Sickness Fund	10,181	10	6
Annuity Fund	8,423	8	10
Life Assurance Fund	1,984	15	0
Management Fund	1,862	13	0
Interest (not yet divided)	145	3	7
	22,602	10	11

This, the aggregate present worth of the Society, represents an increase on the quarter of £1,760 18s. 10d., and on the year of £6,594 18s. 3d. Of the above total, £21,635 0s. 10d. is invested in the names of the trustees at an average interest of 3½ per cent. the remaining amount (£967 10s. 1d.), and a further sum of £77 14s., to meet outstanding cheques, being with the Union Bank of London in the names of the treasurers, no cash balances ever remaining in the hands of any of the officers. The investment are all of a trustworthy and secure nature, and are here stated, the price actually paid for them by the Society. This, however, is considerably under their true value, as the £5,353 invested in saleable stocks with fluctuating values is, at the present price, worth nearly £500 more than cost price, and this profit can be realised should a sale and reinvestment be thought advisable. The remainder of the investments are made at par, and are not capable of increase or depreciation in value.

THE PROPOSED TAX ON PLEASURE HORSES.

THE following letter has been forwarded to the Chancellor of the Exchequer from the Metropolitan Counties Branch:

82, Brook Street, Grosvenor Square, London, W.,
April 17th, 1888.

To the Right Hon. G. J. Goschen, M.P., Chancellor of the Exchequer, etc.

SIR,—On behalf of this Branch, which includes upwards of one thousand members of the British Medical Association, we venture to draw your attention to the hardship which will be inflicted upon members of the medical profession, particularly those resident in country districts, whose work is of necessity largely unremunerative, if the proposed tax on pleasure horses be applied to those horses which are necessarily used by medical men in their daily avocations and practice. We, therefore, respectfully beg that you will take into your favourable consideration the justice and practicability of making an exception in favour of such horses so used.

We have the honour to be, Sir, your obedient servants,
(Signed) ARTHUR E. DURHAM, President.

C. BRODIE SEWELL, President-elect.
SEPTIMUS W. SIBLEY, Hon. Treasurer.
GEORGE EASTES, } Honorary
NOBLE SMITH, } Secretaries.

The following petitions against the Horse Tax have been presented from provincial medical men: By Sir J. Pease, from William Robinson, M.D., Stanhope; by Sir W. Foster, from medical practitioners of Ripley, Derbyshire; by Sir J. Pease, from Reginald and Maurice Kottlitz; by Mr. Rankin, from medical men in the Leominster Division of Herefordshire; by Mr. E. R. Wodehouse, from Mr. T. Biddulph Goss; by Mr. C. W. Gray, from the medical profession of Brainree; by Viscount Newark, from Epperstone; by Mr. W. Lowther, from Dr. Palmer, Kirkby-Stephen; by Mr. C. Hall, from the district medical officers of Cottenham, Willingham, and Swavesey; by Mr. L. Fry, from G. D. T. Willett and others; by Mr. Morrison (2), from medical men; by Mr. W. Sidebottom, from medical practitioners at Hadfield; by Mr. F. B. Mildmay, from medical officers of health of Plympton St. Mary Union; by Mr. H. J. Trotter, from medical men of Colchester and neighbourhood; by Mr. Hobhouse, from medical men of Castle Cary; and by Sir J. Whittaker Ellis, from Dr. George Cowen; also a petition from the medical men of Shrewsbury.

ASSOCIATION INTELLIGENCE.

NOTICE OF QUARTERLY MEETINGS FOR 1888.
ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Meetings of the Council will be held on July 18th, and October 17th, 1888. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before each meeting, namely, June 27th, September 26th, and December 23th, 1888.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No member can be elected by a Branch Council unless his name has been inserted in the circular summoning the meeting at which he seeks election.

FRANCIS FOWKE, General Secretary.

COLLECTIVE INVESTIGATION OF DISEASE.

THE Report upon the CONNECTION OF DISEASE WITH HABITS OF TEMPERANCE, which was presented to the Section of Medicine at the Annual Meeting of 1887 will shortly be published in the JOURNAL.

Reports upon the two remaining inquiries, namely, that into EPIDEMIC DIPHTHERIA, and that into the GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES, are in preparation, and will be published as soon as ready.

The following inquiry only of the first series remains open, namely, that on the ETIOLOGY OF PHTHISIS. A fresh inquiry into the ORIGIN AND MODE OF PROPAGATION OF EPIDEMIC DIPHTHERIA has been issued.

Memoranda upon these subjects, and forms for recording observations, may be had on application to the Secretary of the Collective Investigation Committee, 429, Strand, W.C.

BRANCH MEETINGS TO BE HELD.

NORTH OF ENGLAND BRANCH.—The spring meeting will be held at the Infirmary, Sunderland, on Wednesday, April 25th, at 3 P.M. Members intending to read papers or show specimens are requested to communicate at once with the secretary. The dinner after the meeting will take place at the Queen's Hotel, at 5 o'clock. The following papers are already promised:—Dr. Hume: A Case of Congenital Fistula of the Stomach, Cured by Operation. Dr. Coley: On the Treatment of Effusion into the Pleura in Children. Dr. Murphy: A Man 22 Years after Gastrostomy. Dr. Oliver: Notes on an Unusual Case of Hæmaturia. Mr. Morgan will move a Resolution on Quack Advertisements. Mr. Rutherford Morison will read Notes of two cases of Gall-Stones: (1) Operation on Dilated Gall-Bladder: Removal of Stones: Drainage: Cure. (2) Abdominal Section for Intestinal Obstruction: Discovery of Gall-Stone, Incision and Suture of Intestine and Removal of Stone. Specimens exhibited. Mr. Morgan will show (1) a Girl disfigured by Cancer of the Ovary. Dr. Drummond will exhibit some Pathological specimens. Dr. Lindsay will show a patient suffering from Paralysis Agitans.—G. E. WILLIAMSON, F.R.C.S., 22 Eldon Square, Newcastle-on-Tyne, Honorary Secretary.

BORDER COUNTIES BRANCH.—The spring meeting of this Branch will be held at Cockermouth on Friday, May 4th. The chair will be taken by Dr. McLeod, at 3.15 P.M. The following papers will be read: Dr. Campbell (Garlands): On Three Cases of Recovery after a Lengthened Duration of Insanity, with remarks. Dr. Hight (Workington): Notes on a Case of Puerperal Eclampsia. Dr. Black (Keswick): Notes on a Case of Suppurative Peritonitis. Dr. Hight will open a discussion on the subject of Fees Paid to Witnesses. The Secretary will be glad to receive intimation of papers for reading or specimens for showing prior to the 25th.—H. A. LEDDARD, 41, Lowther Street, Carlisle, Honorary Secretary.

SOUTH-EASTERN BRANCH: WEST KENT DISTRICT.—The next meeting of this District will be held at the Hospital, Gravesend, on Friday, April 27th, at 4 P.M. R. J. Bryden, Esq., in the chair. The dinner will take place at the New Falcon Hotel at 6.30 P.M.; charge 6s. 6d., exclusive of wine. Gentlemen who intend to dine are particularly requested to signify their intention to the Chairman, R. J. Bryden, Esq., 21, Harmer Street, Gravesend, not later than April 25th. Papers already promised:—Dr. P. Horrocks: On Puerperal Fever. Dr. Tannahill: On Symmetrical Gangrene. All members of the South-Eastern Branch are entitled to attend this meeting and to introduce friends.—A. W. NARRIVELL, F.R.C.S., St. Bartholomew's Hospital, Chatham, Honorary Secretary.

OXFORD AND DISTRICT BRANCH.—The next meeting will be held at the Radcliffe Infirmary, Oxford, on Friday, April 27th, at 3 P.M. Notice of papers to be read must be sent to W. Lewis Morgan, 42, Broad Street, Oxford, on or before April 18th. A dinner will be provided for those members who signify their intention to dine to the Secretary two days before the meeting.—S. D. DARBISHIRE and W. LEWIS MORGAN, Honorary Secretaries.

SOUTHERN BRANCH: ISLE OF WIGHT DISTRICT.—Annual meeting, Pel's Hotel, Ryde, Thursday, April 26th, 1888, at 4 P.M. J. M. Williamson, Esq., M.D., President, in the chair. Proposed new district member, Edward Pawcett, M.D., Dub., M.Ch., East Cowes. Agenda: 1. The President: Report of the proceedings of the District during the past year. 2. Election of officers and statement of accounts. 3. Next place of meeting. 4. T. A. Buck, M.B.: An address by the President-elect at 4.45 P.M. 5. Charles Fryer, Esq.: Cerebral Aneurysm. Gentlemen who are desirous of introducing patients, exhibiting pathological specimens, or making communications, are requested to signify their intention at once to the Honorary Secretary. Dinner at 5.45 P.M.; charge 6s., exclusive of wine. Please return postcard before Tuesday, 24th. Trains leave Ryde for Sandown, Shanklin, and Ventnor at 7.45; and for Newport at 7.41. [By-law.—When a member cannot attend whose paper is upon the agenda, it should be sent before the meeting to the Secretary for the purpose of being read and discussed.]—W. E. GREEN, Honorary Secretary.

WEST SOMERSET BRANCH: SPRING MEETING.

THE spring meeting of this Branch was held at the Railway Hotel, Taunton, on Thursday, April 12th, at 5 P.M. In the absence of Mr. Edward Stephens, the President, who was professionally prevented from attending, Mr. J. B. SINCOCK was voted to the chair. The minutes of the last meeting were read and confirmed.

Cases.—Mr. W. B. COSENS exhibited a man suffering from Charcot's disease of the knee-joint, and gave a history of the case.—An infant, a year old, suffering from blindness after convulsions, was sent by Mr. STEPHENS and seen by the meeting.

Instruments.—Mr. WREN (Taunton) exhibited some instruments and an electric light for surgical purposes.—Messrs. LYNCH and Co., London, also exhibited an assortment of surgical instruments.

Bone-setting.—After dinner, at which fifteen members and five visitors attended, Mr. W. J. PENNY, of Bristol, opened a discussion on the subject of bone-setting. He described the various affections which were often successfully treated by bone-setters, and by means of drawings and the narrative of typical cases he showed that, for the most part, the pathological condition existing in these affections was that of adhesions in and about joints, by the forcible rupture of which a sensation was given as if a bone which was out of place had been reduced. He pointed out that this practice was much neglected by the profession, and, in conse-

quence, many cases were cured by quacks to the discredit and disadvantage of medical men. He pointed out that the proper cases were healthy subjects, who some months before had sustained an injury, leaving them with a stiffened joint; in such cases the part was usually colder than normal, and there was a good deal of spasm. Cases of a strumous or syphilitic diathesis required great caution in being treated, and, as a rule, were best left alone. The subject was discussed by the members and visitors present, and Mr. Penny replied.

Vote of Thanks.—A hearty vote of thanks was given to Mr. Penny for his interesting and instructive paper.

Specimens.—Mr. LIDDON exhibited a specimen of Epithelioma of the Tongue, which he had removed by splitting the tongue in the middle line, and removing each half separately with the *écraseur*. The patient made a good recovery, and could talk fairly well; but now, five months after the operation, there were signs of recurrence. Mr. LIDDON also exhibited a specimen of a very large Uterine Polypus which he had removed from a middle-aged unmarried woman.—Mr. W. B. COSENS exhibited a specimen of Fractured Femur amputated after a gunshot injury.

SPECIAL CORRESPONDENCE.

BERLIN.

[FROM OUR OWN CORRESPONDENT.]

The Illness of the Emperor.—The German Emperor and Sir Morell Mackenzie.

THE disease from which the Emperor is suffering has, I am sorry to say, made further progress during the last few days. Increased difficulty of breathing suddenly came on. On removing the cannula, Sir Morell Mackenzie made a laryngoscopic examination, and observed that the disease had extended downwards into the trachea, so that the tube had become too short. It is one of the special features of this singular case, that after long pauses the tumour suddenly begins to grow again with great rapidity. Where even the day before the lumen of the trachea was distinctly seen to be quite free, it was now blocked by a large mass. It was necessary therefore to introduce a longer tube. Sir Morell Mackenzie sent a mounted messenger for Professor von Bergmann, who immediately proceeded to Charlottenburg. Professor von Bergmann succeeded in introducing the new tube, and the dyspnoea was relieved. The most remarkable part of the whole matter is, that the worse the local symptoms are, the better His Majesty seems to feel. He still (April 13th) absolutely refuses to give up his daily walks and excursions.

Sir Morell Mackenzie's professional brethren, not only at home but in the colonies and in America, where he has numerous friends and pupils, cannot fail to be gratified by the confidence placed in him by the Emperor Frederick, and by the extraordinarily warm appreciation of the English physician's services which His Majesty has expressed both by word and deed. In conferring on Sir Morell Mackenzie the honours and decorations which he has so well earned, the Emperor added immensely to their value by a letter written with his own hand, of which the following is the full text:—

"Charlottenburg, April 9th, 1888.
"My dear Sir Morell.—You were called in to me at the unanimous desire of my German doctors who were treating me. As I did not know you personally I had confidence in you in consequence of that recommendation, but I soon learned from personal experience how to value you. You have rendered me most valuable services. In recognition of these services, and as a souvenir of my accession to the throne, I have pleasure in conferring upon you the Comthur Cross and Star of my Royal Order of Hohenzollern.—Your well disposed
"FRIEDRICH.

"To Sir Morell Mackenzie."
One does not need to "read between the lines" of this letter to perceive its significance. The first sentence fully disposes of various mythical accounts of the way in which Sir Morell Mackenzie was called in to the case which have been current in the profession and in society. Before subjecting the heir to the Imperial Crown of Germany to a formidable operation—which might possibly be attended with disastrous consequences, not only to the angust patient but to the whole of Europe—Professor von Bergmann naturally wished to have the sanction of an expert whose authority would be generally recognised. The choice lay between the leading English laryngologist and Professor Raucufuss, of St. Petersburg, and the former was selected, as the Emperor says, "at the unanimous desire of my German doctors." The concluding words in which the Emperor speaks of his acces-

sion to the throne prove beyond all doubt that His Majesty believes that it is to Sir Morell Mackenzie's "masterly inactivity" that he owes his present position, with all that it involves. We are pleased to see that the people of Germany are beginning to judge Sir Morell Mackenzie's conduct of a most difficult and anxious case in a fairer spirit than some persons there seemed at first inclined to do.

SHEFFIELD.

[FROM OUR OWN CORRESPONDENT.]

Decline of the Small-pox Epidemic.—New Wards at the Children's Hospital.—Donations.

It is gratifying to notice that the small-pox epidemic, which for so long has hung over this town, and has seriously interfered with trade, is now fast declining. The number of cases admitted to the borough hospital and to the two workhouse hospitals is greatly lessened. In March the number admitted to the borough hospital was 790, whilst in February there were 1,264. The present month has thus far shown a still greater reduction. It was predicted that the effect of the numerous revaccinations would begin to tell about the middle of March, and such has been the case. The public spirit and energy with which the public vaccinators undertook their greatly increased and, in some instances, very arduous labours is worthy of all praise.

The new wards at the Children's Hospital were opened on April 5th by Lady Alice Fitzwilliam, in the presence of a large and influential gathering. Beds have hitherto only existed for 14 patients, but in future there will be accommodation for 34 little sufferers. On the ground floor of the new building are two wards, each 40 feet by 21 feet, and containing between them 30 beds. On the upper floor is an operating theatre and a small ward for 4 beds. The total cost, inclusive of alterations in adapting the old building for administrative purposes and out-patients, is about £2,000. The medical staff and the subscribers may be well congratulated on the success that has attended their efforts to add to the comfort of the little patients, and the usefulness of the charity.

The Committee of the Sheffield and Hallamshire Football Association has handed over the following donations to the Sheffield medical charities: General Infirmary, £50; Public Hospital and Dispensary, £40; Jessop Hospital for Women, £25; Nurses' Home, £5.—Mrs. William Cutts, the daughter of a former resident at Barnsley (Mr. Leadam) has decided to give £1,000 towards the funds of the Beckett Hospital.

CORRESPONDENCE.

THE HORSE TAX.

SIR,—Acting on your advice, I have obtained the signatures of nearly all the medical men in this district to a petition against the horse and carriage tax, which the Hon. Gathorne Hardy has promised to present before Parliament. I would advise medical men still to petition, so that as the Bill comes on in Committee strong feeling may be shown by the medical profession against the tax.

A simple plan to get signatures is to send the petition to a medical man, asking him to get those in his neighbourhood sign, and post it on to another to do the same, and so on.—I am, etc.,
A. H. NEWTH.

Hayward's Heath.

PERICHONDRITIS AND CANCER OF THE LARYNX.

SIR,—Dr. Norris Wolfenden, in his paper on perichondritis of the larynx published in the *JOURNAL* of April 14th, says: "second case of extensive perichondritis of the larynx has occurred in my practice recently, arising out of chronic laryngitis, and which there was no question of syphilis." In this case the cric cartilage was extensively affected and formed a large abscess externally, on opening which a large quantity of sero-sanguine fluid was poured out. The stenosis of the larynx was extra-ordinary and tracheotomy had been performed many months before I saw the case by a surgeon at the Cape of Good Hope.

It being avowedly the object of Dr. Wolfenden's paper to correct the opinions generally held on the etiology of laryngeal perichondritis, I consider it, in the interest of scientific truth, my duty to state that the above-quoted case is not well chosen for support.

his views. The patient in question, who is at this moment an inmate of St. Thomas's Hospital under the care of Sir William MacCormac and myself, suffers beyond doubt from laryngeal cancer; and this disease, not chronic laryngitis, has caused the perichondritis. What Dr. Wolfenden considered to be a large abscess and incised was tumour-mass spreading externally. Hence no pus, but sero-sanguineous fluid, was poured out. The incision wound never healed, the tumefaction rapidly spread, and at this moment the tracheal tube is sticking in an ulcerating mass of cancer. A fragment of this mass has been removed for the purpose of microscopic examination, and the latter, made by Mr. Shattock, has placed the diagnosis of carcinoma beyond dispute. I am ready to give Dr. Wolfenden the opportunity of personally verifying the actual state of matters.—I am, etc.,
39, Wimpole Street.

FELIX SEMON.

ST. JOHN'S HOSPITAL.

SIR,—I will ask you to give me space for the following facts respecting the behaviour of the Board of Management of St. John's Hospital for Diseases of the Skin. Since my connection with the institution I have taken, or have dictated, notes of every case which came before me. After my dismissal by the Board of Management, I wrote to these in authority and asked them to let me have these notes, offering at the same time to defray the expenses incurred by purchasing new books. To this request I received a peremptory refusal from the secretary. I wrote again, asking that some of the notes, which I was anxious to refer to, might be copied by the gentleman (Mr. Jones) who was acting as clinical clerk at the time of my elimination. The answer I received was, that I might send Mr. Jones to select those cases I was anxious to refer to, but they must be copied by an official of the Hospital, for whose services I was to pay. I appealed against this vexatious decision, and in reply received an impertinent letter from the secretary.

I make it a rule of my life not to complain, but surely the facts which I have stated must demonstrate the harshness of the treatment which the Board of Management mete out, and when we remember that on this Board sit two members of our own profession, Mr. Melton and Dr. Dow, I hope I shall be considered to be justified in bringing this before the profession.

It is most irritating to have the labour of some years snatched away from us: it is doubly irritating to know that those who must realise the full value of that labour should be instrumental in supporting the conduct of those whose action might be put down to motives which I do not care to find in my vocabulary.—I am, etc.,
T. ROBINSON, M.D.

9, Princes Street, Cavendish Square, W.

SIR,—Pray allow me to correct an inaccuracy in an annotation published in the JOURNAL on April 14th. It is not in accordance with fact that "charges were brought against the administration of St. John's Hospital, following upon various secessions in the staff." Such a loose version of what really occurred is not fair to myself and my colleagues, who were the first to bring those charges to the notice of the governors, the president, and finally the public; and who, for thus doing our duty as honourable men, were vindictively dismissed by a Board, whose behaviour, both before and since, has amply proved that we were right in protesting as we did.—I am, etc.,
C. M. CAMPBELL, M.D.

37, Queen Anne Street, Cavendish Square, W.

BRANCH PRACTICES IN CHARGE OF UNQUALIFIED MEN.

SIR,—It is hoped that the General Medical Council will actively enforce their memorandum in regard to the employment of unqualified assistants; and not, as has hitherto been the case, allow it to remain practically a dead letter. The memorandum appears to me to be rather vague, and to afford many a loophole of escape for the delinquent.

In Section C it is stated that irregular practice will probably not long continue to exist, because the practitioner cannot recover or services rendered by his unqualified substitute; this argument is fallacious, inasmuch as these gentry take pretty good care to insure ready money. A censure, pure and simple, even from the General Medical Council, will mean nothing whatever to many offenders unless followed up by more active measures. Who cares or a censure? As far as I have been able to gather, the General Medical Council have as yet only struck off the Register those who had already been convicted by a jury—there is nothing at all wonderful in that. What we want them to do is to go a step further—to judge and to punish those who are guilty of professional mis-

conduct. The law provides for those who offend against public morality.

I believe the Incorporated Law Society has power to strike off the rolls any of their members who are guilty solely and simply of professional irregularities, and by no means infrequently make use of their power. Let the General Medical Council do the same if they have the power; if they have not, it is quite time they took means to procure it, in order to rid the profession of the great blot that we all know exists in our midst.

The General Medical Council must do their own "dirty work," for they cannot, for obvious reasons, expect a medical man to take the initiative against an offending brother. Many of us, no doubt, know of cases of irregular practice; but if we take the "law into our own hands," we immediately incur the slur of private malice and professional jealousy. Besides, individually, the "game would not be worth the candle."

If the General Medical Council will only follow up their words by action (on information received, or otherwise), they would gain the great thanks of the profession—be respected and revered, a veritable Alma Mater, which they ought to be. At present one hardly knows what they exist for.—I am, etc.,

WALTER FOWLER, M.A., M.B., F.R.C.S.

145, Bishopsgate Without.

COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES.

SIR,—Dr. Philpot's letter does not touch the points which are raised in mine, except so far that he accepts a responsibility for which I did not give him credit, and which I even now think that he has done chivalrously and not instinctively.

How can he reconcile his duty with his acts? He puts a clause of an Act of Parliament in force against one delinquent without having been able to show the least ill consequences from the "lâches," while he allows the 999 other persons, who, as a class, altogether ignore the provisions of the Act, to escape; he condones their disobedience to law, and makes the dual notification a farce. Infectious disease can only be stamped out by the people themselves, yet Dr. Philpot and the supporters of the dual notification clause are publicly telling them that, in spite of the Act of Parliament, it is a matter with which they have nothing to do, that it is the doctor who has to do all. By what right can he prosecute a professional brother and yet allow the whole class of non-professional persons who ought to notify to ignore the Act and neglect its provisions? He shows that it is not from a desire to compel a compliance with its provisions, otherwise he would be impartial. He is satisfied with a single notification, he proves by his own habit that a single notification is sufficient, then on what ground can he claim a right to prosecute a professional brother, and not take note of the whole class of non-professional delinquents? The law is no respecter of persons, but Dr. Philpot singles out his professional brother and lets the rest alone. If there is a duty cast upon Dr. Philpot then he has failed to do it, for dual notification is not enforced. Dr. Philpot cannot show that dual notification is efficient in stamping out scarlatina; it is not diminished in one town more than another. The Act is nowhere in existence as a dual performance; medical notification is as beneficial when voluntary as it is when it is compulsory, provided a fee is paid for the notice. The cases are at times as numerous in all districts as before notification was observed. The house in question had been disinfected by Dr. Philpot's agents after notice, immediately before the case occurred, about which Dr. Philpot has taken action.

Does Dr. Philpot or anybody else suppose that a 40s. penalty will overcome a man's determination to remain a free agent? Dr. Dalton is not likely to change his conduct at the bidding of a professional rival; he will continue to ignore the Act, and until medical officers of health are prohibited from being in private practice such action as that taken by Dr. Philpot ought not to be. I am not intending to charge Dr. Philpot with having taken this course on account of professional jealousy; it is not his nature, of that I am assured; but it is open to the charge, and it is a false move on his part which all medical men must regret that he has made.

It will be soon enough to put the penal clause in force against the profession when it can be fairly shown that repression cannot be forthcoming without it. This has not hitherto been done.—I am, etc.,
ALFRED CARPENTER.

Duppas House, Croydon, April 16th.

NAVAL AND MILITARY MEDICAL SERVICES.

CHANGES OF STATION.

THE following changes of station among the officers of the Medical Staff of the Army have been officially notified as having taken place during the past month:—

	From	To
Brigade-Surgeon J. Jameson, M.D.	Aldershot	Portsmouth.
J. S. MacAdam	London	Devonport.
Surgeon-Major T. M. O'Brien	Bengal	Colchester.
W. H. Climo, M.D.	Mauritius	Ilong Kong.
J. Fleming, M.D.	Nova Scotia	Netley.
T. Babington	Bengal	Woolwich.
J. P. H. Boileau, M.B.	Netley	Singapore.
J. G. Williamson	—	Dublin.
W. J. Charlton	—	Curragh.
W. A. May	—	York.
Surgeon M. R. Ryan, M.D.	Netley	Portsmouth.
W. A. Parker	—	Dublin.
J. G. MacNeece	Aldershot	Portsmouth.
F. R. Barker, M.B.	Netley	Dublin.
T. Dorman, M.D.	—	Devonport.
T. B. Moffitt	—	Dublin.
C. A. Webb	—	Dover.
J. G. S. Lewis	—	York.
H. Martin, M.B.	—	Dublin.
R. O. Cusack	—	—
E. F. Smith	—	—
W. D. A. Cowen	—	—
S. J. Flood	—	—
G. W. Robinson	—	—
G. F. A. Smythe	Dover	Eastbourne.
A. P. O'Connor	Curragh	Dublin.
J. M. Bolster	Cork	Buttevant.
W. J. Macnamara, M.D.	Woolwich	Netley.
M. F. Macnamara	Tipperary	—
J. O. G. Sandiford, M.D.	Buttevant	—
H. W. Murray, M.B.	Woolwich	—
M. W. Kerio	Cork	Tipperary.
A. Peterkin, M.B.	Shorncliffe	Netley.
W. Heffernan	Fleetwood	Lancaster.
J. G. W. Crofts	—	Netley.
A. P. Hart, M.B.	Colchester	—
T. F. W. Fogarty, M.B.	Dublin	—
G. Coutts, M.B.	Hulme	—
E. Butt	Belfast	—
S. Townsend, M.D.	Queenstown	—
J. Gibson, M.B.	Belfast	—
L. W. Swabey	Fort George	—
R. Porter, M.B.	Dover	—
J. W. Beatty, M.D.	Sunderland	Newcastle.
W. Babbie, M.B.	Bengal	Netley.
J. M'Laughlin, M.D.	Dublin	Belfast.
W. L. Reade	Clifton	Netley.
F. T. Wilkinson	Chatham	—
S. F. Longhead	Belfast	—
W. A. Morris	Bengal	Aldershot.
F. W. Reid, M.B.	Dover	Netley.
T. W. O'H. Hamilton, M.B.	Dublin	Mauritius.
G. M. Dobson, M.B.	Egypt	Dublin.
F. J. W. Stoney	Cork	Ferriby.

THE NAVY.

THE following appointments have been made at the Admiralty: S. W. VASEY, Surgeon, to the *Triton*, temporarily; GARLAND W. L. HARRISON, Fleet-Surgeon, to the *Swiftsure*; JAMES H. MARTIN, Fleet-Surgeon, to the *Boadicea*; BRIEN P. S. M'DERMOTT, Fleet-Surgeon, to the *Eritania*, additional; EDWARD J. SHAROOD, Fleet-Surgeon, to the *Sultan*; CHARLES W. MAGRANE, Staff-Surgeon, to the *Impregnable*; RICHARD D. WHITE, Staff-Surgeon, to the *Duncan*; MICHAEL FITZGERALD, Staff-Surgeon, to the *Swiftsure*; HENRY HARRIES, Surgeon, to the *Boadicea*; CHARLES F. NEWLAND, Surgeon, to the *Calypto*; WILLIAM S. LIGHTFOOT and JOHN B. PENN, Surgeons, to the *Swiftsure*.

THE MEDICAL STAFF.

THE following appointments have been made in the Madras command: Brigade-Surgeon J. Y. DONALDSON, M.D., to be Senior Medical Officer, Bellary station hospital; Surgeon-Major J. A. SMITH, to do duty at the station hospital, Bellary; Surgeon J. ANDERSON, M.B., to do general duty in the Eastern district; Surgeon P. J. NEALON, M.D., to do duty at the station hospital, Bellary; Surgeon J. F. DONEGAN to do duty at the station hospital, Bellary.

Brigade-Surgeon W. GRAVES, serving in the Bombay command, is appointed to the medical charge of the station hospital at Mhow.

Surgeon W. G. BIRRELL, also serving in the Bombay command, having returned from field service in Burmah, is posted to general duty in the Presidency district.

The undermentioned gentlemen, who are serving in Bengal, have leave of absence as specified: Surgeon-Major T. O'FARRELL for six months on urgent private affairs; Surgeon-Major R. F. BUCHANAN, on private affairs, pending retirement from the Service; and Surgeon H. C. DENT and C. O'DONEL each for six months on medical certificate.

Surgeon-Major O'DONOVAN died in Dublin on the 13th ultimo. He entered the Service as Assistant-Surgeon, July 14th, 1854; and became Surgeon, August 6th, 1867; retiring on half pay, October 21st, 1879. He was in medical charge of the 54th Regiment during the burning of the steam transport *Sarah Sands* at sea, on November 11th, 1857. He also served with a force sent against the hostile Indians of Yucatan, in April and May, 1861.

THE INDIAN MEDICAL SERVICE.

SURGEON-MAJOR G. HUTCHESON, M.D., Bengal Establishment, is appointed to officiate as Statistical Officer to the Government of India in the Sanitary and Medical Departments, during the absence on furlough of Surgeon-Major D. WILKIE, M.B.

Brigade-Surgeon E. BONAVIA, M.D., Bengal Establishment, has been permitted to retire from the service, which he entered as Assistant-Surgeon, August 4th, 1857; he attained the rank of Brigade-Surgeon, January 17th, 1855. He has no war record.

The undermentioned gentlemen, all of the Bengal Establishment, have been appointed to the officiating medical charge of the regiments named:—Surgeon H. HAMILTON, 5th Bengal Cavalry, *vice* Surgeon-Major G. S. A. Ranking, M.D., appointed officiating Medical Storekeeper at Calcutta; Surgeon W. R. CLARK, 4th Bengal Cavalry, *vice* Surgeon-Major P. F. O'Connor, M.D., granted furlough; Surgeon J. MURRAY, 15th Bengal Cavalry, *vice* Surgeon D. F. Barry, M.D., granted leave; Surgeon A. W. DAWSON, M.B., 18th Bengal Lancers, *vice* Surgeon-Major G. Griffith, transferred to civil employ; Surgeon A. C. YOUNG, M.B., 4th Bengal Infantry, *vice* Surgeon T. Grainger, M.D., ordered on field service; Surgeon W. H. B. ROBINSON, 43rd Gorkha Light Infantry, *vice* Surgeon-Major R. M. Downie, M.D., who rejoins his permanent appointment in the 29th Punjab Infantry.

The promotion of Deputy Surgeon-General J. PINKERTON, M.D., of the Bombay Establishment, to be Surgeon-General; and of Brigade-Surgeon P. S. TURNBULL, M.D., also of the Bombay Establishment, to be Deputy Surgeon-General, already announced in this JOURNAL, have received the approval of Her Majesty.

The undermentioned gentlemen have leave of absence for the periods specified:—Surgeon R. J. MARKS, Bengal Establishment, for 182 days on medical certificate; Surgeon-Major R. C. SANDERS, M.D., Bengal Establishment, Ophthalmic Surgeon, and Professor of Ophthalmic Surgery, Medical College, Calcutta, for 245 days on private affairs.

THE VOLUNTEERS.

MESSRS. SAMUEL BEATTIE, M.B., and DAVID LAING, M.D., have been appointed Acting Surgeons to the 1st Forfar Artillery.

Mr. D. V. REES is appointed Acting Surgeon to the 1st Volunteer Battalion South Wales Borderers (late the 1st Brecknockshire).

Honorary Assistant Surgeon R. LANPHER, of the 1st Volunteer Battalion Lincolnshire Regiment (late the 1st Lincoln), has resigned his commission, which was dated May 11th, 1880.

EXAMINATION OF VOLUNTEER SURGEONS.

SURGEON writes: Can you kindly inform me what the examination for proficiency volunteer surgeon consists of? When and where are such examinations held?

** See Proficiency Examination for Volunteer Officers, JOURNAL, June 4th 1887, and Volunteer Regulations, 1887, Part I, Section II, para. 144.

MEDICO-PARLIAMENTARY.

HOUSE OF LORDS.—Monday, April 16th.

Smoke Abatement.—Lord STRATHEDEN and CAMPBELL presented a Bill for the abatement of smoke in the metropolis. I was, he said, the same Bill as that of last year, with some modifications suggested by the report of the Select Committee on the subject.—The Bill was read a first time.

HOUSE OF COMMONS.—Thursday, April 12th.

The Leasing Powers of Sanitary Authorities.—Mr. RITCHIE, in answer to Mr. COZENS-HARDY, stated that a sanitary authority could not compulsorily acquire land upon lease instead of purchasing the fee simple; and for the reasons which were stated in the debate which arose on this question when the Allotments Bill was in Committee, it was not the intention of the Government to introduce a Bill conferring this power on sanitary authorities.

Honorary Surgeons to the Viceroy.—Sir G. HUNTER asked the SECRETARY OF STATE FOR INDIA whether honorary surgeons to the Viceroy of India had been prohibited from wearing the aiguillette heretofore used by them.—Sir J. GORST replied that, under the dress regulations of the army, honorary surgeons to the Viceroy had no authority to wear such a decoration. If they had been in the habit of so doing, it had been an irregularity.

Friday, April 13th.

Local Government Bill.—Sir LYON PLAXFAIR, in the course of a long speech, in the discussion on this Bill, said he was anxious that the President of the Local Government Board should consider carefully whether the clauses of the Bill dealing with sanitary matters sufficiently preserved the controlling powers of the acts of the District Councils, which the existing law gave to the Local Government Board. With regard to officers of health, he suggested that they should be servants of the County Council, and not of District Councils. The moment that was done, the County Councils would soon be able to consolidate areas; and would make that compulsory upon them. The beneficial result would be to bring County Councils into touch with the com-

ment District Councils. That could not be accomplished as the Bill stood. He fancied that by a single clause considerable improvement might be effected in the measure. At present about 1,200 medical officers were employed throughout England, with salaries amounting in the aggregate to £130,000. But if, instead of the 1,200, something like 180 medical officers were appointed in consolidated areas, omitting the scheduled towns, immensely better results would be obtained without any extra expense. Unless medical intelligence were brought to the aid of the County Councils in the way he suggested, public health would largely deteriorate, instead of improving. Sanitary science had given enormous benefits in preventing deaths, and in keeping up the living health and productive ability. Diseases which formerly prevailed in this country had almost disappeared since the advance of sanitary science.

Monday, April 16th.

Burgh Police and Health (Scotland) Bill.—The LORD ADVOCATE moved the second reading of this Bill with a view to its being referred to a Select Committee.—Mr. BUCHANAN asked whether the Committee would be composed wholly of Scotch members, and whether the large towns at present mentioned in the Bill as places which would be exempted from its operations were really to be exempted.—The LORD ADVOCATE replied that the Committee could consist largely, but not exclusively, of Scotch members. It would be contrary to usage to nominate only Scotch members to the Committee. To the second question of the hon. member he replied in the affirmative.—The Bill was then read a second time and ordered to be referred to a Select Committee.

Sale of Foreign as English Meat.—Sir MICHAEL HICKS-BEACH, in reply to Dr. CLARK, said he believed, although he could not give an authoritative opinion, that the sale of foreign meat as English when English meat was demanded was an offence under section 6 of the Sale of Food and Drugs Act, 1875.

Tuesday, April 17th.

The Public Safety and Theatres.—Mr. TATTON EGERTON moved the second reading of the Metropolitan Board of Works (Theatres) Bill, the object of which was to continue to the Board the powers given to them in reference to theatres.—Mr. DIXON-HARTLAND moved the rejection of the Bill, mainly on the ground that the Board was threatened with extinction by the Local Government Bill.—Mr. MATTHEWS took the same view, and, after a short conversation, the Bill was thrown out by 144 to 18.

The Medical Staff Corps.—Dr. CLARK asked the Secretary of State for War whether the new general order restricting the enlistment of men for the Medical Staff Corps to three years' army and nine years' reserve service had been considered or approved by the Director-General; and whether he had considered that the result of the new regulations might be that the men of the corps could scarcely have become skilled in their nursing duties as orderlies when they would be removed and replaced by raw, untrained men.—Mr. E. STANHOPE, in reply, said every army order was issued on the responsibility of the Secretary of State after consultation with his professional advisers. The importance of having a large reserve of trained men of the Medical Staff Corps available in war time was so great that the disadvantage of a somewhat curtailed training must be faced.

Irish Prison Surgeons.—Mr. MURPHY asked whether the Irish Prison Regulations (Rule 105) provided that the surgeon might, in case of danger or difficulty, call in medical assistance; whether there was anything in the rules to limit the discretion of the surgeon in selecting the medical assistance he would call in; whether a circular had been sent from the Irish Prisons Board to governors of gaols requiring them to submit a list of names of medical practitioners whom they might consider suitable in their districts for the purpose of being called in consultation; and whether the Prisons Board were justified in attempting to fetter the discretion of the prison surgeons in this matter.—Mr. A. J. BALFOUR replied that the rule was as stated, and a circular had been issued as mentioned. The appointment of medical officers of prisons required the sanction of the authorities, and it seemed to him to be entirely within the spirit of the rules that some effective control should be exercised as to the election of consulting physicians.

The Architects' Registration Bill.—Colonel DUNCAN, in moving the second reading of this Bill, said that its principal object was to throw obstacles in the way of improper and unqualified persons acting as architects.—Sir W. POSTER asked the House not to accept the second reading without having more information upon

the subject.—Sir L. PLAYFAIR said that the Bill was drawn exactly in accordance with the Medical Act, 1886. It was only after consultation with all the examining bodies and the practitioners that he was able to get sufficient support to pass such an Act. The Bill now before the House was framed on exactly the same principle—that was to say, there were certain qualified bodies who were to go upon the General Council. Then there were to be certain representative members elected for the three parts of the kingdom. But who were the representatives in this case? There were no regularly qualified and registered people who could become representatives at the present moment. They were to be constituted by the Bill. The architects, and engineers, and surveyors were not at present identical, and the House could not in justice pass a Bill which met with so much opposition as this Bill did, and which was not founded upon the same conditions as enabled the House to pass the Bill relating to the medical profession.—The Bill was by consent withdrawn.

MEDICO-LEGAL AND MEDICO-ETHICAL.

COVERING UNQUALIFIED PRACTICE.

FAIR PLAY had better communicate with the Clerk to the Society of Apothecaries, Blackfriars.

NATIONAL MEDICAL AID COMPANY.

PRO BONO PUBLICO.—We have already more than once expressed a decided condemnation of the proposed arrangements and proffered terms.

REGISTRATION AND FEES.

MR. GRAME.—In the case of *Leman v. Fletcher*, L. R., 8 Q. B., p. 323, the Court, in putting a construction on the 31st section of the Medical Act, 1858, held that a practitioner must register his qualification, and can only recover according to it, and that in a medical case, in order to recover for medicines supplied, he must be either registered as an apothecary or as a physician. In a surgical case a surgeon, if duly registered, can recover for medicines.

PROFITS OR ARREARS.

M.D. LONDON.—The division of profits must depend on the exact words used in the partnership agreement. Unless words having a different meaning have been used, profits of a practice during a certain period must mean profits earned during that period. Money received then in respect of fees due previously would not be earned during the period, and would not ordinarily be divisible as profits of the practice under the agreement. On the other hand, an outgoing partner would have a right to his share of fees paid subsequently in respect of work done while he was a partner. A division of receipts, irrespective of the matters for which the money is paid, is not a division of profits. The partners may, however, have agreed to treat it as a proper division under their agreement; and if so, the account could not properly be reopened.

If the division has been made under a mutual mistake as to the meaning of the agreement, the lapse of four years is no bar to a proper account being taken.

If further information is wanted, the agreement and a precise statement of facts should be sent.

"THE GREAT ROYAL STAFF OF FRENCH, BRITISH, AND GERMAN SURGEONS."

DR. W. J. McK.—Although we are at all times desirous to respond to the reasonable requests of our Antipodean and other colonial correspondents, we are constrained, owing to the ever-increasing demands on our space, to restrict insertion to matters of practical interest to the profession; for which reason, as will be patent to Dr. McK., we are unable to accede to his request that the circular and extracts from the *Colonist* might appear in the JOURNAL, since they merely tend to establish the too-evident fact that quackery and illegitimate practice, in conjunction with a like gullibility of the public, are as rife in the colonies as in the old country; a regrettable condition of things which may, we think, not unfairly be attributed to the unrestricted facilities for charlatan advertising afforded by the newspaper press, the proprietors of which are naturally unwilling to forego such lucrative advertisements, highly prejudicial though they be to the true interests of the public.

PAYMENTS FOR POST-MORTEM EXAMINATIONS.

M.D. asks if he is entitled to claim a fee for making a *post-mortem* examination without previously having received an order from the coroner for so doing, although at the inquest he gave evidence as to the results of the *post-mortem* examination.

* * Section 4 of the 6 and 7 Will. IV, c. 89, provides as follows: "That no fee or remuneration shall be paid to any medical practitioner for the performance of any *post-mortem* examination without the previous direction of the coroner."

We should advise "M.D.," in similar cases to the one he describes, to communicate at once with the coroner and delay the making of *post-mortem* examinations until he has received an order from the coroner for so doing. It may happen that the friends of a deceased person might accuse the medical attendant of neglect or improper treatment, or indeed he may himself be implicated in causing the death. Under either of these circumstances it is obvious that the *post-mortem* examination should be placed in other hands than his, otherwise the ends of justice might be defeated. We are aware of the difficulties surrounding a case where there may be a strong belief in the

mind of the practitioner that the death did not arise from natural causes, and his reluctance to call for a public inquiry unless the *post-mortem* evidence confirms any suspicion he may entertain. In "M.D.'s" case the *post-mortem* examination was of the utmost importance, and in making it he did not act contrary to the law or unwisely, but unfortunately, he is deprived by law of the fee which he might well expect to receive, being, we presume, previously unaware of the law on the subject.

PARTNERSHIP WITH AN UNQUALIFIED PERSON.

M.B. writes: My brother is at present a medical student, but unqualified; I am a qualified medical practitioner. Can my brother enter into a partnership with me so as to satisfy the condition of a will which requires us to enter into partnership as "medical practitioners" before we can receive a certain legacy left on those conditions?

"* The Medical Acts prohibit unqualified persons from acting as medical practitioners. But the Court of Appeal, in the year 1885, in the case of *Davles v. Makuna*, intimated that there would be nothing illegal if an unqualified person carried on business as a surgeon or apothecary entirely by means of qualified assistants, and not personally. There seems therefore to be nothing to prevent an unqualified person entering into an agreement of partnership with a qualified one, so as to share the profits; but he must take care, while unqualified, to confine his practice to such matters as do not require to be performed by a qualified practitioner.

MEDICAL ETIQUETTE OF SUBSTITUTES.

M.B. Edin. writes: A and B are neighbouring practitioners, residing within less than half a mile of each other. A was engaged to attend Mrs. C. in her confinement in August last, and remained in town until September 13th; then, as the case had not come off (and as A's partner did not undertake midwifery), A asked B to attend for him, which he consented to do, and Mrs. C. was confined on September 21st. B received the fee, which A requested him to keep. On his return, A attended the family from October 27th to December 14th.

On April 6th A heard of the serious illness of Mrs. C.'s baby, and was told that B was in attendance, and on calling at Mrs. C.'s residence found that B had lately given surgical advice to Mrs. C.'s husband, and afterwards was called in to attend the baby. This he did without informing A, although he knew A was their usual medical attendant.

B writes A, saying, "I saw no reason for refusing to attend him (Mr. C.), in fact it never occurred to me to do so. I have not attended him before, and as far as I could see, he was as much my patient as anybody's. Since that time he has called me in to his child, and as I had not attended her (the baby) for anyone else, I did not hesitate."

"* A careful consideration of the correspondence between A and B, in reference to the case submitted by "M.B. Edin.," leaves no doubt upon our mind that B, having gained an introduction to the family in question through the medium of his attendance on Mrs. C., as the officiating friend of A, it was (as we view it) clearly his duty to have declined to take charge of either case, and to have referred Mr. C. to the usual family medical attendant A. We may add that although B, in assenting to attend Mr. C. and the baby may possibly have acted within the strict letter of the law, he certainly failed to fulfil the moral obligation of doing unto others 'as he would wish to be done by, and therefore by such omission contravened the true spirit of medical ethics.

DETENTION OF CERTIFICATES.

M.R.C.S. writes: A week ago I applied to a certain medical man residing in the north of England for an appointment to take charge of a colliery practice, and enclosed him my testimonials. A few days ago I received information that the appointment was filled. I wrote to him requesting him to kindly return my testimonials, which he has not done. I have written to him three letters and can get no reply. I am now in treaty for an appointment to take charge of a branch practice. I will thank you to advise me what steps I ought to take in this matter in order to compel this medical man to deliver up my testimonials.

"* If "M.R.C.S." commences proceedings for the recovery of his testimonials, and in such proceedings ask for damages against the person detaining them, this would soon lead to their return.

UNIVERSITY INTELLIGENCE.

UNIVERSITY OF ABERDEEN. GRADUATION IN MEDICINE.

At the graduation, on April 11th, the following candidates received degrees in Medicine and Surgery.

The degree of M.D.:

F. A. Bennett, M.A., M.B., C.M., Victoria, Australia; J. Glaister, M.B., C.M., Putney, London; J. Jenkyns, M.B., C.M., Belize, British Honduras; W. Lawson, M.B., C.M., West Bromwich, Staffordshire; J. Russell, M.B., C.M., Arbroath; W. R. Tough, M.A., M.B., C.M., Crook, co. Durham; A. Wilson, M.A., M.B., C.M., Middlesbrough.

The degrees of M.B. and C.M. (The awarding of honours has been deferred until the graduation in July):

G. Allan, Fife-Keith; J. Barclay, Dunceath; R. Cumming, Duthil, Strathspay; A. Dingwall, M.A., Aberdeen; J. Don, Cults; A. L. Duke, Arbroath; R. Batough, Brindley, Lancashire; A. D. Ellis, Aberdeen; J. G. Forsyth, Abernethy; A. R. Galloway, M.A., Inverurie; G. Gibb, M.A., Aberdeen; G. Gordon, Huntly; C. Grant, Caithness; T. W. Illigworth,

Scarborough; J. Joss, M.A., Huntly; A. Keith, Turriff; D. A. F. Kydd, Pollokshields, Glasgow; A. Leach, London; W. L. Mackenzie, M.A., Alness; R. G. McKerron, M.A., Aberdeen; W. R. C. Middleton, M.A., Aberdeen; T. M. Rae, M.A., Uday; J. S. Riddell, M.A., Aberdeen; G. R. C. Russell, Orkney; A. M. Saunders, M.A., Woodside, W. St. John Skeen, Aberdeen; R. M. Townsend, Cape Colony; A. M. Will, Aberdeen. J. Grant, Tomintoul, has passed the examinations for the degrees of M.B. and C.M., but will not graduate until he has attained the necessary age.

The diploma in Public Health was conferred on the following gentlemen:

A. C. Ferguson, M.A., M.B., C.M.; G. Rose, M.B., C.M.; A. M. Saunders, M.A., M.B., C.M.

The following candidates have passed the First Division of the First Professional Examination for the degrees of M.B. and C.M.: W. Astin, R. N. de Beauvais, J. Bell, W. L. Collie, D. Crichton, B. Cunliffe, W. W. Forbes, W. L. Heaton, A. Lamont, A. B. Macartney, J. A. Macintosh, F. M'Leod, E. L. Mansel, W. S. Park, B. Saunders, W. J. Soysa.

The following candidates have completed the First Professional Examination:

G. Black, J. W. Bulloch, S. H. Burnett, J. H. G. Cowie, E. J. Cox, W. Davidson, J. A. Davie, R. C. Duthie, J. Fraser, A. Geddes, J. Gray, T. Holt, A. Hunter, J. R. Keith, *C. A. B. Laing, D. Lamond, G. A. Lang, J. B. Lendrum, J. R. Levaek, A. B. Lyon, W. Macbain, F. P. M'Lennan, J. Miller, L. J. Milne, W. S. Park, A. Pickles, *J. Rannie, A. H. Rideal, G. Robertson, A. C. Ross, C. R. Selbie, J. H. Skeen, J. Smith, J. H. L. Sutherland, F. H. Thomson, *D. M. Tomory, J. D. Walker, J. W. Watson, J. S. Williamson, J. Wilson.

The following candidates have passed the Second Professional Examination:

A. Barber, J. F. Black, J. A. Bruce, H. F. Cameron, J. A. R. Cushny, *G. Dean, W. Diack, S. S. Dunn, J. G. Durran, C. F. Fearnside, D. W. Geddie, R. Grant, A. G. Johnston, *A. Little, F. W. Ludlow, D. J. Macdonald, G. Macdonald, *A. M'Gillivray, T. M'Hardy, J. M. Mackay, A. B. Mackin, *A. Noble, J. P. Philip, D. Reid, J. Reid, W. R. Reith, D. Rennet, F. A. Roden, *A. Rose, L. M. Scott, G. J. Silver, D. M. Smith, J. F. Souler, W. H. Stephen, C. W. T. Stephenson, J. A. Sutherland, W. C. Taylor, R. Thomson, J. Troup, J. Valentine.

* Indicates that the candidate has passed the examination with "credit."
† Indicates that the candidate has passed the examination with "much credit."

UNIVERSITY OF GLASGOW.

The following gentlemen have passed the first professional examination for the degrees of M.B. and C.M. (subjects—Chemistry, Botany, and Natural History):

H. C. Anderson, J. W. M. Buick, D. G. Carmichael, A. Chalmers, D. Christie, W. Craik, W. Crichton, J. Falconer, A. Higgin, J. Johnson, D. Kerr, S. R. Lane, H. Lang, C. Lavery, E. L. Marsh, J. W. Mathie, A. M. G. Macdonald, J. A. Macintosh, N. Macintyre, J. M'Kay, Bellshill; R. J. Mackay, G. M'Lauchlan, W. A. Neish, D. W. Reese, R. Reid, J. G. Ronald, R. H. Rothery, C. Symington, W. T. M. Wallace, A. Watson, J. Iz White, J. W. White, J. Whitehouse, B. Williams, J. Zaill.

The following have passed the second professional examination (subjects—Anatomy and Physiology):

P. H. Abercrombie, R. H. Adam, M.A.; C. Bannatyne, J. W. Boyd, R. Brownridge, J. R. Bryce, M. Cameron, J. Caskie, W. Colvin, A. Fairlie, M.A.; A. F. C. Gilmour, J. Hunter, J. H. Jones, C. F. Laing, J. Munro, C. M. C. Macaulay, M.A.; D. Macdougall, P. Rankin, J. Richardson, B.A.; W. J. Robertson, M.A.; A. M. Roy, J. Swanson, M.A.; A. W. Taylor, J. S. Wallace, J. R. Wabert.

The following have passed the third professional examination (subjects—Regional Anatomy, Materia Medica, and Pharmacy):

J. Abbott, *J. Adam, *J. Aitken, W. M. Alexander, *J. B. M. Anderson, M.A.; J. T. Biernacki, *M. Blair, H. M. D. Borland, *W. M. Boyd, J. David, J. H. Dickson, A. Donald, J. P. Dunn, P. Ferguson, A. R. Fraser, M.A.; J. H. Glaister, G. Gordon, *J. G. Gray, *T. B. Hutchison, *C. A. Lewis, G. Lowson, *G. Mathieson, A. W. Miller, A. Morton, *W. Muir, D. M'Callum, J. D. M'Intosh, K. C. Mackenzie, J. B. M'Lean, *D. Revie, J. Robertson, J. Rowan, H. S. Russell, *W. P. B. Sandilands, W. J. M. Sloman, J. Smith, *J. T. Smith, *G. Steele, *H. G. Stewart, *A. F. Walker, M. Whyte, W. M'G. Young, M.A.; H. H. Park.

* Passed also in Pathology.

UNIVERSITY OF ST. ANDREWS.

MEDICAL GRADUATION, Session 1887-88.

The following gentlemen, having passed the required examinations, had the degree of Doctor of Medicine conferred upon them on April 18th, 1888:

J. J. Bingham, M.R.C.S.Eng., L.S.A.Lond., Alfreton; W. N. Elder, L.R.C.P.Ed., L.R.C.S.Ed., Edinburgh; A. Hirst, F.R.C.P.Ed., Prestwick; A. Moir, L.R.C.P.Ed., L.R.C.S.Ed., Edinburgh; W. Richardson, L.R.C.P.Ed., F. and L.R.C.S.Ed., L.M., Reading; J. J. Rutherford, L.R.C.P.Ed., L.F.P.S.Glasgow, L.M., Shipley, E. I. Scott, L.K.Q.C.P.Irel., L.R.C.S.Irel., Brackley; W. W. Smith, L.R.C.P.Ed., L.S.A.Lond., Sittlingbourne; S. Stirling, F. and L.R.C.S.Ed., Edinburgh; W. B. Thorne, L.R.C.P.Lond., M.R.C.S.Eng., London.

DEODORISATION OF THE METROPOLITAN SEWAGE.—The Metropolitan Board of Works have resolved to appoint Sir Henry Roscoe, M.P., consulting chemist to the Board, in connection with the deodorisation of the sewage and the purification of the River Thames, for a period of twelve months.

PUBLIC HEALTH

AND

POOR-LAW MEDICAL SERVICES.

THE TRUE DEATH-RATES OF LONDON DISTRICTS DURING THE FIRST QUARTER OF 1888.

In the accompanying table will be found summarised the vital and mortal statistics of the forty-one sanitary districts of the metropolis, based upon the Registrar-General's returns for the first quarter of this year. The mortality figures in the table relate to the deaths of persons actually belonging to the respective sanitary districts, and are the result of a complete system of distribution of deaths occurring in the institutions of London among the various sanitary districts in which the patients had previously resided. By this means the precise number of deaths of persons actually belonging to the respective sanitary districts is known, as all deaths occurring in institutions of persons who had previously resided in another district have been excluded from the total number of deaths in the district in which the institution is situated, and credited to the districts from which they came. By this means alone can trustworthy data be secured upon which to calculate reliable rates of mortality.

The births registered in London during the first quarter of the current year were equal to an annual rate of 32.2 per 1,000 of the population of the metropolis, estimated at 4,282,921 persons, and showed a further decline from the rates recorded in the corresponding periods of recent years. The birth-rates in the various sanitary

districts last quarter showed the usual wide variations, the age and sex distribution of the population differing greatly. In St. James Westminster, Kensington, London City, and Hampstead the birth-rates were considerably below the average, while in East London, St. Luke's, Southwark, and Fulham, where the population contains a large proportion of young married persons, the birth-rates showed a marked excess.

The 23,164 deaths of persons belonging to London registered during the quarter under notice were equal to an annual rate of 21.7 per 1,000, which, although it exceeded the low rate recorded in the corresponding period of 1887, was below the mean rate in the first quarter of the ten preceding years, 1878-87. The lowest death-rates among the forty-one sanitary districts last quarter were 13.9 in Hampstead, 16.7 in Kensington, 17.5 in Plumstead, 17.8 in Battersea, and 18.1 in Camberwell; in the other districts the rates ranged upwards to 28.3 in Bethnal Green, 28.9 in London City, 29.9 in St. George-in-the-East, 30.2 in Fulham, and 32.8 in Holborn. During the quarter under notice 2,965 deaths resulted from the principal zymotic diseases in London; of these, 1,617 were referred to whooping-cough, 412 to scarlet fever, 307 to diphtheria, 238 to measles, 238 to different forms of "fever" (including 4 to typhus, 224 to enteric or typhoid fever, and 10 to simple and ill-defined forms of fever), 149 to diarrhoea, and 4 to small-pox. These 2,965 deaths were equal to an annual rate of 2.8 per 1,000, which exceeded that recorded in the corresponding quarter of any year since 1882. The lowest zymotic death-rates during the three months under notice were recorded in Hampstead, Strand, St. Giles, Plumstead, Marylebone, St. George Southwark, Woolwich, St. George Hanover Square, Ken-

sington, and St. Saviour Southwark, in each of which it was below 2.0 per 1,000. In the other districts the zymotic death-rate ranged upwards to 4.0 in Stepney, 4.1 in Westminster, 4.3 in Mile End Old Town, 4.8 in Lewisham, 5.0 in Fulham, and 5.6 in Bethnal Green. Compared with the preceding quarter, the fatality of each of the principal zymotic diseases, except whooping-cough, showed a decline. Only 4 deaths from small-pox were recorded in London during the first three months of this year, of which 1 belonged to Bethnal Green, 1 to Mile End Old Town, 1 to Camberwell, and 1 to Greenwich sanitary districts. The number of small-pox patients in the Metropolitan Asylums Hospitals, which had been 7 at the beginning of the year, had increased to 17 in the middle of March, but declined to 9 at the end of the quarter; the admissions were 38 during the quarter, against 37 in the last six months of 1887. Measles showed the highest proportional fatality in Greenwich, Lewisham, Fulham, and St. James Westminster; scarlet fever in Mile End Old Town, Westminster, Bethnal Green, Camberwell, and Greenwich; diphtheria in Westminster, St. Giles, Paddington, and Lewisham; whooping-cough in Fulham, Shoreditch, St. Luke's, and Bethnal Green; and "fever" in Poplar and St. James Westminster. The number of scarlet fever patients in the Metropolitan Asylums Hospitals, which had been 2,049 at the beginning of the year, steadily declined to 1,087 at the end of March; the admissions to these hospitals of persons suffering from this disease, which had risen from 531 to 2,186 in the four quarters of 1887, declined to 1,416 during the three months ending March last.

Infant mortality last quarter, measured by the proportion of deaths under one year of age to births registered, averaged 143 per 1,000, against 133, 149, and 131 in the corresponding periods of the three preceding years, 1885-6-7. Among the various sanitary districts the rates of infant mortality were lowest in Hampstead, St. Giles, Wandsworth, Mile End Old Town, and Lambeth; whereas they showed the largest excess in Lewisham, Woolwich, Rotherhithe, Fulham, Bethnal Green, and Hammer-smith.

HEALTH OF ENGLISH TOWNS.—During the week ending Saturday, April 14th, 6,477 births and 3,952 deaths were registered in the twenty-eight largest English towns, including London, which have an estimated population of 9,398,273 persons. The annual rate of mortality per 1,000 persons living in these towns, which had been 21.5 and 19.9 in the two preceding weeks, rose again to 21.9 during the week under notice. The rates in the several towns ranged from 16.8 in Portsmouth, 17.7 in Huddersfield, 17.8 in Sunderland, and 18.4 in Norwich to 26.2 in Plymouth, 28.1 in Blackburn, 30.0 in Wolverhampton, and 34.9 in Manchester. The mean death-rate in the twenty-seven provincial towns was 23.1 per 1,000, and exceeded by 2.5 the rate recorded in London, which was 20.6 per 1,000. The 3,952 deaths registered during the week under notice in the twenty-eight towns included 358 which were referred to the principal zymotic diseases, against 388 and 371 in the two preceding weeks; of these, 172 resulted from whooping-cough, 46 from scarlet fever, 38 from diarrhoea, 33 from diphtheria, 32 from measles, 21 from "fever" (principally enteric), and 16 from small-pox. These 358 deaths were equal to an annual rate of 2.0 per 1,000; in London the zymotic death-rate was 2.2, while in the twenty-seven provincial towns it averaged 1.8 per 1,000, and ranged from 0.4 and 0.5 in Sunderland and Preston to 3.2 in Salford, 3.4 in Plymouth and in Sheffield, and 3.5 in Blackburn. Measles caused the highest proportional fatality in Nottingham and Plymouth; scarlet fever in Birkenhead, Hull, and Oldham; whooping-cough in London, Leicester, Blackburn, and Salford; and "fever" in Derby. The 33 deaths from diphtheria in the twenty-eight towns included 19 in London, 4 in Liverpool, and 2 in Sheffield. Of the 16 fatal cases of small-pox recorded during the week under notice, 11 occurred in Sheffield, 3 in Blackburn, 1 in Bristol, and 1 in Manchester. The Metropolitan Asylums Hospitals contained 15 small-pox patients on Saturday, April 14th, of whom 7 had been admitted during the week. These hospitals also contained 1,002 scarlet fever patients on the same date, showing a further decline from recent weekly numbers; there were 92 admissions during the week. The death-rate from diseases of the respiratory organs in London was equal to 5.4 per 1,000, and was slightly below the average.

HEALTH OF SCOTCH TOWNS.—In the eight principal Scotch towns, 849 births and 526 deaths were registered during the

week ending Saturday, April 14th. The annual rate of mortality, which had been 23.7 and 21.8 per 1,000 in the two preceding weeks, further declined to 20.8 during the week under notice, and was 1.1 per 1,000 below the mean rate during the same period in the twenty-eight large English towns. Among these Scotch towns the lowest rates were recorded in Leith and Greenock, and the highest in Aberdeen and Perth. The 526 deaths in these towns during the week under notice included 49 which were referred to the principal zymotic diseases, equal to an annual rate of 1.9 per 1,000, which almost corresponded with the mean zymotic death-rate during the same period in the large English towns. The highest zymotic rates were recorded in Edinburgh, Glasgow, and Perth. The largest proportional fatality of whooping-cough occurred in Glasgow and Edinburgh. The three deaths from diphtheria included 2 in Edinburgh; and 5 fatal cases of "fever" were recorded in Glasgow. The mortality from diseases of the respiratory organs in these towns was equal to 5.1 per 1,000, against 5.4 in London.

HEALTH OF IRISH TOWNS.—During the week ending Saturday, April 14th, the deaths registered in the sixteen principal town districts of Ireland were equal to an annual rate of 26.9 per 1,000. The lowest rates were recorded in Sligo and Galway, and the highest in Kilkenny and Lisburn. The death-rate from the principal zymotic diseases in these towns averaged 2.9 per 1,000, and was highest in Lisburn and Lurgan. The 187 deaths registered in Dublin during the week under notice were equal to an annual rate of 27.6 per 1,000, which showed a slight further decline from the rates recorded in the two preceding weeks. The 187 deaths included 15 from the principal zymotic diseases (equal to an annual rate of 2.2 per 1,000), of which 7 were referred to whooping-cough, 3 to measles, 3 to "fever," 1 to scarlet fever, and 1 to diarrhoea.

BELVIDERE FEVER HOSPITAL, GLASGOW.

FURTHER improvements are proposed at Belvidere Hospital, with a view to increase the administrative department. It is proposed to erect new washing houses, with all necessary appliances, and so arranged as to isolate officials, patients, and hospital clothing, a point strongly urged by the medical staff. The present washing houses would then be reconstructed for the accommodation of the house steward's department, stores, etc. The total cost of the new work is estimated at £10,000. It will also provide for the erection of dwelling-house accommodation for the employees other than the nursing staff, who should reside in the hospital.

THE MARGARINE ACT IN OPERATION.

A SECOND prosecution under this Act has occurred in Glasgow, in which a penalty has been imposed. The shopkeeper was fined for having lumps of margarine exposed for sale unticketed. Beside the margarine there was butter labelled as such. The suggestion was that the lumps of margarine were meant to be covered by the butter label.

THE GOVERNMENT SANITARY SURVEY.

MR. J. DAVIES.—The sanitary survey in question was made by the Medical Department of the Local Government Board. It was begun in the summer of 1884, when cholera first began to threaten us from the Continent, and it was continued until the close of 1886. It did not include every sanitary area in the kingdom, but that was not the fault of the Department. It embraced however, all the coast districts, and such of the inland areas as were special liable to the importation of infection, or had shown by their sickness and other records evidence of doubtful sanitation. The results of the survey have not been issued in an absolutely separate form, but are contained in the Papers on Cholera, published as a supplement to the Fifteenth Annual Report of the Local Government Board (Command Paper 4,873, Session 1886, price 2s.), and in the Report of the Medical Department, published as a supplement to the Sixteenth Report of the Board (Command Paper 5,171, Session 1887, price 7s.). These reports can be obtained from the Queen's Printers, or from any of the agents who sell Parliamentary papers. An article on this subject will be found at page 787 of the JOURNAL for April 9th, 1887.

DUTIES OF MEDICAL OFFICERS OF HEALTH WITH REGARD TO NUISANCES.

ALPHA asks: I. What is my duty with regard to nuisances if the inspector of nuisances is under the control exclusively of the Sanitary Committee? Am I responsible for the reporting of all nuisances?

ANS.—It is your duty to report generally as to the necessity for removing nuisances in your district, and you would necessarily call attention to special causes of ill-health, but the duty cannot be performed in the detail way that is required of an Inspector of nuisances, and we hold you have no responsibility for reporting all.

OBITUARY.

SURGEON-MAJOR R. H. GARDNER, M.S.

THE death of Surgeon-Major Gardner occurred at Cheltenham on March 19th of fever contracted at Dune Dune. The deceased officer was in his thirty-seventh year. The following is an account of his public services.

He was gazetted Surgeon September 30th, 1874. He served in India (Madras Presidency) and Burmah from 1875, and in the first Egyptian campaign of 1882, and was at the engagement at El Magfar, in two actions at Kassassin, and at Tel-el-Kebir (medal with clasp and Egyptian bronze star). On his return he was in medical charge of the Station Hospital, Sheerness, when he was again ordered to Egypt for duty during the cholera epidemic of 1883. Returning to England in 1884, he did duty in the Station Hospital, Dover, and at the end of the year he was again ordered to India, and did duty in Fort William, Calcutta, till November, 1885, when he left for Burmah in medical charge of the King's Liverpool Regiment, and was present at the capture of the Minhla Forts, and when King The-baw was taken prisoner, and accompanied him in medical charge from Mandalay to Madras (Burmah medal with clasp). In March, 1886, he returned, and took over the duties of Staff-Surgeon at Fort William, and on May 10th, 1887, was appointed to the medical charge of the Station Hospital, Dune Dune. During his service he had many severe illnesses, which so undermined his constitution that he never recovered from the effects of the fever attack, though a change first to Ceylon and then to England was tried.

HENRY JAMES DWELLY, L.R.C.P. EDIN., M.R.C.S.E.

THE death of Mr. Dwelly occurred at his residence, Rye Lane, Peckham, on Sunday, April 8th, at the age of 45. The deceased gentleman was born in London, and had been in practice at Peckham for the last twenty-three years. He took an active part in the Volunteer movement, and at the time of his death held the office of major of the 1st City of London Artillery. The immediate cause of his death was inflammation of the lungs, to which he succumbed after five days of suffering. He was widely known in his district as a busy practitioner, and highly esteemed for his pleasant social qualities. He was buried with military honours. He leaves a widow and three children.

MEDICAL NEWS.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the Second Examination in Anatomy only at a meeting of the Board of Examiners on April 11th, namely:—

F. A. Field, C. H. Whiteford, R. A. Walter, F. Johnson, J. B. Anderson, G. E. Bensley, W. W. Nuttall, R. S. McD. Pullen, E. C. Bridges, M. Swabey, W. W. Smith, A. W. Tidbury, and J. H. Tootal, students of St. Bartholomew's Hospital; E. G. Renny and P. C. Phillips, of St. Thomas's Hospital; E. K. Goodwin, of King's College; M. C. Langford, of London Hospital; W. E. Passmore, of Westminster Hospital; W. K. Bell, of Charing Cross Hospital and Mr. Cooke's School of Anatomy.

Passed in Physiology only.

J. M. Rogers-Tillstone, R. E. Wickes, E. E. Wilbe, and A. W. Lemarchand, of St. Bartholomew's Hospital; M. F. Agar and A. W. Sturdee, of London Hospital; T. S. Byass and F. S. Colton, of University College; G. Liechl and H. G. Biddle, of Guy's Hospital; T. Prescott and J. B. M. Kennedy, of King's College; W. D. Lockhart, A. R. Chater, and H. J. L. Bullen, of St. Mary's Hospital; W. White, of Middlesex Hospital; W. F. E. Milton and J. R. Scott, of St. Thomas's Hospital.

Passed in Anatomy only on April 12th.

C. W. Grant, E. W. Everett, A. O. Hubbard, and J. E. S. Frazer, of St. Bartholomew's Hospital; C. E. M. Hey, A. E. F. F. Huntsman, and E. M. Knott, of St. Mary's Hospital; E. J. MacGrath and J. C. Ellis, of St. George's Hospital; G. Padmore, of St. George's Hospital and Mr. Cooke's School of Anatomy; E. B. Smith, F. Dove, and C. T. W. Hirsch, of London Hospital; E. M. Rooke, F. A. Osborn, and W. A. Higgs, of Guy's Hospital; J. Yeomans, of University College; E. C. MacLeod, of Westminster Hospital; A. R. McFarlane, of Middlesex Hospital; and E. D. Dunn, of St. Thomas's Hospital.

Passed in Physiology only.

