurses themselves—who can foretell where the influence of their example will end? It will perhaps be the means of showing women in other walks of life that they, too, can combine successfully for the manifest advantage of themselves, their fellow workers, and society in general, in a united striving after higher things. I should like to say how much I feel personally the great honour which has been done me in your allowing me to become a fellow worker in this great movement, and I will conclude with some words which seem to me to embody the true spirit of nursing. They are:—

"Perfect service rendered, duties done,
In charity, soft speech, and stainless days,
These riches shall not fade away in life,
Nor any death dispraise."

The CHAIRMAN said the cause they had at heart was so good and strong that it needed no advocacy to commend it to the acceptance of all. Even those who thought lightly of doctors

were able to appreciate good nursing, and who, when illness came upon him, dreamed of refusing such help? In no department of their art had there been a more signal advance than in that of nursing. Some of them were old enough to remember by what class of persons the nursing in their wards and sickrooms was formerly carried on—the lineal descendants of the old hospital nurse, as she was called. Those of them who could remember these and knew what our wards and sickrooms were now might perhaps realise the vast improvement which had been effected. He who watched most closely would be able to appreciate most fully the debt they owed to good nursing. For many years their faith in drugs and specific remedies had gradually declined, while they had learned to attach more importance to matters of hygiene and to good nursing. The time had come when some definite organisation should be established for those who devoted themselves to the duties of nursing. In the first place, a system of registration by a body of competent authorities would secure a simple guarantee to all that those whose names appeared on the register were duly qualified for their work. It would accomplish for nurses what the registration of the medical profession secured for them, and they and those ladies who were at the head of their department would see that the character and credentials of the Association were such that no question could be raised with regard to its competency or worthiness. Such an Association, by the judicious distribution of distinctions, might do very much to increase excellence and to bring to the front those who were best qualified to help and advise others. As in the church, in the law, and in medicine, by a recognised course of study and by examination, security was given to the public that those who offered their services were at least in some degree qualified for the work, so in the case of nurses for the sick should the public look for such evidences of character and education as that Association would be able to offer. With all his heart he said God speed the Association, might it prosper as it deserved to do. The loyal and devoted work which the nurses did had been recognised by the Queen; her recent gift had expressed her sympathy with their work.

SIR DYCE DUCKWORTH moved the first resolution: "That this meeting, desiring to express its cordial sympathy with the British Nurses Association, pledges itself to support the Association by every means in its power, and urges upon all nurses in the United Kingdom who are eligible for membership that they should join the Association for the sake of promoting the advancement of their profession." He regarded the present meeting as very strong evidence that the whole body of nurses, and those who were interested in their career and good work, were not satisfied with things as they were, and that, therefore, it was intended that something should be done to put those good women who were engaged in that useful work in a better position, for the benefit of both themselves and the public. It was now difficult to give a definition of what was meant by a "trained nurse." When that Association was set on foot that difficulty would no longer exist. He thought it would certainly be one of the duties of the Association to lay down the conditions of education, and to instruct the public as to what was meant by a "trained nurse." He had no doubt that in the future a three years' curriculum would be required for a trained nurse. He regarded nurses as units, who would be better for a little cohesion; by cohesion and co-operation very great benefit might be derived, both for the sick and the public. Such an institution as they were proposing to build up could only be carried on and regulated by those who understood the work best. They believed it was not a work in which the laity could take any active, if any, part at all, for the work required very special knowledge. By the adoption of a register the public would be able to distinguish those nurses who were thoroughly trained from those who were not. Those not accepted by the Association might be safely taken as inefficient and imperfectly trained. The time, he thought, had come when they might fairly stand by themselves. He would urge the nurses very strongly to come forward and enrol themselves in the Association, because he could not conceive under any circumstances whatever, either now or at any future time, that such an opportunity as now existed would present itself again.

MR. BRUDENELL CARTER seconded the resolution, which was supported by DR. MATTHEWS DUNCAN and by DR. NORMAN MOORE, who reminded them that the attempt had been made before under much less auspicious circumstances in the year 1834, when the then existing nurses of London endeavoured to become incorporated to the College of Physicians, having a very powerful advocate in Dr. Peter Chamberlain. They were at that time an un-

educated and almost untrained body, and they were then unable to secure the support of the College of Physicians.

Miss Wood (the Secretary) said they all knew what a large number of people were pressing into the nursing profession, and it seemed necessary that they should have some means of distinguishing between those who were suitable and those who were not. No such guarantee was at present afforded by the hospitals, as sometimes nurses went out without sufficient training, and called themselves "trained nurses." Nurses who had been properly trained wished to band themselves together to promote the advancement of their profession. The way in which that would be done would be, of course, a matter to be considered in detail as time went on. No nurse would bear the name of a trained nurse until she had been in training for a period of three years; as to that she thought they would have a consensus of medical opinion. They did not want to make it in any way a trades union; they had no idea of dictating terms of contract between employer and employed. What they aimed at was that when the nurse went forth to do her work she should do so as a trained nurse, and for that object they were seeking to obtain a charter which would give them the legal right to register nurses after examination either by their own hospital or a central body. Having satisfied the leading members of the medical profession, and of the nursing profession, that they knew by practice as well as by theory what they professed, they would then be registered, and have the right to practise as nurses. The Association would not interfere with hospital custom, but they did intend, as far as possible, to prevent nurses who were insufficiently trained going out to nurse in private families as "trained nurses." The public were not yet educated in the matter of nursing. She concluded by urging all nurses to come forward and make the Association what it ought to be, a very great success.

Mr. Cross and Miss MOLLETT having spoken, the resolution was carried unanimously.

Sir HENRY ACLAND, in proposing a vote of thanks to Princess Christian for accepting the presidency of the Association and for the active interest and work she was devoting to its progress, recalled the fact that Her Royal Highness was the translator of Esmarch's *First Aid to the Sick and Wounded*, and spoke of the great interest shown by her in the work of nurses and in nursing institutions, referring also to the great national association organised by her sister in Germany for that great purpose. They were at the present meeting responding to that splendid national sentiment which would raise one of the grandest monuments to the greatest monarch of England, who had decided that that magnificent gift which the nation had given to her should be given back to assuage the sickness and sorrows of the people under their care.

Dr. QUAIN seconded the vote of thanks, which was heartily accorded.

A vote of thanks to the Chairman, proposed by Sir JOSEPH FAYRER and seconded by Dr. DOUGLAS POWELL, closed the proceedings.

DEGREES FOR LONDON MEDICAL STUDENTS.

PETITIONS TO THE PRIVY COUNCIL.

THE PETITION OF WESTMINSTER HOSPITAL MEDICAL SCHOOL.

(In Support of the Petition of the Association for Promoting a Teaching University.)

THE following petition has been signed by the majority of the teachers at Westminster Hospital School, and forwarded to the Privy Council.

We, the undersigned teachers of the Westminster Hospital Medical School, and members of the staff of the Westminster Hospital, respectfully beg to lay before the most Honourable Privy Council, the following reasons, in so far as they concern the medical faculty, in support of the petition now before the said Council from the Association for Promoting a Teaching University in London.

1. We fully admit the necessity which exists for providing a medical degree for students of the metropolitan medical schools on conditions less restrictive and less prohibitive than those at present imposed by the University of London.

2. We are of opinion that in any plan proposed to meet this need there should be an intimate association of the teaching and examining functions; both being directly controlled by the same

governing body. In such way do we conceive that the true principles of a university are to be satisfied.

3. We regard the proposal made by the Royal Colleges of Physicians and Surgeons as the least satisfactory way of meeting the acknowledged requirements; since it maintains only an indirect association of the teaching and examining functions, and would merely confer the title of university on an examining board. Such a plan we feel sure would not provide a satisfactory medical degree, nor one that would be valued as it should by possessors, although we fully recognise the excellent general character of the present examinations of the said board for qualifying purposes.

4. We are of opinion that either the proposal of the Association for Promoting a Teaching University in London, or that of the University and King's Colleges, now before the Privy Council, would satisfy the requirements, and by associating together the various teaching bodies, properly qualified, would establish a university that would be real, and not one in name only; offering also the opportunity for compelling some general training in arts, which is in almost universally accepted accordance with the spirit of a university degree, and is virtually disregarded by the proposal of the Royal Colleges of Physicians and Surgeons.

5. Having regard to the legitimate interests of existing medical schools, we are of opinion that the objects sought will be best attained by the plan proposed by the Association for Promoting a Teaching University in London.

THE PETITION OF THE UNIVERSITY OF OXFORD.

(In Opposition to the Petition of the Royal Colleges of Physicians and Surgeons.)

ON February 15th, the Convocation of the University of Oxford resolved by ninety-eight votes to thirty-four to affix the seal of the University to a petition against a proposal now before the Queen in Council for conferring upon a Senate of the College of Physicians and the College of Surgeons the power of granting medical degrees to persons qualified under the Medical Act. The petition objects that these titles should be conferred only on those who have undergone a preparatory education in literature and science, and whose proficiency in these subjects has been tested by examination. It points out that Oxford medical degrees are conferred only upon Bachelors of Arts. Professor Price explained that University College and King's College, London, had presented similar petitions. The Regius Professor of Medicine, Sir Henry Acland, urged that the two great medical Colleges might surely be trusted to take such steps as were best for the profession. It was a mistake to suppose that culture was not provided for nor tested.

THE PETITION OF THE UNIVERSITY OF CAMBRIDGE.

OUR Cambridge correspondent telegraphs that the petition to the Privy Council against the scheme of the Royal Colleges passed the Senate on Thursday without a dissentient voice. No discussion takes place on such occasions. The common seal of the University was duly affixed.

It is stated to be the intention of the members of the West Herts Medical Association to invite Dr. C. E. Saunders, Medical Officer of Health for the Combined Districts of Middlesex and Hertfordshire, to a dinner, on his retiring from that official connection, as a mark of respect and regard, and an acknowledgment of the efficient manner in which he has performed his duties for a period of fourteen years.

LADY DUFFERIN'S FUND.—The third annual meeting in connection with Lady Dufferin's Female Medical Aid Fund was held at Calcutta on February 8th. The Viceroy presided. Among the speakers were the Governor of Madras, the Lieutenant-Governor of Bengal, the Maharajah of Durbunga, and the Nawab of Moorshedabad. A resolution was passed that the Association should be incorporated. The report showed that the financial position was highly satisfactory, and that the Association now possesses investments giving an annual income of 30,000 rupees.

BEQUESTS.—By the will of the late Miss J. A. Peterson, Cumberland House, the following legacies have been paid by the trustees:—The Glasgow Royal Infirmary and the Western Infirmary, £1,000 each; Association for the Relief of Incurables, £200; the Maternity Hospital and a number of other charities in Glasgow not medical, £50 each.

ASSOCIATION INTELLIGENCE.

NOTICE OF QUARTERLY MEETINGS FOR 1888.

Meetings of the Council will be held on April 18th, July 18th, and October 17th, 1888. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before each meeting, namely, March 28th, June 27th, September 26th, and December 28th, 1888.

ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council, or by any recognised Branch Council.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No member can be elected by a Branch Council unless his name has been inserted in the circular summoning the meeting at which he seeks election.

FRANCIS FOWKE, *General Secretary.*

COLLECTIVE INVESTIGATION OF DISEASE.

THE Report upon the CONNECTION OF DISEASE WITH HABITS OF INTEMPERANCE, which was presented to the Section of Medicine in the Annual Meeting of 1887, and a further portion of the Report upon OLD AGE have been completed, and will shortly be published in the JOURNAL.

Reports upon the two remaining inquiries, namely, that into DIPHTHERIA, and that into the GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES, are in preparation, and will be published as soon as ready.

The following inquiry only of the first series remains open, namely, that on THE ETIOLOGY OF PHTHISIS.

A fresh inquiry into the ORIGIN AND MODE OF PROPAGATION OF EPIDEMICS OF DIPHTHERIA has just been issued.

Memoranda upon these subjects, and forms for recording observations, may be had on application to the Secretary of the Collective Investigation Committee, 429, Strand, W.C.

BRANCH MEETINGS TO BE HELD.

STAFFORDSHIRE BRANCH.—The second general meeting of the present session will be held at the Railway Hotel, Stafford, on Thursday, February 23rd. Mr. W. D. Spanton, the President, will take the chair at 3.30 P.M.—VINCENT JACKSON, General Secretary.

GLOUCESTERSHIRE BRANCH.—The next ordinary meeting will be held on Tuesday, February 21st, 1888, at 7.30 P.M., at the Infirmary, Gloucester, under the presidency of Dr. Currie. Agenda: 1. A petition will be laid on the table for signature by members in support of the Architects and Engineers Bill, a Bill to be presented in Parliament next session by Colonel Duncan, R.A., C.B., M.P. 2. A discussion will be opened by Dr. Currie on the Present Position of Homœopathy in Relation to Regular Medicine. 3. Cases of interest in the Infirmary.—G. ARTHUR CARDEW, Honorary Secretary.

YORKSHIRE BRANCH.—A meeting of this Branch will be held at the Clayton Hospital, Wakefield, on Wednesday, February 22nd, at 3 P.M. The following papers will be read: Mr. Snell: On Prevention of Blindness by the Ophthalmia of the New-born. Mr. T. R. Jessop: On Transfusion as a means of averting death from Hamorrhage. Dr. Adolf Bronner: Ozæna; its Nature and Treatment. Cases: Mr. A. W. Mayo Robson: Three successful Cases of Transfusion. Dr. J. Gordon Black: The Treatment of Chronic Ulcers of the Leg. Mr. H. Hendelack Hewetson: (1) Suggestions as to the Relationship existing between Chronic Constipation, Chlorosis, and occasional Optic Neuritis; (2) Salycilic China Grass, with remarks.—ARTHUR JACKSON, Secretary, Sheffield.

BORDER COUNTIES BRANCH.—The next meeting will be held at the County Hotel, Carlisle, on Friday, February 24th. Dr. McLeod will take the chair at 6 P.M. Dr. Ryrom Bramwell, of Edinburgh, will read a paper and introduce a discussion on the Process of Compensation and its Bearing on Prognosis and Treatment. Dr. Muir Selkirk will read notes of a case of Hypertrophy of the Mamme. Dr. Altham Penrith will read (1) A Case of Hemorrhage from the Rectum treated by removing the redundant Skin around the Anus; and (2) A Case of Strangulated Hernia with Cysts in the Omentum extracted. Dr. Hamilton Hawick will read a paper on Pneumoparesis. Mr. T. P. Devlin, Carlisle, will read Notes of a Case of Intra-cranial Hemorrhage in a Young Subject. Supper in the hotel at 9 P.M.—H. A. LEDIARD, Honorary Secretary, 41, Lowther Street, Carlisle.

CORRECTION.—In the report of the meeting of the North London District of the Metropolitan Counties Branch it was erroneously stated that Dr. Stretch Dowse demonstrated the practice of massage on a male patient with the assistance of a *masseuse*. The word ought to have been *masseur*, and the correction is important, as it is inadvisable to employ a female for performing massage on a male.

METROPOLITAN COUNTIES BRANCH: SOUTH LONDON DISTRICT.

A MEETING of this District was held in the Greenwich Hospital School (by permission of Captain Collins, R.N., the Superintendent) on February 4th. The chair was taken by Dr. FREDERICK TAYLOR, Vice-President of the District. The minutes of the previous meeting were read and confirmed.

Cases Exhibited.—Dr. TREVELYAN, House-Physician to the Seamen's Hospital, showed for Dr. CURNOW the following cases:—1. Early Locomotor Ataxy, with Atrophy of Optic Discs; 2. Paralysis of the Muscles of the Front of the Right Leg of Doubtful Origin; 3. Left Hemiplegia from Syphilitic Thrombosis; 4. Phthisis with a Large Dry Cavity at the Right Apex; 5. Tubercular Ulceration of Epiglottis; 6. Syphilitic Disease of the Larynx.—Dr. FREDERICK TAYLOR and Dr. PITT discussed the cases, and Dr. TREVELYAN replied.

Vice-President's Address.—Dr. FREDERICK TAYLOR, as the first Vice-President of the District, then read an introductory address. He thanked the members of the District for the honour they had done him, and reviewed the history of the District from the first meeting in 1878 under the presidency of Mr. John Wood, specially mentioning the loss sustained of late years by the death of Dr. Carrington. He referred to an idea which had become current in one part of the District, that in having a meeting at Greenwich the Association was trying to compete with the local West Kent Medico-Chirurgical Society, and pointed out that meetings could only occasionally be held in Greenwich in consequence of the size of the South London District, and also that the present President of the local Society was a member of the Committee of the District, which facts were a sufficient guarantee against any clashing of meetings or subjects of discussion. He further drew attention to the fact that only about half of those members of the Association who reside in the South London District were members of the Branch, and hoped to see a large increase in numbers. He reviewed the progress of medicine and surgery during the past twenty or thirty years, and ended by congratulating the District on having again started on an active career after a period of quiescence.—Mr. SANGSTER moved, and Mr. JOHNSON SMITH seconded, a vote of thanks (which was carried unanimously) to Dr. Taylor for his valuable address.

Radical Cure of Hernia.—Mr. JOHNSON SMITH then read a paper on the radical cure of hernia, after which there was a short discussion. A vote of thanks was passed.

Vote of Thanks.—The proceedings concluded with a vote of thanks, moved by Dr. FEGAN and seconded by Dr. PITT, to Captain Collins for the use of the room.

NEW SOUTH WALES BRANCH.

THE sixty-ninth general meeting of the New South Wales Branch of the British Medical Association was held in the Royal Society's Room Sydney, on Friday, December 2nd—present: the Hon. Dr. Creed, M.L.C. (President) in the chair; Drs. Clubbe, Sydney-Jones, McCormick, Brady, Chambers, Hankins, Scot-Skirving, Fiaschi, Contie, McCulloch, Worrall, and Crago were present.

The minutes of the previous meeting were read and confirmed. **Fracture of the Acetabulum.**—Dr. CLUBBE read some notes on a case of fracture of the acetabulum.—A discussion ensued in which Drs. SYDNEY-JONES, BRADY and MCCORMICK took part.—Dr. CLUBBE replied.

By-Laws.—The by-laws were then considered and discussed, and after some slight alterations were made they were passed.

Digestive Ferments.—Dr. MCCORMICK, of Macquarie Street, read a paper on digestive ferments. Some very interesting demonstrations were made, illustrating the action of certain ferments.

ROYAL VISIT TO VENTNOR HOSPITAL.—The Queen, who was accompanied by Princess Beatrice and Princess Victoria of Schleswig-Holstein, paid an informal visit to the Royal National Hospital for Consumption and Diseases of the Chest on February 11th. This is the first time Her Majesty, who is the Patroness of the institution, has visited the hospital, though she has on many occasions shown her sympathy with it and contributed liberally to its funds. The whole of the 120 patients, with the exception of a few who were too ill to leave their rooms, assembled in the new dining-hall to greet the arrival of the Royal visitors. A bouquet of flowers was presented by Master Coghill to Her Majesty, who then visited several of the blocks, and expressed the deep interest she felt in all she had seen.

Copaiva Eruption.—Antipyrin in Nocturnal Emissions.

THE appearance of an eruption after the use of balsamum copaivæ is not a rare occurrence, but the anatomical changes in these cases have not hitherto been investigated. Professor Neumann recently excised a part of the skin in such a case, and examined it microscopically. The papillary layer was normal, and the affection had its seat chiefly around the blood-vessels, the sebaceous glands, hair follicles, and sudoriferous glands, just in the same way as in measles.

In a recent number of the *Wiener Medizinische Blätter*, Dr. Thör, of Bucharest, gives some particulars as to the effect of antipyrin in cases of nocturnal emissions. Lupulin and camphor had been justly abandoned in such cases. Curschmann ("Functionelle Störungen der männlichen Genitalien," in *Ziemssen's Handbuch*, 1878, p. 518) states that the sedative effect of lupulin on the genital organs, in spite of all the recommendations, was not proved. As to camphor, it has, according to his opinion, no better effect. Fürbringer (*Krankheiten der Harn- und Geschlechtsorgane*, 1884, p. 347) is of the same opinion. Zeissl (*Syphilis*, 1882, p. 112) recommends it in the first place, as do Purgsz (*Recept-Taschenbuch für venerische Krankheiten*, 1883, p. 21), and other writers. The effect of nuxvomica, arsenic, and atropine is also often uncertain. Among all the remedies hitherto employed, bromide of potassium or bromide of sodium was the most useful. Diday (*La Pratique des Maladies vénériennes*, 1886, p. 538) recommends it to the exclusion of every other drug. Bromide of potassium, from two to five grammes in a glass of water, taken just before going to bed, will, according to his experience, exert a prompt effect and check the pollutions. The prolonged use of the preparations of bromide, however, as is well known, produced an acne-like eruption, and the use of the remedy had, for this reason, often to be discontinued. Dr. Thör states that he has found antipyrin an excellent substitute for the bromides. He gives it in doses of from half a gramme to one gramme, to be taken by the patient a short time before going to bed. In seven cases it had proved very successful, and checked the pollutions. No disagreeable after-effects were observed. In "neuroasthenia sexualis" in the sense of Beard (*Die sexuelle Neuroasthenie*, 1885) antipyrin could also be used with good results; but the dose had in these cases to be sometimes increased from one gramme to two grammes a day.

Is Pelada Contagious?—Action of Nickel.—Clinical Photography of the Eye.—Cheap Artificial Arm.

At a recent meeting of the Académie de Médecine the question whether pelada is or is not contagious was hotly discussed. In 1875 an epidemic of this affection appeared at the Collège de Vannes. M. Hardy and Hillairet, who were consulted by the Minister of Public Instruction, made the following recommendations. Newly arrived pupils were to have their heads closely examined by the school physician. The heads of the pupils were to be examined every fifteen days. Immediately a child showed a, and not allowed to return until pelada he was to be sent home, appeared. A law rendering the affection had entirely disappeared. M. Hardy cited several instances in which pelada had proved contagious. M. Ollivier stated that pelada was not contagious, but had ignored the numerous instances in which it had not proved are useless. The most cases the preventive measures employed by M. Besnier, Le Fort, frequently interfered with their career. M.

Larret, and Bergeron suggested that, before resuming the discussion, M. Ollivier should endeavour to procure some proof of his assertions, which at present rested on no sure foundation.

M. Riche is engaged in studying the action of nickel. From his experiments he concludes that nickel is absorbed without danger by guinea-pigs and dogs. He believes that vessels made of this metal may be used without risk for the purpose of holding food.

M. Paniel has invented a photographic machine by which the fundus of the eye may be photographed in a few seconds. This machine will enable a physician having a certain knowledge of photography to produce the image of a lesion situated in the eye.

M. Griponilleau has invented an artificial arm, costing only forty francs, which will allow the wearer to dig, load, wheel a barrow, mow, etc. This arm, which is applied to the shoulder where the limb has been amputated, is made of wood, zinc, and sheet-iron.

SWITZERLAND.

[FROM OUR OWN CORRESPONDENT.]

An Administrative Campaign against British Practitioners in the Grisons; Protest of the Engadine British Colony; Protest of the Swiss Hotel-keepers' Society; Opinion of the Swiss Daily Press.—The Grisons Health Resorts and National Wealth.

THE Chur Sanitätsrath has recently prohibited, under a heavy penalty, any further medical practice to several English physicians who reside in the Engadine and other health resorts in the Grisons, and are practising exclusively amongst the English-speaking community. The prohibition may be regarded as a somewhat late retaliation for the fact that a Swiss medical man is not permitted to practise in England until he has obtained a British qualification. To judge, however, from a correspondence in the *Berner Zeitung* (February 7th, 1888), the step so abruptly taken by the Grisons sanitary authorities seems to be directed impartially against all foreign physicians who may choose to settle at any of the local health resorts for the purpose of practising there without previously obtaining a Swiss diploma. As a matter of principle, every lover of fair play will readily admit that the Grisons Sanitätsrath was under present circumstances fully justified in taking this step with the view of protecting the interests of the native practitioners, who have long complained most bitterly of the gross injustice done to them in this regard (*vide the JOURNAL*, June 12th, 1886, p. 1139). It is not quite so clear, however, that the measure, though doubtless legal, is expedient. As a matter of fact, it has, as might have been expected, caused a revolt amongst the English community.

According to the *Bund* (February 6th, 1888), as many as 150 British subjects, residing in the Engadine, have without delay sent in a petition to the British Ambassador at Berne, in which they protest against the Chur decree, and request him to take such steps as may be necessary to allow them to retain the indispensable services of their old medical attendants. The *Bund* (a semi-official and most ably conducted organ) observes, in referring to the episode, that "though the Sanitätsrath is fully in the right, its decision all the same must have an injurious effect on the Swiss health resorts." Similarly, the influential *Berner Zeitung* (February 7th, 1888), the organ of the Berne Radical party, which is now in the ascendant, calls the Chur edict "unüberlegte" ("inconsiderate" or "rash"). It states, also, that the Schweizerischer Hoteliersverein, which has just held an extraordinary meeting to discuss the situation, has unanimously passed a strong resolution, disapproving of the action of the Sanitätsrath, and at the same time demanding that "all foreign practitioners, whether they possess the Swiss diploma or not, should be allowed to practise freely at health resorts, especially amongst the foreign colonies."

To show how foreign visitors enrich certain sections of the Grisons population, the *Bund* adduces the following remarkable statistics. The taxable capital (*Steuercapital*) at Davos in the twenty years 1866 to 1886 rose from 3,250,000 francs to 8,879,000, that at St. Moritz from 642,000 to 5,250,000, and that at Pontresina from 1,715,000 to 3,756,000. The *Schweizerische Morgen-Zeitung* (January 31st, 1888) adds that in 1866 the capital subject to State taxation at Chur amounted only to 19,000,000 francs, while in 1886 it rose to 29,000,000. According to the *Freier Rhaetier* (January 29th, 1888), in Grisons there exist now as many as twenty communes (*Gemeinden*) whose taxable capitals equal and exceed 2,000,000 francs. Since so considerable and rapid an increase of wealth can be ascribed only to a growing "hotel industry" in the canton, and

the Grisons population, naturally enough, looks to foreigners as the most welcome guests, one may venture to prophesy that the Chur Sanitätsrath will soon be compelled to yield to popular pressure, and to cancel its edict as suddenly as it was promulgated.

NEWCASTLE - UPON - TYNE.

[FROM OUR OWN CORRESPONDENT.]

The Newcastle Infirmary.—The Inquiry at the Workhouse.—The Durham Guardians and their Medical Officer.

THE annual meeting of the governors of the infirmary was held last week, and a very favourable report was presented. This was the first report since the hospital has been made free. During the year many changes have been adopted; the system of admitting patients by letter has been abolished, the Committee and Medical Board have been amalgamated, the out-patient and casual departments have been remodelled, the special out-patient departments of the skin, throat and ear, and diseases of women have been closed, the only special departments kept on being those of the eye and teeth. A fee of £2 2s. for one session, or a composition fee of £6 6s., is now charged from all students for the privilege of attending the hospital. The working-men subscriptions have increased very considerably during the past year, though a perfect state of equilibrium has not yet been arrived at between income and expenditure. The number of patients treated during the year was 3,020, as against 3,175 during the previous year; the average number of patients in the hospital per diem was 241.79, last year it was 257.5; the average stay of each patient in the hospital was 29.2 days; the average cost per patient was £3 12s. 7d.; the death-rate for the year was 6.82. Of general and constitutional diseases there were 19 cases of rheumatic fever, 14 of diabetes mellitus, 3 of purpura hæmorrhagica, 2 of pernicious anæmia, 3 of beri-beri, these last occurring in Chinese sailors staying in the Tyne, awaiting the completion of war ships for the Chinese navy; of diseases of the circulatory system there were 10 cases of thoracic and 2 of abdominal aneurysm. Twenty-three cases of poisoning were treated during the year, 2 being fatal, 1 from phosphorus and 1 from coal gas. There were 893 operations during the year, with 16 deaths: ovariectomy was performed 8 times without a fatal case; 5 cases of abdominal section are recorded, with 3 deaths, 1 being a uterine fibroid, the 2 others being cases of intestinal obstruction; there was 1 case of successful gastrotomy, and a successful case of laparotomy. Twelve cases of stone were treated, 5 by suprapubic lithotomy and 7 by crushing, without fatal result. There were 17 primary amputations with 2 deaths, and 43 amputations for disease without a death. There were 6 excisions of the hip, 7 of the knee, 1 of the ankle, 2 of the shoulder, and 3 of the elbow, all successful. Nephrorrhaphy was successfully performed by Mr. Dodd, the senior assistant surgeon.

Some weeks ago an inquiry was held by Mr. Knollys, the Local Government Board Inspector, into existing irregularities at the workhouse. The decision of the Board has just been published. The following is a copy of portions of the letter addressed to the medical officer, Mr. N. Hardcastle. "The Board have carefully considered the inspector's report, and have arrived at the conclusion that it is proved you have been guilty of very grave neglect of duty as medical officer of the workhouse." The letter then specifies the distinct charges of carelessness in examination of the patients in a recent outbreak of scarlet fever, devotion of insufficient time to the cases during the progress of their ailments, incorrect entering in the medical relief book, insufficient precautions in disinfecting own person after visiting the fever cases. The letter finishes by saying that "the Board are unable to consider they would be justified in allowing you to retain the office of medical advisor, and they regret they must call upon you forthwith to place your resignation in the hands of the guardians." Dr. Hardcastle has held the appointment of medical officer for many years. Latterly things have not gone smoothly between him and the master of the institution. The unpleasantness has at length culminated in a Government inquiry and the dismissal of both the medical officer and the master. I understand that Dr. Hardcastle has appealed against the decision of the Board. Should the decision be upheld, the Guardians will most probably elect a resident medical officer whose whole time shall be devoted to the duties of the office.

At the last meeting of the Durham Board of Guardians, Dr. E. Jepson, the medical officer to the Durham Workhouse applied for

permission to make *post-mortem* examination of all paupers dying in the institution, providing the relatives make no objection; also to introduce a pupil to attend him during his visits to the hospital; also for leave to perform any operation which he considered necessary on any pauper, and to obtain the necessary medical assistance, leaving the question of remuneration for the after-consideration of the Board. One would have thought there was nothing very alarming in Dr. Jepson's request, but the members of the Board were strong in their language and in their refusal. One gentleman said if the request was acceded to, it would make them worse than the days of Burke and Hare. The request was most unjustifiable and repugnant to the right feeling of every Englishman. Finally, as it appeared that Dr. Jepson had performed a *post-mortem* last July without asking the permission of the Guardians, it was decided to report him to the Local Government Board.

MANCHESTER.

[FROM OUR OWN CORRESPONDENT.]

Small-pox Epidemic.—Owens College and the Royal Infirmary.—Victoria University.—Secretary to Board of Medicine.

IN the neighbourhood of Manchester several cases of small-pox have occurred; several new cases have occurred at Stalybridge and at Ashton-under-Lyne, while at Accrington one death from this disease is recorded. At Stockport also there are several cases.

We understand that the authorities of Owens College are anxious to establish more intimate relations between the Royal Infirmary of Manchester and the Owens College Medical School. To this end we believe a conference of certain authorities of both institutions has been held. There cannot be any doubt that the more intimate the connection between the theoretical teaching on the one hand and its practical application as exemplified in the wards of a hospital, the better it will be for everyone concerned. There will soon be one or more vacancies in the medical staff of the hospital, owing to the retirement of certain members of the staff, who have almost reached the age laid down by Infirmary rules in such cases.

Sunday last was hospital day in Manchester, when, as usual, collections on behalf of the hospitals were made in churches and elsewhere. The sum collected has not been announced. Saturday next will be Hospital Saturday.

The written examinations for the intermediate and final examinations for M.B. in Victoria University begin simultaneously in Manchester and Liverpool on Friday, March 16th.

Owing to his removal to London, Dr. Cullingworth has resigned the office of Secretary to the Departmental Board of Medicine and Surgery in Victoria University. Professor Stirling has been elected to the office. Dr. Cullingworth officiated as Secretary for about four years.

CORRESPONDENCE.

REFORM AT THE ROYAL COLLEGE OF SURGEONS.