S. A. Ord-Mackenzie, A. S. Jones, and A. C. Black, of University College; B. F. Parish, L. A. Francis, E. G. Boon, and G. R. M. Gideon, of St. Mary's Hospital; J. Wells and S. R. Strouts, of London Hospital; J. H. Roberts and C. E. Pollock, of Guy's Hospital; S. Gresswell and A. R. Badger, of St. Bartholomew's Hospital; J. W. Williams, of Middlesex Hospital.

Passed in Anatomy and Physiology on April 13th.

J. Grimshaw, of London Hospital.

Passed in Anatomy only.

E. Henry and H. F. Luckie, of St. Bartholomew's Hospital; C. E. Salter, of Guy's Hospital; E. C. Walter, J. S. Bradish, E. P. Isaacs, and A. S. Gedge, of St. Thomas's Hospital; G. E. Gillett, R. Jackson, P. A. Green, J. E. S. Passmore, E. J. F. Moore, and C. H. Hemming, of London Hospital; H. C. Nicholls, of Charing Cross Hospital; A. J. Lattev, H. W. Roberts, and G. Y. C. Hunter, of St. George's Hospital; H. G. Beville, of St. George's Hospital and Mr. Cooke's School of Anatomy; C. S. Bowker, of Middlesex Hospital.

Passed in Physiology only.

H. Hodgson, of Guy's Hospital; H. E. Burch, A. C. Durham, W. Watkins, and A. Plumble, of London Hospital; J. H. Hadaway, of Middlesex Hospital; R. H. Collins, of Charing Cross Hospital; H. J. Curtis, of University College.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—At the usual monthly examination meeting of the President and Fellows, held on Friday, April 13th, 1888, the following registered medical practitioners, having passed the necessary examinations, were duly admitted Licentiates of the College.

For the Licences to Practise Medicine and Midwifery.—W. G. Rutherford, L.R.C.S.I., Tipperary.

For the Licence to Practise Medicine.—A. D. MacLeod, L.R.C.S.I., Portlinton, Queen's County.

For the Licence to Practise Midwifery.—E. A. C. Baylor, M.B. Univ. Dub., Fermoy, co. Cork; J. W. Gallagher, L.R.C.S.I., Strabane; E. J. Jacob, L.K.Q.C.P., Maryborough.

At a special examination for the Licence in Medicine of the College, held on Thursday, March 22nd, 1888, the undermentioned candidate was successful.

C. Westbrook, L.S.A. Lond.

At a meeting of the President and Fellows, held on Friday, April 6th, 1888, the following candidate was elected a Fellow of the College.

G. P. L'Estrange Nugent, M.B. Univ. Dub. 1878, L.K.Q.C.P.I. 1885, M.K.Q.C.P.I. 1887, Physician to the House of Industry Hospitals, Dublin.

STRAY AND RABID DOGS.—We glean from the report of Mr. Charles Colam, Secretary of the Dogs' Home at Battersea, that the number of stray dogs which entered the home during last year was considerably smaller than during the previous twelve months. This is regarded as the natural result of the rigorous enforcement of the police orders respecting stray dogs issued in 1885 and 1886. During the year 12,881 were brought into the home. It is satisfactory to learn that during the past year only one dog in the whole of the metropolis was afflicted with rabies, a fact which seems almost incredible when it is remembered that three years ago there were no fewer than sixty so attacked, and a year later fourteen. This points to the practical extinction of this dreadful disease. It is a matter for regret that this institution, which has done so much to stamp out hydrophobia, has not received more substantial support. An unsuccessful application has been made to the Government for an increase in its subscription, which amounted only to £10 per annum, and an appeal to the Metropolitan Board of Works for a special donation has also been made in vain. There is still a debt of £1,000 upon this institution.

THE HOSPITALS ASSOCIATION.—The next evening meeting of the Hospitals Association will be held in the Governors' Hall of St. Thomas's Hospital, Albert Embankment, S.E., on Wednesday, April 25th, at 8 P.M. The President of the Association, Dr. J. S. Bristowe, will preside, and a paper will be read by Mr. W. Burdett-Coutts, M.P., on "Contributions by Patients in relation to the Financial Condition of London Hospitals." Cards of admission can be obtained on application from Mr. Howard J. Collins, Secretary to the Hospitals Association, Norfolk House, Norfolk Street, W.C.

A CHARGE OF NEGLECTING TO NOTIFY.—A charge which created a good deal of local medical interest was brought a few days since by the Jarrow Corporation against Mr. W. M. Jennings, M.R.C.S., a medical practitioner of the borough, of neglecting properly to notify cases of infectious disease to the authorities. Mr. Jennings had, it appears, informed the mother that the children were suffering from scarlatina, and that scarlatina was one of the diseases mentioned in the Act. The Town Clerk eventually admitted his inability to carry the case any further, and it was therefore dismissed, as were three other charges of a similar character. Each party had to pay their own costs.

DR. JAMES HUTCHISON, Paisley, has just been presented with a purse containing 120 sovereigns, and a gold Albert, by gentlemen in Paisley and neighbourhood, on the attainment of his jubilee as a medical practitioner. A short time ago Dr. Hutchison also

received a presentation, with congratulations on his jubilee, from his professional brethren in Paisley.

THE St. Pancras Vestry have decided, by a large majority, to contribute £30,000 to the fund for the acquisition of Parliament Hill.

A WHOLESALE provision dealer at Shrewsbury has been fined £20 for supplying to the Salop Infirmary margarine containing eighty parts of foreign fat, for butter.

DR. H. F. BURNES, of Dalmeny House, Tufnell Park Road, has been elected a guardian for the Lower Holloway Ward, on the Islington Board of Guardians. The superannuation of medical officers will early occupy the attention of the board, and Dr. Burnes promises to be a firm friend of professional rights on the board.

MEDICAL VACANCIES.

The following Vacancies are announced:

BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon, Salary, £150, and £30 extra for cab hire. Applications by May 10th to A. Forrest, Esq., Secretary.

BIRMINGHAM GENERAL HOSPITAL.—Assistant House-Surgeon. Residence, board, etc. Applications by April 28th, to the House Governor.

BIRMINGHAM GENERAL HOSPITAL.—Resident Surgical Officer. Salary, £130 per annum, with board and residence. Applications by April 30th to the House Governor.

BOROUGH OF BRIGHTON.—Medical Officer of Health. Salary, £500 per annum. Applications by May 2nd to F. J. Tillstone, Esq., Town Clerk.

BRISTOL ROYAL INFIRMARY.—Honorary Assistant Physician (to out-patients). Applications by May 5th to the Secretary.

DURHAM COUNTY HOSPITAL.—Honorary Surgeon. Applications by April 30th to the Secretary.

DURHAM COUNTY HOSPITAL.—Honorary Surgeon-Dentist. Applications by April 30th to the Secretary.

HERTFORD BRITISH HOSPITAL, Paris.—House-Surgeon. Applications to the Secretary, Rue de Villiers, Levallois, Paris.

HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen Square, W.C.—House-Physician. Salary, £50 per annum, with board and residence. Applications by April 30th to B. Burford Rawlings, Esq., Secretary-Director.

LIDDELL PROVIDENT DISPENSARY, Jarrow-on-Tyne.—Medical Officer. Salary, £200. Applications to John Christie, Esq., 28, Cobden Street, Jarrow.

LIVERPOOL INFIRMARY FOR CHILDREN.—Assistant House-Surgeon. Board and residence. Applications by May 2nd to the Honorary Secretary.

LONDON SKIN HOSPITAL, 47, Cranbourn Street, W.C.—Assistant Medical Officer. Applications by May 1st to the Secretary.

LONDON THROAT HOSPITAL, Great Portland Street, W.—Surgeon. Applications by May 1st to W. R. H. Stewart, Esq., Honorary Secretary of Medical Committee.

NEWPORT AND COUNTY INFIRMARY.—House-Surgeon. Salary, £100 per annum with board and residence. Applications to J. K. Stone, Esq., The Infirmary, Newport, Mon.

NORFOLK COUNTY ASYLUM, Thorpe, near Norwich.—Junior Assistant Medical Officer. Salary, £100, with board, etc. Applications by April 21st to Dr. Thompson, Medical Superintendent.

NORTH-WEST LONDON HOSPITAL, Kentish Town Road.—Senior Resident Medical Officer. Applications by April 23rd to the Secretary.

ROTHERHAM HOSPITAL.—Assistant House-Surgeon. Board, etc. Applications by April 27th to the House-Surgeon.

ROYAL SOUTH HANTS INFIRMARY, Southampton.—Assistant to House-Surgeon. Board and residence. Applications by May 5th to Dr. Thomas, Angelsea Place, Southampton.

SEAMAN'S HOSPITAL SOCIETY.—Visiting Physician. Applications by May 5th to P. Michelli, Secretary, Seaman's Hospital, Greenwich, S.E.

ST. LUKE'S HOSPITAL.—Resident Clinical Assistant. Board and lodging. Applications by April 28th to the Secretary.

WARWICK COUNTY LUNATIC ASYLUM, Hatton, near Warwick.—Assistant Medical Officer. Salary, £100 per annum, with board, etc. Applications to the Superintendent.

MEDICAL APPOINTMENTS.

BOTCOTT, W. F., M.R., C.M., Ed., appointed Senior House-Surgeon to the Ancoats Hospital, Manchester, vice A. W. Hutton, M.R.C.S., L.R.C.P. Lond., resigned.

BREWSTER, Wm. Moss, M.R.C.S. Eng., L.R.C.P., L.M. Ed., 7 late Chloroformist to the Liverpool Royal Infirmary, appointed Honorary Assistant Surgeon to Seacombe Hospital, Birkenhead.

BROADBENT, Frank, M.R.C.S., L.R.C.P. Ed., appointed Medical Officer of Health for the Northern Division of the Newark Union.

BOOKS, Samuel John, M.R.C.S. Eng., L.S.A. Lond., appointed Medical Officer of Health to the Lanchester Urban and Rural Sanitary Authority; Medical Officer to the Lanchester Workhouse, to the No. 6 and No. 8 Districts respectively; Public Vaccinator to the Borough of Lanchester, vice G. Sargent, M.R.C.S., L.S.A., resigned.

DOBBS, Thomas Anthony, L.R.C.P. Ed., M.R.C.S. Eng., appointed Consulting Medical Officer to the Newcastle-on-Tyne Workhouse Hospital.

HEBB, R. G., M.A., M.D. Camb., M.R.C.S., Pathologist to the Westminster Hospital, appointed to the Lectureship on Morbid Histology at that school, vice Dr. Henegar Gibbs, resigned.

JONES, Robert, Honorary Surgeon to the Liverpool Stanley Hospital, appointed Consulting Surgeon to the Manchester Ship Canal from Lymm to Liverpool.

MCLEAN, Allan, M.B., C.M., appointed Medical Officer of Health to the Portland Urban Sanitary Authority.

MANNING, L. S., M.B., C.M., appointed House-Surgeon to the Central London Ophthalmic Hospital, Gray's Inn Road, W.C.

MURRAY, R. M., M.B., C.M., appointed House-Surgeon to the Infirmary for Children, Liverpool, vice E. L. Fox, M.B., M.R.C.S. Eng., resigned.

SCATLIFE, A. W., L.R.C.P., L.R.C.S., L.M. Ed., L.S.A., appointed Medical Officer of Health for the Margate Urban Sanitary District, vice W. K. Treves, F.R.C.S., resigned.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.

MEDICAL SOCIETY OF LONDON, 8.30 P.M.—Mr. J. Astley Bloxam: On the Treatment of Syphilis by the Intra-Muscular Injection of Mercury. Dr. Handford (Nottingham): On Albuminuria in Enteric Fever.

TUESDAY.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8.30 P.M.—Dr. Archibald R. Garrow: A further Contribution to the Study of Rheumatoid Arthritis. Dr. Haig: Effects in Diseases connected with Uric Acid of some Drugs which cause retention of Uric Acid, in contrast with the Action of Salicylates, as shown in a previous Paper.

WEDNESDAY.

ROYAL METEOROLOGICAL SOCIETY, 7 P.M.—Papers:—Mr. James B. Jordan: Jordan's new pattern Photographic Sunshine Recorder. Mr. William Doberck, Ph.D., F.R. Met. Soc.: On the Meteorology of South-Eastern China in 1886. Professor A. S. Herschel, M.A., F.R.S.: Lightning in Snowstorms. Mr. Rupert T. Smith, M. Inst. C.E., F.R. Met. Soc.: Insolation.

BRITISH GYNÆCOLOGICAL SOCIETY, 8.30 P.M.—Specimens will be exhibited by Dr. Purcell, Dr. Fancourt Barnes, Mr. Lawson Tait, the President, and others. Dr. William Alexander: A new Method of treating hitherto incurable cases of Incontinence of Urine in Women. Council, 8 P.M.

HUNTERIAN SOCIETY, 8 P.M.—Dr. A. D. Davies: A Case of Paralysis Agitans. Dr. Stephen Mackenzie: On the Skin Affections connected with Rheumatism. Dr. Dundas Grant: (1) Cancer of the Larynx benefited by Tracheotomy; (2) A Nasal Trephine. Dr. Carpenter (for the President): Hereditary Absence of the Iris associated with Talipes.

HOSPITALS ASSOCIATION, 8 P.M.—Mr. W. Burdett-Coutts, M.P. (at St. Thomas' Hospital): Contributions by Patients in relation to the Financial Condition of London Hospitals.

ROYAL MICROSCOPICAL SOCIETY, 8 P.M.—Conversation.

FRIDAY.

CLINICAL SOCIETY OF LONDON, 8 P.M.—Mr. B. Wainwright: Case illustrating Advantage of early Incision with Drainage as opposed to Excision of Joints. Dr. Hale White: On Perihepatitis. Mr. Lucas: Case of Tumour of Right Ovary in a Child aged 7, associate with Precocious Puberty: Ovariectomy: Cure. Mr. Symonds: Case of Rupture of the Urinary Bladder, in which the Rent was Sutured.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d. which should be forwarded in stamps with the announcement.

MARRIAGES.

BRISTOW-McVEAGA.—On April 11th, at St. Osburgh's Church, Coventry, by the Rev. A. Pereira, O.S.B., Rector, William Frederick, second son of William Bristow, "Woodlands," Blackheath, to Catherine Stuart (Kate), second daughter of Dr. McVeagh, J.P., Coventry.

CLELAND-BALFOUR.—At St. Giles' Cathedral, Edinburgh, on April 18th, by the Very Rev. Principal Caird, LL.D., assisted by the Rev. W. Lockhart Collins, John Cleland, M.D., F.R.S., Professor of Anatomy in the University (Glasgow), to Ada Marian Spottiswood, eldest daughter of the late J. Balfour, M.D., F.R.S., Professor of Botany in the University of Edinburgh.

CROFT-STORY.—On April 18th, at St. Matthew's, Lightcliffe, Yorks., Edward Octavius Croft, M.R.C.S., L.R.C.P., of Clarendon Road, Leeds, eighth son of the late Charles Hederton Croft, F.R.C.S., of the City of London, to Eleanor Annie, second daughter of John Storey, Esq., of Newcastle-Tyne.

GODFREY-POWELL.—On April 12th, at St. Philip's Church, Sydenham, by the Rev. J. G. Holmes, Vicar, Henry William Godfrey, M.B., M.R.C.S., Ventnor, only son of Charles Godfrey, of Colchester, High Bailiff of Court and Official Receiver in Bankruptcy, to Florence, youngest daughter of the late A. J. Powell, Esq.

HOLMES-WALKER.—On April 17th, 1888, at St. Mark's Church, Peterborough, by the Very Rev. the Dean of Peterborough, assisted by the Rev. Edward Holmes, father of the bridegroom, and the Rev. J. H. Molesworth, vicar of the parish, the Rev. William Perowne Holmes, vicar of Longthorpe, minor canon of Peterborough Cathedral, to Ethel Margaret, eldest daughter of Thomas James Walker, of Peterborough, M.D. and J.P.

PHILIP-SEDDON.—At Bridge of Allan, on April 19th, by the Rev. George Philip, M.A., Free St. John's Church, Edinburgh, father of the bridegroom, Robert William Philip, M.A., M.D., F.R.C.P.E., Edinburgh, to Beatrice, youngest daughter of the late John F. Metherwell, Cultbar House, Couglis, and widow of the late Isaac Cooke Seddon, solicitor, Melbourne.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY.....10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's (Ophthalmic Department); and Royal Westminster Ophthalmic.—2 P.M.: Metropolitan Free; St. Mark's; Central London Ophthalmic; Royal Orthopaedic; and Hospital for Women.—2.30 P.M.: Chelsea Hospital for Women.

TUESDAY.....9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's; St. Bartholomew's (Ophthalmic Department); St. Mary's; Royal Westminster Ophthalmic.—2 P.M.: Westminster; St. Mark's; Central London Ophthalmic.—2.30 P.M.: West London; Cancer Hospital, Brompton.—4 P.M.: St. Thomas's (Ophthalmic Department); Brompton.—National Orthopaedic.—10.30 A.M.; Royal London Ophthalmic.—1 P.M.: Middlesex.—1.30 P.M. St. Bartholomew's, St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: London; University College; Westminster; Great Northern Central; Central London Ophthalmic.—2.30 P.M.: Samaritan Free Hospital for Women and Children; St. Peter's.—3 to 4 P.M.; King's College.

THURSDAY.....10.30 A.M.: Royal London Ophthalmic.—1 P.M.: St. George's.—1.30 P.M.: St. Bartholomew's (Ophthalmic Department); Guy's (Ophthalmic Department); Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Central London Ophthalmic; Hospital for Diseases of the Throat; Hospital for Women.—2.30 P.M.: North-West London; Chelsea Hospital for Women.

FRIDAY.....9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.15 P.M.: St. George's (Ophthalmic Department).—1.30 P.M.: Guy's; Royal Westminster Ophthalmic.—2 P.M.: King's College; St. Thomas's (Ophthalmic Department); Central London Ophthalmic; Royal South London Ophthalmic; East London Hospital for Children.—2.30 P.M.; West London.

SATURDAY.....9 A.M.: Royal Free.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: King's College.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Middlesex; Royal Free; Central London Ophthalmic.—2.30 P.M.: Cancer Hospital, Brompton.

HOURS OF ATTENDANCE AT THE LONDON HOSPITALS.

CHARING CROSS.—Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; Skin, M. Th., 1.30; Dental, M. W. F., 9.

GUY'S.—Medical and Surgical, daily, 1.30; Obstetric, M. Tu. F., 1.30; Eye, M. Tu. F., 1.30; Ear, Tu. F., 12.30; Skin, Tu., 12.30; Dental, Tu. F., 12.30.

KING'S COLLEGE.—Medical, daily, 2; Surgical, daily, 1.30; Obstetric, Tu. Th. S., 2; o.p., M. W. F., 12.30; Eye, M. Th., 1; Ophthalmic Department, W., 1; Ear, Th., 2; Skin, Th.; Throat, Th., 3; Dental, Tu. F., 10.

LONDON.—Medical, daily, exc. S., 2; Surgical, daily, 1.30 and 2; Obstetric, M. Th., 1.30; o.p. W. S., 1.30; Eye, W. S., 9; Ear, S., 9.30; Skin, Th., 9; Dental, Tu. S., 9.

MIDDLESEX.—Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; o.p. W. S., 1.30; Eye, W. S., 8.30; Ear and Throat, Tu., 9; Skin, Tu., 4; Dental, daily, 9.

ST. BARTHOLOMEW'S.—Medical and Surgical daily, 1.30; Obstetric, Tu. Th. S., 2; o.p., W. S., 9; Eye, Tu. Th. S., 2.30; Ear, Tu. F., 2; Skin, F., 1.30; Larynx, F., 2.30; Orthopaedic, M., 2.30; Dental, Tu. F., 9.

ST. GEORGE'S.—Medical and Surgical, M. T. F. S., 1; Obstetric, Tu. S., 1; o.p., Tu., 2; Eye, W. S., 2; Ear, Tu., 2; Skin, W., 2; Throat, Th., 2; Orthopaedic, W., 3; Dental, Tu., S., 9, Th., 1.

ST. MARY'S.—Medical and Surgical, daily, 1.45; Obstetric, Tu. F., 1.45; o.p., M. Th., 1.30; Eye, Tu. F. S., 9; Ear, M. Th., 3; Throat, Tu. F., 1.30; Skin, M. Th., 2.30; Electrician, Tu. F., 2; Dental, W. S., 9.30; Consultations, M., 2.30; Operations, Tu., 1.30; Ophthalmic Operations, F., 9.

ST. THOMAS'S.—Medical and Surgical, daily, except Sat., 2; Obstetric, M. Th., 2; o.p., W., 1.30; Eye, M. Th., 2; o.p., daily, except Sat., 1.30; Ear, M., 12.30; Skin, W., 12.30; Throat, Tu. F., 1.30; Children, S., 12.30; Dental, Tu. F., 10.

UNIVERSITY COLLEGE.—Medical and Surgical, daily, 1 to 2; Obstetrics, M. Tu. Th., F., 1.30; Eye, M. Tu. Th. F., 2; Ear, S., 1.30; Skin, W., 1.45; S. 9.15; Throat, Th., 2.30; Dental, W., 10.30.

WESTMINSTER.—Medical and Surgical, daily, 1.30; Obstetric, Tu. F., 3; Eye, M. Th., 2.30; Ear, M., 9; Skin, Th., 1; Dental, W. S., 9.15.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS respecting editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

In order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the office of the JOURNAL, and not to his private house.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL, are requested to communicate beforehand with the Manager, 429, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication. CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

QUERIES.

SMELL OF IODINE IN BEDROOM.
 IODINE wishes information from members as to the best way to remove the smell of iodine from a bedroom, inhabited during the winter, by a patient who has freely used the same.

PRACTICE IN AMERICA.
 STARS AND STRIPES begs to return his thanks to the gentlemen who kindly answered his queries, and to ask further: 1. What are the most suitable American and Canadian States for rheumatics to live in? 2. Can a medical man who is without friends or private means hope to be able at once to make a livelihood by his profession. 3. The usual way of starting in practice; whether as assistant, house-surgeon, dispensary doctor, or in a private capacity? 4. In the event of a medical man being unable to support himself by his profession, would he be able to learn a livelihood by teaching, writing, acting in the capacity of clerk, etc., or are all these offices (as in the old country) overstocked?

NASO-PHARYNGEAL ULCERATION.
 A MEMBER asks for advice in the treatment of the following case: Miss—, aged 19, has suffered for two years from superficial ulceration (not syphilitic) of the naso-pharyngeal surface. There is no oedema, no pain, no fetor. Some membranous fragments mixed with mucus and pus, but no blood, constitute the discharge. She is anæmic and strumous-looking. The lungs are healthy. Remedies hitherto used: cod-liver oil, Fellowes's syrup, ferri iodid, and other tonics; inhalations of chloride of ammonium; gargles of borax, Condy, and Sanitas; brushing with boroglyceride, iodine, iodoform, arg. nit., dilute carbolic acid; snuffs of diluted hydrastin, etc.; vapour of terebene; generous diet, and residence by the sea. So far I can only say that she is no better and no worse than she was a year ago. There are no vegetations in the naso-pharyngeal cavity.

MEDICAL HEROISM.
 DR. D. MITCHELL (Renton) asks whether any publications exist which contain the records of instances of heroism displayed by medical men, both civil and military. If no such publication exists, whether there is any information regarding some such instances as may be found in a scattered form in many publications.

CLIMATE FOR RHEUMATISM.
 C. M. asks for the best places in England for a person suffering from rheumatism in the winter to reside in. A large town preferred, and one where rents are low and living cheap.

ANSWERS.

RUPTURED PERINEUM.
 PROVINCIAL SURGEON asks: Having, during a period of over twenty years' practice in midwifery, met with about eight cases of ruptured perineum, I would like to ask through the medium of the JOURNAL if any of your contributors would inform me whether, in their experience of such cases, it is always accompanied by retention of the urine. I may mention that I have attended nearly 5,000 cases, a great number of them being instrumental, in consequence of a peculiarity in this district of most of the midwifery being attended by midwives, and the use of the forceps is so frequently called for in their difficult cases; but the cases of perineal laceration that I have met with have in every case happened where no instruments have been used; the perineum having been well supported, but the force of the pains has driven the child's head through, and lacerated right up to, but not through, the sphincter, and in each case retention of the urine has followed, necessitating the use of the catheter, in some cases twice a day for a month, in others for shorter periods. All the cases were rigid perineums of primiparæ. I have looked in half a dozen works on midwifery, but cannot find any statement about this being one of the sequelæ, and therefore should like to have the opinion of some more experienced obstetricians than myself, and any suggestions as to the future treatment to prevent the use of the catheter, which to lady patients is most objectionable. I know that it will be said that these accidents should not occur, but I think from my having only had eight cases in 5,000, I shall have the credit given me of using every needful care.

* Retention of urine is most frequent when the patient is a primiparæ. There can be no direct relation between that complication and rupture of the perineum.

POST-PARTUM HÆMORRHAGE.
 D. H. G. writes: "Felix" asks for the experience of others as to the efficacy of ergotin. A few weeks back I also asked for an expression of the experiences of members in Burroughs and Wellcome's ergotinin (1 in 150) tabloids, which I have found most satisfactory and rapid in their action, given hypodermically. Ergotin either in pills or solution I have not found reliable.

NOTES, LETTERS, ETC.

A CASE OF DISTRESS.

Second List of Donations.

	£	s.	d.		£	s.	d.
A gentleman, on £90 being collected	90	0	0	Dr. H. Joy Clarke, Doncaster (per Dr. O. C. Jonsou) ...	1	1	0
Dr. J. F. Goodhart	2	2	0	M.B., Torquay	0	10	0
				Mrs. Luscombe	1	0	0

The donations already received, thanks to the generosity of the donors, will enable one of the children to obtain an immediate presentation to St. Anne's School, in compliance with the offer of a gentleman to give half the amount necessary for that purpose.

Any further donations will be applied to the relief of the family, and towards providing for the education of the other children.

ERRATUM.—The donation from "Two Friends at St. Bartholomew's Hospital" should have been entered as £2 0 0, instead of as printed in part of our edition.

ERYTHEMA NODOSUM.
 MR. BEAMISH HAMILTON (Tonby) writes: I have recently treated two cases of erythema nodosum by perforate rubber bandages with most gratifying results. The first, an anæmic young woman aged 50, who could not stay in bed

and on whom tonics of various kinds seemed to have no effect, got immediate relief from pain, and made a speedy recovery. The second, a very stout woman, aged 52, had a very painful and red eruption, with considerable swelling of both legs and feet. I treated her with the bandages only; her progress was quick and complete, and she went about her household work during the attack with very trifling inconvenience.

THE CLIFTON LUNACY CASE.

MR. W. H. HARSANT (Clifton) writes: Will you be kind enough to give publicity to the accompanying additional list of subscriptions to the Marshall and Shaw fund?

	£	s.	d.		£	s.	d.
Amount already acknowledged	159	18	6	Lawrence, A. E. Aust, M.D.	2	2	0

THE UNGUAL FURROW.

DR. GODRICH (Surbinton) writes: It would be interesting to learn whether or not this stage of discontinuity is coincident with the period of the febrile rigors. At all events it (the furrow) is always found at the very earliest period of the disease. The hair and skin are equally influenced by this discontinuity; the former falling off, and the latter either scurfing or peeling. In scarlatina this process seems to attain to its maximum. I have noticed it in cases of simple gonorrhoea, catarrh, and in fact in every case, however slight, where there is a febrile condition. I found that the furrow takes about eight months to reach the free edge of the thumb-nail, and about four to five for the little finger. Trousseau gives the credit of its discovery to his clinical assistant, Dr. Peter. This would be about twenty years ago.

THE "MEDICAL DIGEST."

A MEMBER writes: I notice the puff oblique from "H. M. D." respecting the above in the JOURNAL of April 14th. About two years since I ordered the work on seeing a similar notice, but was annoyed to find it nothing but an index to seven or eight medical journals. I quite fail to see where the help to a busy practitioner comes in, even if he has all these numbers to refer to. Fancy relying on such help in an emergency, and finding reference merely to page so-and-so, in such-and-such publication, year 1873!

STATE EXAMINATION.

M.D., F.R.C.S.I. writes: May I venture to suggest the propriety of asking the State to grant to those members of the profession who have competed for entry into the public medical services, and passed a satisfactory examination in the various subjects laid down, a certificate that they have gone through a "State examination with credit?" I think you will agree with me that men who pass what is considered a pretty stiff examination, and gain a good number of marks, say 50 per cent., might be considered entitled to some such certificate. It need not cost the State anything, as those earning it might be willing to pay any small charge for the document. It might also act as a stimulus to candidates to try and obtain the necessary number of marks, and not rest satisfied with a "pass examination" only.

A CASE OF MYXEDEMA.

DR. FRED. TRESILIAN (Ebbw Vale, Mon.) writes: In my description of a case of myxœdema which you published, I inadvertently omitted to state the condition of the thyroid gland. As usual, neither the gland nor its isthmus could be felt, so that it was very probably atrophied. I may state that I am trying the effect of the liquid extract of jaborandi in half-drachm doses, three times a day.

COMMUNICATIONS, LETTERS, etc., have been received from

Mr. W. A. Jayasingha, Balangoda, Ceylon; Surgeon-General Cornish, London; Mr. F. J. Warwick, London; The Secretary of the Anatomical Society of Great Britain; D. Mitchell, M.B., Renton; Surgeon R. R. Weir, London; Messrs. Carr and Co., Carlisle; The Secretary of the Richmond Hospital, Richmond; Dr. T. Cranston Charles, London; Dr. McVeagh, Coventry; Mr. J. W. Shore, London; Mr. M. F. Cox, Dublin; The Secretary of the Devonshire Hospital and Buxton Bath Charity, Buxton; Dr. V. Uekerman, Kristiana, Norway; Our Berlin Correspondent; Justice; Professor Schafer, London; Mr. G. R. BOOKS, ETC. RECEIVED.

Physiological and Pathological Researches; being a Reprint of the Principal Scientific Writings of the late F. R. Lewis, M.B. Arranged and edited by Sir W. Aitken, M.D., F.R.S.; G. E. Dodson, M.B., F.R.S.; and A. E. Brown, B.Sc. Published by the Lewis Memorial Committee, with the permission of Her Majesty's Secretaries of State for War and India.

Mechanics and Experimental Science, as required for the Matriculation Examination of the University of London; Chemistry, with numerous woodcuts. By Edward Aveling, D.Sc. London: Chapman and Hall, Limited, 1888.

Year-Book of the Scientific and Learned Societies of Great Britain and Ireland: compiled from official sources. Fifth annual issue. London: Griffin and Co.

A Textbook of Biology, comprising Vegetable and Animal Morphology and Physiology. By J. R. Ainsworth Davis, B.A. London: Griffin and Co.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE "BRITISH MEDICAL JOURNAL."

Seven lines and under	£0	3	6
Each additional line	0	0	4
A whole column	1	15	0
A page	5	0	0

An average line contains seven words.

When a series of insertions of the same advertisement is ordered, a discount is made on the above scale in the following proportions, beyond which no reduction can be allowed.

For 6 insertions, a deduction of	10 per cent.
" 12 or 13 "	20 "
" 26 "	25 "
" 52 "	30 "

Special terms for occasional change of copy during series: 20 per cent. if not less than 26 pages be taken } or their equivalent in half or quarter pages.

For these terms the series must, in each case, be completed within twelve months from the date of first insertion.

Advertisements should be delivered, addressed to the Manager at the Office, not later than noon on the Wednesday preceding publication; and, if not paid for at the time, should be accompanied by a reference.

Post-Office Orders should be made payable to the British Medical Association at the West Central Post-Office, High Holborn. Small amounts may be paid by postage-stamps.

REMARKS.

BRASSWORKERS' DISEASES:

BEING A THESIS FOR THE DEGREE OF M.D. IN THE UNIVERSITY OF CAMBRIDGE.

By ROBERT M. SIMON, M.D., M.R.C.P. LOND.

Assistant Physician to the Birmingham General Hospital, and Visiting Physician to the Jaffray Suburban Hospital.

This subject is one of the greatest interest to those who live in manufacturing towns, such as Birmingham, where large numbers of men are employed in the brass trade. That brassworkers are exposed to unhealthy conditions is fully recognised by the men themselves, as well as by their employers, who speak of the trade as a most unhealthy one. Brassworkers rarely attain old age, and formerly provident sick societies either altogether refused to enroll them on their lists, or accepted them as members at greatly increased rates.

The recognition of working in and making brass as causative of disease is due to Dr. Headlam Greenhow, who, in 1862, read before the Royal Medical and Chirurgical Society a paper on Brassfounders' Ague. This was based on his experience gained while paying a brief holiday visit to Birmingham in 1858, in connection with his investigation of trades injurious to health. It is curious that he should have selected for his title the name of a disorder which undoubtedly occurs, but which, as I shall endeavour to show, is only an acute expression of a chronic disease, and one which rarely or never comes within the range of experience of practising physicians.

In the out-patient departments of the Birmingham hospitals one meets with an enormous number of brassworkers complaining of various pulmonary and gastric disorders; but in over eight years' experience among over 30,000 patients, I have never yet been consulted by anyone in the matter of this so-called ague, although questions will very frequently elicit the statement of its occurrence.

The literature of this subject is very scanty, but Greenhow quotes Thackrah's essay on the *Effects of Arts, Trades, and Professions on Health and Longevity*, published about 1830, as well as the writings of a few Frenchmen, who have not, however, materially advanced our knowledge of the disease. Thackrah's observations were clearly inaccurate and imperfect, for he mentions only "ague," which he speaks of as an intermittent fever, attacking brassworkers from once a month to once a year, and leaving them in a state of great debility.

Dr. Hogben, Physician for Out-patients at the Queen's Hospital, Birmingham, published a very interesting paper on this subject in the *Birmingham Medical Review* in May, 1887. Dr. Greenhow refers only to ague and bronchial disorders, and very cursorily to nervous troubles, as resulting from brass-casting; but Dr. Hogben mentions also the colic, constipation, and dyspeptic troubles which result from this occupation. Dr. Greenhow, on the one hand, refers all the symptoms to intoxication by zinc, while Dr. Hogben thinks they should rather be referred to chronic copper poisoning. These two metals are the principal ingredients in the making of brass, which needs a brief description.

Copper is put into crucibles, which are plunged into a sunken furnace, and covered in order to exclude the air. When the copper is melted, the crucible is removed, and zinc—about 30 per cent.—and small quantities of lead, tin, and brass dust are mixed with the molten copper, which is hot enough to melt them. When the whole mass is molten, it is poured into moulds called sows; during the pouring the zinc desintegrates, and a dense white smoke is formed, which almost instantaneously fills the atmosphere of the casting shop. This smoke is rapidly converted into snow-white flakes and white powder, consisting of the oxide of zinc, which remains for some time diffused through the atmosphere of the shop, and, in ill-ventilated casting shops, collects upon the rafters and ceiling in the form of a dense white incrustation. The quantity of these fumes depends, first, upon the amount of zinc employed; secondly, upon the ventilation of the casting shops; and, thirdly, upon the weather—a dull foggy day preventing their

escape. The shops in newly-erected factories are only one story high, and have large sliding panels in the roof to permit free escape of the fumes, but in the older buildings they sometimes have other rooms above them, and free ventilation is impossible. It is a matter of experience that workers in ill-ventilated shops suffer much more from ague and bronchitis than those who work in the better buildings. The men who do this work are called mixers, and protect themselves to some extent by tying handkerchiefs over the nose and mouth to prevent as far as possible inhalation of the fumes. From the mixers the work goes to the casters or founders, who remelt the pigs of cold brass, at a lower temperature than is required for melting copper, and pour it into the sand moulds, which are faced with a fine powder of loam, charcoal, coal, and bean flour. From this powder rises a dense cloud of dust, and from the molten metal a cloud of zinc-oxide, though not so much as in the mixing shop. Founders suffer principally from bronchitis, or asthma as they call it, and ague, though in a lesser degree than the mixers. From the casters the work goes to the warehouse, where it is sorted and sent to be polished, or dipped and bronzed.

By the polishers, emery, fine sand, lime, and rouge are used on rapidly revolving brushes, or wooden wheels faced with leather. From these considerable dust is given off, and bronchial troubles are caused; but "ague" does not affect the polishers.

The dippers work under a shed open on all sides to the air, and immerse the brass in a weak solution of sulphuric acid; it is then dipped into water, then into a stronger acid solution, again into water, once more into acid, then into a solution of soda, finally into pure acid, and washed in water. There are always exhalations of acid, and in warm weather these are especially troublesome. It is noteworthy that, though dippers do not suffer from ague or intestinal troubles, their occupation is considered by masters and workmen alike to be the most unhealthy of all, on account of the great bronchial irritation from the acid fumes.

From the bronzers the work is sent to the lacquerers, who are nearly always females, and suffer nothing from their occupation. From them it goes to the dressers to be fitted, and finally to the warehouse.

It will appear from this account of the process, that those who deal with the molten metal are the only ones to suffer from brass ague, while they, as well as those occupied in shops where there is much dust or acid fumes, are liable to bronchitis and asthma. Moreover, all brassworkers except dippers and lacquerers are subject to colic, constipation, and various other disturbances of the gastro-intestinal system.

That Thackrah was in error in speaking of brass-ague as an intermittent affection, occurring once a month or once a year, is clearly proved by the following positive observation, which is supported by all brassworkers. Ague never occurs among the regular workers, but always affects those who are new to the work, or who resume work after an absence of even a month or a fortnight. If a man resumes work, that is, melting or casting, after ever so brief an interval, he is sure to have an attack of ague; but he will have only one attack, and remain free until after his next holiday. There is most certainly no kind of regular intermission, and, according to brassworkers themselves, they only suffer until they are inured to the poison.

The following are the symptoms of this so-called ague: after working a few hours, a man becomes languid, depressed, and feels very cold. He is very pale and almost in a state of collapse; his face is covered with a cold perspiration, he shivers, his teeth chatter, and he is restless and anxious. His head aches, there is much nausea and complaint of muscular pains. As a rule he goes or is led home, where he drinks freely of milk and goes to bed. The symptoms continue until he has vomited, either as the result of taking an emetic or independently of it. Vomiting is usually followed by sleep or recovery, with more or less of debility and lassitude on waking.

Dr. Greenhow and Hogben speak of a more or less marked hot stage following the cold, and following the hot stage they mention profuse sweating. The hot stage may be absent, but the sweating, according to these writers, invariably occurs.

My own observations, based on inquiry amongst those who have suffered from this ague, have never elicited a statement of these hot and sweating stages. Even direct questions as to their occurrence have always been met with positive negation, though some have spoken of free perspiration in the stage of collapse. How to reconcile these statements I do not know.

The cycle of events, as recorded by Greenhow, is just that of

ordinary ague, from which this disease differs, otherwise than in the suggested sequence of symptoms, *in toto*. The inquiries I have made do not support such a sequence, and certainly not a relationship to malarial ague. The symptoms are just such as would be caused by the ingestion of a quantity of an irritant metal, sufficiently large to cause vomiting and its attendant depression. Such, indeed, is my opinion of the causation of the symptoms, and therefore the name "ague" should not be continued, as being wrongly suggestive and misleading.

It will be remembered that it is only when fresh to the work that brassworkers suffer from "ague;" but, though they do not suffer from acute metallic poisoning, they do suffer from its chronic effects, and it is extremely probable that, as with arsenic and opium eaters, they may become inured to the use of the metals. It is not very common for brassworkers to use tooth-brushes, and the accumulating tartar will be found coloured green. If every effort be made to cleanse the teeth, there will yet be generally green discoloration of them. This has been proved to be due to the presence of copper. White hair is often coloured green among these workmen, and the underclothing is often stained green by the perspiration. The gums may be slightly blackened at the edges, but there is nothing distinctive as in the case of the blue line of lead poisoning; nor, indeed, beyond the green colouring of the hair and teeth, do brassworkers present any unequivocal evidence of their calling.

Ague is not a disorder for which brassworkers consult a medical man; they know how to treat it themselves, and also that it is transitory in its effects; but they come to hospitals in large numbers to be treated for bronchitis. About this there is nothing special. They suffer from it in common with all workers in dusty trades; and, so far as I can learn from the secretary of the Brassworkers' Organisation, they usually die from chronic bronchitis or fibroid phthisis, unless they succumb to some acute malady.

The existence of nervous disorders, especially paralysis agitans, has been said to be common amongst them, but I cannot find that a larger percentage of brassworkers than of the rest of the community suffer from diseases of the nervous system. It is common, however, amongst them to meet with complaints of disturbance of the digestive function. They suffer from dyspepsia, loss of appetite, gastro-intestinal catarrh, nausea, vomiting, metallic taste, thirst, colic, constipation, and diarrhoea. They are often nervous and hypochondriacal, complaining of headache and muscular pains. There is nothing distinctive about any of these disorders, except the obstinacy with which they resist ordinary methods of treatment, and the readiness with which they yield to the administration of iodide of potassium in combination with the other drugs indicated by the various conditions of ill-health. All the symptoms bear a remarkable resemblance to those produced by chronic copper poisoning, and in Guy and Ferrier's *Forensic Medicine* an outbreak of copper poisoning from the use of copper vessels in cooking is recorded, in which the symptoms were almost identical with those here mentioned.

The inmates of a convent suffered severely from obstinate and severe colic, retching, and bilious vomiting, costiveness and flatulence, burning pain in the pit of the stomach and extremities, and paralytic weakness in the arm. According to Stevenson, it is impossible to distinguish between the symptoms produced by zinc and copper poisoning; these are just such as brassworkers suffer from, and it is therefore impossible to say which metal—copper or zinc—is most concerned in the production of these symptoms.

Dr. Greenhow attributes them all to the inhalation of the de-flagrating zinc; this forms zinc oxide, which is only sparingly if at all soluble, and therefore is not likely to be freely absorbed in the stomach; but he pays little or no attention to the common and chronic gastric and intestinal troubles to which brassworkers are liable. These affect all those engaged in the various processes by which either in vapour or in minute particles copper and zinc—that is, brass—are distributed in the atmosphere.

Dr. Hfobgen, on the other hand, considers copper alone to be the efficient cause of the symptoms, and advances the following arguments:

1. We have no evidence that the internal administration of zinc ever produces the symptoms of brass-ague. Enormous doses of the oxide have been administered without apparently producing the characteristic febrile reaction of brass-ague.

2. The malady is observed in individuals whose work is other than casting.

3. The malady is not observed in operatives such as galvanised ironworkers, who work with zinc and are exposed to its fumes.

4. Zinc is rapidly excreted, and does not, like lead, mercury, or copper, become fixed in the body, and produce chronic affections.

It seems more probable that, accepting Stevenson's statement of the impossibility of distinguishing between the effects of acute copper or zinc poisoning, the symptoms of ague are due to an admixture of the two metals, whereas for the chronic complaints the copper is responsible.

How the practice of taking milk during an attack of so-called ague has arisen is not clear, but its wisdom is proved by the fact that in cases both of copper and zinc poisoning, milk is one of the best antidotes, since it precipitates both these metals into insoluble albuminates.

It is abundantly evident that brassworkers are specially liable to diseases from the use of the metals employed in its manufacture, but they are not new disorders; they are either proofs of chronic poisoning by zinc or copper, or as in the so-called ague, are due to intoxication by them.

For much of my information as to the effects of this work I am indebted to Mr. Lilly, the local secretary of the Brassworkers' Association.

ON TESTING THE COMPETENCY OF THE VALVES OF THE HEART BY MEANS OF AIR.

By D. J. HAMILTON, M.B., F.R.C.S.E., F.R.S.E.,
Professor of Pathology, University of Aberdeen.

THE ordinary method of testing the competency of the valves of the heart with water is admittedly faulty in many respects. It can be applied only to the aortic and pulmonary artery orifices, and even with them the pressure of $1\frac{1}{2}$ to 2 inches of water which alone can be retained in the attached portions of the vessel does not represent anything like the pressure to which they are naturally subjected. Hence a valve which during life might have been sufficiently incompetent to give rise to a murmur, may be found after death to be perfectly competent. The water method is also defective from the fact that the cusps of the valve are not seen in motion, so that the mechanism by which a murmur may have been elicited is incapable of being demonstrated in the *post-mortem* room. We possess, moreover, no exact method of gauging the amount of incompetency of the mitral and tricuspid, nor of ascertaining when they are competent.

For some time past I have been in the habit of demonstrating to my class the natural action of the valves by driving air into the instead of water, and also of reproducing the murmurs heard in disease of the valves by several simple modifications of the same method.

The ascending aorta with the attached valve is cut off from the heart of an ox. A brass tube attached to a bellows is introduced into the distal end of the aorta. The aorta is now fixed in a nearly as possible its natural position, and air is driven in from the bellows with a sharp click, so as to imitate as closely as may be the effect of the arterial recoil. With each inflation of the bellows the cusps are retracted, to be closed again as soon as the air is expelled; and so perfect is their adaptation, even after death, that not only do they prove perfectly competent when the heart is healthy, but the sharp sound elicited bears a remarkable resemblance to the second sound of the heart. The valve can be turned up in any position, so as to be made readily visible to the whole class.

The same means may be employed to display the action of the pulmonary artery valve. In the case of the mitral and tricuspid the respective auricles should be cut away close down to the orifices. The nozzle is pushed down through the aorta or pulmonary artery, as the case may be, past the valve, so that it enters well into the cavity of the ventricle. It is tied into the vessel, as to prevent regurgitation of the air.

It struck me that the same means might be utilised for testing the competency of the valves in the *post-mortem* room; and, having employed the method lately in a number of cases, I find that it works admirably. It can be applied almost as quickly as the water test, and has the great advantage of being available for all the orifices.

The procedure I adopt is the following. An opening is made into the left auricle, so as to expose the auricular aspect of

mitral. Any *post-mortem* clots which may be adhering to the edge of the valve are removed with care, so as not to disturb the position of the cusps. An aperture sufficiently large to admit the brass nozzle is next made into the apex of the left ventricle in the line of incision which will afterwards be required to lay the ventricle open. The nozzle is then introduced, and air driven in by the bellows in the manner before described. The heart should meanwhile be suspended by the cut edges of the auricle. A series of hooks fixed on supports is useful for this purpose, the supports being movable so as to allow of the proper apposition of the cusps.

The slightest incompetency can be detected quite as much by the irregular manner in which the cusps mutually adjust themselves, as by the escape of air between them.

The same means of demonstration is to be followed in the case of the tricuspid; and, after its condition has been ascertained, the incision in the left ventricle is carried up as close as possible to the root of the aorta, without, of course, injuring the aortic ring. The heart is now suspended, as before, by the cut edges of the ventricle, and the nozzle is tied into the distal end of the aorta. The aorta should either be cut off at the termination of the ascending part of the arch, or be laid open up to this point. The nozzle both in the case of the mitral and in that of the aortic may be simply held in with the hand, or it may be tied in; or, what is even preferable, a simple clamp apparatus may be attached to its extremity, which seizes the cut edge of the vessel or cavity into which the nozzle is introduced, and holds it air-tight or nearly so. In watching the action of the valve, the ventricular aspect should be turned upwards, the air being driven in from below.

The pulmonary artery orifice is next tested in the same manner.

In a perfectly healthy heart it will be found that the aortic, mitral, and pulmonary artery valves are quite competent, but, so far as my present experience goes, I have never met with a tricuspid in man which will stand the test. There is always a slight leakage, even when the cusps are perfectly free to move.

THE PROCESS OF COMPENSATION AND SOME OF ITS BEARINGS ON PROGNOSIS AND TREATMENT.

By BYROM BRAMWELL, M.D., F.R.C.P. EDIN.,

Assistant Physician to the Edinburgh Royal Infirmary; Lecturer on the Principles and Practice of Medicine in the Extra-Academical School of Medicine, Edinburgh, etc.

(Concluded from page 840.)

Compensation in Cardiac Lesions.—One of the most common and obvious methods of compensation is the increase (hypertrophy) of muscular tissue which takes place in muscular tubes and muscular organs when an increased effort is frequently and repeatedly demanded of them. The hypertrophy of the bladder, esophagus, and intestine in cases of organic stricture are familiar examples; but there is, perhaps, no organ in which compensatory hypertrophy is more beautifully developed than in the heart. But, although hypertrophy of its muscular walls is by far the most important manner in which valvular lesions are compensated, it must also be remembered that in some forms of valvular disease a certain limited amount of dilatation and alterations in the frequency of the cardiac contractions also take part in the compensation, and assist the hypertrophy to restore and maintain the balance of the circulation. It may be stated broadly that in obstructive valvular lesions compensation is effected by muscular hypertrophy, aided, in some cases, by slowing of the cardiac action, while regurgitant lesions are compensated by hypertrophy, aided by a certain but strictly limited amount of dilatation, and it may be by increased frequency of the cardiac contractions. The manner in which the different valvular lesions are compensated is briefly as follows:—

In stenosis of the aortic orifice, compensation is chiefly effected by hypertrophy of the left ventricle, by means of which an increased quantity of blood is forced through the narrowed orifice at each ventricular contraction. The duration of the ventricular systole is at the same time lengthened, while the frequency of the cardiac contractions is diminished rather than increased, with the result that more time is afforded for the hypertrophied left ventricle to discharge its contents. In aortic stenosis, dilatation of the left ventricle affords no aid as a means of compensation, and when it does occur, it is a secondary and injurious result.

In stenosis of the mitral orifice, compensation is partly due to hypertrophy of the left auricle, but chiefly to hypertrophy of the right ventricle. Prolongation of the ventricular diastole, increased duration of the auricular systole, and slow action of the heart are also, when present, important factors in the compensation, since they facilitate the flow of an increased quantity of blood through the stenosed orifice during each cycle of the heart. At the best, however, the compensation in severe mitral stenosis is imperfect, much less perfect than it is in many cases of aortic stenosis, for even when fully developed the pulmonary circulation is subject to some strain. The most that the compensation can do in mitral stenosis is to enable the left ventricle to supply an adequate quantity of blood to the peripheral tissues, and to protect the organs and tissues which are situated behind the right heart from the effects of venous engorgement. In mitral stenosis, the pulmonary circulation is exposed to engorgement and all its secondary consequences, for the obstruction in front (that is, at the mitral orifice) is not suddenly relieved, as it is in mitral regurgitation, by the bursting open of the mitral valve and the suction action of the left ventricle. Even in these cases, then, in which the compensation is most perfect, the blood-vessels of the lung are exposed (in consequence of the obstruction in front and the powerful action of the right ventricle behind) to increased pressure and the injurious consequences which may result therefrom.

In stenosis of the pulmonary orifice, compensation is partly due to hypertrophy of the wall of the right ventricle, but chiefly in congenital cases (which comprise the great majority of cases of pulmonary stenosis) to the fact that the foramen ovale remains patent and allows a portion of the blood to avoid the lungs and to make a short cut, as it were, from the right to the left heart. The imperfect aëration of the blood which results from this arrangement is, of course, a disadvantage, and the compensation is, consequently, always imperfect; but if the foramen ovale did not remain open, the circulation could not be carried on with the extreme contraction of the pulmonary orifice which is present in some cases of this description, for the blood which could get through the contracted pulmonary orifice and lungs to the left heart would be inadequate to distend the arterial system, while the engorgement of the venous circulation behind the lesion would be too great to allow of the long continuance of life.

In incompetence of the aortic orifice, compensation is effected chiefly by hypertrophy of the left ventricle, partly by a certain but limited amount of dilatation of the left ventricle, and partly by shortening of the ventricular diastole, and, it may be, by increased frequency of the cardiac contractions. When the dilatation of the left ventricle is just sufficient to accommodate the blood which regurgitates through the aortic orifice, and, at the same time, to receive the normal quantity of blood from the left auricle, and, when the hypertrophy is sufficiently great to enable the cavity to empty itself at each systole, compensation is as perfect as circumstances will allow. The circulation in the parts behind the mitral valve is little, if at all, interfered with; and, provided that the arterial anæmia, due to regurgitation from the aorta during the ventricular diastole, is not great, there are few, if any, symptoms. But in free aortic regurgitation, compensation can never be perfect for any length of time, for a greater amount of dilatation than the theoretical minimum required for the perfect restoration of the balance of the circulation is sooner or later established; this necessitates a proportionate excess of hypertrophy if the cavity is to be completely and satisfactorily emptied, and this dilatation and hypertrophy tend to go on increasing. Again, the increased frequency of the cardiac contractions and the diminished duration of the ventricular diastole prevent the normal amount of blood flowing into the left ventricle from the left auricle, and consequently tend to cause some obstruction to the blood-flow behind the mitral valve and left heart. The sudden and excessive distension of the arterial system is also apt to produce dilatation in the aorta and the vessels arising from it.

In incompetence of the mitral orifice, compensation is effected in a still more complicated manner—namely, partly by dilatation and hypertrophy of the left auricle, partly by hypertrophy of the right ventricle, partly by dilatation and hypertrophy of the left ventricle, and perhaps to some slight extent by diminished duration of the ventricular diastole and increased frequency of the heart beats.

When the dilatation of the left auricle is just sufficient to accommodate the blood which regurgitates through the mitral orifice, and at the same time to receive the normal amount of

blood passing to it from the lungs; when the hypertrophy of the right ventricle and left auricle is sufficient to drive the normal amount of blood through the lungs and to empty the left auricle of the normal and abnormal (regurgitant) blood which it is just sufficiently dilated to contain; when the left ventricle is sufficiently dilated to receive the abnormally large quantity of blood from the left auricle, and sufficiently hypertrophied to expel all the blood (part of it passing forwards into the aorta in the normal course, and part passing back into the left auricle), the compensation is as satisfactory as it is possible to be under the circumstances; but in free regurgitation satisfactory compensation does not, as a rule, last long.

In mitral regurgitation, so long as the compensation is good, the engorgement of the pulmonary circulation is not so continuous as it is in mitral stenosis, for relief is afforded and pressure is removed with the occurrence of ventricular diastole and the bursting open of the mitral valve. But in free mitral regurgitation the theoretical minimum of dilatation of the left auricle required for satisfactory compensation is sooner or later exceeded; the lungs become engorged, and there is a tendency to dilatation both of the left and right ventricles; to venous engorgement in the parts behind the right heart, and to arterial anemia in the parts in front of the left heart, and hence to the production of symptoms.

In *incompetence of the tricuspid orifice*, the compensation can never be satisfactory if the regurgitation is at all free. Compensation in this case entirely depends upon the condition of the right auricle. If the cavity of the right auricle could become just sufficiently dilated to accommodate the blood which regurgitates from the right ventricle and at the same time to receive the normal amount of blood passing into it from the venæ cavae, and if its wall could become sufficiently hypertrophied to expel all this blood into the right ventricle, the compensation would be as perfect as it could be under the circumstances. As a matter of fact, too much dilatation and too little hypertrophy are almost always the result; and even in the earlier stages of anything like free tricuspid regurgitation, engorgement of the peripheral venous circulation takes place.

The relative order of gravity of the different cardiac valvular lesions is a question which has given rise to a good deal of debate, though authorities are now pretty well agreed, except perhaps as regards the relative gravity of aortic regurgitation and mitral stenosis. I shall be glad to hear the opinion of members on this point. For my own part, I believe, for the reasons advanced above, that free aortic incompetence is, as a general rule, more progressive and more rapidly fatal than advanced mitral stenosis. It seems to me that in free aortic regurgitation the lesion must of necessity get the upper hand, and the compensation prove inadequate before very long, but that there is no such necessity in advanced stenosis, provided that the patient leads a quiet, vegetative life. The following is a case in point.

Some few years after entering practice I examined *post mortem* the body of a woman, aged 56, who had been under my father's observation with advanced mitral disease for more than thirty years. For the greater part of this long period she had been a helpless cripple from left-sided hemiplegia, the result of embolic plugging of the right middle cerebral artery, and had lived a vegetative life. The mitral valve was so much contracted that it would not admit of the tip of the little finger; and, still more remarkable, considering the extreme mitral stenosis and the comparative absence of all lung symptoms, the left lung was, to a large extent, useless, being compressed into small size by a very much dilated left auricle, and bound by adhesions to the upper and back part of the chest.

Now I very much doubt if a relatively great aortic incompetence could have been compensated and tolerated (even under the same circumstances) for such a length of time. I am prepared, therefore, to allow that a free and progressive aortic regurgitation of necessity tends to a more rapid breakdown of the compensation than an advanced degree of mitral stenosis, even when all the other conditions for compensation are as favourable as could be wished. I believe this is the general rule when the lesion is a serious one, but there are certainly exceptions to it—cases, on the one hand, in which free aortic incompetence is tolerated for a long time, and, on the other, cases of mitral stenosis in which compensation fails much more quickly than is usually the case; but when the lesion is slight in degree or stationary, aortic incompetence is I think in many cases—and this is perhaps the general rule—less serious than mitral stenosis. Slight aortic incompe-

tence causes, in my experience, less disturbance of the circulation, less discomfort to the patient, is compatible with a more active and often also with a longer life, than the same (relative) amount of mitral stenosis. The "accidental risk" of aortic incompetence (death from syncope) is also, I think, less in such (relatively slight and not progressive) cases, than the "accidental risk" of mitral stenosis, namely, embolism.

From this description it will be apparent that hypertrophy of the muscular wall of some one or other of the cardiac cavities is the chief means by which valvular lesions are compensated. When, therefore, an organic valvular lesion is established, and more especially when that lesion is a serious one, or when, though slight at first, it is progressive, the prognosis depends largely on the probability of a sufficient and satisfactory amount of muscular hypertrophy being produced.

It must, of course, be remembered that in forming a forecast or prognosis in cases of cardiac valvular disease, many other considerations—besides the capability of a sufficient amount of muscular hypertrophy being produced—have to be taken into account. In fact, the more important points which enable us to determine the prognosis are as follows: (1) the form of valvular disease and the risk of its causing sudden death; (2) the severity of the lesion; (3) the stationary or progressive character of the lesion; (4) the capability of compensation in the heart itself and the power of resistance possessed by the peripheral tissues; (5) the occupation, circumstances, and surroundings of the patient, and the possibility or probability of his carrying out the treatment which is recommended; (6) the mental temperament of the patient; (7) the presence or absence of complications, more especially the presence or absence of disease of the kidney.

Time does not permit me to enter into details with regard to all these matters; nor, indeed, do I desire to do so, for I have already considered most of them elsewhere.⁵

But I may perhaps be allowed to say that for the production and maintenance of a sufficient and satisfactory muscular hypertrophy, the following conditions are necessary:—

1. The muscular tissue must be healthy, or at all events sufficiently healthy to become hypertrophied. When the wall of the heart is in a condition of fatty degeneration or fibroid disease the hypertrophy is never very satisfactory.

2. The cardiac muscle must receive a sufficient supply of healthy arterial blood.

3. The waste products of its combustion must be sufficiently quickly removed.

4. Its trophic nerve apparatus must be healthy. In short, the heart muscle must possess the conditions which are essential for rapid development and healthy growth.

The age of the patient, the etiology of the case, and the facility with which the cardiac muscle responds to cardiac tonics (digital and strophanthus), together with the general condition of the patient and the state of the other tissues and organs, are the chief means by which we endeavour to form an opinion as to the condition of the cardiac muscle.

In young persons the muscular tissue is, as a rule, healthier, and the capabilities of repair and of the production of compensatory hypertrophy are generally greater than in older people. When, too, the valvular lesion has resulted from acute endocarditis, the capabilities of repair are, speaking generally, greater than when the lesion is due to atheroma or senile or degenerative changes. There are, however, many exceptions to this general statement. The endocarditis may have been complicated with pericarditis, or with myocarditis, and the valvular lesion may therefore be associated with a damaged cardiac muscle, a condition which may interfere with the production of satisfactory hypertrophy, and materially add to the gravity of the case. It must not, indeed, be supposed that in cases of cardiac valvular disease all the advantages are on the side of youth. In old people who lead quiet vegetative lives there is little strain put upon the damaged heart and for this reason, if other things were at all equal, the valvular lesion would be more likely to remain stationary, and the call for repeated and renewed compensation would certainly be less than in children, youths, and active adults, who are with difficulty kept quiet, and who, notwithstanding all the advice which we can give them, are only too apt to over-exert themselves and to put a injurious strain upon the damaged heart.

In trying to ascertain whether a sufficient amount of arteri-

⁵ See my *Diseases of the Heart*. Sections devoted to the general pathology of the heart and the prognosis in valvular lesions. Also my *Practical Medicine*. *Medical Diagnosis*. Sections devoted to the prognosis.

blood is supplied to the cardiac muscle, and whether the products of its waste are satisfactorily removed, we observe the condition of the peripheral, arterial, and venous circulations.

A badly filled radial pulse or atheroma of the superficial vessels is suggestive that the coronary arteries are also badly filled or diseased, and therefore that the supply of arterial blood to the muscular wall of the heart is deficient. Angina-like pain in the region of the heart is also suggestive of disease of the coronary arteries, and of fibroid or fatty changes in the wall of the heart.

A dilated right heart and engorgement of the systemic veins suggest that the veins of the heart are also engorged, and that the removal of waste products from the cardiac muscle is defective.

As yet we have no satisfactory means of ascertaining the condition of the trophic nerve apparatus connected with the heart. Indeed the exact nature of this mechanism is not as yet thoroughly understood, though Gaskell's brilliant researches seem to show that the vagus exerts some sort of stimulating and trophic influence upon the cardiac muscle. But be that as it may, the course of cardiac valvular lesions (and perhaps, too, the amount of muscular hypertrophy, and compensation which are developed) is largely determined by the condition of the nervous system, and by the mental temperament of the patient. In no affections are the beneficial results of a healthy nervous system, and of a serene, happy, placid disposition more manifest than in cardiac valvular lesions.

The power of resistance possessed by the peripheral tissues and organs to the injurious effects of cardiac valvular lesions depends, as in the case of the heart itself, upon (1) the condition, healthy or otherwise, of the peripheral tissues; and (2) the fact whether the conditions for their nutrition are satisfactory or not.

Here, as in the case of the heart muscle itself, the tissue must receive an adequate supply of healthy arterial blood; the waste products of its metabolism must be satisfactorily removed, and its trophic condition must be satisfactorily regulated by the nervous system.

It is quite obvious, therefore, that the presence or absence of complications, more especially of diseased conditions of the stomach and other organs which manufacture the nutrient fluid; of the kidneys, liver, and intestines and other organs, which purify it; and of the nervous system, which exerts such an important influence upon all the processes of nutrition and resistance are most important factors in enabling the peripheral tissues to resist the injurious effects of valvular lesions, and to protect themselves (in some cases by the production of an increased amount of connective tissue) against the injurious effects of venous engorgement. And, *vice versa*, that the presence of disease in any of these organs adds most materially to the gravity of the prognosis.

The important bearing which these facts have in the treatment of cardiac valvular lesions is obvious. It is now an acknowledged axiom in cardiac therapeutics that the muscular hypertrophy, which was at one time thought to be injurious, and, therefore, a condition to be attacked and removed by treatment, is the best thing which can result under the circumstances, and is, therefore, to be encouraged. Our therapeutic efforts are now directed to sustaining the vitality of the cardiac muscle. Our main object is to reduce and remove the lesion on which the cardiac hypertrophy depends, but, so long as the lesion persists, to sustain the hypertrophy, which is Nature's chief means of compensating it. The more I see of cardiac valvular lesions, the more I am convinced that digitalis, strophanthus, and other remedies of a similar kind, are much too freely and too frequently used in the earlier stages, and that the indiscriminate use of these remedies is often most injurious. It is only when compensation fails, either in the earlier stages, as the result of some temporary overbalance of the compensation, such as is so frequently occasioned in mitral cases by an intercurrent attack of bronchitis, or, in the later stages, when the period has at length arrived at which Nature's reserve is exhausted, when the lesion has gained the upper hand, when the cardiac muscular fibre is undergoing degenerative changes, and when dilatation is succeeding to hypertrophy, that digitalis or other remedies are called for. So long as the natural compensation is sufficient to meet the lesion, our chief efforts should be directed, *first*, to removing all sources of cardiac strain and excitement. *Secondly*, to maintaining the general health in the best possible state of efficiency, by (a) careful regulation of the diet, exercise, rest, sleep, whole mode of life, and general hygienic condition of the patient; (b) by attention to the condition of the

blood-forming and blood-depurating organs, more especially of the stomach, liver, intestine, kidneys, and skin; (c) by the administration of such general tonics as arsenic, quinine, and strychnine; and (d) by avoiding all causes of nervous exhaustion, and by promoting, as far as possible, a tranquil, happy, and healthful state of mind. And here I must again emphasise the all-important influence which the mental condition has upon all the processes of nutrition and repair, and the value of what I term mental therapeutics—the influence produced on the mind of the patient by a judicious and hopeful medical adviser, by the avoidance of all worry and anxiety, and by cheerful and pleasant surroundings. *Thirdly*, to avoid all conditions which are likely to aggravate the lesion or to produce those complications and accidents to which the disease predisposes and renders the patient liable.

The Importance of forming a Correct Estimate of the "Reserve," for the Purposes of Prognosis.—In forming an opinion as to the chances of recovery, both in acute and chronic affections, it is of the utmost importance to endeavour to estimate correctly the amount of reserve on which the patient can fall back, and the power of compensation which he possesses. In order that this estimate may be correct, it is necessary (1) to be acquainted with the mental temperament of the patient; for this, as I have elsewhere tried to show, exercises a most important influence on the chances of recovery, more especially in cases of acute disease (*Practical Medicine and Medical Diagnosis*, page 141); and (2) to gauge correctly the condition, not only of the part which is primarily affected, but of all the tissues and organs. In illustration of the importance of the latter point, I need only instance the extreme gravity of acute croupous pneumonia in the presence of a weak or fatty heart, and of typhus or typhoid fever when the kidneys are diseased. The advantage which a knowledge of these particulars gives the ordinary medical attendant over the consultant is so obvious that I need hardly refer to it.

Compensatory Protection.—Closely allied to these processes, which we truly term compensatory, by which Nature endeavours to counteract or minimise the effects of lesions such as I have already described, there are many other methods by means of which the causes of disease are got rid of, or the injurious effects of disease prevented. The vomiting and diarrhoea which are due to the introduction of irritants into the stomach or intestine; the contraction of the peripheral blood-vessels which results from exposure to external cold; the board-like rigidity of the abdominal muscles which is present in perityphlitis; and many reflex nerve alternations, such, for example, as the beautiful reflex process by which the peripheral blood-vessels are relaxed when too great strain is suddenly thrown on the left ventricle of the heart, may be mentioned as illustrations.

Probably the process of suppuration, as Mr. Bland Sutton has so ingeniously theorised, is also a protective and compensatory condition, the pus corpuscles endeavouring to take up, devour as it were, and carry off the irritative particles on which the inflammatory condition depends.

Whether the pyrexia which so frequently follows the introduction of noxious materials—more especially particulate organic poisons—into the blood has any beneficial and compensatory action, or whether it is wholly injurious, we do not at present know.

The adhesive inflammation which prevents the production of pneumothorax in cases of phthisis and the perforation and peritonitis in some cases of ulcer of the stomach, and the obliterative process which seals up the blood-vessels and prevents the occurrence of hæmoptysis in cases of phthisis are also beautiful examples of Nature's protective processes.

The Value of the Local Application of Cold in the Treatment of Hæmoptysis; and the Treatment of Acute Perforative Peritonitis.—And here I would raise two practical questions: First, what, in the opinion of the members of the Branch, is the value of the local application of cold to the exterior of the body in the treatment of hæmoptysis, and indeed in the treatment of localised internal inflammations such as acute pericarditis or acute peritonitis?

Although personally I have until comparatively recently been in the habit of recommending the application of an ice-bag to the surface of the chest, at a point superficial to what appears to be the source of the bleeding in cases of hæmoptysis, I have never felt thoroughly satisfied as to the practical value of the treatment, and for some time past I have had grave doubts as to the correctness of the theory on which it is based. It is supposed

that the local application of cold produces, by means of reflex nerve action, contraction of the blood vessels of the internal organ, which is situated beneath the part of the surface to which the cold is applied. But the experiments of Dr. Milne Murray, and the practical experience both of surgeons and gynecologists have conclusively shown that the application of very hot water is a much more powerful means of arresting hæmorrhage and of producing marked and sustained contraction of the blood-vessels than the local application of cold water. The question naturally arises whether, instead of applying an ice-bag, we should not rather apply a bag containing very hot water over the part of the surface which is superficial to an inflamed or bleeding part. I have hopes that Dr. Milne Murray will clear up this very important practical question by an additional series of experiments; but pending such direct evidence I shall be glad to elicit the opinion and to learn the practice of the members of the Branch on this point.

Secondly, I would ask has any gentleman present seen a case of recovery from peritonitis due to the perforation of an ulcer of the stomach; and what practice is it advisable to adopt in the treatment of this most serious accident?

Personally I have never seen a case of recovery, though cases do without doubt occur. For my own part, I am disposed to think (since by means of transfusion we are able to temporarily restore the patient, and so greatly minimise the danger of death from shock during or soon after the operation) that the proper plan of treatment is first to transfuse the patient, and then to open the abdomen, wash out the peritoneum, and stitch up the opening in the stomach. I am not of course oblivious of the gravity of this procedure and of the difficulty, perhaps the impossibility, that there would often be of carrying it out in private practice; but I shall be glad to hear the opinion of the surgeons on the point.

Euphoria.—Whether the feeling of well-being and hopefulness which is present in some affections, notably in many cases of phthisis, has any special or beneficial effect on this disease, and why this peculiar condition of mind is associated with some affections, and present in some cases and not in others, it is perhaps impossible to say. That the opposite condition of mental depression, which is often associated with derangement of the functions of the liver, has a distinctly prejudicial effect, no one, I presume, will deny. The causation and significance of the remarkable hopefulness which is present in some cases of advanced organic disease requires, I think, more attention than that which it has hitherto received. One of the most remarkable cases of the kind which has come under my own observation occurred in the person of a medical friend, aged, I think, 56. While in charge of an important appointment in the Indian Medical Service he began to fail in health. He was seen by several medical men, and a small hard tumour about the size of an egg was discovered in the epigastric region. The patient was of an extremely nervous and anxious disposition, and since the exact nature of the tumour was

not very obvious, it was not thought advisable to inform him of its presence. He was therefore advised to come home on sick leave; this he accordingly did. He arrived in Edinburgh some two months after the tumour was first noticed, under the firm belief that there was nothing of any importance the matter with him, and that his great weakness and extreme emaciation were entirely due to the effects of very small doses of morphine, which he had been in the habit of taking on the voyage to relieve the uneasiness (not actual pain) which he felt in the abdomen. Both the patient and his wife, a most intelligent, sensible, and sober-minded lady, were fully persuaded that there was no serious organic disease, and that the patient had only to come to Edinburgh to get thoroughly restored to health. I saw the patient a few

hours after his arrival, and my wonder was that he had been able to complete his journey. Profoundly cachectic-looking, emaciated to the last degree, so weak that he was unable to walk across the room, with an unhealthy sloughing ulceration of a few days' duration on the cornea, it was obvious, without any further examination, that he was dying from some serious organic disease. On uncovering the abdomen the cause was at once apparent, for a large tumour, fully the size of a child's head, of great hardness, and evidently malignant, occupied the upper and central part of the cavity. The new growth appeared to be (chiefly, at all events) an enlargement of the abdominal glands; but as no *post-mortem* examination was made, the exact connections of the tumour and the organs which were involved were not ascertained. Both the patient and his wife seemed amazed when the presence of the tumour was pointed out to them. How it could possibly have escaped the attention of the patient, a most cultured and intelligent medical man, I am utterly unable to conceive, for it was impossible to place the hand on the abdomen without at once recognising the large tumour and its dense, hard, character. Nothing, of course, in the way of an operation was possible, though Dr. Keith was kind enough to see the patient with me, and to corroborate my opinion on this point. The patient died, I think, on the second day after I saw him first.

Advanced Organic Disease without Symptoms.—The manner in which the most serious disease is tolerated, and, indeed, in some cases borne with-

out any apparent suffering or distress, is sometimes very remarkable. Why there should be this extraordinary tolerance in some cases and not in others, it is difficult to say. One of the most remarkable cases of the kind which has come under my own personal observation was a case of aneurysm of the thoracic aorta. All physicians and pathologists are, of course familiar with the fact that sudden death not infrequently results from the rupture of a thoracic aneurysm whose presence was unsuspected during life. In most cases of this kind the aneurysm is of small size, usually deep seated, often arising from the first part (root) of the aorta; and seldom so situated as to have compressed such important structures as the œsophagus and trachea

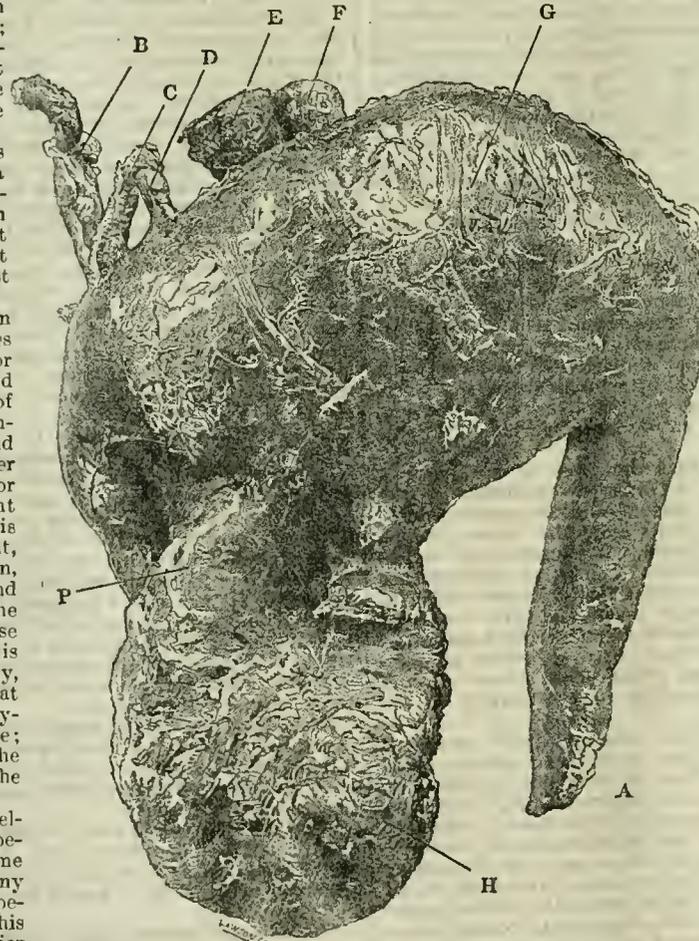

Fig. 8.—The heart and thoracic aorta in the case of J. G., from the front, showing an enormous aneurysm of the ascending and transverse portions of the aortic arch (copied from a photograph of the dried preparation). The size of the preparation is 10½ inches vertically and 7½ inches transversely. The figure measures 4½ inches vertically and 3½ inches transversely. The letter A points to the descending thoracic aorta; B to the innominate artery, from which a piece of cotton-wool is projecting; C to the left common carotid, and D to the left subclavian arteries; E to the trachea; F to the œsophagus; G to the aneurysm; H to the heart; and P to the pulmonary artery.

The case which I am about to relate is a remarkable exception to these statements. It is probably unique when the enormous size of the tumour is considered (it is, I think, the largest entirely *intra-thoracic* aneurysmal sac which has come under my own notice), and when it is remembered that there is an entire absence of symptoms, the patient having regularly followed his employment without ever making complaint of illness until an accident to the eye caused him to seek admission to the infirmary, where the aneurysm was discovered almost by accident the very day before the fatal rupture occurred. Further, it is important to note that not only was the main tumour of such great size, but that a small secondary sac (which cannot be seen in the figures) sprang from the primary tumour, and was in direct contact with the trachea. It is remarkable that, so far as I have been able to ascertain, the patient did not complain of shortness of breath until the night before he died, for the small secondary aneurysmal sac was not only in contact with, but had evidently pressed upon and flattened the trachea. The notes of the case are as follows:—

Enormous aneurysm of the ascending and transverse portions of the aortic arch, entire absence of symptoms, death from rupture into the left pleural cavity.

J. G., aged 58, was admitted to the Edinburgh Royal Infirmary under the care of Dr. Argyll Robertson on March 11th, 1885, suffering from an injury to the right eye. The patient stated that on March 9th a piece of wood struck his eye with great force. Upon admission the lens was found in the anterior chamber; it had already caused a considerable amount of irritation.

On March 12th, Dr. Robertson (to whom I am indebted for this clinical note) removed the lens with the scoop. On the evening of March 14th, the patient complained of difficulty of breathing, and when examined by the clinical clerk, Mr. Pettie, he was sitting up and labouring under considerable dyspnoea. In the course of a little time, and after the administration of an antispasmodic, the difficulty of breathing subsided. Mr. Pettie then examined the chest, and found extensive dullness and very marked heaving pulsation over the whole of the upper

part of the front of the thorax, more especially on the left side. The following day, March 15th, the patient suddenly died, before any further examination of the chest had been made.

The *post-mortem* examination was made by me on March 18th, 1885. The body was well nourished, and the patient had evidently been a very muscular man. The capacity of the thorax was great in proportion to his height, the length of the body being 66 inches, and the circumference of the thorax 41 inches.

The left pleural cavity was filled with blood, for the most part clotted, which had escaped from a huge aneurysmal sac, which occupied a large part of the thoracic cavity (see Figs. 8 and 9). The aneurysm involved the terminations of the ascending and the whole of the transverse portion of the arch of the aorta. It was lobular in form, and measured transversely (from a point a little

above the letter P, to a point a little below the letter G. in Fig. 8) 21 inches; and in circumference, the tape being passed round the distended and dried sac between the left subclavian artery (D) and the trachea (E, in Fig. 8) 16 inches. Without any exaggeration, the distended dried sac is larger than a child's head.

A small secondary sac, about the size of a walnut, sprang from the upper and posterior surface of the large tumour, and pressed directly upon the trachea. This pressure had evidently been considerable, for the trachea was distinctly compressed and flattened. The aneurysm contained a large quantity of laminated clot; the sac had ruptured just above the root of the left lung, and a very large quantity of blood had escaped through the wide laceration into the sac of the left pleura. The aneurysm was in contact behind with the trachea, esophagus, and spinal column; there had apparently been little if any pressure on the spinal column, for there was no erosion of the vertebrae. The left lung was extensively adherent to the exterior of the tumour; and the left recurrent and vagus nerves were incorporated in the anterior wall of the sac.

The sac wall was remarkably friable, and on microscopic examination the structures composing it were found to be markedly fatty. The heart was of small size; it was not weighed, for this would have necessitated detaching it from the aneurysmal sac. The exterior of the heart was covered with a moderately thick layer of fat; the muscular tissue of the organ was in an advanced condition of fatty degeneration; its valves were healthy.

The question naturally arises whether this fatty condition of the heart and the low arterial tension which we would expect in such a condition may not to some extent account for the absence of symptoms in this remarkable case. The descending thoracic aorta and the great vessels arising from the sac were dilated. The lungs were deeply pigmented, but otherwise healthy. Permission was restricted to the cavity of the thorax; the other organs were consequently not examined.

The history of the case seemed so remarkable that I wrote to Messrs. Tancred, Arrol and Co., in whose employment the patient was; and also to Dr. James Hunter, the medical officer of the Forth Bridge Works. I append the answers which they kindly sent me. It is, perhaps, right to mention that the men employed at the Forth Bridge Works can have the benefit of Dr. Hunter's advice and attendance simply by asking for it. It is, therefore, very unlikely that this man could have been ill without Dr. Hunter hearing of it.

Copy of Letter from Messrs. Tancred, Arrol and Co.
 "Forth Bridge Works, South Queensferry, N.B. June 16th, 1885.
 Dear Sir,—Referring to yours of yesterday, we have the pleasure in giving you the following information. The man you refer to worked here under the name of J. G. for about two years, first as a fitter, but latterly in looking after the planing machine, neither of which is heavy or severe work. So far as we can make

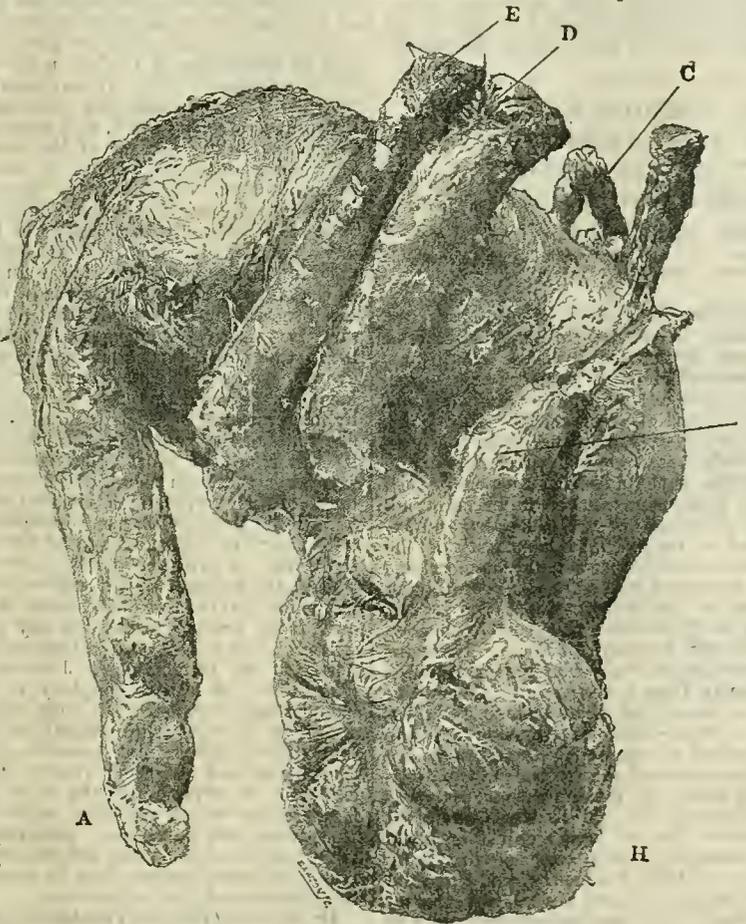

Fig. 9.—The heart and thoracic aorta in the case of J. G., from the back, showing an enormous aneurysm of the ascending and transverse portions of the aortic arch (copied from a photograph of the dried preparation). The size of the preparation is vertically 10½ inches and transversely 7½ inches. The figure measures 4½ inches vertically and 3½ inches transversely. The letter A points to the descending thoracic aorta; B to the superior vena cava; C to the left common carotid artery; D to the trachea; E to the esophagus; and H to the heart. The heart, aneurysm, arteries, trachea, and esophagus were first filled with cotton wool; the preparation was then dried, varnished, and photographed.

out he was not under medical care here, nor did he complain of illness at any time. We trust the above information will suit your purpose, and are, yours faithfully, TANCRED, ARROL AND Co.
—Dr. Byrom Bramwell."

Copy of Letter from Dr. James Hunter.

"The Priory, Queensferry, December 29th, 1887. Dear Dr. Bramwell,—J. G. was a member of the Forth Bridge Workmen's Club, in virtue of which he was entitled to medical advice at any time. Up to the date on which he met with the accident to his eye I had not been asked to see him professionally. Indeed, I am not aware that he was on any occasion absent from his duties at the bridge.—Yours sincerely, JAMES HUNTER."

The details of another case of aneurysm (which is reported in the *Edinburgh Medical Journal* for April, 1888) were also given, in which the patient was able to work for a period of eight years with an aneurysm projecting through the front wall of the thorax.

CASE OF SERIOUS HÆMORRHAGE FROM THE CAVITY OF THE TYMPANUM IN AN INFANT (OTITIS MEDIA HÆMORRHAGICA).

By THOMAS BARR, M.D.,

Surgeon to the Glasgow Ear Hospital; Lecturer on Aural Surgery, Anderson's College, etc.

BLEEDING from the ear may occur in various affections of that organ. Thus it is not uncommon in purulent diseases associated with polypi, granulation tissue, or caries; in these conditions, however, it is rarely more than sufficient to tinge the discharge. A moderate escape of blood is also not unusual in otitis externa and in myringitis, from the rupture of hæmorrhagic elevations, either on the osseous portion of the external canal or on the tympanic membrane. In otitis media hæmorrhagica the source of the hæmorrhage, as the name implies, is the middle ear, especially the cavity of the tympanum, the mucous membrane of which is in a state of acute inflammation. The walls of the distended and engorged vessels give way, blood is poured into the cavity of the tympanum, the tympanic membrane is ruptured, and hæmorrhage takes place externally. The following case is probably unique in respect of (1) the tender age of the patient, and (2) the serious loss of blood. A baby (girl) of 9½ months was sent to me on November 17th last by Dr. Sinclair Kennedy, of Perth. I was informed that, five weeks previously, the baby had become restless, uneasy, and sleepless, apparently from severe pain. These symptoms continued for about a week, and then seemed to be explained by the appearance of muco-purulent secretion from the left ear. There was also noticed a considerable swelling in the neck below the left ear. This escape of matter was on the evening of Friday, and on Sunday night the mother awoke, and was dismayed to find the upper part of the child's dress saturated with blood; she was of opinion that at least a cupful of blood must have escaped. Dr. Kennedy says, in a letter of November 15th, "I was sent for at 5 A.M. on Monday, when I found the child deluged with blood from the left ear. I used a weak injection of acetate of lead, and enjoined rest. The bleeding returned once or twice during the day, but not to so great an extent. I had Dr. Bramwell seeing her with me in the afternoon, and we tried to see the state of the tympanum, but she was so restless we left her alone. We thought she must have had some inflammatory mischief of the middle ear, with rupture of the membrane. Under the ear there was a swelling as large as a walnut, and tender to touch, with a brawny feeling around. She had no pain over the mastoid process, but did not like to be touched over the head of the lower jaw-bone. She was put on iodide of potash, with liq. hydrarg. perchlor. and tinct. of iodine. Iodoform was put into the ear on cotton-wool, and iodoform and vaseline applied to the swelling under the jaw. Some hours after the first bleeding a troublesome dry cough came on, without any chest symptoms, and as we concluded it was aural. The bleeding again returned on Tuesday morning, and I put her on gallic acid internally. From this time there was no return of the bleeding. In a few days the swelling under the jaw went completely away. The discharge from the ear by Thursday, the 21st, was colourless and odourless. On her recovery I tried to examine the ear, but she was restless with me. However, I felt satisfied. I saw a ragged tear of the upper half of the tympanum."

When I examined the patient, there was neither discharge from the ear nor perforation of the tympanic membrane; but a small cicatrix on the antero-inferior part of the membrane indicated the recent existence of a perforation. The membrane had not the ordinary lustre, and the vessels of the manubrium were somewhat injected. The Eustachian tube was permeable. I had no doubt that a perforation had recently existed in the tympanic membrane, and that the hæmorrhage had its source in the middle ear. The child was decidedly anæmic, but, according to the statement of the parents, the pallor was much less than it had been soon after the bleeding, when the face was quite blanched.

In regard to the explanation of the hæmorrhage in a case such as this, it has been argued that the dilated and engorged arterioles in the tympanic mucous membrane give way under the influence of the partial or complete vacuum produced in the tympanic cavity from the closure of the Eustachian tube. It is urged that just as rarefaction of the air in the tympanum may so act upon the blood-vessels of the mucous membrane of the middle ear as to produce a serous exudation (*hydrops, ex vacuo*), so when acute inflammation exists with, as a consequence, dilated and engorged arterioles on the surface of the mucous membrane, the suction may in time lead, not simply to transudation of serum through the coats of the vessels, but to their rupture, with free hæmorrhage into the cavities of the middle ear. In this case, however, there was probably perforation of the tympanic membrane two days previous to the hæmorrhage, which would remove the vacuum, unless, indeed, which is quite conceivable, the aperture in the membrane was afterwards closed temporarily by inspissated secretion, so as again to lead to partial rarefaction of the air. But while admitting the possibility of the vacuum theory, it must be pointed out that such conditions frequently exist—in every case of otitis media, a very common affection—without hæmorrhage; and therefore it is probable that in cases attended by hæmorrhage there is, in addition, some peculiar weakness of the walls of the vessels of the middle ear. Such weakness may be the result of morbid changes due to Bright's disease, and several cases are on record of hæmorrhage from the mucous membrane of the tympanum associated with, and probably the result of, chronic Bright's disease, corresponding, as has been suggested, with the retinal hæmorrhage of the same disease. In this child there was no evidence of the existence of Bright's disease, and, indeed, the age was quite opposed to the supposition of changes in the arterial coats from chronic Bright's disease. Apart, however, from Bright's disease or any other chronic affection, there was probably in this child a hæmorrhagic tendency which predisposed to the hæmorrhage. Just as ophthalmic surgeons recognise a form of retinal apoplexy in the young, due simply to a hæmorrhagic tendency, so may such a case as this (tympanic apoplexy) have its origin mainly in the same predisposition. The immediately determining cause may have been the action upon the dilated and engorged vessels of the partial vacuum in the cavity of the tympanum. In view of the predisposition to the hæmorrhage which probably existed in this child, the parents were instructed to use every precaution in order to avoid, if possible, future inflammatory attacks in the ear.

The following authors may be consulted by those interested in the literature of this subject:—

Mathewson and Newton; Schwartze in a paper in *Archiv für Ohrenheilkunde*, entitled "Ein Fall von Bluterguss in die Paukenhöhle bei Morbus Brightii," Bd. iv; Dr. McBride on Otitis Hæmorrhagica in *Archives of Otolaryngology*, vol. xv.

LUMBAR COLOTOMY; THE CAUSES OF FAILURE IN FINDING THE COLON, AND HOW THEY MAY BE OBVIATED.

By HERBERT W.M. ALLINGHAM, JUN., F.R.C.S.,

Surgeon to the Great Northern Hospital; Demonstrator of Anatomy at St. George's Hospital.

MANY surgeons commence the operation of lumbar colotomy under the impression that it may be impossible to find the colon, or almost all of us have seen the best operators experience difficulty, and even failure in finding the gut. Cases, too, have been reported in which the small intestine has been opened by mistake. Knowing this, and having read Mr. C. B. Lockwood's interesti-

pamphlet on the development of the colon and the abnormal positions it may take up, it occurred to me to try and find out these causes of failure, and, what is more important, the ways by which they may be overcome. All will agree that unless one of the longitudinal muscular bands (which are invariably and only found in the large intestine) be seen, the intestine should not be opened from the loin. These bands are described as being situated, one on the anterior surface, another along the inner part, and the third at the posterior aspect of the gut. It is this posterior band that is looked for, and generally supposed to be seen, when searching for the bowel in lumbar colotomy. It is thought by some authorities that these bands can be easily detected without opening the peritoneum, but this is not so, except in a very few cases. For I find from an examination and dissection of over one hundred ascending and descending colons, that the bands are always more easily and distinctly seen when they are covered by the peritoneum, which makes them hard, prominent, and shiny; whereas when the peritoneum is stripped off them, these characteristics are lost. I admit that in eight cases out of the one hundred examined one or two of these bands could be seen, but not very distinctly, on the posterior part of the intestine, although they were uncovered by peritoneum. When the peritoneum only covers about one-half or two-thirds of the circumference of the gut, it is generally reflected off the gut at the longitudinal bands on to the walls of the belly. Thus, unless the peritoneum is stripped off, the bands are not visible. If an attempt is made to expose these longitudinal fibres the peritoneum, owing to its being so firmly adherent to them, is frequently torn and the abdominal cavity opened perhaps unknown to the operator.

It is argued in favour of lumbar colotomy that the large intestine can be reached without opening the abdominal cavity. This, of course, is possible. Yet it is much more important to make absolutely certain that the large intestine is being opened by first seeing the longitudinal bands. This, from the anatomical points I have mentioned, can only be done by opening the peritoneum. Moreover, I propose to prove that in this way only can the large intestine be found with certainty in most cases. I am strengthened in these conclusions by three cases in which I operated on the right side on the dead subject, where it afterwards appeared that, if I had not looked carefully for the longitudinal bands, the descending portion of the duodenum would have been opened instead of the large intestine. This occasionally happens when operating on the living.

Some years ago my father came to the conclusion, after careful investigation, that the best incision from which the colon could be found was one with its centre quite half an inch posterior to midway between the anterior superior and posterior superior spines of the ilium, and midway between the last rib and the crest of the ilium. This incision should be limited in length to between two and three inches, for this compels the operator to cut down exactly in the position in which the colon generally lies; whereas if, as is frequently the case, the length of the incision is five or six inches, the operator runs the risk of missing the gut. Moreover, another advantage of the small incision is that afterwards there is no collapse of the gut and very considerable sphincter power is obtained. For it is obvious that if a large wound is made, which does not heal by first intention at the anterior and posterior part, a weak cicatrix is left in the abdominal wall, and there is consequently a loss of muscular power over the new anus.

I will now consider the various positions which the right and left colons may occupy with regard to their peritoneal covering. The general position (as shown in Diagram 1) is where the peri-

toneum only covers a half or two-thirds of the circumference of the gut, leaving the posterior part uncovered, with the intestine bound down to the loin. This, according to Mr. Treves is found to be the position in

74 cases out of 100 on the right side,
64 " " " 100 " left "

My own observations, assisted by Mr. Stewart Pollock and Dr. Penrose at St. George's Hospital, show

11 cases out of 60 on the right side,
10 " " " 60 " left "

This, by taking the percentage, is

18½ cases out of 100 on the right side,
16½ " " " 100 " left "

From this it would appear that the position above described is less general than is popularly supposed. With the intestine in this state and a longitudinal muscular band seen, which must be uncovered by the peritoneum, all should go well, and there is little or no difficulty in operating. But when no bands can be seen, owing to the peritoneum covering them, the best distinction between large and small intestine is wanting. Therefore, knowing that the small intestine is frequently exposed by opening the peritoneum unwittingly, I consider that it is much more advisable to open the peritoneum intentionally and search for a piece of intestine with longitudinal bands than to run the risk of opening the small intestine, under the impression the peritoneum has never been opened at all, and that it is the large intestine with which you are dealing.

In Diagram 2 the colon is represented entirely surrounded by firmly adherent peritoneum, and having a comparatively short

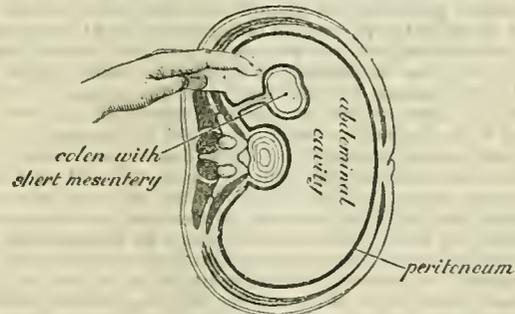

Diagram 2.

mesentery, and in such a condition that it is absolutely impossible to reach it or to see the longitudinal bands without first opening the peritoneal cavity.

The ascending and descending colons were found to have a mesentery of varying length, according to Mr. Treves, in

26 cases out of 100 on the right side,
36 " " " 100 " left "

I have observed this in

49 cases out of 60 on the right side,
50 " " " 60 " left "

showing, by taking the percentage,

81½ cases out of 100 on the right side,
83½ " " " 100 " left "

In Diagram 3 it will be seen that this condition of mesentery is much intensified, and that the intestine, although it may rest in the loin, can so alter its position in the belly that when operating

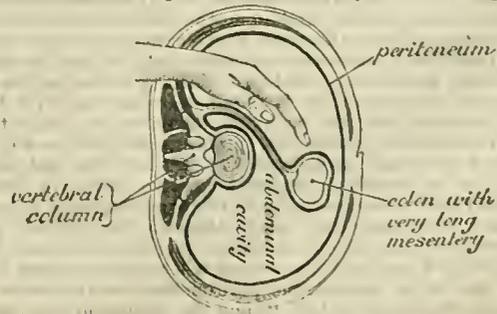

Diagram 3.

on either side it may lie on the side of the belly opposite to that

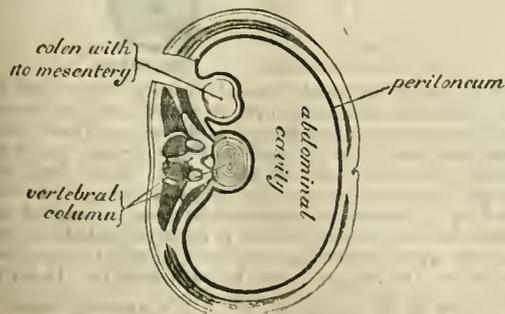

Diagram 1.

in which the incision is made. It then, in the cases reported, was said and supposed to be impossible to find the colon from the lumbar region.

The last two examples show how imperative it is to make sure that it is the large and not the small intestine, or even the stomach, which is going to be opened. At the risk of reiteration I must impress upon my readers the necessity of following the lines laid down for ascertaining that it is the large intestine which the operator is bringing to the loin. The presence of the appendices epiploicæ may also inform the surgeon that he has found the large intestine, but I do not consider these as so important as the longitudinal bands, since the appendices may not always exist on the piece of large gut brought to view. Bearing in mind these anatomical facts, we must now consider how they may be dealt with successfully.

In a case represented by Diagram 1, after exposing a piece of intestine, and failing to see a longitudinal band, I make a small incision into the peritoneum, and convince myself, by finding a band, that it is the large intestine. The posterior part of the intestine is then taken hold of, drawn to the surface of the wound (the gut being pulled out as far as possible, so as to obtain a good spur), and carefully stitched with interrupted sutures all round to the edges of the skin, without perforating the mucous lining. The intestine may then be left unopened for some hours, or, if necessary, opened at once; provided that it is carefully attached at every point to the surrounding edges of the wound.

When a condition occurs, as is represented in Diagram 2, of course in the first place a sufficient search should be made for the gut about the subperitoneal tissue, under the assumption that it is in its normal position; but should this search fail, all the loose pieces of fat must be sponged out of the wound, and the peritoneum at the anterior angle of the wound, deliberately opened (and the edges clipped), just sufficiently to admit the index finger. This finger I pass towards the vertebrae, and then sweep it over the front of the kidney and quadratus lumborum, and the gut, although it be in the position represented in Diagram 2, can be easily felt, hooked up, and the longitudinal bands seen. I then open the peritoneum to the extent of the wound, and introduce a sponge, with string attached, to keep the intestine out of the way while the edges of the cut peritoneum are drawn up and sutured to the skin in the manner I adopt in inguinal colotomy. This entirely shuts off the cut abdominal muscles from the peritoneal cavity. Occasionally this stitching is not easy to do, either on account of the depth of the wound, or from the firm adherence of the peritoneum to the abdominal wall. The rest of the operation is completed in the usual way, as described in Case 1. Here, if the mesentery be sufficiently long, a stitch may be passed through it, fixing it to the surface of the wound; thus a good spur is obtained.

In dealing with the third position, as represented in Diagram 3, after proceeding in the manner described in Cases 1 and 2, and failing to find the colon, I then enlarge the external wound forwards and backwards sufficiently to admit the hand. I next open the peritoneum to a corresponding extent, and, having well cleaned the hand, I introduce it into the abdomen. If it is the left colon that is to be operated on, I first pass the hand upwards towards the spleen, and feel for the splenic flexure. Hereupon I draw the hand down the intestine until the piece opposite the wound is found and brought to the surface. Failing to find the intestine at its splenic bend, I pass the hand towards the rectum or across the abdomen (keeping the back of the hand in contact with the posterior aspect of the anterior abdominal wall), towards the hepatic flexure, and then slip the hand along the large intestine, and draw a piece to the surface. Of course I take care to ascertain that this piece of intestine has the characteristic longitudinal bands. By these means I have never found any difficulty in finding the colon.

When the large intestine is found, command it with forceps that will not perforate the gut, and introduce a sponge to keep the small intestines, which may prolapse, out of the way while the wound is treated as follows. At the anterior and posterior parts, if the incision is six inches long, two inches in front and two behind should be dealt with as in an ordinary case of abdominal section, by passing the suture through the skin and peritoneum, so as to bring the cut peritoneal edges in contact. But at the middle two inches of the wound where the intestine is to be brought up to the surface, the peritoneum should be sutured to the skin as described in Case 2, and the operation completed in the same way. In this third condition a good spur can and should always be made, and when the gut is opened its promi-

nent edges ought to be cut away in the manner I suggested in my paper on inguinal colotomy.

I cannot help thinking that the above described methods of treatment must have occurred to, and been used by, some surgeons when performing lumbar colotomy.

I am much surprised, considering the frequency of the operation, that these details are so little known, or, at any rate, practised. Yet, as far as I am aware, no account of these important details in finding or treating the large intestine from the loin has, up to now, been brought before the profession. This silence on the subject has encouraged me to express my views, and I am confident that I shall never undertake this operation with any fear of failing to find the colon. I do not at all advocate lumbar colotomy when it is possible to perform the inguinal operation, for the lumbar is certainly the more difficult; the patient runs greater risks and recovers with less rapidity, and the after results are not so satisfactory. Nevertheless, for those surgeons who persist in the lumbar operation, and in cases where the obstruction is at the upper part of the sigmoid flexure or in the transverse colon, I hope that these remarks may assist in simplifying the supposed difficulties, and minimise the mistakes not infrequently made.

SUCCESSFUL EXTRACTION OF A PIECE OF GLASS FROM AN EYE WHERE IT HAD LODGED FOR MORE THAN TEN YEARS.

By T. H. BICKERTON, M.R.C.S.,
Oculist, Liverpool Royal Infirmary.

HAVING, in the literature of ophthalmic surgery, been able to find but four cases mentioned¹ where glass has been found in the anterior chamber of the eye, a record of the following case may not be without interest.

Mr. H. T., aged 29, was, more than ten years ago, watching closely the manufacture of oxygen. Suddenly the glass retort burst, and, on Mr. T. recovering himself, numerous pieces of glass were found sticking in his face; his lip was cut in two, and he could not see well with the left eye. Owing to a severe cornea wound, he was for a fortnight kept in a darkened room, for three weeks longer he had a bandage over both eyes, and for about six months he wore dark protectors. The following is his statement as to the progress of affairs:—"My eye gradually got better, useful sight was regained; and for years it gave no trouble, though in cold winds it used to inflame now and again. Within the last four years it has given more trouble, but this was ascribed to a granular condition of the lids; and rubbing with blue stone gave relief. Still there was always a red look about the eye. In a fierce sun it was weak, and often, when playing tennis it would water much and become red and irritable. Once, when bending over a dog, he suddenly jumped up, and his nose coming in contact with my eye caused pain. This year I have played tennis vigorously, and found the eye getting more and more red and irritable; and the local application of the blue stone, which up to this attack had always given relief, was now of no benefit.

On July 15th, 1887, the condition was as follows:—Right eye, V. $\frac{20}{20}$. J. i, normal in all respects; pupil $\frac{4}{16}$ m. Left eye, V. $\frac{20}{20}$.

Left Eye.

Line of incision. Glass. Glass in situ.

I letter J. i; small brownish corneal cicatrix below and to the inner side of the centre of the pupil, to which a tag of the surface of the iris (not the pupillary margin) adheres, and from it a faint cicatricial line runs up to the centre of the cornea; pupil $\frac{2}{3}$ m. and slightly irregular; iris acting well to light; lens normal. Lying at the bottom of the anterior chamber, not quite horizontal but tilted up to the outer side, can be seen, on careful oblique illumination, a foreign body, which is indistinguishable in certain positions, but which, when the eye is so directed as to allow the light to fall on its margins, can be seen readily. It lay in the

¹ Theobald, von Graefe's Archiv, vol. xxx, p. 2; Ammon's Zeitschrift, iii, p. 103; Critchett, Moorfields Reports, vol. i, Ferguson, Ophthalmic Review, vol. iv, p. 293.

inus between the cornea and iris, and was not imbedded in the latter. The iris in its neighbourhood seemed to be slightly cloudy, but this appearance might have been due to a condition of the cornea or aqueous humour. The ocular conjunctiva around his part of the cornea was very hyperæmic, and it had slightly encroached upon the cornea. There was also localised ciliary congestion. The attacks of irritation could now be accounted for on the supposition that the active exercise—tennis, shooting, riding, &c.—in which Mr. T. engaged caused some slight movement of the glass; and he could now recollect that each fresh attack had followed exercise.

A quiet life was advised, and in two months the muddiness of the iris and the ciliary congestion had disappeared, and much of the conjunctival redness had gone.

On September 12th, 1887, the operation was performed; and I may here thank Dr. Fox, of Philadelphia, an old Moorfields friend, for the good advice and able assistance he gave me. Eserine having been freely applied, in order to cause firm contraction of the iris, and the eye placed thoroughly under the influence of a 1 per cent. solution of cocaine, a horizontal, purely corneal incision was made by puncture and counter-puncture with a Graefe's knife across the front of the cornea, at the junction of the lower third with the upper two-thirds, the aqueous being allowed to escape slowly. A curette was then introduced between the lips of the wound and passed on in front of the iris to a position behind the foreign body, in order to fix it. This being done, a pair of fine forceps was introduced to the bottom of the anterior chamber, and the glass, being seized at the first attempt, was removed entire. At the moment of withdrawal a speck of blood appeared on the surface of the iris, evidently being due to its having been pricked by a fine needle-like point which projected from one of the ends of the glass. Ice-d compresses were applied, and the eye made an uninterrupted good recovery, though, in spite of frequent instillations of eserine, a slight adhesion took place between the surface, not the pupillary margin, of the iris and the outer part of the corneal incision.

Two months after the removal all conjunctival redness had gone; the pupil was almost regular, and had increased in size to 4 mm. Vision $\frac{4}{2}$ letters, J. i.

The glass measures in its greatest length $4\frac{3}{4}$ mm., in its shortest length $3\frac{3}{4}$ mm. It is 1 mm. in breadth, and $\frac{3}{4}$ mm. in thickness.

A NOTE ON THE CONDITION OF THE BLOOD IN MALARIA.

By J. F. EVANS, SURGEON, I.M.S., MANDALAY.

MALARIAL fevers have naturally always obtained a great deal of attention from medical men throughout the Indian Empire. In 1855, according to Surgeon-General Thomson's report, one-fourth of the admissions to the European military hospitals of the Bombay Presidency were for this disease. But, while the mortality is very high, the debility that results from repeated attacks is a much more serious matter. Englishmen who have been living in a malarious climate occasionally suffer from ague after their return to their native home, pointing to some effect on the tissues persisting subsequent to exposure. An officer who had been some years in India told me that his first attack of ague was when taking his first leave home.

It may be that malarial poisoning is a gradual process, and that a condition of semi-tolerance is established, and that the chill or exposure, of which Dr. Oldham writes, is the immediate exciting cause. In 1879, Klebs and Tommasi-Crudeli professed to have successfully inoculated rabbits with malarial fever, and to have discovered the bacillus malarie; their experiments do not seem to have been confirmed by other observers. Marchiafava and Celli, in 1885, published a detailed account of the changes observed by them in malarial blood, with which the later researches of Dr. Laveran greatly coincide (*vide* BRITISH MEDICAL JOURNAL, October 29th, 1887). There has of late, in the military hospitals of Mandalay, been a wide field for research into the pathological changes induced by malaria. I have never examined a single specimen of blood taken from a patient suffering from ague or remittent fever without finding some definite change.

The following are the changes observed by me:

1. In health the red blood cells are with difficulty stained by aniline dye, but, after even a single attack of ague, the red blood cells can be readily stained by an aniline solution of gentian

violet; a small area, however, in most being left unstained. This unstained area is not constant in size, nor in its position in the corpuscle, in some involving nearly the whole corpuscle, in others so small as to be easily ignored. In specimens of unstained blood I have recognised the hyaline material replacing the hæmoglobin of the red corpuscles, as described by Marchiafava and Celli, who state that this hyaline material can be readily stained with methyl blue; but hitherto I have not been successful in obtaining this reaction. The globule of new hyaline matter in the red corpuscles can be seen slowly to change its shape from time to time, which Marchiafava and Celli pointed out. Whether this hyaline material coincides with the unstained area, I am not at present able to decide. In cases of malarial cachexia, the softening and crenation of the red corpuscles is a marked feature; in such cases, it is difficult to find in a specimen of blood a corpuscle with normal outline. This crenation is certainly more marked in the blood of natives than in that of Europeans, and may be due in part to the deficiency of nitrogenous matter in their diet. It is due probably to a gradual loss of the cell contents, and may serve to account for the intense anæmia that occurs in malarial cachexia. The red corpuscles are not only altered in structure by this disease, but are absolutely destroyed in the process; they can be seen in every stage of destruction, from mere erosion of the margin to almost complete obliteration, a thin semilunar rim of pellicle being left. As might be expected in blood undergoing a process of slow deterioration, small free masses of pigment are often met with.

2. In addition to the structural changes already mentioned in the blood-corpuscles, I have found free spherical bodies in the serum and in the corpuscles. These spherical bodies are possessed of movement, both rotatory and from place to place. They are of two perfectly distinct kinds, and I shall, for purposes of description, describe them as nucleated and non-nucleated, although not considering the nuclear body of the nature of a nucleus:

a. The non-nucleated spherical bodies are dark in colour, of the same consistence throughout, and about $\frac{1}{2}$ th to $\frac{2}{3}$ th the diameter of a red corpuscle (that is to say, 0.2μ to 0.3μ in diameter). They are to be met with either moving freely about in the serum, or else stationary inside the red corpuscles; when immured in a red corpuscle they as a rule remain fixed, but rotatory movements are to be observed sometimes. Three or four of these bodies generally occur in the same corpuscle together, beneath the pellicle, at one point; they frequently occur in the corpuscles undergoing the hyaline degeneration noted by Marchiafava and Celli, and also in those cells where this degeneration cannot be distinguished. I have never seen any of these organisms inside a white blood-corpuscle. I have found them in the serum and red cells of the blood of men suffering from beri-beri; and similarly in the serum and red cells of the blood of horses suffering from *sarrah*, in company with Surgeon Hendley, who tells me that he has observed similar bodies in the blood of rats, and of a dog ailing with fever. More numerous and more freely movable than the nucleated spherical bodies, it is only possible to suggest that they may have some relation to the nuclear-like bodies of the latter, although up to the present this has not been traced.

b. The nucleated spherical bodies are of a greenish-yellow tint, circular single contour, brighter than the red corpuscles, and with a highly refractive outline; varying slightly in size, they are about $\frac{1}{4}$ th to $\frac{1}{3}$ th the diameter of a red blood corpuscle (about 1μ to 0.7μ). The nuclear-like body can be easily distinguished inside the sphere, which is often little more than an enclosing capsule. Like the spherical body in which it is enclosed, this nucleus has free rotatory movement.

The nucleated, like the non-nucleated bodies, have movements rotatory and from place to place, though not so freely as the latter; they are also not so numerous, but, like them, are found floating freely in the plasma and stationary in the corpuscles. They usually occur singly in the blood cells, and I have seen them occasionally in the white blood cells as well as in the red. They often occur with the non-nucleated in the same red corpuscle; but I have never found them in corpuscles undergoing the hyaline degeneration. My first acquaintance with these nucleated spherical bodies was in the blood of horses suffering from *sarrah*, where they occur like the non-nucleated. I have not seen them, however, in the blood of beri-beri, where the non-nucleated occur, and in which disease, on two occasions quite recently, I have found a streptococcus, in chains of three cocci each, not very unlike the cocci occurring in *kumri*. The appearance of these nucleated spherical bodies would justify the assumption of their being monococci. I have not yet, however, succeeded in staining them. Accordingly,

without this and cultivation on nutrient media, and the reproduction of the disease from culture, it would be unwise to pronounce as to their nature.

The larger spherical bodies, described by M. Laveran as slightly larger than red blood cells, I have not hitherto seen; but I am inclined to believe that, what are described by him as the larger spheroids are red blood cells invaded by the parasitical elements I have observed. The white blood-corpuscles in malaria are not increased; they are apparently little affected by the disease, being invaded occasionally by the nucleated spheroids; and, when studded with pigment granules, as sometimes occurs, they present the appearance indicated by M. Laveran as the "*leucocytes melanifères*."

THE CHEMICAL INCOMPATIBILITY OF ANTISEPTIC AGENTS.

By ROBERT BOXALL, M.D., M.R.C.P.,

Physician to the General Lying-in and to the Samaritan Free Hospitals.

THE necessity of employing antiseptic agents in solution of definite strength will be, I presume, on all hands conceded; for, if the solution be too attenuated, the object in view will fail in its accomplishment, and, if too concentrated, considerable damage will in many cases be wrought, not only locally on the tissues to which the application is made, but also on the body generally as the result of absorption. The borderland between safety and success is, in many instances, a very narrow one. The possibility of reducing the strength of the solution, or of altering its nature through the chemical incompatibility of the materials employed, has hitherto received but little attention. The important practical bearing which this may exert on their efficiency as antiseptics must prove my apology for drawing attention to the matter.

By way of example, I have selected five of the more important antiseptic agents in general use, and, for ready reference as to the incompatibilities of each, the results of the experiments are presented in a tabular form, showing the action not only of these agents on one another, but also of certain lubricants with which they are frequently combined and brought into contact, and of soap with which they are apt to be contaminated in the process of washing and disinfecting the hands and instruments.

In view of the practical utility of these observations, the experiments were made, not with concentrated materials, but with solutions of the strengths usually employed in practice, and were carried out at temperatures not exceeding that of the body.

	1. Sublimat.	2. Carbolic.	3. Iodine.	4. Salicylic.	5. Condy.	6. Olive Oil.	7. Vaseline.	8. Glycerine.	9. Soap.
1. Corrosive Sublimate Solution (Perchloride of Mercury) ...	—	—	1	—	—	—	—	—	2
2. Carbolic Solution (Phenol) ...	—	—	3	—	4	5	—	—	—
3. Iodine Solution (Iodine and Iodide of Potassium) ...	1	3	—	—	—	—	—	—	6
4. Salicylic Solution (Salicylic Acid) ...	—	—	—	—	7	—	—	—	5
5. Condy's Fluid (Permanganate of Potassium) ...	—	4	—	7	—	9	—	10	11

The following incompatibilities were observed:

1. *Corrosive Sublimate and Iodine*.—No precipitate of mercuric iodide is at any stage of the admixture formed. A small addition of sublimate solution fixes the free iodine, as may be seen by the immediate bleaching of the iodine solution, and confirmed by the subsequent addition of starch paste, which produces no blue coloration. One part by volume of sublimate solution (1 in 1,000) is just sufficient to fix the whole of the free iodine in 4 parts by volume of iodine solution (tr. iod. B.P. 5j in Oj). N.B.—This forms a rough and ready test for the strength of sublimate solutions.

2. *Corrosive Sublimate and Soap*.—An insoluble soap is produced even when a neutral soap solution is used. This is of special importance in consideration of the small admixture with soap which is required to throw down the whole of the mercury from solutions of the strength usually employed.

3. *Carbolic and Iodine*.—An exceedingly small admixture with phenol is sufficient to fix the whole of the free iodine as in (1). One part by volume of carbolic solution (1 in 20) removes the

whole of the free iodine from 2,000 parts by volume of iodine solution of the strength indicated above.

4. *Carbolic and Condy*.—This is perhaps the most generally recognised of these incompatibilities. Admixture with phenol immediately turns permanganate brown.

5. *Carbolic and Olive Oil*.—This is of importance and of special interest when taken in conjunction with the researches of Koch, of Berlin, who has shown that bacillus spores are capable of living and developing after having been immersed in carbolised oil (1 in 20) for 4 months. The oil appears to enter into some combination with and to fix the phenol. If a drop of tr. ferri perchlor. B.P. be shaken up in a test tube with carbolised oil (1 in 20) no change is found to have been produced in the iron as it gravitates to the bottom. Moreover, if carbolised oil be shaken up with a few drops of water, the water allowed to separate out at the bottom of the tube and a drop of iron solution conveyed into it, the characteristic purple coloration with phenol is not produced unless the shaking has been very prolonged and energetic, and then only to a slight degree. By strongly heating the carbolised oil phenol is again set free, and the above reaction can then be obtained.

6. *Iodine and Soap*.—No action is produced by a neutral soap solution, but ordinary soap, which contains an excess of alkali, at once removes the free iodine.

7. *Salicylic Acid and Condy*.—A very dilute salicylic acid solution (1 in 800) slowly removes the colour from permanganate.

8. *Salicylic Acid and Soap*.—A drop of dilute salicylic acid solution gives a white precipitate even when a neutral soap solution is employed.

9. *Condy and Olive Oil*.—When permanganate solution is shaken up with olive oil its violet colour is changed to brown.

10. *Condy and Glycerine*.—When permanganate solution is added to glycerine its colour slowly changes.

11. *Condy and Soap*.—This incompatibility is also generally recognised. Soap, even when a neutral solution is employed, readily turns permanganate brown.

I do not pretend to any precise knowledge of the bodies produced, some of which may, for all I know, possess powerful antiseptic properties. But until this point is settled by direct observation, when chemical incompatibility exists, the antiseptic properties of the original solution must be regarded as weakened if not wholly destroyed.

The moral conveyed by the above experiments is obvious; avoid as far as possible the admixture of antiseptic agents and their contamination with lubricants and with soap when incompatibility exists. For instance, in employing corrosive sublimate it is advisable to use the same solution for disinfecting the hands (carefully avoiding contamination with soap) and for cleansing instruments as for irrigating the parts, to employ a mercurialised lubricant and to use alembroth dressings. If for any reason it becomes requisite to substitute one antiseptic agent for another, second should be chosen which is not incompatible with the first and the same precautions should be observed throughout the series.

The above observations deal with one phase only of the subject. I am content to leave to more able hands the elaboration of further details. The second question—the chemical nature of the bodies produced—is for the chemist to answer; the third point—the antiseptic value of these bodies—still remains for the germ culturist to determine. When these points have been settled and acted upon, less scepticism as to the value of antiseptic agents may be looked for. The fault lies not so much with the antiseptics themselves as with the unscientific method in which they are often employed.

¹ Here, again, a caution is requisite, for copper and steel, unless nickel plated are apt to decompose the solution and to cause precipitation of the mercury as a free state.

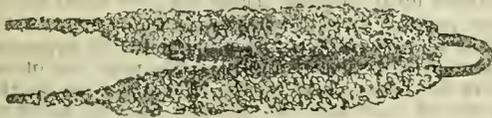

TESTIMONIAL.—Dr. Williams, who was recently compelled resign his appointment of medical superintendent of the Sussex Lunatic Asylum at Hayward's Heath in consequence of ill-health has been presented by upwards of one hundred members of the staff of that institution with an illuminated address in the form of an album as an expression of their appreciation and regard.

At a meeting of the Committee of the Home and Infirmary for Sick Children, Lower Sydenham, S.E., on April 2nd, a unanimous vote of thanks was passed to Dr. Spencer Smyth, F.R.C.S., for valuable services rendered to the institution for so long a time. Honorary Surgeon and Consulting Surgeon. Dr. Smyth has gone to reside at Bournemouth.

SURGICAL MEMORANDA.

REMOVAL OF HAIRPIN FROM THE FEMALE BLADDER.

On June 22nd, 1887, I was asked to see E. P., a domestic servant, aged 25, who, about three weeks previously, whilst assisting in spring cleaning, strained herself, and had since suffered from constant pain in the bladder and womb, with a frequent desire to pass urine, the urine being offensive, and containing a quantity of thick tenacious sediment. Standing or sitting aggravated the pain and discomfort. She had been seen and prescribed for by another medical man, but, getting no relief, she came home. A digital examination revealed nothing wrong. Subsequently, being informed by her mother that the girl had confided to her that, at the time of straining herself, she felt "something come down," which she tried to replace with a hairpin, that the hairpin had slipped out of her reach and had not since been seen by her, I decided to pass a catheter into the bladder, when, almost immediately, I felt it impinge upon a hard, roughened substance. The nature of the case was now evident; accordingly, I determined to dilate the urethra with sponge-tents, with a view to removing the foreign body. Before proceeding, however, I introduced a fine urethral forceps, and, to my great satisfaction, succeeded in grasping the object, which I was able to remove without much difficulty, and with but slight pain to the patient, who, the following day, was up and about, apparently perfectly well. The foreign body proved to be an ordinary black, japanned hairpin, as shown in the accompanying sketch. It was coated with a thick deposit of gravel

and, from the manner of the coating, it was evident that the position of the pin must have been reversed soon after its introduction to the bladder, the thicker and heavier deposit being towards the curved end. The absence of deposit at the head, or curve, is accounted for by the pressure of the forceps in its removal. The pin, with its coating, weighed forty-eight grains, and measured two and a half inches in length by half an inch in its greatest width. A microscopical examination of the deposit showed it to consist chiefly of crystals of uric acid, triple phosphates, cystine, with numerous epithelial casts.

Epping.

RUPTURE OF MIDDLE MENINGEAL ARTERY.

C. D. aged 10 years, a small boy, received about noon, Saturday, October 8th, 1887, a blow from a stone. There was no complaint of pain or illness during the remainder of the day, nor did the blow cause any immediate symptoms.

On October 9th there was slight tenderness behind the left ear, and slight headache, but no mention was made by the patient to his parents of any blow. On October 10th the lad went to school as usual, and in the evening was rather noisy and more than usually cheerful and mischievous. He went to bed at about 10 o'clock. At 12 o'clock his father was called to him, he was crying with headache and was very sick. The father stayed with him until he appeared more quiet and went to sleep(?).

Early on October 11th I was sent for to see the child. He was quite unconscious, both pupils were widely dilated, not acting to light, and he was sick. The extent of paralysis could not be recognised as there was complete insensibility. The bowels and bladder had been emptied unconsciously during the night. The pulse was very feeble; the temperature was below normal. At his time I did not know of any injury. He continued in the same condition until noon, when he died.

Necropsy.—There was a slight bruise over the left temporal region; behind the ear the squamous portion of the temporal bone was very thin, not thicker than a sheet of brown paper. The anterior branch of the middle meningeal artery was ruptured, the dura mater was separated from the skull, and there was a large clot the size of the palm of the hand, between the skull and the dura mater. All the other organs were healthy.

REMARKS.—In this case there was an interval of sixty hours between the injury and any acute symptoms. The boy had eaten a

considerable number of acorns on Monday, and it seems just possible to me that the artery may have been only bruised in the first instance, and subsequently ruptured by the sudden straining of the vessels caused by the sickness, which perhaps was due to the acorns, and at this time not to active cerebral mischief. Of course there may have been slow hæmorrhage during the whole time.

Redhill.

H. W. EWEN.

A CASE OF TRAUMATIC PERICHONDRITIS OF THE LARYNX.

THE following case is of interest, first as an example of a somewhat rare accident, and secondly as confirmatory of my contention that caries is not a necessary sequence of perichondrial inflammation, as is held by most authors, for in not a few cases the inflammation terminates in resolution with more or less thickening and functional impairment, but without caries or separation of any portion of the cartilages. I take this opportunity also of saying that I have long held the opinion, as is evidenced in my published writings, that perichondritis may arise independently of any specific dyscrasia, syphilitic, tuberculous, or cancerous.

Mr. J. R. J., lieutenant in the Royal Navy, consulted me on February 26th, 1888, stating that he had received a blow from the elbow on the left side of the pomum Adami, in the previous October, while playing football.

There was no visible bruise, but there was considerable pain with slight external swelling. His voice was entirely lost for forty-eight hours, and was afterwards husky for some days. The further effect on his voice was peculiar; for even after recovery of phonation, he experienced the greatest difficulty in controlling his speaking voice, and especially in giving the word of command, which was attended with more than ordinary difficulty, he being engaged in gunnery experiments. He had formerly pitched his voice for this purpose in a rather higher tone, but this he found himself now unable to do. Before his accident he had a fine singing voice, with a range of fully two octaves from E to E, and even to F. On recovery of his speaking voice, he attempted to sing, but found that he had lost five or six notes, his limit then being G, in the fourth space of the bass clef. His lower notes had remained unaltered.

On laryngoscopic examination I found that there was swelling and redness of the left arytenoid cartilage, and slight congestion of the cartilaginous portion of the vocal cords. There was also distinct tenderness on palpation of the left side of the larynx. At no time had there been any pain on swallowing.

Treatment has consisted in complete vocal rest, the nightly use of a wet compress over the larynx, and the application by means of a compressed air spray of a solution of iodide of zinc, ten grains to the ounce. The patient may now be considered well, and will immediately resume duty, but he reports that he has only regained one note and a half of his singing voice, and that after vocal exertion in even ordinary conversation his throat becomes painful.

LENNOX BROWNE, F.R.C.S.Ed.

Weymouth Street, Portland Place, W.

TREATMENT OF CARBUNCLE.

I AM quite at one with Dr. Henry Lowndes, of Liverpool, in the treatment of carbuncle. I have seen nearly all the various methods of treating carbuncle tried, and I am decidedly in favour of sulphide of calcium with carbonate of iron, generous diet, and locally cleanliness with linseed meal poulticing as occasion demands. I have, without exception, had good results, and now in all cases I never think of using the lancet. The old method of resorting to the knife in all cases of carbuncle I think is to be deprecated.

Glasgow.

QUINTIN McLENNAN, M.B., C.M.

In the report of a lecture by Mr. Page in the JOURNAL of March 24th, in speaking of the treatment of carbuncle by potassa fusa, he says: "Others think the separation of the slough may be hastened by pushing small pieces of potassa fusa through the skin holes into the gangrenous tissue beneath." From this expression it is sufficiently obvious that he has no knowledge or experience of this plan of treatment. I made it the subject of the surgical address when our Association met in Bristol, under the presidency of the late Dr. Symonds, in 1863, and since that time I have always used the caustic, and with unfailing success, in my own cases and in consultation.

A deep central circular slough, which may include some of the apertures, if any, that are already formed, must be made by the

application of the caustic, and its size must vary with the size of the carbuncle, meaning perhaps the third or fourth of its diameter; and when I entered the profession we had frequently to make caustic issues near the joints or on the arm or any other part, and we learnt that to form a slough involving the whole thickness of the cutis will require the continued application of the potash for ten minutes or a quarter of an hour.

When the slough has been formed the patient is at once relieved of the pain, and pressure, and tension of the disease, which from this time ceases to extend, and as a rule the recovery is uninterrupted.

I have never employed the method of scraping, having complete faith in the caustic treatment. I agree, however, in one particular with Mr. Page, namely, in hoping that he will not have a carbuncle.

AUGUSTIN PRICHARD, F.R.C.S.

Clifton, Bristol.

IN the JOURNAL for March 3rd, 1883, p. 417, Mr. H. B. Hewetson, of Leeds, gives an account of a case of carbuncle successfully treated, in which he employed both scoop and scissors for the free removal of all dead and doubtful tissues.

Following Mr. Hewetson's lead, I have similarly treated three cases:—

1. T. L., aged 60, admitted April 3rd, 1883, ill two weeks with carbuncle four inches in diameter, situated on the back of the right chest, and suppurating through several small openings on its surface. Under ether the diseased tissues were freely removed by scoop and curved scissors. Iodoform powder was used as dressing for a few days. Recovery was complete on May 25th, having been delayed by large size of sore.

2. M. B., aged 60, admitted in January, 1884, with very large carbuncle on the back of the neck, treated as last case; recovery in six weeks.

3. M. A., aged 49, admitted on December 3rd, 1885, with carbuncle two inches in diameter, situated behind the right ear; ill twelve days; entirely removed at once as before; recovery in five weeks.

In all the cases pain, previously intense, was immediately removed, and the site of the carbuncle was in a very short time converted into a healthy sore.

Mr. Rushton Parker, on page 691 of this year's JOURNAL, insists on the free removal of carbuncle; in this he was anticipated by Mr. Hewetson. Mr. Parker recommends the knife in addition to the scoop, while Mr. Hewetson recommended scissors, a more serviceable instrument for the purpose.

Mr. Teale's description of the removal of carbuncle by scraping errs in not advocating a free enough removal of the diseased tissues; it is impossible to satisfactorily deal with a carbuncle by the scoop alone.

JAMES ALLAN, M.A., M.D., Leeds Union Infirmary.

NOVEL METHOD OF APPLYING TAXIS.

A FEW days ago a native presented himself at the dispensary of this hospital with a right large scrotal hernia, which had been down for some months. The man was placed on his back, and the tumour manipulated. The coverings were fairly tense. Before attempting reduction I casually asked the patient if the tumour ever got smaller; he replied "Yes," and proceeded to give me a demonstration in taxis which I had not previously heard of, and which will probably be new to many readers of the JOURNAL. Lifting up the tumour with his left hand, he placed his right thigh on his abdomen, then crossed it over to the left side, catching the tumour between the pubes and thigh, then applying pressure. The hernia disappeared with a gurgle and a snap before I had time to call the attention of the students to this novel procedure. The reduction was complete.

G. JAMESON, M.B., I.M.S.,

Resident Surgeon, Medical College Hospital, Calcutta.

ABDOMINAL PUNCTURE IN TYMPANITES.

SIR,—Having resorted to abdominal puncture in tympanites several times during the last thirteen years, I have read with interest your report of Dr. Kyle's case (JOURNAL, April 14th, p. 79).

I first adopted this method in the year 1875 under the following circumstances:—A gentleman, aged 30, was suffering from peritonitis, resulting from a chill, and on or about the eighth day the tympanites gave rise to great distress, and all the usual methods

adopted in such cases failed to give relief. On the morning of the tenth day I was called up at 3 A.M., as the nurse thought the patient was dying, and on my arrival I found him in a most critical condition. The pulse was almost imperceptible at the wrist, the breathing was quick and shallow, the heart's action was alarmingly tumultuous and rapid, and the countenance was pinched, with a cold, clammy forehead. It was evident that unless the tympanic distension was diminished a fatal result would occur, and I, therefore, decided to puncture the most resonant part, and did so with a hypodermic needle. It was most gratifying to notice that in a few minutes the breathing became deeper and the heart's pulsations steadier. The patient after this progressed favourably, and is still alive and well.

In all the other cases in which I have punctured much benefit has resulted, and in no case has any unfavourable symptom arisen from the procedure.

When I adopted the plan in 1875 I had not heard of it being used or even suggested, and I certainly consider that it is a procedure which might be adopted very frequently.

AUBURN WILKINSON, M.B., F.R.C.S. Eng.

Tynemouth.

A CASE OF INTESTINAL OBSTRUCTION, WITH RUPTURE OF THE BOWEL: OPERATION: RECOVERY.

W. V., a grocer's assistant, aged about 29, sent for me early one morning in July, 1885. He stated that on the previous evening, when chopping up firewood, he felt a pain in the stomach, which had continued until morning. There had been slight sickness, but the bowels had not acted for twelve or fourteen hours. I found the patient in bed, complaining of pain in the hypogastric and right inguinal and lumbar regions. The pain was increased by pressure in the hypogastric region. There was no marked dullness or tumour. An aperient pill and dose of castor-oil were given, but both were rejected with vomited food. The castor-oil was repeated, and one pill of opium (half a grain) and belladonna (quarter of a grain) given every three hours. In the night vomiting was distinctly greenish and sour. As there was no action of the bowels, an injection of soapy warm water, castor-oil, and turpentine was given. This succeeded in clearing out the colon, and it was followed in six hours by a very slight action. Vomiting continued every few hours. The abdomen was increasingly tender, and there was dullness over an area of four or five square inches to the right of the umbilicus, and three inches below. There was slight tympanites. No improvement followed, and the patient having been removed to the hospital, it was decided at midnight (four days after first symptoms) to operate. The patient was almost moribund, the abdomen was greatly distended, temperature 104.5°; pulse 135, and quite characteristic; respiration was short, rapid, and laboured. The A.C.E. mixture was administered. The usual median incision was made through the abdominal wall, and afterwards carried two inches above the umbilicus. (By the courtesy of the surgeon of the hospital, I was asked to assist in the operation.) The peritoneum was carefully divided on a grooved director. No sooner was the abdominal cavity thus laid open, than out there gushed a large volume of horrible faecal gas, followed by a copious outflow of thin yellow greenish fluid, containing a quantity of flakes of lymph, and bits of faecal matter. The small intestines were distended with gas. The peritoneum was intensely injected. We bled out the abdominal cavity with a teacup. Then slight bilateral pressure caused a small fountain to well up from the deep part of the abdominal cavity. Taking this fountain for my guide, I passed the index finger of my right hand through the aperture into the bowel, upwards and downwards. I strongly advocated resection, but was overruled, and consequently sewed up the parietal wound. The man to all appearance seemed on the point of expiring. The wir sutures all in turn gave way, quantities of faecal matter and fluid continued to escape from this wound for several weeks. The ruptured bowel became disengaged, and rose to the surface of the parietal (operation) wound. The latter became agglutinated in mass of granulations. The abdominal cavity was once more restored. Faeces passed *per anum*, and the patient, passing through a long convalescence, escaped with a very small fistula, the size of a hempened, and is now otherwise in the enjoyment of perfect health and strength.

St. Leonard's-on-Sea.

THERAPEUTIC MEMORANDA.

JAMBUL IN DIABETES.

A LADY, aged 65, has been a diabetic since 1876, and under a restricted diet has, with the exception of some physical weakness and failing sight, enjoyed pretty fair health until about twelve months ago, when she commenced to urinate much more frequently, to suffer from excoriation of the vulva, and to be so weak that walking alone became impossible. These symptoms were quickly relieved by codeia, alternated with sodium salicylate and occasionally Bethesda water, and she rapidly came to her usual state of passing four or five pints of urine daily, specific gravity 1030, and containing about 10 grains per ounce of sugar. A friend in London, also a diabetic, recently recommended her to try jambul seeds, and sent a supply in tablets, one of which was to be taken three or four times daily. Under less than a fortnight of this treatment the urine became more than trebled in quantity, specific gravity 1045, 40 grains of sugar per ounce. Patient got intensely thirsty and extremely weak, but in spite of this persevered as long as she possibly could with the jambul, having remembered that codeia had disagreed with her at first. Now, after ten days' cessation of jambul and resumption of codeia, she is much stronger, passing five or six pints of urine a day, containing 17 grains per ounce, of sugar, and specific gravity 1030.

I may mention that the tablets were procured from a first-rate London chemist. In the friend mentioned above as also suffering from diabetes, the jambul effected no improvement whatever.

Peel, Isle of Man. J. M. COATES COLE, L.K.Q.C.P.I.

STROPHANTHUS.

RECENTLY I have tried strophanthus in two cases, one mitral regurgitation, the other aortic valvular disease. The first case, a young man aged 23, had been ill for six months; he had taken digitalis for some weeks, and, as he expressed it latterly, the medicine had done him no good. One evening I was sent for; he was propped up in bed; had a quick, thready pulse; face and extremities cold from venous congestion; respiration 46. I was afraid he was sinking, and so I expressed myself to his friends. I ordered one-drop doses of Burroughs's tincture of strophanthus very hour for six hours, then the dose to be repeated every two hours. What was my surprise in about twelve hours after to find him much better; pulse slower and fuller; the congestion disappearing; free perspiration and diuresis. Eventually he got out of doors, and has been better for nine months. In the other case, I gave tincture of strophanthus as soon as I commenced attending the case, and was puzzled at the uncertain effect. I tried fresh infusion of digitalis, which had a marked beneficial effect for three or four weeks; soon afterwards the patient had an attack of congestion of the lungs, which left his trunk and legs much swollen and oedematous, his urine albuminous. I got a fresh supply of tincture of strophanthus from London, which had a similar effect as in the mitral case, and now I am glad to say the man is much better, able to do light work, not having taken any of the medicine for ten weeks. Combined with iron and quinine, I have found strophanthus beneficial in functional derangement of the heart.

THOMAS JACKSON, M.D.

Hull.

PHENACETINE.

URING the past three weeks I have been using this drug as an antipyretic, and I can confirm Dr. Bell's statement as to its efficacy. I find that it is quite equal to antipyrin, but it is not nearly so powerful as antifebrin.

Phenacetine in moderate doses is not followed by any disagreeable after effects. Antifebrin, on the other hand, causes profuse respiration accompanied with great depression and should be given with care, not more than five grains at a time to an adult. Rigors occur after both antipyrin and antifebrin, but I have not observed them after phenacetine.

From five to ten grains of phenacetine may be safely given to an adult and frequently repeated. It reduces the temperature considerably in two or three hours, but the reduction is a very transient one, lasting a few hours only.

I consider sponging with tepid or cold water to be far more effective and agreeable than any of the antipyretic drugs, and it not only reduces the temperature but it relieves thirst, induces sleep, and is agreeable to the patient.

Birmingham. C. W. SUCKLING, M.D.

COCAINE IN ACUTE TONSILLITIS.

RECENTLY I began to suffer from a very sharp attack of acute tonsillitis of the right side, with a considerable injection of the surrounding parts. Two days after I experienced the most excruciating pain in swallowing, also severe pain in the right ear, and I could only with great difficulty speak. In the afternoon of this day my friend Mr. Thomas swabbed out my throat three or four times with a 4 per cent. solution of cocaine, and poured a few drops of the same into my ear. The relief which I experienced was so great that I could soon after speak fairly easily, and swallow with very much less difficulty. I continued to apply the cocaine every two hours during the day with continued success for five days, then a day in the country put me right.

Cardiff. P. RHYB GRIFFITHS, B.S., M.B.Lond.

CLINICAL MEMORANDA.

ANALYSIS IN AUSCULTATION.

WILL you allow me to suggest to those who are specially interested in the study of cardiac murmurs and *bruits*, and morbid sounds generally, a mode of examination and an arrangement of stethoscopic apparatus, which I have found of very great service? The principle of procedure is to collect the sounds produced by the respective valves, or at several points, and to bring them to the ear together; which, obviously, facilitates the formation of a correct judgment of their comparative intensities; and then to suddenly eliminate one or another set of sounds, thereby rendering the determination of what belongs to each severally a matter of far greater ease than the same discrimination when the valves, etc., are examined separately; while the accurate placing of such sounds as the early, middle, and late diastolic (presystolic) murmurs involves little difficulty. The method is *analytical*; the aggregate sound, or sounds, produced by the movement of the blood-current or the several parts of the cardiac or pulmonary organs being, so to say, taken to pieces under the ear of the auscultator, thus enabling him to appreciate with clearness the part played by each in the production of the whole.

The stethoscopic arrangement consists in connecting two or more ordinary elastic tubes of suitable lengths, by means of an X piece, to the distal ends of a binaural instrument, in such manner that the chest-pieces may be applied at pleasure over distant areas simultaneously, and each instantly lifted so as to step out all sound that arises from any particular region at will. The arrangement is so simple, and at the same time so effective, that I think it desirable to call attention to the matter. It differs from that of the ordinary differential stethoscope in that the sounds are brought to the two ears simultaneously, and the whole of the auditory power is, therefore, at work on the same subject, which, as I have said, is analysed, by a process of exclusion, to the very great advantage and ease of the listener in forming his judgment. The arrangement can be carried out by any medical instrument maker.