SIR.—The first thought that must strike any reader of the manifesto of the President of the Royal College of Surgeons, which is likely for many reasons to become a historical document, can be none other than one of deep regret. Not only is it an illustration of the time-worn saw *parturient montes*, but it does no credit to an ancient corporation such as this that, even in the defence of an untenable position, such a lamentable gathering of ill-assorted arguments should be marshalled. The battalion might well have been collected from the *anthropophagi*; for the reasoning employed is of such a nature that one proposition devours its neighbour. We are unfeignedly sorry to reflect how little such a reply as this will add to the reputation of the College, for it does not need a man of the legal acumen of Lord Cranbrook to spy out at once the inconsistency of this remarkable fulmination. The "reply" is nominally directed to the statement of the Association of Fellows; but as it deals as much with the claims of the Members as with those of the former body, we beg your indulgence for a few remarks thereon. We should trespass too much upon your space did we deal with each clause *seriatim*, and therefore must single out one or two of the most glaring defects.

The very first statement contains a misstatement, for it numbers the members at 18,000, though both Mr. Holmes and Dr. Danford

Thomas informed the Council at the last general meeting of the results of our scrutiny of the "List of Members." Under 12,000 was the number we arrived at after most careful search through the last *Medical Register*. Surely the Council might have instructed the College Secretary to verify or disprove our assertion before making public so incorrect a computation! No, there was a purpose in allowing the higher figures to stand. The petition of the Members had been signed by 4,665 Members, and that, of course, was a much smaller proportion of 18,000 than of 12,000. The Council states that there was "no evidence before the Council that the majority of even the Members themselves are in favour of the claims set up on their behalf." Has the Council ever sought for such evidence? No; yet it has been abundantly supplied to it, not only when it was informed on November 3rd, 1887, of the number of signatures, and that in many large towns from two-thirds to three-quarters of the Members living there had actually signed; not only in the ridiculous number of dissentient Members (fourteen) who had recorded their disapprobation of the petition, but also in the enormous majorities in favour of the resolutions passed at the College at successive general meetings. Is this evidence? If not, why did not the Council poll its own Members? The Members would not have grudged the expense involved—considerably under £100. As to its poll of the Fellows, the disingenuity of that you have long ago exposed. Yet the Council, which treats so lightly a matter of nearly 5,000 signatures, plumes itself upon a document signed by the magnificent total of "over six hundred," and on a majority of six out of eighteen in the first, thinly attended and badly advertised, of the series of general meetings. It is careful also to include two propositions in one sentence, and to make its lame answer to one only do duty for a judgment on both. This is a very poor feint. It has been maintained ere this, on behalf of the Council, that it would be unfair to deprive the Fellows of the electoral value for the extra money defrayed by them upon an extended course of professional study; but now the Council tries to make a point out of the present possibilities of obtaining the Fellowship "without any further special curriculum of professional study involving additional expense." One clause objects to Members of twenty years' standing being eligible to the Council on the ground that it would substitute mere seniority for professional distinction. There is no question of substitution, for the proportion of seats asked for by the Members is small, and they may be trusted to take care that they elect men of "professional distinction," for such are not unknown among the ranks of the general practitioners. The time limit may also be looked upon as a self-denying ordinance on the part of the Members.

We are not at present so directly interested as the Fellows are in the question of the election of the President; but may point out that Clauses *c*, *d*, *e*, and *f* are mutually antagonistic in their bearings, and that Clause *f*, where the Council speaks of the danger of placing the election of the President in the hands of "a comparatively small number," is an instance of the Council being judged out of its own mouth, not only on this, but on the larger question of the Members' claims. We are informed, however, on the highest authority, that the Privy Council does not look so slightly as does the College President upon the petition presented by 4,665 Members of the Royal College of Surgeons, and that that body looks upon it as a most important and weighty document, over the discussion of which much time must yet be spent. We have no misgivings as to the result.—We are, etc.,

WARWICK C. STEELE, } Hon. Secs. Assoc.
WM. ASHTON ELLIS, } M.R.C.S.

February 8th, 1888.

REGISTRATION OF TRAINED NURSES.

SIR,—Being present at the remarkable gathering of medical men and nurses at St. George's Hall, I desire to ask, through the medium of your columns, a question to which, although I listened attentively to all the admirable speeches, I could find no answer.

The British Nurses Association (President, Her Royal Highness Princess Christian) is founded to supply the profession and the public with a really good article in the shape of thoroughly trained nurses, who are to be registered, and form members of a new and rising profession. My question is, "What is this trained nurse of the future to be like, and what are to be her qualifications and training?"

The medical profession is fairly well marked out into the three great divisions of medicine, surgery, and obstetrics, besides the army of general practitioners. There are the two separate

diplomas of medicine and surgery with their Colleges, obstetrics not yet standing alone.

In nursing, as far as I understand it, these three classes, the monthly, the medical, and the surgical nurse are still more clearly differentiated. Most women who enter the profession now display a marked aptitude for one or other, and the training for each must be distinctly specialised.

Are the trained nurses of the future to be a vast body of general practitioners trained in medicine, surgery, and obstetrics, or are we to have the three branches specialised, with diplomas and registration for each? I venture to think the latter arrangement vastly preferable. A highly trained surgical nurse is not always a good hand at washing a baby, or a medical nurse at dressing a wound; and considering the distinctions are as well marked as in our profession, I was surprised, when so much allusion was made to the difference between a surgeon and physician, that this point was not touched on at all.

In conclusion, I venture to think that both the public and the profession will better value and better understand the meaning of a trained and registered nurse if it be stated what she is trained for, and if her studies be specially shaped for that end.—I am, etc.,

A. T. SCHOFIELD, M.D.
141, Westbourne Terrace, Hyde Park, W.

THE METROPOLITAN PROVIDENT DISPENSARIES AND THEIR OPPONENTS.

SIR,—It is to be hoped that the committee lately formed, and over which Dr. Paramore presided, are really in earnest in helping on the above movement, but are equally determined to make the scheme as perfect as possible. They give several reasons for objection, and only one of these has any solidity in it. They object to allowing anyone to enter when ill, or in other words to paying a "sick entrance fee." To call such a scheme an "insurance against sickness, during health," is absurd, and altogether opposed to any system of solid insurance. In fact, if any other society started an insurance with such a clause, it would crack up in a few months. Their income from premiums would not supply the demands for benefits. If the "sick entrance fee" were a keystone of the provident scheme, one could wish it to be retained; but it is not, and more certainly, it never can be, therefore it should be dropped.

As to the objection that it is "an advertising concern," this will not hold water. Our annual hospital reports, our insurance company's prospectuses, our health-officers' appointments, our having our names printed in the directories, are all advertisements, more or less, just as the provident prospectus is.

The Committee object also, that it is not needed, for the hospitals and club doctors, and parish authorities are amply sufficient. This is not so. In the Sturge Prize Essay, I lately showed that in twelve months, and at 130 hospitals, 50,935 in-patients, and 1,179,661 out-patients received treatment; now it is well known that the majority of these out-patients can pay the fees of a provident system. Indeed, the fear is that a good many would be disqualified from joining a provident dispensary. However, a well worked "wage limit" would look to this. At 72 of these hospitals the patients paid £36,334, while at 82 hospitals the doctors were paid £15,225 19s. Now if these people had been in a provident scheme they would have paid more, and the doctors would have received larger salaries. This statement then does away with their objection—that the scale of payments to a provident dispensary is ridiculously low.

If again one takes the club-doctor system, it is found to be very poor as regards payment of doctors. I know of one doctor who has seven clubs. He says it does not pay him, and to prove this he has an unqualified assistant at £50 a year. He calculates that, if he gets the confinements, vaccinations, and treatment of the children of club members, this goes to repay him; but he complains bitterly that, when he sends in his account for the treatment of the club members' wives, the men threaten to have him kicked out (*sic*) if he insists on their paying. It is well known that a club doctor's life is a broken-hearted life, full of insults and worries. Then look at the fearful abuses of the club-doctor system. Anyone can join; they sneer at the idea of a "wage limit." Take the Clerks' Association at Liverpool: any member, even those making £600 per annum, can have a doctor and medicine for *four shillings* a year! The Foresters and Oddfellows are the same.

Now, granting some go to the hospital who should not, and that the same holds good of clubs, is there not room for a provident scheme in London? It is sad to see that the chief oppo-

nents of the system are our club doctors and those at the hospitals. It is a matter of observation that many club doctors shift their patients into the hospitals, so as to get rid of them. In this way the two classes help each other.

The Committee point out that the scale of fees is degrading. Well, for that matter, so are all our fees, even those of club doctors, hospital men, ship surgeons, and general practitioners. But we hold the remedy in our own hands. For years I have asked my medical neighbours to fix the minimum fee for the district; but will they? From fourpence to tenpence (not including the supply of drugs) is the rate per visit of the provident dispensary system to their doctors. This might be improved upon, and I hold that the working expenses of a provident dispensary should be defrayed by honorary subscriptions. All provident societies have such. The Foresters have 13,971 such, paying from 10s. 6d. upwards. Each club has its concert or raffle. In Germany, where there is compulsory national insurance against sickness and accident, the employer pays one-third opposite the two-thirds paid by the workman. Capitalists sink their money in insurance companies before a single premium has been paid.

I shall be glad to send anyone information on the provident dispensary system. Let it have a fair trial. But, to be a success, it must have hospital co-operation, without which it will be a farce and a complete failure.—I am, etc.,

Liverpool.

ROBERT R. RENTOUL, M.D.

THE NOMENCLATURE OF NEURASTHENIC CONDITIONS.

SIR,—The enclosed communication from Mr. Howell is a sort of note or postscript to his paper on Hysteria, read before the Hunterian Society, an account of which appeared in the JOURNAL of February 11th. There can, I think, be no doubt that a revised nomenclature will be of service in connection with the theory of the subject in question.—I am, etc.,

H. GERVIS.

40, Harley Street, Cavendish Square.

February 12th, 1888.

"NEUROKINESIS: NEURASTHENIA: HYSTERIA.

"MR. PRESIDENT,—It seems to me that some word is needed to define the condition of the nervous system which ensues upon shock, either physical or moral, or breakdown from overstrain more closely than neurasthenia, which may mean a natural state, or hysteria, which implies a special source or cause. This condition—which is attended by loss of physical power, paresis, etc.; by loss of moral power, irresolution, etc.; by susceptibility to pain, hyperæsthesia, and irritation in all forms; by a readiness, to take on perverted action, paroxysm or emotion, on the one hand, or to fall to pieces, as it were, as if the screws were loose or fallen out, prostration of power, on the other; by a loss of integrity of nerve power, or of some element that is essential to it—might, perhaps, be represented by neurokinesis, that is, nerve shock or shaking; a nerve commotion.

"Revision and improvement in nomenclature necessarily attend upon advance of science. No one, in the present day, would think of confounding typhus with typhoid fever, or of adopting in the one case the treatment suitable for the other. So the emotion which ensues upon shock is simply emotion; it is not hysteria; to call it hysteria is to attribute to a natural consequence a special cause that does not appertain to it. Obviously the treatment of emotion *per se*, and of hysteria, *per se*, ought to be essentially different.

"Again, loss of power of the will, of self-reliance, irresolution, etc., is another effect and result of shock. This condition palpably stands in need of help to restore the will which is in abeyance, and to rouse to resolute action the power that is temporarily suspended and prostrated. If this need of aid is ignored because it is either not recognised or not understood, it becomes an unrelieved want, the repeated representation of which by the patient is very liable to be misinterpreted into a craving for sympathy by the doctor, who thus fails to see the true state of the case. Let the patient once see that her condition is rightly understood, and that it will meet with attention, and this reputed craving will cease; at least, this is in accordance with my experience. When once hysteria ceases to be a "disorder with which everyone is familiar, but which nobody understands," the treatment will become more rational and more successful. Hitherto it has represented neither the science nor the art of medicine.—I am, yours truly,

"February 10th, 1888. "D. DE BERDT HOWELL.

"To the President of the Hunterian Society."

INTRACAPSULAR INJECTION IN THE EXTRACTION OF CATARACT.

SIR,—I took part in this correspondence chiefly with the object of protesting, as I was bound to do, against the use, twice made by Dr. McKeown, of statistics of my hospital of some eleven or twelve years ago. Having entered this protest, I should not trouble you further in the matter, but that it might be taken as a want of courtesy on my part were I to pass over in silence some points in Dr. McKeown's last letter (JOURNAL, 11th February). I hope, therefore, you will permit me once more to intrude upon your space.

And, first of all, referring to an observation in Mr. Bell's letter in the same JOURNAL, I do not know whether I am included amongst those whose attitude with regard to this procedure seems hostile or even unscientific, but, to my mind, neither of these epithets can be applied to an attitude which consists in declining to call a certain procedure good, when the results of its principal advocate do not show it to be good. I have no "hostile" feeling towards the intracapsular injection, nor would it be inconsistent with anything I have said were I to adopt the method at some future time, when it may have been placed on a surer footing than at present.

With respect to Dr. McKeown's letter:—1. Quite apart from his invitation, it is my intention to give the results of my cataract extractions as soon as I possibly can. For the present I may say that I am almost, if not altogether, satisfied with those results. But, whatever they may be, I fail to see how they can be of use to Dr. McKeown, for I operate only on ripe, or very nearly ripe, cataracts. If, therefore, my results are better than his, this may depend upon the difference of the material operated on; indeed, Dr. McKeown has himself reminded us that "we have no analogous statistics." If my statistics are bad, or are only middling, Dr. McKeown will not wish to compare his with them at all, but, if comparison there can be, will prefer to place his statistics beside those of more successful operators.

2. With regard to Dr. McKeown's suggestion that I should supply him with the details and results of cataract operations performed by other surgeons, I am afraid I must ask to be excused, for the task would involve some hours' work over the back numbers of about a dozen journals, not to speak of hospital reports, in different languages. I may, however, mention that, in a publication I received to-day, there is a table giving the results obtained by 17 operators, and they are all better than Dr. McKeown's results. The number of operations opposite the names of some of these surgeons is too small to render their percentages of results of much value; but the series recorded by five of them is sufficiently long. No. 1 operated on 101 cataracts; losses, 2.0 per cent. No. 2 operated on 381 cataracts; losses, 2.88 per cent. No. 3 operated on 155 cataracts; losses, 1.29 per cent. No. 4 operated on 116 cataracts; losses, 1.18 per cent. No. 5 operated on 107 cataracts; losses, 0.94 per cent.

3. Dr. McKeown said it is not proved that antiseptic measures have accomplished anything for cataract operations, if only the hospital be sanitary. To this I can only say that I hold precisely the opposite opinion as do all the most successful operators in Europe and America. The proof lies in the almost complete freedom from suppurative processes which we now enjoy.

4. With respect to the modification which, in the hands of most operators, has or has not taken place in the section, I am not well acquainted with the present practice at Moorfields, but I should not be surprised to learn that what is there called Graefe's method receives that name, and properly too, because the operation is done with a Graefe's knife, and includes an iridectomy, while the section may be much less peripheral than von Graefe made it. On the Continent (Germany and France) I know of only one operator who still clings to the old von Graefe's section.

5. Dr. McKeown states that Forster's artificial maturation is very little practised. "Very little" is a relative term, but I can assure him that it is used by very many ophthalmic surgeons whenever occasion requires, and that it is coming more and more into use. My experience extends to some half a dozen cases in which I thought it indicated, and it acted well.

6. The quotations from MM. Panas and de Wecker, with which Dr. McKeown supplements mine, do not bear him out in his view, except in so far as that, in some exceptional cases of unripe cataract, the latter author evacuates cortical masses partly by washing them out and partly by pressure with the lower lid.

As I do not think that a correspondence in the JOURNAL is a

snitable medium for the thorough discussion of such a subject, and as there is always danger of the personal element creeping into a correspondence like this, I shall ask you, Sir, to consider this one now closed, so far as I am concerned.—I am, etc.,

23, Merrion Square, Dublin.

H. R. SWANZY.

February 15th.

APPOINTMENT TO HAYWARD'S HEATH ASYLUM.

SIR,—Your correspondent "G." has certainly not overstated his case, for he has omitted to point out that the new medical superintendent has, for many years, held a post as district medical officer of health, and has been presumably debarred from the ordinary practice of his profession.

He is at least forty-five years of age, his earliest qualifications being dated three years after those of his predecessor, whose pension of £500 per annum has been strongly protested against by the Sussex Guardians; in face of this, the Committee of the Asylum have elected a man who, in five years, might also be pensioned at £500 per annum. Unfortunately, the antagonism to pensions this is likely to raise will extend to other counties.

"G.'s" letter suggests the idea that if one of the Lord Chancellor's visitors were shortly to retire, it would be very natural and probable that their *protégé* should be nominated to the vacancy. The possibility of such promotion is calculated to harm the Asylum Medical Service by deterring good men from entering a speciality, in which the prizes may thus be withdrawn from competition.—I am, etc.,

14th February, 1888.

* * * We have received a copy of the rules of the Sussex Lunatic Asylum, Hayward's Heath, approved by the Home Secretary in 1870 and 1873, and we are informed that the requirements as to the qualifications of the medical superintendent therein contained are those which were advertised as applicable to candidates for the vacancy recently filled up. The opposite was implied in the letter of our correspondent "G." published last week, and the correction was received too late for insertion then.

INJURY TO SIGHT BY SHUTTLES.

SIR,—In the JOURNAL of February 11th you quoted from the annual report of the Preston Eye Infirmary (Mr. Winkley Langdon) regretting that shuttle accidents cannot be prevented. In a memoir which I had the honour to present to the Society for the Prevention of Blindness (Paris), 1886, this subject was fully and exhaustively discussed, statistics given from the Manchester Eye Hospital showing the alarming nature of the accident, and accompanying this was a drawing to scale by a mechanical engineer of great skill, showing a weaver's loom with the patent shuttle guard of "Wirth" attached; the patent is a German one, but I am assured admirably fulfils its intention. Shortly it consists of three rods in a hinged fall, which is attached to the beam of the reel; the guard rods are sufficiently near to prevent the shuttle flying through; and when we know that a full shuttle weighs nearly one pound, is tapered at either end, shod with iron, and thrown 8 feet from side to side 120 times a minute, some idea can be formed of the formidable nature of this engine of destruction. Happily, improved machinery has much reduced this accident, so also has the Employers' Liability Act, but no knowledge nor skill can prevent an occasional knot in the yarn, which deflects the point of the shuttle and forces it to leave the simple groove in which it plays.

There can be no doubt of the admirable service Mr. Langdon does by calling attention to these preventable accidents, but the operatives are often to blame, for they refuse to use safeguards which slightly hinder their work.—I am, etc.,

20, St. John Street, Manchester.

P. H. MCLES, M.D.

VENTRAL NEPHRECTOMY FOR HYDRONEPHROSIS.

SIR,—In reply to the letter of Mr. Clement Lucas in the JOURNAL of February 11th, I desire to state that I entirely disagree with him that the treatment adopted by me was what he considers as heroic, or other than the case demanded, and for the following reasons:

In the first place, the correct treatment of hydronephrosis is at the present time an open question, and is, in my opinion, ever likely to remain so, each case requiring to be treated on its own merits.

Again, there is no analogy betwixt hydrocele and hydronephrosis, either in their pathology or treatment. Aspiration in a case of distended kidney pelvis is a much more risky proceeding than in that of hydrocele. The fact of the cyst so often refilling

was sufficient evidence that simple tapping would have been useless as a permanent cure, which was what the patient desired. Incision and drainage I look upon as a very unsurgical proceeding, and quite unsuited to such a case.

As regards removal through the loin, I question if in any case, more especially in a very stout subject, there is any less danger in this operation than in the other; but, in my case, I am confident from the extensive adhesions, the operation would never have been completed, even by one who had had experience in such cases.—I am, etc.,

R. H. A. HUNTER, M.R.C.S., etc.

Clifton House, Battersea, S.W.

PATHOLOGY IN DUBLIN.

SIR,—While in the main I agree with much you have written by way of commentary on Dr. Mapother's remarks regarding the teaching of pathology in Dublin, there are one or two points on which I should like to express my dissent. It is quite incorrect to say that teaching in pathology is "totally and confessedly non-existent." It could hardly be so in the city which gave an impulse to the teaching of pathology everywhere by the foundation of the old Pathological Society. In the hospitals it is taught, not systematically, I admit, but with all the force and advantage which come from an intimate knowledge of the clinical history of the cases. Several of the hospitals have small pathological museums. The Richmond has one of considerable extent and wide fame, and with the specimens there the teaching in the wards is made clearer and more forcible. In the Trinity College School, Professor Purser gives a full course on pathological histology, and no more able teacher is to be found.

The fault lies not in the difficulty of having the subjects well taught, but in the omission of the licensing bodies to have attendance on a course of lectures and demonstrations made compulsory. As a member of the Senate of the Royal University, I have moved and carried the introduction of such a course into the curriculum. Following up that success, I brought the matter formally before the Dublin Branch of the British Medical Association in 1887, and a motion was again carried this year enforcing the importance of systematic teaching. It is now for the other licensing bodies in Ireland to follow the example of the Royal University. If they will only require attendance on a three months' course, there will be no difficulty about the teachers.

But I wish to say, nevertheless, that we are not such an ignorant class as your leader implies. With many disadvantages to struggle against, we do know something about pathology: there are some branches which have been worked as fully here as anywhere else in the world. We do not intend, however, to rest satisfied; to use your own words, we will not "be contented with anything lower than the first position."—I am, etc.,

34, Harcourt Street, Dublin.

W. THOMSON.

CIRRHOSIS OF THE LIVER.

SIR,—In connection with Dr. Drummond's case of cirrhosis and Dr. Wilk's interesting remarks thereon, I send you the following abstract of a case that was under the care of Dr. Churton in the Leeds Infirmary.

A man, about 55, was admitted with ascites. He had great enlargement of the veins about the umbilicus, and hepatic cirrhosis was diagnosed. He was tapped once and steadily improved, the abdomen remaining small. I then ventured to offer to the clinical class as an explanation of the non-reaccumulation of the fluid the establishment of collateral venous circulation. A year afterwards he was readmitted with a very extensive purpuric condition of the skin of the legs and trunk, and slight reaccumulation of ascitic fluid. He slowly sank into a semicomatose condition, became faintly jaundiced, and died gradually. *Post mortem* we found cirrhosis of the liver well marked, and retroperitoneal extravasation of blood. In the free margin of the falciform ligament a large vein passed from the left division of the portal trunk to the superficial veins around the umbilicus. This vessel was thick walled, and as large as a goose quill.

I can call to mind one case of ascites, under the care of Dr. Clifford Allbutt, who, diagnosing cirrhosis, directed me to tap repeatedly, the case not having been in any way affected by a lengthened use of diuretics. This was done, and the fluid ultimately did not reaccumulate. In this case there was not much enlargement of the superficial veins, and possibly a collateral circulation may have been established through the ductus venosus or other channels.—I am, etc.,

Leeds.

T. WARDROP GRIFFITH.

NAVAL AND MILITARY MEDICAL SERVICES.

CHANGES OF STATION.

THE following changes of station among the officers of the Medical Staff of the Army have been officially notified as having taken place during the past month:—

	From	To
Surgeon-General W. A. Mackinnon, C.B.	London ...	Gibraltar.
" Sir J. A. Hanbury,	M.B., K.C.B. Gibraltar ...	Madras.
" W. M. Webb ...	York ...	Aldershot.
Deputy Surg.-Gen. J. Ferguson	Bengal ...	York.
Brigade-Surgeon J. Inkson, M.D.	Aldershot ...	Madras.
Surgeon-Major W. J. Fawcett, M.B.	Clifton ...	Bengal.
" H. W. Joynnt ...	Jamaica ...	Canterbury.
" J. M. Namara, M.D.	W. Africa ...	Aldershot.
Surgeon W. R. Henderson, M.D.	Cork.
" D. O'Sullivan ...	Fleetwood ...	York.
" G. Coutts, M.B. ...	Bombay ...	Hulme.
" J. Battersby, M.B. ...	Boyle ...	Dublin.
" E. J. E. Risk ...	Oxford ...	Portsmouth.
" J. W. Beatty, M.D. ...	Bengal ...	Newcastle.
" L. E. Anderson ...	Netley ...	Jamaica.
" G. B. Russell, M.B. ...	Peruany ...	Cahir.
" J. S. Green, M.B. ...	W. Africa ...	Dublin.
" J. Rose ...	Madras
" J. Moir, M.B. ...	Devonport ...	Ceylon.
" J. F. S. Fowler, M.B. ...	Aldershot ...	Nova Scotia.
" J. R. Burrows, M.D. ...	Cork ...	Hong Kong.
" E. S. Marder ...	Gosport ...	Bengal.
" A. L. F. Bate ...	Dublin
" E. A. Burnside ...	Portsmouth ...	Ceylon.
" J. W. Cockerill ...	Aldershot ...	Dover.
" J. W. Bullen, M.D. ...	Queensdown ...	Roscrea.
" H. E. H. Smith ...	Portsmouth ...	Sts. Settlements
" W. Hallaran, M.B. ...	Aldershot ...	Madras.
" R. Crofts ...	Cork ...	Sierra Leone.
" L. E. A. Salmon ...	Newcastle ...	Preston.

THE NAVY.

MR. MICHAEL RONAN, B.A., Staff Surgeon, has been appointed to the *Fearless*.

THE MEDICAL STAFF.

SURGEON-GENERAL T. W. FOX, M.B., is granted retired pay. He entered the service as Assistant-Surgeon July 23rd, 1852; became Surgeon, September 18th, 1860; Surgeon-Major, July 3rd, 1872; Brigade-Surgeon, November 27th, 1879; Deputy Surgeon-General, June 23rd, 1880; and Surgeon-General, May 18th, 1887. He was with the 14th Light Dragoons in the Persian war of 1857, and was present at the bombardment of Mohumrah; he received the medal and clasp for the campaign.

Brigade-Surgeon W. B. RAMSDOTHAM, M.B., has also been granted retired pay; his commissions bear date: Assistant-Surgeon, March 10th, 1883; Surgeon, March 1st, 1873; Surgeon-Major, April 1st, 1873; and Brigade-Surgeon, October 1st, 1883. The granting a step of honorary rank on retirement has been discontinued. Brigade-Surgeon Ramsbotham served in the Afghan war of 1878-80 (medal), and in the Egyptian war in 1882 (medal and Egyptian bronze star).

Quartermaster G. W. M. JOHNSTON has likewise retired. He entered the service as Lieutenant of Orderlies, June 25th, 1873; became Captain, April 30th, 1879; and was made Quartermaster, Medical Staff, from July 1st, 1881. He was engaged in the campaign in the Eastern Soudan in 1885, and obtained the medal and clasp and the Egyptian bronze star.

Surgeon-Major METCALFE JOHNSON, of the 4th Battalion Royal Lancaster Regiment (formerly the 1st Lancashire Militia), has resigned his commission, which bore date March 1st, 1873; he is allowed to retain his rank and uniform.

Deputy Surgeon-General P. B. SMITH, M.D., on relief from the Allahabad Division of the Bengal Army, is appointed to the administrative medical charge of the Oude Division and Rohilkund district, *vice* Deputy Surgeon-General Slaughter, who has been transferred to the Home Establishment.

Deputy Surgeon-General E. H. ROBERTS, on arrival from England, is appointed to the administrative medical charge of the Allahabad division of the Bengal army, *vice* Deputy Surgeon-General P. B. Smith, transferred.

Surgeon D. SEMPLE, M.D., serving in Bengal, has been appointed to the charge of the civil medical duties at Dum Dum.

Surgeon-Major J. E. V. FOSS, M.D., serving in the Bombay command, is appointed to the medical charge of the station hospital at Deesa.

THE INDIAN MEDICAL SERVICE.

THE promotion of Brigade-Surgeon W. R. RICK, M.D., Bengal Establishment, to be Deputy Surgeon-General, already announced in this JOURNAL, has received the approval of the Queen.

Surgeon-Major C. F. OLDFHAM, Bengal Establishment, is promoted to be Brigade-Surgeon. He entered the service as Assistant-Surgeon July 27th, 1859, and was made Surgeon-Major January 3rd, 1877. He was with the 1st Goorkhas in the operations in the Malay Peninsula in 1875-76 (medal with clasp), and with the same regiment in the war in Afghanistan in 1878-79 (medal).

Brigade-Surgeon C. STUBBORPE, Madras Establishment, Professor of Anatomy, is appointed Professor of Surgery and Clinical Surgery at the Medical College, *vice* Surgeon-Major J. J. S. RATTON, M.D., retired.

Surgeon-Major H. ALLISON, M.D., Madras Establishment, Professor of Hygiene, is appointed Professor of Anatomy at the Medical College, *vice* Brigade-Surgeon Sibthorpe.

Surgeon T. H. POPE, Madras Establishment, is appointed Professor of Hygiene, *vice* Surgeon-Major Allison.

The services of Surgeon F. C. REEVES, of the Madras Establishment, are placed temporarily at the disposal of the Chief Commissioner of the Central Provinces, from the date on which he may be relieved of his acting appointment as Deputy Assay Master, Calcutta Mint.

Surgeon W. G. P. ALPIN, Bengal Establishment, Resident Surgeon in the Eden Hospital at Calcutta, is appointed to officiate as Medical Officer of the Bhopal Battalion and Agency, during the absence on furlough of Surgeon-Major A. H. C. DANE, M.D.

Surgeon E. W. REILLY, Madras Establishment, is appointed to officiate as Medical Officer 3rd Native Cavalry.

Brigade-Surgeon A. H. HILSON, M.D., Bengal Establishment, with temporary rank of Deputy Surgeon-General, is appointed to the officiating administrative charge of the Gwalior and Sangor District, *vice* Deputy Surgeon-General R. F. HUTCHINSON, M.D.

The undermentioned gentlemen have obtained leave of absence for the periods specified:—Surgeon D. R. ROSS, M.D., Bombay Establishment, Medical Officer of the Political Residency in the Persian Gulf, for eighteen months; Surgeon-Major D. WILKIE, M.D., Bengal Establishment, Statistical Officer to the Government of India in the Sanitary and Medical Departments for one year on private affairs; Surgeon-Major W. B. JOHNSON, Madras Establishment, Secretary and Statistical Officer to the Surgeon-General H.M.'s Forces, for one year on medical certificate.

THE VOLUNTEERS.

ACTING-SURGEON C. S. YOUNG, of the 3rd Volunteer Battalion Black Watch (formerly the 3rd Forfar), has been promoted to be Surgeon, and Mr. M. F. ANDERSON, M.B., has been appointed Acting Surgeon in his stead.

The undermentioned gentlemen have been appointed Acting Surgeons to the corps specified:—HUGH HEALD, 16th Lancashire; F. H. STAW, 4th Volunteer Brigade, Cinque Ports Division, Royal Artillery (late the 1st Cinque Ports Artillery); F. P. F. RANSOM, 3rd Volunteer Battalion, Suffolk Regiment (late the 1st Cambridgeshire).

RANK OF ARMY MEDICAL OFFICERS.

A CORRESPONDENT writes that he wishes to give some facts supplying yet another instance of the absolute necessity of giving medical officers honorary—or, at all events, some definite and comprehensive—military rank. He says he was detailed as a member of a mixed sanitary board, in a station of which he happened to be the actual sanitary medical officer. His seniority should have placed him next to the president, a junior major of a regiment. Nevertheless, he was detailed in order at the bottom, below a captain of Engineers and some budding subalterns of the garrison. The president markedly treated him as a nobody, never even asking his opinion, etc. He adds: "I think I have due grounds for feeling aggrieved."

. Undoubtedly. This board seems to have been a farce from a sanitary point of view, and its intelligent conclusions probably on a par with the courtesy of its president. The medical officer, being detailed a member and not a mere "attending" sanitary expert, should have asserted his seniority—probably, however, to be met with the answer that medical officers were not now in the possession of any army rank whatever!

REFORM OF THE DIRECTOR-GENERAL'S OFFICE.

A CORRESPONDENT suggests a Royal Commission to throw light into the dark subjects of promotion, retirement, the roster, and general administration in the Army Medical Service. Especially he advocates that the post of confidential secretary to the Director-General should be in the hands of an experienced medical officer, and not of a civilian clerk.

STATEMENT OF RANK IN THE GAZETTE.

AN administrative medical officer writes that "on all occasions when medical officers are gazetted, their military rank should be fully stated." This would include retirements, as well as appointments and promotion.

ESPRIT DE CORPS.

SENIOR SURGEONS writes: One point in recent discussions in the public press on the efficiency (or inefficiency) of the Army Medical Staff must have struck many of my brother officers as well as myself. I refer to the silence maintained throughout by those in other branches of the service, who, under many personal obligations to officers of the medical staff—obligations privately willingly admitted—or, it may be, for good offices (to which they were by no means entitled by regulation) rendered to some near and dear one in their families, apparently are not so strongly felt as to prevent silent assent to scurrilous detractions which they well know are totally unjust. Let us not forget this attitude.

Since my attention was drawn to the fact, in the evidence given before Lord R. Churchill's Committee, that the public had to pay £25,000 yearly for drugs used in the army, I have made various calculations, which confirm the opinion that the necessity for this large expenditure is partly due to the large consumption of drugs by officers' wives and families; and I would suggest to economists of the Labouchere type that, if the wives and children of officers were not held entitled to attendance and medicines at the public expense, not only would a direct saving ensue in the reduction of the drug bill, but also an indirect one in medical officers' salaries, as the army could do with fewer surgeons. The suggestion would also meet the views of those combatant officers who have been trying to prove that civilian surgeons are always to be preferred to military. It would, moreover, be a logical continuation of the policy by which officers' wives and children abroad were recently struck off "rations" issued at a nominal cost to themselves.

ROYAL PUBLIC DISPENSARY, EDINBURGH.—The annual meeting of the Royal Public Dispensary was held recently, the Lord Provost of Edinburgh in the chair. The report stated that during the past year 7,697 patients had been attended by the staff of the dispensary; of these, 5,397 had personally visited the outdoor department, 1,531 cases of a more serious nature had been attended at their own homes, 630 children had been vaccinated, and 139 women had been attended in their confinements. There was an increase of 123 patients on the previous year, although the institution was closed for a fortnight. Dr. G. Balfour was elected consulting physician for the ensuing year.

MEDICO-LEGAL AND MEDICO-ETHICAL.

THE APOTHECARIES' SOCIETY AND ILLEGAL PRACTICE.

AN important case under the Apothecaries' Act came before the judge of the Burslem County Court on Monday last. Edward Middlebrook, of Burslem and Smallthorne, was sued, at the instance of the Apothecaries' Hall, for practising as an apothecary without having obtained a certificate under the Act. It was stated that the defendant had for some time past carried on an extensive business in Burslem as an apothecary and surgeon without any qualifications. He had also a dispensary, called "Middlebrook's Provident Dispensary," at Smallthorne, and described himself as "E. Middlebrook, L.M. Dublin, Surgeon Accoucheur," etc.

It was contended, on behalf of the defendant, that the Act of George III, under which action was taken, was not intended to apply to a case like the present, and that a surgeon, merely as a surgeon, was not entitled to practise under this Act of Parliament, under which men holding the qualifications of M.R.C.S., M.D., and F.R.C.S. might be prosecuted. The meaning of the Act was that a man of absolutely no qualification should not be allowed to go about holding himself out as a medical man. But Mr. Middlebrook was a Doctor of Medicine of an American University, and had obtained a qualification from the Coombe Hospital, Dublin, which would entitle him to practise in midwifery and diseases of children. It was contended that there was no evidence that Mr. Middlebrook had held himself out as an apothecary.

The Judge, in giving judgment, said an apothecary had been defined by Mr. Justice Creswell as one who judged of internal diseases by its symptoms, and who set himself to cure that disease by medicine. It was proved to his (the Judge's) entire satisfaction that the defendant had practised as an apothecary without a certificate. A verdict was given for a penalty of £20 and costs.

CORONERS AND UNQUALIFIED ASSISTANTS.

J. M. SMITH, M.D., C.M. (London, N.), forwards us an account of an inquest recently held in the eastern district of the metropolis, in which it appears that our correspondent has come somewhat into collision with the coroner who presided on the occasion. The subject of the inquiry was a domestic servant, aged 48 years, who died at her sister's residence after a short illness of less than three hours' duration. In her evidence at the inquest the sister stated that the deceased—who was single, suffered from delusions, and was eccentric in her habits—paid her a casual visit one afternoon, and soon afterwards complained of a severe pain in her back. Becoming worse, our correspondent was sent for, and, not being at home, his unqualified assistant attended, saw the deceased, and prescribed for her, the friends being under the impression that the deceased was receiving the services of a duly qualified medical man. On Dr. Smith's return, some hours after, he went to visit the patient, and found she was dead, and, not having seen her alive or diagnosed her case, he declined to certify as to the cause of the death, and an inquest in due course was held, to which Dr. Smith, his assistant, and other witnesses were summoned.

No *post-mortem* examination was ordered, and when Dr. Smith was called upon to give evidence, he stated that he knew nothing about the case, and could assign no cause of death, he never having attended the deceased woman. The coroner then examined the assistant, who stated that he was a dispenser of drugs to the last witness; that, in the absence of his principal, he had visited and prescribed for the deceased. In answer to questions, he further stated that he considered the case "a very serious one indeed," but did not think it necessary to tell the friends he was not qualified, or to send for a medical man, as he was expecting Dr. Smith to return.

The coroner (severely): "That has nothing to do with the patient's life. You thought the case a serious one, and the friends were under the impression that the deceased was being treated by a fully qualified medical man, and so did not trouble. I think it is scandalous. It is over and over again that I have cases where people think their friends are being attended by duly qualified medical men and they are not."

Dr. Smith then appears to have contended that this was a case where a *post-mortem* examination should have been ordered; but the coroner evidently at first took an opposite view, presumably on the supposition that, had a duly qualified medical man attended the deceased instead of the dispenser of drugs, a proper diagnosis of the case would have been made during the three hours' illness prior to death, and an opinion given at the inquest, which would, from a legal coroner's point of view, have been sufficiently satisfactory without a *post-mortem* examination, and thus, as intimated, "not have wasted the public money when it might be avoided." The inquest, however, was adjourned, and a medical man unconnected with the case made a *post-mortem* examination, which showed that death was due to failure of the heart's action from fatty degeneration, accelerated by excessive indulgence in alcohol.

"* * * Apart from the question of *post-mortem* or no *post-mortem* in this case, our correspondent naturally feels aggrieved that he should be expected to assign a cause of death without knowing it, and that unpleasant observations should be made at the inquest about himself and his assistant. Having no knowledge of the deceased person till after death, he could not under the circumstances state the cause of it; but we would venture to remind him that if he employs an unqualified assistant—or, as the assistant described himself, "a dispenser of drugs"—to conduct his practice during his absence, he will from time to time find himself in collision, not only with the coroner, but

with the public generally and his patients in particular; and he must not be surprised if some amount of indignation is expressed when it is discovered that his representative has not even attained that minimum of knowledge which the State requires to be verified by registration before it sanctions an appointment of a medical officer to attend upon the very poorest in the land. We are sorry to gather from the statements of the coroner that this objectionable mode of practice is not uncommon in the eastern district, and that it has necessitated expressions of opinion from him which were distasteful to our correspondent.

With regard to *post-mortem* examinations, it is usual for the coroner to send his order to the medical man who last attended the deceased, or who was called in at the time of or immediately after the death; nevertheless, it is within the discretion of the coroner to issue the order to any other duly registered medical man. In the present case he appears to have departed from the usual rule; possibly he feared that, if our correspondent's drug dispenser was considered sufficiently to represent him at the bedside of the sick and the dying, he might be thought by his principal competent to preside at the *post-mortem* table.

BRANCH SURGERIES.

X. Y. Z. writes: A. has for over thirty years had a few private and several club patients in a village four miles from the nearest medical man. B. has the parish appointment and the bulk of clubs. Is A. justified in (1) setting up a surgery or place of call? and (2) if so, is it necessary to acquaint B. of the fact before doing so?

"* * * If our correspondent's statement had been more explicit and definite we should have been able to answer the two questions submitted. In the absence, therefore, of certain details, our reply is unavoidably based on the assumption that B., as well as A., is at the present time a non-resident practitioner in the village alluded to. In such case, unless a mutual arrangement existed between them to the contrary, A. would be "justified in setting up a surgery or place of call, without previously acquainting B. with his intention to do so." At the same time, we deem it judicious to add that, in our opinion, duplicate surgeries, unless absolutely necessary for the convenience of the practitioner, are more than objectionable, and tend more or less to degrade the profession.

A CASE OF ETIQUETTE.

S. asks for an opinion on the following: A. B. is medical superintendent of a union infirmary of 600 beds, and C. D. is the assistant medical officer there. C. D. is laid up for two days through an accident. A. B. does his work in the wards during that time, and sees a case for whom C. D. has prescribed a few days previously. The patient has had some vomiting following the original symptoms. One of the items of C. D.'s prescription is *vin. ipecac.* in 7-drop doses. A. B. ordered C. D.'s prescription to be repeated, with the omission of the *vin. ipecac.*, but does not mention the alteration to C. D. When C. D. returns to duty, he writes to A. B., accusing him of committing a "gross breach of medical etiquette" in altering his prescription without consulting him. Has A. B. done so or not, and in either case is C. D. justified in using these terms under the above circumstances?

"* * * The one essential point for consideration in the above case is the manner in which the change (by the simple omission of a drug) in the medicine was carried out. If it were effected with scrupulous care, so as not in any way injuriously to affect the repute or wound the feelings of the assistant medical officer in question, the latter's imputation against his responsible senior is, from our point of view, altogether indefensible, and, strictly speaking, constitutes an act of insubordination. At the same time, although A. B., as the responsible superintendent of the union infirmary and in actual charge of the case, was fully justified in omitting the *vin. ipecac.* (as the probable cause of the supervening symptom of vomiting), without previous consultation with the temporarily incapacitated assistant, he would have done well—as a matter of courtesy, if not of right—to have intimated to his touchy subordinate the nature and cause of the change made in the prescription. In neither case, however, can A. B.'s conduct, in our opinion, be regarded as, or approaching thereto, a "gross breach of medical etiquette."

MEDICO-PARLIAMENTARY.

HOUSE OF COMMONS.—Friday, February 10th, 1883.

The Dublin Barracks.—In answer to Mr. NORRIS, Mr. STANHOPE said: Thirty-nine deaths occurred in all the Dublin Barracks during the year 1887 among the warrant officers, non-commissioned officers, and men of the garrison. No officer died during that period. It is impossible to say how many of these deaths were attributable to causes intrinsic to the barracks. Four were due to enteric disease and eight to pneumonia. Referring to the report by Sir Charles Cameron and Dr. Grimshaw, of which we were enabled to publish a full account last week, he said under many of the heads the requisite measures have been taken, or are in hand. But there are two of grave importance as to which no final action has yet been taken. One is the erection of a new hospital for the isolation of infectious cases. We are trying to set aside another

hospital for this purpose. The other is the demolition of a large portion of the barracks on the ground that some of the old buildings are too much crowded together. Unfortunately, it is very difficult to provide other accommodation in Dublin at this time of the year for the troops, who would thereby be turned out of the Royal Barracks, and the new barracks now being commenced cannot be ready for some time. We are, however, trying to make such arrangements as will enable the most unhealthy part of the Royal Barracks to be vacated as soon as possible. As regards Dover, I caused an inspection to be made by an inspector of the Local Government Board. A considerable expenditure has been incurred in carrying out his recommendations, and the sanitary condition of these barracks is believed to be satisfactory.

Monday, February 13th.

Insanitary Dwellings.—In reply to Mr. THORBURN, Mr. RITCHIE said that, in view of the work which the Government had in hand, they could not undertake to deal with the question of the compulsory periodical inspection of dwellings.

Tuesday, February 14th.

The Treatment of Accidents at Sheerness.—In reply to Mr. KNATCHBULL-HUGESSEN, Lord G. HAMILTON said: It has been the practice to send accident cases occurring in Sheerness Dockyard to the Royal Naval Hospital at Chatham, for treatment, when the nature of the injury admitted of their removal. Injuries of a nature to render removal undesirable would be treated locally at the dispensary of the Royal Naval Barracks at the dockyard. Under these circumstances it appears to be unnecessary to ask the military authorities to receive accident cases. Since January, 1887, there have only been three cases necessitating removal.

Local Government, Scotland.—Mr. W. H. SMITH, in reply to Mr. BARCLAY, said: It is not anticipated that there will be time this session for Parliament to consider the Local Government Bill for Scotland. Leave will be asked to bring in a Bill dealing with the question of local government boundaries in Scotland so as to facilitate the passing of the Local Government Bill in the ensuing session.

The Sweating System.—In answer to Mr. PICKERSGILL, Mr. W. H. SMITH said: The Secretary of State some time ago instructed the Chief Inspector of Factories to institute special inquiries into the sweating system at the East End of London, with the help of inspectors drawn for the purpose from other districts. The report of the Chief Inspector is daily expected, and it is hoped that it will materially assist the Government in deciding whether anything can be done by legislation to remedy the evils complained of.

Scotch Sanitary Legislation.—Upon a division being taken, leave was given to introduce a Bill by the Lord Advocate for regulating the police and sanitary administration of towns and populous places, and for facilitating the union of police and municipal administration in burghs in Scotland.

Wednesday, February 15th.

New Bills.—On the motion of Mr. ELTON for leave to introduce a Bill for the better regulation of temporary dwellings, Dr. TANNER objected. A Bill to facilitate the better housing of the working classes in London was introduced by Mr. REID, and was read a first time.

NOTICES OF MOTION.

Among the Bills and motions of which notices have already been given are the following:

- Mr. QUILTER: Bill for the better securing the purity of beer.
- Mr. GILHOOLY: Bill for the better housing of the working classes in Ireland.
- Mr. ISAACSON: Bill to amend the law relating to the election of coroners.
- Mr. DIXON-HARTLAND: Bill for the better regulation of theatres and music halls in the metropolis.
- Mr. G. O. MORGAN: Bill further to amend the law relating to burials.
- Mr. S. HILL: Bill for the sanitary inspection of dwellings.
- Sir E. GREY: On Tuesday, March 6th, to move a resolution in favour of the repeal of the carriage tax.
- Mr. PICTON: Bill relating to the practice of vaccination.
- Mr. MILVAIN: Bill to amend the law in relation to punishment by whipping, and for the better protection of women and children.

A FIRE broke out last week at the buildings of the Faculty of Medicine of Paris just at the hour when students adjourn to the library. It was due to overheated calorifères, and spread to the grand amphitheatre. Fortunately plenty of assistance was at hand, and a disaster was averted before much damage had been done.

UNIVERSITY INTELLIGENCE.

UNIVERSITY OF LONDON.—Intermediate Examination in Medicine. January, 1888. Pass list. Entire Examination.

First Division.—H. S. Ballance, King's College; A. E. Berry, Owens College; A. W. Boring, University College; C. R. Box, St. Thomas's Hospital; P. R. Dodwell, University College; J. McD. Gill, Guy's Hospital; F. W. Hall, Guy's Hospital; E. V. Hugo, St. Bartholomew's Hospital; R. E. Lord, B.Sc., Owens College; A. W. Lyons, King's College; H. J. M. Playfair, King's College; H. S. Sandifer, King's College; J. H. Sykes, Owens College.

Second Division.—A. M. Cass, Owens College and Manchester Royal Infirmary; B. E. Dawson, London Hospital and University College; H. Distin, King's College; P. W. Dove, St. Bartholomew's Hospital; E. R. C. Earle, University College; C. J. Girling, Guy's Hospital; G. S. Johnston, Queen's College, Birmingham; H. B. Kitchin, University College; T. F. Ricketts, B.Sc., Guy's Hospital; L. Roberts, St. Bartholomew's Hospital.

Excluding Physiology.

First Division.—W. A. Clark, St. Bartholomew's Hospital.

Second Division.—E. L. N. Pridmore, University College; J. A. Waring, University College.

Physiology only.

First Division.—A. W. W. Lea, Owens College; S. W. Morgan, Bristol Medical School; J. A. Pickels, Owens College.

Second Division.—E. G. Hall, Bristol Medical School; H. Langdale, Owens College; F. R. P. Taylor, Westminster Hospital.

UNIVERSITY OF CAMBRIDGE.—The following were on February 9th admitted to the degree of Bachelor of Medicine.

E. Cautley, King's; T. Redmayne, Trinity; E. T. Wynne, St. Catharine's; C. J. Whitby, Emmanuel; R. Major-Brown, Downing.

The following gentleman was at the same time admitted to the degree of Bachelor of Surgery.

E. Cautley, King's.

MR. FRANCIS DARWIN, M.A., M.B., has been nominated by the Council of the Senate a member of the Special Board for Medicine, in the room of the late Mr. Coultts Trotter.

UNIVERSITY OF DUBLIN.—At the Spring Commencements of Hilary Term, held according to custom on Shrove Tuesday, February 14th, 1888, the following degrees in Medicine, Surgery, and Midwifery were conferred by the University Caput, in the presence of the Senate assembled in the Examination Hall of Trinity College.

Bachelor of Obstetrics.—S. W. Allworthy, E. B. Ffennell, H. N. H. Joynt, A. G. Price, J. D. Wright.

Bachelor of Surgery.—S. W. Allworthy, E. B. Ffennell, J. E. Hadden, W. M. Jennings, H. N. H. Joynt, J. F. Knott, A. G. Price, J. D. Wright.

Bachelor of Medicine.—H. N. H. Joynt, A. G. Price, J. D. Wright.

Doctor of Medicine.—R. J. Baker (in *Coloniis*), H. T. Bewley (stip. cond.), C. Mallius (in *Coloniis*), J. P. Henry, E. Hogben (stip. cond.).

PUBLIC HEALTH

AND

POOR-LAW MEDICAL SERVICES.

HEALTH OF ENGLAND AND WALES DURING 1887.

FROM the last quarterly return of the Registrar-General we are enabled to summarise the vital and mortal statistics relating to England and Wales for the year 1887. The birth-rate was equal to 31.4 and the death-rate to 18.8 per 1,000 of the population, estimated at twenty-eight and a quarter millions of persons. The birth-rate was lower than in any year since 1838, and the death-rate was actually the lowest on record. It is worthy of note that in each year since 1880 the death-rate has been lower than in any year on record prior to that date. This marked and continued reduction in the national death-rate implies that more than 400,000 persons in England and Wales have survived whose deaths would have been recorded had the rate of mortality remained the same as that which prevailed during the ten preceding years, 1871-80. The natural increase of population during 1887, or the excess of births over deaths, was 355,440, which showed a further decline from the numbers in recent years. According to returns issued by the Board of Trade, it appears that 286,969 emigrants of British origin left the various ports of the United Kingdom during the year under notice; of these, 172,334 were English, 35,039 Scotch, and 79,596 Irish. The amount of emigration from each division of the United Kingdom showed a further increase upon that recorded in the two preceding years.

The 530,577 deaths from all causes in England and Wales during

last year included 64,676 from the principal zymotic diseases, of which 19,302 were referred to diarrhoea, 16,297 to measles, 10,661 to whooping-cough, 7,719 to scarlet fever, 5,653 to "fever" (including typhus, enteric, and simple or ill-defined fever), 4,339 to diphtheria, and 565 to small-pox. These 64,676 deaths were equal to an annual rate of 2.29 per 1,000, against 2.19 and 2.36 in the two preceding years, 1885-86. Compared with the numbers recorded in 1886, the fatality of measles, scarlet fever, diphtheria, and small-pox showed an increase, while that of diarrhoea, whooping-cough, and fever had declined. The death-rate from measles exceeded that recorded in any year since 1840. The rate of mortality from scarlet fever, although slightly exceeding the very low rates in 1885 and 1886, was lower than that recorded in any previous year. The death-rate from diphtheria was lower than in any of the three previous years. The rate of mortality from small-pox showed an increase upon the unprecedentedly low rate in 1886, although it was considerably below the average of the six preceding years, 1881-86. The death-rate from whooping-cough was lower than in any year on record, and that from "fever" was also the lowest on record.

The 530,577 deaths at all ages registered in England and Wales during 1887 included 128,436 of infants under 1 year of age, equal to a proportion of 145 per 1,000 of the registered births, against 138 and 149 in the two preceding years. In the seven years of the current decade, 1881-87, the rate of infant mortality has averaged 141 per 1,000, against 149 in the preceding ten years 1871-80. Among elderly persons the rate of mortality during 1887 differed but slightly from that recorded in recent years.

HEALTH OF ENGLISH TOWNS.—In the twenty-eight large English towns, including London, which have an estimated population of 9,398,273 persons, 6,182 births and 3,993 deaths were registered during the week ending Saturday, February 11th. The annual rate of mortality per 1,000 persons living in these towns, which had steadily declined in the first five weeks of this year from 23.8 to 21.9, rose again during the week under notice to 22.2. The rates in the several towns ranged from 15.2 in Brighton, 16.8 in Derby, 17.4 in Sunderland, and 17.6 in Halifax, to 28.1 in Wolverhampton, 28.2 in Manchester, 28.9 in Plymouth, and 36.4 in Preston. In the twenty-seven provincial towns the mean death-rate was 22.0 per 1,000, and was slightly below the rate recorded in London, which was 22.0 per 1,000. The 3,993 deaths registered during the week under notice in the twenty-eight towns included 212 which were referred to whooping-cough, 75 to scarlet fever, 56 to diphtheria, 40 to measles, 38 to "fever" (principally enteric), 36 to diarrhoea, and 36 to small-pox; in all, 492 deaths resulted from these principal zymotic diseases, against 478 and 506 in the two preceding weeks. These 492 deaths were equal to an annual rate of 2.7 per 1,000; in London the zymotic death-rate was 3.3, while in the twenty-seven provincial towns it averaged only 2.3 per 1,000, and ranged from 0.0 in Brighton, Birkenhead, and Halifax, to 4.9 in Oldham, 5.3 in Blackburn, and 6.5 in Sheffield. Measles caused the highest proportional fatality in Derby, Blackburn, and Plymouth; scarlet fever in Hull, Blackburn, and Oldham; whooping-cough in Sunderland, Bolton, London, Wolverhampton, and Portsmouth; and "fever" in Nottingham and Blackburn. Of the 56 deaths from diphtheria recorded during the week under notice in the twenty-eight towns 49 occurred in London, 4 in Manchester, 2 in Liverpool, 2 in Oldham, and 2 in Huddersfield. The 36 fatal cases of small-pox included 31 in Sheffield, 2 in Oldham, 1 in Bristol, 1 in Nottingham, and 1 in Leeds. The number of small-pox patients in the Metropolitan Asylums Hospitals was 8 on Saturday, February 11th, of which 3 had been admitted during the week. These hospitals also contained 1,453 scarlet fever patients on the same date, against numbers steadily declining from 2,602 to 1,558 in the ten preceding weeks; there were, however, 145 admissions during the week, against 133 and 96 in the two preceding weeks. The death-rate from diseases of the respiratory organs in London was equal to 6.1 per 1,000, and was considerably below the average.

HEALTH OF SCOTCH TOWNS.—In the eight principal Scotch towns, 798 births and 566 deaths were registered during the week ending Saturday, February 4th. The annual rate of mortality in these towns, which had been 23.3 and 22.4 in the two preceding weeks, was again 22.4 during the week under notice, and slightly exceeded the mean rate during the same period in the twenty-eight large English towns. Among these Scotch towns,

the lowest rates were recorded in Leith and Greenock, and the highest in Perth and Glasgow. The 566 deaths in these towns during the week under notice included 69 which were referred to the principal zymotic diseases, equal to an annual rate of 2.7 per 1,000, which almost corresponded with the mean zymotic death-rate during the week under notice in the large English towns. The highest zymotic rates were recorded in Greenock, Leith, and Perth. The highest proportional fatality of whooping-cough occurred in Leith and Glasgow; from scarlet fever in Dundee, Glasgow, and Perth; from measles in Leith and Edinburgh; and from diphtheria in Greenock and Perth. The mortality from diseases of the respiratory organs during the week under notice in these towns was equal to 5.9 per 1,000, against 6.3 in London.—During the week ending Saturday, February 11th, 822 births and 568 deaths were registered in the eight principal Scotch towns. The annual rate of mortality, which had been 22.4 per 1,000 in each of the two preceding weeks, was 22.5 during the week under notice, and slightly exceeded the mean rate during the week in the twenty-eight large English towns. Among these Scotch towns the lowest rates were recorded in Perth and Leith, and the highest in Glasgow and Aberdeen. The 568 deaths in these towns during the week included 72 which were referred to the principal zymotic diseases, equal to an annual rate of 2.5 per 1,000, which was slightly below the mean zymotic death-rate during the same period in the large English towns. The highest zymotic death-rates were recorded in Glasgow, Leith, and Edinburgh. The highest proportional fatality of measles occurred in Leith and Edinburgh; from scarlet fever in Glasgow; from diphtheria in Edinburgh; and from whooping-cough in Leith, Paisley, and Aberdeen. The mortality from diseases of the respiratory organs in these Scotch towns during the week under notice was equal to 5.4 per 1,000, against 6.1 in London.

HEALTH OF IRISH TOWNS.—During the week ending Saturday, February 4th, 493 deaths were registered in the sixteen principal town districts of Ireland, equal to an annual rate of 29.5 per 1,000. The lowest rates were recorded in Londonderry and Wexford, and the highest in Belfast and Newry. The death-rate from the principal zymotic diseases in these towns averaged 4.8 per 1,000, and was highest in Cork, Newry, and Kilkenny. Measles showed fatal prevalence in Newry and Kilkenny, and whooping-cough in Belfast. The 202 deaths registered in Dublin during the week under notice were equal to an annual rate of 29.0 per 1,000, which showed a decline from the high rates in recent weeks. The 202 deaths included 25 from the principal zymotic diseases (equal to a rate of 3.7 per 1,000), of which 10 were referred to whooping-cough, 6 to scarlet fever, 4 to "fever," 3 to diarrhoea, and 2 to measles.—In the sixteen principal town-districts of Ireland the deaths registered during the week ending Saturday, February 11th, were equal to an annual rate of 29.6 per 1,000. The lowest rates were recorded in Drogheda and Kilkenny, and the highest in Newry and Lurgan. The death-rate from the principal zymotic diseases in these towns averaged 4.5 per 1,000, and was highest in Cork, Lurgan, and Newry. Measles showed fatal prevalence in Cork and Newry. The 202 deaths registered in Dublin during the week were equal to an annual rate of 29.9 per 1,000, corresponding with the rate in the preceding week, the rate during the same period being only 22.0 in London and 22.2 in Edinburgh. The 202 deaths included 21 from the principal zymotic diseases, equal to an annual rate of 3.1 per 1,000, of which 9 resulted from whooping-cough, 6 from scarlet fever, 3 from diarrhoea, 2 from fever, and 1 from measles.

MEDICAL PRACTITIONERS AND OFFICERS OF HEALTH. In his annual address as President of the Birmingham and Midland Counties Association of Medical Officers of Health, Dr. Bosstick Hill complained of the manner in which some practitioners failed to co-operate with medical officers of health in preventive measures. He said "A medical man in practice was openly stating, much to the alarm of the inhabitants of the district, that he had at one time under his care fourteen cases of diphtheria. I was informed of this, and wrote to him asking if what I had heard was true, and, if so, whether he did not think it desirable to give me some information that I might endeavour to trace the cause of the disease. His reply was unique. He said that as there was no chance of an improvement in the condition of sewers, he did not see the use of giving any information as to the whereabouts of

the cases. I pointed out to him the necessity of the sanitary authority endeavouring to prevent the spread of the disease by disinfection and other measures, and the impossibility of doing this in the absence of information as to where the cause existed. His replies are again worthy of being recorded. He did not see why he should do my work, as it was my duty to inspect the district in such a way that I should discover all cases of infectious disease for myself. I should add that the gentleman was careful to sign himself 'EX.M.O.H.'"

VACCINATION AND SMALL-POX AT SHEFFIELD.

WITH reference to the inquiry of our correspondent respecting the statistics quoted by Mr. Ritchie, in his recent speech at Sheffield, showing the beneficial effects of vaccination amongst the children under 10 years of age, living in Sheffield during the current epidemic of small-pox, we are not aware that the correctness of Mr. Ritchie's figures has been impugned. In the local publication of some earlier statistics respecting the epidemic, some accidental error occurred in the printing, but this was immediately corrected. We have every reason to believe that the figures quoted by the President of the Local Government Board are quite correct. We would remind our correspondent that Mr. Ritchie did not say that his information as to the number of vaccinated and unvaccinated in Sheffield was obtained by a house-to-house visitation.

The calculation was probably made from the published returns of the Registrar General and of the vaccination officers, and can therefore be readily verified. So also can the facts as to the vaccination of the children under 10 years of age, who were attacked with small-pox and died. It may interest our correspondent and others to know that in a recent report Mr. Willey, the medical officer of the Sheffield Borough Hospital, states that during the month of January 160 cases of small-pox were admitted to the hospital (37 of them being unvaccinated), which, added to the 136 already in the hospital from the previous month, made a total of 296 under treatment within the month. Amongst these there were 32 deaths, 21 being amongst the unvaccinated, and 11 amongst adults who had not been vaccinated since infancy. The average age of these latter cases was 30 years. Experiences of a similar sort are reported by the health officers of the Chesterfield Rural and Stapleton Urban District, where small-pox has lately been somewhat severely prevalent. In fact, such experiences are repeated during every epidemic.

MEDICAL NEWS.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—The undermentioned Licentiate in Medicine of the College, having complied with the by-laws relating to Membership pursuant to the provisions of the Supplemental Charter of Queen Victoria, dated December 12th, 1878, has been duly admitted a Member of the College.

M. A. Boyd, Lic. Med. 1869, Physician to the Mater Misericordiarum Hospital, Dublin.

At the examination for the Diploma in State Medicine, held on Tuesday, Wednesday, and Thursday, February 7th, 8th, and 9th, 1888, the following candidate was successful.

W. Hartigan, M.K.Q.C.P., 1880, Hermitage, Hong Kong.

At the usual monthly examinations for the Licences of the College, held on Monday, Tuesday, Wednesday, and Thursday, February 6th, 7th, 8th, and 9th, 1888, the undermentioned registered medical practitioners were successful.

For the Licence to Practise Medicine and Midwifery.—J. J. H. Jackman, L.R.C.S.I., 1883, Dunmore East, Co. Waterford.

For the Licence to Practise Midwifery only.—R. Bryans, M.B., R.U.I., 1887, Mountaghlan.

MEDICAL VACANCIES.

The following Vacancies are announced:

ATHLONE UNION.—Medical Officer, Moate Dispensary. Salary, £140 per annum and fees. Applications to Mr. Luke Egan, Honorary Secretary. Election on February 21st.

BIRMINGHAM CHILDREN'S HOSPITAL.—Assistant Resident Medical Officer. Salary, £10 per annum, with board, etc. Applications by February 21st to the Secretary.

BIRMINGHAM GENERAL HOSPITAL.—Assistant House-Surgeon. Applications by February 25th to the House Governor.

BRISTOL ROYAL INFIRMARY.—Dental Surgeon. Applications by February 18th to the Secretary.

CANCER HOSPITAL, Brompton.—Pathologist. Honorarium of £80 for twelve months. Applications by February 21st to the Secretary.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's Inn Road, W.C.—Assistant Surgeon. Applications by March 6th to the Secretary.

CIRENCESTER UNION.—Medical Officer. Salary, £115 per annum, and extras. Applications by February 20th to W. L. Cooke, Esq., Solicitor, Cirencester.

EARLSWOOD ASYLUM FOR IDIOTS, Redhill.—Medical Superintendent. Salary, £500 per annum, with apartments, etc. Application by February 21st to the Board of Management, 36, King William Street, E.C.

EAST SUFFOLK HOSPITAL, Ipswich.—Assistant House-Surgeon. Applications by February 21st to the Secretary.

FRENCH HOSPITAL, Leicester Square.—Resident Medical Officer. Salary, £90 per annum, with board, etc. Applications to the Secretary.

LINCOLNSHIRE COUNTY ASYLUM, Bracebridge, near Lincoln.—Assistant Medical Officer. Salary, £150 per annum, with board, lodging, and washing. Applications by February 25th to J. W. Marsh, Esq., Superintendent.