J. MORTIMER GRANVILLE, M.D.

14, Hanover Square, W.

OBSTETRIC MEMORANDA.

RUPTURE OF THE UTERUS.

Mrs. D., aged 35 years, was the mother of four children, the youngest of whom is 4 years old. Since its birth she has had six abortions.

Pregnancy had advanced to the eighth month. The head presented in the first position, and the delivery of the fœtus passed off naturally, the first stage lasting about four hours, and the second two. The child had evidently been dead for some time, and its abdomen was distended by ascites. Twenty-five minutes after the fœtus was born there was some contraction of the uterus, when the placenta came partially through the os, but afterwards receded again; the patient, however, did not complain of any excessive pain. Ten minutes later I observed a sudden increase in the rapidity of the pulse, and a collapsed state of the patient, so I at once introduced my hand, which went in with very little resistance; but it passed through a large hole into the cavity of the abdomen, which evidently contained a large quantity of blood. I found the placenta to be adherent above, and separated it without much difficulty; but, after removing it, I found another large mass in the vagina, which I also removed.

It proved, on examination, to be a fibroid thickening of the uterus, forming a tumour weighing over two pounds. I kept up compression of the abdominal aorta all the time, but the patient was in a very collapsed state, and died shortly afterwards. Dr. Tresilian kindly made a *post-mortem* examination for me, which revealed the following conditions.

The cavity of the peritoneum was full of blood. There was a large perforation of the uterus; in fact, the upper and anterior wall had come away, evidently containing a large intramural fibroid tumour.

The point of interest of this case seems to be the fact that the rupture probably took place after the fetus was born, though at what time exactly I am unable to say.

Ebbw Vale, Mon. ALEX. S. PATTON, M.B., B.Ch., Univ. Dub.

AFTER-TREATMENT OF ABORTION.

I HAVE read with great interest Dr. Murdoch Cameron's article on the Pathology of Abortion, in Relation to Treatment, in the JOURNAL of March 31st, and cite briefly two cases which have come under my own notice.

CASE I.—Mrs. B., on my arrival, I found suffering from severe hæmorrhage from the uterus; a fetus of the third month having been expelled. The placenta was within reach of the finger, but apparently detached. The os was pretty dilatable but very slightly dilated. After several attempts at removal, which proved futile, I was on the point of sending for assistance when, to my great surprise and pleasure, on another attempt with two fingers, while pressing on the fundus uteri, through the abdominal wall, the placenta slipped through the os. The hæmorrhage ceased, and the patient made a good recovery.

CASE II.—Mrs. G., complained of hæmorrhage and severe pain, chiefly located in the lumbar and hypogastric regions. She had not menstruated for three months. A soft mass was easily felt within the uterus. All attempts at removal with the fingers were fruitless. I plugged with pieces of cotton wadding, tied to a piece of string, at intervals of about six or seven inches, dipped in a carbolic solution (1 to 40). This method of plugging was approved of and recommended by Dr. W. L. Reid, and greatly facilitated removal afterwards. The plugs were left in about twelve hours; on their removal the soft mass was still *in situ*, and adherent. I introduced my hand into the vagina without administering chloroform, and with little difficulty scraped away and removed what afterwards proved to be a true mole. In this case chloroform should have been used. This patient is under my care now. She has not menstruated for four months. She presents symptoms of threatened abortion, otherwise she is comparatively well.

I can thoroughly endorse the opinion of Dr. Murphy (Sunderland), that chloroform and fingers are to be preferred to any kind of mechanical instrument for removal of retained placenta after abortion. In every case, pressure over the fundus uteri through the abdominal wall greatly helps in the operation.

Newmilns, Ayrshire.

T. C. DUNLOP.

CURIOUS DEFORMITY IN A TWIN.

I WAS called by a midwife to a patient who had been delivered of a well-developed, eight months' infant three-quarters of an hour before my arrival. The patient, a 7-para, was found to have considerable hydramnios, and a second child was found presenting in the R.O.P. position. I ruptured the membranes, turned and expelled the child by suprapubic pressure. The single, large, placental mass was expressed, and was found to have the cord of the first child attached centrally; that of the second was an "insertio velamentosa." This latter insertion, although not as a rule directly hindering the development of the fetus, may affect its life: (1) from the fact that the branches of the umbilical vessels may be pressed on during labour; or (2) from the circumstance that the membranes may rupture at a part over which one or more of these branches ramify, hence causing hæmorrhage fatal to the fetus. This insertion is frequent in multiple pregnancies.

It is well known that hydramnios and deformities of the fetus (and, curiously enough, often of the last born of the two) are frequently associated with twin pregnancies. In this case the second child was the subject of the following deformity: The right hand was articulated to the lower and outer surface of the radius, about one inch from its lower extremity, and the movement of this anomalous joint was good as regards flexion and extension, but lateral movements, as might be expected, were impossible. The radial and ulnar inferior extremities were

pointed, and no articular surface was to be felt. The entire thumb was wanting, neither a rudiment of the first metacarpal nor any traces of the thenar eminence being present. No contracture or paralysis of the radial group of muscles was discovered. The opposite limb was normal, and the child was well-nourished but smaller than the first. It died on the third day after its birth, and, as I was at the time from home, neither the cause nor mode of death was ascertainable further than that "it gradually sank." The probable cause was asthenia produced by hæmorrhage induced by either of the accidents incidental to the velamentous insertion of the cord. No necropsy was permitted, which I much regret, as the arrangement of tendons, vessels, and articulations would have completed the record of a most singular deformity.

REPORTS

OF

HOSPITAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN, IRELAND, AND THE COLONIES

ST. BARTHOLOMEW'S HOSPITAL.

A CASE OF INTESTINAL OBSTRUCTION: LOCALISED PERITONEAL SUPPURATION; INCISION, WASHING OUT, AND DRAINAGE: RECOVERY.

(Under the care of Mr. WALSHAM.)

[From notes by Mr. C. M. POWELL, Dresser of the Case.]

R. D., aged 32, was admitted on January 20th, 1888, under the care of Mr. Walsham, to whom he had been sent on the recommendation of Mr. T. H. Evans.

On the evening of January 18th, while sitting still after an ordinary meal, he was seized with great pain in both inguinal and umbilical regions, accompanied by swelling and tension of the lower part of the abdomen and rumbling flatus, followed by retching and sickness. The vomit began to be stercoraceous on the morning of January 19th. He had suffered from inguinal hernia on the right side since he was two years old, and wore a truss till he was seven. During youth and ever since he had been troubled with occasional attacks of giddiness and vomiting until about six or seven years ago, when they gave place to attacks of abdominal pain, centering in the umbilical region, transient in character, and unattended by intestinal obstruction. The hernia had frequently descended, but had never become strangulated, and had always been replaced, though often with difficulty. No blood had ever passed *per anum*. Four months ago, he was seized with pain and swelling in the abdomen, with inability to pass motions; this condition was preceded by motions of small calibre for about two days; it lasted ten days, during which salines were given, and then a drastic purge. The illness left him very weak. The motions had since been no thicker than his little finger, and passed generally twice a day. He had repeatedly of late tried to do his work, which was laborious, but was always disabled by increase of pain in the abdomen. His family history was good.

When admitted, the patient looked pale and ill, but said he had always had great muscular strength. There was moderate distension of the abdomen, with some muscular tension, equal on both sides, but with slight fulness over Poupart's ligament on the right side. On percussion, there was comparative dullness in the right inguinal region. The pain was also greatest there, but was generally everywhere below the umbilicus on the slightest pressure; there was dull pain at all times. The rectum was normal. No hernia could be felt, and the external ring was enlarged. The vomit of the previous night (small in quantity) was thin and bile-stained. No feces had passed at all during this illness, but a little flatus after an enema. The breathing was shallow and mainly thoracic. The temperature was 98°, rising to 100.4° at 1 P.M.; pulse 108; respiration 24; urine acid, specific gravity 1035, slight albumen. The abdominal organs could not be examined owing to tenderness of the abdomen. Tongue fairly clean. Opium and belladonna were given; small quantity of ice to suck; no food.

From this date up to January 27th, the abdomen continued in much the same condition, the tenderness and swelling, however, becoming more localised to the right iliac fossa, and the skin in this region appearing mottled-red and very slightly oedematous.

After an enema, given on January 24th, a scanty motion was passed; and, from this date till the 27th, several motions were passed daily. He was given at first only half a pint of whey a day, but subsequently half a pint of milk was added to the whey, and still later increased to a pint, as the vomiting did not return. The temperature never rose above 101°, and varied from day to day between this and normal. The pulse continued of fair volume, and varied from 88 to 112.

January 27th. After a consultation with Mr. Willett and Mr. Baker, Mr. Walsham decided to explore the abdomen in the right inguinal region. An incision was made, beginning half an inch above the middle of Poupart's ligament, and running parallel to it outwards for two inches. The abdominal muscles having been severally divided, the peritoneal cavity was carefully opened, and about a pint of dirty yellow pus, with a strong faecal odour, was let out. The cavity was irrigated with a solution of iodine, decolorised with carbolic acid, till the fluid flowed away perfectly clear. It was then found that the cavity was bounded by highly inflamed and matted-together coils of intestines. The cavity extended towards the middle line, but in a downward direction further than the finger could reach, and into this the irrigating tube was passed for about eight inches. A similar sinus, between coils of adherent intestine, also extended in an upward and inward direction, and further than the finger could reach. A large-sized drainage tube was placed in the cavity, and the wound sprinkled abundantly with iodoform, and dressed with iodoform gauze and wool. On the morning after the operation, the temperature had fallen to 98°, and the pulse was 100, of fair volume and strength. Locally the wound appeared quiet, and the washings from the cavity were clear. There was no pain nor tenderness, the patient expressed himself as feeling very comfortable, and was in excellent spirits. From this date he made a progressive and uninterrupted recovery. The tube was gradually shortened as the cavity slowly closed from the bottom.

On February 1st, slop diet was changed for fish, which was on the 3rd replaced by meat diet. On the 15th the wound had healed, and the patient was discharged in excellent health and spirits to the Convalescent Home at Swanley.

REMARKS BY MR. WALSHAM.—The cause, I believe, of the obstruction was inflammation in and around the cæcum; and, from the frequency with which, on *post-mortem* examination, such recurring attacks of typhlitis have been shown to depend on mischief of some kind in the vermiform appendix, it is probable that his might be the primary cause. On the patient's admission, the question of opening the peritoneal cavity in the region of the cæcum and exploring the condition of the parts was raised; but, in the whole it was considered, at a consultation that was held, that it would be better to wait for a few hours. As, under the influence of belladonna and opium, and the total abstinence from all nourishment, the acuteness of the symptoms subsided, the vomiting ceased, and the bowels were relieved, while the general pain and tenderness over the abdomen became less, the exploratory incision was put off till it became fairly clear that suppuration had occurred. From the condition of the cavity when the peritoneum was opened, and the length of the sinuses extending amongst the inflamed intestines, it was evident that there was extensive peritonitis, involving more or less the lower half of the abdomen. In one direction the irrigating tube was passed fully eight inches into the peritoneal cavity amongst the intestines, and the lower portion of the peritoneal cavity was thoroughly washed out. The case was clearly more than one of a mere localised peritoneal collection around the cæcum; and although the inflammation undoubtedly started at this spot, it had extended, as manifested both by the symptoms and the state of the parts found at the operation, more or less over the whole of the lower half of the abdomen. This case in many respects appears similar to those described by Mr. Treves, Mr. Marsh, and others, and is, I think, another example of what may be accomplished by washing out in suppurative peritonitis.

On two other occasions I have opened the abdomen for peritonitis, and attempted washing out. In neither of these cases was there suppuration. I found the sticking together of the coils by the lymph prevented the free passage of the irrigating fluid amongst them, and in no sense could a thorough washing out of the peritoneum be said to have been accomplished. The condition of the patients was too serious to permit of any extensive exposure with a view of supplementing irrigation by sponging. Both cases ended fatally. In such cases, I fear, little can be expected from this procedure.

QUEEN'S HOSPITAL, BIRMINGHAM.

THREE CONSECUTIVE SUCCESSFUL CASES OF TREPHINING.

(By AUGUSTUS CLAY, Senior Casualty Surgeon, Queen's Hospital, Birmingham.)

CASE I.—J. G., aged 6, was brought to the hospital on September 6th, in a semiconscious condition, having fallen out of a window, a distance of about twelve feet; upon examining his head, a simple depressed fracture of the vault of the skull was discovered. The precise situation of the depression was the right parietal bone, a little behind the coronal suture and about three-quarters of an inch from the median line—thus corresponding to the upper part of the ascending frontal convolution. The patient became unconscious, and violent twitchings of the leg, arm, and face of the left side soon occurred. The right pupil was dilated and inactive. Pulse slow, but not particularly full. When I saw the child, there was complete paralysis of the arm and leg, although the twitchings still continued in the face. The breathing was stertorous, very slow and shallow—so much so that it was feared it would cease altogether. The sphincters had relaxed. Trephining was decided upon, and he was hurriedly taken into the operating theatre, where the operation was commenced by the usual crucial incision. It was then seen that a part of the bone, the size of half-a-crown, was simply depressed, with the exception of a linear fracture (half an inch long) situated at the anterior edge of the circular depression. A three-quarter-inch trephine was applied, and a disc of bone (just taking in the fracture) was quickly removed, the surrounding bone being then easily elevated. There was a little hæmorrhage, which was allowed to continue to relieve the venous congestion; after which the wound was syringed with corrosive sublimate lotion (1 in 2,000), a drainage-tube inserted, and the edges brought together by silver sutures. Dressings of absorbent tissue, moistened with boroglyceride, were used. Almost immediately after the bone had been raised, the left arm and leg became convulsed, and the twitchings already existing in the face became more marked. In about a couple of minutes all the epileptiform convulsions had entirely ceased, and the pulse and respiration improved considerably. The operation was performed without chloroform, and, before all the sutures could be introduced, consciousness had so far returned that the boy cried with the pain and raised his hand to his head. Three-quarters of an hour after, the patient answered questions, and in an hour he asked for some water to drink. On the second night the little patient woke up suddenly, and complained bitterly of pain in his head; however, he soon went to sleep again, and was quite lively and playing with some toys next morning. On the fifth day his bowels were obstinate, and there was a slight elevation in his temperature, which was otherwise normal throughout.

The head was dressed daily with iodoform gauze, and the drainage-tube removed on the fourth day. The patient made a rapid and uninterrupted recovery; but, on account of his inordinate appetite and his "rumbustical" nature, he was not discharged until six weeks after the operation.

CASE II.—E. B., aged 26, was admitted on July 10th, 1887, about an hour after having received a blow on the head with a stick. At the time he was struck he did not appear to be very badly injured, as he was able to walk some distance to a neighbouring surgeon; but on reaching the house he fainted, and was forthwith sent to the hospital. On examination, there was found, slightly above and external to the left frontal eminence, a vertical linear wound, one inch in length, which led down to a depressed and comminuted fracture. The patient was very drowsy, but could be roused by speaking loudly to him. His statements and answers were incoherent, and he only desired to curl himself up and sleep. There was no paralysis nor monospasms; but before the arrangements for the operation could be completed, he became somewhat comatose. The original wound was enlarged and intersected by another at right angles, when it was found that a fragment of bone, one inch by three-quarters (consisting of both tables) was driven into the skull. This aperture was conveniently enlarged by a chisel, and the piece of bone above referred to, with several comminutions of the inner table—sufficient to cover a florin—were removed. The dura mater was perforated, the brain contused, and covered with blood at the seat of the injury. Perchloride of mercury lotion (1 in 2,000) was used; a drainage-tube inserted; stitches being put in the scalp only. Absorbent gauze, moistened with boroglyceride and covered with gutta-percha tissue, was the dressing employed. A saline purge was administered six hours after the operation. The diet consisted for ten

days of milk and soda-water, after which fish was allowed. The head was dressed daily. The wound healed primarily, with the exception of the part in contact with the tube, which was shortened at each dressing, and finally removed on the fifth day. On the eighth day the temperature, which was otherwise normal, rose to 100°; the patient seemed somewhat depressed, and complained of pain in his left eye. The eye was kindly examined by my colleague, Mr. Priestley Smith, who reported it to be healthy. From this date the patient progressed very satisfactorily, and was discharged on the eighteenth day from the injury. I saw him four months later, when he was quite well, and had not experienced a bad symptom since he left the hospital.

CASE III.—J. R., aged 36, was received as an in-patient on October 27th, 1887, having met with an injury to his head. He was quite conscious, and gave the following account of the accident: While at work with a forge-hammer, a pin or bolt required to be readjusted, and he stooped down for that purpose. Unfortunately, he reached too far forwards, and so placed his head partially between the steam hammer (weighing 10 cwt.) and the anvil. The blow was directed obliquely, the force knocking the patient from under the hammer and against another part of the machinery, causing a small scalp wound over the occiput, but not exposing the bone. He was stunned for a while, but soon recovered himself, and walked to one of his fellow-workmen for assistance. On examination there was found a contused wound of the forehead one inch and a half long over the left frontal eminence, and the bone in a corresponding situation was found comminuted and depressed for nearly a similar extent. Hæmorrhage had taken place beneath the conjunctivæ and into the eyelids, which soon became discoloured and so prominent as to obstruct the sight; there was no paralysis of the orbital muscles, nor hæmorrhage from the nose. The patient was placed under chloroform, and an incision one inch long was made at right angles to the original wound, but only intersecting one side of it. The pericranium having been raised, a three-quarter inch trephine applied, and the disc removed, six pieces of bone, varying from one inch and a quarter in length and half an inch wide were then taken away. It was observed that the bone on one side of the cavity was fractured and depressed (after the manner of "gutter fractures"), but was not quite separated. This was, with some difficulty, elevated, and allowed to remain. A linear fracture extended antero-posteriorly for some distance beyond the seat of the depression and the limit of the incision. The dura mater apparently was not injured. The wound was antiseptically treated with lotio hydrarg. perchlor. (1 in 2,000), five silver sutures put in the scalp, and a drainage-tube inserted. Dressings were similar to those used in Case II. The tube was shortened daily, and permanently removed on the sixth day. The patient got up on the fourteenth day of the accident, and was discharged three days later, having made a most uneventful recovery.

REMARKS BY MR. AUGUSTUS CLAY.—Case II is very interesting from a surgical point of view, inasmuch as he was trephined eleven years previously by my colleague, Mr. Wilders. He had a "buffer" injury to his occipital region, causing great comminution and depression. As far as I am able to learn, this case is unique for its double successful trephining.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, APRIL 24TH, 1888.

Sir E. H. SIEVEKING, M.D., President, in the Chair.

A Further Contribution to the Study of Rheumatoid Arthritis.—Dr. A. E. GARROD read this paper. The study of the nervous theory of rheumatoid arthritis, commenced in a former paper, was continued; the muscular atrophy, deformities, and dystrophies of the skin and nails met with in the course of the disease being examined with a view to seeing whether their occurrence afforded any evidence in support of this theory. The muscular atrophy had been regarded by some as part of the disease itself, by others as merely an example of ordinary arthritic muscular atrophy, and by others again as the result of changes in the peripheral nerves. Evidence was brought forward in favour of the view that the muscular atrophy met with in rheumatoid arthritis was not peculiar to that disease. The result of an examination of the tendon-reflexes in fifty cases was given, and it was shown that, whereas the jerks were usually exaggerated, this was not an invariable

rule, and it was suggested that peripheral neuritis, the presence of which had been demonstrated in such cases, might act as a disturbing factor. This same condition might account for the occasional occurrence of numbness and tingling of the extremities in rheumatoid arthritis, examples of which were given. Where these were met with, the jerks were not found to be increased. Attention was called to the importance of excluding cases in which sensory and motor disturbances were produced by pressure on the nerve-roots, when the disease had attacked the vertebral column. It was pointed out that changes in the joints, indistinguishable from rheumatoid arthritis, were met with in cases in which other nervous phenomena had preceded the articular disease; but these cases were regarded as belonging to a somewhat different category from ordinary examples of the disease. The conclusion was drawn that the ordinary muscular atrophy of rheumatoid arthritis was, as Dr. Charcot believed, a secondary phenomenon, and as such afforded no evidence as to the origin of the primary disease. The deformities due to muscular spasms were also regarded as secondary, the spasm to which they were due being of the same nature as that usually met with in the neighbourhood of diseased joints. These deformities were not peculiar to rheumatoid arthritis; the skin changes were regarded as being probably due to peripheral neuritis, but whether this neuritis was a primary or secondary phenomenon there was not as yet sufficient evidence to show. Some facts seemed to indicate that it was of a primary nature.—Dr. MACLAGAN thought the paper a valuable contribution on an obscure subject, but had not much to say upon it. It tended to confirm his view of the neurotic origin of the disease; but how far it was due to the central or the peripheral nervous system was more than he could at present tell. The coincidence of peripheral neuritis was not likely to be entirely fortuitous; its occasional appearance was very probably the reason of the eccentricity of the reflex phenomena.—Dr. HADDEX considered that there should be much caution in the introduction of peripheral neuritis into the symptoms. The only distinct evidence that had been given was from two or three cases of Pitres and Vaillard. He had himself read a paper on the same subject four years ago to the Clinical Society, and thrown out the same suggestion, but he had had no further distinct confirmation. In one of his cases he had noticed, along with advanced changes in the carpus, patchy anæsthesia in the arms, legs, and face. This was most marked in the legs, where the joints were very little affected; in fact, the nerve changes did not go along with the joint changes. He had examined many old cases in which there was no loss of sensation, and no atrophy beyond what would be accounted for by disuse, and found the reflexes variable, some in excess, some normal. Another patient had been a woman who had had acute rheumatism, a year before, and slight recurrence of rheumatic pain; and along with this recurrence, the typical glossy skin of such states in one hand, with loss of sensation and marked atrophy of nails and of the forearm. It seemed a genuine neuritis; a relapse, in fact, affecting the nerves and not the joints. The increased reflexes he had found very inconstant; ankle clonus he had seen at least three times. Charcot guessed it to be due to change in the cells, not in the peripheral nerves, but in the spinal cord.—Mr. W. A. LANE was sorry to find that, after careful consideration of the nervous theory, and much dissection of affected cases, he was unable to accept it. He found the changes described as those of rheumatoid arthritis in many cases where he could only suppose them the normal consequences of the habits of life as in carpenters, coal-heavers, etc. Beyond such as were due to rheumatism or senile change, he considered the rest due to sudden or habitual pressure.—Dr. HERRINGHAM was anxious to call Dr. Garrod's attention to a possible explanation of the position of the fingers in rheumatoid arthritis. They were turned nearly always to the ulnar side of the hand. If there was any atrophy or weakness of the abductor indicis, as there nearly always was in the disease, it would be found that tension of the extensor muscle pulled the index and, to a less extent, the middle finger over towards the ulnar side of the hand, and this, he thought, was the ordinary beginning of the ulnar deviation of the fingers. One started, it was quickly increased, and the other fingers were pressed out of position.—Dr. A. MONEY could not help expressing the interest he felt in these questions, and hoped they might look for more contributions from Dr. Garrod. There was a long chapter still to be written, he thought, on the phenomena of sweating in rheumatic and rheumatoid disease. He had noticed in perspiration sometimes alkaline, and also oddly distributed over parts where neither tendons nor muscles nor joints were affected.

as if it might possibly be the result of a nervous anomaly. It also came and went, sometimes without apparent reason. In these cases gastric crisis occurred, sometimes in a form quite indistinguishable from that of locomotor ataxy. The gastric secretion which was vomited was extremely acid, and contained both sarcinae and torulae in cases in which there was no sign of pyloric obstruction. The urine showed remarkable changes; there was sometimes transient glycosuria and sometimes rapid transitory changes in the amount of uric acid and urea secreted.—Dr. A. E. GARROD, in reply, said he quite agreed that there must be great caution in assuming neuritis, and that much more observation was necessary. Considering the small amount of *post-mortem* observation possible, he thought it remarkable that MM. Pitres and Vaillard had found it in all their cases. He agreed with Dr. Hadden that joint lesions did not go *pari passu* with nerve lesions. In reply to Mr. Lane's theory that pressure was an efficient cause, he did not see that it sufficed to explain why rheumatoid arthritis was specially a disease of women, and at the menopause why it affected the peripheral joints, and such parts as the temporo-maxillary joint; why it was symmetrical, and why it attacked the Duchess as much as the washerwoman. He was much obliged to Dr. Herringham for his suggestion as to reflection, but was inclined to think no explanation at present completely satisfactory.

Effects in Disease connected with Uric Acid of some Drugs which cause Retention of Uric Acid in Contrast with the Action of Salicylates (as shown in a previous paper).—Dr. ALEXANDER HAIG read this paper. He said a large part of the value of salicylates in uric acid diseases was due to their preventing acids from causing retention of uric acid, as pointed out in a previous paper. Some drugs that had the opposite action of causing retention of uric acids were contrasted with the salicylates and their actions in some diseases compared. The drugs whose action on uric acid excretion was now brought forward were lead, iron, and lithia, and it was shown that they caused retention of uric acid, though lithia produced this effect in an indirect manner. The doubtful value of lithia in gout and as a solvent of uric acid was pointed out. The relation of dyspepsia to the uric acid headache, and the way in which it explained the periodicity of the attacks, was referred to. The effects on the nerve-centres of any causes of depression in headaches and epilepsy were described. Sir A. Garrod's investigations on chronic lead poisoning, the presence of uric acid in the blood of such cases, and the action of lead in precipitating an attack of gout were stated to be in accord with the facts now brought forward. Lead was mentioned as a cause of epilepsy, which could be easily explained if epilepsy was due to uric acid. Iron caused a relapse in gout, and did harm in epilepsy and in uric acid headache. Salicylates were valuable in gout, chiefly in prevention; they did not act promptly in acute gout. Reasons were given for believing that some cases of epilepsy were due to uric acid, just as some cases of headache had been shown to be in previous papers. Recent observations by the writer in the *Neurologisches Centralblatt* were referred to. Attention was called to the close parallel between epilepsy and the headache in question, and also to the close clinical relationship of both to gout. It was suggested that epileptic fits might be prevented by salicylates in place of bromides. Salicylates prevented accumulation of uric acid, and thus stopped fits due to such accumulation. Such cases of epilepsy might probably be cured by the diet which was so useful in the uric acid headache. When alkalis were given along with bromides in epilepsy, less bromides would suffice to keep off the fits. The observations of Dr. Radcliffe on this point were referred to. This result was due to the fact that alkalis (as previously pointed out by the writer) prevented retention and accumulation of uric acid; hence, as there was less of the irritant, less bromide would suffice to stop the fits. Dr. Radcliffe's remarks about iron and diet pointed in the same direction as to the causation of epilepsy by uric acid. The same reasoning was applied to attacks of gout and their prevention by salicylates.—Dr. ORMEROD was glad to hear of any fresh palliative, or possibly curative, treatment for epilepsy. He confessed that the theory he had just listened to seemed to him to be based on very few facts, and inapplicable to the great majority of cases of epilepsy. At any rate, a long clinical testing was required. He had had experience that afternoon of two interesting cases of epilepsy in this connection. One was in a young man who had typical attacks of migraine, beginning with flashes of light in the eyes, and going on to vomiting and headache. The remarkable point was that exactly similar flashes of light in him some-

times led up to epileptic convulsions and biting of the tongue. There was no history of gout. In the other case, a boy 11 years old, there was a strong rheumatic history in the family, and he had prescribed sodium salicylate, 10 grains three times a day. For five weeks there had been no fit, but after that there came a batch of fits as bad as ever.—Dr. LAUDER BRUNTON considered Dr. Haig's paper a valuable attempt to solve one of the most difficult of medical problems—the cause of gout. He thought no sufficient distinction had been made between retention of uric acid and diminished formation. Sir Alfred Garrod had first shown how lead brought on gout in persons who had not inherited it. He had been himself much struck by a case of diarrhoea, in which, after all the vegetable drugs had failed, he had given acetate of lead, and that had brought on rapidly a condition of red and swollen joints. In epilepsy he must beg to insist that there were many factors at work. So, too, in migraine there might be local conditions, such as decayed teeth or anomalies of vision and inequalities of the two eyes, which were shown to be the determining factors, because with their correction the headaches ceased. Defects of vision he had found to affect headache in nearly nine cases out of ten that he saw. In a lady who had come from Massachusetts there was much pain in the back of the neck, which he had at first attributed to some local disease, probably of the bones, and Dr. Ferrier had come to the same conclusion; but nevertheless they found that the pain completely disappeared when her eyes were properly suited with spectacles. In considering the effects of lead, they must not forget that it had a definite effect on the cells of the cerebral cortex. It would be interesting to see if in some cases of epilepsy it could be removed by solvents, and the epilepsy thereby cured. When he had been working at the effects of the bromides, he had noticed that some German observers attributed all results to the potassium, and some to the bromine, and this had led him to try the effect of common salt on a number of epileptics. There were some good results, some failures; and he thought it possible that its use might arise from its causing the patients to drink more and wash out the cells of their brain. Dr. Haig recommended sodium benzoate, and he thought it would be worth while to try that along with potassium bromide.—Dr. W. H. WHITE had noticed in Dr. Haig's tables that iron was represented as causing a greater retention of uric acid than lead. This retention, they were told, was the cause of epilepsy; but were there any cases of iron epilepsy to bring forward? Saturnine epilepsy he admitted was well known, and lunacy was another nervous effect of lead; was that produced by this retention of uric acid? And what effect had potassium bromide on this retention? If epilepsy depended on this poisoning of the system, he was surprised to find its effects beginning generally unilaterally.—Dr. HAIG was much obliged for the favourable reception of his paper, but wished to deprecate any too sanguine expectations from its conclusions. He pointed out that migraine resembled epilepsy in so far that in both at the time of the attack the excretion of uric acid was increased. He had found some good results from the use of salicine in epilepsy. As to retention of uric acid, he considered it would be shown to be separate from diminished formation. The local conditions, such as anomalies of vision, etc., he admitted might cause irritability and susceptibility to the uric acid poison. The effects attributed to lead in the cortex of the brain might, perhaps, be due to combined lead and retained uric acid. In comparing the results of lead and iron, it should be noticed that the amounts of iron taken were much the larger. He had made experiments on the effects of potassium bromide on the retention of uric acid, but found no variation caused by it. Sir Alfred Garrod, twelve years ago, had shown that uric acid was in excess in the blood in epilepsy, and he hoped soon to be in a position to argue more generally from its excess in the urine to its excess in the blood.

MEDICAL SOCIETY OF LONDON.

MONDAY, APRIL 23RD, 1888.

EDMUND OWEN, F.R.C.S., Vice-President, in the Chair.

Intra-muscular Injection of Mercury in the Treatment of Syphilis.—Mr. J. ASTLEY BLOXAM read a paper pointing out that the subject of the injection of mercury into the tissues had received but scant attention in this country, although largely practised abroad, especially in Germany. His attention had been drawn to

the subject in the first instance by the benefit derived by a patient of his, during a stay in Berlin, from the treatment of Dr. Lewin, who used a solution of the perchloride of mercury for injection. He then carried out the method at the Lock Hospital on a large scale. He found that certain precautions were necessary in using the solution, in order to avoid the formation of abscesses. Dr. Lewin used three solutions, containing respectively four, six, and eight grains of the salt to the ounce, the quantity used varying with the frequency of the injection and the condition of the patient. He claimed for the method that it was more prompt in action, enabled the medical man to know exactly what amount of mercury was being absorbed at any given time, and spared the patient the gastric derangement apt to follow the administration of the drug by the mouth. Mr. Bloxam said he had employed the drug in this way in all stages of the disease with uniformly successful results. He had tried the preparation of calomel in glycerine (1 in 10) and calomel in vaseline (1 in 5), but found that both were very painful and prone to give rise to the formation of troublesome abscesses. He gave quotations from textbooks showing how little the subject and the *modus operandi* were understood. His own plan was to inject ten drops of a solution of sal alembroth, containing one-third of a grain of the salt. This he injected deeply into the muscular substance of the buttocks once a week, changing sides at each injection. The pain was but slight, the induration little marked except bleeding took place, and in no instance was followed by abscess. This solution kept well, was clear, and was not liable to fungoid growth or precipitation. The primary sore had generally healed by the second injection, and the secondary symptoms soon cleared up, leaving only the throat and the glands as evidence of the disease. As this stage the injection need be given only once a fortnight, and, still later, only once a month, continuing the treatment thus for a year or eighteen months, some eight or ten grains of the salt sufficing for the whole course of treatment. Mr. Bloxam brought several cases under treatment, showing the effect of the method, and demonstrated the *modus operandi*.—Mr. EDMUND OWEN said he was interested rather than convinced by the paper, but he expressed his intention of giving the method a trial. He asked whether infiltrations were frequent after injection, and as to when Mr. Bloxam would use the injection. Also, did he find the method prevent the occurrence of secondary symptoms, and were relapses more or less frequent? He suggested that the method was one which presented certain difficulties in carrying it out in private practice, especially in respect of women.—Mr. JOHN MORGAN said that Mr. Bloxam had, at any rate, shown how mercury might be safely introduced into the tissues, his results comparing favourably with what he had seen of Sigmund's plan, as carried out in Vienna. He had given the system a trial, but although there had been no bad results, he had not obtained any particularly good ones.—Mr. BERNARD PITTS explained that he had announced Mr. Bloxam's paper in advance by mistake for the previous week. He said he should have to see a good deal more before he could realise that a medicine given once a week could act as well as one given like a food. He pointed out that the results obtained in one of the cases, at any rate, were not better or even as good as those obtainable by the ordinary means. He mentioned that with small doses of grey powder he had succeeded in preventing the secondary symptoms, even in cases of undoubted syphilis.—Dr. HANDFORD mentioned that in Vienna he had usually seen used a combination of the perchloride of mercury with peptones. He himself had used a simple solution of the perchloride, but the pain produced was so great that patients begged that the treatment should not be continued. He had, however, obtained very satisfactory results with it.—Dr. T. OTTERTON WOOD said that the pain attending the injection by Mr. Bloxam was very slight, and patients often asked for it to be repeated oftener than once a week.—Dr. HERON quoted the case of a medical man who had suffered from syphilitic manifestations for upwards of twenty years, who had improved materially under the injection treatment. He (Dr. Heron) had injected himself on one occasion, to test the amount of pain, and found that while the pain at the time of injection was not very great, the subsequent pain was far more considerable. He added that, if any great advantage could be shown to be obtainable by this method, patients would probably be willing to agree to it, though there might be a difficulty with regard to lady patients.—Mr. BLOXAM, in reply, explained that infiltration only occurred when bleeding followed the puncture. He always waited for clear evidence of syphilis before beginning treatment. He did

not believe that it was possible entirely to suppress the secondary symptoms. He employed it in private practice without any difficulty. Relapses were not more common than with the other methods of treatment.

Albuminuria in Enteric Fever.—Dr. HANDFORD gave an account of his observations in 75 successive cases that had been under his care during the past three years in the Nottingham General Hospital. There were 10 deaths, 7 of them due to perforation, giving a mortality of 13.3 per cent. In 8 of the cases a *post-mortem* examination was made, followed by a microscopical examination of the viscera. The account of the lesions in the kidney was based on these and on two or three other cases not included in the series. Murchison gave 549 cases by 10 observers where albuminuria was observed in 157, or 28.6 per cent. In the 75 cases observed by Dr. Handford the urine was examined by himself in every case (save one not included in the tables) several times, and in most daily during the severity of the disease. Albumen was present in 42 and absent in 32: that is to say, it was found in 56 per cent. of the cases. Of the 42 cases with albuminuria 9 died, giving a rate of 21.4 per cent. Among the 32 without albumen there were no deaths. Among the 42 cases there were 3 children, whereas in the 32 there were 14, showing that there is much less liability in children to the albuminuria of enteric fever. The cases of albuminuria were classified under three heads: 1. Those with pre-existing definite kidney disease. These cases seemed very rare. 2. When there was abundant and persistent albuminuria, often to the extent of 0.05 up to 0.1 per cent. Among these the mortality was very high. The most marked change in the kidney in such cases was found to be interstitial or diffuse nephritis, with glomerulitis and hæmorrhage. The nephritis was probably of septic origin, like so many other complications of enteric fever. 3. Where the albumen only existed as a trace, and that only for a short time. Among these the mortality was much less. The renal changes were much less definite, and sometimes scarcely any alteration could be detected. The chief alterations appeared to be vascular engorgement with capillary hæmorrhage, slight cellular infiltration and multiplication of nuclei, and cloudy swelling of the epithelium. Marked parenchymatous nephritis with fatty degeneration of the epithelium was not found, though some degenerative changes were generally present, but difficult to distinguish from alterations which occur so rapidly *post mortem*, especially in death from peritonitis due to perforation. Numerous drawings of microscopic preparations were shown.

HARVEIAN SOCIETY OF LONDON.

THURSDAY, APRIL 19TH, 1888.

WILLIAM SEDGWICK, M.R.C.S., President, in the Chair.

Alopecia Areata.—Dr. ROBINSON read a paper on alopecia areata. He described two varieties, a parasitic and non-parasitic. The former had a relationship to ringworm. He had found life in the open air one of the most efficacious modes of treatment.—Dr. LYLE had not seen alopecia follow ringworm.

Ovarian Tumours in Pregnant Women.—Dr. BRAXTON HICKS read two cases of ovarian tumour, associated with pregnancy, in which the removal of the tumour had been followed by recovery. In the first, labour had continued thirty hours. The tumour came down, and prevented the head being seized with forceps, and turning was tried, and found impossible. The child was finally delivered with long forceps, and was still living. The placenta required removal. The tumour grew rapidly after delivery, and was removed. It was adherent everywhere, and was compound in character, nearly colloid. The patient made an excellent recovery. In the second case there was an ovarian tumour which reached rather above the umbilicus. It was diagnosed to be composed of two cysts. The woman had missed two periods, and it was proposed to wait until after the middle of pregnancy. However, the cyst became tense, with pain, and was removed. The pedicle was found twisted, and the tumour adherent and becoming necrosed. No uterine action came on for two weeks, when an ovum was expelled. The cases showed that when ovarian tumour and pregnancy were concurrent, if the tumour gave signs of irritation, the sooner it was removed the better.—Dr. HANDFIELD-JONES spoke of the rapid growth of ovarian cysts after the uterus had been emptied. He had known them within two months attain enormous size, and contract adhesions. He thought, therefore, that ovarian tumours ought to be removed as soon as possible after delivery.

Venesection.—Dr. FRANKISH then read a paper on venesection.

He had found it of particular benefit in cases of uræmia and cerebral congestion. He had seen puerperal convulsions, in cases where there was albumen in the urine especially benefited by it. In spite of popular prejudices, he thought it ought often to be practised.—Dr. ROBINSON was accustomed to bleed in cases where there was much venous congestion.—Dr. BRAXTON HICKS had considerable experience of bleeding, and had done the opposite, transfusion, eight times. Venesection had been most beneficial in cases of puerperal convulsions.—The PRESIDENT felt that popular opinion rendered venesection difficult to practise, although often beneficial. The older practitioners used to bleed in the early ages of collapse, especially those due to perforation. It was also practised in collapse due to cholera.—Dr. HANFIELD-JONES mentioned a case in which he had bled for amenorrhœa with excellent result.—Dr. FRANKISH replied.

BRITISH GYNÆCOLOGICAL SOCIETY.

WEDNESDAY, APRIL 11TH, 1888.

ARTHUR W. EDIS, M.D., F.R.C.P., President, in the Chair.

Ruptured Tubal Pregnancy occurring twice in the same Patient.—Mr. LAWSON TAIT read notes of this case, which will be published in the JOURNAL in full.

Removal of the Uterine Appendages.—Dr. G. GRANVILLE BANCROFT exhibited a number of specimens illustrating many forms of disease to which the uterine appendages are liable: 1. Cirrhosis of the Ovary. The patient, a married woman, aged 29, the mother of two children, had been the subject of most severe dysmenorrhœa, rendering her perfectly incapable of following her usual avocations. The cervix had been dilated with temporary benefit, but the dysmenorrhœa returned in a few months with increased severity, and with the addition of more or less constant pain. At the urgent entreaty of the patient, and on the ground of negative evidence from the absence of any enlargement and inability to feel the ovaries in a favourable subject, which induced him to conclude that the ovaries were cirrhotic, he removed the appendages. The result had been a complete cure, both in the arrest of menstruation and the relief of pain. 2. Salpingitis in association with an Ovarian Tumour with a Twisted Pedicle. In this case the tubes were as large as the index finger, that on the side opposite to the tumour being closely adherent to the posterior aspect of the broad ligament. The patient was a married woman, aged 40, without family. 3. An example of Abscess of the Right Ovary with Salpingitis, and Adhesions and Chronic Salpingo-ovaritis on the left side. The patient was a single woman, aged 36, who had one child some years before. The operation was a very formidable one, owing to adhesions which involved the cæcum, but its success was complete. 4. A recent specimen from a single woman, aged 24, illustrating the conditions of Hæmatosalpinx in the uterine end of the left tube, and Pyosalpinx in the outer portion, in which the contents had undergone caseous degeneration. In the right tube there was pyosalpinx in the same stage, together with almost complete severance of the tube by a constricting band of adhesions. The patient was progressing well. Dr. Bantock stated that in all the cases brought forward he had been able to ascertain by the physical signs that the cases were suitable for operation. Even in the case of cirrhosis he had diagnosed this condition; it was not necessary to make an accurate diagnosis in such cases. It was impossible to diagnose a blood-cyst in one case, or an abscess of the ovary in another, associated as they were with extensive adhesions and enlargement of the tubes. It was sufficient to be able to say that there was disease which nothing but abdominal section could clear up.

Pyosalpinx.—Dr. FANCOURT BARNES exhibited an ovary with the left Fallopian tube, which he had removed six weeks previously from a patient who had been a chronic invalid in consequence of her sufferings. She had left the hospital a fortnight before perfectly relieved. He had not made a differential diagnosis between pyo- and hydrosalpinx in the case; it was sufficient to diagnose one or the other.

Intra-uterine Medication.—Dr. ROBERT BELL (Glasgow) read his paper. He considered the uterus in a large majority of cases as the source of the mischief in a great many of the various affections to which the tubes and ovaries were liable. It was, therefore, by suitable treatment of the uterus that such evils were to be averted. Iodised phenol was the preparation which gave the best results. It was aseptic and antiseptic in the highest degree, and the carbolic acid exercised a powerful anodyne effect on the perimetrium; it possessed also powerful alterative properties.

In treating cases of long-standing endometritis it was necessary to remove the granular condition of the mucous membrane as a preliminary to the strictly medical part of the treatment. This was effected by means of the curette. He had also found intra-uterine medication useful in a class of cases where it was not usually employed—namely, in displacements. Displacements were invariably associated with a softened condition of the uterine walls from a congested condition of the parts. In conjunction with the use of pessaries, intra-uterine medication did much permanently to remove the displacement. The treatment of such cases, as a rule, occupied three to four months.—In the discussion which ensued, Dr. HEYWOOD SMITH, Dr. BANTOCK, Dr. AVELING, Dr. FANCOURT BARNES, Dr. PRIDHAM, Dr. MANSELL MULLIN, and the PRESIDENT took part.—Dr. BELL replied.

MIDLAND MEDICAL SOCIETY.

WEDNESDAY, APRIL 4TH, 1888.

ROSS JORDAN, M.R.C.S.E., President, in the Chair.

Lupus Vulgaris.—Dr. KIRBY showed a case of lupus vulgaris, of seven years' duration, on the arm of a girl, aged 14, who was recovering rapidly under treatment by Unna's plaster. There was no history of struma in the family, but several relatives had died of cancer.

Encysted Hydrocele of Epididymis.—Mr. JORDAN LLOYD showed a case of this disease.

Urethral Calculus.—Mr. JORDAN LLOYD also showed a large urethral calculus that had been passed by a boy.

The Davos and Engadine Valleys.—Dr. FOXWELL read a paper on this subject.

Pancreatic Cyst.—Mr. BENNETT MAY reported a case of pancreatic cyst for which he had operated. The operation resulted in the removal of a large gall-stone from the gall-bladder. The cyst had collapsed previous to the operation, but two months before that a quart of fluid was removed by aspiration. The necropsy showed that death was caused by gangrene of the pancreas. The cyst had a large aperture of communication with the duodenum. It appeared probable that it was a retention-cyst (gall-stone in the common orifice), as there was a well-marked history of attacks of severe biliary colic with jaundice.

Vesical Calculi.—Mr. BENNETT MAY also showed a number of vesical calculi.

Drop-wrist and Extensive Muscular Atrophy from Lead-poisoning.—Dr. SUCKLING showed a young woman who had worked as a maker of paper bags four years ago, and who had to give up her work on account of paralysis of the upper extremities. She had suffered from colic and constipation. There was a well-marked blue line on the gums, and double wrist-drop. The supinator longus on each side was much weakened. The thenar and hypothenar muscles on each side were wasted, and the *main en griffe* was present. The muscles of the forearms and shoulders were also much atrophied. The intrinsic muscles of the hands and the extensors of the wrist did not respond to the faradic current.

Senile Chorea.—Dr. SUCKLING showed a woman, aged 62, who had suffered from chorea for nine years. She had suffered from chorea when 12 years of age, but recovered completely from this attack in about three months. She had an attack of rheumatism when she was 45 years of age. There were jerky spontaneous movements of both the upper and lower extremities, and the tongue and lips were especially affected. There was considerable inco-ordination, and the disorderly movements were intensified by emotional disturbance, and ceased during sleep. The intellect was unaffected, there were no sensory disturbances, and no signs of heart disease. The patient attributed her illness to worry and anxiety.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

THURSDAY, APRIL 5TH, 1888.

J. HARRIS ROSS, M.D., in the Chair.

Gangrene of Penis.—Dr. J. HARRIS ROSS showed a man who had suffered destruction of the penis from gangrene during an attack of diphtheria.

Adenoid Vegetations of the Naso-Pharynx.—Mr. CRESSWELL BABER showed photographs, before and after operation, of a man, aged 25, from whom a large quantity of these growths was removed under chloroform at one sitting, and drew attention to the improvement in the appearance of the face produced by the restored nose breathing.

Obscure Cerebral Case.—Dr. WHITTLE read notes of the case of a man, aged 20, who had received a blow on the head when a boy, from which permanent deafness resulted. He had had two severe illnesses abroad attributed to sunstroke, and had been subject to vertigo (? aural). He appeared in good health till February 25th, when, after exposure to cold, he was attacked with frontal headache, pain in the right shoulder, and a feeling of weakness. Motor paralysis rapidly developed in the right arm, then extended to the left arm and both legs. He complained of difficulty in breathing. There was loss of superficial reflex, and extensive, but not absolute, sensory paralysis. His mind was clear till within a short time of his death, which occurred on the eleventh day with signs of apnoea. The *post-mortem* examination threw no light on the cause or nature of the disease.

The Principles and Practice of the Local Treatment of Diphtheria.—Mr. R. SANDERSON read a paper on this subject. He argued that, apart from Oertel's elaborate researches, there was sufficient clinical evidence to show that diphtheria was primarily a local disease. The local lesion should be regarded bacteriologically as a "cultivation" upon human mucous membrane; and *cæteris paribus*—that is, assuming a uniform healthiness of organism—the constitutional poisoning was directly proportional to the area occupied by the cultivation. The diphtheritic membranes were a protecting blanket under which and in which this cultivation thrived, and, moreover, were in themselves a mechanical danger, and aided the spread of the cultivation by transplantation and continuity. They should, therefore, be thoroughly dissolved early, and redissolved as soon as reformed. He knew of no solvent better than Finkler's papain, and described the method of applying it. Having thus exposed the cultivation, a germicide should be at once used; he preferred glyc. acid. carbolic. ʒj, glycerine ʒj. He maintained that by taking a case early and treating the local lesion rationally on the above lines, the area and consequently the toxæmia could be controlled, and the danger of invasion of the nose and larynx minimised.—Dr. BLACK thought that the general symptoms were not always proportionate to the local lesion.—Mr. ALFRED SCOTT agreed with Dr. Black. Albuminuria did not in his experience always come on at the commencement.—Mr. ALGERNON HODSON mentioned a series of cases which he had treated with large doses of perchloride of iron.—Dr. PALEY thought that after tracheotomy children still died of suffocation; this happened in at least two-thirds of his cases of tracheotomy. He had found good effects from a spray of papain into the trachea after tracheotomy.—Mr. NICHOLLS and Mr. JENNER VERRALL also made some remarks, and Mr. SANDERSON replied.

PATHOLOGICAL SOCIETY OF MANCHESTER.

WEDNESDAY, APRIL 11TH, 1888.

J. DIXON MANN, M.D., Vice-President, in the Chair.

Case of Diabetes Mellitus in which Acetonæmia was induced by the Shock of a Strangulated Femoral Hernia.—Dr. RAILTON showed sections of various organs from this case, which was that of a woman, aged 56, who had been under treatment for diabetes at the Manchester Clinical Hospital for Women and Children for sixteen months. During that period she never had any symptoms of acetone in the blood, or aceto-acetic acid in the urine. A femoral hernia, from which she had suffered for many years but had failed to mention, became strangulated. Acetonæmia at once ensued, and although herniotomy, with local anaesthesia from cocaine, was performed by Mr. Southam, she became comatose and died. The sections from the cortex of the brain, the medulla, and the cervical cord showed nothing abnormal. The liver presented a general dilatation of the intralobular capillaries, with some slight atrophy of the cells and deposit of pigment; the kidneys showed degeneration of the epithelium of the convoluted tubes, with slight fibrosis, thickening of the intima of arteries and dilatation and engorgement of the capillaries. The heart muscle showed but slight degenerative change—granules at the poles of the nuclei, but no loss of striation. There were no signs of phthisis about the lungs, but a slight amount of broncho-pneumonia existed in the left base. The pancreas was not examined. No trace of peritonitis was discovered, the bowel at the seat of the strangulation being quite healthy. An interesting point about the case was, that the temperature became subnormal at the onset of the acetonæmia, and remained so until death.

Sections of Liver from an Unusual Case of Cirrhosis.—Dr. WILD showed sections of cirrhotic liver, from a girl aged 9 years, who

died after a prolonged illness, the chief characteristics of which were ascites, hæmatemesis, emaciation, and progressive exhaustion, leading to death. No history of alcohol or of congenital syphilis could be obtained. The liver was harder than normal, the surface uneven but not "hobnailed." On section, polygonal areas of yellow liver tissue were seen, surrounded by white lines—the new-formed fibrous tissue. Microscopically the cirrhosis was of the multilobular form, more advanced in some parts than others; the fibrous tissue contained a large number of round cells. There was no marked proliferation of bile-ducts, no thickening of the capsule.

Malignant Disease of Jaws.—Mr. JONES related these cases, and showed the specimens. 1. A man, aged 55, was admitted into the Manchester Royal Infirmary on December 18th, 1887. He noticed swelling on the right side of his nose nine months before, which gradually attained considerable dimensions. The growth, which was painful on pressure, obstructed the nostril, and caused a bulging of the hard palate. There was slight ulceration on the cheek, and a discharge. Beneath the lower jaw and along the sterno-mastoid there was a chain of enlarged glands. The superior maxilla was removed on December 22nd, the enlarged glands being taken away at the same time. The patient recovered sufficiently to be transferred to the Convalescent Home at Cheadle on January 11th, 1888. On his return there were some indications of recurrence of the disease, which was epitheliomatous in character. 2. A man, aged 23, was admitted on January 23rd, 1888. In November, 1886, he had a constant tic in the left cheek; the pain disappeared about July, 1887, when he noticed a small swelling above the gum on the left side of the upper jaw. This swelling increased upwards and inwards, and loosened the premolar teeth, so that he could easily extract them with his fingers. On admission a large ovoid swelling occupied the region of the left cheek, pushing down the angle of the mouth. Its upper limit reached the orbital ridge of the superior maxilla. The hard palate bulged considerably, and in the centre of the bulging was a small ulcer, the edges of which were not undermined or everted. The surface was not raised. No enlarged glands could be detected. The left upper jaw was removed on January 26th. The skin incision readily healed, one-third of the sutures (fine silk) were removed on the 30th, and the remaining ones on February 3rd. When he left for Cheadle on February 7th, very slight disfigurement could be noticed. The disease was spindle-celled sarcoma. 3. A woman, aged 39, first seen in November, 1887. Five years before she had the left lower wisdom tooth extracted for caries, with toothache. For the last three years at least she had always had some discomfort in the situation whence the tooth was removed. Eighteen months ago she noticed a swelling of the gum, and for six weeks she had been unable to take any solid food, owing to the pain at the roots of all the teeth on the left side of the lower jaw. On examination it became evident that the bone was expanded by a tumour centrally situated. The portion of bone implicated was removed on November 12th. The patient made a rapid and complete recovery, very slight deformity being left.

Specimens.—Mr. YOUNG, Dr. HUTTON and others showed various Preparations.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, APRIL 6TH, 1888.

E. ATKINSON, M.R.C.S., President, in the Chair.

Suprapubic Prostatectomy.—The PRESIDENT gave an account of two cases in which he had removed portions of the gland by Mr. McGill's process. In the first case a farmer, aged 66, was admitted to the Leeds Infirmary with a five-years' history of repeated attacks of retention, requiring catheterism, the urine drawn off containing blood. The last attack occurred two days before admission. The bladder was much distended; there was free urethral hæmorrhage, and the prostate was much enlarged. A catheter drew off dark chocolate-coloured urine with numerous clots. The urine was regularly drawn for eight days and the bladder irrigated. The rectum was distended by a bag containing 12 ounces of water, and the bladder injected with 10 ounces of boracic solution, and opened over the pubes. A growth about the size of a cricket-ball was found to spring from the right lobe of the prostate. There were two openings into the bladder, one below and behind the growth, the other, which seemed to be a false passage, through the centre. The mucous membrane being incised, a considerable portion of the growth was enucleated in

veral portions. There was free hæmorrhage, and the patient's condition caused some anxiety for some days after the operation. On account of vomiting, diarrhoea, and great weakness, but he made good recovery, and was discharged well twelve weeks after the operation, passing urine freely by the natural passage. Case II.—A man, aged 71, had had symptoms of enlarged prostate two years and retention for four days before admission. The bladder had not been emptied for two days, and was much distended. A catheter withdrew 50 ounces of deeply blood-stained urine. After six days of regular catheterisation and irrigation of the bladder with astringents without restraining the hæmorrhage, turpentine was administered successfully as regards the hæmorrhage. The bladder was opened, and two large masses were found projecting to the viscous on each side of the urethral orifice. A small undulcated growth, projecting from the mesial surface of the left enlargement, was removed with scissors (this appeared to block the urethral orifice), and the two larger masses were enumerated by the fingers. There was little bleeding. The bladder was as at a later period drained by a long tube into a vessel placed under the bed. The patient did well for a month, and he was allowed to get up. Six days after, however, he was seized with acute pleurisy, of which he died. The local conditions, however, were quite satisfactory.—Mr. JESSOP mentioned a case in which he had performed the operation, the patient dying from acute proctitis. He asked whether enucleation from the rectum might be sometimes be practicable.—Mr. MCGILL said prostatic enlargement might be divided into two classes, according as they grew mainly towards the rectum or towards the bladder. In the latter category he included those in which, without much enlargement, there existed the valvular collar arrangement first described by Mr. B. Brodie. The first class caused no bladder symptoms, and therefore he thought the operation suggested by Mr. Jessop unnecessary. In one case of his own, which proved fatal, there was albuminuria at the time of operation. The patient sank gradually, and *post mortem* the walls of the bladder were found to be very thick, and there was suppuration in the cavity of Retzius. He thought the prognosis better with a thin than with a thick walled bladder. He had recently operated successfully in a case where the portions removed weighed 2 ounces.

Antiseptic Midwifery.—Dr. PURDY maintained that strict antiseptic precautions were impossible in private practice, and said that among the heads of the profession there existed great difference of opinion as to the best methods and the best antiseptic agents. He had seen much harm ensue from the routine washing of the vagina by nurses.—Mr. WM. HALL thought we must not lose sight of the fact that there was a serious and highly infectious malady in puerperal fever, and there could not be a too careful disinfection of the person of the obstetrician.—Mr. C. J. RIGHT pointed out that the adoption of strict antiseptic precautions had lowered the mortality in lying-in hospitals from 7 per cent. to less than 1 per cent., but that by antiseptic midwifery he understood every precaution which ensured complete cleanliness, not merely the use of a particular disinfectant.—Dr. MILLER and Dr. BRAITHWAITE also made some remarks.

Pathological Specimens.—Dr. ALLAN: 1. Tibia, three months after comminuted fracture. 2. Extreme Granular (Gouty) Kidneys.—Mr. TURNER: Microscopic Sections of (1) Mammary Tumours; (2) Interstitial Hepatitis.

Cases.—Dr. BARRS showed three cases of Myxœdema.—Mr. ATKINSON showed a patient on whom Thiersch's operation for removal of the Genitals had been performed.

CAMBRIDGE MEDICAL SOCIETY.

FRIDAY, MARCH 2ND, 1888.

H. STEAR, M.R.C.S., President, in the Chair.

Congenital Malformation of the Pulmonary Valves simulating aneurysm of Arch of Aorta.—Dr. WM. COLLIER (Oxford) showed the heart and large vessels of a woman, aged 33. She had enjoyed good health until the age of 18, when she had rheumatic fever, followed by constant pain over the upper half of the left side of the chest, and dyspnoea. She was believed to be suffering from aortic aneurysm, and after treatment by rest and diet for twelve months, Mr. T. Holmes tied the left common carotid, the operation being followed by marked relief to the symptoms. Thirteen years later the patient died of phthisis in Oxford, when a *post-mortem* examination showed that all the symptoms were due to a congenital malformation of the pulmonary valves, and that an aortic aneurysm had never existed. The case is fully reported in vol. ix, 114, of the *Clinical Society's Transactions*.

A Case of Charcot's Disease of the Knee-Joint (specimen shown).—Dr. WM. COLLIER referred to the discussion on Charcot's disease at the Clinical Society, as to whether the disease was a form of rheumatic arthritis altered by locomotor ataxy, or whether it was a special disease in no way connected with rheumatic arthritis. He thought the history of his own case pointed to its being a special disease. The knee-joint shown was that of the woman, aged 41, who had first come under observation 2½ years previously with marked locomotor ataxy, with a strong history of syphilis, but none of either gout or rheumatism. Twelve months before her death the left limb was noticed to be swollen, but no change could be found in the joint, with the exception of fluid effusion. For the sixteen months previous to this she had been practically bedridden, as the ataxy had been so severe as to prevent her standing without support on either side. Six months later it was found that in the space of six months the joint had become totally disorganised; the bones were freely movable in every direction; there was very marked grating, but no pain. After death it was found that enormous loss of tissue had occurred, the crucial ligaments had entirely disappeared, the external condyle had gone, and yet, as he had stated elsewhere, a large amount of new bone had been formed in the immediate neighbourhood of the destruction.

Thoracic Tumour; Recovery whilst taking Chian Turpentine.—Dr. BRADBURY related the case of H. J., aged 39, widower, admitted into Addenbrooke's Hospital on November 26th. There was a history of cancer in two sisters, and his father had died of "tumour." The patient had had several attacks of severe epistaxis since boyhood. When 19 years old he had some disease in the left lung, and lately had had several attacks of hæmoptysis. The present illness began with cough and pain in the right side of the chest and shoulder, blood-stained expectoration, and night-sweats. On examining the chest there was a smooth elevation as large as the palm of the hand, extending from the clavicle down to the third rib, just to the right of the sternum. No pulsation was felt, and there was no enlargement of the superficial veins. Percussion was impaired over this region and caused some pain, and respiration was feeble there, with occasional rhonchus. No murmur was audible over the swelling, and the heart sounds were normal. There were no signs of aneurysm, and the lymphatic glands were not enlarged. The swelling increased in size and became more prominent, causing pain and slight fulness of the right arm. On several occasions he had epistaxis. He was given five-grain doses of iodide of potassium for a few days, and on December 11th he was ordered fifteen minims of ethereal solution of Chian turpentine three times a day. The swelling continued up to December 25th, and then gradually diminished, so that on December 31st there was no prominence and only some hardness, the physical signs also clearing up. He still had attacks of epistaxis. He was discharged, well, having gained 22 pounds in weight.—In the discussion which ensued as to the nature of the tumour, the probability of hæmatoma was raised, associated with the tendency to epistaxis.—Dr. BRADBURY, in reply, thought the situation was unusual for hæmatoma, and the history was quite as much in favour of cancer. Its origin might possibly be inflammatory.

Intussusception in an Infant.—Dr. EASBY said on February 17th he was asked to see H. W. F., aged 7 months, a male. On his arrival he found he was suffering from well-marked symptoms of intussusception, the first appearance of which had been noticed on the 14th. On rectal examination a sausage-like tumour, four inches in length, was found high up. The child was placed under chloroform, and with a seamless Higginson's enema syringe he commenced to inflate. In about two minutes there was a rush of air past the nozzle, the distension of the abdomen subsided, and on introducing the finger the sausage-like tumour had gone. Minim doses of *tr. opii* were ordered, and, for food, lime water and milk. On the 18th a good motion was passed, and on the 24th the child was well.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

THURSDAY, APRIL 12TH, 1888.

M. M. DE BARTOLOMÉ, M.D., President, in the Chair.

Extra-uterine Fœtation.—Dr. MARTIN showed the uterus and appendages from a patient, in the Jessop Hospital, who had died from rupture of the sac. The woman, aged 23, was married; had three children, the last four years ago. She had suffered from endocervicitis and endometritis. The fœtation was tubal, in the right side, the fœtus being about three months' growth; a large

rent was seen in the posterior part of the foetal sac. Dr. Martin remarked on the difficulties attending a diagnosis in this case.

Diabetes Treated by Codeia.—Dr. STOKES related a case occurring in a man, aged 65, exemplifying the value of this drug.

Fracture of Olecranon by Indirect Violence.—Dr. SYMES (Chesterfield) related this case. The patient, a man, had, whilst working in the pit, put out his hand to stop a coal tub, and he immediately felt something give way. He was admitted into the Chesterfield Hospital on the third day after the accident. The olecranon process was then found detached, and could be readily moved from side to side. The fragment was not much displaced upwards. There was great swelling of the joint. The result was good.

Cancer of Breast.—Mr. H. JACKSON read a paper entitled *Carcinoma of the Breast; its Treatment.*

Urinary Calculi.—Mr. FAVELL showed a calculus, weighing nearly five ounces, which he had removed by lateral lithotomy from a patient a few days previously. The man had done well. —Mr. BALDWIN showed a calculus, weighing fifteen grains, which he had removed from the urethra. —Dr. MORTON exhibited a calculus, weighing ten grains, which he had extracted from the urethra of a girl, aged 6.

Specimens.—Dr. STOKES showed an Aneurysm of the first part of Arch of Aorta. —Dr. SYMES exhibited the Tibia and Fibula from a limb which he had amputated. They were both thickened, and were handed over for careful examination.

REVIEWS AND NOTICES.

MEDICAL LECTURES AND ESSAYS. By GEORGE JOHNSON, M.D., F.R.C.P., F.R.S., Emeritus Professor of Clinical Medicine, and Consulting Physician to King's College Hospital, etc. London: J. and A. Churchill. 1887.

THERE is certainly no lack of books in every department of medicine and surgery, written by young men who write to live; admirable as many of these books are, learned, elaborate, and complete as are some of the best of them, the disappearance of the majority would not perhaps be a serious loss, for their places would presently be supplied by the next generation of industrious and ambitious young men. On the other hand, it is a fair matter of complaint against too large a proportion of the senior and leading members of the profession, against physicians of such standing especially, that they do not sufficiently often, or sufficiently fully, give to the world the result of their ripe experience. The portly volume, therefore, which contains the latest and most matured opinions of a past-master like Dr. GEORGE JOHNSON, on such subjects as the various forms of Bright's disease, the relation of membranous croup to diphtheria, the proximate cause of epileptiform convulsions, the nervous disorders that result from overwork and anxiety, and on thoracic and abdominal aneurysm, to mention only a few of its leading topics, is sure of a respectful welcome.

Most readers will be disposed to turn first to Chapter XLV, which is in fact a new edition revised, and in part re-written of the author's *Lectures on Bright's Disease*; it is a long chapter, perhaps the longest in medical literature, but interesting and instructive from the first to the hundred-and-sixtieth page. Dr. Johnson summarises his views in five "propositions," which in aim amount to this, that chronic Bright's disease is a constitutional malady, characterised by a morbid state of the blood, which leads first to changes in the secreting cells of the kidney, and secondly to alterations in the blood-vessels of the kidneys and other organs. It will be at once seen that the objections to this theory which will have to be met are, the alleged existence of primary interstitial nephritis, and the alleged occurrence of primary arterio-capillary fibrosis. Dr. Johnson naturally and properly lays stress on the indisputable connection between acute nephritis and certain acute general diseases, of which scarlet fever is the most typical example; in these there is at least very strong presumptive evidence that the connecting link is the morbid state of the blood, the kidney cells being damaged by the poisonous bodies which they endeavour to excrete. The researches of Klebs and Klein must not be overlooked in this connection, because they tend to prove that the stress of the disease falls equally upon the glomeruli and arterioles, and upon the excreting

epithelium, if indeed the latter do not suffer less than the former. Dr. Johnson finds in the granular kidney intrinsic evidence in support of his position: "it is called," he says, "and correctly called, the small red granular kidney," for it retains, even in the most advanced stage, some of its vascularity, and consequently of its red colour, and he argues that if the change were primarily intertubular the result would be early anemia and consequent pallor. Microscopically he finds the intratubular changes far advanced while vascular changes are still absent or little marked, and he urges that if there were much interstitial growth of connective tissue, the intertubular capillaries would be compressed and the Malpighian capillaries in consequence engorged, a condition which would lead to early and copious albuminuria and hæmorrhage, whereas, as is well known, albumen is less copious than in any other form of Bright's disease. In the advanced stage the granular kidney undoubtedly contains an amount of connective tissue, that is to say, non-secreting tissue, out of all proportion to the quantity in the healthy kidney; this excess is partly due to actual overgrowth of connective tissue due to perverted nutrition, but the justice of Dr. Johnson's views as to the origin of the greater part will probably be generally recognised. "When a granular kidney," he writes, "has been reduced to the half or one-third of its normal size and weight, there can be no question that this is mainly due to the destruction and disappearance of the gland cells, and that in what remains of the wasted organs, there must be an enormous relative excess of fibroid tissue composed of fibrillated basement-membrane, thickened Malpighian capsules, and bloodless capillaries." This view is adopted in the well-known *Lectures on Pathological Anatomy*, by Drs. Wilks and Moxon, and it is not easy to see how its force can be diminished by any arguments founded on microscopical appearances, since the question in dispute is not whether there is an excess of fibroid tissue, but how large a proportion of admitted excess is derived from fibrous basement-membranes which have persisted after the secreting cells are destroyed. It would seem that pathologists have been rather led away by the supposed analogy between granular kidney and cirrhosis of the liver, whereas the essential difference between the functions of the organs ought to have prevented any attempt to explain the morbid anatomy of the one by direct reference to the other.

Upon this view of the pathology the thickening of the arterioles remains to be accounted for. In the renal arterioles this thickening occurs in the intima, the connective tissue which exists between the endothelium and the elastic lamina becoming very greatly increased in bulk. There are at least three theories to account for this overgrowth. One which Dr. Johnson sets in the forefront to demolish would attribute it to endarteritis; and although it is, we take it, almost certain that an inflammatory process is the initial lesion in the kidney, or at least accompanies that lesion, we are not aware that it has ever been given an application universal either in extent or time. Another theory is that the overgrowth is mainly degenerative, involving a replacement of highly-specialised by lowly-specialised tissue—a process with which we are familiar in a variety of chronic maladies. The third theory—that advocated by Dr. Johnson—is that the thickening is "a physiological overgrowth having a conservative purpose and tendency," which, by strengthening the arterioles in their longitudinal direction, enables them the better to resist the strain and the resulting tendency to elongation to which they are subjected by the impulse from the greatly-hypertrophied ventricle. This view is ably defended by arguments drawn from the morbid appearances as well as by general pathological considerations. It is stated that the thickening is always associated with "hypertrophy of the muscular coat, and bears a constant relation to it; that the structural character of the thickening is remarkably uniform; that every artery in the kidney is affected to a uniform degree; and that the thickening is strictly limited to the intima. Some very striking drawings, from preparations made by Dr. Heneg Gibbes, are given to illustrate these points; but it may be doubted whether the statements can be received in this absolute form without certain limitations. As has been already said, Dr. Johnson looks to a modified condition of blood associated with gout, dyspepsia, or some other derangement of the general health as the immediate cause of initial renal changes. The morbid condition of the blood leads to morbid nutrition of the excretory cells, which in time decay and are disintegrated, the basement membrane of the tubules subsequently thickening and contracting. The secreting tissue of the gland being thus very greatly diminished, it requires less blood, and the renal arterioles, "unde-

the influence of the vasomotor nerves, now regulate the blood supply in accordance with the diminished requirements of the gland. This regulating action continues and increases month after month, year after year, and the physiological result of this persistent overaction of the minute renal arteries is that their walls become hypertrophied."