LIVERPOOL NORTHERN HOSPITAL.—Assistant House-Surgeon. Salary, £70 per annum, with board and residence. Applications by February 22nd to the Chairman of the Committee.

MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT, Bowdon, Cheshire.—Resident Medical Officer. Salary, £80 per annum, with board, etc. Applications by February 23rd, to the Secretary, Manchester.

METROPOLITAN HOSPITAL, Kingsland Road, E.—Ophthalmic Surgeon. Applications by February 20th to the Secretary.

NATIONAL ORTHOPEDIC HOSPITAL.—Surgical Registrar and Anaesthetist. Honorarium, £20. Applications by February 21st to the Secretary, Great Portland Street, W.

OUGHTRARD UNION.—Medical Officer, Oughterard Dispensary. Salary, £112 per annum and fees. Applications to Mr. Robert Mons, Honorary Secretary, Drummakill Lodge. Election on March 7th.

OUGHTRARD UNION.—Medical Officer to the Workhouse, Infirmary, and Fever Hospital. Salary, £70 per annum. Applications to Mr. J. Gilmore, Clerk of Union. Election on March 7th.

ROXBURGH DISTRICT ASYLUM, Melrose.—Assistant Medical Officer. Salary, £80 per annum, with board and residence. Applications to Dr. Johnstone.

ST. GEORGE'S AND ST. JAMES'S DISPENSARY.—Physician. Applications to S. L. Bunnett, 60, King Street, Regent Street, W.

STAFFORDSHIRE GENERAL INFIRMARY.—Assistant House-Surgeon. Applications by February 18th to the House-Surgeon.

TARBAT (ROSS-SHIRE).—Medical Officer. Salary, £115 per annum. Applications by February 29th to Finlay Munro, Esq., Rockfield-by-Fearn, N.B.

THURLES UNION, Templemore Dispensary.—Medical Officer. Salary, £140 per annum, and fees. Applications to Mr. John O'Meara, Honorary Secretary, Colleshill. Election on February 22nd.

UNIVERSITY OF GLASGOW.—Four Examiners in Medicine. Annual fee, £40 and £30 respectively. Applications by March 5th to the Secretary of the University Court, G. D. McLellan, Esq., 145, West George Street, Glasgow.

WEST BROMWICH DISTRICT HOSPITAL.—House-Surgeon. Salary, £80 per annum, with board. Applications by February 25th to William Bache, Esq., Churchill House, West Bromwich.

YORK COUNTY HOSPITAL.—Senior House-Surgeon. Salary, £100 per annum, with board, etc. Applications by March 1st to the Secretary.

YORK DISPENSARY.—Three Resident Medical Officers. Salary, £130 per annum, with furnished apartments, etc. Applications by February 29th to S. W. North, Esq., 84, Micklegate, York.

MEDICAL APPOINTMENTS.

ABBOTT, C. E., L.K.Q.C.P.I., M.R.C.S.Eng., appointed Medical Officer of Health for the Braintree Urban Sanitary District, Essex.

BARKLEY, C. H., L.R.C.P., L.R.C.S., L.M.Édin., appointed Anaesthetist to the National Dental Hospital, *vice* H. F. Winslow, M.D., resigned.

BARRETT, C. W. Sessions, M.B., C.M., appointed Honorary Surgeon to the Hants County Hospital, Huntingdon.

BOWIE, Alexander, M.D., M.Ch.St. And., appointed Assistant Physician to St. John's Hospital for Diseases of the Skin.

DOCKRELL, Morgan, M.D., M.A., B.Ch.Dub., appointed Assistant Physician to St. John's Hospital for Diseases of the Skin.

FLOOD, E. F., L.A.H.Dub., appointed Medical Officer for the South Division of the Dundalk District of the Dundalk Union.

FROST, Francis T., M.R.C.S.E., appointed Junior House-Surgeon to the Huddersfield Infirmary, *vice* W. J. W. Marshall, M.R.C.S.E., resigned.

GIBBS, A. N. Godby, L.R.C.P.Lond., M.R.C.S.Eng., L.S.A., appointed Honorary Assistant Surgeon to the Bristol Eye Hospital.

GILLARD, R., M.R.C.S.Eng., L.S.A., appointed Medical Officer and Public Vaccinator for the Ugborough and Brent Districts of the Totnes Union.

HAYES, Clements D. G., C.M., M.D., etc. Edin., appointed Honorary Assistant Surgeon to the Bristol Eye Hospital.

HITCHINS, T. J., L.R.C.P., M.R.C.S., appointed Assistant Physician to St. John's Hospital for Diseases of the Skin.

JONES, E. Lloyd, M.B., C.M., B.A., appointed Junior House-Surgeon to the Western General Dispensary, Marylebone Road.

PRIESTLEY, R. C., M.A., M.B.Camb., M.R.C.S., appointed Registrar and Pathologist to the Hospital for Sick Children, Great Ormond Street.

SELLERS, J. C., L.K.Q.C.P.I., appointed Medical Officer for the North Division of the Dundalk District of the Dundalk Union.

SYMINGTON, Johnson, M.D., F.R.S.E., appointed Examiner in Anatomy to the University of Edinburgh, *vice* Professor D. J. Cunningham, M.D., F.R.S.E., whose term of office has expired.

TREVELYAN, E. F., M.D.Lond., B.Sc., M.R.C.S., appointed House-Physician to the Seamen's Hospital, Greenwich, *vice* E. H. Booth, M.D.Lond., M.R.C.S., L.R.C.P., resigned.

ROYAL COMMISSION ON THE BLIND, DEAF AND DUMB, AND IMBECILES.—On Tuesday, February 7th, Dr. Francis Warner gave evidence as to weak-minded children in public elementary schools, and on Wednesday, February 8th, Dr. George Shuttleworth, medical superintendent, and Mr. J. Wiggins, secretary, Royal Albert Asylum, Lancaster, were examined as to the provisions in England, educational and otherwise, for the imbecile class.

SANITARY ASSURANCE ASSOCIATION.—The seventh annual meeting of the members of this Association was held on February 13th. Professor Roger Smith, F.R.I.B.A., presided. Mr. Joseph Hadley read the annual report, which stated that with newly built property there had been a continued improvement, necessitating fewer alterations to secure the sanitary certificates. Annual inspections for the renewal of sanitary certificates continued to be made. Mr. Mark H. Judge, A.R.I.B.A., proposed, "That the Right Hon. Lord Chelmsford, G.C.B., be requested to take charge of the Sanitary Registration Bill in Parliament this session, and to introduce the Bill into the House of Lords at as early a date as possible." Sir Peter Lumsden, G.C.B., seconded this resolution, which was supported by Mr. H. Rutherford, barrister-at-law, Dr. Willoughby, and others, and was carried unanimously. The retiring members of the Council were re-elected: Sir Joseph Fayer was re-elected President of the Association, and Professor T. Roger Smith were re-elected Vice-President.

INTER-HOSPITAL (RUGBY) FOOTBALL CHALLENGE CUP.—*Second Round.*—On February 13th St. Thomas's beat University. The strong forward team of St. Thomas's quite overpowered University, whose three-quarters were unable to show their powers. R. L. Thomas, of the losing team, unfortunately broke his collar-bone before half-time—4 goals, 6 tries, and 1 minor (161 points), to *nil*. On February 14th, St. Bartholomew's v. St. George's resulted in a win for the former by 1 try 1 minor (11 points), to 1 minor (1 point). This game was played with a layer of snow over the ground; the game was almost entirely confined to the forwards, and sternly contested. On February 16th London v. St. Mary's; Middlesex, a bye.

THE FRENCH HOSPITAL.—At the annual banquet of the French Hospital at London, which took place on Saturday evening last at Willis's Rooms, His Excellency the French Ambassador in the chair, supported by the Lord Mayor, the report for 1887 was read by the Honorary Secretary, M. Rüffer, showing that the total receipts for that year amounted to £3,551 15s. 6d., being less than the preceding year by £126 10s. 7d. The expenditure amounted to £2,266 18s. 6d. for maintenance and £274 18s. 1d. for management. Upwards of 11,000 out- and 422 in-patients were relieved during that time. These figures reflect every credit on the management of the hospital for economy in administration.

THE METROPOLITAN ASYLUMS BOARD.—The last fortnightly returns from the fever and small-pox hospitals of the Metropolitan Asylums Board showed 260 patients admitted, as against 297 in the previous fortnight. In the same time 39 had died, as against 42 in the previous period; and 370 had been discharged, as against 505 in the previous fortnight. There were, on the morning of February 10th, under treatment 1,685 patients in the various hospitals.

The Cambridge Sanitary Authority have decided to adopt the "broad irrigation" system for the disposal of sewage, provided that land can be purchased at a reasonable price. They also decided that no scheme for the conveyance of the sewage to the pumping-station be adopted unless it be connected with a scheme for the reconstruction of all existing sewers and drains which are found to be sewers of deposit or otherwise defective.

THE PARKES MUSEUM.—The Merchant Taylors Company have recently voted ten guineas to this museum, to aid in its work of practical teaching and demonstrating sanitary science.

MR. WILLIAM E. CASS, M.R.C.S.Eng., late medical officer to the Goole Union, has obtained a superannuation allowance of £160 per annum.

PUBLIC VACCINATION.—Mr. Crocker, Bingley, has received for the fourth time the Government grant for efficient vaccination.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 P.M.—Professor William Watson Cheyne, F.R.C.S.: Lecture on Suppuration and Septic Diseases.

MEDICAL SOCIETY OF LONDON, 8.30 P.M.—Mr. Hutchinson: The Abortive Treatment of Syphilis.

TUESDAY.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, 5 P.M.—Inspector-General Lawson: The Milroy Lectures.—Lecture I. Epidemic Influences.

PATHOLOGICAL SOCIETY OF LONDON, 8.30 P.M.—Specimens.—Mr. Sutton and Mr. Shattock: Report on a case of Parasitic Forus. Mr. D'Arcy Power: Congenital Fatty Tumour connected with Bone. Mr. T. F. Chavasse: Parotid Tumour. Dr. Crooke: Pulmonary Endarteritis. Mr. Stoham: Complex or Vertical Hermaphroditism. Mr. Doran: Papilloma of Fallopian Tubes. Sir Wm. MacCormac: Epithelioma of Kidney, associated with Calculus. Mr. Pitts: Villous Carcinoma of Breast. Dr. Wooldridge: New Constituent of the Blood. Card Specimens.—Mr. Stoham: Tumours of Bone. Mr. Chavasse: Peculiar Vesical Calculus. Mr. Bruce Clarke: Stone in Intra-Portion Pouch. Mr. Walsham: Volvulus of Cecum and Lower Portion of Ileum. Mr. Shattock: Dermoid Cyst from the Third Branchial Cloft. Dr. Leddard: Enchondroma of Flogers.

WEDNESDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 P.M.—Professor William Watson Cheyne, F.R.C.S.: Lecture on Suppuration and Septic Diseases.

BRITISH GYNÆCOLOGICAL SOCIETY, 8.30 P.M.—The adjourned discussion on Ectopic Gestation will be opened by Dr. Barnes. A large collection of specimens illustrating Ruptured Tubal and other forms of Ectopic Gestation will be exhibited by Mr. Lawson Tait. Council, 8 P.M.

HUNTERIAN SOCIETY, 8 P.M.—Mr. R. Clement Lucas: President's Address. Dr. F. J. Smith: The Influence of the Discovery of Micro-organisms on Treatment.

THURSDAY.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, 5 P.M.—Inspector-General Lawson: The Milroy Lectures.—Lecture II. Epidemic Influences.

BURIAL REFORM ASSOCIATION, 3.15 P.M. (Portman Rooms, Baker Street).—Conference on Burial, Funeral, and Mourning Reform; Sir E. Sieveking, Dr. B. W. Richardson, F.R.S., Hon. Dudley Fortescue, Dr. Danford Thomas, and others.

FRIDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 4 P.M.—Professor William Watson Cheyne, F.R.C.S.: Lecture on Suppuration and Septic Diseases.

MEDICO-PSYCHOLOGICAL ASSOCIATION, 4 P.M.—A quarterly meeting of this Association will be held at Bethlem Hospital, St. George's Road, London. A meeting of the Council will be held at 3 P.M.; Dr. Hughlings Jackson will read a paper on Post-Epileptic States. A special meeting will be held at 5.30 P.M. "to consider the recent appointment at the Hayward's Heath Asylum." The members will dine together in the evening at 7 P.M., at the Holborn Restaurant. Members intending to dine are requested to communicate with Dr. Paul, The Terrace, Camberwell.

QUEKETT MICROSCOPICAL CLUB (University College, Gower Street), 8 P.M.—Annual General Meeting. President's Address.

CLINICAL SOCIETY OF LONDON, 8 P.M.—Mr. Holmes: (1) Case of Laceration of Axillary Artery in attempted Reduction of Dislocation of Shoulder; Death from Exhaustion, with symptoms of Septicæmia. (2) Sequel to a case reported in vols. ix and x, under title of Ligature of Left Carotid. Mr. J. R. Lunn: Case in which the Superficial Femoral Artery was Ligatured for a Popliteal Aneurysm without Rupture of the Walls of the Vessel. Mr. B. Pitts: Case of Amputation of the Hip-Joint for Osteo-sarcoma of Femur; Secondary Hemorrhage; Ligature of Common Femoral; Recovery. Living Specimens:—1. Case of Cured Subclavian Aneurysm; Dr. Barlow and Mr. Ruffer. 2. Case of Traumatic Meningocele; Mr. Silcock. 3. A patient upon whom Loret's Operation on the Stomach was performed two months ago.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 5s. 6d., which should be forwarded in stamps with the announcement.

BIRTHS.

BRUNTON.—On February 12th, at 10, Stratford Place, W., the wife of T. Lauder Brunton, M.D., F.R.S., of a daughter.

CHILD.—On January 22nd, at 2, College Park Villas, Harrow Road, W., the wife of Warwick L. Child, M.D., M.R.C.S.Eng., of a daughter.

DAVIS.—On February 14th, at 14, St. James's Square, Bath, the wife of Robert Davis, M.R.C.S.Eng., of a daughter.

LLOYD-ROBERTS.—On February 13th, the wife of J. Lloyd-Roberts, M.B., of Denbigh, North Wales, of a daughter.

PARSLOE.—On February 10th, at The Larches, Black Torrington, Devon, the wife of H. Heath Parsloe, M.R.C.S., L.R.C.P., of a son.

MARRIAGES.

ROBERTS-PRICE.—On February 7th, at the Parish Church, Holywell, by the Rev. R. O. Williams, M.A., Vicar, assisted by the Rev. Llewelyn Jones, M.A., curate, Richard Pritchard Roberts, M.R.C.S.Eng., L.S.A.Lond., of Bethesda, to Maggie, eldest daughter of the late John Price, of Holywell.

TURNER-SILCOCK.—On February 7th, at Chittisbam, George Turner, of Holledon, to Eleanor Charlotte (Lillie), second daughter of Edward Clowes Silcock, Wood House, Ely.

DEATHS.

HARRISON.—On February 9th, at The Grange, York Road, Birkdale, Southport, Josephine C., the dearly loved wife of G. Cooper Harrison, L.R.C.P., L.R.C.S.E., and daughter of the late J. J. Godfrey, M.R.C.S., of Liverpool.

SMITH.—On February 9th, at Southport, from the effects of an accident, Edward Mortimore Smith, L.R.C.P., L.R.C.S., aged 29 years. R.I.P.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY.....10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's (Ophthalmic Department); and Royal Westminster Ophthalmic.—2 P.M.: Metropolitan Free; St. Mark's; Central London Ophthalmic; Royal Orthopaedic; and Hospital for Women.—2.30 P.M.: Chelsea Hospital for Women.

TUESDAY.....9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's; St. Bartholomew's (Ophthalmic Department); St. Mary's; Royal Westminster Ophthalmic.—2 P.M.: Westminster; St. Mark's; Central London Ophthalmic.—2.30 P.M.: West London; Cancer Hospital, Brompton.—4 P.M.: St. Thomas's (Ophthalmic Department);

WEDNESDAY.....10 A.M.: National Orthopaedic.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: Middlesex.—1.30 P.M.: St. Bartholomew's, St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: London; University College; Westminster; Great Northern Central; Central London Ophthalmic.—2.30 P.M.: Samaritan Free Hospital for Women and Children; St. Peter's.—3 to 4 P.M.: King's College.

THURSDAY.....10.30 A.M.: Royal London Ophthalmic.—1 P.M.: St. George's.—1.30 P.M.: St. Bartholomew's (Ophthalmic Department); Guy's (Ophthalmic Department); Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Central London Ophthalmic; Hospital for Diseases of the Throat; Hospital for Women.—2.30 P.M.: North-West London; Chelsea Hospital for Women.

FRIDAY.....9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.15 P.M.: St. George's (Ophthalmic Department).—1.30 P.M.: Guy's; Royal Westminster Ophthalmic.—2 P.M.: King's College; St. Thomas's (Ophthalmic Department); Central London Ophthalmic; Royal South London Ophthalmic; East London Hospital for Children.—2.30 P.M.: West London.

SATURDAY.....9 A.M.: Royal Free.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: King's College.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Middlesex; Royal Free; Central London Ophthalmic.—2.30 P.M.: Cancer Hospital, Brompton.

HOURS OF ATTENDANCE AT THE LONDON HOSPITALS.

CHARING CROSS.—Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; Skin, M. Th., 1.30; Dental, M. W. F., 9.

GUY'S.—Medical and Surgical, daily, 1.30; Obstetric, M. Tu. F., 1.30; Eye, M. Tu. Th. F., 1.30; Ear, Tu. F., 12.30; Skin, Tu., 12.30; Dental, Tu. Th. F., 12.

KING'S COLLEGE.—Medical, daily, 2; Surgical, daily, 1.30; Obstetric, Tu. Th. S., 2; o.p., M. W. F., 12.30; Eye, M. Th., 1; Ophthalmic Department, W., 1; Ear, Th., 2; Skin, Th.; Throat, Th., 3; Dental, Tu. F., 10.

LONDON.—Medical, daily, exc. S., 2; Surgical, daily, 1.30 and 2; Obstetric, M. Th., 1.30; o.p. W. S., 1.30; Eye, W. S., 9; Ear, S., 9.30; Skin, Th., 9; Dental, Tu. 9.

MIDDLESEX.—Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; o.p. W. S., 1.30; Eye, W. S., 8.30; Ear and Throat, Tu., 9; Skin, Tu., 4; Dental, daily, 9.

ST. BARTHOLOMEW'S.—Medical and Surgical daily, 1.30; Obstetric, Tu. Th. S., 2; o.p. W. S., 9; Eye, Tu. Th. S., 2.30; Ear, Tu. F., 2; Skin, F., 1.30; Larynx, F., 2.30; Orthopaedic, M., 2.30; Dental, Tu. F., 9.

ST. GEORGE'S.—Medical and Surgical, M. T. F. S., 1; Obstetric, Tu. S., 1; o.p., Tu., 2; Eye, W. S., 2; Ear, Tu., 2; Skin, W., 2; Throat, Th., 2; Orthopaedic, W., 2; Dental, Tu., S., 9, Th., 1.

ST. MARY'S.—Medical and Surgical, daily, 1.45; Obstetric, Tu. F., 1.45; o.p., M. Th., 1.30; Eye, Tu. F. S., 9; Ear, M. Th., 3; Throat, Tu. F., 1.30; Skin, M. Th., 9.30; Electrician, Tu. F., 2; Dental, W. S., 9.30; Consultations, M., 2.30; Operations, Tu., 1.30; Ophthalmic Operations, F., 9.

ST. THOMAS'S.—Medical and Surgical, daily, except Sat., 2; Obstetric, M. Th., 2; o.p., W., 1.30; Eye, M. Th., 2; o.p., daily, except Sat., 1.30; Ear, M., 12.30; Skin, W., 12.30; Throat, Tu. F., 1.30; Children, S., 12.30; Dental, Tu. F., 10.

UNIVERSITY COLLEGE.—Medical and Surgical, daily, 1 to 2; Obstetrics, M. Tu. Th., F., 1.30; Eye, M. Tu. Th. F., 2; Ear, S., 1.30; Skin, W., 1.45, S. 9.15; Throat, Th., 2.30; Dental, W., 10.30.

WESTMINSTER.—Medical and Surgical, daily, 1.30; Obstetric, Tu. F., 3; Eye, M. Th., 2.30; Ear, M., 9; Skin, Th., 1; Dental, W. S., 9.15.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS respecting editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

IN order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the office of the JOURNAL, and not to his private house.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate beforehand with the Manager, 429, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication. CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

QUERIES.

A COUNTRY MEMBER asks where to purchase a cheap couch or chair-couch suitable for ordinary gynaecological necessities such as one has to attend to in one's own surgery.

EUCALYPTUS LOTION.

M.B. wishes to know what formula is generally used in the preparation of eucalyptus lotion for surgical dressings.

** Oil of eucalyptus is only used, so far as we are aware, in various forms as a dressing; it is not employed in the form of a lotion.

DOES CIDER TEND TO PRODUCE GOUT AND GRAVEL?

O. V. writes: Is cider drinking beneficial or otherwise in cases of a gouty description? More particularly, does it tend to produce or to prevent the formation of stone in the bladder? or does it have no effect either way?

CLIMATE FOR HAY FEVER.

M.D., who has not been able to find the desired information in books, wishes to hear of the best localities inland, both in this country and abroad, for invalids who wish to avoid the cold east winds of spring, and the hot weather—and especially attacks of hay fever—in June and July.

NIGHT BLINDNESS.

CHARLES À COURT writes: The *Cologne Gazette*, in describing some night manoeuvres which recently took place in Russia, stated that much confusion arose owing to the large number of men in the ranks afflicted with "hühnerblindheit"—that is, literally, "hen-blindness"—and it further ascribed the frequency of this affection, which prevented men from seeing anything on a moderately dark night, to the inferior diet of the Russian peasant class. Can you oblige me with any explanation of this curious statement?

** Swanzy and other authorities believe that defective nutrition plays an important part in rendering patients liable to nyctalopia, or night-blindness. Nyctalopia is a constant symptom in syphilitic retinitis, even when hereditary, and in retinitis pigmentosa. It may accompany scurvy.

ANSWERS.

DUBITANS might consult Dr. De Watteville's *Practical Introduction to Medical Electricity*, second edition.

M.R.C.S. should communicate with the Clerk to the Society of Apothecaries, Apothecaries' Hall, Blackfriars, E.C.

NOTES, LETTERS, ETC.

SURGEON-MAJOR S. SMITH, W.C.E., M.V.I., F.A.S., M.S.A., etc., informs us that he was unanimously elected a Vice-President of the Association of Members of the Royal College of Surgeons at its last meeting.

AN APPEAL.

JAMES McDONALD, L.F.P.S.Glasg., 1875, late medical officer for Barvas, Stornoway, N.B., died suddenly of an attack of apoplexy in July, 1884, leaving a widow and four young children wholly unprovided for. Mrs. McDonald's health had broken down some time before her husband's death, owing to a slight hemiplegic attack, after which she never quite regained the use of her right hand. But, through the help of her sister, she has been able to do a little towards her own and her family's support by keeping lodgers in a rented house in Stornoway. However, there is reason to believe that of late she has been in very straitened circumstances; and, as if to crown her misfortunes, her only son, the eldest of the family, a fine promising boy of 10 years, was cut down about two months ago by an attack of measles.

Mr. McDonald was highly respected as a conscientious and painstaking practitioner, who never spared himself in the interests of his numerous but poor patients; and it is to be hoped that the members of the medical profession, and others as well, will respond liberally to this appeal on behalf of his helpless widow and three orphan girls. Subscriptions will be gratefully received and acknowledged either by C. M. McEae, M.D., Stornoway, N. B. or by R. Ross, L.R.C.P. and S. Ed., Barvas, Stornoway, N. B.

THE TITLE OF DR.

L.R.C.P. Ed. writes: In answer to "Anxious One," in the JOURNAL of February 11th, you say: "The Edinburgh College of Physicians have discouraged all the Fellows, Members, and Licentiate from using the title of Dr." I should like to say that this answer, though correct as far as relates to the last ten years or so, is not correct as regards licentiate admitted prior to 1870.

EARLY MENSTRUATION.

DR. W. F. SHEARD, Medical Officer to the Putney District, writes: The following case of youthful precocity is now under my care. M. S. was born in August, 1878. The catamenia appeared last August (1887), and she has continued regular every month since. She is a dark, swarthy child, of small size for her age, but with a large head, and she has had fairly good health, with the exception of a severe attack of acute rheumatism. Her father is a cabman, who suffers much from rheumatoid arthritis, and her mother is a strong healthy woman.

SACCHARIN.

DR. C. J. R. MACLEAN (Yeaton) writes: I see a correspondent last week writes, stating saccharin to have produced some nausea and persistently remaining sweet taste, and suggesting that the cause might be that some of the saccharin is excreted with the saliva. I have at present a patient who has taken saccharin tablets instead of sugar for his breakfast and tea, and also to sweeten aerated waters, for a space of three months with scarcely an intermission, and without experiencing any nausea or after-effect whatever. I would here state, however, that some of the cheaper specimens of saccharin which I have tried

REPORTS
OF THE
COLLECTIVE INVESTIGATION
COMMITTEE
OF THE
BRITISH MEDICAL ASSOCIATION.
REPORT ON INQUIRY No. III.

ACUTE RHEUMATISM.

PREPARED BY THOMAS WHIPHAM, M.B., F.R.C.P.,
Physician to St. George's Hospital.

THE invitation to the medical practitioners of the United Kingdom to furnish reports of cases of rheumatism which had come under their observation was issued by the Collective Investigation Committee of the British Medical Association on April 22nd, 1882, and the last report came to hand on June 5th, 1886. The result has been that observations on 655 cases have been sent to the Committee for comparison and analysis. It will be at once agreed that such a number of cases, recorded more or less in detail, is extremely creditable, when the arduous labours and the scanty leisure at the disposal of busy country practitioners (most of whom supply these records) are taken into consideration. It shows, moreover, how great is the interest which such men take in the advancement of the science of their profession.

The recorded cases have been considered for the most part in the order following:—1. Sex; 2. Age; 3. Occupation; 4. Habits; 5. Food; 6. Locality and Atmosphere; 7. Previous Illnesses; 8. Recent Antecedents; 9. Severity and Sweating; 10. Influence of Treatment on Duration of—*a.* Fever, *b.* Pain, *c.* the whole Attack; 11. Extent of the Joint-Affection; 12. Complications; 13. Relapsing Cases; 14. Deaths; 15. Skin Eruptions; 16. Subcutaneous Nodules; 17. Common Ailments; 18. Sequelæ.

SEX.

Of the 655 cases, 375, or 57.25 per cent., were males; 279, or 42.59 per cent., were females. In one case (133) the sex is not mentioned.

The difference in the numbers is not great, and it may be accounted for by the greater exposure to weather, etc., which the occupations of men entail upon them; added to which is the fact that men are, as a rule, more addicted to the consumption of beer and other forms of alcohol, which, though not perhaps an actual cause of rheumatism, certainly increases the liability to it in those who have once suffered from the disease.

AGE.

Of the whole number (655) of cases recorded, the ages of 6 males and 1 female are not mentioned, leaving a total of 647, or 369 males and 278 females, in which to calculate the average age in which the rheumatic attack occurred, including No. 133, in which the sex is omitted. The figures come out as follows:—In 369 males the average age of rheumatic attack, 26.55. In 278 females the average age of rheumatic attack, 23.82. Average age of the 647 cases, 25.38. Thus it is evident that the age difference between the two sexes, so far as the age of incidence is concerned, amounts practically to nothing.

Arranged in decades, the cases give the following result.

	Males.	Females.	Total.
Under 10	18	14	32
" 20	90	106	196
" 30	135	91	226
" 40	76	32	108
" 50	37	23	60
" 60	11	10	21
" 70	2	2	4
" 80	1	—	1
Age not mentioned	6	1	7

655

It will be seen from the above that by far the greater number of cases occurred between the ages of 20 and 40—namely, 80.94 per cent.; that is, males 45.98 per cent., females 34.96 per cent.

[1417]

The greatest proportion in any one decade was between 20 and 30—namely, males 38.74 per cent., females 30.07 per cent. This is probably in accordance with general experience.

CASES OCCURRING AT EXCEPTIONAL AGES. 1.—IN PERSONS OF ADVANCED AGE.

Under this head five cases require especial notice, namely:

No. 14 (R. W. Barrow, Liverpool). Female, aged 66, married; third attack, the first occurred at the age of 33. Temperate habits and sufficiently fed. Locality, high, dry, and exposed; atmosphere wet and cold, with S.E. wind. Had previously suffered from sunstroke, glaucoma, and cardiac dropsy. The determining cause was attributed to over fatigue. Attack moderate in severity, with slight sweating. Duration of the fever and pain were 5 days and 8 days respectively; and the whole attack lasted 9 days. Many joints were affected; the pains migratory. Mitral systolic murmur of old standing; the apex being half an inch external to the nipple. The patient suffered frequently from urticaria and sick headaches. Recovery was complete.

No. 146 (J. W. Martin, M.D., Sheffield). Male, aged 63, a weighman, of temperate habits and sufficiently fed. Locality, low, dry and confined; atmosphere, wet and cold; wind N.E. He had had no previous illness, and the attack was attributed to exposure. It was a severe attack, with considerable sweating. Duration of fever and pain 20 days respectively, and the whole attack 26 days. Pains migratory, affecting many joints. No cardiac affection, and no previous rheumatic attacks. Recovery complete.

No. 153 (Thomas Fuller, M.D., New Shoreham). Male, aged 62, wheelwright, of temperate habits and sufficiently fed. Locality, high, dry and exposed; atmosphere, dry and mild, wind S.W. He had had no previous illness. The attack was a severe one, with considerable sweating. Duration of fever and pain 2 days respectively, and of the whole attack 21 days. Many joints affected; no record of any cardiac affection; third attack. Recovery complete. A relapse occurred 18 days after convalescence, and lasted 12 days, yielding to same treatment; namely, sodium salicylate.

No. 281 (E. A. Gibson, M.D., Edinburgh). Female, aged 68, widow, of temperate habits and sufficiently fed. Locality, high, dry and exposed; atmosphere, dry, cold, changeable; wind E. There had been no previous illness; the attack was ascribed to exposure to cold on the previous day. Attack severe, with considerable swelling. Duration of fever and pain 30 days and 5 days respectively, and of the whole attack 30 days. The muscles only were affected, and severely. She died of meningitis, there being no evidence of previous cardiac disease. No previous rheumatism. The case was complicated by pericarditis, and threatened pneumonia of the left lung.

No. 367 (T. H. Morehead, M.D., Cootehill, Cavan). Male, aged 80, farmer, of temperate habits and sufficiently fed. Locality, low, damp, confined; atmosphere, wet and cold; wind N.W. No previous illness. Tonsillitis was a recent antecedent, and the attack was attributed to exposure to wet and cold. It was a severe one, accompanied by night sweating. Duration of fever and pain 12 days respectively, and of the whole attack 42 days. Many joints were affected, and the pains were migratory. There was no cardiac affection; it was the first attack of rheumatism. Relapses occurred at intervals of 2 or 3 weeks. Recovery was complete.

The most remarkable of these five cases is the last, in which a first attack of rheumatic fever occurred at the age of 80, the attack being one of great severity. In this case recovery was complete. In a severe first attack, however, in another case (281), a woman of 68, death occurred after 30 days' illness. In a third case (143) a first attack occurred in a male aged 63.

2.—IN YOUNG CHILDREN. EIGHT CASES.

No. 13 (C. H. Hill, M.D., Islington). Male, aged 3; insufficiently fed. Locality, high, dry, and confined; atmosphere, wet and changeable; wind S.W. The attack was attributed to exposure to cold 3 days previously; it was mild, but attended by considerable sweating. Duration of the fever was 7 days; of pain 4 days; and of the whole attack 8 days. Few joints were affected; the pains were fixed; the child was liable to tonsillitis and bronchitis. Recovery was complete. A mitral murmur became audible during the attack, but afterwards was inaudible, the apex beating in the fifth space.