The theory is consistent, its parts cohere naturally, and it is argued with great ability and fertility of resource; it supplies a reasonable logical substitute for the somewhat vague statements about a degenerative tendency to fibrous overgrowth—a part of a general decay—which are favourite generalities with some writers, and has this great advantage that it has a very obvious clinical moral; if chronic granular kidney is to be traced to chronic toxæmia due to gout, dyspepsia, or suppression of cutaneous secretions, then we have a rational basis on which to found a method of treatment which may be efficient to check the progress of the disease.

There is a very valuable chapter on the various modes of testing for albumen in the urine. Dr. Johnson considers that picric acid is a more delicate test for minute traces of albumen than either acetic or nitric acid, or than both these tests combined. In order to justify this claim, the picric acid must be used with certain precautions; if very alkaline, the urine ought to be acidulated with acetic or citric acid, although the picric acid solution is itself sufficiently alkaline to dissolve the phosphatic deposit which results from boiling a slightly alkaline urine; a long test tube is used, and into it is poured a column of urine about four inches high, then holding the tube in a slanting position, the picric acid solution is gently poured on to form a column about one inch high, which, owing to its low specific gravity (1.007), will float on the surface of the urine; where the two liquids meet, a rather free intermixture occurs, and, if albumen is present, it is precipitated in this area, and a cloudy ring is produced; if the albumen is in very small quantity, the application of heat to this turbid layer will increase the turbidity. If the specimen of urine which has to be examined is turbid, it must be cleared by filtration before applying the test. Picric acid, like nitric acid, will produce an immediate turbidity, due to precipitation of urates in urine containing an abundance of these salts, but this turbidity disappears with heat. It is, however, desirable in every case to let the urine cool before making an examination: the excess of urates separates in the cold, and may be filtered off; the liability to this source of fallacy is thus greatly diminished. A more real objection is, that in a few urines picric acid will cause a precipitate of uric acid crystals, and thus produce an opacity which is not removed by heat, and can only be recognised on microscopical examination. Peptones, also, it ought to be remembered, give a precipitate, but this is dissolved by boiling; by making use of this fact, Dr. Johnson has found it easy to detect and separate peptones in albuminous urine. On adding the saturated solution of picric acid in the cold to such urine both these proteids are precipitated, but the peptones are dissolved up on heating, and, if the liquid is filtered hot, will pass through the filter in solution, and separate out in the filtrate on cooling. A caution must be added against the use of acetic or citric acid to acidify the urine, unless that fluid be very alkaline; in any case, if one of these acids be added, it is safest to filter, in order to get rid of the mucin.

Some excellent observations are made on the proper mode of searching for albuminuria. Most readers are now alive to the fallacies involved in examining the morning urine only, but a new heresy appears to be springing up; so much has been written of the necessity, in diabetes, and in the so-called renal inadequacy, of obtaining a specimen from the whole bulk of the day's urine, that a disposition is shown to extend the recommendation to cases of suspected albuminuria also. Of course, if it is desired to obtain a quantitative estimation, this is right; but in the cases now referred to it is the existence of albumen which has to be established. For instance, in the slight albuminuria which so often persists for some weeks or months after scarlatinal nephritis, the abnormal constituent may only be present after food and exercise, and when looking for albumen in such a case the obvious and reasonable course is to examine the urine passed after food and exercise. If a trace is present, then it has, as is generally believed—and we are glad to see that Dr. Johnson fully endorses the opinion—a serious clinical significance; by diluting this specimen of urine, which contains the clue to the whole position, with all the urine of the twenty-four hours, we are digging a pit into which to fall.

Another valuable monograph contained in this volume is that on the pathology and treatment of epidemic cholera; it extends to 112 pages, and is a powerful exposition of the principles upon which the evacuant treatment of cholera has been founded. A careful perusal leaves upon the mind a very strong impression of the validity of the arguments advanced; that during an attack of cholera there is a morbid material actually in the blood has been rendered more than ever probable by recent researches, and that this material is in some way intimately associated with morbid changes occurring in the intestines can hardly be disputed. The tone in which the subject is discussed is unnecessarily polemical; it is probably because cholera is so terrible a disease to witness that every difference of opinion as to its nature or treatment leads to an embittered controversy. Men are terribly in earnest about it, and it is not easy to be tolerant.

The evacuant treatment of cholera consists in the administration of some laxative—calomel, according to the older Indian writers, castor oil, according to Dr. Johnson—in frequent doses, with the object of emptying the intestines of the morbid material, solid as well as liquid, which they contain. The theory as generally understood is that the alarming symptoms of the algid stage are due to the presence of a peculiar poison in the blood. The modern theory, which has been especially favoured by Koch and his fellow-workers, is that, whether the disease is primarily intestinal or not, the morbid process is kept up by the intestinal derangement; that, in fact, the intestines are the laboratory in which the poison, ptomaine or whatever it may be, is manufactured. Dr. Johnson fights against this theory, if we understand him aright, with unnecessary vehemence.

A fairly extensive acquaintance with the literature of cholera fails to afford an instance of a writer who has given so philosophical an explanation of the symptoms of the algid stage. Dr. Johnson is right in insisting that it is not a mere form of ordinary collapse. There is good reason to believe that it is a toxæmia, and Dr. Johnson makes out a strong case for the theory that the cholera poison is a lung (asphyxiating) poison. But a distinction must be drawn between the cholera poison—which may, for the sake of argument, be assumed to be a ptomaine—and the cholera virus; the latter is capable, the former incapable, of self-multiplication. Although the view is nowhere specifically stated, Dr. Johnson appears to hold that the symptoms of cholera are produced by a single dose of the cholera poison, and that cholera is therefore directly analogous to poisoning by—to quote instances mentioned by him in illustration of his arguments—muscain or tinned meats. The current theory is that the virus of cholera, at a certain period of its evolution, finding its way into the intestines while they are in a favourable state, therein multiplies, giving rise to a poisonous body or bodies, which produce systemic poisoning evidenced by the algid state, and also cause the peculiar flux. The evacuant treatment would appear to be indicated upon either theory; on Dr. Johnson's, to remove the ptomaine from the blood by unloading the venous system, and on the other to remove not only the ptomaine from the blood, but also the virus from the intestine. Unfortunately there is a serious conflict of evidence when we come to inquire how the evacuant system works in practice. Dr. Johnson writes very strongly in its favour, and quotes many striking cases; but current Indian opinion is certainly opposed to it. Mr. Macnamara, speaking in the debate at the Royal Medical and Chirurgical Society in 1885, said that he had gone out to India a thorough believer in the evacuant treatment, but had soon been led to abandon it. In this state of doubt this question must be, for the present, left; but we would strongly recommend all medical practitioners, civil or military, who may be called upon to treat cholera, to study this monograph; it contains a great deal of information and the results of much thought, and its perusal will have the further important effect of stimulating thought.

Though so much space has been devoted to these two important essays, it must not be supposed that the volume does not contain many other shorter essays of great value. For instance, in a lecture on hysteria which forms the eleventh chapter of the volume, there are some interesting observations on globus and on laryngeal spasm, a subject which is further elaborated in a clinical lecture founded on a remarkable case of hysterical spasm, and in a paper on the laryngeal symptoms resulting from pressure on the vagus and recurrent. From the fact that the inhalation of chloroform immediately arrested the stridor of hysterical spasm, Dr. Johnson was led to give chloral internally, and with great success. He states that the drug is also of great value in laryngismus

stridulus, and suggests that it will probably be found useful as a palliative in spasm excited by pressure on the pneumogastric. The production of bilateral spasm or palsy by pressure of an aneurysm or other tumour on the trunk of the vagus on one side is discussed at length, and the development of the conviction that it was due to morbid changes induced in the vagus centres by irritation of the afferent fibres is traced. This view has been accepted by Sir Morell Mackenzie in his work on Diseases of the Larynx, and its correctness is now, we believe, generally admitted. There is also a whole series of essays on other subjects, more or less nearly connected with laryngology. Special mention may be made of those on croup and diphtheria, and of an interesting anecdotal chapter on foreign bodies in the throat and air passages.

There is another series of lectures and essays on diseases of the heart and aneurysms of the aorta containing many valuable clinical observations, and numerous illustrative cases. There are also a number of lectures and essays on detached subjects, among which a particularly valuable paper on latent peritonitis, and a paper containing a series of cases of poisoning by the homeopathic tincture of camphor may be specially mentioned on account of their direct clinical bearing.

The volume is a remarkable monument to the industry, the extensive experience, and the wide range of reading of its author. If it stood alone it would represent a life's work of which any man might well be proud, but we are glad to remember that Dr. Johnson is still with us in the full vigour of his faculties, and still hard at work, as is evidenced by the suggestive essay on "Albuminuria a frequent Result of Sewage Poisoning," published in these pages since the volume now reviewed was issued from the press.

MEDICAL HISTORY OF THE MEATH HOSPITAL AND CO. DUBLIN INFIRMARY. By LAMBERT HEPENSTAL ORMSBY, A.B., M.D. Univ. Dub., F.R.C.S., Member of the King and Queen's College of Physicians, Ireland, Surgeon to the Meath Hospital, etc. Dublin: Fannin and Co. London: Baillière, Tindall, and Cox.

THERE is scarcely one of the medical and surgical institutions connected with the Dublin School that has acquired so great, and we will add so deserved, a reputation as the Meath Hospital and Co. Dublin Infirmary. This it has gained from its having been the arena for the labours of so many worthies who have shed lustre on the Dublin School, among whom may be mentioned among others, Crampton, Porter, Rynd, Smyly, Macnamara, Graves, and Stokes. It is gratifying to note that the same zeal and energy that characterised the staff in the past are still apparent in its present members. Among these Mr. ORMSBY has been conspicuous for his untiring energy, and no small amount of the high state of efficiency that at present characterises the Meath Hospital is unquestionably due to his steady determination to make it, especially as regards the nursing and general management, second to no other similar institution in the United Kingdom.

We congratulate Mr. Ormsby on the satisfactory completion of the medical history of the Meath Hospital, and sincerely hope that the good example he has shown may be promptly followed by the medical officers of our other hospitals.

The motto that has been affixed to the official seal of the hospital, "Que regio in terris nostri non plena laboris?" we think very appropriate, and feel confident that the many pupils of the "old Meath" now practising in the British islands, in the East and far West, will gladly welcome and become possessed of Mr. Ormsby's most interesting book, in which their names appear, as it will give them ample opportunity of reviving many pleasant reminiscences of their student days.

As regards the printing, paper, and illustrations, with which latter the volume abounds, we have little to say save in the way of praise.

A JUNIOR COURSE OF PRACTICAL ZOOLOGY. By Professor MILNES MARSHALL, M.D., F.R.S., etc., and Mr. C. H. HURST. London: Smith, Elder and Co. 1887.

THIS useful manual for dissection met with so much approval on its appearance last year, that we are glad to hear that a second edition will shortly be issued. The book deals with all those animal-types required for the Preliminary Science Examination (M.B.) of the London University, together with some other equally important types, amongst these being *Amphioxus*. This is the

first concise and accurate description, in English, of this interesting vertebrate, and is accompanied by five excellent woodcuts. A description of the life-history of the liver fluke also makes its appearance for the first time in a students' manual.

The arrangement of the types follows that which is found in the first edition of Huxley and Martin's *Practical Biology*, commencing with *Amaba*, and advancing through the more complex forms to the mammal. The bird-type, however, is dealt with after the rabbit—a course which is, in many respects, convenient although not strictly scientific. In fact, it appears to us a great pity that the London University does not require the *Amphioxus*, in place of the much less important bird.

The instructions for dissection are preceded in each case by a short life-history of the animal under discussion; the various organs are treated systematically, instead of topographically; and the woodcuts have the great advantage that they do not take the place of sketches which should be made by the student, but are in most cases longitudinal or transverse sections, more or less diagrammatically represented, and are of considerable aid in teaching. The book is clearly printed on good paper, the names of organs being in thick type; the woodcuts are most carefully executed; and at the end is a useful list of reagents, together with the methods of preparing them. The manual will be found most handy alike by teachers of zoology and by students.

THE COMPARATIVE ANATOMY OF DOMESTICATED ANIMALS.

Part I.—OSTEOLOGY. By J. McFADYNEAN, M.B., etc. Edinburgh: W. and A. K. Johnston.

THE book is written, nominally, for students preparing for the veterinary examinations, and deals with the skeletons of the horse, cow, sheep, pig, dog, cat, and fowl.

The skeleton of the first animal is described in great detail, the description being in large type, the names of bones and their parts being in thick type; the description of the skeletons of the other animals is in small type, and is, of course, less detailed. A large number of woodcuts accompany the letterpress, and these would in some cases (for example, Fig. 57) have been rendered considerably more useful and distinct if less shading had been introduced. Moreover, it appears to us advisable to give references to the figures in the letterpress, although the woodcuts are themselves sufficiently explained.

Preceding the more special part is a short chapter on the histology of bone, and the mode of development of "cartilage bone" and "membrane bone," the value of which would have been enhanced by the introduction of woodcuts representing the process. The mode of development follows the description of each bone. It is a pity that the old plan has been retained of employing the terms "anterior" and "posterior" for those surfaces of a skull which, to the comparative anatomist, are known as dorsal and ventral; also "superior" and "inferior" for the posterior and anterior surfaces. Again, "inferior maxilla" is retained for the mandible, "squamous temporal" for squamosal, and so on, although, in most cases, the zoological terms are mentioned in the text.

In speaking of the fowl, the statement as to the number of vertebrae is different from what is given in other textbooks; for example, the cervical region of the domestic fowl is said to consist of twelve vertebrae, whereas in reality there are fourteen, without counting the two hindermost, which carry freely articulating ribs.

The book, on the whole, will be found very useful to veterinary and medical students, as well as to zoologists.

NOTES ON BOOKS.

Guide to the Administration of Anæsthetics. By HENRY DAVIS, M.R.C.S. (London: H. K. Lewis. 1887).—The literature descriptive of anæsthesia has received no additions of any importance for many years past, that is to say, no volume has been published in England of any note. Fugitive papers there have been, dealing with matters germane to the subject, and some of considerable importance, but no attempt has been made to gather these fragments into one compact whole. Mr. Davis has not attempted to treat his subject from a scientific point of view, aiming at giving in "a concise form, the chief details which are requisite for the safe administration of the various anæsthetic

gents throughout the civilised world." The account given of these various agents, although very scanty, is fairly accurate, but in some instances is not up to the knowledge of the time. In speaking of chloroform, the writer does not enforce its dangers with sufficient emphasis, while, in dealing with the A.C.E. mixture, Mr. Davis is much too brief. He dismisses the subject in three lines, neglecting to mention how to administer it, its undoubted advantages in many cases, and its dangers and peculiarities. The same brevity characterises his treatment of all the less usual æsthetics. Mr. Davis's style is easy, if not polished, but he is not always accurate. On page 16 the figure given is not, as it is stated, that of a Junker's inhaler, but a modification due to Dr. Dudley Buxton, and described in the *Lancet* some years ago. Simsby's inhaler is further described as having been invented to overcome inconveniences, if such there be, of Clover's instruments, a statement not borne out by history, as Clover's apparatus was chronologically the second. Mr. Davis's book will doubtless prove useful to many, and he has certainly done his best, and taken great pains to compress into a very small space a good deal of useful information.

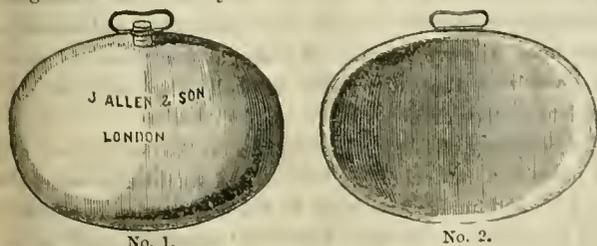

REPORTS AND ANALYSES
AND
DESCRIPTIONS OF NEW INVENTIONS,
IN MEDICINE, SURGERY, DIETETICS, AND THE
ALLIED SCIENCES.

THE RANELAGH PORTABLE GYMNASIUM.

We have received from Messrs. Walkley and Co., 5, Strand, W.C., one of the Ranelagh Pocket Gymnasiums (F. Milne's patent), of which they are the agents. It is claimed for this simple machine that it produces a high form of healthy bodily development, with perfect safety, and that it establishes and maintains a vigorous tone in the whole muscular system; the series of india-rubber bands (which govern the strength) being so constructed as to prevent any jerk in the motion; and that, therefore, it is superior to either Indian clubs, dumb bells, or other heavy weights, and is equally suited to the most delicate child and the strongest man. It consists of a series of six india-rubber strands, with handles attached by means of cords working on a system of pulleys. It is fixed to a hook in the wall, and can be pulled out to any desired extent by the user making a forward movement. We have tested it and have formed the opinion that it is undoubtedly a useful invention, and may be recommended also on account of its great stability and moderate cost. It occupies, when packed, about 14 1/2 by a foot square. It is made in various degrees of strength: No. 1, suitable for ladies or children, can be procured for half-a-crown; No. 2, for gentlemen, at 14s. 6d.; while they can supply the same of extra strength at 18s. 6d. This is by far the most portable gymnasium we have seen.

ALLEN'S HOT-WATER AND ICE BOTTLES.

We have received from Messrs. J. Allen and Son, 21 and 23, Arylebone Lane, specimens of their improved hot-water and ice bottles in white polished metal, which are vastly superior to anything of the kind we remember before to have seen both in shape, construction, and general adaptability. Being made in two pieces instead of four, and put together in a form which renders the same stronger and more durable, there is far less danger of leakage than with many of the old forms of bottle. Another

No. 1.

No. 2.

noticeable feature is the comparative lightness of the improved bottle, being neither so heavy or cumbersome, and possessing a more shapely appearance, with fewer angles than met with in many of the bottles in use. All the stomach warmers have

rounded edges, rendering injury to the patient impossible, and being convex on the upper and concave on the under surfaces. They will fit that part of the body for which they are intended (see Figs. 1 and 2).

The ice bottles for the chest, stomach (see Figs. 3 and 4) head, and knee (see Figs. 5, 6, 7) are equally well adapted for their

No. 3.

No. 4.

No. 5.

No. 6.

No. 7.

several uses, and are fitted with large filling screws for facilitating the filling with broken ice, but this of course does not prevent their being utilised when required as hot-water bottles. They are moderate in price, and can be procured in tin at 3s. and 5s., or in copper at 6s. or 7s. each.

ROYAL COLLEGE OF PHYSICIANS.

An ordinary meeting of the College was held on Thursday, April 26th; Sir ANDREW CLARK, Bart., the new President, in the chair.

On the motion of Sir ALFRED GARROD, seconded by Dr. QUAIN, a vote of thanks to the retiring President, Sir William Jenner, Bart., K.C.B., was unanimously adopted by the College.

The following gentlemen were admitted Members of the College: John Duff, M.D.Glas.; Henry John Tylden, M.B.Oxon.; Henry Waldo, M.D.Aberd.; Joseph Wigglesworth, M.D.Lond.; and Arthur Thomas Wilkinson, M.D.Lond.

Licences to practise were granted to seventy-four gentlemen, who had passed the required examinations.

The examiners for the Murchison Scholarship reported that six candidates had been examined, and that all had done well.

The scholarship was awarded to Mr. Henry John Tylden, M.B. Oxon., of St. Bartholomew's Hospital. The examiners added that Mr. Starling and Mr. Fenwick were also deserving of honourable mention.

The annual election of Fellows was then proceeded with. The names of those on the list nominated by the Council having been submitted one by one to the judgment of the College, they were all elected, namely: Thomas Cole, M.D.Lond.; George Blundell Longstaff, M.B.Oxon.; Richard Caton, M.D.Edin.; Frederick G. D. Drewitt, M.D.Oxon.; Walter Baugh Hadden, M.D.Lond.; Howard Henry Tooth, M.B.Camb.; Charles Edward Beevor, M.D.Lond.; James F. Parry McConnell, M.D.Aberd.; William Hale White, M.D.Lond.

Communications were received from the Board of Trade and from the Colonial Office.

A letter was received from Dr. Curnow resigning his appointment as Examiner in Anatomy.

The quarterly report of the Finance Committee and a report from the Committee of Management were received and adopted.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1888.

SUBSCRIPTIONS to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the West Central District Office, High Holborn.

 The British Medical Journal.

SATURDAY, APRIL 28TH, 1888.

THE ARMY MEDICAL RESERVE OF OFFICERS.

WHEN the Warrant seeking to create a reserve from medical officers of the auxiliary forces was issued about two months ago, we offered a few friendly criticisms on its provisions, although we confess to having had grave misgivings about it as a whole. Further consideration, in the light of many hostile criticisms which have reached us, now strengthens the opinion that the scheme is not likely to come to much, for the simple reason that it has, in truth, no substantial element of success in it.

We fail to find in the April *Army List* even a beginning of the Auxiliary Reserve List; but we hear some have actually joined, as against several volunteer surgeons who hastily sent in their names, but withdrew them equally quickly. We are not surprised; rightly read the scheme is wholly in favour of the War Office, at the expense of those who are expected to embrace it. Its authors must have curious notions as to who the great bulk of the auxiliary medical officers are, and how they get a living. Is it imagined they are idle medical gentlemen, anxious to serve for practically nothing, provided they can air their names prominently in the *Army List*? They are, indeed, mostly hard-working civilians, with large private interests wholly dependent on their individual exertions. What are they asked to do? They are invited to place—without retaining fee or any adequate prospective pecuniary advantage—their personal independence, their practice, patients, and private interests entirely on one side, and, with unheard-of disinterestedness, give their individual professional services at the cheapest rate whenever the War Office finds it convenient—or necessary, in a medical sense—to declare “national emergency.”

This is asking too much! We doubt not our medical volunteers are quite prepared to make great personal sacrifices alongside of the volunteers of all ranks when real national danger unfortunately comes about; but it is entirely another matter to ask them to risk private professional ruin when the emergency may be not national at all, but only medical and artificially brought about by reckless docking of the regular medical vote.

Many things indicate that Finance is at the bottom of this reserve scheme. It was, for instance, lately naively remarked

by one of the “Service” papers that the scheme would, at all events, be agreeable to the “taxpayers”! From this it appears that, although medical men of course pay taxes like other citizens, they are further coolly expected to tax themselves doubly by rendering military services at a personal loss in order to please the general taxpayer! Medical men, indeed, have too often to sacrifice themselves in civil life; but why should “doctors” alone be asked [to offer themselves meekly on the altar of public economy? Lawyers, engineers, traders, and workmen are not asked to do so.

We before pointed out that the scheme was crude and unstatesmanlike, because it tried to stop a gap while actually creating another and a bigger one. The auxiliary forces will be in want of their own medical officers when real national emergency arises; they could not spare them to do duty with regular troops. This reflection forces the conclusion that the authors of the scheme could hardly have had a national, but only a factitious, “medical emergency” in view. The idea was less to support than, if difficulties arose with the medical profession, to altogether supplant the regular medical service. It was no doubt foreseen that, if the regular medical service be recklessly cut down at the bidding of one-eyed economists, our first small war will inevitably bring about a medical emergency, and full terms, under pressure, would then have to be made with civilian practitioners; so, it was meanwhile desired, under the conditions of a reserve, to secure the obligatory services of certain medical men on cheap terms which will prove wholly ruinous to those with even the smallest private practices. Very few men will risk such conditions. Volunteer medical officers, moreover, will not allow themselves to be played off so palpably against their regular brethren to merely help political financiers to starve the medical vote.

If no trace of the auxiliary reserve is to be found in the April *Army List*, we do find in it a change for the better in the reorganisation of the regular medical reserve. The list of retired officers in reserve used to be headed “retired medical officers eligible for temporary employment;” it is now worded “retired medical officers liable to be recalled to service.” This is a distinct improvement, exhibiting those officers in the true light of a genuine reserve, and more in accordance with the wording of the Warrant under which they have liability; but we think the words should have been added “under Article 23 of the Royal Warrant, December 2nd, 1879.”

The article runs thus: “23. Any officer of Class A who shall voluntarily retire before the age of 55 years shall be liable to be called upon to serve, in a case of national emergency, in a rank not lower than that from which he shall retire until he shall complete the age of 55.”

The Secretary of State’s instructions on the article are: “3. The name of a medical officer who retired voluntarily before the age of 55, and, under Article 23, is liable until then to be called upon to serve in any case of national emergency, will be retained in italics in the *Army List* with those of effective officers.”

We find the number of retired officers liable to be recalled, in the April *Army List* (whose names, however, are not in italics)

tated at 133, of whom twenty-three are now actually temporarily employed. Now, this is a very valuable and true reserve; are fully experienced and highly trained; not a few of them well known as among the ablest men in the Department. Numbers will constantly vary no doubt, from death, illness, and attainment of 55, but others will yearly be added. When an agitation was lately attempted against the early retirement of medical officers, not a word was said about the existence of this most valuable and reliable reserve; it was carelessly concealed from the public that the early retirements alone enabled this great reserve to be formed. The change in the *Army List* indicates that the authorities now mean that the Reserve List shall be clearly shown. Let them cultivate it; it will stop a gap in a *bona fide* manner during emergency, and not the auxiliary forces of their proper medical officers.

There are one or two points connected with this regular medical reserve we should like to see cleared up. Are retired medical officers liable to be recalled for service outside the United Kingdom? We see nothing in the articles quoted to show they are, although it is universally understood they are only liable for service at home.

Then, why are some retired medical officers, apparently equally able and liable with the others, not put in the Reserve List, but shunted altogether away on the "Non-effective List"? This no doubt be satisfactorily explained, but we cannot think of a reason in certain individual cases.

THE LAW OF ANTAGONISM.

The Friday discourse delivered at the Royal Institution on the 20th on War in Nature has a special interest for us, because Sir William Grove, who before he earned distinction as a lawyer and a judge had gained lasting fame as a physicist, approached the subject from the physical side. The lecturer, whose most valuable contribution to science in the past was his exposition of the theory of the conservation of energy, set himself last week to show that the universality of antagonism had not received the attention it deserved, the element of force having been mainly taken into account, and too little stress having been laid on the element of resistance. Some aspects of the problem involved in the doctrine of antagonism have been appreciated by medicine from the earliest times, and to the biologist the idea has been familiar long before the phrases "struggle for existence" and "survival of the fittest" came into vogue.

We may observe at least three forms of antagonism between man and the rest of the living world: the antagonism with other individuals of the same species—the wars of earlier, the keen intellectual competitions of later ages—the antagonism with other species of the higher mammals, which species man either seeks to exterminate or to bend under his yoke; and lastly, the somewhat one-sided antagonism in which a vastly inferior species attacks a superior, where the superior can gain nothing beyond a mere perpetuation of individual life, while the inferior—bacterium or helminthic parasite—not only sustains its life, but perpetuates its species at the expense of the higher.

There is no medical saw more hackneyed than that which speaks of the *vis medicatrix nature*; it expresses a well-grounded confidence in the result of the conflict between the forces of the body and the external forces which have put it in peril. Socrates in the *Republic* (Book III), quotes from the *Iliad* that when Menelaus had been wounded by the spear of Pandarus, the sons of Asclepius "sucking the blood from the gash, laid mild simples upon it," knowing, says Socrates, "that the simples were sufficient to cure men who before receiving the wounds were healthy." The physician, in fact, played the part of Lord Palmerston's "judicious bottle-holder," believing that if he could afford a fair field and no favour, the "war of Nature" would end favourably to his client. This is, in fact, the attitude of the scientific physician in every age. Much of the advanced surgery of the day is based on a profound conviction of the greatness of the *vis medicatrix nature*. Take, for instance, the operation of abdominal section for purulent peritonitis. The cells of the peritoneum have been defeated in their conflict with the forces of disorganisation; by removing the accumulated morbid secretions the surgeon seeks to equalise the battle, and, by diminishing the number of their enemies, to give the cells a fresh chance of destroying those which remain. An eminent ovariotomist has suggested that the plan of washing out the peritoneum with large quantities of tepid water was successful because it broke up the dead tissue, which might become the seat of decomposition, into microscopic scraps, which the active peritoneal cells could destroy. The surgeon relies upon the power of resistance of the peritoneum, and thus affords a practical illustration of the advantages which may be gained by leaving the principle of antagonism to work itself out.

Man, in common with all other living—and, Sir William Grove would add, inanimate—things, has to contend also with the forces of inanimate Nature, and it is in this conflict that the good results of antagonism, not altogether beyond recognition in the other conflict, are most easily perceived. It might not have been easy to foresee that the conditions of life on these islands should have been so peculiarly favourable to the development of the human race; yet they have produced the dominant race of the world, at an epoch when the struggle for supremacy is the keenest.

There is, in fact, a mean between the external conditions belonging to the class generally reckoned unfavourable and the internal powers of resistance, which gives as a resultant a state of health and energy of mind and body far better for the individual and for the race than that produced under conditions at first sight more favourable. A question of surpassing interest is, why under the most favourable circumstances this balance cannot be long maintained, and why the period for which it can be maintained is approximately the same in each individual of the same species, though so widely different in different species? Why do we grow old, but not even Professor Humphry can tell us why. The conditions which govern the duration of life in various species have never been

made out; the bulk of the animal may have some influence, since a large animal will, *cæteris paribus*, require a longer time to secure the surplus of nutriment required for reproduction, and the degree of structural complication will also tend to fix a minimum time, because it also will have a share in determining the time at which reproductive power is attained. It is no explanation to say that Nature takes no thought of the individual, but merely provides for the perpetuation of the species; this is merely to express the facts in anthropomorphic terms. We are driven to adopt the colourless view that the duration of the life of the individual is determined by its innate power of resistance to external forces. Where the external conditions are extremely unfavourable, the reproductive powers diminish, and so contribute to the disappearance of the species; where external conditions are so favourable that the species not only continues, but increases, still the individuals succumb to the antagonistic forces; the only conclusion to be drawn is, as has been recently pointed out by Weismann and others, that, in the words of a writer in *Nature*, "the occurrence of death at all is a provision to secure the greatest possible number of individuals of full strength. Death makes room for new complete individuals."

THE LOCAL GOVERNMENT BILL.

ALTHOUGH the Local Government Bill has been read a second time in the House of Commons without a division, it was not until many of its provisions had been severely criticised, both from the Conservative and from the Liberal benches. No serious opposition to the main features of the measure has, however, developed, and the Government have thus been encouraged to use their best efforts to pass it into law during the present session.

The defects which have been discovered in the Bill will be more seriously discussed in Committee, and doubtless remedies for many of them will then be strenuously pressed upon the acceptance of the Government. By no means the least important of these flaws, not only from the point of view of the medical profession, but from that of the ratepayer who desires to secure wholesome surroundings and good sanitation throughout the country, is the proposal relating to the appointment and tenure of office of medical officers of health. We have on several occasions recently called attention to this matter, and on the 13th instant the question was ably discussed in the House of Commons by Sir Lyon Playfair, when he advocated the vesting of the appointment of health officers in the new County Authorities, instead of in the District Councils as proposed by the Bill. But unless Mr. E. Stanhope's criticisms are to be taken as indicating the views of Mr. Ritchie, no official statement has been made as to the attitude of the Government towards the question. We feel sure that Mr. Ritchie will give careful consideration to the weighty arguments in favour of Sir L. Playfair's contention.

Mr. Stanhope is of opinion that a medical officer of health appointed by a local board would in many cases have more in-

fluence with that board than would any person imposed upon them from headquarters. But as the health-officer acts simply in an advisory capacity we do not regard this objection as a serious one. It is of the first importance that every District Council should have properly-qualified and fearless advice. Whether that advice is acted upon or not, is a matter for them to decide and to settle with their constituents. Moreover, the supreme County Council appointing the officer will themselves have been directly elected by the ratepayers on the same franchise as the District Councils; and it is further worth noting that, although the coercive powers of the Public Health Act are to be transferred to the County Councils, Mr. Ritchie's Bill does not propose that the Councils shall have the power of the duty of providing themselves with the advice of a skilled medical officer.

There are undoubtedly many very conscientious health-officers in our rural districts who have performed their duties with great efficiency for a merely nominal remuneration. But, on the other hand, there are many who have no special qualification to advise on sanitary matters, and who act on the principle that their slender salary is to pay them for doing nothing. It cannot be denied that the best work has been accomplished in those areas where the medical officer of health gives his whole time to the duties, and is specially qualified to advise in preventive medicine. As long ago as 1855 the General Board of Health, in their instructional minute relative to the duties and qualifications of officers of health, expressed the opinion that, "where possible, it will be well to debar the officer from the private practice of his profession—first, because the claim of such practice would be constantly adverse to those of his public appointment, the duties of which (especially at times of epidemic disease, when his official activity would be most needed) private practice could scarcely fail to interrupt an embarrass; secondly, because the personal relations of private practice might render it difficult for him to fulfil with impartiality his frequent functions of complainant; and, thirdly, because with a view to the cordial goodwill and co-operation of his medical brethren, it is of paramount importance that the officer of health should not be their rival in practice, and that his opportunities of admonitory intercourse with sick families should not even be liable to abuse for the purposes of professional competition." The same opinion applies at the present day. In small districts, however, the whole time of a health officer would be an unnecessary extravagance, unless several districts are combined for the joint employment of the same officer. But experience has shown that voluntary combination in such cases is not to be relied upon, whilst compulsory combination is obviously objectionable.

The further argument advanced by Mr. Stanhope—that, if the appointment of health-officers be vested in the County Council those bodies will be saddled at their formation with an enormous expenditure—is untenable on close examination. Fewer officers—probably not more than 200—would be needed for the whole country, and the united cost of this staff of special-

and officers would very slightly, if at all, exceed the united number of the 1,300 officers at present holding appointments. The question of compensating those officers who would be superseded would very seldom arise, as the appointments are at present mostly made for a year only.

It is to be hoped that Mr. Ritchie will see his way to adopt the suggestion that the officers of health should be appointed by County Councils instead of by the District Councils. The result would undoubtedly be a more efficient sanitary service and administration throughout the country, and a consequent diminution of sickness, with its attendant misery and loss.

THE LONDON UNIVERSITY AND METROPOLITAN MEDICAL STUDENTS.

An opinion is entertained in some quarters that the University of London might still, by reforming its regulations, and in some directions relaxing their rigidity, solve the problem of providing the expansion of the higher education in London, by constituting itself a true University for the metropolis. Those who hold this opinion have given evidence of their sincerity by proposing a great variety of reforms, and we learn that the Committee appointed by the Senate to report on the regulations for degrees in medicine has drawn up a report conceived in a very liberal spirit.

Whatever reception this report may meet with from the Senate it is possible to foresee, though that body is evidently more alarmed at the dangers which threaten the University from all sides, and not from the medical alone, than was the case a few years ago. Meanwhile it may not be amiss to indicate some of the reforms that are most urgently needed. Regulations for the pass and honours examinations at the Intermediate Examination in Medicine, which came into force last year, have been universally condemned, and, we apprehend, cannot be continued; the old regulations, with, perhaps, some slight modifications, which would have the effect of allowing the candidates who had done well in the pass examination to proceed to the honours examination, would be far more satisfactory. The regulations for the preliminary scientific examination also stand in great need of amendment; as the present framed they have too little regard to the real requirements of the medical profession, and are too tender to the susceptibilities of the professors. A strict limitation of the examination to subjects which afford an education really preliminary to the strictly professional subjects would be an immense gain; and if candidates were to be permitted to take the subjects *seriatim*, the rigidity which is now so much complained of would be diminished.

It may be hoped, however, that the rumour which credits some members of the Senate with a disposition to increase the rigidity of the matriculation examination may turn out to be unfounded. That examination is already almost encyclopædic in extent, and has probably done more than any one other circumstance to deter students from becoming members of the Uni-

versity. It is no doubt true, as has often been urged, that a great many of the failures to pass or to attempt the examination are due to the fact that students of medicine are often not aware of the advantages conferred by matriculation until after they have entered at the medical schools, and are thus more or less committed to the curriculum of the Conjoint Board. But it is also true that the examination as a mere test, preliminary to entering on a university education, is absurdly severe. It is so severe owing to the immense number of subjects which must be passed simultaneously; if the University is ever to become a popular institution, ever to do the work which it was created to do, and might do, this examination will have to be revised. At present the educational enthusiasts on the Senate will hold up their hands in pious horror at the proposal to allow the Matriculation Examination to be passed in two parts, but every proposed reform has thrown them into the same attitude for a time. We firmly believe that a relaxation of the present hard and fast rules would add to the honour and dignity, as well as to the popularity, of the University, and would have the most beneficial effect on the higher education. A letter from the officers of the medical school of the Middlesex Hospital, which is printed at page 928, will show how hardly some of these regulations bear on men whom it would be to the advantage of the University to enrol among its members, and the fact that this reasonable request was not immediately acceded to will show how strong are the forces of obstruction within the Senate.

The University, moreover, might well do more than this for the medical profession. It must be remembered that the medical Faculty in this, as in other universities, has a closer relation with the life of a great profession than is the case with any other Faculty. The circumstances, moreover, of the medical student are different from those of the student of any other Faculty, because the curriculum is stringently prescribed by the General Medical Council acting in the interests of the public. Yet it is in this Faculty alone that the University of London, with that curious inability to march with the times which characterised its counsels until within the last year or two, has imposed a rigid curriculum. The time has now come when the degrees in Medicine may safely be given on the same terms as those in Science or in Arts. The University will give a degree in these Faculties to any undergraduate who can pass the necessary examination. Thus the degrees of B.A. or of B.Sc. can be obtained in less than two years from matriculation, and the candidate may be engaged—as, indeed, many are engaged during this period—in the exercise of a calling, as, for instance, that of a school teacher, by which he maintains himself.

We can conceive no sound objection to applying this precedent to degrees in medicine. There is a certain gratification in being able to quote a precedent, because thereby the party of obstruction is hoist with its own petard. Though the University is only half a century old, some of its Fellows speak as though all its regulations were sacred and inviolable. The University owes its existence to the crass obstinacy of the older universities in failing to move with the times, yet now

that these venerable bodies have begun to move, with, it may be, unexpected speed, there are some who desire to make the younger body stand still apparently as a protest.

The University of London might not only make this concession, but it might do much more; it might arrange to grant its degrees after proper examination to registered medical practitioners of a certain standing; there are many men who would gladly avail themselves of such an opportunity to gain a degree in medicine upon equitable terms, and we have reason to believe that a proposal of this nature will shortly be considered by the Senate. If the University discovers any serious desire to reform itself, it will undoubtedly be much strengthened when it goes before the Royal Commission which is about to be nominated. But if it is really to fill the place of a university for London it will have heartily to consent finally to lay aside the policy of immobility, which has governed it too long.

MR. RICHARD MIDDLEMORE has given £1,000 to the Birmingham and Midland Eye Hospital for the endowment of a lectureship.

WE understand that the differences at the Cancer Hospital are likely to be brought before a court of law, Mr. Jennings being the plaintiff in an action against Dr. Herbert Snow for alleged libel.

ROYAL COMMISSION ON UNIVERSITY EDUCATION IN LONDON.

LORD SELBORNE, who as Sir Roundell Palmer was for many years standing counsel for the Royal College of Physicians, will, we understand, be chairman of this Commission. The Commission will consist of seven members, and will not, we believe, include any member of the medical profession.

SIR HENRY ACLAND.

THE members of the General Medical Council proposed to invite Sir Henry Acland to a banquet in testimony of their sense of his past services as Chairman. Considerations of health connected with his recent ophthalmic operation have, we regret to learn, compelled him to decline the invitation.

STUDENTS OF GERMAN-SPEAKING UNIVERSITIES.

THE number of medical students in the following universities in the winter session just elapsed is:—In Vienna, 2,287; Munich, 1,369; Berlin, 1,316; Würzburg, 956; Leipzig, 794; Prague, 566; Graz, 501; Griefswald, 471; Breslau, 382; Freiburg, 350; Halle, 293; Bonn, 291; Zürich, 265; Marburg, 256; Erlangen, 255; Strasburg, 253; Königsberg, 243; Innsbruck, 243; Tübingen, 242; Berne, 233; Göttingen, 221; Kiel, 214; Heidelberg, 212; Jena, 201; Rostock, 136; Giessen, 134; Basle, 122.

BOLDIN, A NEW HYPNOTIC.

BOLDIN is the glucoside obtained from boldo leaves, and Dr. Junanville highly praises it in a recent number of the *Progress Médical*, as a hypnotic "far exceeding opium and chloral." This is saying a good deal for it. We are told also that boldin is not disagreeable to take, has no unpleasant effects, increases the appetite, and has a "strengthening" influence on the patient. Between 5 and 10 grammes were given daily to various patients. The sleep induced by this substance is of a natural kind, and the

breathing is regular and tranquil. Boldo leaves contain about 3 per cent. of boldin. It may be given in capsules in doses of 0.2 grammes (three grains), repeated as necessary, or (diluted 1 in 20 in water) subcutaneously.

THE GREAT INSURANCE FRAUDS.

FOR the credit of the "cloth" it ought to be known that "Dr. Henri Castelnau, who is now on his trial for having conspired with Scheurer and others to defraud certain insurance offices has no legal right to that learned prefix. He was educated for the medical profession, and had a fairly distinguished career as a student, having even held the much-coveted post of *interne*; but for some reason or other he never took his degree. Though a man of considerable ability, his whole life seems to be a record of failure, or worse. As a journalist, he is said to have used his opportunities of "candid friendship" to levy blackmail from prominent members of the profession. Nélaton, who had the misfortune to have been a fellow-student of his, was a favourite object of these polite attentions. Whenever Castelnau's funds were low, a gross personal attack on Nélaton was sure to appear in some journal, and the great surgeon was weak enough—more from good nature, it is supposed, than from any fear of awkward revelations—to stop his scurrilous mouth with money.

A LAW DISPENSARY.

THE boast of the medical profession that it alone of all the learned professions gives its services absolutely free to the deserving poor would appear to have excited the rivalry of some lawyers in New York, for it is reported that a "Law Dispensary" has been established in that city "under the auspices of reputable lawyers in connection with the Rev. Mr. Goss's People's Mission." This is a hint for the committee of lawyers in this country who call themselves the Society for the Preservation of Personal Rights, or so such name, and whose public appearances have reflected more honour on their forensic erudition than their common sense. The *Boston Medical and Surgical Journal*, in which we read this piece of news, truly observes: "It is to be hoped, however, that in the dearth of opportunity to give away advice on 'real property,' 'contracts,' 'wills,' and similar subjects, the philanthropic law-dispensers will not devote themselves to giving instruction as to actions of tort to such of their patrons as are also constant attendants at the multitudinous medical dispensaries. Too much of such advice has been given by lawyers in the past, and it is better dispensed with than dispensed."

THE TITHING OF MINT AND CUMMIN IN INDIA.

WE have had to notice, not with approbation, the style and frequency of the circulars issued from the office of the Surgeon-General at Simla to medical officers under his orders, as well as their too often vexatious and trivial nature. We are glad to learn that these Simla "circular showers" are more intermittent than they were. This is something; but we must be allowed to question whether the Surgeon-General cannot see his way to consult his own dignity and that of his profession, and the *amour propre* of his officers better than by (presumably at the suggestion of the apothecary it pleases him to substitute for the commissary secretary supplied by the State) issuing a circular on the breach of a hospital saltcellar, value some three farthings! We do not expect the apothecary-secretary to be familiar with the oft-quoted law maxim, *De minimis non curat lex*, but surely it cannot be strange to a man in the responsible position of the Chief Medical Officer of the army of India. When we reflect on the serious matters that should fill the minds of the Medical Staff of the army, it is with something more akin to sorrow than mere surprise that we see this highly-placed official thus taking "titling mint and cummin." The impression throughout both me-

vices in India is that the tours of the Surgeon-General and his thecary-secretary are more costly to the State than profitable to the sick, to say nothing of the irritation awakened in the minds of his highly-competent deputies, by this petty interference. If they cannot be trusted with the small details of hospital administration, on what principle can their pay, position, and authority be justified?

THE BRAZILIAN POISONING MYTH.

A appalling tale of wholesale poisoning of natives in Brazil which has gone the round of the press this week has now been officially contradicted. The story was, on the face of it, so grotesquely improbable that we are surprised it should have been believed for a moment. There was an epic completeness about the catastrophe which was in itself a highly suspicious feature. Granting that Senhor Joaquin Bueno (surely a most inconspicuous name in this connection) might have "conceived such a plan of campaign," it is difficult to see how it could have succeeded. Strychnine, as is well known, is most intensely bitter, and corrosive sublimate has a taste the reverse of agreeable. It is hardly credible that any large number of persons should have taken a poisonous dose of either of these substances at the same time; and in the case of strychnine, at least, the symptoms, both subjective and objective, are sufficiently pronounced to be at once ascertained even by ignorant people to their real cause. The first to eat the poisoned food or drink would no doubt perish, but the rest of their sufferings would effectually deter the survivors from following their example. On the whole, therefore, we cannot see that the tale of horror had even the merit of being well told.

MEDICAL CONGRESS IN SPAIN.

Independencia Medica states that a Medical Congress will be held at Barcelona from the 9th to the 15th of September, in connection with the Universal Exhibition which is shortly to be opened there. Among the subjects down for discussion we observe the following, which will suffice to show that our Spanish brethren are well abreast of the medicine and surgery of the day: Measures to be taken by the State for the prevention and cure of blindness; for the improvement of the condition of the blind in Spain; present state of leprosy in Spain, and how to prevent it from spreading; indications for surgical interference in intestinal obstruction; identity or difference of scrofula and tubercle; localisation of lesions in diseases of nervous centres; application of hypnosis and "suggestion" to the treatment of nervous affections; micro-organisms in mineral waters, their influence on the chemical constitution and therapeutic effects thereof; laparotomy as an exploratory measure in penetrating wounds of the abdomen (more especially gunshot wounds); antiseptic midwifery; etiology and prophylaxis of cholera and yellow fever. A Pharmaceutical Congress will meet at the same time.

THE PAY SYSTEM IN HOSPITALS.

A REPORTER on "The Pay System in Hospitals" was read by Mr. E. Lett Coultts, M.P., at a meeting held under the auspices of the Hospitals Association, at St. Thomas's Hospital, on Wednesday, April 25th, in which the opinion was expressed that, if a proper pay system were adopted in both the out-patient and in-patient departments, the extraordinary deficiency would be made up by the payments of patients. There was a great blot in the present system. Of charity there was enough; but, under the present system, what might be called the incidence of charity was wrong, those who could help themselves wholly or in part were helped entirely from charity, and those who could not help themselves were, therefore, pushed to a certain extent into the cold. Every man should, he advocated, pay what he could; and there should

be, where possible, a remunerative ward, such as St. Thomas's Home. He referred to the working of the pay system in the provinces, abroad, and particularly in America, as illustrating the advantages that might be expected from its adoption; and suggested a fixed scale of graduated payment, according to the class of ward occupied. Sir E. Hay Currie and Sir S. Waterlow thought it would be an injustice if the pay system were introduced at the expense of the provident system. If they could begin *de novo*, Sir S. Waterlow observed, he would like to see pay and free hospitals kept entirely distinct. Mr. Carr Gomm, Chairman of the London Hospital, thought the pay system would be an injustice and injury to the medical men in the district. The discussion on the paper was adjourned until June 20th.

THE EMPEROR OF GERMANY.

A SPECIAL telegram from Charlottenburg, received as we go to press, states that the Emperor is now able to take solid food with hearty appetite. The highest temperature on Wednesday was 102.3° F.; the lowest on Thursday morning 99.3° F. Less pus is discharged. The august patient feels better, but is rather weaker and thinner, as the result of fever and suppuration. This report agrees with those which have been published during the last two or three days, and may be looked upon as relatively favourable. It will, of course, be understood that it refers only to the incidental complications which have recently arisen, and not to the essential disease, which appears to make steady progress, though with alternations of quiescence and activity which have already on several occasions given rise to delusive hopes, followed by paroxysms of somewhat exaggerated alarm. We regret to see that the suspension of hostilities—diplomatic rather than based on any real "unanimity" though it may have been—agreed upon among the Emperor's medical advisers at San Remo, has come to a premature end. We think it due to Sir Morell Mackenzie and Mr. Hovell to point out that all the evidence shows that the truce was not broken by them. They were attacked in so grossly personal a manner by certain German newspapers, that they have been compelled to invoke the aid of the law. Actions for libel have already been instituted against the *Kölnische Zeitung* and the *Kreuz-Zeitung* for publishing definite accusations of professional incompetence which, we understand, have no shadow of foundation. From information we have received from a trustworthy source we have reason to believe that a false passage was made in replacing the tracheotomy tube, as this operation was followed by considerable hæmorrhage; but it can, we are informed, be clearly proved that neither of the Emperor's English medical attendants is responsible for this unfortunate occurrence.

TEACHING STUDENTS TO THINK.

It is often a subject of regret to teachers in our medical schools that the work of the first two years is so soon forgotten; a man who has passed his preliminary examinations frequently so far forgets his scientific subjects in six months as to be unable when in the hospital wards to give a description of the cerebral supply to parts of the body, the convolutions of the brain, and the cranial nerves, or the minute anatomy of the kidney and liver; still, such students may have dissected diligently, attended lectures, and read at night, but they have not learnt to think or are not trained to think systematically and correctly. This defect is, we suspect, not entirely the fault of the students, but is also in part due to defects in teaching. When observing students under examination, both for University degrees and on the lower examinations, it has often been obvious that failure to pass the standard may depend upon inaccurate methods of thinking and speaking—or upon no previous thinking—quite as much as from ignorance of the subject matter. Observing the objects of study

in the dissecting room does not necessarily teach thinking; to observe is to receive impressions, thinking may or may not follow observing. We have no intention of suggesting formal teaching of the laws of thought in the form of logic, though this useful science used to be one of the extra subjects in the Arts examination of the Apothecaries' Society. It does, however, seem needful to call attention to the importance of educating students to think as well as to observe facts; the scientific subjects and the teaching of medicine afford plenty of scope for both. The student is generally interested in the application of scientific knowledge to practice, and to show him such connections early in his career stimulates thinking. The constant application of anatomy, physiology, chemistry, comparative anatomy, and the principles and facts of vegetable biology, to what is seen in patients, produces an expansion of the subjects of thought, and engenders habits of correct thinking. To follow well made analogies, and to answer questions which exercise the imagination in a scientific manner, as in describing the minute conditions of circulation and the cause of nerve-currents in reflex actions, necessitates correct thinking. A student will often say that he hears a systolic mitral *bruit*, and is satisfied with his achievement, without understanding that the sound heard suggests an hypothesis which requires to be fully worked out before he can know the condition of the patient. A man well trained, not only in observation but also in rapid and correct thinking, will get through much more good work in practice than one less thoughtful. Thought, preceding action, guides him rapidly to make the necessary observations in the case before him, till thinking becomes automatic, and his opinions are rapidly formed upon brief observations, and what is ill termed "clinical instinct." In making these remarks we by no means wish to depreciate the necessity of thorough and systematic examination of all the organs as a matter of primary necessity.

LOCAL GOVERNMENT BILL.

THERE is one aspect of the working of the new Local Government Bill, in respect to its 11th clause, which has not yet received the attention it deserves, and unless that clause be modified it will undoubtedly have the effect of creating a new monopoly, to the detriment of the public, and to the benefit of landlords, wine merchants, and publicans. At present the granting of "off" licences, that is, of licences for wines, etc., sold in sealed vessels in given quantities, and not to be consumed on the premises, is limited only by certain conditions of a formal character, intended to ensure respectability on the part of the vender. The provision has worked exceedingly well, and as a Committee of the House of Lords ascertained, and as we have always contended, it has a two-fold advantage. It has secured to the middle classes a supply in every small district of wines, etc., which they desire to use in their own homes, of good quality, and at moderate price, and by reducing the value of the monopoly of the publican and the temptation to drink in public-houses, has worked in every way for the public good. If now on the operation of the Bill this, too, becomes a monopoly in a few hands, the first effect will be to give an immense bonus to landlords, who will at once raise rentals. It is known that this effect is already beginning to operate, and that renewals of leases are only being made under conditions of increased rental if this clause should become law. It is the force of the vested interests, and the immense accumulated fund created by the monopoly in the beer and spirit trade, which has made that question so difficult and so costly to deal with; and it is much to be hoped, in the interests of the general public, that such a mistake will not be committed in the present legislation. The great object should be, while satisfying all legitimate requirements of those who wish to consume alcoholic liquors, whether in the form of wines or spirits, in their houses, to diminish the temptation for drinking in public-houses, and to avoid adding to the value of the

existing monopoly of landlords and publicans. Clause 11, although no doubt framed with the best intentions, will really, as the Bill at present stands, have no other effect than to present a magnificent bonus to both these classes, with the immediate result of adding to the cost of the wine used by the middle classes, for it is the holders of the "off" licences who practically supply the wine cellars. To cut off arbitrarily the trade of the holders of "off" licences who have held them in many instances for twenty-five years, without any corresponding advantage to the public but really to the public detriment, would be an act of confiscation which has nothing to justify it. If all licences were to be confiscated without compensation, we should have no objection to make, but the class of traders whose trade is the most blameless and least open to abuse ought not to be made to suffer alone.

THE VIVISECTION ACT AND THE INOCULATION OF ANIMALS.

THE President of the Privy Council (Lord Cranbrook) and the Home Secretary (Mr. Matthews) received a deputation from the Royal Agricultural Society and the Royal Veterinary College on Tuesday last to urge that the Vivisection Act should be amended so as to allow of inoculation of animals and prevention of disease. Lord Egerton of Tatten, and Professor Brown having spoken, the Home Secretary said that the difficulty all arose from the use of the word "experiment" in the Act. The Act did not define the word, and he was bound therefore to apply it. Professor Brown agreed with his own interpretation; but the professor suggested that there should be this addition made, not a belief that the operation performed would produce good results, in which case it would become treatment and be exempted under the Act, but that if there was a *bona fide* desire to benefit the animal without a belief or knowledge one way or the other whether it would benefit the animal or not, that that should be taken out of the class of experiment and put into the class of treatment. But such a case as that would come perilously near to the experimental stage. Mr. M. W. Ridley said Professor Brown had been carrying on experiments for two years with reference to swine fever, and he had come to the conclusion that a certain injection into the skin of the pig would most probably protect from swine fever not only the particular pig operated upon, but the whole tribe of pigs. He was allowed to have this performed by competent veterinary surgeons all over the country. Lord Cranbrook thought it was pity that they had not the decision of a court of law upon the subject; and if that should be against them, then they might get remedied by Parliament. The Home Secretary observed that unless some action of this kind were taken he was afraid they would not get the House of Commons to amend the Act. The deputation then withdrew.

NURSE-REGISTRATION.

WHETHER nursing is to be regarded as a trade or profession, there can be little doubt that its claims to public sympathy have won for it a place in public esteem very different from that which was thought possible to attain a few years ago. Many cases have contributed to this result. Perhaps the most influential of all can be traced to the establishment of nurse training schools in most of the large and in some of the smaller hospitals where young women of good character and antecedents, as well as gentlewomen are initiated to the work. With its progressive development, it is not surprising that there should be a desire expressed to regulate the employment, by instituting an educational curriculum to which all nurses should be subject. Upwards of a year ago a movement was set on foot by the Hospitals Association having this object in view, as well as to consider the expediency of establishing a collective register for qualified nurses, since there is every reason to expect that at no distant date the whole subject

their educational training and the practice of their art might be considered worthy of legal supervision. From inquiries made at the chief hospital centres it appears very doubtful whether the matter is ripe for adjustment, nor is there any agreement among the authorities consulted as to the body to whom such a power should be delegated. The whole question is bristling with difficulties, not likely to be lessened by the ardour of the enthusiasts who are now loudly clamouring for legislation on their behalf, without giving a thought of the dangers in their path. We have the greatest possible sympathy with the women and their work, but we are not prepared to follow the lead of any association which professes to represent the vocation, far less to promote legislation in its behalf, without first ascertaining from an exhaustive inquiry what are the needs and wishes of the many. The heterogeneous character of the class now following nursing as a means of livelihood, and the various branches of the art practised in town and country, render it very inadvisable that it should be placed under an exclusive jurisdiction. The important interests involved, ranging from those of the cultured lady-superintendent to the nurse who dispenses her medical comforts to the village poor, are numerous and conflicting; nor is it the technical knowledge or hospital experience, however valuable, which renders the nurse best fitted for her work. Too little account is taken of those natural gifts of temper, tact, and disposition, which cannot be registered, but which after all contribute more essentially than anything else to the formation of character in a nurse. Nor is it to be supposed that the midwife, the monthly nurse, and the masseuse or other specialist can take common ground with the certificated hospital nurse, who has spent some of the best years of her life at a small remuneration, that she may arrive at a supposed standard of efficiency, or, rather, that she may conform to the exigencies of the hospital in which her lot is cast. It is but fair that the distinctive terms "binding" and "training," which in practice are almost synonymous, should be better understood. The binding renders the probationer subject to a moral contract to continuous employment for periods varying from two to three or more years, and may prove advantageous to herself, as it certainly does to the hospital which receives her services, but it hardly meets the approval of charitable and other agencies, which must be at the cost of training their own nurses in separate institutions, for the special duties they will afterwards be called on to perform. Co-operation is, no doubt, a good thing when it can be managed without friction, but, in the face of the great diversity of opinion which exists on the subject, coupled with the manifest obstacles to harmonious action inherent in a novel organisation, the question of collective nurse-registration is not ripe for solution. Let each hospital and training school look well to its own register, and to the educational facilities afforded to its nurses, so that it may be possible in the course of time to adopt one uniform basis which would be acceptable alike to the leading hospitals, the profession, and the public.

SCOTLAND.

We are informed that Professor Rutherford has returned to Edinburgh, and will resume his duties on May 1st. It ought to have been stated in a paragraph published a fortnight ago that Dr. J. Berry Haycraft, who has conducted the course of Physiology during the last winter, took an equal share in the recent Second Professional Examination with Dr. Caton and Dr. Paton.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

At the meeting of the Obstetrical Section, Dr. Stirten read notes of forty cases of uterine fibroids, treated by Apostoli's method. About one-half of the cases had been benefited by the treatment.

The harder and more encapsuled the tumour, the less was the effect produced; while the more rapidly growing tumours, and especially those endangering life by profuse hæmorrhage, were most amenable to the treatment.

GLASGOW SOUTHERN MEDICAL SOCIETY.

Dr. ARCHIBALD JOHNSTONE showed an interesting case of extroversion of the bladder in a child aged 4½ months. Dr. Gilmour also showed drawings of a similar deformity in a boy aged 10 who had formerly been under his care, and described the nature of the defect in development and the treatment of such cases.

GLASGOW UNIVERSITY UNION.

A LITTLE more than three years ago it was resolved, at a largely attended meeting of the students and graduates of Glasgow University, to establish a University Union, and a Committee was appointed to carry this resolution into effect. This Committee had just commenced its duties when it was announced that a gentleman, whose name was not at first disclosed, but who is now known to be Dr. John McIntyre, Odiham, Hants, had offered to the Senate the sum of £5,000 for the purpose of providing the necessary building. The offer was promptly accepted, and a suitable building has now been erected on the University grounds, and is almost ready for occupation. The building contains a large hall for debates, a spacious library and reading room, a dining room, smoking room, several committee rooms, porter's house, and other accommodation. To provide the funds necessary for its furnishing and for a sufficient endowment for its maintenance, it is proposed to hold a fancy fair early next year.

THE UNIVERSITIES (SCOTLAND) BILL.

THE Senate of the Glasgow University have forwarded to the Secretary for Scotland a memorandum setting forth their views in regard to university legislation. The Senate approve generally of the new Bill, but strongly object to the affiliation clauses, as introducing a principle of an altogether novel and unprecedented character, and involving fundamental changes in the Scotch university system. The subject of affiliation is not one on which public opinion is ripe, and is surrounded by difficulties and complications which have not been considered in the drafting of the Bill, or which it makes no attempt to solve. These clauses should therefore be deleted from the Bill, and the Commissioners be instructed to take the whole matter into their careful consideration, and report to the Queen in Council. The Senate also object to the great diminution of their powers, and their altered relations to the University Court. They hold it to be essential that the Senate should retain the whole of the educational functions they have hitherto exercised, and that if any power of initiation in such matters be granted to the Court, it should be exercised only after reference to, and report by, the Senate. At the usual monthly meeting the governors of Glasgow Technical College resolved, after discussion, to approve the Bill as a whole; while desirous that in any new system arrangements be made for enabling the teachers of the College to qualify in part for university degrees, they considered it essential that the governing bodies of colleges thus affiliated should retain full control over their own finances and internal arrangements. They were therefore strongly opposed to the provisions of the Bill by which affiliated colleges would be brought under the control of the University Court, and resolved to petition in favour of the Bill as a whole, reserving the subject of affiliation for the consideration of the Commissioners.

ST. MUNGO'S COLLEGE BILL.

A SPECIAL general meeting of the Merchant's House was held on April 19th to consider the Universities Bill and the St. Mungo College Bill. The Chairman, Lord Dean of Exild, moved "that this meeting express approval of the intent and principles of the

Universities (Scotland) Bill, and generally of its provisions, but strenuously object to the proposal contained in Clause 14 (1) to transfer the patronage of bursaries now vested in private individuals, or corporate or other bodies, to the University Court, and are of opinion (1) that more full provision should be made in the Bill for the recognition by university courts of the certificates of extra-mural teachers as qualifying students for examination for university degrees; and (2) providing for such examinations being conducted by persons other than teachers of the students applying for examination." This very remarkable resolution, showing how thoroughly some of the gentlemen of the Merchant's House understand medical affairs in Glasgow, was carried unanimously. Thereafter, on the motion of Mr. William Macewen, it was unanimously resolved to petition Parliament in favour of the St. Mungo's College Bill, and the Chairman, ex-Lord Provost Ure, and Mr. Macewen were appointed a committee to proceed to London, if necessary, in the interests of the Merchant's House to promote the passing of the Bill. The University Club, of which Mr. J. S. Campbell, M.P., is Honorary President, has petitioned against the Bill. Ayr Town Council, at a special meeting on April 20th, after hearing a deputation consisting of Dr. McVail, Sir James Bain, and Mr. George Gibson, also unanimously agreed to petition in favour of the Bill.

THE PRIVILEGES OF THE ROYAL COLLEGES OF EDINBURGH.

THE privileges of the Fellows of the Royal Colleges of Physicians and Surgeons of Edinburgh, in respect of hospital and other similar appointments, have just been called in question. Dr. John Haddon recently raised the question in the General Council of Edinburgh University, and moved a resolution bringing before the University Court the gross injustice and great hardships to medical men in Edinburgh that the degree of Doctor of Medicine of Edinburgh University was not recognised by the rules of any of the medical charities in Edinburgh, and asking that steps be taken to obtain that all Doctors of Medicine should be fully qualified to hold appointments in these charities. Dr. Haddon drew especial attention to the Royal Infirmary, where the only acknowledged qualification was the Fellowship of the Royal College of Physicians. Dr. Peel Ritchie, President of the Royal College of Physicians, deprecated the transmission of the motion on the grounds of inexpediency, inasmuch as the University and the Royal Colleges were acting in perfect harmony. Discussing the merits of the question, he drew attention, in a historical sketch, to the position which the Royal College of Physicians occupied as the founders of the Royal Infirmary. Dr. Cadell moved a direct negative to Dr. Haddon's proposal. Ultimately, on the motion of the Rev. Professor Flint, it was agreed by a majority to transmit Dr. Haddon's motion to the University Court, without expressing any judgment on it.

IRELAND.

OUTBREAK OF MEASLES IN DROGHEDA UNION.

DR. CALLAN, medical officer of the union, has reported that an epidemic of measles has broken out in his district; also sporadic cases of German measles. No cases, so far, have resulted fatally and precautions have been taken to prevent the disease from spreading.

THE VACANT INSPECTORSHIP, LOCAL GOVERNMENT BOARD.

DR. EDWARD THOMPSON, surgeon to the Omagh Infirmary, has been selected as inspector under the Local Government Board, in room of Dr. O'Farrell, appointed to the Prisons Board. The probability of this appointment has been already referred to in the

JOURNAL. There is much dissatisfaction because so many other excellent candidates, who had the advantage of being trained in the service, have been passed over.

A MEDICAL PRACTITIONER SENT TO PRISON.

AT the Armagh Quarter Sessions, held recently, Dr. Arthur McKeown was sentenced to three months' imprisonment with hard labour for having assaulted a bailiff last February. As Dr. McKeown has offered to give compensation to the bailiff, a memorial will be forwarded to the Lord-Lieutenant that the sentence be reduced.

THE FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS, IRELAND.

THE Council of the College of Surgeons has just issued revised rules in reference to the Fellowship. From and after October, 1888, candidates will be examined in the months of January, May, and November. There will still be two grades—candidates under ten years' standing, and candidates of more than ten years' standing. For the first grade there will be a written examination in anatomy, physiology, and surgery, extending over six hours. Second day, oral surgery, one hour; surgical pathology, half an hour. Third day, clinical surgery, one hour; histology (laboratory), one hour; dissections, half an hour; oral, anatomy, one hour; physiology, half an hour. Fourth day, operative surgery, one hour. Grade II.—First day, papers: surgical anatomy, three hours; surgery, three hours. Second day, oral surgery, three-quarters of an hour; morbid anatomy, quarter of an hour; clinical surgery, one hour. Third day, operative surgery, one hour; surgical anatomy, half an hour. A gross total of 60 per cent. shall be considered the passing mark. A candidate who has scored less than 60 per cent. but more than 30 per cent. in a particular subject or subjects other than anatomy and surgery, shall be passed or rejected by the majority's vote of the whole Court. Licentiates of the College will be permitted to present themselves for the primary part of the examination at any period after their admission as Licentiates.

UNIVERSITY OF LONDON: APPOINTMENT OF EXAMINERS.—At the meeting of the Senate, held on April 25th, the following gentlemen were appointed examiners for the ensuing year in the Faculty of Medicine: Dr. Cayley and Professor F. T. Roberts, in Medicine; Mr. Marrant Baker and Professor Christopher Heath, in Surgery; Professor Curnow and Dr. Alexander Macalister, in Anatomy; Professor Schäfer and Mr. J. N. Langley, in Physiology; Dr. Champneys and Professor John Williams, in Obstetric Medicine; Dr. Bruce and Dr. Frederick Taylor, in Materia Medica and Pharmaceutical Chemistry; Professor Poore and Dr. Stevenson, in Forensic Medicine.

PROVIDENT SURGICAL APPLIANCE SOCIETY.—This Society, of which the sixteenth anniversary festival was held last week, has since 1872 been doing a useful work in supplying patients of small means with surgical appliances or artificial limbs of the best manufacture at nominal prices, or on a provident system of payment. Since its foundation 42,000 articles have in this way been issued by the Society; and with the object of extending the usefulness of this Society, a branch has this year been successfully opened at Norwich.

MEDICAL MAGISTRATE.—Dr. Thomas Allan Wotherspoon, of Brampton, has been placed on the Commission of the Peace for the County of Cumberland.

THE Committee on Pleuro-pneumonia and Tuberculosis, appointed by the Agricultural Department of the Privy Council, have chosen Mr. Jacob Wilson as Chairman; Mr. Victor Horsley is a member of the Committee.

ARRANGEMENTS for holding an international exhibition at Carlsbad, during the summer season of 1889, have been definitively made.

THE prizes in the Faculty of Medicine of University College will be distributed by Mr. John Marshall, President of the General Medical Council, on May 17th, at 3 P.M.

LIST OF AUTHORS AND OTHERS WHO HAVE PRESENTED BOOKS TO THE LIBRARY OF THE BRITISH MEDICAL ASSOCIATION.

Presented by J. S. BARTNUM, Esq., Bath.

THE SANITARY CONDITION OF HAILEYBURY COLLEGE, HERTFORD.

Owing to several cases of diphtheria suddenly breaking out at Haileybury College during last term, which resulted in the death of one boy, the illness of five others, and the consequent breaking up of the school before the Easter vacation, we instructed our Special Commissioner to visit the College and investigate its sanitary condition, so as to enable us, if possible, to allay the anxiety which has arisen amongst the parents and friends of the boys owing to the sudden breaking up of the school; and to point out if possible, to the governing Council any existing flaws in the sanitary arrangements for the advantage of the future.

Our Commissioner, Mr. E. Bailey-Denton, visited Haileybury on April 7th, and reports as follows:—
 "I carefully inspected Haileybury College, in company with the College Steward, on Saturday, April 7th, with the ready permission of the Rev. James Robertson, the Head Master, who kindly consented to my inspecting everything in and about the place, so that I might the more accurately discover and realise its sanitary condition.

For the sake of clearness and distinction, I purpose dividing my remarks under three heads: I. General Sanitation; II. Water Supply; and III. Milk Supply.

I.—SANITATION.

The College is situated about two miles from Hertford, on a hill and in a position as naturally conducive to health as would be a peer possible.

External Arrangements.—The liquid refuse of Haileybury College is conveyed by 15-inch pipes to a small sewage farm situated at a distance of about one-third of a mile from the building, where it is applied to eleven acres of land by means of surface irrigation. The position of the farm is isolated, and its condition, though perhaps not showing the tidiness which ought to distinguish sewage farms, is certainly not such as to be in any way prejudicial to health. There are no tanks for the deposition of solid matter, and consequently no concentration of bad smells; the fresh sewage is applied to the land without any treatment, and the effluent, after passing over it, flows into a brook in an unobjectionable condition, though not critically pure. The outfall sewer from the College to the farm is well ventilated, has a good gradient, and is effectually disconnected from the College at the upper end. It is, therefore, next to impossible for any gases generated along its course to find their way into the school building to disseminate disease. All the rain-water and other pipes are disconnected from the sewer, and discharge their contents into traps, whilst all junction chambers have ventilating shafts carried up to the roof of the College, out of the way of the upper window.

There are no water-closets upon the premises, either for the use of the boys or servants, and only two in the Master's house. Earth closets, which are kept very clean and attended to daily, are adopted throughout. The earth before use is carefully dried and sifted, and after use is kept in open sheds, mixed with cinders, and utilised on a garden specially reserved for the purpose. When the manurial properties have been extracted, the earth is again used, and thus the system is regularly maintained. The urinals are

pt filled with sawdust, which is removed daily and utilised on the land.

The laundry and bakery attached to the College are both exceptionally clean and perfectly disconnected with the sewers, and the swimming bath and gymnasium are all that could be desired.

Internal Arrangements.—The kitchens, sculleries, and pantries are clean and sweet, showing clearly that the upper servants are true to their responsibility and duties. The dormitory slop-sinks and baths, which are sufficiently numerous for all purposes, and amply supplied with hot and cold water, are disconnected from the sewers. One earth closet is fixed and attached to each dormitory for night use.

The air space allotted to the boys throughout the dormitories is good, being 800 cubic feet in the older and about 1,000 cubic feet in the modern rooms. The ventilation, however, is not so satisfactory as it should be, although there is nothing connected with it which could be called a factor for the propagation of disease. The method adopted of allowing the foul air of the lower dormitories to escape by openings in the ceilings, and, after mixture with fresh air brought in from the outside between the dormitories, to enter the upper dormitories at the floor level, is wrong in principle, and should be certainly remedied. The medical officer of health, indeed, allows that this method of ventilation is faulty, and he states that it has, in consequence, been condemned. In his annual report to the Council for 1887, he states, "The system of ventilation cannot be considered satisfactory." In my opinion, it could be easily improved, at a small outlay, without any material alteration of the buildings, and, no doubt, the governing body will sanction the improvement without further delay. The "Tobin tubes" in the "sick house" are not placed at a proper level to secure ventilation without discomfort to the inmates.

The arrangements for sick boys at Haileybury have been well considered, and are satisfactorily carried out. Those suffering from temporary disorders of a non-contagious character are kept in the "sick house," which is a part of the College itself; whilst those suffering from contagious complaints are relegated to the "sanatorium," which is a spacious building standing well away from the college, where the best possible medical attention and care are bestowed on them.

It will be seen by the above remarks that the sanitation of Haileybury is decidedly good, and, indeed, I believe there are few public schools in the kingdom which can compare with it; it is, therefore, all the more necessary that the authorities should remove the only flaw in its character—that is, the dormitory ventilation. One more remark only is necessary under the head of aerial sanitation, and that is, that the state of the ditches in Little Wymondley, a village close to the College, where the boys constantly play, is objectionable. These ditches apparently contain sewage matter, and in the summer must emit effluvia of a malarial character. The College authorities should bring pressure to bear to remedy this evil.

II.—WATER SUPPLY.

The water supply is derived from a deep well under the building, passing through the clay to a depth of about 50 feet into the chalk, the total depth to the bottom of the well being 228 feet. The water is pumped up from this well by a $7\frac{1}{2}$ h-p. steam engine to a tank at the top of a water tower, whence it is distributed, after undergoing Porter Clarke's water-softening process, to the various cisterns throughout the College.

There is no doubt whatever that the position of the well is inviting to pollution, which no amount of steining and clay puddling can prevent. The very reason which the late Dr. de Chaumont gave, when he was called upon to report on an outbreak of typhoid fever which occurred at Haileybury in 1881, "that the water cannot be contaminated because it passes through clay before reaching the chalk," appears to prove the reverse; for the water comes discoloured with clayey material. It would appear, therefore, that some disturbing influence causes this discoloration, which, if it has not already been proved so, turn out to be pollution. It is not within the province of a civil engineer to analyse water, especially as I understand that Dr. Stevenson, of Guy's Hospital, has been lately supplied with a sample for analysis, which will probably throw some light on its present quality. The public will anxiously await his verdict; but, in the meantime, I should fail in my duty if I did not state that the proximity of the well, notwithstanding its depth and its steining, to the urinals and various gulleys down which sewage is thrown, suggests dan-

ger. Any well in close proximity to a large establishment, and immediately under the foundations of the building, receives by ordinary gravitation the oozing wetness of the ground, and in time allows polluting matter to descend with it to the water level by imperceptible passage, either inside or outside the brickwork with which such well may be steined; and the fact that the water does at certain seasons become discoloured, as I myself saw, proves that the views I have expressed cannot be far fetched.

It would be impossible to say that any of the cases of diphtheria which recently occurred are in any way traceable to the drinking of polluted water from the well in question, for none of the other 478 boys, or any of the masters, their children or servants, who all drank of the same water, and who practically breathed the same air, suffered in like manner, whilst the previous analysis made by Dr. Stevenson showed the water to be "pure." The last samples handed to him contained, I am told, yellowish vegetable matter, which, the authorities aver, enters the well at the bottom after percolating laterally from the Lea, through the chalk and clay, and must, therefore, be innocuous. Many people will probably decline to accept this conclusion; and as no expert can decide the case on the present premises, it may be well to consider if the presence of vegetable matter is not due to imperceptible soakage from the surface immediately above the well.

III.—MILK SUPPLY.

The milk supply for both masters and boys is derived from a farm at Hertingfordbury, about five miles distant from Haileybury, in the occupation of Mr. Wells, who has supplied the College for some few years. The dairy and cowhouses at this farm are healthy and good, and all the dairy utensils were upon the day of my visit, which was quite unexpected, clean and sweet.

The water for cooling the milk and general washing purposes is obtained from a well sunk in the chalk in proximity to the farm buildings, whence it is pumped into a tank over the cow-house. It is here that I consider that there is a serious defect in arrangement. This tank is placed in the roof of the cow-house itself, with the cooling apparatus beneath it. There can be no doubt that this is open to much objection; for the fœtid impurities of the air, due to the emanations from twenty-one cows, standing in one building, especially when confined at night time, must to a certain extent be absorbed by the water. I have no hesitation, therefore, in saying that the College authorities should require the removal of this tank to a more suitable and healthy position.

Summary.—Having thus reviewed in detail the sanitary arrangements of the College, with a view, if possible, to trace the cause of the late outbreak of diphtheria, I admit that I cannot directly connect it with anything associated with that establishment.

The history of the outbreak is briefly this: Two new boys, who were inseparable companions, went for their *evreat* together on March 5th, returning to the school on March 7th, and were admitted to the sanatorium on March 19th and 20th, suffering from diphtheria. Between the 22nd and 28th of the same month, four more cases were admitted—the first two were severe cases, resulting in one death; and the remaining four were mild in character.

The cause of the outbreak, therefore, must, in my opinion, be sought in the first-mentioned case; and, in fairness to the College authorities, who, in conjunction with their medical officer, Dr. Shelly, are most anxious to discover the origin, I would add that, until the patient who is now on the road to recovery is sufficiently well to be questioned as to where he and his friend went, what they did, and what they drank on their way to and from their homes on the occasion of their *evreat*, all judgment should be suspended.

Under any circumstances, I am of opinion that, in order to place Haileybury where it ought to be, in the foremost rank of public schools *quâ* health, and to avoid the suspicion attached to the well, the school authorities should consider whether they might not advantageously change its position; for the subterranean source of supply would be the same in any case; and in like manner they would do well immediately to perfect the dormitory ventilation, and remedy the faulty arrangements at the farm at Hertingfordbury, whence the milk supply is obtained.

BEQUESTS.—The trustees of the late Mr. D. Maclure, lithographer, of Glasgow, have ordered payment of the following legacies, among others, free of duty:—Royal and Western Infirmary, each £25; Eye Infirmary, £10; Lock Hospital and Home for Incurables, £10.

THE SOCIETY OF MEDICAL OFFICERS OF HEALTH AND THE LOCAL GOVERNMENT BILL.

THE provisions of the Local Government Bill as affecting sanitary administration were discussed at some length by the Society of Medical Officers of Health at a meeting held on Friday, April 20th, at the Scottish Corporation Hall, Crane Court, Fleet Street, Dr. ALFRED HILL, President, in the chair.

The CHAIRMAN reported that the subject had already been under the consideration of the Council, who suggested the opinion "that the interests of the public would be best served by the appointment of medical officers being entirely vested in the County Councils, instead of in the District Councils, as arranged in the Local Government Bill." The Chairman reported that a meeting had been held an hour before, convened by some of the principal medical officers of combined districts in the country, who were most nearly interested in the matter, and he was pleased to say there seemed to be a very common feeling that the propositions submitted by those gentlemen were acceptable to the general body of medical officers. In fact their first resolution, passed without the knowledge of the Council, was very much the same in effect as the resolution of the Council, and he hoped in general meeting they would be able to fix on some form which should meet the views of gentlemen of combined districts as well as of the meeting generally.

Dr. WILSON proposed, and it was seconded and carried, "That the report of the Council be adopted."

The following resolution, passed at the informal meeting, was now read:—"That as the Bill proposes to transfer to the County Councils the powers for uniting sanitary districts for the appointment of medical officers which are now vested in the Local Government Board, it is desirable in the interests of increased efficiency and economy that these powers should be generally exercised as regards all urban and small rural districts, and that the appointment of medical officers of health should be entirely vested in the County Councils, instead of being primarily in the District Councils, as at present provided by the Bill."

Dr. WILSON'S opinion was, when he read the notice on the agenda paper that it hardly went far enough, and that some definite opinion should be expressed as to the impossibility of medical officers of health holding appointments in rural and small urban districts and still being allowed to practise. He thought it impossible that these gentlemen could discharge their duties satisfactorily to the public and to their private patients. They wished, if possible, for some expression of opinion from the Council as regards the doing away of appointments in some small urban and rural districts.

Dr. ARMISTEAD (Cambridge) proposed as an amendment words identical with the words of the resolution of the Council given above. He thought it would be a mistake to go beyond that, and that all that Dr. Wilson desired would follow as a matter of course. If the appointments were vested entirely in the County Councils, it was not likely for their own sake they would have more medical advisers than they could possibly avoid. The counties of Rutland, Huntingdon, and Bedford, were contrasted with Liverpool with its population of 550,000, Manchester with something like 300,000, each managed by one medical officer. Why, he asked, should a County Council, with only a population of 5,000, require more than one medical officer? And the same with the county of Rutland. They might safely say every county with a population of less than 100,000 would not require more than one medical officer; a county with 200,000 would probably require two. The larger counties, such as Yorkshire and Lancashire, would have their numbers diminished by the creation of the new counties.

A MEMBER asked what compensation would be given to members who were squeezed out?

Dr. ARMISTEAD replied by asking what compensation could be given to medical officers who were at present engaged in private practice, and who only held their certificates for one year, at the end of which they would have to be reappointed by the County Councils instead of the District Councils, and they would not appoint more than they could possibly avoid. There was Essex with twenty-four medical officers, and the county of Cheshire with thirty-four. Of this number thirty-two were appointed to one-tenth of the county, and the other two medical officers were responsible for the rest.

Dr. ARMSTRONG (Newcastle) said Dr. Robinson had spoken of

advisers to the Council. He should very much like to see some thing introduced into the Bill referring to a larger set of officers than mere officers of what he would call combined districts. If thought they were limiting themselves to a body whose income would average something like £600 to £700 a year, and that it was detrimental to the public service and themselves as a whole. There should be a larger set of officers than those whose income would average £600 or £700 a year—a superintending officer appointed as adviser to one, or possibly to two, County Councils. It would, he thought, raise their status, and Mr. Stanhope's speech of the previous evening tended, he thought, to underrate the position of the medical officer.

Dr. BOND (Gloucester) agreed that they should look upon the matter from the broadest possible point of view. He thought they would have no *locus standi* either with Mr. Ritchie or the Government if they were not prepared to show that any recommendations they made were made in the interests of the public. He thought it desirable that they should not introduce details more than absolutely necessary, and that they should limit their recommendations as far as possible to matters of prime urgency. There were, it seemed to him, two great blots in the Bill. One was that it perpetuated a system by which medical officers of health in rural and small urban districts were primarily elected by what would be the local District Councils, and the other was that although the Bill imposed upon the County Councils very large and important supervisory functions, it made no provision whatever for attaching to these Councils any competent advice or assistance—such assistance as was provided by the Local Government Board at the present time (from whom there was to be a large devolution of powers), such as was possessed by the smaller sanitary authority. He thought if they saw their way to meet those two essential blots, they would accomplish all they wished to achieve. The only other matter to which he wished to refer was the blot referred to by Sir Lyon Playfair in his admirable speech, and that was that all reports and returns were to be made according to the Bill as at present drafted, directly to the Local Government Board without the County Councils having any means of acquainting themselves with the contents of these documents, and therefore of being adequately acquainted with the sanitary condition of their district. The Government, it appeared, had recognised the blot, and Mr. Stanhope, referring to Sir Lyon Playfair's criticism, said "there was no reason why copies of these reports should not be furnished to the County Councils. That could obviously be effected in one of two ways, either by the Local Government Board sending down to report, or what seemed to be a more simple way, that all reports should be first transmitted to the County Councils, and then to the Local Government Board. They might assume that that deficiency in the Bill would certainly be rectified. They had before them at the present time only the consideration of the first—namely, the desirability of transferring to the County Councils the appointment of medical officers of health, and he thought that was a position which could be amply justified on the grounds both of increased efficiency and economy. He thought it was sufficiently recognised that, at any rate, it was desirable to make the areas supervised by medical officers of health large rather than small; and that was admitted, it followed as a matter of course the principle of combination must be adopted in some shape or form, or might be entirely superseded by the fact that the County Councils, having the appointment of all medical officers of health, would practically make combinations of their own by either appointing one officer for the whole county, or one officer for each section of a county, as they might consider it advisable in the interests of the public. He thought confidence should be shown by giving the County Councils the largest possible powers to do what they considered right in the public interest. It had been asked what did they propose to do with all the medical officers of health now in existence? Did they propose to supersede them all at once? He neither proposed nor suggested it. He thought it exceedingly undesirable to make violent or sudden changes in their organisation. What they had got to do was to look at existing facts as existing facts, and to make the best of them, but to take care in the future they would effect improvement gradually as opportunity arose. He thought if that fact was distinctly impressed upon the President of the Local Government Board, and if it could in any way be incorporated in the Bill, it would answer every reasonable objection. If the County Councils could have it statutorily imposed upon them to effect combinations, or rather to avail themselves, as opportunity

y occurred, of enlarging the areas of sanitary supervision, he thought they would have laid the foundation for what would ultimately be the most desirable arrangement—the enlargement of the areas of sanitary supervision by the medical officer of health to the largest extent compatible with efficient work. He (Dr. Bond) and Dr. Wilson had drafted a modification of the proposal of the Council, in which it was suggested that the principle of combination should be carried out as opportunity arose. He did not wish to enforce that modification if it was not considered advisable. He hoped they would have an opportunity of submitting their view to the President of the Local Government Board, and it would be sufficient then to be prepared, if he raised an objection, to meet it by admitting that they did not desire a violent disturbance of the existing system of things; all they suggested was that the County Councils should be invested with the largest possible powers in regard to the appointment of all medical officers of health, and then that it should be left to them to consolidate, when and as they might see it desirable to do so in the interests of the public.

Dr. TATHAM said that, having carefully considered the Bill in relation to sanitary administration, it struck him that if the suggestion made could be adopted, the President of the Local Government Board would be simply extending to the counties the principle which he admitted worked so well in the boroughs. He did not know of any borough in England in which the duties of that borough appointed a medical officer separately, and Dr. Ritchie would not be inconsistent if he applied the same principle to the County Councils. He agreed with Dr. Bond on the question of what was to be done with the present medical officers. He knew it to be the fact that there was a large number of badly paid officers who would be exceedingly glad to be relieved of their present duties; as regards the other men who took up public health work because they liked it, he thought there would be no means easily found for extending their work and giving them more to do; and they might trust to the process of evolution to take matters right.

Dr. HIME said reference had been made to the possibility of the services of gentlemen being cut off, and their means of livelihood, and the action of the Bill. He did not think their sufferings would be very great in the case of gentlemen who received the munificent sum of £3 a year for devoting scientific energies to an area of 1000 acres, and including many thousands of individuals. Referring to points in the Bill as to which he thought representations could be made and pressed upon the Government, Dr. Hime spoke of the unsatisfactory character of the vaccination clauses in the Bill. He thought it by no means a foregone conclusion at the County Councils when appointed under the Bill would amalgamate districts; the experience of the past and the present had been just the opposite. He did not think there was any reason to suppose the County Councils would act differently. So far as he could judge, the County Councils would be elected by the same franchise as the Borough Councils and local boards, and he could not see that they were to anticipate that the County Councils would consist of men of a superior type to the existing ones. He thought their representations should go into some detail, and that the adoption of large areas should be put forward as a very important factor in the successful administration of the health of the country. The Society ought, he thought, to express a strong opinion as to the absolute necessity of appointing scientific advisers not only to the County Councils but to the central body in London—such should exist for the benefit of the country at large. He suggested that a subcommittee should be appointed to draft such recommendations as they might think desirable.

The CHAIRMAN said no doubt a great deal that Dr. Hime had said as regards matters of detail would be acted upon; they would not be introduced into a resolution, but could be submitted to the President of the Local Government Board, when the discussion waited upon him.

Dr. SYKES thought that it would be seen by those who tried to follow out in imagination the working of the Bill that the County Councils would have a number of sanitary duties to perform which would necessitate their calling in skilled opinion, and at the conference required would necessitate amalgamation. One-half of the fees was to be paid by the County Council, which he did not suppose they would amicably do without having some voice in the appointment.

Dr. SEATON, referring to the subject of the extent of the area most suitable for the supervision of the medical officer of health, thought a district with a population of 100,000, as suggested by

Sir Lyon Playfair, much too small. If they wanted a good sanitary service they must have something like prizes in the profession; in districts of only 100,000, he took it, there would be none.

Dr. FOSBROKE, speaking in favour of large areas, said of course a medical officer could supervise a much larger population in a thickly populated town than where the population was distributed over a large area.

The following resolution, proposed by Dr. ARMISTEAD, and seconded by Dr. TATHAM, was unanimously carried:

“That the interests of the public in regard to efficiency and economy would be best served by the appointment of the medical officer of health being entirely vested in the County Councils instead of as arranged in the Local Government Bill.”

The next resolution put from the chair was the following, proposed by Dr. BOND, and seconded by Dr. ARMISTEAD, which was also carried unanimously:—

“That as no provision is made in the Bill for furnishing the County Councils with the sanitary advice and assistance which is essential to enable them to carry out properly the responsible duties of supervision with which it is proposed to entrust them, it is desirable that such provision should be made, and that this object will be promoted by the foregoing resolution, which will enable the Council to arrange the sanitary service of their districts so as to secure for themselves such advice and assistance, and to adopt in its fullest degree the principle of consolidating the areas supervised by medical officers of health which experience has shown to work satisfactorily.”

Dr. HIME proposed the following resolution:—
“That in the interests of the public health of the country it is desirable that skilled medical officers be appointed as advisers of County and District Councils, who shall not be engaged in the private practice of the profession.”

Dr. WILSON seconded it.

It being evident from various expressions of opinion that Dr. Hime's resolution did not meet with the unanimous approval of the meeting, he ultimately withdrew it as a matter of expediency.

It was decided to circulate the above resolutions among medical and other members of Parliament.

Mr. SHIRLEY MURPHY read a letter from Mr. Ernest Hart, the Chairman of the Parliamentary Bills Committee of the British Medical Association, stating that at the last meeting of that body a resolution was passed favouring the attachment of medical officers of health to the County Councils, and that a subcommittee had been appointed to carry out that object; that it was resolved to seek the co-operation of the Society of Medical Officers of Health in the matter. It was, Mr. Hart said, proposed to approach Mr. Stansfeld as the author of the Public Health Act, the President of the Local Government Board, Sir John Lubbock, and Sir Lyon Playfair. Mr. Stansfeld was willing to have a private conference with them any morning, and he wished to know whether they were willing to co-operate.

It was decided to accept the invitation of the Parliamentary Bills Committee of the British Medical Association, and to appoint a committee for the purpose; and, as soon as the exact amendments were thought out, to go before Mr. Ritchie as President of the Local Government Board, and state the result of the conference with Mr. Stansfeld.

The following committee was appointed: Dr. Alfred Hill (Birmingham), Dr. Bond (Gloucester), Dr. Corfield (London), Mr. Shirley Murphy (London), Dr. Armistead (Cambridge), Dr. Tatham (Salisbury), Dr. Woodforde (Reading), Dr. Hime (Bradford), Mr. Armstrong, M.R.C.S. (Newcastle-on-Tyne), Dr. Seaton (London), Dr. G. Wilson (Leamington), Mr. G. Fosbrooke, M.R.C.S. (Bideford), Dr. Thursfield (Shrewsbury), Mr. G. Turner (London).

At the close of the meeting Dr. CORFIELD referred to the death of Professor de Chaumont, to whose eminence as a sanitarian and kindness of disposition he paid a well-deserved tribute, and proposed that a letter of condolence should be sent to his widow and family.—Dr. BOND, as one who had enjoyed his professional acquaintance for twenty-five years, seconded the motion, which was carried *nem. con.*

DONATIONS.—The Clothworkers' Company have given £250 (additional) to the Charing Cross Hospital, and £50 to the Royal National Hospital for Consumption and Diseases of the Chest at Ventnor.—The Vestry of the Parish of St. Martin-in-the-Fields have given 200 guineas to the Jubilee Fund of the Charing Cross Hospital.—The Hon. Algeron G. Tollemache has given £100 to the Charing Cross Hospital, and £100 to St. Mary's Hospital.

THE LONDON UNIVERSITY AND METROPOLITAN MEDICAL STUDENTS.

The following letter was read at the last meeting of the Senate of the University of London:

The Middlesex Hospital, W., April 14th, 1888.

We, the medical officers and lecturers of the Middlesex Hospital, beg leave to represent to the Senate of the University of London that, in our belief, it not infrequently happens that students and medical practitioners otherwise well qualified are prevented from taking degrees in medicine at the University because they have not passed the matriculation examination before commencing their medical studies. Afterwards, when they would be glad to have an opportunity of presenting themselves for examination, they are debarred because they would be required again to go through the whole of their medical curriculum.

We believe it would facilitate the obtaining of degrees in medicine by many capable students and practitioners if the Senate would, under certain circumstances, so far relax the existing regulations as to accept attendance at lectures and hospital practice before passing the matriculation examination, and to admit such candidates to the examinations without requiring them again to go through their curriculum.

Signed on behalf of the medical officers and lecturers,

J. W. MULKE, Chairman.
W. CAYLEY, Treasurer.
A. PEARCE GOULD, Dean.

ASSOCIATION INTELLIGENCE.

NOTICE OF QUARTERLY MEETINGS FOR 1888. ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Meetings of the Council will be held on July 18th, and October 17th, 1888. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before each meeting, namely, June 27th, September 26th, and December 28th, 1888.

FRANCIS FOWKE, *General Secretary.*

COLLECTIVE INVESTIGATION OF DISEASE.

THE Report upon the CONNECTION OF DISEASE WITH HABITS OF INTEMPERANCE, which was presented to the Section of Medicine in the Annual Meeting of 1887 will shortly be published in the JOURNAL.

Reports upon the two remaining inquiries, namely, that into DIPHTHERIA, and that into the GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES, are in preparation, and will be published as soon as ready.

The following inquiry only of the first series remains open, namely, that on the ETIOLOGY OF PHTHISIS.

A fresh inquiry into the ORIGIN AND MODE OF PROPAGATION OF EPIDEMICS OF DIPHTHERIA has been issued.

Memoranda upon these subjects, and forms for recording observations, may be had on application to the Secretary of the Collective Investigation Committee, 429, Strand, W.C.

BRANCH MEETINGS TO BE HELD.

BORDER COUNTIES BRANCH.—The spring meeting of this Branch will be held at Cookermouth on Friday, May 4th. The chair will be taken by Dr. McLeod, at 3.15 P.M. The following papers will be read: Dr. Campbell (Garlands): On Three Cases of Recovery after a Lengthened Duration of Insanity, with remarks. Dr. Hight (Workington): Notes on a Case of Puerperal Eclampsia. Dr. Black (Keswick): Notes on a Case of Suppurative Peritonitis. Dr. Hight will open a discussion on the subject of Fees Paid to Witnesses. The Secretary will be glad to receive intimation of papers for reading or specimens for showing prior to the 25th.—H. A. LEDIARD, 41, Lowther Street, Carlisle, Honorary Secretary.

SOUTH WALES AND MONMOUTH BRANCH.

The spring meeting of this Branch was held at Pontypridd on April 13th. Present: J. ADAMS RAWLINGS, M.R.C.P.Ed., President, in the chair, and about thirty-five members.

New Members.—D. R. Bowen (Morriston), J. Barrie, M.B. (Car-

diff), Ivor H. Davies (Porth), A. N. Loveridge (Newport), D. Lloyd (Newcastle Emlyn), T. H. Morris (Aberdare), were elected members of the Association and Branch; and W. W. David (Tonypandy) and Dr. Walford (Cardiff) members of the Branch.

President-Elect.—Dr. C. T. Vachell, of Cardiff, was unanimously elected.

Papers.—Mr. J. ARNALLT JONES (Aberavon) read notes of a curious case of Oedema of the Hand, for which he had performed amputation above the wrist, and showed the specimen.—TATHAM THOMPSON, M.B. (Cardiff), read a paper on Detachment of the Retina, and showed specimens and drawings.—Mr. E. STANLEY WOOD (Pontypool) read notes of a case of Griggs's amputation at the Knee-joint, and showed a plaster cast of the resulting stump.—Mr. H. N. DAVIES (Cymer) showed a boy in whom Pirogoff's amputation in the right foot and Chopart's in the left foot had been done eight years before. The resulting stumps were very good, and he could get about without trouble.

Congenital Absence of Both Patellae.—Mr. T. W. PARRY (Ferdale) showed a patient having congenital absence of both patellae, with a deformity at each elbow, consisting of a surplus amount of bone. The patient had ten children, all healthy, except that, in the fourth child, exactly similar deformities were reproduced.

Biliary Calculi.—Dr. TAYLOR (Cardiff) showed a number of biliary calculi. The patient was a woman, aged 38. During a course of four months she had paroxysms of severe pain, with attacks of jaundice, and passed about twenty angular-shaped stones. The pain was much relieved by hypodermic injections of morphine on each occasion.—Mr. H. N. DAVIES mentioned a case where 200 were passed; and Mr. EVAN JONES one in which a much larger number came away.—Mr. WOOD referred to the value of chloride of ammonium in possibly preventing their formation, and referred to an illustrative case.

Suggestion as to Meetings.—Mr. A. P. FIDDIAN, M.B. (Cardiff), read a paper, urging the more frequent holding of district meetings for working purposes only, and a committee was nominated to consider the matter.

Petitions.—Petitions were adopted: (1) Against the Horse Tax; (2) In favour of the Architects, Engineers, and Surveyors Registration Bill; (3) In favour of a Welsh Centre in connection with the proposed Nursing Institute; (4) On Fees paid to Medical Witnesses.

Dinner.—The members and friends afterwards partook of an excellent dinner at the New Inn Hotel.

SOUTH AUSTRALIAN BRANCH.

The monthly meeting of this Branch was held at the Adelaide Hospital, on February 23rd. Present: The President (Dr. Davies Thomas), Drs. Lendon, Mitchell, Poulton, Symonds, Todd; Messrs Aitken, A. A. Hamilton, Hayward, and the Honorary Secretary, Mr. Cleland).

The minutes of the meeting held on January 26th were read and confirmed.

New Members.—A. E. Wigg, M.D., M.R.C.S., was elected a member of the British Medical Association, and of its South Australian Branch.

Pterygium.—Dr. SYMONS read some notes on pterygium occurring in South Australia.

Laparotomy.—Dr. GÜRGER's paper on laparotomy, and notes on cases was taken as read, owing to the writer's unavoidable absence. Any discussion thereon, or of the subject, was postponed until the March meeting.

Treatment of Polyuria.—Mr. CLELAND read a paper on his experience of the action of a preparation of hamamelis virginica in a case of polyuria, and the subsequent employment of codeia, in which the latter failed to produce any effect in diminishing the quantity of urine.

ABSTRACT OF PROCEEDINGS OF COUNCIL.

At a numerously attended meeting of the Council, held in the Council Room at the offices of the Association, 429, Strand, W.C. on Wednesday, April, 13th, 1888, Dr. BRIDGWATER, President of the Council, in the Chair, it was

Resolved: That the financial statement for the year ending December 31st, 1887, as certified by the auditors, be approved and published in the JOURNAL, in accordance with By-Law 26.

The remainder of the proceedings of the Council will appear in next week's JOURNAL.

BRITISH MEDICAL ASSOCIATION.
FINANCIAL STATEMENT FOR THE YEAR ENDING DECEMBER 31st, 1887.

22nd March, 1888.

BRITISH MEDICAL ASSOCIATION.

FIFTY-SIXTH ANNUAL MEETING.

The fifty-sixth Annual Meeting of the British Medical Association will be held at Glasgow, on Tuesday, Wednesday, Thursday, and Friday, August 7th, 8th, 9th, and 10th, 1888.

President: John T. Banks, M.D., D.Sc.(Hon.), F.K.Q.C.P.I., Regius Professor of Physic in the University of Dublin.

President-Elect: Professor W. T. Gairdner, M.D., LL.D., Professor of Medicine in the University of Glasgow.

President of the Council: Thomas Bridgwater, M.B., J.P., Harrow-on-the-Hill.

Treasurer: Constantine Holman, M.D., J.P., Reigate.

An Address in Medicine will be delivered by Thomas Clifford Allbutt, M.D., Consulting Physician, Leeds General Infirmary.

An Address in Surgery will be delivered by Sir George H. B. Macleod, M.D., Surgeon in Ordinary to Her Majesty in Scotland.

A Special Address on his "Recent Investigations in Surgery" will be given by William Macewen, M.D., Lecturer on Clinical Surgery, Glasgow Royal Infirmary.

An Address in Physiology will be delivered by John Gray McKendrick, M.D., LL.D., F.R.S., Professor of Institutes of Medicine, University of Glasgow.

A. MEDICINE.—*President,* T. McCall Anderson, M.D. *Vice-Presidents,* W. L. Bowles, M.D.; George F. Duffey, M.D. *Honorary Secretaries,* J. McGregor Robertson, M.D., 400, Great Western Road, Glasgow; Robert M. Simon, M.D., 27, Newhall Street, Birmingham.

B. SURGERY.—*President,* George Buchanan, M.D. *Vice-Presidents,* James Dunlop, M.D.; Charles Robert Bell Keetley, F.R.C.S. *Honorary Secretaries,* David Neilson Knox, M.B., 8, India Street, Glasgow; Walter Pye, F.R.C.S., 4, Sackville Street, Piccadilly, London, W.

C. OBSTETRIC MEDICINE.—*President,* Thomas More Madden, M.D. *Vice-Presidents,* William Leishman, M.D.; J. Halliday Croom, M.D. *Honorary Secretaries,* William Walter, M.D., 20, St. John Street, Manchester; W. L. Reid, M.D., 7, Royal Crescent, Glasgow.

D. PUBLIC MEDICINE.—*President,* Henry Duncan Littlejohn, M.D. *Vice-Presidents,* James Christie, M.D.; D. Page, M.D. *Honorary Secretaries,* Ebenezer Duncan, M.D., 4, Royal Crescent, Crosshill, Glasgow; John C. McVail, M.D., Holmhead, Kilmarnock.

E. PSYCHOLOGY.—*President,* James C. Howden, M.D. *Vice-Presidents,* James Rutherford, M.D.; Julius Mickle, M.D. *Honorary Secretaries,* A. R. Urquhart, M.D., Murray House, Perth; Alex. Newton, M.D., Ticehurst, Sussex.

F. ANATOMY AND PHYSIOLOGY.—*President,* John Cleland, M.D., LL.D., F.R.S. *Vice-Presidents,* R. J. Anderson, M.D.; Henry Edward Clark, F.F.P.S.G. *Honorary Secretaries,* John Barlow, M.D., 27, Elmbank Crescent, Glasgow; Charles Barrett Lockwood, F.R.C.S., 19, Upper Berkeley Street, Portman Square, W.

G. PATHOLOGY.—*President,* Sir William Aitken, M.D., F.R.S., K.C.B. *Vice-Presidents,* Alexander Davidson, M.D.; Joseph Coats, M.D.; Charles Roy, M.D., F.R.S. *Honorary Secretaries,* G. Sims Woodhead, M.D., 6, Marchhall Crescent, Edinburgh; J. Lindsay Steven, M.D., 34, Berkeley Terrace, Glasgow.

H. OPHTHALMOLOGY.—*President,* Thomas Reid, M.D. *Vice-Presidents,* J. R. Wolfe, M.D.; C. E. Glascott, M.D. *Honorary Secretaries,* Henry Bendelack Hewetson, M.R.C.S., 11, Hanover Square, Leeds; A. Freeland Fergus, M.B., 41, Elmbank Street, Glasgow.

I. OTOTOLOGY.—*President,* Thomas Barr, M.D. *Vice-Presidents,* John Astley Bloxam, F.R.C.S.; J. J. K. Duncanson, M.D. *Honorary Secretaries,* Johnstone Macfie, M.D., 23, Ashton Terrace, Glasgow; James Black, F.R.C.S., 16, Wimpole Street, London.

J. DISEASES OF CHILDREN.—*President,* Walter Butler Chadde, M.D. *Vice-Presidents,* James Finlayson, M.D.; Henry Ashby, M.D. *Honorary Secretaries,* George S. Middleton, M.D., 23, Sandyford Place, Glasgow; W. Arbuthnot Lane, M.S., F.R.C.S., 14, St. Thomas's Street, S.E.

K. PHARMACOLOGY AND THERAPEUTICS.—*President,* James Morton, M.D. *Vice-Presidents,* John Dougall, M.D.; Theodore Cash, M.D., F.R.S. *Honorary Secretaries,* Alexander Napier, M.D., 3, Royal Terrace, Crosshill, Glasgow; Sidney Harris Cox Martin, M.D., 60, Gower Street, London, W.C.

L. LARYNGOLOGY AND RHINOLOGY.—*President,* Felix Semon, M.D. *Vice-Presidents,* George Hunter Mackenzie, M.D.; Peter

McBride, M.D. *Honorary Secretaries,* D. Newman, M.D., 18, Woodside Place, Glasgow; A. E. Garrod, M.D., 9, Chandos Street, Cavendish Square.

Honorary Local Secretaries, John G. McKendrick, M.D., F.R.S., 45, Westbourne Gardens, Glasgow; James Christie, M.D., Hillhead Glasgow; John Glaister, M.D., 4, Grafton Place, Glasgow.

PROGRAMME OF PROCEEDINGS.

TUESDAY, AUGUST 7TH, 1888.

9.30 A.M.—Meeting of 1887-1888 Council.

11.30 A.M.—First General Meeting. Report of Council. Reports of Committees. Service in the Cathedral.

8.30 P.M.—Adjourned General Meeting from 11.30 A.M. President's Address.

WEDNESDAY, AUGUST 8TH, 1888.

9.30 A.M.—Meeting of 1888-89 Council.

10.30 A.M. to 2 P.M.—Sectional Meetings.

3 P.M.—Second General Meeting. Address in Medicine by

Thomas Clifford Allbutt, M.D., F.R.S.

THURSDAY, AUGUST 9TH, 1888.

9.30 A.M.—Address on his Recent Surgical Investigations by William Macewen, M.D.

11 A.M.—Meeting of Council.

10.30 A.M. to 2 P.M.—Sectional Meetings.

3 P.M.—Third General Meeting. Address in Surgery by Sir

George H. B. Macleod, M.D.

7 P.M.—Public Dinner.

FRIDAY, AUGUST 10TH, 1888.

10.30 A.M. to 1.30 P.M.—Sectional Meetings.

3 P.M.—Concluding General Meeting. Address in Physiology

by John G. McKendrick, M.D., F.R.S.

SATURDAY, AUGUST 11TH, 1888.

Excursions.

April 18th, 1888.

FRANCIS FOWKE, *General Secretary.*

SPECIAL CORRESPONDENCE.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

Test for Hydrochloric Acid in the Gastric Secretion.—Erythrophlovin.—*Electricity of the Human Body.*—*Telepathic Remedies.*—*Oxide of Zinc in Infantile Diarrhœa.*—*Contagious Pneumonia in Pigs.*—*Antipyrin in Labour.*—*Relation of Erysipelas to Puerperal Fever.*—*Diphtheria in Man and Animals.*—*Treatment of Gunshot Wounds of the Abdomen.*—*An Ambulance Service for Paris.*

At a meeting of the Academy on January 17th, Professor G. S. communicated the results which he had obtained by the use of Gungshot's test for hydrochloric acid in the gastric secretion of dyspeptic patients by means of a solution of phloroglycine vanillin. In order to obtain the secretion M. Sée gives the patient hard boiled white of egg and a glass of water. An hour later he extracts a portion of what the stomach contains, and examines with the reagent just mentioned. In certain cases he perceives a red colouring, which proves the presence of an inorganic acid, which M. Sée says is chlorhydric acid. M. Faucher, who has repeated M. Sée's experiments, finds that the test is an extremely delicate one; in the presence of sulphuric acid, nitric acid, hydrochloric acid, etc., it produced a red colouring, while inorganic acid chemically pure, such as lactic acid, tartaric acid, etc., produced no effect. M. Faucher then took eggs of various degrees of freshness, and after having them boiled hard he took an equal weight of their whites, and triturated them with a given weight of distilled water. He then tried the reagent (phloroglycine vanillin) upon the liquids separately. The new-laid egg showed no definite reaction; the egg five days old became rose-coloured; three eggs of doubtful freshness gave an intense dark red colour; in short the intensity of the reaction was in proportion to the amount of the egg, which is explained by the increasing quantity of sulphuric acid. It has also been proved that a drop of sulphuretted hydrogen, prepared by the help of well purified gas, phosphate of soda, and tribasic phosphate of lime also produced a red colouring. These experiments have been frequently repeated, and always with the same results. M. Faucher therefore concludes that it is impossible to prove the presence of hydrochloric acid in the products of digestion by the use of phloroglycine vanillin.

Dr. Trousseau has made some experiments with erythropleth with the following results. After from five to ten minutes the eye was complete anaesthesia of the cornea, not extending to the conjunctiva or to the eyelids, but limited to the transparent membrane; its duration varied from half an hour to an hour

Trousseau performed the operation for cataract on three eyes after injecting erythrophloëin. There was no pain, but cornea remained clouded for some time after the operation. Inflamed eyes the agent had no effect. On the whole he finds erythrophloëin has less effect on the conjunctiva than aine, and that it is a much less powerful local anæsthetic.

M. Charles Féré publishes in the *Compte Rendu des Séances de Société de Biologie* for January 20th, 1888, some interesting remarks on the electricity of the human body. It is well known that certain individuals become charged with electricity in dry, cold weather, especially in hard frost. Sparks or flashes of light appear, especially from the hair when combed, with a dry crackling sound. M. Féré relates the following case, which came under his own notice some years ago. Madame X., of a neurotic stock, amongst other troubles suffered from nervous anorexia, which had lasted since childhood. She had (at least temporarily) ovarian peræsthesia on the left side, and sensory anæsthesia on the same side. When about 15 she noticed crepitation in her hair in frosty weather, and flashes of light in the dark. At the age of 27 this electricity manifested itself with greater intensity. Madame X.'s fingers attracted light bodies, such as fragments of paper, ribbon, &c. Her hair not only gave forth sparks, but became rebellious and difficult to keep smooth. When her clothes touched her body luminous crepitation was produced, and her clothes adhered to her body. The luminous crepitation was increased by friction, by pressing the comb repeatedly through her hair. Under the influence of moral emotions, also, the electric tension and the manifestations increased. After Madame X. had been listening to music the crepitation was highly exaggerated, and a disagreeable pricking sensation was felt, especially in the legs. In 1884 Madame X. had œdema of the legs; her skin became so dry that it chapped on the least exposure to cold, even in the parts of the legs not affected by the œdema. M. Féré ordered her to wear black clothes, and to powder her skin with lycopodium, in order to moderate the electric phenomena. He also prescribed daily baths of static electricity. Since this treatment has been pursued her health has been better, although the electric phenomena have persisted. Madame X. has a son eleven years of age who for three years has suffered from nervous anorexia, hysterical phenomena, excessive sensibility of the left testicle, left hemianæsthesia, spinal pains, hyperæsthesia of the scalp, and dyæsthesia of the sole of the foot. For the last few months he has so presented electric phenomena under the same circumstances as his mother. Examined with the aid of a hygrometer, both presented extreme dryness of the skin, especially on the left side. The electrometer showed that Madame X. produced a slight deviation to the right, which was increased when the left hand was in contact with the apparatus (75 to 100 volts). After friction of the hands, both patients caused a deviation to the right—the mother 40 volts, and the son 500 volts. Under the influence of peripheral stimulation, a deviation to the right (125 volts) was caused by Madame X. when she looked through a blue glass. The deviation reached 700 volts when a bottle of ether was held near the patient. M. Féré thinks that the existence of these electric phenomena may give the key to phenomena of transfer, polarisation, electric sensibility, and the effect of certain substances at a distance.

M. Dujardin-Beaumetz's report, on behalf of the commission appointed by the Academy to investigate M. Luys's observations on the therapeutic effects of telepathic remedies on hypnotised patients effectively disposes of all the fanciful notions that have been entertained on this matter. The commission found that empty tubes had more effect on the patients than those filled with active substances, and the same drugs could be made to produce diametrically opposite effects when tested on the same patient at intervals of a few days. The report proves the utility of putting faith in any phenomena caused by the unconscious freaks of "hysterical" patients.

M. Dupré stated at the Société Médicale de Reims that oxide of zinc is by far the most effectual remedy in infantile diarrhoea. It could be prepared as follows:—R Sublimed oxide of zinc, 3.50 grammes; bicarbonate of soda, 1.50 grammes; tincture of krameria, 3 drops; plain syrup, 30 drops. A teaspoonful of this preparation is given every half hour until vomiting and diarrhoea have ceased. The first teaspoonful stops the vomiting, and the third or fourth of diarrhoea. In the few cases in which this treatment fails in entirely checking the disease, it gives great relief and prevents complications. From 1884 234 cases, all of which occurred during the months of July, August, and September, were treated by

oxide of zinc, and among these only eight deaths were registered, the death-rate being thus only 4.7 per 100.

At a recent meeting of the Académie des Sciences, an essay by M. Fouque (of Marseilles) on the development and progress of contagious pneumonia in pigs in the South of France was read. The following is a summary of its conclusions:—1. That the epidemic of contagious pneumonia which broke out in 1887, and in a few months caused the death of more than 20,000 pigs in the Bouches du Rhône department alone, was imported by Algerian pigs from the province of Oran. 2. That young pigs, from eight to nine months old, English (Yorkshire and Berkshire) as well as Russian and Marseilles mixed breed, are more exposed to the contagion of that distemper than the African and fat pork. 3. That fifty young pigs, from two to three months old, from the Haute Garonne, were removed to Gignac about two months ago, and placed in a badly disinfected pen. They have remained in good health, while more than one hundred cases of pneumonia were contracted in the same sty. 4. The cause of this natural immunity from distemper presented by the Haute Garonne pigs, which seems to resemble that attributed by M. Chauveau, some years ago, to Algerian sheep against bacterial anthrax, is being inquired into.

At a meeting of the Académie de Médecine on March 13th a letter was read from M. Queirel (of Marseilles), on the use of antipyrin in labour. He gave subcutaneous injections of twenty-five centigrammes to twenty patients. The head presented in all the cases. Fifteen out of the twenty had perfect anæsthesia, and all felt a remarkable diminution of pain. The antipyrin did not seem to interfere in any way with the normal course of the labour.

At the same meeting a communication from Dr. Doyen, of Rheims, was read on the affinity of erysipelas and puerperal fever. Dr. Doyen has always found, both in mild and severe cases of puerperal fever, a streptococcus similar to the streptococcus of Rosenbach and the streptococcus of Fehleisen, the streptococcus pyogenes, and the streptococcus aureus. The cultivations of this microbe are similar to those of the streptococcus of erysipelas, the streptococcus pyogenes, and the streptococcus aureus. M. Doyen made some inoculations, in order to determine the relationship of these streptococci. The streptococcus of puerperal fever caused erysipelas, and the streptococcus of erysipelas developed puerperal fever. A number of clinical facts also demonstrate the analogy of these affections, and prove that the streptococcus pyogenes sometimes causes puerperal fever, and that the streptococcus of puerperal fever may cause erysipelas. Dr. Doyen believes that the microbe of puerperal fever is the same as that of erysipelas.

M. Paulinis published an interesting article in the *Bulletin Médical* of January 22nd, on the relation of human diphtheria to that of domestic birds. In 1878 and 1879 Nicati, of Marseilles, observed facts tending to prove that diphtheria can be conveyed from fowls to children. Mégnin, supported by numerous cases of non-contagion and microscopic examinations, denied the identity of the two affections. Since then bacteriology has made great progress, and almost identical bacilli have been found in the diphtheritic false membranes of birds and children, but proof of the transmission of the disease from the one to the other has been wanting. In 1881 M. Menziès published an essay on diphtheria, in which he maintains that the disease is caused by the excrements of birds. He cites a case of diphtheria which came under his notice at Posilippo, near Naples. Four children in one family were attacked by diphtheria, and died. M. Menziès attributes the epidemic, which spread among the inhabitants of the neighbouring houses, to the patients having drunk the water from a well, into which the excrements of numerous fowls and pigeons had been washed by the rain. All who had drunk the water were attacked, and the brother of the four children above mentioned escaped, because he never drank the water. Dr. Paulinis relates an epidemic in the little island of Skiatos, of which the climate is very salubrious, and where, until 1884, diphtheria had never been known. In June, 1884, Dr. Paulinis was called in to a little girl who had been ill four days. She was feverish, and had sore throat and dysphagia. False membrane was noticed on the tonsils, extending towards the pharynx. The girl died on the following day. The same day Dr. Paulinis was called in to three houses in the same quarter of the town to sick children. The seven children were ill with diphtheria, and five died. As they were all ill at the same time, it could not be supposed that diphtheritic virus had been transmitted from one to the other. The epidemic spread amongst the inhabitants of the town; it lasted five

months, and, out of the 125 attacked by it, 36 died. At the beginning of the epidemic, Dr. Paulinis was informed that some turkeys, which had been brought over from Salonica, were ill in a garden belonging to their owner, to the north of the town. Two were ill when landed, and died in the garden after three days' illness. The others fell ill, and, when examined by Dr. Paulinis, presented all the symptoms of human diphtheria. The north wind, which blows periodically in the island, passed over the garden to the neighbouring houses. The temperature (20° C.) at that time of year facilitated the development of the diphtheritic virus, which was conveyed by the wind to the neighbouring quarter, where the first victim of the disease actually lived. From these facts Dr. Paulinis draws the following conclusions: 1. That turkeys are subject to a kind of diphtheria resembling that of human beings in its symptoms, evolution, and severity. 2. That its virus can be transmitted by the atmosphere to man, give him the disease, and develop an epidemic. Furthermore, when the epidemic was over, germs of diphtheria remained in the island, which from time to time became developed, like those of erysipelas, carbuncle, puerperal fever, and tetanus. Diphtheria is now endemic in the island, which before was totally free from this disease. Dr. Delthil, of Nogent, publishes, in the *Journal de Médecine*, the following remarks on the affinity of human diphtheria with that of animals: The different theories regarding the transmissibility of the affection and its principal agents are as follows. 1. Some authorities believe that the inhalation of the surrounding atmosphere is the only means of infection. 2. Others, admitting that the air is the chief agent of transmission, believe in direct contagion, either by the application of a surface denuded of its epithelial layer to a diphtheritic centre, or inversely by applying diphtheritic matter to a part deprived of its integumentary covering. 3. A few authors affirm that contagion is possible at a distance without direct contact. Dr. Delthil himself transmitted the disease from a person in Paris to a patient at Nogent. 4. For the last few years a certain number of authorities have made observations tending to prove that the diphtheria of human beings and that of animals is identical, and may be transmitted from one to the other. Trendelenburg inoculated sixty-six rabbits after tracheotomy, introducing diphtheritic false membrane into the trachea; eleven cases resulted in death from diphtheria. He afterwards performed tracheotomy on other rabbits, and introduced foreign bodies, skin, india-rubber, etc., into the trachea; no cases of diphtheria resulted. Oertel introduced into the trachea of twelve rabbits, after tracheotomy, fragments of diphtheritic exudations; five rabbits died after the development of false membranes. Zahn, Gerhardt, Labadie-Lagrave, and Francotte made experiments on rabbits, all tending to prove that human diphtheria may be transmitted to animals. On the other hand, many high authorities, such as Trousseau, Raynal, Bouley, etc., opposed this doctrine. Loeffler and Cornil found in the diphtheritic exudations of birds micrococci very similar to those found in the false membranes of human beings; the discovery did not, however, convince them of the identity of fowl and human diphtheria. It must be remembered that, in order to obtain a perfect result, the place chosen must be acid, in order to aid diphtheritic proliferation; the time between making the wound and inoculation must be long enough to allow of the necessary fermentative inflammation; and the diphtheritic matter must be applied to an extensive wound. Dr. Delthil concludes, from many cases attended by him, that the frequency of diphtheritic affections in and near Paris is owing to the presence of badly kept poultry yards.

The Congrès Français de Chirurgie discussed on Tuesday, March 13th, the treatment of gunshot wounds of the viscera. Most of the communications related to wounds of the abdomen. M. Chauvel maintained that it is necessary to intervene in all cases on account of the dangers of fecal extravasation and septic peritonitis. M. Reclus replied that intestinal perforations are not nearly so grave as M. Chauvel supposes, and that laparotomy is not so infallibly efficacious as M. Chauvel says. M. Reclus has observed, in experiments made on dogs, a great many perforations, which were cured without the least intestinal trouble. He concludes that men have been cured also in many cases where perforation was indicated by hæmatemesis and melæna. These experiments with dogs were far from convincing MM. Chauvel and Trélat. M. Chauvel pointed out that no comparison could be made between the dogs which were purged and gorged with opium before being wounded and soldiers whose stomachs and intestines were full. M. Trélat remarked that the intestine and stomach are quite different in a human being and a

dog. Besides, after peritonitis has declared itself, there is no hope of operating successfully. The surgeon must operate without loss of time in cases of hæmorrhage or fecal extravasation.

It is announced that ambulances are to be established for use in the city of Paris itself. The idea was started by M. Nachtel. Special telephones will connect the St. Louis Hospital with chemists and police stations in twenty-seven different quarters of Paris; an ambulance wagon is to be kept always ready to start from the St. Louis Hospital; on the alarm being given by the telephone it will set off with a house-surgeon to the scene of accident. Help will thus be forthcoming in ten minutes at most. It is hoped that this method of giving succour will prove so effectual that the citizens of Paris may later on be induced to provide funds for its maintenance.

VIENNA.

[FROM OUR OWN CORRESPONDENT.]

A Case of Laparotomy.—Tubercular Disease of the Ear.

At a recent meeting of the Imperial Royal Society of Physicians of Vienna, Professor von Dittel related a case in which he had recently performed laparotomy on a woman aged 24, who had suffered from acute cystitis for two years. In the autumn of last year the patient for the first time noticed blood in her urine, and a swelling developed above Poupart's ligament on the right side. Examination revealed a tumour about the size of a man's fist, and closely resembling a kidney in shape. Hæmaturia was also present at the time, but it could not be decided whether the blood came from the bladder or the kidney. The diagnosis which seemed most probable was that of movable kidney, the hæmorrhage being supposed to be due to torsion of the renal pedicle. Laparotomy was resorted to; the swelling was found to be covered by omentum, which contained many dilated veins. This was detached, and the rosy colour of the capsule of the tumour at once showed that it was not a kidney. In the meanwhile, and before the operation was completed, the patient was attacked with severe syncope, and died in spite of repeated and long-continued artificial respiration. The operation lasted about three-quarters of an hour, and not more than 10 grammes of chloroform were used. Dr. Zemann then described the result of the *post-mortem* examination. On raising the epiploön, a tumour became visible, from which a cord was prolonged towards the fundus of the stomach. This tumour was the spleen, enlarged to eight times its normal size. The bladder was small and thickened; the surrounding tissue was very tough. The right kidney was almost entirely destroyed, owing to pyelo-nephritis, and the left one was in a condition of advanced amyloid degeneration, so that the patient in any case could have lived only for a short time. Professor von Dittel went on to point out that the mistake in diagnosis was due to the fact that movable kidneys were met with very frequently, whereas movable spleens were observed only very rarely; moreover, movable spleens were, according to Rokitan'sky, who had described three such cases, always situated on the left side; in the present case, however, it was found on the right side. Professor Kundrat mentioned other cases of movable spleen with twisted pedicle, and said that in all cases of movable spleen this organ was to be found on the right side.

Dr. Habermann recently made a communication on tubercular disease of the ear to the Verein Deutscher Aerzte of Prague. He had seen eighteen patients affected with tuberculosis who suffered from hardness of hearing and otorrhœa. In nine of these cases he detected the presence of tuberculosis of the auditory apparatus; in seven, purulent otitis media; and in two catarrhal swelling of the mucous membrane of the middle ear was present. He described two of these cases in detail. In a child aged 1½ year, there was tuberculosis of the mucous membrane of the middle ear, beginning at the isthmus tubæ and reaching as far as the antrum mastoideum. There was no perforation of the membrana tympani. This case was remarkable on account of the localisation of the affection. Various parts of the mucous membrane of the middle ear were found to be affected with tuberculosis, and evidence was thus given of the spread of the disease in the middle ear by infection from contact. The possibility of infection of the ear taking place through the Eustachian tube was, by such observations, rendered more probable. By way of illustrating infection by contact in such cases Dr. Habermann showed the membrana tympani of a man, age 31, which presented a large perforation at the anterior part, and three small perforations at the posterior one; the latter were due

the fact that the membrana tympani was attached at that point to the mucous membrane of the promontory, which was affected with advanced tuberculosis. The second case which he described, particularly referred to the condition of the internal ear, as the middle ear had already been completely destroyed by the disease. The disease, in this case, had supervened in the middle ear, a year and a half before the patient's death; later on it gave rise to perforation of the wall of the labyrinth, and to extension of the disease into the internal ear. Proof of this was afforded by the fact that the morbid process in the internal ear had already, in part, undergone retrogressive metamorphosis, when the progressing carious process of the bone led to a new affection and destruction of the structures of the internal ear.

BERLIN.

[FROM OUR OWN CORRESPONDENT.]

The Emperor's Illness.—Olive Oil in the Treatment of Gall-stones.—Electrolysis in Enlarged Prostate.

It is almost impossible now to obtain trustworthy information as to the present state of health of His Majesty the Emperor. The Emperor has again become a subject of violent controversy among the different political parties. One newspaper states that there is a great difference of opinion between the German and the English physicians, and alludes to intrigues carried on by both parties. Another, again, maintains that there is perfect unanimity of opinion among the doctors, and that their personal relations are of the most millennial character. One party makes Dr. Mackenzie and Hovell responsible for the present situation; the other abuses von Bergmann. The "English" party affects a useful frame of mind; the "German" one already speaks of the Emperor in the aorist tense. The general public does not know what to believe in such a vortex of contradictory stories, all told with equal confidence. In my last letter I told you that the original cannula had been replaced by a longer one. The night before it was changed His Majesty's attendant, Beerbaum, was dismissed. He had observed that the Emperor's breathing was more frequent than usual, so he woke Mr. Hovell, who saw at once that there was no dyspnoea, but only some quickness of respiration. He therefore went back to bed. Beerbaum, however, summoned the physician in ordinary, Generalarzt Dr. Wegner, who also found no cause for anxiety. In spite of this, the Emperor was again twice asked the Emperor if he felt any difficulty in breathing. This alarmed His Majesty, who complained about the matter in the morning, and Beerbaum was dismissed. The *Deutsche Zeitung* recently stated that Mr. Hovell had irritated the Emperor's wound in attempting to replace the tube. Mr. Hovell has written to that journal flatly denying this. He asserts that there is no bleeding till Professor von Bergmann vainly tried to introduce the new cannula—an operation which had finally to be performed by his assistant, Dr. Bramann. As Dr. von Bergmann has contradicted this statement, it may be accepted as true. Immediately after the introduction of the new tube the Emperor's temperature became raised, and there was a purulent discharge from the wound. For two days it was feared that pyæmia would ensue. Professors Leyden and Senator, who were called in, agreed that the lungs were not affected. Since then no authentic news has been published. The official bulletins tell little or nothing of any real importance. The fever is believed to be due to some accumulation of pus in the neighbourhood of the trachea. One thing is unfortunately too clear, namely, that the illness is rapidly tending to a fatal issue.

Dr. Rosenberg lately presented to the Berlin Medical Society a case of gall-stones cured by large quantities of olive-oil, a method which has been recommended by some American physicians. The lady had been ill for five years. No treatment had done any good, not even the Carlsbad waters. The weight of the lady had diminished to an extraordinary degree. She had lost all appetite, and suffered from almost continual sleeplessness. She took 820 grammes of oil in five doses, and in her stools there were 629 stones, from the size of a hazel nut to that of a pin's head. It is probable, however, that there were at least 200 stones more, which have not been found. The liver, which was much enlarged, cannot now be felt. Appetite and sleep have returned, though she still feels a little pain. This proves that there are still more stones in the gall-bladder.

Dr. Leopold Casper reported to the same Society on a new method of curing hypertrophy of the prostate by electrolysis. He had used it in four cases, with good results in two.

SWITZERLAND.

[FROM OUR OWN CORRESPONDENT.]

Menthol in Surgical Practice.—Menthol in Anorexia.—Hydrofluoric Acid in Pulmonary Phthisis.—Cocaine in Sea-Sickness.—Saline Transfusion in Acute Anæmia.—"Spontaneous Resection" of the Small Bowel.—A Bit of Family Medicine.—Dental Inspection at the Aarau Cantonal School.—Winter Swimming-Baths for School Children at Zurich and Berne; Professor Adolf Tegt and School Hygiene at Berne.

At a meeting of the Medicinisch Pharmaceutischer Bezirksverein von Bern, Dr. Girard read a paper on the use of menthol in surgical practice. Good results obtained lately by some practitioners from the internal administration of the drug in pulmonary tuberculosis had induced the author to try a mixture of equal parts of menthol and iodoform, in the form of a dry powder, in fourteen cases of scraping out and resection of tuberculous bones and soft parts, the wound being either rubbed or plugged with the powder. In every instance the wound healed more rapidly and kindly, and generally the whole course of the case seemed to be more favourable than in another series of similar cases where iodoform alone was employed. As far as Dr. Girard's personal experience goes, menthol causes but trifling local irritation and pain, while it is said to be the best deodoriser in regard to iodoform.

During a discussion on Dr. Girard's paper, Dr. de Giacomi stated that he had employed a 20 per cent solution of menthol in a case of lupus of the ear with most satisfactory results. On the other hand, Dr. de Giacomi was disappointed with the internal administration of menthol in one-gramme doses as a remedy for anorexia. The latter observation was endorsed by Dr. Daetwyler, who gave the drug in daily doses varying from three to five grammes in several cases of anorexia, the remedy causing nausea instead of improving appetite.

As is known, some time ago Drs. Seiler and Garcin published a remarkable paper on the treatment of pulmonary tuberculosis by inhalation of hydrofluoric acid. According to their statements, out of 100 patients under their care who were treated by this method, as many as 35 were cured, and 41 showed a more or less considerable improvement, while 14 remained unbenefited, and 10 died. In favourable cases the authors observed a very rapid improvement both in point of appetite and sleep, and a marked diminution of fever, night-sweats, and dyspnoea, while expectoration became scanty and less viscid, the tubercle bacilli gradually disappearing. Being struck with these results, Dr. de Giacomi, of Berne (*Correspondenz-Blatt für Schweizer Aerzte*, March 1st, 1888, p. 142), proceeded without delay to test the treatment in eight advanced cases of his own. He simplified the Seiler-Garcin method in so far that a mixture of 100 grammes of fluorine hydrogen with 300 grammes of water was heated in an open leaden vessel by means of a spirit-lamp. The patients sat around the vessel and inhaled the vapours for an hour daily. Dr. de Giacomi's experience was not so favourable as that of the French observers. In six of the eight patients the result was absolutely negative; in a seventh some temporary improvement of appetite and decrease of dyspnoea were observed; in the remaining case a striking relief of all symptoms ensued after the very first sitting. The author, however, reasonably enough, hesitates to attribute such an extraordinary and sudden change to the treatment employed; the improvement might have been purely accidental. At all events, he thinks that the method deserves a further and more extensive trial. The inhalation does not cause any discomfort to the patient. The only drawback which he mentions is that window-panes gradually become opaque under the influence of hydrofluoric vapours. As the acid has a violent caustic action on the skin, Dr. de Giacomi recommends the utmost caution in manipulations with the solution. Dr. Collon employed the method in two cases of advanced tuberculosis with high fever and extreme emaciation, and did not see any good beyond some amelioration in respect of sleep.

Dr. Dufour, of Lausanne, says that, while suffering from seasickness, he successfully employed cocaine in doses of one decigramme every half hour. Drs. Rogivue and Denuéville obtained very satisfactory results even with doses five or ten times smaller.

In the *Revue Médicale de la Suisse Romande*, January, 1888, p. 40, Dr. C. Morel, of Lausanne, records a successful case of acute anæmia treated by the transfusion of a saline solution. The patient, a woman, aged 39, when in the fifth month of her eleventh

pregnancy, fell ill with violent gastritis, associated with high fever (40.5° C). The latter soon caused abortion, followed by profuse uterine hemorrhage and uncontrollable vomiting. Ergot and stimulants were returned immediately after being swallowed. The woman's state rapidly growing worse, one litre and a half of a saline solution (a 6 per cent. solution of common kitchen salt in distilled water, heated to 37° C.) was injected into the central portion of the left median cephalic vein. The apparatus consisted of a simple glass vessel, to which a piece of india-rubber tubing, with a metal cannula, was attached. The improvement was immediate. The pulse, which had been irregular and almost imperceptible before the operation, became stronger and steadier during the transfusion. Referring to Professor Demitry Ott's researches (see *London Medical Record*, February, 1886, p. 60-76), and to numerous similar successful cases published during the last four years, Dr. Morel expresses a hope that the transfusion of saline fluids will gradually supersede that of blood, which is far more dangerous and less advantageous than the former (see also the *JOURNAL*, September 25th, 1886, p. 601).

At a meeting of the Société Vaudoise de Médecine, Dr. Krafft communicated an interesting case of "spontaneous resection" of the small intestine. The patient, aged 28, was admitted on account of chronic tuberculous ostitis of the head of the tibia. Some time after his admission he began to complain of agonising abdominal pain, and violent diarrhoea supervened, which persisted in spite of bismuth, opium, codeia, etc. Nothing abnormal could be made out on careful examination of the abdomen. Only nausea, but no vomiting, was present, while the motions remained free from blood and pus. Two days after the onset of the symptoms (the seventh day after resection of the diseased knee-joint) there was found in the stools a complete piece of the intestinal tube measuring sixty centimètres in length, with all its three coats complete, but gangrenous at several points. The patient was very much exhausted after the evacuation of the slough, but his appetite remained good and the abdominal pain disappeared. The surgical wound, however, did not show any sign of healing, while about the fifth day after the passing of the slough, acute pyrexia came on, which induced Dr. Krafft, without further delay, to perform amputation of the thigh, some distance above the knee. This wound rapidly healed by first intention. At the date of the report (nine days after the discharge of the intestinal slough), the man's general state was good, the only morbid symptom being diarrhoea, with an occasional slight admixture of pus and blood.

An extraordinary instance of domestic medical practice was lately published by the *Enmenthaler Volksblatt* (March 10th, 1888). An inhabitant of Coeuve, whose little daughter was suffering from lice, attempted a radical cure by pouring petroleum over the unhappy child's head, and then lighting it. The child was in a hopeless state at the date of the paragraph quoted, and probably has died long ago from extensive burns.

According to the *Berner Zeitung* (March 14th, 1888) Professor Muehlberg has lately examined the teeth of 125 pupils of the Aarau Cantonal School (*Kantonschule*). The outcome of his investigation is by no means very comforting. His interesting table shows that only 4 pupils had a perfectly sound set of teeth. In 37, though the full number was present, many of the teeth were already more or less carious. In the remaining 84 children the set was incomplete, either from spontaneous falling out or owing to removal for disease. The total number of teeth extracted up to the date of Professor Muehlberg's inspection was 204, that of the teeth found more or less diseased was 512.

The *Bund* (March 16th, 1888) says that the Züricher Hygienischer Verein has decided to establish a permanent winter swimming bath for school children. The bath, which will be opened in the course of next autumn, will be the second of its kind in Switzerland. The first was established two years ago at Berne, by the local Society of Public Hygiene and Social Aspirations, on the initiative of the indefatigable Professor Adolf Vogt (see the *JOURNAL*, June 18th, 1887, p. 1359), who is always sure to be at the head of every movement promoting the health and comfort of the community. The Bernese children are indebted to his energetic agitation for their having obtained last winter a gratuitous skating rink at Holligen, arranged and kept up at the expense of the Commune (*Gemeinde*) and several District Aid Committees (*Leiste*). About three years ago, on the initiative of the same philanthropic professor, a *Knabenbund* (Boys' Union) was organised, chiefly for the purpose of supplying the Berne school-boys with a common playground, of a most suitable kind, and organising their games, etc., in the best way.

GLASGOW.

[FROM OUR OWN CORRESPONDENT.]

Glasgow University Council Association.—*Glasgow and Ayrshire Missions to the Deaf and Dumb.*—*Port Glasgow Ambulance Class.*—*The Measles Epidemic in Port Glasgow.*—*Glasgow University Extension Board.*

THE annual general meeting of the Glasgow University Council Association was held on April 19th in Glasgow. In a letter of apology for absence, Mr. J. G. Baird, M.P., said he regarded the affiliation clauses as among the most important in the Bill, and he hoped the Association would affirm the general principle of affiliation. The report contrasted the inadequate reform offered in the last Bill, which the Association resolutely opposed, with the much more thorough-going character of the new proposals. The committee of the Association believed that the Bill was in all essentials adequate to the ends of a great reform. In discussing the constitution of the University Court, the Committee pointed out that the number of members who might be thought of as independent of academic party fell short of that representing the Senate, instead of being, as it ought rather to have been, if unequal at all, in excess. It was objected, also, that the assessor nominated by the Chancellor might be in the future, as he had always been in the past, a person suggested by the Senate, and apt to be guided by its influence, and that the assessors nominated by the Crown might be in the same position, unless it was explicitly enacted that they should be chosen from among the heads of local public bodies. In spite of such serious objections, the Committee advised the Association to accept the constitution as it stands, in consideration of the whole scope of the Bill, provided no attempt was made by the Senate to alter the character of the Bill for the worse, from the Association's point of view. The provision for the Council electing an assessor every year was emphatically approved of, and the Committee extended a similar approval to the provisions dealing with the powers of the Court, Senate, etc., observing that no power proposed to be conferred upon the Commissioners involved the possibility of greater or more beneficial issues than the power to affiliate duly incorporated and endowed colleges. The report also discussed St. Mungo's College Bill, and the Committee declared that, having taken the Bill and relative statements into consideration, they were of opinion that the case for the establishment of a college in the east end of the city was completely made out. They reserved judgment on the details of the Bill, but they approved in general of its provisions, as quite in the line of the Association's aim. In reference to the whole question of the means of University extension provided for in the Bill, the Committee expressed the opinion that "no previous Universities Bill has come near the present one in the breadth of view and the grasp of facts with which it approaches the problem of reform." The Rev. Dr. Watt moved the adoption of the report as printed, with the addition of a paragraph which admitted that the provisions of the Bill seemed open to objection on the ground of their giving affiliated colleges or incorporated colleges a share in the direct administration of the original college, while the original college had apparently no share in their management. Dr. Watt expressed the opinion that the attack on the Bill would be delivered by the University authorities on the affiliation clause, and asked the Association to affirm that the removal of that clause would compel them to oppose the Bill. The motion was seconded by the Rev. J. W. King. Professor Edward Caird moved the following amendment: "That the whole section in the report relating to St. Mungo's College Bill should be deleted, and that the following words should be substituted: 'That this Association regrets the publication by the executive of a report which contains an approval of St. Mungo's College Bill, seeing that that Bill goes against the principle recognised by the Association, and seeing further that the Bill is an attempt to anticipate the decision of the Commissioners as to the conditions on which colleges should be affiliated.'" Professor Caird took occasion to object strongly to the personal references made to him in the report, and to the tendency to represent him as in any way representing the views of the Senate. He pointed out that the paragraph in reference to St. Mungo's College Bill committed the Association to a new principle, which did not fall under that adopted by the Association last year. He objected to the Bill because it tried to anticipate the general method of dealing with the question of affiliation by the Commissioners, and to force a new college into the University before the conditions of the new system—a system

which was a new thing in Scotland, and which, in the exact form proposed, was not exemplified, in any other country—had been carefully considered and impartially determined by the Commissioners. He was not opposed to the adoption of a method by which the teaching of the Royal Infirmary should be brought within the system of the University. But he contended that the methods and conditions of the affiliation of colleges should be determined before any individual case was considered. Mr. Dyer opposed the amendment. The discussion was engaged in among others by Dr. McVail, who, in the course of his remarks, referred to the recent extraordinary appointment by the University Court of an Edinburgh graduate of two years' standing as an examiner in Medicine. On a division 55 voted for the motion and 12 for the amendment. Professor Caird then resigned his membership of the Association, and withdrew from the meeting. Subsequently it was unanimously agreed to petition Parliament in favour of the Universities Bill, and the Committee was empowered to take such steps in connection with the progress of the Bill through Parliament as seemed expedient in furtherance of the objects of the Association.