No. 109 (S. C. Smith, M.D., Halifax). Male, aged 6; sufficiently fed. Locality, low, damp, and confined; atmosphere, wet and cold. The patient had scarlatina just before. Attack a moderate one, with considerable sweating, lasting about 5 weeks. Many

joints were affected; the pains were migratory. There was a systolic mitral murmur developed during the attack. No previous rheumatism. Recovery partial.

No. 245 (J. T. Collin, M.D., Lincoln). Male, aged 4; sufficiently fed. Locality, high, dry, and exposed; atmosphere, wet and cold; wind N.E. Had measles 2 years previously. Attack ascribed to exposure to cold 3 days before; it was a moderate one, but attended by considerable sweating. Duration of fever and pain 21 days and 14 days respectively; and of the whole attack 21 days. Few joints affected; pains migratory. No previous rheumatism. Death from pericardial effusion and exhaustion.

No. 450 (Edwin Jackson, Whalley Range, Manchester). Female, aged 5½; sufficiently fed. Locality, dry and flat; atmosphere, wet and cold; wind W. Whooping-cough at 4½. The attack was attributed to exposure to wet two days previously; it was a moderate one, attended by slight sweating. Duration of fever and pain 8 days and 6 days respectively, and of the whole attack 8 days. Many joints were involved. There was no cardiac complication, and no antecedent rheumatism. Recovery was complete.

No. 511 (D. J. Mackenzie, M.D., Glossop). Male, aged 5; sufficiently fed. Locality, low, damp, confined; atmosphere, dry, hot sun. Had measles six weeks before; attack attributed to exposure to wet and cold three days previously; it was a mild one, with slight sweating. Duration of fever and pain 6 days and 5 days respectively; and of the whole attack 6 days. Few joints were affected; the pains being fixed. Both pericarditis and endocarditis (mitral regurgitation) occurred during the attack, which was further complicated by bronchitis. No previous rheumatism. Recovery complete.

No. 587 (D. J. Mackenzie, M.D., Glossop). Male, aged 4; sufficiently fed. Locality, high, dry, exposed; atmosphere, wet and cold; wind W. Slight chorea 10 days previously. The attack was moderate, with very slight sweating. Duration of fever and pain 8 days and 12 days respectively, and of the whole attack 12 days. Few joints were affected; the pains were fixed. A systolic apical bruit was developed. The child was subject to catarrh and convulsions, but had had no previous rheumatism. A thread-worm was said to have been expelled by santonin before the child came under observation. Recovery was complete.

No. 620 (J. Mackenzie Booth, M.D., Aberdeen). Male, aged 4; sufficiently fed. Locality, low, damp, confined; atmosphere, wet; wind E. There had been marked anaemia for some weeks. The attack was attributable to exposure to wet and cold, with over-fatigue 2 days previously; it was a severe one, with slight sweating. Duration of fever and pain 6 days respectively, and of the whole attack 6 days. Many joints were involved; the pains were fixed. There was an apical systolic murmur, and the disease was complicated by conjunctivitis and keratitis. No previous rheumatism. Bronchitis supervened 2 days after convalescence became established. Recovery was complete.

No. 627 (C. P. Coombs, M.D., Castle Cary). Male, aged 6; sufficiently fed. Locality, dry; confined; atmosphere, dry, cold, changeable; wind E. The attack was severe, with slight sweating. Duration of fever 17 days, and of the whole attack till death about 40 days. Pericarditis was developed, and the disease was complicated by chorea of one arm and aphasia; then by indications of spinal meningitis. Death was the result of embolism. The child had previously suffered from three or four attacks of subacute rheumatism; the first at the age of 5.

OCCUPATION.

The occupation of the patients who were the subjects of the record are varied, and are as follows.

Domestic servants 71	Colliers	9	Sempstresses	4	
School children ..63	Tailors	8	Bakers	4	
Married women ..46	Masons	8	Bricklayers	4	
Labourers	24	Soldiers	7	Brickmakers	4
Clerks	21	Iron workers	7	Sailors	4
Agricultural labourers ..16	Cotton hands	7	Carmen	3	
Farmers	13	Engine drivers	6	Nailmakers	3
Shopmen	13	Carpenters	6	Furnace cokers	3
At home (females chiefly)	13	Waggoners	6	Navvies	3
Innkeepers	13	Nurses	6	Painters	3
Factory hands	11	Governesses	6	Weavers	3
Grocers	10	Coachmen	6	Druggists	3
Medical practitioners	9	Laundresses	5	Shoemakers	2
		Blacksmiths	5	Brewers, etc.	2
		Gamekeepers	5	Gamekeepers	2
		Dressmakers	4	Plumbers	2

Quarrymen	2	Mineral borer	1	Porter	1
Gasfitters	2	Bléacher	1	Circus tent maker ..	1
Fruiters	2	Weighman	1	Assistant warder ..	1
Dairymen	2	Wheelwright	1	Barnmaid	1
Whitesmiths	2	Cabman	1	Open air	1
Charwomen	2	Gentleman	1	Purser's clerk	1
Maltsters	2	Undergraduate	1	Milk carrier	1
Warehousemen	2	Commission agent ..	1	Cabinet designer	1
Paper mill hands ..	2	Hay dealer	1	Printer	1
Coopers	2	Grinder	1	Fisherman	1
Various trades	2	Railway guard	1	Prostitute	1
Police constables ..	2	Signalman	1	Bookseller	1
Postmen	2	Canal boatman	1	Reformatory boy	1
Telegraph messengers ..	2	Higgler	1	Literary	1
Pilot	2	Pilot	1	Pupil in colliery	1
Tube makers	2	Stationer	1	Vice maker	1
Solicitor	1	Saddler	1	Builder	1
Oilman	1	Drilling machine hand ..	1	Casting dresser	1
Railway porter	1	Electric worker	1	Lace darning	1
Screwer	1	Mercantile	1	Stono printer	1
Postmaster	1	Tin opener	1	Boot tip, stamper ..	1
Cutler	1	Rope maker	1	Bookkeeper	1
Machine maker	1	Dancing mistress	1	Skin dresser	1
Filler	1	Fitter	1	Potter	1
Brick carter	1	Fireman	1	Card room hand	1
Traveller with steam engine ..	1	Servant in asylum	1	Message boy	1
Gunner	1	Vinegar maker	1	Ship chandler	1
Infirmary matron	1	Bandsman	1	Upholsterer	1
Pupil teacher	1	Watchmaker	1	Analytical chemist ..	1

Inspection of the above list at first sight appears to negative the explanation advanced above, of the difference between the numbers of males and females in the tables, namely, that the exposure necessarily entailed on men by the nature of their occupation is a cause of their being more frequently the subjects of rheumatism. It must, however, be remembered that the cases reported are simply those which different medical practitioners have been able to record during the time allowed them for furnishing the results of their experience. They are by no means to be received as a record of the prevalence of rheumatism in various trades or occupations. If it were common experience would lead one rather to place such occupations as sailors, soldiers, brewers, bricklayers, coachmen, cabmen, police constables at the head of the list. It cannot be denied, however, that the number of domestic servants (71) is a remarkable occurrence. This may be partly accounted for by the inordinate consumption of alcoholic drinks—especially beer—and meat to which persons in that station of life are addicted. To this may be added want of proper exercise, with its consequent accumulation of nitrogenous compounds in the tissues.

One important omission must be noted in the tables, namely, an inquiry as to any hereditary tendency to rheumatism. Had this been available for analysis, it might have afforded an explanation of the great number of children (63) which comes second on the list.

CLASS IN SOCIETY.

Instead of grouping the cases in the different classes, namely, upper, middle, and lower, it has been deemed preferable to give the list in full, as showing more accurately the class to which the majority belong. It will be seen at a glance that the lower greatly preponderates over the middle and upper classes.

HABITS.

In calculating the numbers given in the tables under the three heads—temperate, intemperate, and total abstainers, it was thought well to group separately children under 14 years of age who were under close supervision either at home or at school. Such young persons who were engaged in any occupation which necessarily removed them from the supervision of the parents or school teachers, when not under 14 years of age, have been placed among the adults in the class to which they belong. There are, therefore, 647 cases to be dealt with under this head, excluding those in which no mention of the habit is made, namely:—

	Males.	Females.	Children under 14. Males.	Females.
Temperate	263	177	9	15
Intemperate	32	2	—	—
Total Abstainers	47	54	22	26
No mention made	5	3	—	—
Total	347	236	51	41

In order to trace the effects of habits in acute rheumatism, it will be necessary to make an analysis of the tables, and by so doing the following results come out:—

TOTAL ABSTAINERS (including Children).

Males	69	or 10.53 per cent.
Females	80	" 12.21 "
Total	149	" 22.74 "

Average age of total abstainers:—

Males	18.86
Females	18.96
Total average age	18.17

Decade.	Males.	Females.	Total.
Under 10	13	11	24
" 20	33	42	75
" 30	11	19	30
" 40	9	2	11
" 50	2	3	5
" 60	1	3	4
	69	80	149

Previous attacks of rheumatism occurred in total abstainers in

Males	19	or 27.53 per cent.
Females	29	" 36.25 "

Average age of previous attack:—

Males	16.26
Females	16.41

Average number of previous attacks:—

Males (69 cases)	0.56	(exclusive of Nos. 353 and 469, in which no mention is made)
Females (80 cases)	0.60	(exclusive of Nos. 53 and 205, in which no mention is made)

Average duration of fever:—

Males (64 cases)	11.59 days	(no data in 5 cases)
Females (77 cases)	10.37 days	(no data in 3 cases)

Average duration of pain:—

Males (61 cases)	11.31 days	(no data in 8 cases)
Females (76 cases)	12.22 days	(no data in 4 cases)

Average duration of whole attack:—

Males (60 cases)	27.26 days	(no data in 9 cases)
Females (70 cases)	38.08 days	(no data in 10 cases)

Deaths.

Males	4	
Females	3	(excluding No. 112, in which death occurred from enteric fever)
Males	5.79 per cent.	
Females	3.75 "	

or a total death-rate of 4.69 per cent. in total abstainers.

Recovery.

	Complete.	Partial.

* No data.

† No. 259; no data.

‡ Nos. 603, 337; no data.

§ No. 579; no data.

This table is drawn up in order that the course and complications of rheumatism, as set forth in the records, which occurred in teetotallers, temperate, and intemperate persons may be more easily compared. It must be borne in mind, however, that in intemperate females but two cases are given; no importance must therefore be attached to the figures under this heading. The table speaks for itself. On the whole, the figures are in favour of the teetotallers; but in three of the most important points it is distinctly the reverse, and it is somewhat surprising to find, first, that the average duration of the whole attack is 23.6 days in intemperate males, as against 25.27 days in temperate males and 27.26 days in teetotallers; secondly, that the percentage of deaths in teetotallers is more than double that of temperate persons; and, thirdly, that the percentage of heart affection is in teetotallers 54.41, as against 40.59 in temperate males and 46.87 in intemperate males.

It was thought advisable to make a brief analysis of the tables in children under 12 years of age with the view of eliciting any facts from the information given under the more important headings.

In the tables records are given of 51 cases of children under the above-mentioned age, namely: males, 25; females, 26.

Average age, males, 7.72; females, 9.15.

The attack was severe in: 8 (33 per cent.) Males. 6 (23.07 per cent.) Females.
" moderate or mild: 16 (66 per cent.) 20 (76.92 per cent.)

The joint affection was:

	Males.	Females.
Many affected: pains migratory	...	9
Few " " fixed	...	4
" " " migratory	...	4
Many " " fixed	...	2
Few " " "	...	1

Average duration (in days) of fever:
Males ... 22 cases (72, 109, 121 no data) 10.72
Females ... 25 " (337 ") 8.76

Average duration (in days) of pain:
Males ... 21 cases (72, 109, 466, 627 no data) 11.09
Females ... 25 " (337 ") 10.00

Average duration (in days) of the whole attack:
Males ... 24 cases (121 no data) ... 22.12
Females ... 25 " (205 ") ... 15.96

Recovery.

Complete		Partial.	
Males	...	19 or 76 per cent.	21 or 80.76 per cent.
Females	...	4 " 16 "	4 " 15.38 "
Deaths	...	2	1

Heart affections:

	Males.	Females.
Mitral regurgitation	7	6
Pericarditis and mitral regurgitation ...	4	3
Pericarditis	2	3
Aortic obstruction	2	—
Aortic and mitral	1	—
Pericarditis and murmur	1	—
" " aortic obstruction	—	1
" " mitral regurgitation (old) ...	1	—
	18	13
Percentage of heart affections... ..	72	50

Inspection of the above figures brings out one fact, namely, that the percentage of children in whom the articular affection was severe and extensive is 36 per cent. in males and 42.30 per cent. in females. This is contrary to the received opinion, but the discrepancy may perhaps be accounted for by the small numbers here available. The duration of the fever, pain, and of the whole attack is about the same as in adults of the most approved habits; and this remark applies, generally speaking, to the percentage of complete recoveries. In the percentage of heart affection among males, the excessive liability of children is clearly shown by the figures, namely, 72 per cent. in children, against 54 per cent. in total abstainers, 40 per cent. in temperate males, and 46 per cent. in intemperate males. In the case of females the difference is much less.

Food.

Apparently but little information is to be gained under this head, the numbers being—

Food sufficient	626
" insufficient	27
" more than sufficient	1
Not stated	1
	655

It is unnecessary therefore to state the proportion of males to females.

LOCALITY.

The numbers come out as follows:—

High, dry, exposed ... 161	High, damp, confined ...	9
Low, damp, confined ... 98	Low, confined ...	8
High, dry 52	Low, damp	6
Low, damp, exposed ... 46	Damp	5
Low, damp 35	Dry, confined	5
High, damp, exposed ... 31	Damp, exposed	5
High, exposed 31	Low	4
High, dry, confined ... 28	At sea	3
Low, dry, confined ... 26	Confined	2
Low, dry 19	Damp, confined	2
Low, dry, exposed ... 18	Exposed	2
High 14	Medium	1
High, damp 11	Travelling	1
Dry, exposed 10	Dry, flat	1
Dry 9	Flat, dry, confined ...	1
Not mentioned	9	

This is a somewhat remarkable list. It is a general opinion that rheumatism is more prevalent in low and damp localities, and it is certainly surprising that by far the greater number of cases (in 24.92 per cent.) occurred in a "high, dry, exposed" locality, and that, on the other hand, only two cases out of 646 in which data exist in the tables, occurred in a "damp, confined" locality. It is true that the next number (93 cases) occurs under the heading "low, damp, confined," but this is followed by 52 cases in a "high and dry" locality; the result of examination of the above list being that no facts of real value come out under this head.

ATMOSPHERE.

Wet or damp, cold, and cloudy	307
Wet, mild, and changeable	156
Dry, hot, sun for the most part	63
Dry and cold	57
Dry, mild, changeable	37
Wet	10
Damp	4
Not mentioned	21

Under this head the numbers come out in accordance with prevailing opinion. By far the greater number (307, or 47.66 per cent.), occurred in a wet, damp, cold, and cloudy atmosphere.

PREVIOUS ILLNESSES—TONSILLITIS.

In 158 cases, or 24.12 per cent., the patients were the subjects of tonsillitis, and it is worthy of remark that the numbers were the same in the two sexes, namely, 79, or 12.06 per cent. Again, sore-throat (the exact nature of which is not specified) occurred in 10 males and 10 females.

Of the 158 cases, 12 males and 15 females were the subject of tonsillitis as a common ailment, that is, the patients were liable to attacks of inflammation of the tonsil apart from any definite manifestation of rheumatism.

Of these cases—

No. 53. Female, aged 17, was attacked with tonsillitis three days after exposure to wet and cold.

No. 435. Male, aged 12. The tonsillitis lasted throughout the rheumatic attack (twenty-one days), and continued after convalescence was established.

No. 481. Female, aged 28. The attack commenced with tonsillitis.

No. 497. Female, aged 20. Tonsillitis supervened on the third day of the rheumatic attack.

No. 604. Male, aged 49. Tonsillitis preceded the rheumatism by six days, and recurred five days after recovery from the rheumatism.

No. 613. Female, aged 30. The patient had three attacks of tonsillitis each followed by acute rheumatism.

With the exception of the above cases specially mentioned, the tonsillitis preceded the rheumatism at variable intervals. Two cases (103, 494) as long as fourteen years previously; one case (11) five years previously; one case (638) four years previously; one case (517) tonsillitis and scarlet fever three years before; four cases (107, 189, 305, 516) two years before; seven cases (105, 317, 332, 438, 502, 635, 647) between one and two years. Of the remainder, tonsillitis occurred at periods varying between twelve months and the actual day of the onset of the rheumatism. In all those cases in which any cause for the tonsillitis or rheumatism is distinctly stated, exposure to wet, cold, or over-fatigue, or all three combined, is given. It is unnecessary therefore to print the exact numbers.

SCARLET FEVER AS AN ANTECEDENT.

Scarlet fever is mentioned as an antecedent in 88 cases only out of the total number, 655, or 13.43 per cent. It is probable, however, that this number does not represent the actual fact, and that the disease, as an antecedent of rheumatism, is not stated by many reporters, simply because no special inquiry was made as to particular fevers.

Of the 88 cases 43 or 6.41 per cent. were males
45 or 6.71 " " females.

It is not possible, by reason of the scanty data, to draw any conclusions as to the origin of valvular disease of the heart in specific fever other than rheumatism, but the following case may be noted as the only one having any special bearing upon this point.

No. 130 (James Barr, Bolton). Male aged 18; gasfitter. No previous rheumatic affection. Patient a total abstainer. He had measles 10 years and scarlet fever 8 years before the rheumatism, which was apparently induced by over-fatigue and exposure to wet on the day previous. When the patient came under observation a systolic aortic and a mitral murmur were heard, and on the termination of the rheumatism at the end of a fortnight, the heart's apex was 1 inch external to the nipple, showing clearly that the valve disease was of old standing.

In many of the cases of antecedent scarlet fever old valvular disease of the heart is recorded, but in them there had been at least one previous attack of rheumatism. The above-mentioned case forms the only exception. The incidence of the scarlet fever was, as common experience would show, in the earlier years of life, that is, before 20.

MEASLES AS AN ANTECEDENT.

Measles is recorded in 21 males or 63.63 per cent.
" " 13 females " 39.39 "

34 cases in all.

As in scarlet fever, the reports are insufficient for any definite conclusions, but the following cases are worthy of mention as bearing upon the question of the causation of heart disease.

No. 1 (Theophilus Trend, M.D., Southampton). Male, aged 32; solicitor. Had measles in childhood, followed by rheumatism.

He had an aortic murmur (systolic) when he came under observation, but at the termination of the attack it had diminished in intensity, and the apex beat was in its normal position.

No. 130 (James Barr, Bolton). Male, aged 18; gasfitter. Had scarlet fever 8 years and measles 10 years previously. He had an old systolic aortic and mitral murmur, and at the end of the rheumatic attack the apex was 1 inch external to the nipple. He had had no previous rheumatism.

No. 180 (C. Harrison, M.D., Lincoln). Female, aged 23, single, a cook. Had measles 21 years and scarlet fever 2 months previously. She had a systolic murmur observed during the attack of rheumatism, but it is not stated whether the murmur existed at the onset of the rheumatism, or whether it persisted after the convalescence was established. She had had no previous rheumatism.

As in the case of scarlet fever, the measles occurred in early life, and before 20 years of age.

Measles was associated with scarlet fever as an antecedent in 7 cases, of which Nos. 44, 103, 117, 130, 277, 365, 434 were males, and 1, No. 180, was a female. It was associated with varicella in 1 male (No. 309); with tonsillitis in 2 males (Nos. 1 and 11), and 1 female (Nos. 502); with tonsillitis and pertussis in 1 male (No. 103); with pertussis in 1 male (No. 420), and 3 females (Nos. 132, 392, 574); with tonsillitis and scarlet fever in 1 female (No. 229); with tonsillitis and chorea in 1 male (No. 433). In the remaining 15 cases measles was the only antecedent—namely, in 8 males and 7 females.

TYPHOID AS AN ANTECEDENT.

This occurred in 11 cases, of which 6 (295, 356, 389, 483, 518, 612) were males, and 5 (94, 139, 357, 360, 481) were females; of these, enteric and scarlet fever were antecedents in 5 cases.

No. 139. Female, aged 28, had enteric fever 25 years previously, and scarlet fever in childhood; 1 previous rheumatic attack at 19. No morbus cordis.

No. 357. Female, aged 8, recovered from enteric fever 2 months previously to the rheumatism, having had scarlet fever 14 months before. No previous rheumatism; no morbus cordis.

No. 389. Male, aged 17, had scarlet fever 8 years previously; the date of the enteric was uncertain. No previous rheumatism; no morbus cordis.

No. 360. Female, aged 22, had enteric fever, scarlet fever, small-pox, and whooping-cough as antecedents, but the dates of the fevers are not stated; 1 previous rheumatic attack at 19. No morbus cordis.

No. 481. Female, aged 28, had scarlet fever 19 years previously; the date of the enteric was unknown; 5 previous rheumatic attacks. Old morbus cordis.

No. 518. Male, aged 20, had enteric fever 6 years and tonsillitis 6 months previously; 1 previous rheumatic attack at 18. No morbus cordis.

Of the remaining 5 cases, enteric fever was the only antecedent, namely, in 2 males and 4 females.

TYPHUS AS AN ANTECEDENT

Occurred in—

No. 174 (W. Easby, M.D., March). Male, aged 18; 11 years previously. No previous rheumatism. No morbus cordis.

No. 372 (C. B. Richardson, M.D., Brighton). Female, aged 21; 5 years previously; this patient had scarlet fever when young; 1 previous rheumatic attack at 15. Old morbus cordis.

No. 441 (J. W. Miller, M.D., Dundee). Male, aged 47; twice previously; the patient had bronchitis 7 years, and otitis 5 years before; 3 previous rheumatic attacks, the first at 12. No morbus cordis.

VARIOLA AS AN ANTECEDENT

Occurred in 4 cases—3 males and 1 female, namely:

No. 126 (J. H. Jackson, M.B., Wigan). Male, aged 36, had variola 32 years, and pneumonia 20 years previously; 1 previous rheumatic attack at 19. No morbus cordis.

No. 370 (Thomas F. Raven, Broadstairs). Male, aged 40, had variola 7 years previously. No previous rheumatism. No morbus cordis.

No. 451 (John Reid, Rochdale). Female, aged 15, had variola 7 months previously. No previous rheumatism. No morbus cordis.

No. 645 (B. Roberts, M.D., Eastbourne). Male, aged 29; variola 18 years; scarlet fever 24 years previously; 1 previous rheumatic attack at 20. Old aortic disease.

(In No. 451 a mitral systolic murmur was heard during the

rheumatic attack, and in No. 645 an old aortic murmur, but in none of the others is any cardiac disease recorded.)

OTHER ACUTE SPECIFIC DISEASES AS ANTECEDENTS.

Whooping-cough occurred in 6 cases, namely, 3 males and 3 females.

Rötheln occurred in 2 cases, both females.

Mumps " 1 case, namely female.

Erysipelas " 1 " " "

Varicella " 1 " " "

" Fever " 1 " " "

In none of the above was there any heart affection unconnected with the rheumatism.

Syphilis is specially noted in 4 cases, namely, 1 male and 3 females.

No. 2 (Charles Ede, Guildford). Female, aged 40; syphilis was doubtful; the patient had suffered from eczema for 1 year previously.

No. 167 (T. Hyde Hills, Cambridge). Male, aged 32; cabman; the date of infection, etc., not stated.

No. 332 (W. Shaw, M.D., Maidstone). Female, aged 36, married; infected 4 years previously.

No. 424 (Thomas F. Raven, Broadstairs). Female, aged 35; infected 4 years previously by husband.

ANÆMIA AS AN ANTECEDENT.

Anæmia is recorded in 17 cases, or 2.59 per cent.; of which 3 or 0.45 per cent. were males, and 14, or 2.13 per cent., females.

No. 37. Male, aged 6; anæmic child; 1 previous attack of rheumatism at 3 years of age.

No. 47. Female, aged 14, single; errand girl; anæmia for two months previously.

No. 59. Female, aged 19, single; dressmaker; anæmia, no date given.

No. 78. Female, aged 28, married; anæmia, no date given. Phlebitis after parturition 38 days previous to rheumatism; 1 previous rheumatic attack at 14.

No. 94. Female, aged 15, single; house work; anæmia, no date given. Enteric fever 3 years previously.

No. 138. Female, aged 22, single; servant; anæmia, no date given.

No. 252. Male, aged 26; joiner; anæmia, no date given; neuralgia; 2 previous rheumatic attacks; first at 22.

No. 302. Female, aged 24; servant; anæmia, no date given; neuralgia, scarlet fever in childhood; 3 previous attacks of rheumatism, first at 13.

No. 340. Female, aged 24, married; anæmia, no date given; 2 previous attacks of rheumatism, first at 18.

No. 360. Female, aged 22, single; milliner; anæmia, no date given; 1 previous attack of rheumatism at 19. Scarlet fever, enteric fever, variola. Pertussis in former years.

No. 372. Female, aged 21, single; shopgirl; anæmia, no date given; 1 previous attack of rheumatism at 15. Typhus and bronchitis 5 years before second rheumatic attack. Scarlet fever in former years.

No. 423. Female, aged 20, single; at home; anæmia, no date given; migraine, debility, hysteria; insufficient diet; 1 previous rheumatic attack at 16.

No. 499. Female, aged 18, single; servant; anæmia, no date given; bronchitis, otitis in former years.

No. 549. Female, aged 24, single; servant; anæmia, no date given; 1 previous rheumatic attack at 15.

No. 520. Male, aged 4; anæmia some weeks previously; conjunctivitis, keratitis.

No. 622. Female, aged 27, married; anæmia, no date given; abortion and flooding 8 months previous to rheumatic attack; 5 previous rheumatic attacks, first at 8.

No. 647. Female, aged 17, single; servant; anæmia, no date given; scarlet fever at 5 years of age; tonsillitis 21 months before the last attack of rheumatism; old cardiac disease; no previous rheumatism.

In 5 of these cases cardiac complication existed, namely, in No. 37 a mitral systolic bruit was developed during the rheumatism, there having been one previous attack at the age of 3; 78, an old systolic mitral murmur, the patient having had an attack of acute rheumatism 14 years previously; 302, a mitral systolic murmur (probably of old-standing), there having been 3 previous attacks of acute rheumatism; 372, a mitral systolic murmur (but whether old or recent is not stated), with an attack of rheumatism 6 years previously; 647, a mitral systolic bruit (possibly of old standing),

with previous history of scarlet fever, but without any record of rheumatism.

It will be seen, therefore, that anæmia cannot, so far as these cases are concerned, be regarded as a cause of cardiac disease, but that in those instances in which it existed it must be attributed rather to rheumatism (4 cases), or to scarlet fever (1 case).

PULMONARY DISEASES AS ANTECEDENTS.

Bronchitis occurred in 15 cases=10 males, 5 females.

Pneumonia " " 7 " = 3 " 4 "

Pleurisy " " 2 " = 2 " " "

Pleuropneumonia " " 1 " = 1 " " "

WHOOPING-COUGH AS AN ANTECEDENT

In 6 cases=3 males and 3 females.

Namely...No. 199. Male, aged 31; no date given.

" 392. Female, " 7 " " "

" 420. Male, " 8 " 7 years previously

" 450. Female, " 5 " 4 " " "

" 574. " " 10 " 5 " " "

" 629. Male, " 14; no date given.

CHOREA.

It is not a little remarkable, considering the recent observations of Dr. Stephen Mackenzie and others, that chorea is mentioned in this series of 655 cases as an antecedent or concomitant of rheumatism in 13 instances only, or 1.98 per cent., namely, males, 0.76 per cent.; females, 1.22 per cent. No apology is needed therefore for a statement of the chief particulars in each case.

No. 49 (F. Marsh, Stafford). Female, aged 24; single; housemaid; temperate; sufficiently fed. Locality, low, damp, exposed; 2 previous attacks of rheumatism, the first at 13. Scarlet fever 12 years previously; chorea at the same time. A mitral systolic murmur was heard at the commencement of the rheumatic attack, for which the patient was under treatment; but at the termination of the attack the apex was normal in position, although the murmur persisted.

No. 74 (S. Moritz, M.D., Manchester). Female, aged 25; single; factory hand; temperate; insufficient diet. Locality, low, damp, confined. Chorea 4 months previously, during pregnancy; no previous rheumatism or other illness; no cardiac affection.

No. 209 (G. W. Homan, Lichfield). Male, aged 27; single; clerk; temperate; sufficient diet; 1 previous attack of rheumatism at 19; chorea in childhood. A systolic mitral murmur was heard at the commencement of the present attack, and remained during the attack; the apex beat being then half an inch internal to the nipple. The patient did well till the seventh day, when sweating ceased; and in the evening the temperature rose to 110° F., and he died in 5 hours, the temperature being then 106.9° F.

No. 238 (W. F. Brook, Farcham). Female, aged 11; sufficient diet. Locality, high, dry, exposed. No previous attack of rheumatism; chorea 2 years previously. The attack of rheumatism was severe; pericarditis complicated the attack, and death occurred on the seventh day, from asphyxia, the result of pericarditis and "great bronchial secretion."

No. 433 (F. Wachter, Canterbury). Male, aged 14; cabinet maker; sufficient diet. Locality high. No mention made of previous rheumatism. The patient had measles with enlarged tonsils, but the date is not given; 2 attacks of chorea 7 and 2 years ago. A mitral murmur was audible throughout the attack and at the termination of rheumatism after 21 days. The apex beat was normal in position. Recovery complete.

No. 469 (E. J. Allan, M.D., Dock Street, E.). Female, aged 24, single; temperate; sufficient diet. Locality, low, damp; 1 previous attack of rheumatism at 16; liable to bilious attacks; chorea in childhood. A mitral systolic murmur was audible throughout the attack, and at the termination of the rheumatism on the eleventh day. The apex beat was one inch to the left of the sternum; the murmur had been present since childhood, and was heard before the chorea attacked her. Recovery was complete.

No. 466 (H. S. Renshaw, M.D., Sale). Male, aged 9; temperate; sufficient diet. Locality, dry, exposed. No previous attack of rheumatism; aortic and mitral murmurs during the rheumatic attack; apex 1 inch below, and internal to nipple; murmurs disappeared 21 days after the onset of the rheumatism; "chorea remained." Recovery from rheumatism was complete.

No. 493 (W. Frew, M.D., Galston, Ayrshire). Female, aged 19;

single; lace maker; total abstainer; sufficient diet. Locality, low, damp. One previous attack of rheumatism at 16; chorea 9 years previously. A systolic mitral murmur audible throughout the attack (14 days' duration); at the termination the apex beat was in the sixth interspace, 1 inch external to the nipple line. Recovery was complete.

No. 524 (G. H. Mackay, M.B., Elgin). Female, aged 19; single; no occupation; temperate; sufficient diet. Locality, low, damp. No previous rheumatism; chorea 18 months previously; tonsillitis 4 days before. A mitral and aortic murmur was heard during the attack, and at its termination at the end of 3 weeks; the apex was just within the nipple. The patient had dropsy from heart disease.

No. 547 (W. H. Dobie, M.B., Chester). Female, aged 17; single; lady; temperate; sufficient diet. Locality, low, damp, confined. One previous attack of rheumatism at 12; chorea 5 years previously; systolic and presystolic mitral murmurs audible during the attack; no mention of position of apex. Chorea accompanied the previous attack of rheumatism, which was attended by violent delirium and severe pain; present attack mild, and terminating on the tenth day.

No. 587 (D. J. Mackenzie, M.D., Glossop). Male, aged 4; total abstainer; sufficient diet. Locality, high, dry, exposed. No previous rheumatism; chorea was slight, and occurred 10 days previous to the onset of rheumatism. There was a systolic mitral murmur from the third day of the attack, but the apex was normal. Recovery was complete.

No. 589 (D. J. Mackenzie, M.D., Glossop). Female, aged 14; temperate; sufficient diet. Locality, high, damp, exposed; 2 previous attacks of rheumatism (age of first not given); chorea is said to be "still present." A "murmur" was noticed when the patient came under observation; the apex was widely diffused. Recovery was complete.