By means of the Glasgow and Ayrshire Missions to the Deaf and Dumb, 104 afflicted persons belonging to Glasgow and the rest of Scotland have been attended to during the past year. Of a total number aided, 51 were children, who were maintained and educated. The report of the Glasgow organisation states that not a poor deaf and dumb person had been left unattended. Donations had been secured for 41, of whom 28 were men. The Ayrshire Mission had expended in its work nearly £600, and its total receipts had been £738.

The ambulance class, taught by Dr. Crawford, of Port Glasgow, as examined on April 18th by Dr. Wallace Anderson, of Glasgow. There were thirty-five members present, and at the close of the examination Dr. Anderson expressed his satisfaction with the proficiency displayed, and congratulated Dr. Crawford on his successful teaching.

The outbreak of measles in Port Glasgow is now on the decline. One of the public schools has been closed for four weeks, nearly 50 of the scholars having been attacked. It has now, however, been reopened.

A meeting of the Glasgow University Extension Board was held at Glasgow on April 23rd, presided over by the Lord Provost. Ratification was expressed at the favourable reception which the extension scheme had met with from the press and the public, and it was intimated that tentative steps had been entered upon at Paisley, Kilmarnock, Dumbarton, Ayr, Stirling, Ardrossan, and other places. An interim list of lectures was announced, in which, among others, the names of Mr. Patrick Geddes and Mr. Somerville appear as lecturers on Botany and Zoology; those of Drs. Mackay and Bruce Young as lecturers on Anatomy; Dr. McGregor Robertson and William Snodgrass on Physiology; Mr. G. Henderson, B.Sc., on Chemistry and Mineralogy; Mr. David Forsyth, B.Sc., on Physiography; and Mr. J. H. Fullarton, B.Sc., on Zoology and Geology.

LIVERPOOL.

[FROM OUR OWN CORRESPONDENT.]

The Registration of Plumbers.—Birkenhead Borough Hospital.—Orange-peel on the Streets.—Salt Water for watering the Streets.

WITH reference to the question of sanitary plumbing and the registration of plumbers, it is true that, as stated in the JOURNAL of April 21st, the medical officer of health for this city brought the matter before the Health Committee. Dr. G. Walter Reeves, the medical officer of health for Toxteth, struck by the fact that Liverpool seemed to be behindhand in the subject, determined first of all to bring it under the notice of the profession, and also to make the movement known in other directions. To this end he has been working hard for several weeks past, and until now a general interest appears to have been excited. On April 12th Dr. Steeves delivered an admirable address at the Liverpool Medical Institution. He first of all gave a concise history of the movement; next alluded to the steps that had been taken in other cities; and concluded by enumerating the conditions under which plumbers are admitted to the Register of the London Plumbers Company, and mentioned the mode of working of the "district councils." Dr. Steeves then moved the following resolution: "That the members of this institution are

strongly of opinion that an organised and efficient system of registration of plumbers should be put in force in Liverpool and district." This was seconded by Dr. Hope, the assistant medical officer of health to the city. It was also warmly supported by the President, Dr. Carter, in a most able and telling speech, and by Dr. Harvey, the medical officer of health for Wavertree, and being put to the meeting, was unanimously carried. The following motion was afterwards proposed, seconded, and carried: "That copies of the resolution be sent to the chairman of the Liverpool Health Committee, and also to the chairmen of the various local boards throughout the district." At the meeting of the Architectural Society on April 16th, Dr. Vacher's paper proved an admirable pivot on which to hang a resolution. Accordingly, a resolution similar to the one passed at the medical meeting was put before this meeting also.

At the end of the last financial year the Birkenhead Borough Hospital was in debt to the extent of £200. A very successful ball was held on April 18th in the new town hall, and it is confidently expected that the surplus proceeds will be sufficient to clear off the debt.

Throwing orange-peel on the pavement is being dealt with sternly in St. Helen's. A Liverpool paper gave a full account of the action of the chief constable of that borough, suggesting that the same course should be taken here. This newspaper article has had the effect of setting a local antiquary to work. It appears that there is a very comprehensive local enactment on the subject, contained in the Liverpool Improvement Act of 1842, Section 149. It is sincerely to be hoped that the magistrates will do their duty in the matter here, where accidents occur weekly from orange-peel, etc., lying on the pavements.

The corporation have taken definite action to avail themselves of a supply of water from the river in watering the streets.

CORRESPONDENCE.

COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES.

SIR,—I cannot allow Dr. Philpot's letter in the JOURNAL of April 14th to pass unnoticed. He states that the facts which he gives "differ entirely from those related in Dr. Carpenter's letter." In this he seems to me mistaken, his facts being supplementary, but not contradictory, to the facts given by Dr. Carpenter. I have carefully read Dr. Carpenter's letter, and, if for "town clerk" he substituted "Town Council," I do not see that his statement of facts requires any modification.

I regret that any suggestion of personal feeling, as existing, or likely to arise, should have been made. The town clerk acted throughout with perfect courtesy and consideration, and with the medical officer of health I had no communication, either private or official, regarding the case in question. My difference is with the Town Council as a body, and has arisen solely because it seeks to exercise its powers under the Notification of Infectious Diseases Act in a way that seems to me to be unfair and in a manner not intended when the Act was passed. The object of the Council in taking proceedings was apparently to coerce me into compliance with its mode of working the Act. In this it failed, and so gained nothing but, as Dr. Carpenter puts it, revenge.

Both the town clerk and medical officer of health were, I believe, unpleasantly surprised when they found I would not accept the terms offered, and that they had to carry on the proceedings.

Dr. Philpot is mistaken in supposing that I relied on upsetting the proceedings on technical grounds, and I distinctly stated, after raising the question whether the death certificate was admissible as evidence (bearing, as it does, a distinct statement that it is intended solely for the use of the registrar, and a caution from the Registrar-General to all persons against using it for any other purpose whatever), that I was quite prepared to answer the summons on other grounds. My answer was as follows:

1. That the Corporation did not exercise its powers fairly and justly; the Act requiring dual notification, the Corporation ignoring those sections which relate to the infectious persons and householders, and only seeking to obtain notification by the medical attendant, thereby placing him in the position of informer.

2. That information had been given by the householder of the previous existence of scarlatina in his house, and that in this particular case he had given information within forty-eight hours of

the time when I first saw the patient, and about or quite as soon as I could myself have given definite information as to the nature of the disease.

3. That as the Corporation is satisfied with one notification when given by the medical attendant, and never in such case takes proceedings against the householder, so the Corporation ought in fairness to be satisfied with one notification when made by the householder, and not take proceedings against the medical attendant.

4. That the spirit of the Act having been so fully complied with in this case, the Corporation had really no valid reason for setting the law in action.

The householder had no less than three times informed the sanitary authority of the existence of scarlatina in his house; twice when he applied for disinfection of rooms and bedding, and once in intentional compliance with Section I of the Act. This latter notice, given at my instigation, was not sent direct to the medical officer of health, but to the office of his subordinate officials, and, therefore, is called by Dr. Philpot informal; it no doubt was so, but this was simply from oversight. No record of it had been made, and the books of the sanitary authority were so badly kept as to the entry of dates and other particulars that I could not establish from them, as I had expected to be able to do, several points, and more especially the fact that information reached the officials two days after I first saw the case, and that they disinfected the room the next day. Although I have refused to notify in the manner wished for by the Corporation, I have frequently given information personally to the medical officer of health, and in most instances the occurrence of infectious disease amongst my patients has been made known to him in one way or another. Dr. Philpot made the statement in court that in his opinion the Act was working satisfactorily, and that I was the only practitioner in the borough of Croydon who failed to notify. After the threat of proceedings was made, I asked some of the other practitioners what they did with regard to notification. Five, like myself, habitually neglect to do so, and two who generally notify admitted that in some cases they did not. Such being the result of a very limited inquiry, I cannot but think that a more extended one would show that in concentrating its attention on myself, the Corporation has been straining at a gnat and swallowing a camel.

The Corporation of Croydon has hitherto evaded the difficulty of getting its burgesses to notify infectious diseases, but, as the public has been taught its duty as to the registration of births, and, more onerous still, its duty to report the amount of annual income, it would surely not be a hopeless task to try and teach it to report the occurrence of infectious disease. When the Corporation of Croydon honestly takes this task in hand, they will have my sympathy and co-operation.—I am, etc.,

B. N. DALTON.
South Norwood, April 17th, 1888.

SIR,—I would not trouble you on this subject had not Dr. Philpot, in the JOURNAL of April 14th, endeavoured to justify the prosecution of Dr. Dalton for refusing to inform the Croydon sanitary authority of a case of scarlatina which had been attended by him.

Dr. Dalton deserves the thanks of the medical profession for his determined stand in refusing to be constituted a private detective and public informer, and he evidently is one who feels that whatever a medical man learns in the discharge of his private professional duties should be treated as private and confidential.

Dr. Philpot says that the Act of Parliament was "obtained with considerable trouble," and that they "were bound to take proceedings to enforce it." Is it not unfortunate that those who introduced the Act to Croydon did not experience even more trouble and fail in the attempt, and thus save Dr. Dalton the indignity of a prosecution? Some years ago "considerable trouble" was also taken here to force the Act upon us, but a strong protest was made by the profession, which prevented such a calamity. One medical man, who could not attend our meeting, wrote to me to say that, "rather than be compelled to be informer, I would decline to attend a case of fever;" and we fully endorsed his sentiments.

All interested in the subject would do well to read Dr. Alfred Carpenter's letter in the JOURNAL of April 7th, in which he clearly gives a few reasons why a medical man should not be compelled to give information regarding his patients. Notice particularly objections 1 and 2, page 767.

Most medical men recognise the importance of requiring the householder or person in charge to inform the sanitary authority of all cases of fever, and I never find much difficulty in getting my patients to give the necessary information when such cases occur in their homes; indeed, they sometimes authorise me to do so for them. I then feel free to act.—I am, etc.,

T. M. WILLS.
Bootle, Liverpool, April 16th, 1888.

SCARLATINA AND PUERPERAL SEPTICÆMIA.

SIR,—I very much fear that the interesting discussion on this subject at the last meeting of the Obstetrical Society may tend to diminish the wholesome dread of carrying scarlet fever to lying-in patients which has hitherto so powerfully influenced the conduct of obstetrical practitioners. That the infection of scarlatina is capable of producing a virulent form of septicæmia, generally unattended with local symptoms, I have not the smallest doubt. In April, 1863, I was called in to see a case of this kind occurring in a primipara. She was attacked about five days after delivery, and on the day following her husband was attacked with scarlet fever. He recovered very well, but she died after four days' illness. Her case was a typical one of what used to be called malignant puerperal fever. She had no rash of any kind, and no marked abdominal tenderness. We made a *post-mortem* examination, but found no uterine lesion and no sign of abdominal inflammation; but decomposition had set in most rapidly. In fact it was a case of blood-poisoning of the worst kind.

About fifteen years ago a medical practitioner (who has since left Bristol) called me in to a patient he had attended in her confinement about four days previously, but who was attacked in a similar way to the case just mentioned, except that there was some abdominal tenderness. She died on the ninth day after delivery. About three days before she died her husband was attacked with scarlatina, but ultimately recovered. On making strict inquiry of the medical practitioner who attended her, he acknowledged that at the time when the husband came to fetch him to his wife his own children were lying ill of scarlatina.

There can be no doubt that in each case the husband and wife were infected from the same source—in the first instance, I believe, from a servant; and in the second from the medical attendant himself. I have seen many similar cases to these, but not of so well-marked a character. We know that people who have once had scarlatina are generally protected against a second attack, but yet that, if they are again exposed to infection, they may get troublesome sore throats in consequence. In the same way I believe that a puerperal woman who has had scarlatina before may get a sufficient amount of the poison to induce fatal septicæmia—unaccompanied, however, with the rash or other characteristic signs of scarlatina. The poison of scarlatina is so subtle a character, and creeps in through so many channels that ordinary antiseptic treatment is of little avail against it. In fact, the longer I live and the more experience I gain, the more determined I am to keep clear of scarlatina in any shape or form.—I am, etc.,

JOSEPH GRIFFITHS SWAYNE.

74, Pembroke Road, Clifton, Bristol.

PERICHONDRITIS OF THE LARYNX.

SIR,—In Dr. Norris Wolfenden's paper on Perichondritis of the Larynx, and in respect of the first case he mentions, he tells us that on November 1st the patient became suddenly worse and that on December 19th he coughed up a piece of bone. Would it be trespassing too far on Dr. Wolfenden's goodness to ask him—1. Where the bone is supposed to have come from originally? 2. How long it was in the larynx? 3. Is it not reasonable to suppose that it (the bone) was the cause of the laryngeal trouble?—am, etc.,

GEORGE STOKER.

14, Hertford Street, Park Lane, W.

DENTAL DEPARTMENTS OF HOSPITALS.

SIR,—I was glad to see Mr. Henry Sewill's letter on the subject of my paper, in the JOURNAL of April 14th, and I quite agree with him that there is no reason that each Medical School should not eventually include a Dental School. At the present time, however, I am recommending all dental students to go to the Dental Hospital in Leicester Square, for the reason that, as things stand, they can obtain far better training there than we could offer them at Guy's. But the two dental hospitals in London, as Mr. Sewill points out, will soon be unable to accept more students, and it will then become necessary to found another special hospital, or undertake dental education at the medical schools. This desirable transfer

ould be made easy by the immediate development of the existing dental departments of our hospitals. I could mention numerous metropolitan general hospitals which applied for and received from the College of Surgeons recognition of their dental departments as schools where students might obtain the two years' dental practice required from candidates for the L.D.S. diploma. Dental surgeons connected with these hospitals should feel and to do their best to approximate the calibre of their teaching and practice to the standard of the special hospitals. By diminishing the impression that there is anything in dentistry that cannot be done and shown in a general hospital, we shall remove the chief impediment to the restoration of the specialty to its proper educational sphere.—I am, etc.,

F. NEWLAND PEDLEY, F.R.C.S. and L.D.S.
Devonshire Place, Portland Place, W.

PERINEAL CYSTOSCOPY; OR, THE CONJUNCTION OF THE NEW ELECTRIC CYSTOSCOPE WITH THE BOUTONNIÈRE OPERATION.

SIR,—The JOURNAL of April 7th contains a description by Mr. Walter Whitehead of the first departure from the size and the projected use of the original incandescent lamp cystoscope (JOURNAL, February 4th). This consists in employing a No. 40 French sized instrument for the electric illumination of the urinary bladder through a perineal incision, instead of a No. 22 gauge by the urethral route.

Now, although Mr. Whitehead's innovation traverses the very *raison d'être* of the electric cystoscope, the small size and adaptability of which causes it to rank immediately before, and partially to supersede, digital exploration of the bladder in the diagnosis of obscure vesical disease, yet it is none the less valuable. Even from a very limited experience of this large-sized perineal cystoscope, I may safely predict its utility in three directions.

In that class of case in which digital exploration fails because the finger cannot reach the bladder by reason of certain mechanical obstacles (*vide* Whitehead and Pollard, *Lancet*, 1883, October 6th, 1883). As an example, a case under Dittel of sacculated stone with enlarged prostate may be cited (Schustter *Wien. Med. Woch.*, 1886, No. 13). The finger could not reach the bladder through the perineal route, and the Nitze-Leiter cystoscope revealed the calculus in a diverticulum.

In cases of subvilloid papillomatous growth in the bladder that is, a carpeting of the mucous membrane with stunted villi like the pile of velvet), the exploring finger sometimes does not possess sufficient tactile delicacy to detect the disease which the perineal cystoscope would immediately reveal. This case is well illustrated by a patient who came under the care of me, of New York, after having had cystotomy twice previously performed without the discovery of an existent subvilloid condition (*Journal of Genito-Urinary Diseases*, July, 1887, p. 247).

To regulate the complete removal of vesical growths by the perineal route, just as a dentist would control the burring of a vicious tooth by means of a mirror preparatory to stopping it.—I am, etc.,

E. HURRY FENWICK.
Old Burlington Street.

NAVAL AND MILITARY MEDICAL SERVICES.

THE ESTIMATES COMMITTEE.

Mr. Knox, the able and impartial Accountant-General, underwent examination before the Estimates Committee a few days ago. On the 4th Vote 4, "Medical Establishments." In reply to Mr. Brodrick he said that while it was a "moot point" whether it was necessary to give medical officers £1 a day retirement after twenty years' service, "it was a bargain with the medical profession in order to get competent men to serve in the army."

This is a plain fact well known to all the War Office permanent officials; and as a bargain it has been readily forthcoming. It has been honourably adhered to. To another question by Mr. Fowler he prudently refrained from committing himself to the suggestion that "the whole (medical) expenditure is on too high a scale, and could be reduced without impairing the efficiency;" he simply said, that while the number of officers employed does appear large, "they have multifarious duties to perform, and abroad it is necessary to be prepared for emergencies." Mr. Knox here clearly recognises another plain fact, that medical attendance on the sick

is but a part of a multitude of military duties and responsibilities which devolve upon the army medical officer.

Mr. Knox so far was on safe ground, but when closely pressed by Mr. Fowler on the question, "As permanent financial head of the department (Accountant-General), in the public interest do you think this branch (medical) of the service could be managed more economically?" he replied, "I think the number of medical officers certainly might be reduced." This was probably the answer such a stern economist as Mr. Fowler wanted to extract, but we fear it is an admission Mr. Knox will have some difficulty in demonstrating. Mere reduction of numbers is a very rough and ready method of practising economy in a public department, but it too often leads to lavish expenditure afterwards. How does Mr. Knox propose to meet "emergencies abroad" and carry on the "multifarious duties" everywhere with a diminished Medical Staff? We are presuming that up to this hour the responsible advisers of the War Office have not needlessly kept up a redundant number of medical officers. It would be possible no doubt by making medical officers do double work, and by increasing their spells of foreign service, to diminish their numbers; but that would not meet such "emergencies" as the sudden mobilisation of an army corps, or of even a division or two to carry on some of our small wars in unhealthy countries.

We fear that Mr. Knox, able as he is, is not in a position to be oracular on such a purely military question as the organisation of an army corps, or the medical necessities of our world-spread army; these are hardly questions for a civilian to determine.

We notice that Mr. Fowler embalms in his question that now venerable phrase of the Manchester school of economists, "the public interest," as against an army, or navy, or civil service interest. As if there could in these days be any such divided interests in the nation! It is vital to the "public interest" that the public services should be maintained in efficiency; there can be no antagonism; mere blind economy is often directly against the "public interest."

CLASS BLACKBALLING.

SIR,—The following notice has been put up at the Junior United Service Club, Charles Street, St. James's.

"Notice is hereby given that an extraordinary general meeting of the Club will be held on Monday, 7th May, 1888, at 2.30 P.M., to consider the following motion of the Committee: 'That the undermentioned candidates, who were rejected at the ballot on 7th instant, being in every way eligible, and their rejection constituting class blackballing, they be elected members of the club.'" (Here follow the names of two army medical officers, one officer of Militia, and one officer of the Commissariat and Transport Staff.)

From correspondence in your columns your readers will remember that certain officers, particularly army medical officers, have been lately blackballed at this Club; and the Club Committee have very properly now taken up the question, which is prejudicial to the interests, and contrary, it is believed, to the wishes, of the majority of the members; and when it is remembered that one black ball in ten excludes, you will easily understand how a few narrow-minded men can operate against a particular class of officers. Through your columns I wish to ask such of your readers as are members of the Club to be present, if possible, on May 7th, and endeavour to break down the influence of a "clique."—I am, etc.,

A CORRESPONDENT.

THE ARMY MEDICAL RESERVE.

RESERVE writes: I have read the last Warrant, and the Secretary of State's instructions thereon, also your editorial comments, etc., in the JOURNAL of March 17th. Precisely as it appears to me you have clearly and consistently and justly upheld the cause of the officers of the Medical Staff in the grave questions at issue between them and the War Office; so now, by the caution you inculcate upon medical officers of the reserve forces as to accepting the terms of the new Warrant, it is apparent that your views on this, the last, move of the authorities are sound and worthy of universal adoption by all whom it may concern.

At all army stations it is the custom to prepare a list of all medical officers in the district. This list is arranged in order of precedence, and whenever help has been needed it has been readily forthcoming. The help to which I allude is that described under Article (2) of the Warrant, and further detailed under Articles (5) and (6) of the "Instructions." Such help I can personally attest is given at great individual disadvantage to the civilian practitioner, and is not of a remunerative character. If any practitioner doubts this, let him try for himself when occasion offers, and he will soon be convinced.

Yet this is the only bait held out as an inducement to make a display of cheap patriotism on our part. I venture to assert that if we yield to the temptation we shall incur the charge of preferring our own superficial and unreal advantage to the interests of our medical brethren on the regular Medical Staff.

Pressing emergency at the present time there is none. "Grave national emergency" is a phrase that requires definition. We are all animated, by patriotic sentiments, else why should we give our time and trouble as we do for nothing? In the hour of danger and trial we are all ready to do our best for the country, but whilst the atmosphere is serene let us not forget the obligations of professional brotherhood. If only we can act unanimously in declining to help Mr. Stanhope out of a scrape, we need fear no reproaches from any quarter save from the unseem but not unfelt advisers of that right hon. gentleman, who seem to pursue the unfortunate officers of Her Majesty's Medical Staff with unremitting spite and malignity.

THE QUEEN has been pleased to give and grant unto Surgeon William Henry Phillips Lewis, Army Medical Staff, Her Majesty's royal licence and authority to accept and wear the insignia of the Order of the Osmanieh of the Fourth Class, conferred upon him by His Highness the Khedive of Egypt, authorised by His Imperial Majesty the Sultan.

VOLUNTEER AMBULANCE SCHOOL OF INSTRUCTION.

A COURSE of six lectures will be delivered in the headquarters of the London Scottish Rifle Volunteers, commencing Monday, April 23rd, at 7.30, by Leslie Ogilvie, M.B., and Walter Pearce, M.D., Acting Surgeon Artists Rifle Volunteers, of which the following is the syllabus: 1. The Air we Breathe: Breathing Space and Ventilation. 2. The Water we Drink: Bathing and Personal Cleanliness. 3. The Food of the Soldier: Cooking: the True Value of Alcohol. 4. The Clothing and Equipment of the Soldier: Climate. 5. Exercise. 6. Training. Diseases liable to occur in field service will be described, with their probable causes and methods of prevention.

THE RANK OF MEDICAL OFFICERS.

"JUSTICE" suggests that the pamphlet issued from the office of this JOURNAL on the rank question should be more freely circulated by medical officers to those friends who are working to secure the just recognition of the status of the medical profession in the army. Those good friends should have their hands in every way strengthened.

A CORRESPONDENT sends us a letter cut from the *Irish Times* disclosing the following: After a recent Castle levée the medical officers who attended were grouped together in the official lists simply as "Surgeons" at the tail end of everything; not only was their army rank and precedence absolutely ignored, but even their departmental rating among themselves was treated with contemptuous indifference, as the Principal Medical Officer figured well down the list below the latest joined surgeon from Netley. This is the last outcome of the persistent endeavours to civilise the department. Ireland used to furnish a large proportion of medical recruits to the services; we wonder what the proportion will be in the future?

PENSIONS TO ARMY MEDICAL OFFICERS.

AN INTERESTED ONE writes: Should the intention of the Government of not allowing medical officers to retire on a pension after twenty years' service be carried out, it will be most unfair and a breach of agreement to the great number who came into the service under the Royal Warrant of November, 1879, and who entered solely for the privilege of being able to retire after twenty years' service. I would recommend that a vigorous protest be at once set on foot.

THE NAVY.

THE following appointments have been made at the Admiralty: R. B. BRAY, Surgeon, to the *Duke of Wellington*; J. L. AHERNE, Surgeon, to the *Fernon*; W. M. CRAIG, Surgeon, to the *Invincible*; G. A. DRAPPER and G. H. FOOT, M.D., Surgeons, to the *Sultan*; J. J. McDONNELL, Surgeon, to the *Agincourt*; R. B. RIDDULPH, Surgeon, to the *Téméraire*; C. S. WOODWRIGHT, Surgeon, to the *Boscaven*.

Surgeon W. O. SPILLER, who entered the service August 20th, 1856, has been placed on the retired list of his rank with a gratuity.

THE MEDICAL STAFF.

SURGEONS-MAJOR G. E. DONSON, M.B., F.R.S.; E. V. McSWINEY, M.D.; A. H. L'ESTRANGE, P. T. FRAZER, and F. A. L'ESTRANGE have been granted retired pay. The commissions of all these gentlemen were contemporaneous, namely: Assistant-Surgeon, March 31st, 1868; Surgeon, March 1st, 1873; and Surgeon-Major, March 31st, 1880. Surgeon-Major Donson served in India and in the Zulu campaign of 1879 (medal). He is well known as a distinguished zoologist and comparative anatomist, and graduated B.A.T.C.D. 1869 (1st gold medal in Experimental and Natural Science at the Degree Examination and 1st Senior Moderator); M.B. and Ch.M. 1867; and M.A. 1875. He is a Fellow of the Royal, Linnæan, and Zoological Societies, a member of the Senate of the University of Dublin, and author of numerous contributions to various scientific journals, and of separate works, among which may be noted *Essay on the Diagnosis and Pathology of the Injuries and Diseases of the Shoulder-joint* (awarded gold medal of Pathological Society of Dublin); *Medical Hints to Travellers* (published by the Royal Geographical Society); *Catalogue of Chiroptera in the British Museum; Monograph of the Insectivora, Systematic and Anatomical*, 4to, 1832-33; "Insectivora," "Chiroptera," "Rodentia," in article *Mammalia*, *Encyc. Britan.*, 1883; and articles "Mole," "Shrew," and "Vampire," in the same publication. Surgeon-Major A. H. L'Estrange was engaged in the operations in the Malay Peninsula in 1875-76 (medal with clasp). Surgeon-Major Frazer was in the Afghan war in 1879-80, first in medical charge of Royal Artillery at Lund Kotal during the occupation of the Khyber Pass, and afterwards with the 13th Hussars at Candahar and with the Southern Afghanistan Field Force until the evacuation of the country in 1881 (medal). Surgeon-Major P. A. L'Estrange had medical charge of the 1st West India Regiment during the Ashantee war in 1873-74, and was at the battle of Amoaful and the capture of Coomassie, and was afterwards Transport Medical Officer for the embarkation of the sick and wounded (medal with clasp); he also served with the Nile Ex-

pedition in 1884-85, (medal with clasp and Egyptian bronze star). Surgeon-Major McSwiney has no war record.

Surgeon-Major H. H. PITCHING has been recorded for service with the Egyptian army.

Surgeon J. DONALDSON, who is serving in the Madras command, is directed to report himself to the Principal Medical Officer, Upper Burma, Mandalay for orders.

Surgeon-Major W. OREYK, serving in Bengal, has leave of absence on private affairs pending retirement from the service.

Surgeon-Major R. M. CHATEL, serving in the Bombay command, having returned from field service in Burma, is posted to general duty in the Presidency district.

ARMY MEDICAL RESERVE.

THE undermentioned officers are appointed Surgeons-Major (ranking as 1st Lieutenant-Colonels) in the Army Medical Reserve of officers: Surgeon-Major C. L. CRAWFORD, M.D., 3rd Battalion North Staffordshire Regiment (late the 2nd King's Own Stafford Militia); Surgeon-Major C. M. MACQUIBBAN, M.D., 3rd Battalion Gordon Highlanders (late the Aberdeen Militia); Surgeon and Honorary Surgeon-Major MATTHEW BAINES, M.D., 1st Middlesex Engineer Volunteers.

The following are appointed Surgeons (ranking as Captains): Surgeon F. J. MANBY, 3rd Volunteer Battalion South Staffordshire Regiment (late the 4th Stafford Volunteers); Surgeon R. J. COLLE, M.D., 3rd Volunteer Battalion Durham Light Infantry (late the 3rd Durham); Surgeon C. S. YOUNG, 3rd Volunteer Battalion Black Watch (late the 3rd Forfar); Surgeon F. H. APPLEBY, 4th Volunteer Battalion Derbyshire Regiment (late the 2nd Notts); and Acting-Surgeon C. A. MACMURDO, 3rd Volunteer Battalion South Staffordshire Regiment (late the 4th Stafford).

THE INDIAN MEDICAL SERVICE.

SURGEON W. L. PRICE, M.B., Bengal Establishment, is appointed to the medical charge of the 23rd Pioneers, vice Surgeon H. Hamilton, who has been transferred to the 5th Bengal Cavalry. Surgeon G. F. W. BRADY, Bengal Establishment, takes the officiating medical charge of the regiment, pending the return of Surgeon Price from Upper Burma.

Surgeon W. VOST, Bengal Establishment, is appointed to the medical charge of the 25th Punjab Infantry, vice Surgeon-Major G. H. Beevor, ordered on leave of absence.

Surgeon D. PRIN, Bengal Establishment, Curator of the Herbarium, Cuttack Botanic Gardens, is appointed to act as Superintendent of the Botanic Gardens.

Surgeon D. BASU, Bengal Establishment, Civil Surgeon of Furruckpore, directed to act as Civil Surgeon at Mymensingh.

Surgeon H. A. F. NAILER, M.B., District Surgeon at Chingleport, has leave of absence for one year on medical certificate.

Surgeon H. P. JERVIS, Bombay Establishment, in medical charge of the Native Infantry, is granted leave out of India on private affairs for one year.

Surgeon M. A. KER, Bengal Establishment, is appointed to the officiating medical charge of the 31st Pioneers, vice Surgeon-Major C. W. S. DEAK appointed officiating Medical Storekeeper at Meer Meer.

Surgeon G. JAMESON, Bengal Establishment, is appointed Acting Resident Surgeon at the Eden Hospital, Calcutta.

The undermentioned probationers for the Indian Medical Service, having completed a course of instruction at the Army Medical School, and being reported qualified, have been appointed Surgeons on the Madras Establishment: W. M. INGRAM, F. J. DEWES, J. O. PINTO, P. C. H. STRICKLAND, and T. STEWART.

Surgeon-Major T. C. H. SPENCER, Madras Establishment, is appointed to the officiating medical charge of the 4th Light Cavalry, vice Surgeon-Major S. Dobie.

THE VOLUNTEERS.

ACTING-SURGEON C. B. RENDLE, of the 1st Volunteer Battalion Suffolk Regiment (late the 1st Suffolk), has resigned his commission, which bore date October 25th, 1876.

Mr. T. G. HALL is appointed Acting-Surgeon to the 1st Volunteer Battalion West Riding Regiment (late the 4th West Riding).

Mr. D'ARCY POWER, M.B., is appointed to the London Division of the Volunteer Medical Staff Corps, and Mr. DR BURGH BIRCH, M.D., Surgeon to the London Division.

MEDICO-LEGAL AND MEDICO-ETHICAL.

A QUESTION OF CHARGING.

VIATOR writes: I have been attending a gentleman for nearly two months, suffering from a "Pott's fracture" of the leg. The gentleman in question (qualified L.S.A.) about thirty years ago, but never practised at all, and at present speculates in stocks. His being a man of some means was I expect the reason for his not entering into the work of his profession. Would it be right for me to send in my bill in the ordinary course, just as I would to any ordinary patient?

"* * Under the exceptional circumstances related by "Viator," there can we think, be a doubt that he will be fully justified in charging "L.S.A." as an ordinary patient (the general rule of the profession to the contrary notwithstanding), inasmuch as, although he qualified some thirty years ago as an apothecary, he has never practised as such, and in our opinion therefore is not entitled to the gratuitous services of the profession.

ETIQUETTE OF SUBSTITUTES.

A. is attending a labour close to B.'s house, and he leaves it to go to a distant party at a distance. B. is suddenly sent for, as "the child is born." He completes the case (placenta, bandage, etc.), and departs, leaving his

illments to A. The next day A. calls on B., who is out, and leaves a polite message of thanks. So far, good; but is B. entitled to something more, namely, half the fee; and, if so, what does he do to get it? Does he write to remind A.; or does he ask it of the patient?

* * * The following rule, extracted from the *Code of Medical Ethics*, page 71, applicable to the case of A. and B.:

"When a practitioner is called in or otherwise requested to attend at an accouchement for another, and completes the delivery, or is detained for a considerable time, he is entitled by custom (except in the case of illness, etc., provided for by Rule 3) to one-half of the fee; but, on the completion of the delivery, or on the arrival of the pre-engaged accoucheur, he should resign the further management of the case. In a case, however, which gives rise to unusual fatigue, anxiety, and responsibility, it is right that the accoucheur in attendance should receive the entire fee. Note.—In either event, when the officiating accoucheur is a stranger, or a non-acquaintance of the family doctor, the full fee should be tendered to him."

COSTS OF PARTNERSHIP DEEDS.

WOMEN would be glad to know, in a question of partnership where money has been paid over, which of the partners should pay for the stamps on the deed.

* * * If the partnership deed is prepared in duplicate, the better course is for the parties to send them to Somerset House and have one stamped with the full duty (*ad valorem*), and the other as a duplicate copy. By this means the parties have to pay half the duty otherwise paid (that is, if they are stamped separately, full duty is charged on each). The costs would then, of course, be divided equally between the parties.

CONTRACTS BY TELEGRAM.

DOM TENENS received a telegram at 8.30 P.M. to go at once and take charge of a practice on account of sudden illness of incumbent. He wired that he was coming. On arrival by train he was met by a person who informed him that another locum tenens, who had been sent by an office, arrived before him. It was too late to return by train, so he stayed at an hotel for the night, and charged for hotel and travelling expenses and one week's salary, 33s. Can he recover it?

* * * A contract may be made by telegram. Whether it was so made in the present case must depend on the wording of the telegram. If it contained a definite offer of an engagement, the intending locum tenens would be entitled to recover damages for the breach of contract and the expenses which he incurred in consequence.

FEE FOR INSURANCE CERTIFICATE OF CAUSE OF DEATH.

THE fee is no legally recognised scale of fees in such cases. The fee recoverable would therefore be what is reasonable. The issue of an action to recover the excess beyond the 10s. 6d. paid would be very doubtful, and clear evidence that a guinea is the fee usually charged would be necessary in order to win. In such cases a practitioner is under no obligation to give a certificate, and the best course is to decline to part with it until the proper fee is paid.

MEDICO-PARLIAMENTARY.

HOUSE OF LORDS.—Monday, April 23rd.

The Royal College of Surgeons.—In reply to Lord SUDELEY, scout CRANBROOK said that he did not think that the petition of the Royal College of Surgeons for a supplementary charter, though it raised points of some importance, could be properly referred to the Commission which was about to be appointed to consider the question of a new university.

HOUSE OF COMMONS.—Thursday, April 19th.

Medical Officers of Health and the new Local Government Bill. Mr. E. STANHOPE, in the course of the discussion on the Local Government Bill, referred to Sir Lyon Playfair's speech, in which he dealt with the subject of public health. The right hon. gentleman, he said, was perhaps the greatest authority in that House on such a question as that, and it was with much diffidence that he ventured to criticise some of his observations. By the 14th section of the Bill the powers of existing sanitary authorities were transferred to the District Councils, while certain powers of the Local Government Board were transferred to the County Councils. The right hon. gentleman complained that the Local Government Board would still retain the power of prescribing the duties of the medical officers of health, although the County Councils would have the power to make regulations with regard to their appointments and with regard to certain of their functions. The object of certain powers over the medical officers of health being retained by the Local Government Board was to secure uniformity of action throughout the country by means of general orders and instructions, which could not be secured if the whole control were handed over to the different County Councils. The right hon. gentleman had also complained that the medical officers of health were to make their reports to the Local Government Board instead of to the County Councils, but there

was no reason why copies of those reports relating to their districts should not be furnished to the County Councils. If the Bill required amending upon this point, no objection would be raised on the part of the Government when the measure reached the committee stage. The right hon. gentleman had proposed a scheme dealing with large sanitary areas under which the number of officers of health would be reduced from 1,200 to 180, each of whom would receive £600 a year. This, however, would leave 1,000 existing medical officers unprovided for, and he was afraid that the result would be to start the County Councils with an enormous expenditure, while many medical officers who had learnt their duties, and had discharged them with great efficiency and industry, would be deprived of their posts. He believed that a medical officer appointed by a Board would have, in many cases, more influence with them than any person imposed upon them from headquarters.

The Spread of Infectious Diseases.—In reply to Mr. BRUNNER, Mr. RITCHIE said his attention had been called to the report of the Medical Officer of Health to the Northwich Rural Sanitary Authority, and he might state that the Government hoped to be able to introduce a Bill to deal with the compulsory notification of infectious disease.

Friday, April 20th.

Cremation.—Dr. CAMERON asked the Secretary of State for the Home Department whether he had yet considered the application of Mrs. Eichbaum for a permit to remove, for the purpose of cremation, the remains of her daughter from the churchyard in which they were recently interred, and whether he proposed to treat the application in any way differently from one for permission to exhume a body for the purpose of reinterment.—Mr. MATTHEWS replied that the application of Mrs. Eichbaum had been under his consideration. He was advised that cremation was not necessarily illegal, and he should not therefore take upon himself to refuse leave to exhume a body merely because the relations intended to cremate instead of reinterring it. In Mrs. Eichbaum's case he had referred the matter back to the inspector, because so long a time had elapsed since her daughter's death that he thought it required consideration whether the body could properly be exhumed for any purpose, or whether special conditions would have to be prescribed.

Monday, April 23rd.

Telegraph Clerks and Infectious Diseases.—Mr. CAREW asked the POSTMASTER-GENERAL whether clerks employed at the Central Telegraph Office were compelled to absent themselves from duty when there was an infectious disease in their homes; whether they were allowed full pay during their enforced absence, whether, if the clerk suffered from an infectious disease himself, one-third of his pay was deducted, and whether he would grant full pay in both cases.—Sir H. MAXWELL, on behalf of Mr. RAIKES, said that the hon. member had stated the practice correctly. Telegraphists at whose homes there were infectious diseases were required to absent themselves; and this absence being not for their own sake, but for the sake of others, it appeared only fair that their pay should continue. But when telegraphists were themselves ill, they became subject to the deduction common to all officers of similar rank.

Prison Surgeons and Chaplains.—Dr. CLARK asked whether it was the case that prison surgeons in the principal prisons in England were appointed at a salary of £400 per annum, increasing to £500 per annum, while the prison surgeons in the principal prisons in Scotland were appointed at £200 per annum, increasing to £300 per annum; whether the prison surgeons in the principal Irish prisons began at £350 per annum, and increased to £400 per annum; whether the prisoners in the principal Scotch prisons were as numerous as in the English and Irish ones; whether the assistant surgeons in England began at £250 per annum, increasing to £300 per annum; whether the prison chaplains in England began at £350 per annum, and increased to £450, while the prison chaplains in Scotland began at £200 and increased to £300; whether the assistant chaplains in England began at £250, increasing to £300; why Scotland was treated in this way; and whether the Treasury intended to level up the Scottish officers or to reduce the English and Irish ones.—Mr. JACKSON said it would not be possible within the limits of an answer to follow the hon. member into elaborate comparisons of salaries in the three kingdoms, though he must not be understood to admit the accuracy of his statements. His whole argument rested on the supposition that the prisoners in the larger Scotch prisons were as numerous as those in England, and that was not a fact. Several first-class prisons in

England contained over 1,000 prisoners, whereas the largest Scotch prison contained only 735 prisoners, and the next two contained 550 and 450 respectively. It must be borne in mind that several of the largest English and Irish prisons, unlike those in Scotland, contained convicts.

Tuesday, April 24th.

Medical Officers in India.—Sir WALTER FOSTER asked the Under Secretary of State for India, whether it was the case that an executive officer of the Medical Staff in India, who officiated for less than one month as deputy surgeon-general, in the absence of the deputy surgeon-general on sick leave or furlough, received no allowances for the period, although he performed the duties in addition to his other duties; whether, in such instance, the "half-staff" of the appointment reverted to the State? Whether the acting officer would be held pecuniarily liable in the event of loss of stores, or other mistakes; whether officers officiating on the Military (Combatant) Staff, in a similar way, would draw the "half-staff" for broken periods; and why the difference was made in the case of the medical officers.—Sir J. GORST said he had been informed that if an officer were regularly appointed to officiate as deputy surgeon-general he would receive pay as such; but if he were merely appointed to take charge of current routine, for instance, the clerical duty of the office, and not its really administrative duties, he would not receive any extra allowance for temporary work. The answer to the second question was "yes." The answer to the third question was that the Government of India reported that he would be liable, but he imagined only to the extent to which he was personally responsible. As to the fourth and fifth questions, he had been informed that there was no parallel between the two cases, the reason given being the one was an administrative department, and the other an executive one.

Contagious Diseases Acts in India.—In reply to Mr. J. STUART, Sir J. GORST said that he had already stated that the Secretary of State would not apply to the Government of India for any reports and papers until the full report promised by the Government of India on the whole question, of which lock hospitals were a part, had been received, considered, and a decision founded thereon.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

PUBLIC HEALTH ADMINISTRATION IN BRADFORD.

ONE of the greatest obstacles in the way of the sanitary improvement of districts is the tendency of combinations to fall to pieces and to lose the advantage of the continuous services of a competent medical officer of health. The large towns are free from this difficulty, but some of them, nevertheless, have adopted the method of appointing their sanitary adviser for a short term of years. This custom is unfortunate, for it is very difficult for any officer who faithfully performs his duties not to offend one or more members of his authority, and a town suffers considerable loss if such a circumstance should lead the officer not to seek re-election. We must quote Bradford as a town which has appointed its health officers for five years, and which has acquired a high reputation for its administration during this period. Happily, there appears no likelihood that it will lose the services of so highly qualified a man as Dr. Ilime, for there seems to be a general wish that he should remain in office for a further period. Memorials, we learn from the local journal, are being largely signed by the medical men engaged in practice in the town and by merchants, and artisans in favour of Dr. Ilime's re-election at the conclusion of his five years of office, a course which the profession, as a whole, will endorse. Bradford is credited with being further sighted than some other towns, and we think it would best maintain its credit in this respect if the Town Council were to put an end to temporary service. If these gentlemen understand the value of public health work they will elect their present medical officer for life, and terminate once for all the uncertainty that must always remain where the appointment is for a fixed period. Any other course will weaken his influence for good, and encourage a less satisfactory service than a town like Bradford has a right to expect.

HEALTH OF ENGLISH TOWNS.—In the twenty-eight large English towns, including London, which have an estimated popu-

lation of 9,398,273 persons, 5,862 births and 3,585 deaths were registered during the week ending Saturday, April 21st. The annual rate of mortality, which had been 19.9 and 21.9 per 1,000 in the two preceding weeks, declined again during the week under notice to 19.9. The rates in the several towns ranged from 15.7 in Brighton and in Derby, and 16.2 in Sunderland to 24.7 in Halifax, 25.4 in Blackburn, 29.1 in Oldham, and 29.6 in Plymouth. In the twenty-seven provincial towns the mean death-rate was 20.7 per 1,000, and exceeded by 1.8 the rate recorded in London, which was 18.9 per 1,000. The 3,585 deaths registered during the week under notice in the twenty-eight towns included 151 which were referred to whooping-cough, 48 to scarlet fever, 44 to diarrhoea, 40 to "fever" (principally enteric), 37 to measles, 25 to diphtheria, and 19 to small-pox; in all, 364 deaths resulted from these principal zymotic diseases, against 371 and 358 in the two preceding weeks. These 364 deaths were equal to an annual rate of 2.0 per 1,000; in London the zymotic death-rate was 2.2, while it averaged 1.9 per 1,000 in the twenty-seven provincial towns, and ranged from 0.0 in Halifax and in Cardiff, and 0.5 in Derby and in Birkenhead to 3.2 in Salford and in Sheffield, and 3.7 in Bolton. Measles caused the highest proportional fatality in Bristol and Nottingham; scarlet fever in Oldham and Blackburn; whooping-cough in Salford, Bolton, and Blackburn; and "fever" in Preston. Of the 25 deaths from diphtheria recorded during the week under notice in the twenty-eight towns, 10 occurred in London and 3 in Brighton. The 18 fatal cases of small-pox included 12 in Sheffield, 3 in Hull, 2 in Oldham, and 1 in Manchester. The number of small-pox patients in the Metropolitan Asylums Hospitals on Saturday, April 21st, was 21, of whom 6 had been admitted during the week. These hospitals also contained 961 scarlet fever patients on the same date, which showed a further decline from the numbers in recent weeks; 91 cases were admitted during the week, against 62 and 92 in the two preceding weeks. The death-rate from diseases of the respiratory organs in London was equal to 4.4 per 1,000, and was below the average.

HEALTH OF SCOTCH TOWNS.—During the week ending Saturday, April 21st, 812 births and 535 deaths were registered in the eight principal Scotch towns. The annual rate of mortality, which had declined from 23.7 to 20.8 per 1,000 in the three preceding weeks, rose again to 21.2 during the week under notice, and exceeded by 1.3 the mean rate during the same period in the twenty-eight large English towns. Among these Scotch towns the lowest rates were recorded in Greenock and Aberdeen, and the highest in Perth and Paisley. The 535 deaths in these towns during the week under notice included 52 which were referred to the principal zymotic diseases, equal to an annual rate of 2.5 per 1,000, which exceeded by 0.5 the mean rate during the same period in the twenty-eight large English towns. The highest zymotic rates were recorded in Glasgow and Perth. The largest proportional fatality of whooping-cough occurred in Glasgow and Leith; and 8 deaths from diphtheria were recorded in Glasgow. The mortality from diseases of the respiratory organs in these Scotch towns was equal to 5.0 per 1,000, against 4.4 in London.

HEALTH OF DUBLIN.—The 168 deaths registered in Dublin during the week ending Saturday, April 21st, were equal to an annual rate of 24.8 per 1,000 (against 27.8 and 27.6 in the two preceding weeks), the rate for the same period being only 18.9 in London, and 20.1 in Edinburgh. The 168 deaths included 12 which resulted from the principal zymotic diseases (equal to an annual rate of 1.8 per 1,000), of which 5 resulted from whooping-cough, 3 from scarlet fever, 2 from "fever," 1 from diphtheria, and 3 from diarrhoea.

OBITUARY.

FRANCIS S. B. F. DE CHAUMONT, M.D., F.R.S.,
Professor of Military Hygiene in the Army Medical School,
Netley.

IN our last issue we announced the lamented death of this distinguished man, cut off at the comparatively early age of 51. Dr. de Chaumont was, as his name indicates, of French extraction on his father's side; his mother was a Scottish lady. He was

in Edinburgh, and educated in the High School and University of that city. After passing through the arts and medical sciences with distinction, he obtained his degree with honours, and entered the medical service of the army, serving in the Rifle Brigade in the Crimea. On the removal of the Army Medical School from Chatham to Netley, Dr. de Chaumont was appointed Assistant Professor of Military Hygiene, under the late Dr. Parkes. In this position he not only assisted his principal in the laborious duty of teaching in the laboratory of the School, but did an immense amount of extra work for Government in the way of analysis, reporting on hospitals and barracks, contributing to the Departmental Blue Book, and papers to scientific journals on health questions. He was also appointed to give instruction to young officers of the Royal Engineers at the School of Military Engineering at Chatham on military hygiene, so far as concerned health arrangements and construction of military buildings, such like matters—instruction which was highly valued, not only by the young officers, but by their seniors also.

On the lamented death of Professor Parkes, Dr. de Chaumont, with the hearty concurrence of the other professors and the War Office, appointed his successor. It is with regret we have to add that the late Professor felt aggrieved with the terms of his appointment. He felt that the Government had driven a hard bargain with him, ignoring his previous military service, exacting much and giving little. Into this unpleasant subject it is vain to enter. Suffice it to say that what Dr. de Chaumont considered unjust treatment was keenly felt by him to the last, and must be regarded as one more example of the little appreciation by the Government of the day—and of all days—in this country, of scientific merit, particularly in the ranks of the medical departments of the public service.

From this time until his health completely broke down, the subject of this notice led a laborious life. In addition to the heavy and responsible duties of his chair, conscientiously discharged, he did an immense amount of work, taking an active part in congresses at home and abroad; inspecting and reporting on hospitals, barracks, and public buildings; giving addresses on health questions to various societies; and, above all, editing the great work of Parkes on *Practical Hygiene*, two editions of which he published, bringing the work up to the latest developments of the science with conspicuous ability, and in such a reverent spirit to the work of his great master as to be highly appreciated by Dr. Parkes's old pupils and friends and the profession generally.

Dr. de Chaumont was elected a Fellow of the Royal Society. It is not possible for us to give in this brief obituary notice a list of his numerous contributions to science; that will be done fully in the *Transactions* of that Society in the usual course. Meanwhile it must suffice to say that the late Professor was *facile princeps* in his own department, and was acknowledged to be so throughout Europe, and in the United States of America more particularly. His scientific knowledge, far from being confined to his own branch, was large and accurate; he delighted in the mathematical science, in which he excelled, and in which, if his other pressing duties and pursuits had permitted, he was capable of greatly distinguishing himself. He was an accomplished linguist, familiar with all the modern languages, and a master of logic, a study very congenial to him. He delighted in music, and a knowledge of its principles that would have been creditable to a professed musician, and far beyond that of amateurs; if time had allowed, he would have excelled as an executant; as it was, some years ago he could "attack" the compositions of the great masters of the piano in a manner not often attempted by amateurs. Like most men of intellectual power, he had a caulay-like tenacity of memory; whatever he read he remembered, and stored in his mind with such order and method that it was available with unflinching readiness at a moment's notice. With all his acquirements he was the most modest of men; all his knowledge was at the service of his friends; he possessed a generous and equal temper, had not a trace of literary jealousy in his nature, and was a loyal colleague.

Into the melancholy details of the ailments that cut short this useful life we do not propose to enter; cardiac failure, the outcome of diabetes and occasional albuminuria, attended of late by profound mental depression, closed the scene. It was too silent to his friends that his life's work was done, and they felt that under the sad circumstances he was fortunate in his death.

His *ultima linea rerum* est.
He was buried in the cemetery of St. Mary's Extra, near

his own residence, Woolston, Southampton. Although rain fell in torrents throughout the day, with a bitter north-east wind, it was attended by the whole of the staff at Netley Hospital, the professors and the surgeons on probation in the Army Medical School, many members of the Southampton Literary and Philosophical Society, of which he was President, the Council of the Hartley Institution, of which he had, until a few days before his death, been a member, and representatives from other public institutions in Southampton, and by a large number of the gentry and medical practitioners in the neighbourhood.

UNIVERSITY INTELLIGENCE.

CAMBRIDGE.

THE following degrees were conferred at the Congregation on Thursday:—M.B. Degree: Chichester Gould May, B.A., Trinity; E. Hunt Cook, M.A., St. John's; Thomas Brushfield, B.A., Caius. B.C. Degree: E. Hunt Cooke, M.A., St. John's.

A grace proposing to put Bachelors of Medicine into the *status pupillaris* was rejected.

MEDICAL NEWS.

MEDICAL VACANCIES.

The following Vacancies are announced:

- ANCOATS HOSPITAL, Manchester.—Junior Visiting Surgeon. Salary, £60 per annum. Applications to the Honorary Secretary.
- BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon. Salary, £150, and £30 extra for cab hire. Applications by May 10th to A. Forrest, Esq., Secretary.
- BIRMINGHAM GENERAL HOSPITAL.—Assistant House-Surgeon. Residence, board, etc. Applications by April 28th, to the House Governor.
- BIRMINGHAM GENERAL HOSPITAL.—Resident Surgical Officer. Salary, £130 per annum, with board and residence. Applications by April 30th to the House Governor.
- BOROUGH OF BRIGHTON.—Medical Officer of Health. Salary, £500 per annum. Applications by May 2nd to F. J. Tillstone, Esq., Town Clerk.
- BRISTOL ROYAL INFIRMARY.—Honorary Assistant Physician (to out-patients). Applications by May 5th to the Secretary.
- BURY DISPENSARY HOSPITAL.—Junior House-Surgeon. Salary, £60 per annum, with board and residence. Applications by May 5th to the Honorary Secretary.
- CALLAN UNION.—Medical Officer, Ballygarry Dispensary. Salary, £120 per annum and fees. Applications to Mr. William Bryan, Honorary Secretary. Election on May 3rd.
- CROYDON GENERAL HOSPITAL.—House-Surgeon. Salary, £100 per annum, with board and residence, increasing to £120. Applications by May 11th to the Honorary Secretary.
- DURHAM COUNTY HOSPITAL.—Honorary Surgeon. Applications by April 30th to the Secretary.
- DURHAM COUNTY HOSPITAL.—Honorary Surgeon-Dentist. Applications by April 30th to the Secretary.
- HERTFORD BRITISH HOSPITAL, Paris.—House-Surgeon. Applications to the Secretary, Rue de Villiers, Levallois, Paris.
- HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen Square, W.C.—House-Physician. Salary, £50 per annum, with board and residence. Applications by April 30th to B. Burford Rawlings, Esq., Secretary-Director.
- HULL ROYAL INFIRMARY.—Junior Assistant House-Surgeon. Salary, £50 per annum, with board and lodging. Applications by April 30th to the Chairman, House Committee.
- LIVERPOOL INFIRMARY FOR CHILDREN.—Assistant House-Surgeon. Board and residence. Applications by May 2nd to the Honorary Secretary.
- LONDON SKIN HOSPITAL, 47, Cranbourn Street, W.C.—Assistant Medical Officer. Applications by May 1st to the Secretary.
- LONDON TEMPERANCE HOSPITAL.—Registrar and Chloroformist. Salary, £50 per annum. Applications by May 5th to the Secretary.
- LONDON THROAT HOSPITAL, Great Portland Street, W.—Surgeon. Applications by May 1st to W. H. H. Stewart, Esq., Honorary Secretary of Medical Committee.
- MONKWEARMOUTH DISPENSARY AND ACCIDENT HOME.—House-Surgeon. Salary, £50 per annum, with board and lodging. Applications by May 5th to T. R. Blumer, Esq., Honorary Secretary, Avenue House, Monkwearmouth, Sunderland.
- NEWPORT AND COUNTY INFIRMARY.—House-Surgeon. Salary, £100 per annum with board and residence. Applications to J. K. Stone, Esq., The Infirmary, Newport, Mon.
- NORTH-WEST LONDON HOSPITAL, Kentish Town Road.—Senior Resident Medical Officer. Applications by May 7th to the Secretary.

PARISH OF LOCHS, Stornoway.—Medical Officer. Salary, £140 per annum; with free house. Applications by May 16th to Mr. H. M. L. Ross, Inspector of Poor, Lochs and Barvas.

ROYAL FREE HOSPITAL, Gray's Inn Road.—Assistant Physician. Applications by May 16th to the Secretary.

ROYAL FREE HOSPITAL, Gray's Inn Road.—Assistant Surgeon. Applications by May 16th to the Secretary.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road.—Junior House-Physician. Salary, £50 per annum, with board and lodging. Applications by May 19th to the Secretary.

ROYAL SOUTH HANTS INFIRMARY, Southampton.—Assistant to House-Surgeon. Board and residence. Applications by May 5th to Dr. Thomas, Anglesea Place, Southampton.

SEAMAN'S HOSPITAL SOCIETY.—Visiting Physician. Applications by May 5th to P. Michelli, Secretary, Seaman's Hospital, Greenwich, S.E.

WARWICK COUNTY LUNATIC ASYLUM, Hatton, near Warwick.—Assistant Medical Officer. Salary, £100 per annum, with board, etc. Applications to the Superintendent.

WESTPORT UNION.—Medical Officer. Achill and Ballycrocy Dispensary. Salary, £117 per annum and fees. Applications to Mr. John Corrigan, Honorary Secretary. Election on May 8th.

MEDICAL APPOINTMENTS.

BARON, Barclay J., M.B. Edin., appointed Lecturer on Pathology and Morbid Anatomy in the Bristol Medical School.

BRETT, W. T., M.R.C.S., appointed Resident Clinical Assistant to the East London Hospital for Children, vice N. Lewis, M.R.C.S., resigned.

BROWN, F. L. Harman, M.B., appointed Assistant Medical Officer to the Bristol Asylum, Stapleton.

HINKELL, J. S., M.R.C.S. Eng., L.S.A., appointed Junior House-Surgeon to the Royal London Ophthalmic Hospital, vice E. T. Collins, L.R.C.P. Lond., M.R.C.S. Eng.

KAUFFMANN, Otto, M.B., M.R.C.S., appointed Resident Clinical Assistant to the Hospital for Consumption, Brompton.

LEK, M. J., L.R.C.P., L.R.C.S. Edin., appointed Medical Officer to the Cloonbur No. 2 Dispensary, Oughterard Union, vice John Gorham, L.R.C.P., L.R.C.S. Edin., resigned.

MORTON, T., M.B., B.S., appointed Medical Officer to the Durham Union Workhouse, vice Edward Jepson, M.R.C.S., L.S.A., resigned.

PEDLEY, George Aston, M.R.C.S. Eng., L.R.O.P. Lond., L.S.A., appointed Deputy Superintendent of Vaccination for Mandalay, Upper Burma.

RAINES, Alwyn, M.B., C.M., appointed Medical Officer to the York Rural Sanitary Authority.

SOMERS, Noble L. U., L.R.C.S.I., L.M., appointed Medical Officer to the Lettermore Dispensary, Galway.

STEDMAN, F. Osmond, M.B., B.S. Lond., appointed Surgical Registrar to Charing Cross Hospital, vice W. J. Roedel, resigned.

WALKER, C. H., M.R.C.S., appointed Senior House-Surgeon to the Royal London Ophthalmic Hospital, Moorfields.

WEIR, G. W., M.D., C.M., appointed Medical Officer to the Liddell Provident Dispensary, Jarrow-on-Tyne, vice J. Johnstone Weir, M.B., O.M., resigned.

WREFOED, J., L.R.C.P. Lond., M.R.C.S. Eng., appointed Junior Assistant Medical Officer to the Norfolk County Asylum, Thorpe, vice F. L. Harman Brown, M.B., C.M. Edin., resigned.

WYNER, W. B., F.R.C.S. Eng., L.R.C.P., appointed Resident Clinical Assistant to the Hospital for Consumption, Brompton.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—At the quarterly court of Directors of the Society, three new members were elected, and the deaths of three announced. The deaths of three widows in receipt of grants were reported. A fresh application for relief was read from a widow for herself and five children, and a grant was made her. Applications for a renewal of their grants were made by sixty-one widows, seven orphans, and three orphans on the Copeland Fund, and a sum of £1,389 10s. was recommended for distribution at the next court. The expenses of the quarter were £57 14s. A legacy from the executors of Mrs. Elizabeth Douglas of £900 was announced. The following gentlemen were recommended for election as directors at the annual general meeting, in the place of those who retire: Dr. Matthews Duncan, Dr. Buzzard, Dr. Glover, Dr. Hett, Mr. Brailey, and Mr. Spencer Watson. The annual general meeting was fixed to be held on May 18th, at 5 p.m. The centenary dinner will be on October 29th.

THE QUINN BEQUEST.—Mr. Henry Quinn bequeathed £50,000 to the charities of London and the neighbourhood, out of which Mr. W. M. Hepper, the executor, has given £5,000 to the Building Fund of the Great Northern Central Hospital (with the condition that a ward in the new building shall be named "The Henry Quinn Ward"); £1,200 to King's College Hospital; £1,200 to the Charing Cross Hospital; £1,000 to University College Hospital; £1,000 to the Richmond Hospital; £500 to the Royal Hospital for Diseases of the Chest; £500 to the National Hospital for Consumption, Ventnor; £400 to the Victoria Hospital for Children, Chelsea; £300 to the Metropolitan Convalescent Institution; £300 to the London Temperance Hospital; £200 to the Royal Hospital for Children and Women; and £200 to the Surgical Aid Society; all less duty.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL: PRIZES AND SCHOLARSHIPS (1887-88).—1st Winter: J. H. Fisher, the William Tite Scholarship, £30; A. Banks, £20; C. S. Wallace, £5; C. S. Jaffe, £5 (College prizes). 2nd Winter: C. P. Lovell, the Peacock Scholarship (40 guineas); W. P. Umney, College prize (£20); H. Burden, College prize (£10). 3rd Winter: A. F. Stabb, second tenure of Musgrove Scholarship (40 guineas) and College prize (£20); S. G. Toller, College prize (£15); W. G. G. Stokes, College prize (£10). The "Mead" Médal for Practical Medicine: H. G. Turney; Messrs. W. H. L. Copeland, T. P. Cowen, and P. C. Thomas were specially mentioned, and obtained marks qualifying for the medal. The "Cheselden" Médal for Surgery and Surgical Anatomy: F. C. Abbott; Messrs. A. N. Boycott and H. H. Hulbert obtained marks qualifying for the medal.

A PROMISING STUDENT.—Complaint is often enough heard that the portals of the medical profession are not guarded with sufficient jealousy against the intrusion of persons of defective education, and examiners, no doubt, often have the delicate adjustments of their higher cerebral centres rudely shaken by the phonetic spelling and ataxic composition of the embryo Jenner, and Pagets who come before them. With all our deficiencies, however, it is doubtful whether even the most hopeless "chronic" could match the following (authentic) specimen of a clinical report which we take from an American contemporary:—"History of Present Illness.—Stranded himself and spit of a brittle red color. Present Condition.—'Have you any fever or nite sweats?' 'No.' Very little expansion of scapular in rite. Physical Examination.—Exaggerated breathing, herd friction sounds, herd snore valves (this statement much puzzled the examiners; ultimately they concluded the candidate referred to 'sonorous râles'). Prognosis.—Can't be cured, but can be sent to Mexico."

PRESTON MEDICO-ETHICAL SOCIETY.—At a meeting of the Society, held on April 5th, a resolution was proposed by Dr. Chas. Rigby, seconded by Dr. Dunn, and carried, expressing the view of the meeting that the necessity imposed upon medical men to keep horses for professional purposes, altogether apart from pleasure should cause them to be exempt from the proposed horse tax. Letters having been read from the local agent of the National Medical Aid Society, it was resolved: "That the members of the Society be recommended to adhere to the resolution of October 1884, counselling them not to become medical officers to any private society started to provide medical attendance to families at a fixed rate." The following officers were elected: Dr. Louis President; Dr. James A. Rigby, Vice-President; Drs. Garner, Smith, Green, Rayner, Charles Rigby, and Anderson, Committee; M. Walmesly, Treasurer; Dr. Sellers, Clinical Secretary; Drs. Kim and Kerr, Auditors; and Drs. Holden and Byrne, General Secretaries.

The *Sydney Morning Herald*, of February 24th, states that Mr. W. H. Paling, of George Street, has most munificently offered to Lord Carrington his estate at Camden, consisting of 450 acres with the entire plant and stock, with the sum of £10,000, for the purpose of establishing and endowing a hospital for convalescents. The hospital is intended as a memorial of the centenary of the colony, and is to bear the name of the present governor. Lord Carrington has been requested to take the necessary steps to carry out Mr. Paling's wish. The property, which is within short distance of Camden, is said to be admirably suited for the purpose intended. A provisional committee is to be formed, and the scheme is to be brought before the public with a view to obtaining additional subscriptions to supplement this magnificent gift.

DEATH OF A FRENCH MEDICAL JOURNALIST.—Dr. Broch, editor of the *Gazette des Hôpitaux*, died recently at an advanced age. For nearly half a century he had held a leading place among medical journalists in France, and he may be said to have ended his life in harness. He was a man of great literary and professional ability, and of singular integrity of character.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.

MEDICAL SOCIETY OF LONDON, 8.30 P.M.—Clinical evening. The President (Sir William Mac Cormac): Case of Osteo-plastic Resection of the Foot (Method of Mikulicz). Mr. Edmund Owen: Case of Reducible Lumbar Hernia cured by Operation. Dr. Hugh Case of Echinopsia Nutans. Dr. Herringham: Case of obstructive Jaundice, with Enlarged Gall-bladder. Cases by Dr. Heron and others.

TUESDAY.

PATHOLOGICAL SOCIETY OF LONDON, 8.30 P.M.—Ordinary Specimens: Mr. Dorn: Primary Cancer of Fallopiian Tube. Mr. Bruce Clarke: Sloughing of Bladder following Cystitis. Mr. Silcock: Cystic Disease in Testis. Mr. J. Hutchinsin, jun.: Dupuytren's Fracture. Dr. M. Murray: Congenital Disease of Heart in Adult. Dr. N. Moore: Examples of several forms of New Growth. Dr. Coats: 1. Multiple Cancer of Brain, Lungs, Bones, etc. 2. Primary Cancer of Brain. Dr. Crooke: Primary Cancer of Liver. Dr. Turner: Extreme Contraction of Orifices of Coronary Arteries. Dr. Pease: Advanced Surgical Kidneys. Mr. Bland Sutton: Mamme in Dermoid Cysts. Card Specimens: Dr. Crooke: Perihepatitis with Cirrhosis of Liver. Dr. H. Habershon: Malformation of Heart and Kidney. Mr. Dunn: Cerebral Tumour. Mr. Shattock: 1. Cyst in Corpus Luteum. 2. Two Specimens of Hammer Toe. Mr. Luun: Pemphigus of Larynx. Mr. Mansell Moullin: 1. Osteoma of Skin. 2. Bladder with Vesical and Prostatic Calculi. Mr. J. H. Morgan: Ulceration of Bladder.

WEDNESDAY.

GYNÆCOLOGICAL SOCIETY OF LONDON, 8 P.M.—Specimens will be shown. Dr. Cullingworth: Cyst connected with the Uterus, and simulating Enlargement of that Organ. Mr. Bland Sutton: The Glands of the Fallopiian Tubes and their Function. Dr. Scougal: A Case of Hemiplegia after Parturition.

COLLEGE OF STATE MEDICINE, Burlington House, 4 P.M.—Mr. R. Brudenell Carter: The Aims and Objects of State Medicine.

PSYCHOLOGICAL ASSOCIATION, Bethlem Hospital, 4 P.M.—Dr. Maudsley: "Some Remarks on Crime and Criminals." A meeting of the Council will be held at 3 P.M.

THURSDAY.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM, 8.30 P.M.—Living and Card Specimens at 8 P.M.—Mr. W. J. Collis: 1. Rare Affections of the Eyelids—Photographs and Drawings. 2. Case of Paralysis of Fifth Nerve with Cataract. Mr. J. B. Lawford: Pathological Specimens. Mr. S. H. A. Stephenson: Case of Optic Neuritis after Measles. Papers: Mr. Charles Higgins: On a Case of Melanotic Sarcoma of Eyeball. Mr. M. McHardy: 1. Primary Tuberculosis of Choroid treated by Enucleation; Recovery. 2. On a Simple Expedient for Enhancing the Cosmetic Effect of Artificial Eyes. Dr. Hill Griffith: Eye Symptoms in Hysteria and Allied Conditions.

OBSTETRIC SOCIETY OF LONDON, 8.30 P.M.—Mr. Watson Cheyne: The Treatment of Spinal Abscess. Mr. C. J. Symonds: On some Obscure Cases of Painful Feet.

ANTHROPOLOGICAL MUSEUM OF HYGIENE, 5 P.M.—Professor T. Hayter Lewis: On Ancient and Mediæval Towns.

FRIDAY.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, 8 P.M.—Pathological Specimens: Mr. Percy Dunn: 1. Rectum, adjacent parts and portion of Sigmoid Flexure, the seat of large Scirrhus growth. 2. Caseous Deposit in Lung of Child 18 months old. 3. Large Hernial Sac and Testis, placed abnormally in the Groin and removed during Life. Clinical Cases: Mr. Bruce Clarke: A Case of Multiple Exostoses in three members of the same family. Mr. Van Buren: A Case of Nævoid Growth in the Lower Jaw of a Child. Mr. Swinford Edwards: A Case illustrating one cause of Failure in the Operation for Fistula in Ano. Mr. Percy Dunn: A Case of Complete Irideremia. Mr. W. Lang: A Series of Cases of Disease of the Conjunctiva and Cornea. Mr. Jonathan Hutchinson, F.R.S., will communicate matter of clinical interest. Papers: Mr. Swinford Edwards: On the Treatment of Piles by Injection. The President (Mr. Keetley): On a Case of Wound (Intra-peritoneal) of the Urinary Bladder treated by Suture.

SATURDAY.

PATHOLOGICAL SOCIETY OF LONDON, Physiological Laboratory, University College, 4.30 P.M.—Professor Schafer: On the Visual Area of the Cerebral Cortex. Mr. E. P. France: A modified Weigert Staining Process. Degenerations following Lesions of the Marginal Gyrus. Dr. Beavor: Sections of Brain stained by Pal's modification of Weigert's method.

BIRTHS, MARRIAGES, AND DEATHS.

Charge for inserting announcements of Births, Marriages, and Deaths is 5s. 6d., which should be forwarded in stamps with the announcement.

BIRTHS.

WIMBORNE.—April 19th, at Southend, Essex, the wife of Robert G. Dempster, surgeon, of a daughter, prematurely.