No. 599 (C. H. Milburn, M.B., Durham). Male, aged 16; weaver; temperate; sufficient diet. Locality, low, damp, confined; 1 previous attack of rheumatism at 12. A mitral systolic murmur was noticed when the patient came under observation; the apex beat 1 inch below the nipple; chorea had occurred 3 years previously. Recovery was complete.

In 5 cases (74, 238, 466, 524, 587) there had been no previous rheumatism.

In 1 case (483) no mention is made of previous rheumatism. In 2 cases (49 and 589) 2 previous attacks of rheumatism had occurred, while in the remainder, 1 previous attack had occurred in each case.

In Nos. 74 and 587 no cardiac disease existed after recovery from rheumatism; the patient having had an attack of chorea 4 months previously.

In No. 238 no cardiac disease was known until the rheumatic attack under which the patient succumbed; but chorea had occurred 2 years previously.

In No. 433 there had been no previous rheumatism, but there had been two previous attacks of chorea, and there had been no previous cardiac disease.

In No. 524 there had been no previous rheumatism. One attack of chorea 18 months previously; the patient suffered from cardiac dropsy; an evidence of old-standing valvular disease.

In these records, then, no valvular disease can be traced in connection with chorea alone, and, though in the majority of these cases in which chorea occurred valvular disease of the heart existed, it was presumably of rheumatic origin, and in all save one (524) the mitral valve alone was affected.

In one case (460) there had been one attack of rheumatism 8 years previously, and chorea in childhood, the date not given; it is specially noted that the mitral systolic murmur was heard "before the chorea attacked her."

In No. 49 chorea occurred at 12 years of age, the patient being aged 24, female.

In No. 74 chorea occurred 4 months previous, the patient being aged 25, female.

In No. 209 chorea occurred in childhood (no date given), the patient being aged 27, male.

In No. 238 chorea occurred at 9 years of age, the patient being aged 11, female.

In No. 433 chorea occurred at 7 and 9 years of age, the patient being aged 14, male.

In No. 460 chorea occurred in childhood (no date given), the patient being aged 24, female.

In No. 493 chorea occurred at 10 years of age, the patient being aged 19, female.
 In No. 524 chorea occurred at 16 years of age, the patient being aged 19, female.
 In No. 547 chorea occurred at 12 years of age, the patient being aged 17, female.
 In No. 587 chorea occurred ten days previously, the patient being aged 4, male.
 In No. 599 chorea occurred at 13 years of age, the patient being aged 16, male.
 Various other "previous illnesses" are recorded in these tables, but the numbers in each case are so small that analysis of them would be useless.

RECENT ANTECEDENTS TO THE RHEUMATIC ATTACK.

Under this head are stated certain previously existing conditions to which the rheumatic attack might probably be attributed, or without which the patient might possibly have escaped.

Over-fatigue and exposure to wet and cold:			
Males	61
Females	37
Not mentioned	1
Total	99 or 15.11 per cent.
Exposure to wet and cold:			
Males	76
Females	30
Total	106 or 16.18 per cent.
Exposure to cold:			
Males	55
Females	36
Total	91 or 13.89 per cent.
Over-fatigue—more or less prolonged:			
Males	12
Females	18
Total	30 or 4.58 per cent.
Exposure to wet:			
Males	38
Females	32
Total	70 or 10.68 per cent.
Over-fatigue—prolonged:			
Males	12
Females	11
Total	23 or 3.51 per cent.
Over-fatigue—sudden:			
Males	7
Females	4
Total	11 or 1.52 per cent.
Pharyngitis:			
Males	10
Females	4
Total	14 or 2.13 per cent.
Parturition:			
2 cases (125 and 406)	6 weeks	previously.	
1 " (305)	5 "	"	
1 " (391)	4 "	"	
1 " (264)	25 days	"	
1 " (606)	22 "	"	
1 " (428)	14 "	"	
1 " (515)	2 "	"	
Shock:			
Males	4
Females	3
Total	7 or 1.06 per cent.

Of the other mentioned recent antecedent diseases, such as gout, gonorrhoea, of each one case; jaundice, catarrh, diptheria, injury, parotitis (two cases), for example, the numbers are so small as to be valueless.

The expression "recent antecedents" here signifies a disease which occurred within six weeks previously to the rheumatic attack for which the patient came under observation.

The numbers in order stand as follows:

Exposure to wet and cold	106 cases.
Over-fatigue and exposure to wet and cold	99 "
Exposure to cold	91 "
Exposure to wet	70 "
Over-fatigue, more or less prolonged	30 "
Over-fatigue, prolonged	23 "
Pharyngitis	14 "
Over-fatigue, sudden	11 "
Parturition	8 "
Shock	7 "
No recent antecedent diseases (males, 39 females, 30)	79 "
No mention of antecedent diseases (males, 27; females, 18)	45 "

PHENOMENA CONNECTED WITH THE PRESENT ATTACK.

Under this head returns are made: 1, as to the severity of the attack and the sweating; 2, the duration of the fever, pain, and whole attack; 3, extent of joint affection; 4, result.

The figures come out as follows:

The rheumatism was severe in	...	178 males, or 27.17 per cent.
" " mild in	...	116 females, or 17.70 "
" " "	...	191 males, or 29.15 "
" " "	...	160 females, or 24.42 "
	...	645
Cases in which no mention is made as to severity, namely, 133, 319, 320, 342, 377, 415, 420, 505, 539, 588	...	10
	...	655
Sweating was considerable in	...	255 males, or 38.93 per cent.
" " slight in	...	166 females, or 25.34 "
" " "	...	116 males, or 17.70 "
" " "	...	107 females, or 16.33 "
	...	644
Cases in which no sweating occurred or no mention is made as to sweating, namely, 9, 46, 132, 133, 336, 407, 493, 520, 573, 608, 638	...	11
	...	655

Examination of the tables were then made with the view of ascertaining the influence of diaphoresis on recovery; the following is the result:

	Males.	Females.
Sweating, considerable	180, or 27.89 per cent.	105, or 16.25 per cent.
Recovery, complete	88 " 13.62 "	82 " 12.69 "
Sweating, slight	64 " 9.90 "	52 " 8.04 "
Recovery, complete	21 " 3.25 "	20 " 3.09 "
Sweating, considerable	11 " 1.70 "	9 " 1.54 "
Death	1	1
Sweating, slight	1	1
Death	1	1
Sweating, none	1	1
Recovery, complete	1	1

Of the 655 cases data were insufficient for the above calculation in 9 males (Nos. 46, 151, 249, 255, 325, 407, 578, 579, 608), and in 9 females (Nos. 9, 81, 132, 150, 322, 520, 567, 573, 638); in 1 case (133) the sex is not mentioned, leaving 646 cases to be dealt with.

The figures lend but partial support to the presumption that free diaphoresis produces a beneficial effect on the course and result of acute rheumatism, when the number of complete recoveries with slight sweating is compared with that when sweating was considerable.

Under "slight" sweating have been grouped cases in which diaphoresis is described as moderate; under "considerable" those in which it was profuse.

INFLUENCE OF TREATMENT ON THE DURATION OF THE RHEUMATIC ATTACK.

With only four exceptions, the cases recorded in the tables were under one or more of various remedies advocated for the relief of the disease, and it has been, therefore, thought advisable to calculate the average number of days' duration of the fever, pain, and of the whole attack (where a sufficient number of cases could be collected to strike an average), under some of the more usual methods of treatment. In a large number of cases the treatment

is different in each; no grouping of them, therefore, is either profitable or even possible.

Treatment.	Average duration (in days) of		
	Fever.	Pain.	Whole Attack.
Salicylates (sodium or potassium)	(173 cases) 8.65 days	(171 cases) 10.18 days	(167 cases) 19.03 days
Salicylic acid ...	(9 cases) 13.8 days	(9 cases) 10.7 days	(9 cases) 10.7 days
Salicin ...	(14 cases) 9.28 days	(14 cases) 15.07 days	(14 cases) 23.92 days
Alkalies ...	(26 cases) 13.23 days	(26 cases) 19.0 days	(26 cases) 36.30 days
Alkalies and then salicylates	(22 cases) 11.54 days	(22 cases) 13.90 days	(21 cases) 22.22 days
Salicylates and alkalies (combined)	(12 cases) 10.83 days	(11 cases) 15.54 days	(13 cases) 34.92 days
Salicylates and then alkalies	(19 cases) 10.78 days	(18 cases) 13.16 days	(17 cases) 30.64 days
Salicin and alkalies ...	(3 cases) 11.6 days	(3 cases) 19.3 days	(3 cases) 24.0 days
Salicylates and potass. iod.	(7 cases) 17.14 days	(6 cases) 24.16 days	(7 cases) 46 days
Salicylates and iron ...	(18 cases) 11.77 days	(19 cases) 10.89 days	(18 cases) 27.7 days
Salicylates and tonics ...	(16 cases) 8 days	(16 cases) 10.18 days	(16 cases) 18.68 days
Alkalies and opium ...	(8 cases) 10.75 days	(8 cases) 12.60 days	(8 cases) 18.75 days
Salicylates, then iron and quinine	(5 cases) 10 days	(5 cases) 13.8 days	(6 cases) 20.33 days
Salicylates and opium ...	(10 cases) 9.9 days	(11 cases) 8.45 days	(9 cases) 30.3 days
Salicylates and blisters...	(7 cases) 6.14 days	(7 cases) 12 days	(6 cases) 15.83 days
Alkalies and then quinine	(6 cases) 13.5 days	(6 cases) 21.6 days	(5 cases) 35 days
Salicylates and quinine...	(6 cases) 10.5 days	(6 cases) 17 days	(6 cases) 31.6 days

Case No. 655 has been excluded from the calculation under salicin as the data are insufficient. The patient was ill 7 days before she came under observation; the pain lasted 1 day, and the duration of the whole attack was 7 days.

In most of the cases treated the dose of salicin was 1 scruple, repeated in intervals of from 1 to 4 hours; and in once case (654) the drug was taken in 1-scruple doses every hour till the patient was well (about the 6th day).

In Case 444 the dose was grains xij, given every 2 hours till bedtime, and then repeated thrice daily. The patient was not seen until the 10th day, and on the 2nd day of treatment the temperature became normal.

CASES IN WHICH SALICIN, SALICYLIC ACID, OR ITS SALTS FAILED.

No. 19 (W. Bruce, M.D., Dingwall). Male, aged 42; shoemaker; temperate; sufficiently fed. Locality, low, damp, confined; atmosphere, changeable; wind W. No previous rheumatism. Present attack attributed to exposure and over-fatigue. The attack was severe, attended by considerable sweating, and many joints (fingers chiefly) were affected. Sodium salicylate was given, 10 grains every 2 hours, and then every 4 hours. Subsequently potassium bicarbonate was administered till the urine became alkaline. Recovery was partial, pain persisting in several joints. The reporter remarks: "Salicylate seemed to have no effect; treatment carefully carried out."

No. 22 (J. A. Erskine Stuart, Healy, Batley). Male, aged 23; single; blacksmith; temperate; sufficiently fed. Locality, high, dry, exposed; atmosphere, damp and cold; wind N. The patient had had several previous attacks of rheumatism, and had "congenital mitral disease inherited from mother." The present attack was ascribed to exposure to wet, and cold, and over-fatigue; it was severe, and the sweating considerable. The duration of the fever, pain, and whole attack was 7 days. The dose of sodium salicylate was 15 grains every 3 hours. The joint affection was relieved in 2 days. The salicylate caused gastro-enteritis and hæmatemesis, and the patient died.

No. 52 (J. Munro, M.D., Barnard Castle). Male, aged 21; single; labourer; temperate; sufficiently fed; locality, high, dry; atmosphere, mild and changeable; wind E. The patient had bronchitis 6 years previously, but no rheumatism. For the present attack no cause is assigned; the attack was severe, with profuse

sweating. The fever and pain lasted 6 days, and the whole attack 35 days; many joints were involved. During the attack a crop of sudamina appeared. Sodium salicylate, half a scruple to one scruple, was given every 3 hours. The reporter remarks that there was an absence of effect of the salicylate on either the fever or the pain. The patient made a complete recovery.

No. 79 (A. A. Cohen, M.B., Burwash). Female, aged 25; single; housemaid; temperate; sufficient food. Locality, high, damp, exposed; atmosphere, wet and cold. The patient had one previous attack at the age of 8. Present attack attributed to wet, cold, and over-fatigue; it was severe, and the sweating was considerable. The duration of the fever and pain were 12 and 14 days, and of the whole attack 14 days. Many joints were affected. Patient was chlorotic. Sodium salicylate was at first administered, and then potass. bicarb. and iod. The reporter remarks: "No benefit from treatment No. 1; rapid effect of No. 2." Recovery complete.

No. 105 (Edward Cureton, Shrewsbury). Male, aged 25; railway labourer; temperate; sufficient food. Locality, low, damp, confined; atmosphere, mild and damp; wind S. Patient had tonsillitis 1 year previously but no rheumatism. Present attack attributed to exposure to wet; it was severe, with considerable sweating. Duration of the whole attack was 49 days. Many joints were affected, and sudamina were present during the attack. Salicylates were administered for 3 days, and then potass. bicarb. Reporter remarks: "Salicylates failed; bruit appeared at the end of first week; case of a relapsing nature throughout. Recovery was complete."

No. 127 (F. B. Mallett, M.D., Bolton). Female, aged 22; single; sempstress; temperate; sufficient food. Locality, high and dry; atmosphere, changeable; wind S.W. Patient had scarlet fever 5 years previously but no rheumatism. Present attack attributed to prolonged over-fatigue; it was severe, with considerable sweating. Duration of fever and pain were 21 and 30 days respectively, and of the whole attack 42 days. Pericarditis and endocarditis supervened during the attack. Sodium salicylate, 2 drachms in 24 hours for several days was the first treatment; afterwards salines were substituted. The remark is: "No relief from treatment 1; good from No. 2." Recovery partial.

No. 143 (Henry Davy, M.D., Exeter). Male, aged 20; single; cutter; temperate; sufficient food. Locality, low, damp, confined; atmosphere, wet and mild. One previous rheumatic attack, at 13. Present attack moderate; slight sweating. Duration of fever and pain 7 and 5 days respectively, and of the whole attack 14 days. Salicylate was given at first in one-scruple doses, and afterwards iron and ammon. acet. Remarks: "Salicis produced no effect on temperature. Relief from treatment No. 2." Recovery was complete.

No. 201 (C. A. McMunn, M.D., Wolverhampton). Female, aged 15; single; schoolmistress; temperate; food sufficient; locality, low, damp, exposed; atmosphere, damp and cold; wind N.E. Patient had had no previous illness. Present attack attributed to exposure to cold and over-fatigue; it was a mild one, but attended by considerable sweating. Duration of fever and pain 14 and 10 days respectively, and of the whole attack 21 days. Few joints were affected. Pericarditis and pleurisy supervened during the attack. Salicin was first administered, and subsequently "sodium salicylate in one-scruple doses every four hours, with alkalies." The reporter observes, "No benefit from salicin." Recovery complete.

No. 212 (M. Messiter, Dudley). Male, aged 17; single; engine-driver; temperate; sufficient food. Locality, high, damp, exposed; atmosphere, wet and cold; wind N.E. No previous illness. Present attack was severe, with considerable sweating. Fever and pain lasted 28 and 20 days respectively; the whole attack 43 days. Few joints were affected. Sudamina appeared during the attack, and roseola afterwards. The dose of salicylate is not given, but the reporter remarks: "Salicylate produced so little relief and so much sweating that it was stopped. No other drug affected the rheumatism."

No. 244 (A. A. Cohen, M.B., Burwash). Male, aged 35; higgler; temperate; sufficient food. Locality, high, dry, exposed; atmosphere, dry, cold; wind S.W. Patient had two previous rheumatic attacks, the first at 27. Present attack attributed to sudden over-fatigue and exposure; it was moderate, with slight sweating. The fever and pain lasted 7 and 8 days, the whole attack 21 days. Many joints were involved. Salicin (dose not stated) was first given; subsequently, two grains of quinine every four hours and a blister to knee. The patient was anæmic. "No benefit from

salicin. After the first dose of quinine, said, "I felt it take all the fever out of me." Recovery partial; pain persistent in one joint.

No. 290 (Jas. McNee, M.D., Inverness). Male, aged 18, single; grocer; temperate; sufficiently fed. Locality, low, damp, confined. No previous illness. Present attack attributed to exposure. Fever and pain lasted 20 and 2 days, and the whole attack 35 days. It was a moderate attack, but attended by considerable sweating. Sudamina appeared on the 9th, and lasted till the 24th day. A mitral systolic murmur came on during the attack. Sodium salicyl. was first given in doses of one scruple every two hours; then salicin in the same doses; and, thirdly, quinine with alkaline effluents. The reporter remarks: "Temperature fell and murmur disappeared with the salicylate. With salicin in same doses, temperature rose and murmur returned."

No. 332 (W. Shaw, M.D., Maidstone). Female, aged 32, married; paper-mill hand; temperate; sufficiently fed. Locality, low, damp, exposed; atmosphere, wet. Patient had four previous attacks of rheumatism, the first at 8, and four years previously suffered from syphilis. Present attack preceded by prolonged over-fatigue; it was a severe attack, with considerable sweating. Duration of fever and pain was 5 and 21 days respectively, and of the whole attack 56 days. Many joints were involved. The treatment is stated to have been alkaline, but the remark of the reporter is, "Almost complete inutility of salicylic acid."

No. 372 (C. B. Richardson, M.D., Brighton). Female, aged 21, single; shop assistant; temperate. Locality, low, dry; atmosphere, wet, cold; wind E. Patient had had a previous rheumatic attack at 15; also scarlet fever when young, and typhus with bronchitis five years previously. Present attack followed exposure to cold; it was severe, and attended by considerable sweating. Duration of fever 40 days, and of the whole attack 280 days. Many joints were involved. During the attack the patient suffered from pleurisy, pericarditis, and double pneumonia. "Salicylates in large doses frequently repeated had no effect on the fever or pain," and recovery was eventually complete on quinine, digitalis, pot. iod., ammonia, and stimulants.

No. 390 (W. Brooks, Fareham). Male, aged 25, single; manservant; temperate; sufficiently fed. Locality, low, damp; atmosphere, dry, hot. No previous illness. Present attack followed prolonged over-fatigue on the previous day; it was moderate in severity, and attended with slight sweating. Fever and pain lasted 20 days respectively, and many joints were affected. Sodium salicylate for one week failed to relieve the symptoms, and recovery was eventually completed under potassium bicarb. and potass. iod.

No. 418 (H. G. Orlebar, M.D., Elizabeth Street, S.W.). Female, aged 18, single; servant; temperate; sufficiently fed. Locality, low, damp, confined; atmosphere, wet, and cold. No previous illness. Present attack attributed to exposure to wet 8 days previously; it was severe, but accompanied by only slight sweating. Duration of fever and pain 21 days and 20 days respectively; of the whole attack 24 days. Many joints were affected. Patient suffered during the attack from pericarditis and intense pain in the cervical spine, and was usually dyspeptic. Sodium salicyl. in 15-grain doses every four hours failed to give relief; slight relief followed potass. acet. and bicarb., while quinine produced great benefit. Recovery was complete under iron and potass. iod.

No. 419 (H. G. Orlebar, M.D., Elizabeth Street, S.W.). Female, aged 25, single; dressmaker; temperate; sufficiently fed. Locality, low, dry, confined; atmosphere, dry, mild. No previous attacks. Present attack followed exposure to wet and over-fatigue just before; it was severe, with considerable sweating. Fever lasted 19 days, pain 17 days, and the whole attack 21 days; few joints were affected. Membranous pharyngitis supervened on the 18th day. Pericarditis during the attack; the patient was, moreover, subject to "bronchial catarrh and sluggish liver." Quinine was administered first, and then sodium salicyl., 15 grains every four hours, with no result. Recovery was finally completed under potass. iod., potass. bicarb., and digitalis.

No. 425 (T. F. Raven, Broadstairs). Female, aged 32, married; temperate; sufficiently fed. Locality, high, dry, confined; atmosphere, dry and hot; wind W. One previous attack of rheumatism at 12. Present attack attributed to exposure to cold and sudden fatigue 14 days previously; it was of moderate severity, but accompanied by considerable sweating. Fever lasted 40 days, pain 49 days, and the whole attack 84 days; many joints were involved. The patient was subject to migraine and was anæmic. "Salicylic acid relieved the fever and pain from time to time, but failed eventually."

No. 448 (G. C. Dickson, M.D., Carnoustie). Female, aged 48, married; temperate; sufficiently fed. Locality, low, dry, confined; atmosphere, dry, cold, changeable; wind W. No previous illness recorded. Present attack followed prolonged over-fatigue and exposure to cold on the previous day; it was of moderate severity, but attended with considerable swelling. Duration of fever and pain 11 days and 21 days respectively, and of the whole attack 21 days; many joints were affected. The patient suffered from hæmorrhoids. The drugs employed were; (1) salicylates, (2) salicin, (3) citrate of iron, as to which the reporter remarks, "No benefit from No. 1; relief from No. 2."

No. 494 (W. F. Brook, Fareham). Female, aged 38, married; housekeeper; temperate, sufficiently fed. Locality, low, damp; atmosphere, wet, cold; wind N.W. No previous rheumatism. Patient had suffered from tonsillitis and pharyngitis 11 years previously, and from erysipelas 5 months before the present attack, for which no cause is assigned; it was a moderate one, with slight sweating. Fever and pain each lasted 25 days, and the whole attack 56 days. Many joints were affected. Sodium salicyl., 12 grains, with sod. bicarb. and ammon. carb., was administered every 4 hours, and Dover's powder at night. The reporter remarks, "No result from salicylate." Recovery was complete.

No. 530 (W. E. Green, Sandown, I.W.). Female, aged 14; nurse; temperate, sufficiently fed. Locality, low, dry, confined; atmosphere, dry, cold; wind N.E. One previous attack of rheumatism at 9. Present attack, not traced to any cause, was of moderate severity, with slight sweating. Duration of fever and pain 15 and 20 days respectively, of whole attack 28 days. Few joints were involved. Patient suffered from acne and dry bronchial cough. The disease was "persistent, notwithstanding salicin," but recovery was eventually complete.

No. 531 (W. E. Green, Sandown, I. W.). Male, aged 51; carter; temperate; sufficiently fed. Locality, low, damp, exposed; atmosphere, dry, hot. Three previous attacks, the first at 39. No cause could be traced for present attack, which was of moderate severity, with considerable sweating. Fever and pain lasted 7 and 5 days respectively, and the whole attack 10 days; many joints were affected. Salicin and actæa racemosa were at first administered, and then salicylic acid and guaiacum. Reporter remarks: "No. 1 failed, No. 2 gave great relief. In the former attack salicin alone was of no service." The dose is not stated. Recovery was complete.

No. 538 (J. Neil Whitfield, Ebbw Vale). Female, aged 20; single; dressmaker; tectotaller; sufficiently fed. Locality, high, damp, exposed; atmosphere, damp and mild; wind S.W. No previous rheumatism. Patient had suffered from measles. Present attack followed exposure to wet 2 days before; it was severe, with considerable sweating. Duration of fever and pain 12 days and 10 days respectively, and of the whole attack 14 days; few joints were involved. Treatment was (1) sodium salicyl.; (2) alkalies and blisters over the heart; (3) digitalis, ammon. carb. and strychn. Reporter remarks: "No good result from treatment 1. Patient died of asthenia from endocarditis."

No. 644 (G. Fisher, Aberdare). Female, aged 21; married; temperate; sufficiently fed. Locality, high, dry, exposed; atmosphere, wet, cold. No previous rheumatism. Present attack followed tonsillitis 12 days, and exposure to wet 2 days previously; it was severe, with considerable sweating; pain lasted two days, and the whole attack 28 days; many joints were involved. Treatment was (1) salicylates; (2) alkalies. Reporter remarks: "No effect from treatment 1; marked improvement under treatment 2."

646 (G. W. Stevens, M.D., Liverpool). Male, aged 29; single; clerk; temperate; sufficiently fed. Locality, high, damp; atmosphere, wet, cold; wind E. Patient had scarlet fever and measles in childhood. Present attack followed exposure to wet and cold on the previous day; it was severe, with considerable sweating. Duration of fever and pain 8 days and 12 days respectively, of the whole attack 21 days; many joints were involved. Patient suffered from neuralgia and general debility. Treatment was (1) sodium salicyl., 15 grains every 3 hours for the first 2 days; (2) sodium salicyl. (dose reduced) and alkalies, blisters, etc. Reporter remarks: "Salicylate treatment had very little, if any, control over pain."

Of the total number, 655 cases, 536 were treated with salicin, salicylic acid, or its salts. In the majority of the cases other drugs were combined with the supposed specific, which failed in only 22 cases, or 4.10 per cent., namely, 10 males and 12 females. Of these, salicylates failed in 16 cases.

No. 22. Sod. salicyl., 15 grains every 3 hours caused gastro-enteritis and hæmatemesis.

No. 79. Salicylate failed, while rapid effect was obtained from alkalies and potass. iod.

No. 418. Salicylate failed, in doses of 15 grains every 4 hours, while quinine was successful.

No. 419. Quinine and salicylates (15 grains every 4 hours) failed, while alkalies and potass. iod. gave a good result.

No. 448. Salicylates failed, while salicin succeeded.

No. 644. Salicylates failed, while alkalies succeeded. In 5 cases salicin failed. Of these:

No. 201. Salicin (dose not stated) failed, while salicylates (1 scruple) with alkalies every 4 hours gave good results.

No. 290. Salicylate (1 scruple every 2 hours) gave good results. With salicin in same doses the temperature rose, and the murmur, which had disappeared under salicylates, returned.

No. 531. Salicin and actæa racemosa failed, while salicylic acid and guaiacum gave great relief.

In 1 case (332) salicylic acid failed; dose not stated.

In 1 case (212) a failure was experienced, but the form of the drug, that is, whether salicin, salicylic acid, or its salts, is not stated.

From recent experience of the treatment of rheumatism by salicylic acid and its salts, the conclusion to be drawn from its failure in the above quoted cases is that the dose administered was far too small, or was not repeated at sufficiently short intervals.

SALICISM.

Untoward symptoms are noted in the report as resulting from the employment of salicin, salicylic acid, or its salts in 14 cases out of the 536, or in 2.59 per cent.

No. 10 (Basil G. Morrison, M.B., Canonbury). Male, aged 30, oilman, temperate. Had 1 previous rheumatic attack at 23, and an old regurgitant mitral murmur. Present attacks moderate, with considerable sweating. Patient was dyspeptic for a fortnight before the attack, which began with severe muscular pain in the neck and back, but with little or no fever at this stage. Sodium salicyl. 15 grains every hour produced "salicisim."

No. 22 (J. A. Erskine Stuart, Healey, Batley). Male, aged 23, blacksmith, temperate. Had had several previous attacks of rheumatism, and had "congenital mitral disease inherited from his mother." Present attack severe, with considerable sweating. Sodium salicyl., 15 grains every 3 hours, relieved the joint affection in 2 days, but produced gastro-enteritis and hæmatemesis. Patient died on the seventh day from "serious cardiac complication."

No. 61 (A. G. McKenzie, Much Wenlock). Female, aged 19, single, living at home, temperate. Had had one previous attack of rheumatism at 17, which had lasted 6 weeks under alkaline treatment. Present attack moderate, with considerable sweating. Sodium salicyl., 12 grains every 4 hours, was administered till salicisim supervened, and was then repeated thrice daily. The attack lasted 4 days only, and recovery was complete.

No. 87 (E. B. Mansell, Hastings). Male, aged 24, carpenter, temperate. No previous rheumatism. Patient had scarlet fever in childhood, and an ischio-rectal abscess 3 years previously; had been exposed to wet and cold a fortnight before. The attack was severe, and all ended with slight sweating. Sodium salicyl. was administered first, in one-scruple doses every 4 hours, and then salicin in the same doses. The salicylate caused great nervous disturbance and delirium, but did not ease the pain; salicin produced marked benefit. The attack lasted 16 days, and recovery was complete.

No. 116 (J. McEwan, M.B., Helensburgh). Female, aged 24, single, living at home, temperate. Had had 1 previous attack of rheumatism at 15; biliousness 1 month ago; unwell and shivery ever since; was liable to sore-throat and asthma (?). The attack was of moderate severity, with considerable sweating. Salicin was administered, half a drachm every 2 hours, from the fifth day; (2) sodium salicyl. (dose not stated) on the eleventh day; (3) salicin again. Patient became deaf, "probably due to salicisim; an acute attack of delirium about the time that sod. salicyl. was given, lasting about 2 days." The whole attack, inclusive of a relapse from slight exposure, lasted 28 days. Recovery was complete.

No. 187 (Edward Williams, M.D., Wrexham). Female, aged 29, married; temperate. Had had one previous attack of rheumatism at 25. Present attack moderate, with considerable sweating. Sodium salicyl. was first administered, and then potash in large

doses. The salicylate produced tinnitus, and was then dropped. The attack lasted 21 days. Recovery was partial.

No. 223 (A. S. Underhill, Tipton). Male, aged 41; innkeeper; temperate. No previous rheumatism, but had had peritonitis (date not given). The attack was severe, with considerable sweating. Sodium salicyl. was administered in half-drachm doses, and caused vomiting, diarrhoea, and headache; pain recurred when it was omitted. Under tonics recovery was complete in 56 days.

No. 229 (E. A. Laurent, M.B., Bedford). Female, aged 25, single; nursemaid; temperate. Two previous attacks of rheumatism, the first about 18. She had had 2 attacks of tonsillitis between 15 and 17; measles and whooping-cough as an infant. The attack was severe, with considerable sweating; many joints were affected. Treatment was (1) sod. salicyl.; potass. iod.; potass. bicarb. for 2 days only; (2) alkalies. Patient was "unable to take the salicylate;" the pains were aggravated at the menstrual period, which occurred on the sixth day of the attack. She was convalescent on the eighteenth day.

No. 297 (L. W. K. Phillips, Hove). Male, aged 13, schoolboy. Measles 11 years previously; no previous rheumatism. Tonsillitis 12 days before present attack, which was of moderate severity, with slight sweating. Many joints were affected, and pericarditis supervened during the attack. Sodium salicyl., half a scruple to 1 scruple, was administered every 2 hours at first, and produced delirium. It was therefore omitted for 1 day, and then recommenced, and gradually reduced for a month. Patient convalescent on the twenty-first day.

No. 428 (T. F. Raven, Broadstairs). Female, aged 35, married; lady; temperate. One previous attack of rheumatism at 23. Patient was anæmic; parturition 14 days previously; "over-fatigue from suckling." The attack was of moderate severity, but sweating was considerable; many joints were affected. Treatment was (1) salicylic acid; (2) quin., iron, arsenic, and alkalies. Salicylic acid was not tolerated; all drugs failed; and the case "gradually emerged into a condition resembling rheumatoid arthritis."

No. 508 (D. J. Mackenzie, M.D., Glossop). Male, aged 34; mason; intemperate; hitherto free from rheumatism. Present attack severe, with considerable sweating, and many joints were affected. Treatment was: (1) sod. salicyl., 15 grains, every 3 hours for 2 days; (2) potass. bromid. and bicarb.; (3) salicylate resumed. The salicylate produced deafness and delirium; no fall of temperature till No. 2 was commenced.

No. 566 (H. B. Pullen Burry, Liphook, Hants). Male, 31; carpenter; teetotaler. No previous rheumatism. Diarrhoea 12 days, and exposure to cold 6 days previously. Present attack severe, with considerable sweating. Few joints were affected. Treatment was: (1) alkalies for 36 hours; (2) potass. salicyl. was given when the temperature was 105.3° F., and 6 days later was 102.8°, when the patient was nearly poisoned, with blackish urine (the drug being presumably contaminated with phenol), and very diæretic pulse. Delirium was absent. Recovery was complete.

No. 598 (G. Birt, M.B., Stourbridge). Male, aged 30; firebrick maker; intemperate. Patient had had 2 previous attacks of rheumatism; the first 5 years ago. Tonsillitis 9 days previously, and was liable to sore throats. He was fat. Present attack severe, with considerable sweating. On the second day sod. salicyl. was administered in 15-grain doses every 4 hours, but was omitted on account of distressing tinnitus. Pericarditis supervened during the attack. On the fifty-sixth day recovery was "nearly complete."

No. 642 (W. E. Green, Sandown, I.W.). Male, aged 24; soldier; temperate. No previous rheumatism. Present attack severe, with considerable sweating; many joints were affected. Treatment was: (1) sod. salicyl. for 2 days; (2) salicin for 1 day; (3) alkalies. Patient "unable to take either salicylate or salicin," "consequently the case ran the old-fashioned course," and recovery was complete after 40 days.

The toxic symptoms which occasionally follow the administration of the salicylates may doubtless often be accounted for by phenol contamination, as was the case in No. 566; but from the immunity of the great majority of the patients from such evil effects, it may be assumed that these drugs, as used in this country, are tolerably pure. In hospital practice it is by no means uncommon that a contaminated supply is sent in, and then toxic symptoms are the rule, even with small doses.

Of these 14 cases, 9 were males and 5 females. The most advanced age of the patients was 41 (No. 223); the youngest, 13 (No. 297).

Two of the males (Nos. 503, 508) were intemperate; 1 (No. 566) was a total abstainer; the remainder were temperate.
 The attack was severe in 7 males and 1 female.
 " moderate in 2 " 4 females.
 " considerable in 7 " 5 "
 " slight in 2 " "

TOXIC SYMPTOMS.

Salicisism (definite symptoms not stated) in Nos. 10, 61, 220, 428, 643=2 males and 3 females.
 Deafness and delirium in Nos. 116, 503=1 male and 1 female.
 Tinnitus in Nos. 187, 598=1 male and 1 female.
 Delirium in No. 297=1 male.
 Nervous disturbance in No. 87=1 male.
 Vomiting, diarrhoea, headache, in No. 223=1 male.
 Delirium, mucous pulse, and blackish urine, in No. 566=1 male.
 Gastroenteritis and hæmatemesis in No. 22=1 male.

DOSE ADMINISTERED.

The dose of the drug is omitted, or it is not stated how often the drug was repeated in 6 of the cases, so that no conclusion can be drawn under this head; suffice it to say that the largest dose given was in No. 116, female, aged 24, namely, salicin half a drachm every two hours, followed on the fifth day by sod. salicyl., with a reversion to salicin (date not given); that the acute delirium supervened about the time the salicylate was commenced; that deafness probably existed before the patient took the salicylate.

The smallest recorded dose which produced toxic symptoms was (No. 61) gr. xij, of sodium salicylate, given every four hours, to a female, aged 19, with a moderate attack, but considerable sweating.

Examination of the 14 cases shows no relation between the amount of sweating or the severity of the attack and the toxic effects of the drug.

EXTENT OF JOINT AFFECTION.

The numbers under this head came out as follows;

	Cases.
Pains migratory—many joints affected	383
" " " few " "	73
Many " joints" affected	18
" " " pains fixed	85
Few " " " "	16
One joint affected	4
Not mentioned	4

A.—It was found that in cases where the pains were migratory, and many joints affected,

That the locality was:

Cases.		Cases.	
High, dry, and exposed	100	High	6
Low, damp, and confined	56	Not mentioned	5
High and dry	36	Low and confined	4
Low, damp, and exposed	33	Damp and exposed	4
Low and damp	22	Damp	3
High and exposed	17	At sea	2
Low, dry, and confined	16	Low, dry, and exposed	2
High, damp, and exposed	16	Confined	1
Low and dry	12	Medium	1
High, dry, and confined	10	Travelling	1
High, damp, and confined	7	Damp and confined	1
Dry	6	Low	1
Low, dry, and exposed	6		
High and damp	6		383

That the atmosphere was:

Cases.		Cases.	
Wet and cold	112	Dry, mild, and changeable	9
Damp, mild, and changeable	33	Dry	7
Damp and cold	31	Mild	7
Dry and hot	30	Dry, cold, and changeable	6
Dry and cold, with sunshine	28	Damp and mild	3
Changeable	20	Dry, cold, with snow	2
Wet, mild, and changeable	16	Cold	1
Not mentioned	14	Damp	1
Wet and changeable	13		
Cold and changeable	10		283

That the wind was:

Cases.		Cases.	
E.	60	S.E. to S.W.	1
N.E.	41	N.W. to E.	1
S.W.	38	E. to N.	1
S.E.	34	W.S.W. to N.W.	1
W.	24	W. to E.	1
N.W.	22	Variable	2
N.	7	Not mentioned	146
N. to E.	5		
S.	19		383

Of the 237 cases out of the total of 383 in which the direction of wind was mentioned, it had an easterly direction in 141 cases, or 59.45 per cent.

B.—Where the pain was migratory and few joints affected, That the locality was:

Cases.		Cases.	
High, dry, and exposed	18	No fixed abode	2
Low, damp, and confined	8	Dry and confined	2
Low and damp	7	Low, dry, and exposed	1
Low, damp, and exposed	7	Low	1
Low and dry	4	Low and confined	1
High and dry	4	High and damp	1
Low, dry, and confined	3	High, dry, and confined	1
High, damp, and exposed	3	Damp and changeable	1
Damp	2	Damp and cold	1
High	2		
High, damp, and confined	2		73

That the atmosphere was:

Cases.		Cases.	
Wet and cold	20	Changeable	3
Dry	10	Damp and mild	2
Wet and mild	9	Damp, mild, and changeable	1
Damp and cold	8	No fixed abode	1
Dry, cold, with sunshine	6	Not mentioned	1
Dry and hot	5		
Wet	4		
Wet and changeable	3		

That the wind was:

Cases.		Cases.	
S.W.	13	N.	2
E.	11	S.	2
N.E.	10	N.E. to S.W.	1
W.	7	E.S.E.	1
N.W.	4	Not mentioned	18
S.E.	3		
E.N.E.	3		73

Of the 55 cases out of the total of 73, in which the direction of the wind was mentioned, it had an easterly direction in 27 or 49.09 per cent.

C.—Where the pain was fixed and many joints were affected,

That the locality was:

Cases.		Cases.	
High, dry, and exposed	18	Exposed	3
Low, damp, and confined	11	Dry	1
Low, damp, and exposed	8	Dry and exposed	1
High, dry, and confined	6	High	1
Low and damp	5	Low, dry, and exposed	1
High and dry	3	High and damp	1
Low, dry, and confined	3	Confined	1
Low and dry	2	High and dry	1
High and exposed	2	Not mentioned	1
High, damp, and exposed	2		
Low and confined	1		73

That the atmosphere was:

Cases.		Cases.	
Wet and cold	21	Damp and cold	3
Changeable	12	Mild	2
Damp and cold	6	Dry	1
Damp and mild	6	Cold, with sunshine	1
Dry and hot	5	Cold and changeable	1
Wet and mild	5	Not mentioned	1
Dry and cold	4		
Wet	4		72

That the wind was:

	Cases.		Cases.
E.	19	N.W.	2
S.W.	8	N.	2
N.E.	7	Not mentioned	20
S.E.	5		72
W.	5		
S.	4		

Of the 52 cases out of the total of 72 in which the direction of wind was mentioned, it had an easterly direction in 31 cases, or 59.61 per cent.

D.—Where the pain was fixed and few joints affected,

That the locality was:

	Cases.		Cases.
Low, damp, and confined	16	Low, dry, and confined	3
High, dry, and exposed	14	Low and dry	2
High, dry, and confined	11	Low, damp, and exposed	2
High and dry	8	Damp and confined	1
High and exposed	6	Low and confined	1
Low and damp	5	Damp	1
High, damp, and exposed	4	At sea	1
High and damp	3	Not mentioned	1
Low, dry, and exposed	3		—
High	3		85

That the atmosphere was:

	Cases.		Cases.
Wet and cold	27	Dry and cold	2
Damp and cold	9	Changeable	2
Dry and hot with sunshine	9	Dry and changeable	2
Wet and mild	5	Cold and changeable	1
Dry and mild	5	Mild and changeable	1
Damp and mild	5	Damp and changeable	1
Not mentioned	5	Cold	1
Wet	4		—
Dry and cold with sunshine	4		85
Damp	2		

That the wind was:

	Cases.		Cases.
E.	13	N.W.	4
S.W.	12	E. to W.	3
W.	7	Not mentioned	28
N.E.	6		85
S.E.	6		
N.	6		

Of the 57 cases, out of the total 85, in which the direction of the wind was mentioned, it had an easterly direction in 28, or 24 per cent.

E.—Where many joints were affected (no mention being made as to whether the pain was migratory or not),

That the locality was:

	Cases.		Cases.
High, dry, and exposed	4	High	1
Low, dry, and confined	2	Low, dry, and exposed	1
Low, damp, and exposed	2	High and exposed	1
Low, damp, and confined	2	Dry and confined	1
Dry	2		—
High, damp, and exposed	2		18

That the atmosphere was:

	Cases.		Cases.
Wet and cold	7	Dry and hot	1
Wet and mild	3	Dry and cold	1
Changeable	3	Dry	1
Dry and mild	1		—
Wet	1		18

That the wind was:

	Cases.		Cases.
E.	5	Not mentioned	4
S.W.	5		—
S.E.	2		18
W.	1		

Of the 14 cases, out of the total of 18, in which the direction of the wind was mentioned, it was easterly in 7 cases, or in 50 per cent.

F.—Where few joints were affected (no mention being made as to whether the pain was migratory or fixed),

That the locality was:

	Cases.		Cases.
High, dry, and exposed	4	High	1
Low, damp, and confined	2	High, dry, and confined	1
High and exposed	2	High, damp, and exposed	1
Dry and confined	2		—
High and dry	2		16
Low and damp	1		

That the atmosphere was:

	Cases.		Cases.
Wet and cold	6	Wet and mild	1
Wet	2	Damp and cold	1
Dry and hot	2	Not mentioned	1
Dry and cold	2		—
Mild	1		16

That the wind was:

	Cases.		Cases.
E.	4	Variable	1
S.W.	2	Not mentioned	1
S.E.	2		—
N.E.	2		16
N.W.	1		

Of the 15 cases, out of the total 16, in which the direction of the wind was mentioned, it was easterly in 8, or 53.3 per cent.

G.—Where the pain was fixed, one joint only being affected.

That the locality was:

	Cases.
Low and damp	1
High, damp, and exposed	1
Low, dry, and exposed	1
High and dry	1

That the atmosphere was:

	Cases.
Changeable	1
Wet and cold	1
Dry and cold	1
Not mentioned	1

That the wind was:

	Cases.
E.	1
W.	1
Not mentioned	2

H.—Where pain was absent,

That the locality was:

	Cases.
High, dry, and exposed	1
High and exposed	1

That the atmosphere was:

	Cases.
Dry and cold	1
Wet and cold	1

That the wind was:

	Cases.
E.	1
N.E.	1

(In 3 cases no mention was made as to pain or joint affection.)

Further analysis of the above tables shows:
1. That the direction of the wind was mentioned in 432 cases, and that it was easterly in 244, or 56.48 per cent.

Under locality, taking the first four headings under which the majority of the cases occurred, the following order is observed:—

	A.	B.	C.	D.	E.	F.	G.	H.
1	High, dry, exposed	High, dry, exposed	High, dry, exposed	Low, damp, confd.	High, dry, exposed	High, dry, exposed	Low, damp	High, dry, expd.
2	Low, damp, confd.	Low, damp, confd.	Low, damp, confd.	High, dry, exposed	Low, dry, confined	Low, damp, confd.	High, damp, expd.	High, exposed
3	High, dry	Low, damp	Low, damp, expd.	High, dry, confined	Low, damp, expd.	High, exposed	Low, damp, expd.	—
4	Low, damp, expd.	Low, damp, expd.	High, dry, confined	High, dry	Low, damp, confd.	Dry, confined	High, dry	—

Similarly under atmosphere the following is the result:—

	A.	B.	C.	D.	E.	F.	G.	H.
1	Wet and cold	Wet, cold	Wet, cold	Wet, cold	Wet, cold	Wet, cold	Wet, cold	Wet, cold
2	Dmp., mid., chngble	Dry	Changeable	Damp, cold	Wet, mild	Wet	Changeable	Dry, cold
3	Damp, cold	Wet, mild	Damp, cold	Dry, hot	Changeable	Dry, hot	Dry, cold	—
4	Dry, hot	Damp, cold	Damp, mild	Wet, mild	Dry, mild	Dry, cold	—	—

A. = many joints affected; pains migratory.
 B. = few " " " " " " " " " " " "
 C. = many " " " " " " " " " " " "
 D. = few " " " " " " " " " " " "

E. = many joints affected; no mention as to pain being migratory or fixed.
 F. = few " " " " " " " " " " " "
 G. = one joint " " " " " " " " " " " "
 H. = where pain was absent.

CARDIAC COMPLICATIONS.

1. Cases in which pericarditis and endocarditis were coexistent. Pericarditis and endocarditis occurred synchronously in 57 cases, or 8.70 per cent., namely, males 29, or 4.427 per cent.; females 28, or 4.274 per cent.

Of these, 2 deaths occurred, both females, aged 29 and 22, and both were treated with salicylic acid.

The following figures show the result under the various treatment employed:

	Males.	Females.
Recovery complete, from the rheumatism, etc.:		
Salicylates ...	10	11
Salicylic acid ...	4	—
Salicylates and alkalis ...	3	1
Salicin and salicylates ...	—	2
Quinine and salicylates ...	1	1
Alkalis ...	1	2
Recovery partial:—

Table showing the period of life at which these affections occurred:—

Between	Males.	Females.
1 and 10 ...	4	2
10 " 20 ...	8	11
20 " 30 ...	7	12
30 " 40 ...	7	0
40 " 50 ...	2	4
	28	29

The greater number in each case occurred between the second and third decades.

PERICARDITIS.

Pericarditis occurred alone in 54 cases, or 8.24 per cent., namely, in 27 males and 27 females.

If this number be added to that of the pericarditis and endocarditis combined, we have 57 + 54 = 111, or 16.94 per cent., of pericarditis in the whole of the recorded cases.

Among these cases 6 died, namely:

No. 12. Male, aged 34, of intemperate habits.

No. 238. Female, aged 11.
 No. 245. Male, aged 4,
 No. 281. Female, aged 68.
 No. 463. Female, aged 16. Death in this case was from bronchitis.

No. 627. Male, aged 6. Death in this case was from embolism. These fatal cases will be considered more in detail under the head of deaths (see p. 401).

Forty of the cases, or 70.17 per cent., were treated, from the commencement of the attack or during its course, by salicin, salicylic acid, or its salts, but the information to be gathered from the tables is necessarily limited; no data are therefore available to show what is the effect of this drug on the serous membrane.

The greater number of cases occurred in males between the second and third decade, and in females between the first and second.

Between	Males.	Females.
1 and 10 ...	2	0
10 " 20 ...	5	14
20 " 30 ...	10	6
30 " 40 ...	8	1
40 " 50 ...	1	5
60 " 70 ...	—	1
Age not stated ...	26	27
	1	—
	27	—

The most advanced age at which pericarditis occurred was in (281) a female, aged 68; the youngest was (245) a male, aged 4.

Table showing the Different Recent Murmurs (that is, Murmurs which Supervened during the Present Attack). They are classed under two heads, namely, those which Recovered and those which were Persistent, and are grouped in columns according to the treatment of each case.

RECOVERY.

	Salicyl.	Alkal.	Alk., etc.	Salicin	Salic.A.	No ment.	Total.
Aortic systolic ...	7	2	—	—	—	—	9
Aortic diastolic ...	2	—	—	—	—	—	2

(Chorea is treated of in a separate section, see page 393.)

HYPERPYREXIA.

Four cases are included under this heading, in which the temperature at any time exceeded 107° F. Of the 4, three were fatal and 1 recovered.

No. 208 (G. W. Homan, Lichfield). Male, aged 47, baker, of temperate habits. Locality, high; atmosphere, dry but changeable; wind S.W. There had been four previous attacks of rheumatism. Present attack mild, but attended by considerable sweating. Patient had been exposed to cold, and shock of his son's death. Many joints were affected, and the pains were migratory. There was no cardiac disease. Treatment was: (1) potass. bicarb. and iod. sod. salicyl.; (2) quinine and opium. For the first 5 days there was wandering pain, but no fever or constitutional disturbance. On the sixth day temperature rose to 101.4° F., and remained between that and 102.2° F. until the nineteenth day. On the evening of the nineteenth day it rose suddenly to 107.4° F., and death ensued.

No. 209 (G. W. Homan, Lichfield). Male, aged 27. (This patient, in the preliminary report published by the Subcommittee in July, 1883, is said to have been a son of the above, 208). Single, a clerk, of temperate habits. No mention is made as to locality; atmosphere, mild and changeable; wind (?) N.W. There had been one previous attack of rheumatism at 19, and the patient had chorea in childhood. He had been exposed to cold 3 weeks previously. The attack was moderate in severity, attended by considerable sweating. Many joints were affected; the pains were fixed. An old regurgitant mitral murmur existed at the time of the present attack. Treatment was: sod. salicyl. 15 grains every 3 hours, and ice packing for the high fever. The case did well till the seventh

day, when sweating ceased, and in the evening the temperature rose to 110° F. He died in 5 hours, with a temperature of 106.9° F.

No. 531 (C. Boyce, M.B., Maidstone). Male, aged 43; intemperate; a vinegar maker. Locality, high and exposed; atmosphere, wet and cold. Patient had had a previous rheumatic attack at 35, and was constantly exposed to wet; the attack was severe, and attended by considerable sweating; many joints were affected; the pains migratory; there was an old mitral murmur (systolic). During the second day of the attack a miliary eruption appeared; the patient was, moreover, liable to dyspepsia and ulceration of the mouth. Treatment (1) sod. salicyl., 15 grains every 4 hours; (2) pot. bicarb.; (3) "cold sponging for hyperpyrexia." The temperature, which reached 107.2° on the fourteenth day, fell 5° in 3 hours under cold sponging. Duration of fever 23 days, of pain 11 days, of whole attack 105 days. Recovery was complete.

No. 560 (James Kaye, M.B., Bromsgrove). Male, aged 35; gardener; temperate. Locality, high and exposed; atmosphere, cold and changeable; wind E. He had been exposed habitually to sudden chills. The attack was a moderate one, with considerable sweating; many joints were involved; the pains were migratory; there was no cardiac complication; in the early part of the attack erythema made its appearance, and, later, sudamina. No previous rheumatic affection. Treatment: (1) pot. iod. and bicarb., with colchicum; (2) sod. salicyl., half a scruple every 2 hours, then 15 grains with sod. bicarb. half a drachm; (3) quinine, half a scruple dose; brandy; cold sponging. From the first to the fourth day the disease simulated gout; from the fourth to the seventh day pain and swelling nearly gone, when patient persisted in going out. On eighth day pain and swelling recurred, but the temperature was nearly normal. On twelfth day temperature 102°; rheumatic fever well developed. All went well till twenty-first day, when hyperpyrexia set in, which, though at first checked by treatment, proved fatal on twenty-third day. Temperature on twenty-first day 110°, on twenty-third 108.6°. The more important facts are shown in the subjoined table:—

Sex.	Age	Habits.	Previous Rheumatic Attacks.	Recent Antecedents.	Heart Disease.	Date of Onset of Hyperpyrexia.
Male	47	Temperate	4	Expd. to cold	None	6th day
..	27	..	1	..	Old mitral	7th ..
..	43	Intemperate	1 wet	..	14th ..
..	35	Temperate	None chills	None	21st ..

RELAPSING CASES.

Out of the whole number of recorded cases, instances of relapse of the rheumatic affection is noted in 70 patients, or 10.68 per cent., namely, males, 44; females, 26. Some had only one relapse, but in 6 males and in 2 females the relapses are stated to have been many. Among the 44 males occurred 63 relapses, and among the 26 females 30 relapses. Search among the tables was then made with the view of ascertaining whether or no treatment had any effect in preventing this recurrence of the rheumatism, but in vain. It was found that 97.18 per cent. of these relapsing cases were treated with salicin, salicylic acid, or its salts, chiefly sodium salicylate.

The only case requiring any special note is, perhaps, No. 155, a male, aged 15, who was immediately benefited by salicylic acid continued for 3 days; at the end of this time it "was omitted, as the patient loathed it." Potass. bicarb. and colchicum was substituted, with the result of an immediate relapse, and a rapid recovery on sodium salicylate. The duration of the fever was 10 days, of the pain 4 days, of the whole attack 10 days. The lad had suffered from two previous attacks of rheumatism, the first 5 years previously.

DEATHS.

In the 655 cases in the tables death occurred in 22, or 3.30 per cent., of which 12 were males and 10 females; 10 were temperate, 3 were intemperate, 8 were total abstainers, and in 1 case no mention is made as to drinking habits; 18 of the cases, or 81.81 per cent., were treated with salicin, salicylic acid, or its salts.

Percentage of deaths in

Total abstainers	...	5.36 per cent. (140 cases)
Temperate	...	3.74 .. (264 ..)
Intemperate	...	8.82 .. (34 ..)

The following table, taken almost verbatim from the tabulated report, gives the more important facts connected with each case:—

Number.	Age.	Sex.	Heart Complications.	Previous Attacks of Rheumatism.	Treatment.	Recent Antecedents.	Day of Death.	
12	34	M.	Pericarditis and mitral regurgitation	—	Quin., ammon., blister, opium, whisky	Exposure to cold and over-fatigue	7th	—
92	23	M.	Mitral regurgitation	Several	Sodium salicyl. and alkali	—	7th	Salicylate caused gastro-enteritis and hæmatemesis. Death from enteric fever.
47	14	F.						
112	47	F.	—	—	—	Exposure to cold and over-fatigue	14th	Dilatation of heart. Temperature, 105.6° F. on 12th day.
119	13	M.	—	—	—	" " "	18th	
165	29	F.	Pericarditis	—	Salicylic acid, calom., op., blister	" " "	11th	Apparently a case of primary endocarditis, followed by congestion of lungs. Temperature 107.4° F., sudden rise before death.
181	40	F.	Presystolic murmur	Several	Sod. salicyl., calom. and opium, leeches to heart	" " "	8th	
208	47	M.	—	4	Sod. salicyl., alk., op., quinine	Exposure to cold and shock	19th	Temperature 110° F. Death from bronchitis and asphyxia.
209	27	M.	Mitral regurgitation	1	" " ice pack	" " "	7th	
238	11	F.	Pericarditis	—	1 salines, 2 sod. salicyl.	" " "	7th	Death from pericardial effusion and exhaustion.

281	68	F.	Pericarditis and mitral regurgitation	?	Sodium salicyl.	—	30th	Death from meningitis.
455	22	F.					Salicylic acid, ammon., port wine	
463	16	F.	—	2	Sod. salicyl. and stimulants	" " "	14th	Death from acute bronchitis. temperature 105.4° F. Temperature 105.8° F.
529	38	M.	Mitral stenosis	—	Sod. salicyl., alk.	Exposure to cold and over-fatigue	18th	
538	20	F.	Endocarditis	—	Sod. salicyl., alk., blister over heart, digit., ammon., strychn.	Exposure to cold and wet	14th	Death from cardiac complications.
544	18	M.	Pericarditis	1	Sod. salicyl.	?	25th	
550	18	F.	Aortic obstruction	—	Sod. salicyl., ammon., alch.	—	—	Death from aortic pulmonary and mitral disease. Temperature, on 21st day, 110.4° F.
580	38	M.	? Mitral regurgitation	—	Alk., pot. iod., colchic., quini., alch., cold sponging	Habitual exposure to sudden chills	23rd	
593	24	M.	Murmur	—	Sod. salicyl., blister over heart*	Exposure to cold and damp	6th	Heart's action suddenly ceased.
594	53	M.	—	—	Rest, stimulants, warmth to joints	Exposure to wet and cold	7th	
627	6	M.	Pericarditis	3 or 4 subacute	Sod. salicyl., alk., quini., bromides and chloral for chorea	?	40th	Death from embolism.

SKIN ERUPTIONS.

Skin eruptions are recorded as shown in the following table:

Before (the attack).		During.		After.	
Cases.	Cases.	Cases.	Cases.	Cases.	Cases.
Eczema ...	22	Sudamina ...	46	Urticaria ...	9
Urticaria ...	11	Miliaria ...	13	Sudamina ...	1
Acne ...	5	Erythema ...	12	Miliaria ...	1
Erythema ...	1	Urticaria ...	10	Acne ...	1
Erythem. nodos. ...	1	Eczema ...	8	Erythema ...	1
Psoriasis ...	1	Purpura ...	5	Purpura ...	1
Schorrhœa ...	1	Erythem. nodos. ...	4	Herpes zoster ...	1
Papular ...	1	Acne ...	3	Papular ...	1
Lepra ...	1	Psoriasis ...	2	Lichen ...	1
Rashes ...	1	Lichen ...	2	Erysipelas ...	1
Acne rosacea ...	1	Vesicular ...	2		
Pustular (10 yrs.) ...	1	Herpes zoster ...	1		
Tinea tonsurans ...	1	Papular ...	1		
Sycosis ...	1	Peliosis rheumat. ...	1		
		Macule ...	1		
		Herpes labialis ...	1		
		Syphilitic roseola ...	1		
		To which may be added:			
		Rose rash ...	2		
		Erysipelas ...	1		
		Typhus ...	1		

Sudamina being such a frequent concomitant of rheumatic fever, it was thought desirable to investigate the connection (if any) between the eruption and the severity of the attack and the extent of diaphoresis. The following table is drawn with the view of showing this:

Attack severe, sweating considerable; males, 20; females, 9 = 29	
" moderate " " " " 8 " 6 = 14	
" (?) " " " 2 " = 2	
" severe " slight " 1 " = 1	
	46

SUBCUTANEOUS NODULES.

Of this affection 36 cases or 5.49 per cent. are mentioned—

They occurred at the following ages:		Male.		Female.	
Age.	Male.	Female.	Age.	Male.	Female.
26	1	—	26	1	—
25	1	—	25	1	—
24	2	—	24	2	1
22	1	—	22	1	1
21	—	—	21	—	1
19	—	—	19	—	3
17	1	—	17	1	—
16	—	—	16	—	1
13	—	—	13	—	1
12	—	—	12	—	—
10	—	—	10	1	—
7	—	—	7	—	1
19	—	—	19	—	16

In one male the age is not given. Nineteen or 52.7 per cent. of those who were affected with subcutaneous nodules had suffered from previous attacks of rheumatism.

The following table shows the number of previous attacks in each case, together with the date of the first.

Age.	Sex.	Previous Attacks.	Age at First Attack.	Age.	Sex.	Previous Attacks.	Age at First Attack.
37	M.	5 or 6	3 to 7	25	M.	3	Childhood
52	M.	1	20	24	M.	1	20
50	F.	1	39	24	F.	1	15
49	M.	1	15	22	F.	3	18
42	F.	3	39	19	F.	2	8
37	M.	Many	31	19	F.	2	13
34	F.	5	16	19	F.	1	14
32	F.	1	24	17	M.	2	13
30	M.	6	9	16	F.	2	8
26	M.	1	18				

Table showing the liability of those affected with Subcutaneous Nodules to Skin-Disease or other Ailments.

Age.	Sex.	Disease.
57	M.	Eczema for 15 years.
53	M.	Bronchitis.
52	M.	Prickly heat in India.
50	F.	Sciatica; erythema, left leg.
49	M.	Miliaria on tenth day of the rheumatism.
45	M.	Alcoholic dyspepsia; debility.
42	F.	Eczema on wrist and ankles second to twelfth day of rheumatism.
42	F.	Great debility.
38	F.	Debility.
37	M.	Sudamina during rheumatism; anæmia.
35	M.	Syphilitic roseola.
34	F.	Neuralgia.
33	M.	Lumbago.
33	F.	Urticaria often.
32	F.	Gout.
30	M.	Eczema on twenty-sixth day of rheumatism.
25	M.	Acne often; erythema and miliaria during rheumatism.
24	M.	Urticaria 7 days before rheumatism.
24	M.	Acne for years.
24	F.	Eczema.
22	M.	Erythema and miliaria during rheumatism.
22	F.	Dyspepsia.
21	F.	Erythema nodosum on ninth day of rheumatism.
19	F.	Anæmia.
19	F.	Eczema 7 years; herpes labialis and conjunctivitis during rheumatism.
19	F.	Eczema 5 years; dyspepsia.
12	M.	Urticaria on fifth day of rheumatism.
17	F.	Erythema nodosum in first week of rheumatism.
?	M.	Gout.

Of the above tendency to skin disease is noted in 17 cases, or 47.2 per cent.

PREVIOUS ATTACKS OF RHEUMATISM.

Previous attacks of rheumatism are mentioned in 230 cases, or 42.74 per cent., namely:

Males ... 156, or 23.81 per cent.
Females ... 124, or 18.93 "

Of these:

The average age of previous attack of the whole number=18.27.
" " " males =18.58.
" " " females =17.89.

COMMON AILMENTS.

Under this head are mentioned various diseases to which the patients were liable apart from the rheumatic attack for which they were under treatment.

The numbers are as follows:

Neuralgic headaches	...	55 cases, or 8.39 per cent.
Dyspepsia	...	36 " 5.49 "
Neuralgia	...	20 " 3.05 "
Biliousness	...	18 " 2.74 "
Bronchitis	...	15 " 2.29 "
Anæmia	...	13 " 1.98 "
Dyspepsia and constipation	...	9 " 1.37 "
Epilepsy	...	4 " 0.61 "
Hæmorrhoids	...	4 " 0.61 "
Dysmenorrhœa	...	3 " 0.45 "
Eczema	...	3 " 0.45 "
Urticaria	...	2 " 0.30 "
Epistaxis	...	2 " 0.30 "
Glandular abscesses	...	2 " 0.30 "
Herpes labialis	...	2 " 0.30 "
Syncope attacks	...	2 " 0.30 "

And one case respectively of boils, ulceration of the cornea, gout and bronchitis, alcoholic dyspepsia, fever and ague, hæmoptysis, worms, dyspepsia and chronic Bright's disease, gout and headache, osteo-arthritis, chilblains, erythema nodosum, gonorrhœa, psoriasis, facial paralysis, periostitis, strumous, celiac, convulsions, otorrhœa.

Although neuralgia occupies the first and third places in the above list, the total number of cases in which a "nervous element"

prevailed amounts only to 79 (neuralgic headaches 55, neuralgia 20, epilepsy 4) cases out of 655. No very strong support, therefore, is furnished by the tables to the theory of the nervous origin of rheumatism.

SEQUELÆ.

Under this head the following ailments occur in order of frequency.

	Males.	Females.	Total.
Anæmia and debility	...	11	9
Chorea	...	4	7

		62	46
			108

Of the cases of chorea as a sequela the affection occurred:

No. 383, in a female aged 13, 6 months after recovery from the rheumatism.

No. 458, in a female aged about 30.

No. 466, in a male aged 9, both as an antecedent and a sequela.

No. 490, in a male aged 13, 14 days after recovery from the rheumatism.

CASES WHICH DESERVE SPECIAL NOTICE.

No 2 (Charles Ede, Guildford). A female, aged 40. The onset was very severe, and accompanied by delirium. During the attack slight pericarditis was developed.

No. 26 (Miles A. Wood, F.R.C.S., Ledbury). Male, aged 26; total abstainer. Had suffered 5 previous attacks, most of which, according to the report, occurred since his marriage 18 months previously, "as if nervous exhaustion had some effect." The other conditions are the same. "He is nervous and delicate."

No. 41 (P. Caldwell Smith, M.D., Motherwell, N.B.). Female, aged 34; total abstainer. Had had 5 previous attacks. She had old mitral disease, and suffered frequently from angina pectoris.

No. 57 (W. Carter, M.D., Liverpool). Female, aged 13. "The attacks came on immediately after a very severe fright, the child up to the moment of the fright being apparently quite well, and never having had any rheumatic symptoms before."

No. 104 (Alfred Eddowes, M.D., Market Drayton). Male, aged 30, previously free from rheumatism. During the present attack developed pericarditis and mitral regurgitation. He had two relapses, and in the second "the pulse dropped to 40."

No. 118 (Dove McCalman, M.D., Ballechulish). Male, aged 24

quarrier; temperate; previously free from rheumatism. A double mitral murmur developed during the attack, and "rapid dilatation of the heart occurred between the second and eighth day, accompanied by a rapid rise of temperature to 105.4° F."

No. 119 (same reporter). Male, aged 13, previously free from rheumatism. Had "rapid dilatation of the heart from the seventh day till death on the thirteenth day. Before the ninth day the temperature was between 101° and 102° F.; from the ninth day it gradually rose to 105.6° F. on the twelfth day."

No. 273 (W. Macfie Campbell, M.D., Liverpool). Female, aged 17½; temperate. Had had one previous attack of rheumatism. In the present attack "fever was the sole primary symptom, followed by erysipelas. Diagnosis was, therefore, difficult."

No. 282 (J. Lardner Green, Salisbury). Male, aged 25; clerk; temperate; previously free from rheumatism. "Rapid consumption set in within a fortnight, of which the patient died (having made a partial recovery from the rheumatism). No obvious signs of phthisis were noticed at the onset of the rheumatism."

No. 296 (R. P. Ogleby, Leeds). Female, aged 25; temperate; free previously from rheumatism. Suffered from acute pyelitis during the attack.

No. 299 (A. W. Mayo Robson, F.R.C.S., Leeds). Male, aged 16; pork butcher; temperate. Had pericarditis and mitral regurgitation during the attack, with absence of joint affection.

No. 325 (T. F. Pearce, M.D., Haslemere). Male, aged 16; intemperate; no fixed occupation. Pericarditis existed 6 days before the joint affection.

No. 336 (G. G. Whitwell, M.B., Shrewsbury). Male, aged 12; total abstainer; diet probably insufficient; previously free from rheumatism; subject to weekly epileptic fits before the onset of the rheumatism. During the attack he had no fits; since recovery the fits have recurred, often more severe than before.

No. 361 (H. R. Hadden, M.D., Dublin). Female, aged 42; temperate; subject to tonsillitis, but previously free from rheumatism. The rheumatic attack was accompanied by "tonsillitis and violent fever," which rapidly subsided under sodium salicylate. From the second to the thirteenth day the patient had eczema on the wrists and ankles, "the eruption being strictly confined to the joints, and attacking one after the other, just as rheumatism does."

No. 398 (G. H. Lilley, M.D., Portland). Male, aged 25; prison warder; temperate, and previously free from rheumatism. "The onset occurred while the patient was in bed for a fractured leg."

No. 419 (H. G. Orlebar, M.D., Elizabeth Street, S.W.). Female, aged 25; single; dressmaker; temperate. No previous rheumatism. Pericarditis and mitral regurgitation were developed during the attack. On the eighteenth day the patient had an attack of severe pharyngitis, with membranous exudation. Recovery complete on the twenty-first day.

Hæmorrhage occurred in three cases worthy of note; namely:

No. 337 (J. P. Willis, M.B., Bexhill). Female, aged 9; sufficiently fed; free from rheumatism hitherto. Patient had profuse epistaxis; slight vaginal discharge of blood.

No. 338 (same reporter). Male, aged 17, brother of the above. Had had one slight rheumatic attack previously. He suffered from profuse epistaxis before and after treatment commenced.

No. 557 (Harold Swale, M.B., Tavistock). Female, aged 20; nurse; total abstainer; previously free from rheumatism. She had severe epistaxis on the second, third, and fourth day (three-quarters of a pint each time). Mother and brother both hæmophilic.

These three patients were treated with sodium salicylate.

The tables were examined with the view of eliciting any facts as to—1, the effect of stimulants; 2, evidence of heredity of rheumatism; 3, the period at which cardiac complications occur; but, as no special inquiry was directed to these points in the formula submitted to the reporters, no information can be obtained from their reports.

THE will of Sir Joseph Ritchie Lyon Dickson, physician to the British Legation at the Court of Persia, has been proved; the personal estate valued at upwards of £7,000.

The senior medical students at the University of Pisa have agreed upon a strike of a novel kind. They have decided not to attend lectures until the five important chairs of clinical medicine, medicine, hygiene, general pathology, and materia medica, which have now been vacant for some time, have been filled up.

LECTURES

SUPPURATION AND SEPTIC DISEASES.

Delivered at the Royal College of Surgeons, February, 1888.

By W. WATSON CHEYNE, F.R.C.S.

Surgeon to King's College Hospital, and to the Paddington Green Children's Hospital; Examiner in Surgery at the University of Edinburgh.

LECTURE I.

In studying the effects of pathogenic bacteria on animals, we frequently see great differences between the effects of the same bacteria on different species of animals, and even on the same species under varying conditions. Inoculate guinea-pigs with tubercle bacilli and we constantly produce a rapid and general disease which has little or no tendency to remain localised, and no tendency to undergo spontaneous cure; we are naturally, therefore, tempted to look on the bacilli as the only noteworthy factor in the causation of the disease, and to think that with the discovery of the bacillus the etiology of the disease has been settled. On the other hand, if we turn our attention to man, we see that opportunities for infection with tubercle bacilli are frequently present without being followed by infection; that the disease assumes a variety of forms under a variety of external conditions; that it has comparatively little tendency to become generalised, and that it has a strong tendency to get well, either spontaneously or under the influence of treatment not directed against the parasites. It cannot be a matter of surprise if, under these circumstances, the clinical observer concludes that the etiology of the disease has not been solved by the discovery of the bacillus, or that he is inclined to regard the organism as a very small portion of the cause, or even as a secondary, and perhaps unnecessary accompaniment.

The fact is, however, that in these diseases we have two opposing forces before us—on the one side the bacteria, on the other the body, and these forces are by no means always equally matched, nor do they always bear the same relation to each other in different species of animals. In some animals the bacteria are more powerful than the body, the resistance on the part of the body being scarcely, if at all, evident; in other species of animals the same bacteria are much weaker than the body, and if they succeed in entering the animal organism at all, they only do so by the aid of other conditions, and when these conditions cease to act the bacteria again die out. In extreme cases these conditions, by determining the seat and the exact nature of the resulting disease, are apt to give rise to the erroneous belief that they are the essential ones.

This is well illustrated, not only by the example given, but also by the case of anthrax. Introduce a single anthrax bacillus into a guinea-pig, and the animal dies with certainty of a general disease, with only œdema at the seat of inoculation. On the other hand, introduce anthrax bacilli into rats, and we have a very different result, and one which varies according to the age of the animal and the other conditions of the experiment. The result of the injection into a young rat, for example, is that the animal becomes very ill—it may be, in some cases, even dies—while there is a production of sero-purulent fluid at the seat of inoculation. The older the rat, up to a certain point, the less are the general symptoms manifest, the purer is the pus which is formed at the seat of injection, and the sooner do the anthrax bacilli die out. In spite of these different results we must none the less admit that in each case the bacillus has been the essential cause of the disease, the difference in the characters of the disease being due to differences in the strength of the opposing forces. In the case of the guinea-pig infected with anthrax, the bacillus is so much more powerful than the body, that the symptoms of resistance on the part of the latter are completely obscured. In the case of the rats, on the other hand, the opposing forces are more or less equal in strength, and consequently other conditions, such as age, seat of inoculation, etc., come into play, and modify the character of the resulting disease.

In our surgical work we have to do with two diseases which

illustrate, in a very marked manner, the action of the various conditions necessary for their production. These are local tuberculosis and suppuration with its allied diseases. I had at first intended to discuss both these diseases from this point of view, and such a discussion would have led to important deductions as regards treatment, especially in the case of the tubercular surgical affections; but when I came to put the material together I found that it was far too great for the time at my disposal, and I therefore resolved to limit myself to a short sketch of the present state of our knowledge with regard to suppuration and septic diseases, with especial reference to the various conditions on the part of the body and on that of the organisms, which are of importance in the commencement and continuance of these affections: and I may at once say that, as regards suppuration, I shall only refer to the acute form, the question of chronic suppuration being intimately bound up with that of surgical tubercular diseases, and differing greatly in its pathology from the other.

DESCRIPTION OF THE PYOGENIC ORGANISMS.

Before going into further details on this subject, it will be most convenient to glance briefly at the various organisms which have been found in association with acute suppuration. These organisms are distinguished from each other by their microscopical appearances, by their characters on cultivation, and by their effects on animals. The information obtained by means of the microscope is not much; in fact, beyond telling us whether we have to do with bacilli or with cocci, and whether we have to do with streptococci or staphylococci, the microscope does not aid us. In order to obtain more precise information, it is necessary to employ various methods of cultivation, and, fortunately, as some of the organisms produce pigment, while others do not, as some liquefy gelatine, and others do not, and so on, we get further information of great value as regards the species present. In some cases, also, it is necessary to resort to the study of their effects on animals, in order to ascertain the existence of any differential character between the organisms.

1. *Staphylococcus Pyogenes Aureus*.—This is the organism most commonly present in acute suppuration. As its name implies, the organisms are cocci, which tend to arrange themselves in the form of bunches. They grow readily at the ordinary summer temperature, but most rapidly above 30° C. When grown in gelatine they soon cause liquefaction of that medium, with the development of an orange-coloured deposit. When grown on agar, kept at the body temperature, we see, even after twenty-four hours, a whitish or light yellow opaque layer at the point of inoculation, which soon becomes more distinct and of a bright orange-yellow colour; on potatoes it grows very readily, and presents the same appearance. These organisms peptonise albumen very energetically; they also give rise to a peculiar sweaty smell, like that of decaying starch. They retain their vitality in the cultivations for a long time, and, in the dry state, they remain alive for at any rate some weeks.

Injection of these organisms into animals gives varying results, according to the number injected and the other conditions of the experiment, but in the case of rabbits it is comparatively easy on subcutaneous injection to produce suppuration; on intravenous injection to set up abscesses in the kidneys, and also in other organs; and, on injury to bone, to cause suppuration in connection with the injured part. Injection of moderate quantities into the knee-joints of rabbits usually causes acute inflammation with suppuration, and ultimately the death of the animals; and in the case of dogs, abscesses result, but not as a rule death. This organism is the same as that described in acute osteo-myelitis, and at first supposed to be the specific organism of that disease.

2. *Staphylococcus Pyogenes Albus*.—This organism resembles the former in its conditions of life outside the body, in the character of its cultivations and in its effects on animals, but it produces no pigment. As regards the effect on animals, it is generally stated that it is somewhat less virulent than "aureus," but my own experience is that, on the contrary, it is rather more virulent.

3. *Staphylococcus Pyogenes Citreus*.—This organism, like the former, liquefies gelatine, and grows both at the body and summer temperature. After twenty-four hours' growth on agar, kept at the body temperature, the cultivations present a light yellow colour, indistinguishable at that period from cultivations of staphylococcus pyogenes aureus; the latter, however, soon becomes darker and orange-yellow in colour, while "citreus" remains of a light yellow or citron colour. In both species the development of pigment only occurs where the colonies are in contact with the

air. The pathogenic properties of "citreus" are said by Passet to resemble those of "aureus" and "albus," though it is not quite so virulent, abscesses following subcutaneous injection, and injection into the knee-joint, while deposits in the kidney occur after injection into the veins. In my own experience these organisms have proved much less virulent than "albus" or "aureus."

4. *Streptococcus Pyogenes*.—These organisms are also cocci which are arranged in chains, often of great length. They grow very slowly on the ordinary culture media at the summer temperature, but with greater rapidity at the temperature of the body. On gelatine they form small, colourless, round colonies, but they do not spread to any appreciable extent on the surface of the gelatine. On agar, kept at the body temperature, they have a tendency to grow in small points, which may attain the size of a pin's head, but, on the whole, the growth is very slow, and, when quantities are sown on agar in the form of lines, the growth does not, even after weeks, attain a greater breadth than that of two to three millimetres. They do not liquefy gelatine, but, like the others, they exert an energetic peptonising action in the absence of oxygen.

When injected subcutaneously into rabbits, unless considerable numbers are introduced, the result is only a slight and transient redness; when larger quantities are employed it is said by some authors that small circumscribed abscesses, resembling chronic abscesses, are formed; when injected into the knee-joint or into the pleura of rabbits they at first apparently cause slight inflammatory effusion, which, however, soon becomes absorbed without further bad consequences. Rosenbach was inclined to think that this organism differs from the form obtained by Fehleisen from cases of erysipelas, but that is a subject to which we shall presently allude.

5. *Micrococcus Pyogenes Tenuis*.—This species is of rare occurrence; in fact, Rosenbach only met with it three times. On agar it forms an extremely delicate, almost invisible, layer. The individual cocci are irregular in shape, and larger than the preceding forms. No experiments have been made on animals.

6. Rosenbach found an oval coccus in one case of acute abscess, which rapidly liquefies gelatine and causes suppuration when injected into the eyes of rabbits. This organism has not been further studied, nor has it as yet received a name.

7. *Staphylococcus Cereus Albus*.—This organism was found in abscesses by Passet. It forms a white, dull, wax-like layer on the surface of gelatine, and greyish-white patches on potatoes. Its name is derived from the appearance of the growth on gelatine, on which the individual colonies look like drops of wax. It is not pathogenic in rabbits.

8. *Staphylococcus Cereus Flavus*.—This organism was also found by Passet, and closely resembles the former, with the exception that the cultivations have a beautiful citron-yellow colour. It is not pathogenic in rabbits.

9. Passet has also found an organism in the pus of acute abscesses which closely resembles Friedländer's pneumococcus. This organism forms greyish white semi-circular elevations on the surface of gelatine, which may attain the size of a pin's head. In the early stage of growth it is indistinguishable from Friedländer's pneumococcus, but at a later period marked differences between the two can be made out, and that not only as regards the mode of growth, but also as regards the effects on animals. In the case of the pneumococcus, growth occurs not only on the surface of the gelatine, but also along the entire track of the needle. In the case of this organism, growth occurs only at the surface, the organism being thus a typical aërobie. As regards the effects on animals the pyogenic organism, when injected into the pleural cavity of mice and rabbits, causes pleuritis, and when injected subcutaneously it, in many instances, leads to the formation of abscesses in the same animals. On the other hand Friedländer's pneumococci are not pathogenic in rabbits.

10. *Staphylococcus Flavescens*.—This organism was found in an abscess by Babes, and occupies an intermediate position between "aureus" and "albus." On gelatine it forms a colourless layer and liquefies the gelatine; on agar the growth becomes yellow after about eight days. It kills mice, sometimes causing abscesses, and sometimes, when in larger doses, septicæmia.

11. *Bacillus Pyogenes Fætidus*.—Passet found this organism in an abscess in the neighbourhood of the rectum. It is a bacillus which grows on nutrient jelly, forming a delicate white or greyish layer on the surface, but it does not liquefy the gelatine. Its growth on agar and potatoes has the appearance of a light brown glistening layer, which has a very foul smell; in milk this smell

is not produced. Traces of the cultivation inoculated into mice do no harm; the injection of several drops causes septicæmia; injection of about ten minims of an emulsion of the cultivation into a guinea-pig causes an abscess in which the bacilli alone are found; injection into the blood stream causes septiciæmia. This organism is not pathogenic in rabbits.

12. In some cases of empyema occurring after acute pneumonia the organism found in the pus is the pneumonia coccus, described by A. Fränkel, and regarded by him as by far the most frequent cause of pneumonia. On the other hand, in ordinary empyema, not in association with pneumonia, the ordinary pyogenic cocci only are present.

One or two other organisms have been described in acute abscesses, but as they are of no importance, I need not take up time in describing them.

13. *Gonococcus*.—The gonococcus is constantly present in, and is undoubtedly the cause of, acute gonorrhœa. The cocci occur in pairs or groups, the individuals not being completely spherical, but flattened on their opposed surfaces. This appearance was at first supposed to be characteristic of the gonococci, but of late it has been found that a number of other cocci, which grow rapidly, present the same characters. In gonorrhœal pus the cocci are frequently present in numbers in the interior of the pus cells, and Bumm regards this appearance as peculiar to these organisms. They have been cultivated outside the body, though with great difficulty; in fact, Bumm was not successful until he employed human blood serum. On this material the organisms form at the body temperature a delicate layer, which ceases to increase after about twenty-four hours, and must then be inoculated on fresh soil; they grow only on the surface of the serum. Bumm has definitely proved that this organism is causally connected with the disease by two observations on man, in one of which the second generation grown on blood-serum, in the other, the twentieth generation were introduced into the healthy female urethra, and caused typical acute gonorrhœa.

As this is a specific organism only occurring in this disease, it need not be considered further in these lectures; it may be mentioned, however, that in a certain number of cases, the ordinary pyogenic cocci are also present in pus from acute gonorrhœa, and that it is just in these cases that suppurative bubo occurs, the pus from the bubo containing the ordinary pyogenic organisms, and not the gonococcus. Hence the occurrence of suppurative bubo in gonorrhœa is evidently accidental, and due to a mixed infection.

14. *Fehleisen's Coccus of Erysipelas*.—Although not a pyogenic organism, this coccus must be shortly referred to. Micrococci have been observed by many investigators in the lymphatic vessels of the skin in cases of erysipelas, in largest numbers at and beyond the spreading margin of the redness, but Fehleisen was the first who succeeded in obtaining cultivations of these organisms, and in demonstrating that they can cause this disease. As has just been said, they are present in the lymphatic vessels at and beyond the margin of the redness, but in the parts where the redness is passing or has passed off the lymphatic vessels and the tissues in their neighbourhood become infiltrated with leucocytes, and the cocci rapidly die out. Fehleisen has succeeded in cultivating them on a number of media; on nutrient jelly they grow very slowly, and the individual colonies always remain small. They do not liquefy the gelatine, and the growth closely resembles that of streptococcus pyogenes.

If these organisms are inoculated on the ear of rabbits, redness occurs, which spreads towards the root of the ear, and, on making sections at the margin of the redness, the lymphatic vessels are seen to be filled with the cocci as in man. Fehleisen has absolutely proved that these organisms are the cause of erysipelas in man by inoculating persons, the subjects of incurable tumours, with pure cultivations of the cocci. Of seven individuals so inoculated, six developed typical erysipelas; in the seventh case the patient had suffered from an attack of erysipelas only a few weeks previously, and was, in all probability, still protected from a fresh attack.

RELATION OF STREPTOCOCCUS PYOGENES TO ERYSIPELAS COCCI.

An important question, and one which has been much discussed of late, is the possible identity of these organisms of erysipelas with the ordinary streptococcus pyogenes. The streptococcus pyogenes is found especially in cases of spreading suppuration in the subcutaneous tissue; and when, along with this, erysipelas is also present, it was at first assumed that we had to do

with a mixed infection by the erysipelas cocci and the streptococcus pyogenes; but the belief seems to be gaining ground that we have here really a different effect of the same organism. In fact, a number of observers now assert that the organisms are the same, and that the different results depend on differences in the other conditions, such as variations in virulence, in dose, seat of inoculation, susceptibility of the host, etc. The earlier observers pointed out certain points of distinction between the cultivations of the erysipelas organisms and the streptococcus pyogenes, but closer examination and comparison of the mode of growth of the two forms under similar conditions has failed to establish any constant difference between the two.

In the case of animals, chiefly rabbits, the statements as to the results of inoculation are very contradictory; for, while some observers seem to have been able to make out very definite points of distinction, others have entirely failed to confirm their results. Thus Hajek states that the erysipelas cocci, when inoculated into the ear of rabbits, cause a wandering inflammation, without any marked swelling at the seat of inoculation; and that they chiefly inhabit the lymphatic vessels, and are seldom found outside them; while the streptococcus pyogenes, inoculated in the same manner, causes wandering erysipelatous inflammation and the production of an inflammatory swelling at the seat of inoculation; and the cocci rapidly pass into the tissue, being found especially in the neighbourhood of the blood-vessels, the walls of which they penetrate and thus reach the blood.—Hoffa also has obtained results of a somewhat similar character. He also notes that a doughy swelling and ultimately a large inflammatory tumour develop at the seat of inoculation of the streptococcus pyogenes, although suppuration does not occur; while the erysipelas cocci simply cause redness, without the development of any inflammatory tumour.—On the other hand, several other observers—Biondi, Passet, Bumm, von Eiselsberg, and others—have entirely failed to establish any such differences in the effects on animals, and have come to regard these organisms as one and the same.

It is thus evident that the whole question is still *sub judice*. In any case these organisms are very closely allied; they are, indeed, probably varieties of the same species, but that we have to deal with absolutely the same organism, and that the differences in action do not depend on differences in their physiological characters, but simply on differences in the conditions under which they act, seems to me somewhat difficult of belief, and somewhat difficult to reconcile with clinical experience. It is quite possible, on the other hand, that two organisms may have the same microscopical characters, may grow in a similar manner in various culture media, and may have much the same effect on certain species of animals, and yet they may not be the same, for when some other species of animal is tested differences may be brought to light, the existence of which was not previously suspected. In proof of this I need only refer to the example of chicken cholera, rabbit septicæmia, and swine fever, the organisms of which very closely resemble each other, but apparently show differences when inoculated into certain species of animals. In the case of the organisms under discussion, it may quite well be that the differences between them are only brought clearly to light when they are inoculated on man.

As a matter of fact, in the cases where erysipelas has been produced by inoculations of pure cultivations, only organisms cultivated from cases of erysipelas have been employed, so that we have no absolute evidence as regards this matter; but there are facts which seem to show that inoculation of streptococcus pyogenes into the human skin does not cause erysipelas. For example, streptococcus pyogenes is not infrequently present in closed abscesses, and when these are opened the skin is inoculated with the organisms; but so far as I am aware we have no evidence that erysipelas has ever resulted in such a case, nor that a surgeon with a wound on his finger gets erysipelas from dabbling in pus containing streptococcus pyogenes.—Rosenbach also mentions a fact which shows the action of streptococcus pyogenes on the human skin; he states that, after opening an empyema which contained streptococcus pyogenes, a dense inflammatory induration, what was practically a boil, developed around the incision; erysipelas did not occur. Till, therefore, more definite evidence in favour of the unity of these organisms is produced than we at present possess, I am inclined to uphold the specific character of the coccus of erysipelas.

OCCURRENCE OF PYOGENIC ORGANISMS IN DISEASE.

The diseases in which these organisms occur are very various;

in fact, they are present practically in all affections accompanied by acute suppuration. Thus they are found in acute abscesses, in boils, carbuncles, whitlows, spreading suppuration, acute osteomyelitis, suppurative inflammation of joints, suppurative peritonitis, empyema, ulcerative endocarditis, pyæmia, puerperal fever, the pustules of small-pox, vaccinia, etc.

As regards the frequency of occurrence of the individual species, Zuckermann has put together the results obtained by a number of different observers in 495 abscesses, and he states that staphylococcus was present in 71 per cent. of the cases, streptococcus in 16 per cent., the two organisms together in 5.5 per cent., and the remaining pyogenic organisms only exceptionally. As regards the pyogenic cocci individually, in 172 cases in which definite statements are made, we found that staphylococcus pyogenes aureus occurred alone or in combination with other staphylococci 123 times, and that streptococcus pyogenes was present alone 35 times, and in combination with staphylococcus 8 times. Staphylococcus pyogenes albus occurred alone 25 times in 133 cases, and in combination with "aureus" also 25 times. The other pyogenic organisms occur comparatively rarely; thus "citreus" was only found 7 times in 133 cases, 4 times alone and 3 times in conjunction with other forms; staphylococcus cereus albus was found 3 times in the same number of cases, and staphylococcus cereus flavus only once. Micrococcus pyogenes tenuis was found 3 times by Rosenbach in 39 cases (two of these were cases of empyema, and one a case of acute abscess); the organism described by Passet as closely resembling Friedländer's pneumococcus was found in 2 out of 33 cases (in one case in an ordinary acute abscess, and in the other in an acute abscess after pneumonia); and the bacillus pyogenes fetidus was only found on one occasion, in an ischio-rectal abscess.

The organism, therefore, which most frequently occurs in these diseases is staphylococcus pyogenes aureus, and the next in frequency is the staphylococcus pyogenes albus. Both are associated with closed acute abscesses, also with boils, acute osteo-myelitis, etc., and "albus" is apparently associated with somewhat more severe inflammations than "aureus;" the combination of the two, in acute osteo-myelitis, for example, seems to be particularly unavourable.

The streptococcus pyogenes is also frequently present, but is especially associated with phlegmonous and erysipelatous processes, where the pus occurs in the form of infiltration of tissue, accompanied by death of portions of tissue. It also occurs, as pointed out by Ogston and Rosenbach, in progressive gangrene, and is the chief organism of pyæmia, having been present in five out of six cases examined by Rosenbach.

Mastitis in women offers a good example of the different mode of action of these two species of pyogenic organisms. The abscesses in the mamma, which are caused by the staphylococci, always begin in the deeper part of the organ, and spread towards the surface, while in the case of the suppurations, which occur in connection with streptococci, the disease commences with a rapidly spreading redness of the skin, extending from some fissure or crack on the nipple, and the suppuration in the deeper parts follows this superficial affection. The explanation of these differences is that the staphylococcus generally spreads up the milk-ducts, and acts from their interior, whereas the streptococcus spreads along the lymphatic vessels, and its pathogenic action commences at the surface. I may say that the action of the staphylococci from the interior of the ducts and acini was ascertained definitely by Bumm, who excised a portion of the wall of a commencing mammary abscess, and was able to demonstrate the presence of the cocci in the acini and their penetration from thence into the interacinous tissue.

THESE ORGANISMS CAN CAUSE SUPPURATION.

We must now pass on to the evidence which leads us to believe that a causal connection exists between the pyogenic organisms and acute suppuration. In the first place they are constantly present in acute abscesses and in suppurations generally; and, as has just been pointed out, certain species are constantly associated with certain types of inflammation; thus the association of streptococci with spreading suppurations and of staphylococci with circumscribed abscesses, being constant, can hardly be accidental.

Numerous experiments have been made on animals which show that these organisms, when introduced under suitable conditions, can set up suppuration; and I have previously mentioned some of their effects on animals. The conditions necessary for infection are very various, more especially as the animals usually employed

for the experiments are not very susceptible to the action of these organisms, but I need not refer to these conditions at present. One experiment will suffice to show that these organisms can cause suppuration in rabbits. Knapp performed experiments in connection with the process of healing of wounds of the eye in rabbits. A similar operation was performed on both eyes; on one eye the operation was performed aseptically, the hands, instruments, etc., being carefully disinfected, and care being taken to exclude organisms during the operation, but no antiseptic was applied to the wound; on the other eye the operation was performed in the same manner, but, after it was finished, the wound was infected with pyogenic cocci, chiefly with the staphylococcus pyogenes aureus. As a result, all the aseptic eyes, though very roughly handled, healed without any trace of suppuration; while almost all the other eyes were destroyed by suppuration, and only in those cases where the operation was superficial and not extensive did suppuration cease without complete destruction of the eye.

Absolute proof of the causal connection of these organisms with suppurative diseases has been furnished by experiments on man, of which we have three kinds. We have, first, a considerable number of experiments, where superficial abscesses have been induced by the introduction of organisms under the superficial layer of the epidermis; secondly, a number of experiments where impetigo pustules, boils, etc., have been caused by inoculation of these organisms into the skin; and, thirdly, experiments where abscesses have been caused in the subcutaneous tissue by subcutaneous injection of the organisms.

As all experiments in which superficial inoculations were made yielded the same result, it is unnecessary to mention more than one as an example. Take, for instance, one of Bockhardt's experiments. He introduced a trace of the mixed cultivations of "aureus" and "albus" into the cutis of his left forefinger; after forty-eight hours, an abscess, the size of a lentil, had formed, and was opened, and the pus contained staphylococcus pyogenes aureus.

Garre's case of inoculation of staphylococcus pyogenes aureus into the skin is probably well known, but I may mention it for the sake of completeness. He thoroughly cleansed the skin of his left forearm with distilled water, and, taking a cultivation of "aureus" in gelatine, rubbed it well into the arm, in the same manner as one would rub an ointment into the skin; for purposes of control, he rubbed a small quantity of sterilised agar jelly into the skin of his right forearm, in the same manner, and it was noted that there was no wound or pustule on the skin of either arm. It may be said at once that the result on the control arm was *nil*. In the case of the other, a burning sensation began at the seat of inoculation six hours later; this burning sensation became more intense, redness and swelling developed, and on the evening of the same day a number of pustules, the size of a pin's head, formed especially in connection with the hairs. On the following day, these pustules had attained the size of a lentil, contained a small quantity of pus, and were surrounded by an inflammatory area. The inflammation increased in intensity, and on the fourth day the seat of inoculation presented the appearance of an enormous carbuncle, surrounded by a ring of pustules. Ultimately, more than twenty openings formed, discharging pus and portions of dead tissue.

Bockhardt performed similar experiments on himself, inoculating in the same manner a part of the skin of the forearm, about the size of a five shilling piece, the part having been cleansed and disinfected, and slightly scraped in parts with his finger nail. The organisms used were a mixture of staphylococcus pyogenes aureus and albus. This mixture was rubbed into the arm at 4 P.M.; at 10 P.M. that is to say, six hours later, the seat of inoculation was slightly reddened, and somewhat painful; at 6 A.M. on the following morning, fourteen hours after infection, there were at the seat of inoculation, twenty-five closely aggregated impetigo pustules, varying from the size of a pin's head to that of a lentil, a few, but not the majority of these being traversed by hairs. These pustules contained the cocci employed, and by about the sixth day they had dried up and disappeared.—Some days later a similar experiment was performed with the same mixture. The inoculation took place at six in the evening; similar cultivations, mixed with sterilised salt solution, being rubbed into the outer part of the forearm. Next morning, at 6 A.M., the seat of inoculation was covered partly with impetigo pustules, of which he counted thirty-five, and partly with small slightly red patches; between 6 A.M. and 11 A.M. he saw twenty-five impetigo pustules form, on these red patches before his eyes, most of these pustules being perforated by a hair. After eight days, most of the pustules had

dried up and disappeared, except two; which developed into large and painful boils, and for the next two or three months he was subject to a recurrence of the impetigo pustules on the skin of his left fore-arm. As will be seen, the result in Bockhardt's experiments were milder than in Garré's; and Baumgarten attributes this, and probably correctly, to the fact that Bockhardt employed a much more dilute mixture of the organisms, and also a smaller quantity of them. That this fully accounts for the differences will be evident when we come to consider the question of the dose of organisms.

Bowen injected pure cultivations of what was apparently staphylococcus pyogenes aureus into the subcutaneous tissue of his own arm, and into the arms of two other persons. The cultivations were mixed with a few drops of salt solution before injection. On each occasion an abscess developed, which varied from the size of a pigeon's egg to that of a man's fist, according to the time which elapsed before they were opened, and these abscesses contained large numbers of the organisms employed.

ANATOMY OF ABSCESS.

As regards the mode in which an abscess is produced by these organisms, a considerable number of facts have recently been obtained from the examination of parts after infection. Where the organisms are circulating in the blood and become deposited in the smaller capillaries in the form of plugs, as is seen in pyæmia, the first effect is the change in the tissue, termed by Weigert "coagulation necrosis," and figured by me in a paper on Micrococci in Relation to Suppuration, etc., published some years ago. On staining sections of tissue in which these plugs are present with the ordinary aniline dyes, it is found that, while the mass of organisms is intensely stained, and while the nuclei in the section have become well coloured, there is a ring of tissue around the central mass of organisms which does not take on the stain, and which presents a homogeneous translucent appearance; this ring evidently results from the action of the concentrated products of the micrococci, the tissue being brought into the condition of coagulation necrosis. After some hours, a second ring appears, at a greater distance from the mass of organisms, this ring being composed of a dense layer of leucocytes, apparently collecting where the chemical substances are more dilute and do not interfere with the life of the cells. As time goes on, the intermediate translucent layer becomes infiltrated, on the one hand with cocci from the central plug, and on the other hand with cells from the outer ring, and the original tissue rapidly disappears, probably as the result of the peptonising action of the cocci. At the same time the fluid effused does not coagulate, probably also on account of the peptonising action of the cocci on the fibrinogen, and thus we come to have a central collection of fluid containing leucocytes and micrococci, surrounded by a wall of leucocytes and cocci—in other words, an abscess.