WIMBORNE.—At Guernsey, on the 22nd April, the wife of R. L. Lovc, M.D., Surgeon Army Medical Staff, of a son, premature, stillborn.

MARRIAGES.

WIMBORNE.—On March 1st, at Melbourne, Victoria. J. W. Dunbar Hooper, L.R.C.P. and S.Ed., to Mathilde, daughter of the late Antoine Hegmann, of Neuchâtel, Switzerland.

WIMBORNE.—April 19th, at Trinity Church, Horwich, Bolton-le-Moors, by the Rev. H. S. Pigot, M.A., Vicar, James Paul McGeagh, M.D., M.Ch., of Stoneycroft, Liverpool, to Mary, eldest daughter of William Howarth, Wallsuches, Horwich.

DEATHS.

WIMBORNE.—April 21st, at Southend, Essex, Dorothy, the infant daughter of Robert and Kate B. Siddieley Dempster.

WIMBORNE.—On the 13th instant, at 16, Deane Road, Fairfield, Liverpool, after a very short illness, James Johnstone Luce, M.D., L.R.C.P., M.R.C.S. Deeply regretted.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS respecting editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

In order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the office of the JOURNAL, and not to his private house.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL, are requested to communicate beforehand with the Manager, 429, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication. CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

QUERIES.

MEMBER would feel much obliged if any gentleman would kindly give him a few particulars about a drug called "havena" or "avena" used in epilepsy.

CONGENITAL SYPHILIS.

HERMES asks for advice in the treatment of the following case: Mrs. S. is nearly three months pregnant; six months before her impregnation Mrs. S. contracted true syphilis—i.e., indurated chancre, followed by copious eruption—and has been treated throughout by mercury. The impregnation took place in the belief that the husband was well; he has now, however, marked "reminders" present. Will the child of necessity be syphilitic? Ought the mother to take mercury? Is it justifiable to procure abortion or induce premature labour?

PERSISTENT YAWNING.

UNIQUE asks for advice as to the cause, prognosis, and treatment of a lady, middle-aged, in fair general health, who suffers from constant and intolerable fits of "yawning;" they do not appear to be due to fatigue or any special debility; beyond slight dyspepsia and constipation, the bodily health is good. The yawning begins in the morning after a good night, and continues at intervals all day. Tonics, alteratives, attention to digestion, etc., have been tried without removing this somewhat unpleasant affection.

ANSWERS.

A. D. asks to be recommended the best recent books on gonorrhoea, acute and chronic, also those on syphilis.

** *Syphilis and Local Contagious Disorders*, by Hill and Cooper; or *Veneral Diseases*, by Bumstead and Taylor. The most recent work on syphilis only is that by Mr. Hutchinson in Cassell's series.

"THE INIQUITOUS TAX ON INDUSTRY."

T. G. S. writes: I started in practice nearly two years ago, and during that time have purchased instruments and surgical apparatus, whenever required, to the extent of £40. The surveyor of income tax from the district claims that this sum of money is "capital," and must not be included among expenses. My predecessor always reckoned such payments as expenses, and so do the other practitioners in the neighbourhood. The tax surveyor is probably making a dead set at me as a newcomer.

** In answer to the above, the Income Tax Repayment Agency, 25, Colville Terrace, Powis Square, London, W., write: "One of the great mistakes in the present system of assessing professional incomes is that there is no uniformity; all depends on the dicta of the surveyor of taxes. We know of cases where no demur is made about allowing the cost of instruments and books; in others the purchase is looked upon as an expenditure of capital. When this is done, the person assessed should put down every year a part of the purchase money as depreciation; for instruments and books decrease very rapidly in value. The tax overpaid would thus be gradually paid back. We would have all medical men recollect that now is the time for claiming repayment of tax on over-assessed incomes."

NOTES, LETTERS, ETC.

PLACENTA PREVIA.

W. F. writes: The successful treatment of a case of the above (left to Nature) recorded by Dr. G. B. Fuller, induces me to send you an experience I have lately had of a much less pleasant nature.

I saw, on Friday, April 6th, at 4 P.M., M. L., aged 40, in her twelfth confinement. During the previous six weeks she had had two attacks of severe hæmorrhage, treated by a midwife. She had been flooding from 2 A.M. on the day I saw her, and had had five or six fainting fits previous to my visit. She was perfectly blanched and pulseless. The vagina was full of clots, and the bedclothing soaked with blood. Having given brandy and beef-tea, and encouraged the countenance of a friend, I brought down a foot very easily, enquired the countenance of a friend, I brought down a foot very easily, enquired the countenance of a friend, I brought down a foot very easily, enquired the countenance of the slight dilatation of the os. In spite of every precaution, on account of the slight dilatation of the os. In spite of every precaution, on account of the slight dilatation of the os. In spite of every precaution, on the fifth day from acute pyæmia.

My first and last experiences of this disease have been unfortunate. The former, in a woman of about the same age, I did not see for several hours

after the onset of the hæmorrhage, and treated by stripping off the placenta from the lower zone (Barnes), and waiting. Sir died on the third day from exhaustion. During the intervening period embraced by these experiences I have had four (complete) cases to deal with, all seen early, all treated by turning, and all successful. This is the method adopted by all the experienced obstetricians in this quarter I have talked to on the subject, and has many things to commend it. Barnes's bags one may or may not have, but one's fingers and the skill they contain are always possessors. I commend to students of this subject the following, from Lusk's admirable book: "In this disease the result depends in a large measure upon the personal qualities of the physician. A self-possessed man, cool and resolute, will, if summoned in season, apparently deprive even placenta previa of a good share of its terrors. This is my own experience, and the way to do it is by turning."

COCAINE AS A LOCAL APPLICATION IN GOUT.

DR. ROBERT BELL (Glasgow) writes: During the past few weeks I have treated several cases of gout by the local application of a 5 per cent. solution of cocaine by means of lint saturated with the lotion and afterwards covered with oil silk to prevent evaporation. In every instance the acute pain has disappeared within a few minutes, and the attack has run a much shorter course than on previous occasions in the same individual. It is only necessary to renew the compress night and morning to insure continuous freedom from pain.

NEALE'S "DIGEST."

H. M. D. writes: Not from any unworthy motive did I write in praise of Neale's Medical Digest, nor do I regret having done so, for it is a most useful work to the busy practitioner in cases of emergency and for deliberate reference. One far greater than myself, Sir James Paget, gave his testimony to the same effect in one of his recent addresses. Many years ago Dr. Parkes expressed his approval of the plan of the work, and it was selected by the New Sydenham Society for publication as early as 1877. The Digest is the outcome of some forty years' labour. I regret that I did not meet with it while I was in arduous general practice. One hint is necessary to purchasers of the work; they must learn how to use this more than "index," that is, spend a few minutes over the directions for its employment and in the perusal of the introduction with a reference to some cases that have cropped up in the course of daily practice.

A great composer headed one of his difficult compositions with these words: "Before you condemn me, learn to play me." In a similar spirit do I reply to "A Member's," note at page 886 of the JOURNAL of April 21st.

THE CLIFTON LYNACY CASE.

MR. W. H. HARSANT (Clifton) writes: Will you be kind enough to give publicity to the following additional list of subscriptions to the Marshall and Shaw fund?

Mr. W. R. Ackland's subscription of £2 2s. was inadvertently acknowledged as £1 1s. in the last list.

Amount already acknowledged	£	s.	d.	Jenner, Sir W., Bart., K.C.B.	£	s.	d.

IDIOSYCRASY TO QUININE.

DR. HENRY H. VERNON (Southport) writes: Some years ago I had a patient who was always attacked by erythema on taking quinine. The first time I gave it to him he recognised the drug, and said he expected in a day or two the rash would come out, and come out it did, and was followed by prœling. On a former occasion another practitioner had given him full doses, and the result was acute erythema, followed by free desquamation in large patches, especially from the palms of the hands. Many years later I ventured upon quinine again, hoping that time might have modified the idiosyncrasy, but the same result followed, though in a less degree, as the dose had been comparatively small. Is this so-called idiosyncrasy an inflex of something which occurs in all cases where quinine is taken, but which in only a few runs on to the extreme phenomena of erythema? If so, does this occasionally violent action of quinine throw any light upon its well known curative effect upon erythema nodosum, or suggest anything as to the action of quinine upon the skin generally?

TREATMENT OF CARUNCLE.

DR. HERBERT SNOW (Bayswater, W.) writes: May I be permitted to endorse Mr. Lowndes's very moderate-voiced condemnation (in the JOURNAL of April 7th) of some recent papers on this topic? However effective and how-ever easy to practise in hospitals, erosion is an unnecessarily severe measure. Patients naturally dread anything which they term an "operation," and the surgeon who in private practice is too fond of resorting to heroic treatment usually gains a somewhat unenviable notoriety.

My own method is very similar to Mr. Lowndes's. I paint the central slough from day to day with liquid carbolic acid, and the surrounding area of inflammation with liniment of iodine, keeping on a linseed poultice. All cases, including very severe ones in aged people—three on the face—have done well under this simple procedure.

COMMUNICATIONS, LETTERS, etc., have been received from

Dr. F. Vacher, Birkenhead; Dr. H. Rayner, Hanwell; The Manager of Alaska and Hudson Bay Fur Store, London; Mr. O. E. Paget, Kenda; M. T. G. BOOKS, ETC. RECEIVED.

Dissolution and Evolution and the Science of Medicine, By E. Pitfield Mitchell. London: Longmans, Green, and Co. 1888.
Treatise on Alcohol, By Thomas Stevenson, M.D. Second edition. London: Gourney and Jackson. 1888.
A Manual of Operations of Surgery, Illustrated, By Joseph Bell, M.D., F.R.C.S. Sixth edition, revised and enlarged. Edinburgh, Oliver and Boyd: London: Simpkin, Marshall, and Co. 1888.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE "BRITISH MEDICAL JOURNAL."

Seven lines and under	£0 3 6
Each additional line	0 0 4
A whole column	1 15 0
A page	5 0 0

An average line contains seven words.

When a series of insertions of the same advertisement is ordered, a discount is made on the above scale in the following proportions, beyond which no reduction can be allowed.

For 6 insertions, a deduction of	10 per cent.
" 12 or 13 "	20 "
" 24 "	25 "
" 52 "	30 "

Special terms for occasional change of copy during series: 20 per cent. if not less than 24 pages be taken) or their equivalent 2) 52) in half or 30) 104) quarter pages.

For these terms the series must, in each case, be completed within twelve months from the date of first insertion.

Advertisements should be delivered, addressed to the Manager at the Office, not later than noon on the Wednesday preceding publication; and, if not paid for at the time, should be accompanied by a reference.

Post-Office Orders should be made payable to the British Medical Association, at the West Central Post-Office, High Holborn. Small amounts may be paid in postage-stamps.

NOTES

ON

A VISIT TO PISTYÁN.

By SIR T. SPENCER WELLS, BART., F.R.C.S.

Consulting Surgeon to the Samaritan Hospital for Women and Children.

I HAD heard occasionally for many years past of remarkable recoveries of patients crippled by gout or rheumatism, or by chronic diseases of joints; also of great benefit derived in many paralytic cases, after a course of the baths at Pistyán, in Hungary; and last September, before attending the Hygienic Congress at Vienna, I determined to visit the place. I could find very little about it in any of the guidebooks, or in works on bathing-places. Bradshaw's *Dictionary* says it is on the route from Vienna to Pesth, which it is not, but on a branch line which turns up northwards at Pressburg. In Baedeker's *Southern Germany*, in the account of the railway route from Pressburg along the valley of the Waag, it is correctly stated that at fifty miles from Pressburg we reach Pistyán, "with the favourite baths of that name, used as a remedy for gout and rheumatism, on an island in the Waag. On the 26th of July, 1599, the Turks attacked the baths when attended by numerous patients, massacred the men and carried away the women as prisoners." This is all that I could learn from books, but fortunately I found an old friend there, a former "opérateur" of Professor Albert's clinic in Vienna, who had been practising there during the summer, and who had been so favourably impressed by what he had observed that he had decided to return there next season. From him, Dr. Wilhelm von Vragassy, I received even more favourable reports of the efficacy of the treatment carried out at Pistyán than I had heard in England; and the few notes I made on the spot may interest practitioners who are consulted as to the choice of a Continental bathing place by patients who desire—in addition to rest and the change of air, scene, diet, and mind to be obtained at almost any of the well-known places of resort—something more decidedly curative in cases of serious chronic disease. The well-known Vienna surgeon, the late Professor von Dumreicher, some thirty years ago recovered from very obstinate sequelæ of blood-poisoning most unexpectedly, and continued to send patients to Pistyán every year until his death. He poisoned the middle finger of his right hand during an operation, and long after danger ceased stiffness of the finger and hand disabled him from operating until he recovered at Pistyán. And Duchenne has spoken of the great use of both the baths, the water taken internally, and the sulphurous mud, in cases of severe sciatica.

The town or village (in the Hungarian language Pöstyén) has about 150 houses and about 1,000 resident inhabitants. There are about 800 furnished rooms for visitors, a comfortable hotel, a *cur-park*, or pleasant public walk on the banks of the river, with a theatre and the usual music and amusements of a German bathing place. All this, at present, is on a small scale, but it is expected that before long a society of neighbouring proprietors will unite in the endeavour to rival Vichy, Homburg, and Carlsbad. The bathhouse is on an island in the park, formed by a division of the Waag into two branches. The season opens on May 1st, and closes on September 30th. In one bathhouse there are about twenty private bathrooms, and one so-called mirror-bath, about 4 feet deep, in which patients may sit or swim. In another house there is a public bath, about 4 feet deep, the water at a temperature of 98° to 104° F., where patients of both sexes in bathing costumes take their baths in company. In the private baths the temperature of the water is usually from 86° to 98°. In this second house there is also the mud bath, 2½ to 3 feet deep, the temperature of the mud varying from 100° to 105°. Here the natural warm water springs up in different places amid the mud, which is the only foundation of the baths. In this building there are also forty cabins for the local application of the mud to joints only or to some special region. Close by are the springs of the mineral water for drinking. The temperature of the water in the springs varies between 45° and 51° Réaumur (132° and 147° F.). It is quite transparent and colourless, has a slight odour of sulphuretted hydrogen, rather a pleasant taste, and slightly reddens

litmus paper. Analysis shows that it contains rather more than a drachm of sulphurous acid in 16 ounces, a little carbonic acid, and some lime, soda, potash, and magnesia, with a trace of phosphate of iron. Another analysis gives rather more than 3 cubic inches of free carbonic acid, and half a cubic inch of free sulphuretted hydrogen to the pound of water. The mud (*Schlamm*) which is found as a foundation wherever the hot water springs up, is of a greyish-green colour, and of the consistence of soft butter. It is much hotter than the water and cools more slowly. This mud is the real *specialité* of Pistyán. It has a much stronger odour of sulphuretted hydrogen than the water. In 100 parts of the mud there are said to be some 65 of silicious earth, 13 chalk, 6 oxide of iron, 14 clay, and a little phosphoric acid with magnesia, and some organic substance.

I took one of the water baths at about 95° for twenty minutes, simply as an experiment. On getting out of the bath an attendant carefully covers up the bather in linen sheets and woollen coverlet, and leaves him to repose and perspire for half an hour or more. In many cases the perspiration is kept up for a definite time, and the patients are not allowed to walk to their apartments, but are taken in a sedan chair or small carriage. Bronchial catarrhs, uterine and bladder catarrhs, and chronic intestinal catarrhs, are all greatly benefited by a course of these baths, and children with whooping-cough are said to be very soon cured by staying in a room which contains the vapours from the Pistyán water. Constipation, hæmorrhoids, and amenorrhœa are also relieved, probably by the continuous free action of the skin lessening venous congestion, restoring the contractility or tone of the relaxed or dilated veins, and leading to increased appetite and better assimilation of food.

But the most remarkable effect of the Pistyán treatment as a whole—baths, water, and mud—is the removal of chronic exudations, especially those about joints and tendons, which have caused the so-called "spurious ankylosis." Patients thus crippled, with more or less evidence of peripheral paralysis, and some where paralytic and neuralgic conditions are evidently associated with, or follow, some serious change in the central nervous system, are among the most numerous and the most successful of the cases which have kept up the reputation of Pistyán. Many inveterate cases of sciatica have been completely cured. In one sentence it may be said (using the words of the late Dr. Scherer, who wrote on the combination of electricity and massage, with the Pistyán treatment) that this combination "stimulates and increases the vital functions of the skin, the mucous membrane, the nervous and circulatory systems, and consequently leads to absorption of pathological products." The last effect is greatly promoted by the mud baths, sometimes used for the whole body, but more often for one joint or limb, either immersed in some suitable vessel, or used like a poultice.

It is evident, therefore, that the Pistyán treatment is resorted to in a great number of different conditions, the chief of them being those which are loosely called "gouty," and which lead to more or less swelling, stiffness, and deformity of the joints, and are associated with the uric acid diathesis. Next to the gouty come the rheumatic affections of muscles and joints, ankylosis, and neuralgias, especially sciatica. Sufferers from chronic rheumatism soon experience remarkable benefit; and so do many with chronic periostitis, whether a sign of tertiary syphilis or not, and many paralytic cases, especially hemiplegia which has followed an apoplectic attack or some wound or injury, or lead or mercurial poisoning. I also heard of some remarkable cures of facial paralysis, and of relief to the pains of locomotor ataxy. These are the cases where electricity and massage are principally employed in addition to the other treatment with a rational surgical and orthopædic treatment on the principles of modern surgery. After the last war a great many wounded men who had suffered from simple and compound fractures of bones, or chronic exudations after other injuries, or neuralgia after amputations or resections, recovered rapidly at Pistyán. And so with other chronic inflammatory swellings of glands, pelvic exudations, metritis, and its results, uterine fibroma and hæmorrhoids. Such are the cases where, as is well known, sulphur baths at Ischia and other places have been the great popular remedy. But at Pistyán we have, perhaps, the best of the sulphur baths hitherto made use of, more powerful and less disagreeable than any of the others.

I can scarcely doubt if the Government, or some powerful association of scientific and moneyed men, carry out a plan which has been proposed for developing Pistyán after the fashion of

better known watering-places which are far inferior in real therapeutic power, that this Hungarian spring will become of far greater use than it has been to suffering humanity, and will be resorted to by invalids, not only from Europe and America, but from India and our colonies, and amply repay the enterprising minister or financier who provides what is required by the invalid traveller in search of health, and by the relatives or friends who accompany him.

REMARKS

ON

DIABETES MELLITUS, AND ITS TREATMENT WITH THE MINERAL WATERS OF CARLSBAD.

By B. HOFMEISTER, M.D.,
Carlsbad.

ABOUT a century has passed since Carlsbad waters began to be used in diabetes mellitus. At that time, when the number of watering places was very small, all patients with chronic, hardly curable diseases, were sent there as a last resource; when it became known that some diabetic patients had derived benefit from its waters, Carlsbad was for a time regarded as a specific. At the present time the number of health-resorts has enormously increased, and some of them boast of the same efficacy in diabetes as Carlsbad; pamphlets have been issued denying that Carlsbad has any efficacy, and various methods of treating the disease have been invented; yet the sufferers from that disease mostly prefer the Carlsbad waters, and the number of them who visit it increases every year. That this reputation is fully justified will be shown in the course of this paper.

I do not propose to discuss the multifarious theories as to the etiology of diabetes which have been propounded by Claude Bernard and so many others, up to the present time; I will only refer to Ebstein's recent hypothesis, which has some relation to the Carlsbad treatment.

Whilst most authors seek the origin of diabetes in a disorder of one organ of the body—the liver, stomach, pancreas, kidney or brain—Ebstein places its seat in the protoplasm of nearly all the cells of the body; but he denies that the presence of sugar in the urine is the result of a deficient combustion of the normal amount of sugar into carbonic acid and water, and refers it to an over-formation of sugar, occasioned by the want of a sufficient amount of carbonic acid in the protoplasm of the cells. By a series of chemical experiments he has found that the capacity of diastatic ferments to decompose hydrocarbon is much restricted by the presence of a certain amount of CO_2 ; when this is lessened, the glycogen in the human tissues, he says, will easily be transformed into sugar. He thus looks upon diabetes as a chemical disorder, due to an anomalous nervous influence, the nature of which, however, he is at a loss to explain.

According to this theory—the truth or falsity of which has still to be established—the direct introduction of CO_2 into the protoplasm by the blood would be a rational method of treating diabetes; Ebstein goes so far as to recommend injections of CO_2 into the rectum. Now, it is certain that alkaline waters containing a large quantity of free carbonic acid, especially those of Carlsbad, tend to lower the amount of sugar in the urine, and consequently somewhat to improve the health; but, on the other hand, it cannot be denied that their curative action is but slight, compared with that of a proper antidiabetic diet, consisting in the main in avoiding sweet and farinaceous food. The combination of both these plans must still be regarded as the best method of treating diabetes; therein all Carlsbad physicians are agreed. They differ only in one point, namely, as to the significance which is to be attached to the quantity of sugar to be found in urine, in regard to the prognosis and treatment of diabetes.

As is well known, two forms of diabetes are usually distinguished; (1) the slight form, the amount of sugar being directly proportioned to that of starch matters taken by the patient, and accordingly entirely disappearing if they are only abstained from;

(2) the severe form, in which more or less sugar is present in the urine, in spite of the strictest antidiabetic regimen, and in which therefore sugar is formed also from albuminates. This classification however, which cannot be applied to each individual case, and does not comprise all cases, has been much criticised of late, and will probably soon be abandoned.

As a guide in treatment, I venture to propose a practical division of diabetes into three large groups.

(a) *Sugar in Proportion to the Severity of the Disease.*—A great many of the most conspicuous symptoms (sugar in the urine from 1 to 7 per cent, polyuria, polydipsia, emaciation, languor, impotence, etc.) were present. This form is by far the most common of all, and, as it can never fail to be clearly recognised, we may call it "diabetes manifestus."

(b) *Much Sugar, with Slight Diabetic Symptoms.*—In patients of this group we may find from 1 to 5 per cent. of sugar, and even more, and yet with such slight diabetic symptoms that they escape the notice both of the patient and the physician. Here we mostly observe disorders of the stomach and intestines, sometimes of the nervous system. The diagnosis is incidentally made by an examination of the urine. This form is more frequently met with than might be supposed, and is rightly called "diabetes decipiens."

CASE I.—T. B., lawyer, middle-aged, had always enjoyed good health. In the year 1887 he first complained of *malaise* and irritability of temper, which he was inclined to ascribe to slight dyspepsia with constipation. Having formerly been of a cheerful disposition, he gradually became moody and irascible, and in August, 1887, he went to Switzerland, thinking that rest and change of scene would do him good. At Geneva he consulted a physician, who accidentally sat at the same *table d'hôte* with him, and thus had the opportunity of observing the patient's inordinate fondness for sugar and sweets. Out of mere curiosity he analysed B.'s urine, and was surprised to find 5.5 per cent. of sugar two hours after dinner, and about 3 per cent. at different hours on the subsequent days.

At the end of August B. came to Carlsbad. Here I could detect no symptom pointing to diabetes beyond a certain degree of nervousness manifesting itself, particularly in headache and insomnia. At first I was inclined to look upon the case as one of simple glycosuria, due to the vast amount of sugar consumed by the patient, although in normal constitutions we find at most very slight traces of sugar from this cause. I soon became convinced, however, that I had to deal with a real diabetes mellitus, for, though the patient abstained entirely from sweet matters, from 2 to 3 per cent. of sugar was still found in the first week of the treatment; the following week it gradually decreased, and in a fortnight it had wholly disappeared. With the cessation of sugar-excretion the patient greatly improved, the headache and insomnia left him, and he regained his natural cheerfulness. The last week he was allowed to take a moderate amount of farinaceous food (80 grammes of white bread in the day), of all sorts of vegetables, and of uncooked fruits, without the sugar reappearing. During the following three years his health remained excellent. When suddenly, without any evident cause, a relapse occurred in July, 1887, which was again cured by the Carlsbad treatment.

CASE II.—B. P., aged 42, was sent in 1886 to Carlsbad for habitual constipation of very long standing. Many remedies had previously been tried in vain. The patient's habits were not sedentary; he did not suffer from hæmorrhoids; his appetite was pretty good; there was no apparent disorder in any other organ. His urine was found to contain 4.6 per cent. of sugar. On being closely questioned he remembered having sometimes felt dryness of the tongue, and he had become somewhat thinner of late. He had always drunk beer very freely, and was not conscious of greater thirst than heretofore. After four weeks of treatment he left Carlsbad without a trace of sugar. Next year, 1887, he came again, but this time only "to show himself," for he had not been troubled with dryness of the tongue, and his bowels acted regularly; in short, he felt perfectly well. I was the more surprised to find again 3.2 per cent. of sugar; he had kept at home on stricter diet only for some weeks, and then, feeling quite well, indulged in ordinary food, like other people. Three weeks of Carlsbad treatment sufficed this time to remove all trace of sugar; the patient on leaving was advised to diet himself strictly for a whole year.

I am of opinion that all forms of diabetes decipiens exist only for a certain time as such, for one year or two at most, after

May [5, 1888.]

which the more conspicuous symptoms of diabetes slowly appear; he cases are a contrast to diabetes acutissimus.

(c) *Little Sugar and Severe Symptoms*.—Patients of this group suffer from severe disturbances in various parts of the system, or a general nutrition, and yet have a minimum of sugar in their urine, not only in the beginning, but sometimes also during a very long period, so that it can be found only by a most careful and thorough examination of the urine by special methods. The direct contrast which this group offers to the preceding one (b) is obvious. From its resemblance in this respect to the form of fever known as "intermittens larvata," in which the characteristic paroxysms are replaced by quite different symptoms, this form may be called "diabetes larvatus."

CASE III.—K. D., merchant, aged 52, who had always been healthy, first became aware of gradual emaciation in the spring of 1885; otherwise, he felt quite well. Some time later a dyspepsia nervosa occurred with loss of appetite; this having been cured by medicine, the emaciation nevertheless progressed in such a measure that his weight fell from 85 to 72 kilogrammes (187 to 158½ English pounds) within eight months. The first analysis of the urine, which was made on November 10th, 1886, showed 0.7 per cent. of sugar. He kept to antidiabetic diet during the whole winter; the sugar disappeared, and his weight increased to 75 kilogrammes (165 pounds). In April, 1887, he returned to ordinary food, when he again began to lose flesh; there was, however, no thirst, no polyuria, no impotence, no skin affection. At the end of May he began to suffer from great nervous irritability, without any apparent cause. He was sent to the seaside, where several, probably superficial, examinations of the urine gave no evidence of sugar. Feeling no better, the patient came to Carlsbad on August 19th, 1887. On the day of his arrival I could discover distinct traces of sugar. I persuaded the patient to live in a strictly antidiabetic manner, and ordered him two tumblersful of Mühlbrunn daily. In two weeks he had gained two kilogrammes (4½ pounds), felt pretty well, and no sugar was to be found. By way of experiment, I then allowed a moderate use of starchy matters for three days, when small traces of sugar were again detected. I therefore recommended him to keep to the strictest diet for a whole year. This patient, whom I accidentally met a short time ago, had followed my advice strictly, and is now much better as regards his nervousness; his nutrition has likewise improved, his weight being 80 kilogrammes (176 pounds).

This case clearly proves that the severe disorders of nutrition—namely, the emaciation in diabetes—is not the consequence of an overformation of sugar from glycogen, nor of its loss by passing out of the body, but that it is as important a symptom of diabetes as the excretion of sugar itself, although there may be no causal connection between them.

CASE IV.—Mrs. G. C., aged 38, who three years before had been plump and rosy, now somewhat thin and pale, had never had any serious illness; four children; menstruation perfectly regular. In 1884 she began to be troubled with such intense itching in the vulva and the surrounding parts that she could not help frequently scratching herself. In this way her sleep was disturbed every night; by-and-by she lost appetite, and fell into a state of melancholy and despair. She could not make up her mind to seek medical advice till the end of 1885, when both her thighs and the lower half of the abdomen were covered with eczema from scratching. She was treated with various plasters and ointments for nearly two years, but all in vain. For a short time she would seem to improve, but this was always followed by relapse. The urine was examined several times, but either a very small quantity of sugar, or none at all was found. I could not learn what method of examination had been used. The patient came to Carlsbad on July 27th, 1887. An immediate examination of the urine showed 0.5 per cent. of sugar. She was then treated like Case III. After one week the itching had nearly subsided, and the eczema had much improved without any local treatment, while sleep was no longer disturbed. In the second week the patient, thinking that she need not keep strictly to the diet I had prescribed, took two rolls of white bread daily at dinner, and in two days was again as bad as before, the sugar, which had entirely disappeared, returning to the extent of 0.4 per cent. After that she followed the treatment strictly, and left Carlsbad wholly cured.

Until recently it was the general belief—and the opinion is still held by some—that small quantities of sugar in the urine are of no particular significance, and do not call for treatment. It is indeed true that it is not the loss of this trifling quantity of sugar

which causes such serious symptoms, since we observe large losses of sugar pretty well tolerated by the system (Group b); but it is, and I lay much stress upon this point, a highly important piece of evidence in the diagnosis and treatment of a series of cases, in which no treatment but the strictest antidiabetic regimen will be of the least benefit. The greater or less amount of sugar in urine—within certain limits—will therefore never give us a reliable ground for prognosis, inasmuch as in some cases it is in inverse ratio to the severity and danger of the disease. Thus, when we meet with various maladies, like neurasthenia, dyspepsia, emaciation, eczema, retinitis, cataract, boils, etc., and in connection with them an excretion of even mere traces of sugar (such excretion being not temporary but permanent), we must not hesitate to diagnose diabetes mellitus, and to treat the case accordingly.

Artificial Glycosuria.—The diagnosis of diabetes larvatus is sometimes rendered difficult by its resemblance to the so-called "glycosuria transitoria," or diabetes alternans. It is well known that there are different maladies (gout, rheumatism, typhoid fever, meningitis, epilepsy), in which small quantities of sugar suddenly appear in the urine. We likewise know that an excretion of sugar may be artificially produced by a severe injury, by serious abdominal operations, especially by lesion of the floor of the fourth ventricle or of the medulla oblongata, and by cutting the roots of the spinal nerves. But this kind of glycosuria cannot be regarded as diabetes mellitus; there is an essential difference between them. 1. The artificial and transient glycosuria disappears with the attack which calls it forth, or lasts some days, or at most some weeks after it. 2. It is never followed by serious consequences. 3. A further distinctive feature is its entire independence of starchy food. The risk of confounding them may therefore be easily avoided.

Prognosis of Diabetes Mellitus.—Regarding the prognosis of diabetes mellitus, one point must be discussed in the first place, namely, whether diabetes is curable or not. In pulmonary phthisis we unhesitatingly make an unfavourable prognosis, and yet there are *post-mortem* evidences enough in old persons of tubercular cavities which have perfectly cicatrised. Is this the case with diabetes? Has a *restitutio ad integrum* ever been observed in true diabetes in the sense that persons who once have suffered from it cease to be compelled to keep to a special diet, without risk of relapse? Such cases have been mentioned by some renowned authors, as well as by old Carlsbad practitioners: for my part, I confess that I am very sceptical, for I have not been so fortunate as to find one case of perfect cure out of eighty-six cases which I have observed since the beginning of my twenty-five years of practice. On this point I entirely agree with Professor Ebstein, who absolutely denies that diabetes mellitus is curable, and only concedes that cases may occur in which a somewhat larger amount of starch and even sugar is well tolerated, diabetes appearing again as soon as these limits are transgressed. There is always, therefore, liability to relapse. On the other hand, it cannot be denied that there are a great many patients who prolong their lives by judicious conduct. I myself know a case of diabetes of almost fifteen years' standing.

CASE V.—In November, 1874, I was consulted by K. F. for chronic dyspepsia, the origin of which I could not easily discover. After some weeks of fruitless hydropathic treatment, diabetic symptoms suddenly came on; analysis of the urine showed 4.5 per cent. of sugar. I immediately recommended him Carlsbad waters, together with antidiabetic diet; since then he has regularly visited Carlsbad for four weeks every year. Whilst there he keeps to the strictest diet, but during the rest of the year he takes a moderate amount of farinaceous food, only avoiding sweet substances. Leaving Carlsbad each time with only small traces of sugar, he yearly returns there with from 2 to 4 per cent. of sugar. With the exception of emaciation (his weight having fallen from 198 pounds to 150 pounds between 1874 and 1887) he feels no illness or discomfort, and can attend to his business as well as ever.

Such cases, however, are exceptional. On an average, the vast majority of cases end fatally in a far shorter time, mostly within from two to five years, the immediate cause of death being some intercurrent disease—such as pneumonia, tuberculosis, cerebral apoplexy, and, lastly, diabetic coma.

Significance of the Quantity of Sugar.—There are no absolutely trustworthy signs which enable us to distinguish the severe cases from the milder ones; in general such cases are to be regarded as bad ones, in which, in spite of medication and strict antidiabetic

diet, sugar persists above 1 per cent. There are, however, exceptions to this rule. In former times great significance was attached to the complication of sugar with acetone or diacetic acid in the urine, but this has proved false, severe and mild cases having been equally observed with and without acetonuria. My experience of late years has taught me to regard the complication with nervousness, especially restlessness, irritability, and sleeplessness, as very serious. The quantity of sugar in itself is, as has already been mentioned, of no great influence upon the prognosis: the largest amount may disappear in the shortest time by proper treatment, while the smallest quantities, as can be gathered from Cases III and IV, are sometimes associated with serious disorders of the system, and cannot be got rid of by any means at our disposal.

Estimation of Sugar in the Urine.—Owing to this fact, it may not be superfluous to add some words about the recent introduction of more accurate methods for the detection of the smallest traces of sugar present in the urine; but from want of space I can only mention those which, from their simplicity, are most available for the ordinary practitioner.

1. *Fehling's Method Modified by Seegen.*—The urine is filtered through a thick layer of animal charcoal (of blood), which absorbs the whole of the sugar; the charcoal is washed out with distilled water, which dissolves out the sugar, which may be tested with Fehling's solution; traces of sugar will be found in the second, and even in the third and fourth washing. This method is mostly used by the chemists of Carlsbad.

2. *Penzoldt's Method.*—Some drops of a solution of acetate of lead, mixed with some drops of ammonia, are poured into a testing tube half filled with urine. If sugar be present, the precipitate will be rose-coloured; if not, white. This is a pretty good and sensitive test.

3. *Johnson's Method.*—Some drops of picric acid are added to the urine, which is then mixed with a solution of potash slightly heated. A light red colour appears in normal urine; the presence of sugar makes the colour deep red. As the difference between the two is only a difference in shade and not in colour, the observer is naturally exposed to optical mistakes, a matter which impairs the value of the test. It can, nevertheless, be recommended for its other good qualities.

4. *E. Fischer's Method Modified by Jaksch.*—This method is highly to be recommended in every respect. It is based on the power of phenylhydrazine to unite with grape sugar and form characteristic crystals. To a measuring beaker half full of water, two drachms of hydrochloric phenylhydrazine and three of sodium acetate are added; the compound having been heated a little, the same quantity of urine is added, and placed in a vessel of boiling water for fifteen minutes; it is then quickly put in very cold water. After standing for some minutes a yellow sediment slowly falls, in which crystals of phenylglucosazon are always to be found if the least quantity of grape sugar be present in the urine. These yellow crystals have the shape of long rods, terminating at each end in round balls or bunches.

5. *Molisch's Method.*—The recently invented double method of Molisch ([1] a naphthol and [2] thymol, both with sulphuric acid) is worthy of mention, as it will detect the presence of even 0.0001 per cent. of grape sugar; it is, however, entirely useless for our purpose, as it produces exactly the same reaction with cane sugar, maltose, and all dissolved albuminates.

Treatment.—There is no general rule for the treatment of diabetes mellitus; each case must be dealt with according to its individual features. It would be a great mistake to allow every patient passing only a trifling quantity of sugar a greater amount of starch; on the other hand, it would be wrong to be too rigorous towards every patient with 5 per cent. and above. The first indication is to improve the general health, remove the most urgent symptoms, and give tone to the nervous and muscular system. We certainly succeed in Carlsbad in some cases in lowering the amount of sugar from 5 per cent. to a mere trace solely by strict diet. This may be done in a very short time, frequently within twenty-four hours; but the patient derives no benefit from the loss of his sugar; on the contrary, he feels daily worse, he declines rapidly, so that we are compelled again to allow him a certain quantity of amylaceous food, with the certainty of increasing the excretion of sugar, but, at the same time, of improving the condition of his health. In like manner we sometimes observe that patients of the c group, with 0.5 per cent., or still less, will not get better as long as this small quantity of sugar is not wholly got rid of by means of the strictest diet (Cantani's).

Yet, setting aside the question of idiosyncrasy, there remains a series of hygienic and therapeutic rules equally suitable for all sufferers from diabetes. Although these are generally enough known, they are of such essential importance that I may be allowed to summarise them.

1. The dietetic and hygienic regimen ought not to be totally changed in a sudden way. Sweet things must be at once forbidden; the amylaceous food should at first be confined to vegetables of all kinds, except the leguminous ones, and bread, 100 grammes of which may be allowed, this quantity being gradually reduced to 60 grammes, and so on.

2. Pure fat and fatty meats are highly to be recommended for their great efficacy against congenital predisposition to diabetes; 150-200 grammes may be allowed daily.

3. An exclusive meat diet (Banting treatment) is rather dangerous in diabetes, because it strongly promotes the disintegration of albumen, that is to say, emaciation.

4. All substitutes for bread are objectionable, partly because they contain a considerable amount of starch, and partly because they are all more or less indigestible. Fürbringer's gum bread (*Kleberbrot*), manufactured by Basserman, at Manheim, seems to be the least injurious of these.

5. Diabetics ought to masticate perfectly each bit of food, eating slowly, in order to mix the food completely with the mucus of the mouth.

6. In all cases in which a somewhat larger indulgence with regard to the diet is admissible, all sorts of vegetables, including the sweet ones (turnips, carrots, cabbages, etc.), only excluding the leguminous (peas, beans, and lentils) are permitted, likewise raw kernel fruits and berries.

7. Milk and wine should be allowed only in small quantities, even in mild cases; half a pint of each daily should be looked upon as the maximum dose. All sorts of beer must be forbidden under all circumstances.

8. Exercise is much indicated, especially as long as farinaceous food is partly allowed. The best time for it is immediately after dinner, and it should be continued for at least two hours. Riding on horseback and hill climbing (if the ascent is not too steep) is certainly preferable to gymnastic movements indoors; but when outdoor exercise cannot be taken we are now in possession of a good substitute, I mean the "ergostat" recently invented by Professor Gärtner, of Vienna (see *JOURNAL*, January 7th, 1888, p. 35). Patients, who, in any stage of the disease, are easily fatigued by the least muscular exertion, will derive great benefit from daily massage of the whole body for twenty minutes (Finkler).

9. Warm baths, as the best means of keeping the function of the skin in order, are very beneficial to sufferers from diabetes, provided that they are used at a temperature of 93° to 94° for fifteen minutes not oftener than twice a week.

10. The mineral waters of Carlsbad are undoubtedly of the greatest use in the dietetic and medical treatment of diabetes; their effect is mostly due to the alkaline salts they contain. Although there are several alkaline springs in Germany and elsewhere which have similar ingredients, though in different proportions, and which boast of still better climatic conditions than Carlsbad, yet in their efficacy against diabetes they are far inferior to Carlsbad.

According to the theory of Ebstein, referred to at the beginning of this paper, the efficacy of alkaline waters in general would be clearly explained by the direct supply of carbonic salts and free carbonic acid to the protoplasm of cells of the whole system; but the question why any other mineral water with as much carbonic acid is not to be compared to those of Carlsbad in efficacy against diabetes remains unanswered. Pfeiffer, of Wiesbaden, attributes to Carlsbad waters the capacity of restraining the organic disintegration, and hence their beneficial influence in diabetes accompanied by emaciation. The quantity to be taken in diabetes is not different from that indicated in other diseases. It is continued till the urine becomes alkaline, or other symptoms of saturation appear.

In severer cases the treatment should be carried out twice a year—in the spring and in the autumn. That drinking the water at Carlsbad itself is of much greater value than drinking it at home is so well known that I need not dwell on that point.

11. Among the innumerable drugs recommended for diabetes, there are but few worth mentioning. In the first place there is opium, the tolerance of which by diabetic patients is remarkable and inexplicable. Opium makes the sugar disappear; it diminishes

May 5, 1888.]

normal tissue-waste, and consequently increases the weight of the body; it causes neither narcosis nor constipation in doses which would be positively dangerous if given in other diseases. Still more efficacious is morphine, in doses of from 1 to 3 grains daily. The beneficial effect of these drugs, however, does not last very long; after three or four months they lose their effect, and here is, moreover, the risk of the opium-habit becoming confirmed. They should, therefore, be taken only at long intervals, and under strict medical supervision. Salicylic acid, phenol, and salicylate of sodium, are far less useful.

In conclusion, I venture to lay down the following propositions, as summing up the results of my studies and observations:

1. We are still in total ignorance as to the etiology of diabetes mellitus.
2. The quantity of sugar found in the urine is of no significance at all in judging of the severity and danger of any particular case of diabetes.
3. The smallest traces of sugar, found only by most careful chemical examination of the urine, are of considerable importance in a great many cases, so that they cannot be left out of account in trying to arrive at a correct diagnosis and prognosis.
4. The dietetic treatment must be adapted to the special requirements of each case, as there are cases in which, without regard to the amount of sugar excreted, complete abstinence from starchy matters is not only useless, but directly injurious.
5. According to the present knowledge, strict antidiabetic diet, combined with the use of the mineral waters of Carlsbad, is the best method of treating diabetes mellitus.

ON DIABETES AND ITS CONNECTION WITH HEART DISEASE.

By JACQUES MAYER, M.D.,
Carlsbad.

A GLANCE at the literature of diabetes, which, more especially since the remarkable discoveries of Claude Bernard, has attained very large proportions, shows us that singularly little is as yet known about certain affections of the heart and blood-vessels which are apt to occur in the course of that disease. This may perhaps be accounted for by the circumstance that those who have occupied themselves with investigating the pathology of diabetes seem to have given their chief attention to the examination of those organs which experimental physiology had shown to be more particularly involved in its production. Thus Seegen, Cantani, Senator, and other authors hardly mention this point at all; while Donkin, Schmitz, Leyden, and others only casually allude to it. Nine years ago I published a paper (*Berliner Klinische Wochenschrift*, 1879, Nos. 21, 31, and 32) on certain symptoms which I had observed in cases of diabetes complicated with obesity. These patients were apt to be suddenly taken with dyspnoea; they complained of pain and oppression in the cardiac region; the pulso was abnormally quick, beating at the rate of 120 to 140 in the minute, with marked want of rhythm (delirium cordis). The pain sometimes spread from the heart to the shoulder or to the left arm. In fact the symptoms were analogous to those of angina pectoris.

Attacks of this kind have come under my notice in the initial stage as well as in the further progress of the disease, but more frequently at an advanced period, after the obesity had more or less subsided; and the physical examination of the heart showed mostly dilatation of the ventricles.

I did not then think that there existed an etiological connection between these symptoms and the diabetic process, or, more strictly speaking, the saccharine blood; more especially so because the same cardiac symptoms and physical state of the heart on which Leyden has thrown a flood of light have also been frequently observed in cases of obesity without diabetes.

Subsequently, however, I discovered similar symptoms in diabetes uncomplicated with obesity, and I then thought it would be important to ascertain accurately, as far as possible, from the very beginning of the disease, the physical condition of the heart in every single instance which came under my observation. I expected to arrive at some interesting results in this matter, as the waters of Carlsbad attract year after year a very large number of

patients suffering from diabetes, who belong to all classes of society, and the cases being in all the various degrees of intensity. I am fully aware that observations of this kind cannot claim the same degree of accuracy as those made in hospital practice, but I have been anxious to atone for this want as far as possible by written notes taken at the time. The number of cases being comparatively large, some degree of value may perhaps be attached to these observations.

From 1879 to 1888 I have had under my care 350 cases of diabetes, of which 266 occurred in males and 114 in females; in the large majority of these cases, namely, 248, occurred between the ages of 40 and 60; 337 cases were in the first, and 43 in the second stage of the disease.

In this, as in previous papers on the subject, I prefer speaking of "stages" rather than of a "mild and severe form;" as experience has shown me that the former classification meets the facts of the case far better than the latter. Out of 43 cases of the second degree, 26 merged, as it were under my eyes, from the first into the second stage.

If we leave out of sight for the present the degree of intensity of the malady, and direct our attention to the general appearance of the patients, we notice certain distinctive features in them, which, though they are not absolutely constant, are yet sufficiently characteristic to enable us to distinguish three well-marked types of diabetic patients.

We have to do then: 1. With patients of a feeble and delicate constitution, a more or less pale complexion, and a timid and anxious expression.

2. With patients who, on the contrary, have a vigorous and healthy appearance, a florid complexion, and a lively and animated expression.

3. With obese patients, some of whom are pale and sallow, while others have either a ruddy or a livid complexion.

In the beginning of the complaint, or soon after it has commenced, the physical examination of the heart and vessels hardly ever shows in any case belonging to the three types just mentioned, that the sugar which is circulating with the blood, or any increased production of urea which may have occurred, have had an unfavourable influence upon the cardiac muscle. Auscultation and percussion reveal the same signs as in patients of similar condition who are not subject to diabetes.

After the malady has, however, lasted for some time, the physical signs undergo certain changes which come on sooner or later according to the individual case. To these I now proceed to direct attention.

In cases belonging to the first type, that is in those of a more or less anæmic and feeble constitution, I have occasionally seen endocarditis supervene after some little time, as described by Lecorché (*Archives Générales*, etc., April, 1882, p. 385), but much less frequently than this author, and not so much in patients of an advanced age.

In other cases of the same type the well-known symptoms of cardiac debility came on suddenly, while the physical signs found on examination of the heart did not show that any morbid changes had occurred either in the endocardium or in the muscular substance of the organ. In these we may however conclude from the quality of the pulse, which is very easily compressible and of varying frequency, as well as from the weakness of the heart's sounds and the occasional presence of the so-called "galloping murmur," that the functional power of the heart is lessened, and that this is owing either to atrophy or to retrogressive changes in the muscular fibres, that is, fatty degeneration.

In a further number of cases the physical examination of the heart, which had in the beginning shown nothing abnormal, revealed as time went on dilatation of the organ, which for a period did not seem to lead to any very striking symptoms, but which was, as soon as an exciting cause of some sort had acted, followed by severe dyspnoea and delirium cordis.

Cases of this kind are analogous to those of over-strain of the heart having a protracted course, in which Leyden (*Die Herzkrankheiten*, etc., Berlin, 1886, p. 34) has, with Da Costa, distinguished a first stage of functional disturbance of the heart's action, and a second period of organic lesion with dilatation of the ventricles.

With regard to diabetic patients of the second type, I have found in the majority of cases, after the malady had lasted for a variable time, a well-marked group of symptoms pointing to the development of cardiac hypertrophy. The complexion becomes reddish, the mucous membrane of the mouth and the conjunctiva

are congested, the eyes are lustrous, and the carotids pulsate strongly as soon as there is the slightest emotional excitement. Vertigo, headache, and ringing in the ears are frequently complained of. The first signs of shortness of breath appear habitually after a somewhat abundant repast; walking exercise after meals causes discomfort; there is pain in the stomach and belching, and the action of the bowels becomes irregular; sleep is broken, and often disturbed by a dry cough. The pulse is full and strong, but does not show unduly high tension. It is regular and not accelerated, but, on the contrary, sometimes rather retarded.

The physical examination of the heart shows a strong impulse, which extends over several intercostal spaces. The apex-beat is either within or without the mamillary line towards the left side, mostly in the fifth or sixth intercostal space. Percussion shows an enlarged sphere of dulness upwards and downwards, and less so in the transverse direction. The heart's sounds are loud and normal. In short, we have to do with idiopathic hypertrophy of the left ventricle, which has become gradually developed.

Further observations have shown me that this condition of the heart may persist for a number of years without producing much systemic disturbance, provided the patient avoids over-exertion and emotional excitement, is temperate in his habits, more especially in regard to alcoholic stimulants, and is careful to take regular exercise. On the other hand, where there is impaired nutrition; where, as is sooner or later always the case in diabetes, the food taken does not suffice to supply the wants of the system; where, therefore, the structure of the organs themselves is called upon for the maintenance of work, or where sedentary habits of life promote arterio-sclerosis, then the functional activity of the heart becomes lessened. The cardiac muscle is then relaxed and dilated, or sooner or later severe symptoms of disturbed balance of power make their appearance. Signs of cardiac debility, in fact, are then of cardinal importance for the further progress of the disease.

In a considerable number of cases of diabetes, therefore, hypertrophy and dilatation of the heart become developed without there being any morbid changes in other organs, such as the kidneys, arteries, etc., which so frequently lead to these affections. They must therefore be owing to chemical irritation of the heart by the sugar and urea which are circulating in the blood. Diabetic patients eliminate more urea, other things being equal, than healthy persons; cases are on record where from three to five times the average quantity of urea has been excreted. The quantity of sugar contained in the blood in this disease likewise far exceeds that which is found in the normal blood, and it may therefore act as an irritant on the heart's structure.

This abnormal condition of the blood leads to polyuria, glycosuria, and agoturia, which are known to have a prejudicial influence on the kidneys by causing hypertrophy and hyperplasia of those organs. In connection with this I may here refer to the experiments of Gravitz and Israel (Virchow's *Archiv*, vol. 86, p. 299), who have produced hypertrophy of the heart in rabbits, first, by causing chronic nephritis, and, secondly, by removing one kidney. These observers explain the increased cardiac function which took place in their experiments by the partial loss of renal function, and conclude that the matters which are excreted from the blood by the kidneys constitute an irritant for the heart leading to increased function, and eventually to increased volume.

Israel has, in another series of experiments, arrived at results which afford a considerable amount of support for the views which I have been led to form with regard to heart affections being the sequelæ of diabetes. He fed rabbits with large doses of urea, and found, after a few weeks, that hypertrophy of the heart came on, which was preceded by hypertrophy of the kidneys, showing that the system gradually gets accustomed to increased claims on the functional activity of the organs, as no serious deviation from health occurred in these animals. A similar result occurred after the introduction of nitrate of sodium, while grape sugar did not appear suitable for prolonged administration. If, however, injections of a concentrated solution of one or two grammes of this substance were made, either into the veins or into the peritoneum, it could be shown with a kymographion that increased blood-pressure was the result.

From these experiments Israel has drawn the conclusion that healthy kidneys will, to a very great extent, answer the increased calls made on their power, but that, in extreme cases, such as diabetes and feeding with urea, they eventually become insufficient, and this sooner or later, according to individual circum-

stances. This insufficiency is then met by increased action of the heart, which, if persisting for a considerable time, leads to hypertrophy of that organ.

It is in this sense that I wish to be understood to account for the hypertrophy and dilation of the heart which is so frequently found in diabetes.

It is well known that the kidneys are often found after death in a state of hypertrophy and hyperplasia; and while the results of necropsies of such cases which are hitherto recorded do not seem to confirm my theory, I would point to the fact that these *post-mortem* examinations have been made on hospital patients, who are generally admitted for more or less acute diabetes, which is connected with rapid wasting of the substance of the organs.

The cardiac muscle in such cases behaves much the same as other muscles when they have to do more work, yet do not become hypertrophied if they are badly nourished.

A very telling analogous instance is furnished by pernicious anemia, where the small quantity of oxydisable constituents of the blood, and the necessity of supplying the system with oxygen, act as irritants on the heart, and would lead to hypertrophy, provided the heart were well nourished; but as such is not the case, and the heart is called upon for undue efforts, fatty degeneration will, on the contrary, be the result.

We may therefore take it for granted that the anatomical lesions to be found in diabetic patients of a better class would differ, so far as the heart is concerned, from those to be met with in average hospital patients.

Considering the fact that of the former class of cases hardly anything is known in this respect, I thought it all the more important to go carefully through the records of the Pathological Institute of Berlin, in order to ascertain any anatomical changes in the latter class, more especially as Israel had already found in 10 per cent. of diabetic cases which had proved fatal in the Charité hypertrophy of the heart without valvular disease, and without affections of the arteries and kidneys.

Professor Virchow was kind enough to allow me to peruse these records from 1856 to 1887. I gave special attention to the stated condition of the heart, blood-vessels, and kidneys, and found that the percentage of hypertrophy and dilatation of the heart was 13.0, while in the cases observed by myself it amounted to 21.6 (82 out of 380).

Want of space prevents me from giving the details of the *post-mortem* records of the Pathological Institute, but I may say that most of them show simultaneous severe affection of the lungs, and nearly all of them morbid changes in the brain; while in my own 82 cases no organic disease could be discovered, either by clinical symptoms or physical examination. The percentage of 13.0 must therefore be looked upon as considerable. I will not omit to mention that in a number of the other *post-mortem* records, hypertrophy of the heart with chronic endo-aortitis, as well as endo-arteritis and hypertrophy, were the primary affections.

While therefore heart disease in diabetes has only quite recently been described, and that by a very few authors, the occurrence of arterio-sclerosis in that disease has been much more fully dwelt upon, more especially by Frerichs. Those who leave out of account the increased functional activity of the heart have to look to the chemical alteration of the blood as the cause of the vascular disease.

We have seen above that the accumulation of sugar and urea in the blood is not proportionate to the quantity of these substances which is eliminated, but that, on the contrary, in consequence of increased cardiac activity, a compensatory elimination takes place in the urine, which is partly owing to enlarged kidneys and partly to changes in the heart's structure. The dilatation of the blood-vessels which occurs subsequently is simply owing to the increased work of the heart, which throws more blood into the vascular system in a unit of time. Vascular disease is the consequence of permanent mechanical irritation.

Sir William Gull's and Dr. Sutton's "arterio-capillary fibrosis" as occurring in nephritis, and Dr. Ewald's "muscular hypertrophy of the arterioles" must be looked upon as secondary consequences of the cardiac disease. In the same way, the occurrence of arterio-sclerosis in diabetes has to be traced to the mechanical influence of cardiac changes.

I hope to have rendered it evident that the cases of cardiac disease which I have observed in patients suffering from diabetes have to be traced to morbid changes of metabolism. My argument is, moreover, well supported by the observations of several authors, such as R. Schmitz, who have apparently found fatty

May 5, 1888.]

degeneration of the heart in a large percentage of cases of diabetes.

If we read such statements by the side of the anatomical records which I have mentioned, it will be seen that they have to be taken for what they are worth; for neither fatty metamorphosis nor infiltration of fat has been at all commonly met with *post mortem*. On the other hand, such observations have a clinical value, since, as far as symptoms are concerned, fatty degeneration, infiltration of fat, brown atrophy, dilatation, and other anatomical lesions of the heart may show at times the same clinical aspect, namely, that of cardiac asthenia, which latter appears to me due to the claims made upon the heart by the diabetic change of metabolism. Compensation under these circumstances must always be temporary, more especially where the nutrition of the system in general suffers at an early period, and where the formation of urea and sugar exceeds that limit within which well-nourished kidneys and a well-nourished heart are able to eliminate these substances.

As far as treatment is concerned, it appears from the foregoing that everything should be avoided that may impair the action of the heart and kidneys; for we know that organs which are in a state of hyperactivity easily become diseased. I may here refer to the frequent occurrence of valvular disease in nephritis, and of nephritis in diabetes. The latter I have found recorded in 30 out of 66 cases contained in the records of the Pathological Institute of Berlin. Stokvis has forcibly drawn attention to the same point in his able paper on diabetes read before the late Medical Congress at Wiesbaden, while I have seen nephritis in 64 out of 180 cases, although not frequently in the form of granular contracted kidney.

The principle of sparing the suffering organs as much as possible has, in my opinion, to be carried out particularly as regards diet. In many cases a rigid nitrogenous diet cannot be enforced. I have, on this account, during the last few years, frequently added milk to the diabetic diet, and can fully corroborate the favourable testimony which Hoffmann gave on this point before the late Medical Congress.

ON THE INDICATIONS FOR THE USE OF THE KREUZNACH WATERS IN STRUMOUS DISEASE.

By DR. HEUSNER,
Kreuznach.

THE motive which leads me to publish this article is the fact that patients are frequently sent from England to Kreuznach suffering from diseases for which the waters of this place are not suitable, while, on the other hand, many persons, for whose successful cure reasonable hopes might be entertained, are not ordered to Kreuznach at all.

General Treatment of Struma.—In the treatment of strumous diseases it is pre-eminently necessary to bring about an improvement in the constitution. The treatment of local affections, though frequently indispensable and very beneficial to the constitution, is seldom in itself sufficient, and will certainly be facilitated and rendered more efficient by the adoption of a suitable general regimen.

Kreuznach Treatment.—The question which I propose to answer is whether a course of the Kreuznach waters is beneficial in all cases of struma, and under what circumstances their use is contra-indicated. I am unable to answer this question by quoting statistical data, partly because a physician practising at a watering-place is apt to lose sight of the majority of the patients after too short a time, and partly because it is extremely difficult to give a decided opinion as to whether the strumous taint is definitely and totally eradicated. In many cases one cannot speak with certainty of a cure, but only of a general improvement. The result of my observations goes to prove that this improvement of the constitution has been attained, with very few exceptions, in nearly all cases after a steady and persevering course of the Kreuznach waters. In many cases the local symptoms so greatly predominate over the constitutional that the improvement of the former directly indicates the degree of constitutional amelioration. The favourable climate, and the possibility of exactly regulating the desired curative action, make a visit to Kreuznach advisable for individuals of the most opposite and varying constitutions. In some

cases, however, the hopes entertained with regard to Kreuznach have been doomed to disappointment, simply because people imagine that a single stay—and that often of very short duration—is sufficient to effect a cure. It is, however, only in very slight cases that a single course of treatment suffices; deep-rooted constitutional affections cannot be so easily eradicated; they necessitate not only repeated and lengthened visits to Kreuznach, but also continuous and careful dietetic treatment; while a subsequent stay at the seaside, or in the mountains, etc., is frequently indispensable.

Contra-indications of the Kreuznach Treatment.—Some complications of strumous disease make a course of Kreuznach waters futile, while others render it objectionable. For instance, I consider it distinctly contra-indicated in decided tubercular disease of the lungs; also in disease of the kidneys at an advanced stage, and in any chronic state of feverishness, from whatever cause. But when slight manifestations of fever are kept up by a strumous affection which, from its very nature, seems to point to Kreuznach as a place where an improvement is to be hoped for, a trial may fairly be made—more especially when it is impossible to attack the disease at its seat, as is the case, for instance, with caries of the vertebrae. Particular care should be exercised with patients suffering from valvular disease of the heart, or from degeneration of the heart-muscle, as the Kreuznach baths often unfavourably influence these complaints. Nor does the warm, dry climate which generally exercises such a beneficial influence on strumous persons, always suit patients suffering from asthma. I have not witnessed any favourable results from the use of the Kreuznach waters in cases of leucæmia or malignant lymphomata (pseudo-leucæmia, Hodgkin's disease, *adénie*), nor in cases of cancer or sarcoma.

The Kreuznach Treatment in Glandular Enlargements.—The obstinacy with which glandular affections resist any treatment is well known, and the question arises whether it is not advisable to extirpate the diseased glands at once before seeking other remedies. A source of tuberculosis is thus removed that might endanger the general health. My opinion is that, as long as the glands do not show decided signs of suppuration, weighty reasons may be urged against their extirpation, one frequent obstacle being the impossibility of removing all the diseased glands. Besides which, the scars of the operation are permanent. A still weightier reason against the operation is, that an outbreak of general tuberculosis has been known, in some cases, to follow immediately on the extirpation of the glands. Even glands that are already softened are capable of reabsorption, as well as the hard tumours mentioned in the preceding sentence. When suppuration has commenced, however—especially if accompanied by feverish symptoms of a more serious kind—surgical treatment undoubtedly affords better prospects of a rapid cure with small cicatrices than any other treatment. But, among the non-surgical curative methods, the treatment pursued at Kreuznach is certainly that most adapted to cause indolent glandular swellings to decrease in size, and even to be entirely reabsorbed. In order to put a stop quickly to suppuration, when it has become established, and to promote cicatrization, a course of Kreuznach waters is frequently a most valuable addition to the surgical treatment. The above remark also applies to cold abscesses, not originating from glandular disease, from which scrofulous people often suffer.

In Skin Disease.—As to eczema and other superficial skin diseases of a strumous nature, they are cured with surprising rapidity by a course of Kreuznach waters. In lupus vulgaris success is more doubtful, though I am of opinion that a relapse may be considerably retarded by a course of Kreuznach. But as, in this insidious disease, no one is secure from the danger of a relapse even after several years, I do not venture to assert that the cure is definitive and permanent.

In Catarrh.—Chronic catarrhs of the various mucous membranes, the obstinate nature of which is well known, are, without exception, favourably influenced by the Kreuznach waters, though of course deeply degenerated mucous membranes cannot be restored to their normal state. This has special reference to the almost unavoidable coryza of strumous patients. In the various catarrhs of the pharynx and fauces, the effects of Kreuznach treatment are most favourable. Adenoid vegetations of any considerable size are not, it is true, diminished by its use to any noticeable degree; but small lymphatic follicles may disappear from the back wall of the fauces. Hypertrophy of the tonsils, it may as well be mentioned here, is but seldom cured or even notably decreased.

In Ophthalmia.—The success attending the treatment of stru-

mous affections of the eyes is particularly striking when the object is to prevent the endless relapses of keratitis. Although the opinion of a considerable part of the medical profession is opposed to the use of Kreuznach waters in florid inflammations and ulcerations, nothing in my experience justifies the laying down of such a contra-indication.

In Ear Disease.—The effects obtained in diseases of the ear are less striking. Catarrh of the middle ear often leads to deep degeneration, shrivelling, adhesions of the mucous membrane, etc., which render all hope of a cure futile. Nevertheless some of the dangerous suppurations of the middle ear, whether connected with an affection of the bone or not, have actually been cured at Kreuznach.

In Bone and Joint Disease.—In speaking of affections of the joints and bones the difficulty is to define the limit beyond which a surgical operation becomes necessary. We have certainly seen several cases cured at Kreuznach in which most surgeons of the present day would have advised an operation. In other cases the removal of the bone, whether desirable or not, is impossible. On the whole I incline to the belief that it is safer, especially when the joints are involved, to operate a little too soon rather than to delay too long. This particularly applies to adults. Among the advantages of such a course we may mention that the transfer of the invalid to Kreuznach, in order to have his strumous ailments attended to after an operation, is generally attended by less difficulty. Besides, should an operation become necessary during the course of treatment, it causes a very unpleasant interruption of the cure. For the definitive and final healing of wounds and ulcerations, the waters of Kreuznach have always proved excellent. Kidney diseases, such as are associated with suppuration of the bones, I have also seen cured when attacked in the beginning, but not after having been allowed to develop fully. Though I have by no means exhausted the list of strumous diseases, nevertheless I think that the foregoing considerations will suffice to determine in each particular case the desirability of a course of the Kreuznach waters.

THE MINERAL WATERS OF BRIDES-LES-BAINS AND SALINS-MOUTIERS.

By P. DELASTRE, M.D.,

Corresponding Member of the Medical Society of Hydrology of Paris; Consulting Physician at Brides and Salins.

BRIDES is a charming little village, situated in one of the most picturesque parts of Savoy, five kilometres and a half from Moutiers, the chief town in the prefecture. The village stands at an altitude of 1,800 feet above the level of the sea. Situated in a valley, it is sheltered particularly from the east, west, and north winds; yet the pure air of surrounding mountains and glaciers of the Tarantaise is invigorating and refreshing to the most delicate constitutions. The country around is remarkable for its picturesque beauty and the variety of its scenery. Brides is accessible from Paris, in about fourteen hours, by the Lyons and Mediterranean Railway. The season is from the middle of May to October. The hotel, lodging, and bath accommodation is excellent.

The springs supply abundant water, at a temperature of 95° F.; they are alkaline, and powerfully diuretic and slightly aperient, containing, as the chief ingredients, sodium chloride, sodium sulphate, magnesium sulphate, with smaller proportions of the alkalies, carbonates, and free carbonic acid, which imparts to them a limpid and slightly sparkling character. The water presents many of the qualities of the famous Carlsbad springs, and, besides possessing valuable diuretic and aperient action, is also tonic and invigorating in debilitated constitutions. Its effects will be found to be especially serviceable in the various forms of functional derangement of the gastro-intestinal tract, especially when associated with abdominal plethora depending on chronic gastro-intestinal catarrh, and congestion of the liver or spleen with constipation. Cases of biliary colic, lithiasis, and functional derangement of the liver, the result of prolonged residence in India and other tropical countries, are almost invariably benefited by their use. In a brochure which I lately published, termed *Etudes sur les Eaux Minérales de Brides-les-Bains et Salins-Moutiers*, I have treated specially of the physiological and therapeutic properties of the various springs. Their action is remarkable in assisting to restore healthy nutrition, and particularly in favouring the elaboration of cholesterine in the liver, and also the elimination of the

products of urea and of phosphatic salts by the kidneys. The use would seem also to favour oxygenation of the blood and the formation of hæmoglobin, at the same time diminishing the tendency to obesity in those so disposed. In gout generally, and specially in atonic cases, the effects are often remarkable. I have found diabetic patients also improve very much under treatment.

The springs of Salins-Moutiers, the natural temperature of which is about 96° F., are rich in sodium chloride, and also contain iron and arsenic. Their properties are even more marked than those of many other waters which possess a similar action, such as Kreuznach, Homburg, Mannheim, and Kissingen. The springs are less than two miles distant from those of Brides. Their use is of great value in children of rachitic or scrofulous constitution, in anæmic chlorosis, and other debilitating conditions in women. In affections of the uterus and appendages, they are of much service. In disordered menstruation, amenorrhœa, dysmenorrhœa, and leucorrhœa, and in fibroid tumours of the uterus, with uterine engorgement, their use is attended with marked benefit. These waters are often of service in conjunction with the use of those of the neighbouring springs of Brides. Dr. Hermann Weber, in his chapter on Climate and Health-resort in the *Book of Health*, refers to Brides and Salins-Moutiers as "among the best summer health-resorts, not only for its springs, but for its delightful salubrious air."

Were the valuable properties of these springs more widely known, as well as the natural charms of the district in which they are situated, I feel sure they would be largely taken advantage of.

OBSERVATIONS ON THE USE OF THE EFFERVESCING CHALYBEATE WATER OF STRATHPEFFER SPA.

By FORTESCUE FOX, M.D. LOND.,
Strathpeffer.

STRATHPEFFER in Scotland and Harrogate in England are commonly associated with sulphur treatment, that it may not be out of place to recall the fact that iron waters, of greater or less value, are almost invariably found in the neighbourhood of sulphuretted springs. At the first-named spa there is, for example, a chalybeate spring to which attention has been lately directed on account of its unusual character. It has been conveyed to the pump-room, where it issues as a water, richly carbonated and aerated in the summer months. Here it is drunk, hot or cold, in a state of cloudy effervescence.

Thus it is usually possible at sulphur spas not only by the use of iron to supplement with advantage the alterative effects of sulphur, but also in an entirely different class of cases to provide a treatment founded on the tonic waters alone. The object of the present observations is to illustrate this latter or primary use of the effervescing chalybeate at Strathpeffer. The cases which appear to have benefited the most by its use tend to fall, on the review of four years, into the following groups, examples of which are appended.

Group I.—Debilitated men of advancing age, with (probably or certainly) renal and vascular lesions, with or without gout.

CASE I.—A gentleman, aged 71, had lost health rapidly during the past twelve months. There was no obvious disease in any organ. The pulse was small and weak; urine normal. He was very anæmic and rather sallow, showing some œdema of the face and hands. The chalybeate was commenced in small doses, and afterward increased to 60 ounces daily. Under this treatment, with judicious dieting, strength and colour returned in a very remarkable manner. This gentleman died in the following year.

CASE II.—A lawyer, aged 54, suffered from overwork and worry under which he completely broke down. He had two passing attacks of aphasia, which led to the discovery of albuminuria after which he was laid by and put upon a milk diet. He arrived at Strathpeffer a few weeks later, complaining much of headache, poor sleep, and great nervousness and lassitude. The chalybeate was persevered in for five weeks, given always in small doses, at short intervals, before breakfast and again at noon, and altogether with the best results. The only remaining symptom was a urine faintly albuminous, but the specific gravity had increased from 1013 to 1018 (or, on the average of 58 ounces in twenty-four hours, 1017).

CASE III.—A gentleman, aged 57, stated (in 1885) that he had

ffered from gout in the feet for about four years. In that year he took for four weeks the strongest sulphur water and baths. In the following season (1886) he returned, having had two very slight attacks of gout during the spring. The general condition was, however, changed for the worse. He was anæmic and anæmic; the urine was very albuminous, although the skin still shed freely. After a few days of sulphur treatment the chalybeate was resorted to with benefit. The next year (1887) he reported himself as moderately well, but he had had several gouty attacks in the feet and knees. One of these had been "brought in by a course of steel." The effervescing chalybeate was taken for three weeks, and he left the spa without gouty symptoms, and much better in every respect, and able to walk several miles a stretch. The urine remained faintly albuminous.

It is thus evident that a sparkling iron water of moderate strength (a third of a grain to the pint) may be useful in gouty cases; or, rather, it may be proper to disregard the gout and treat in this manner the more serious maladies to which it has given rise. But whether gouty or otherwise, a condition exists of pre-ature senility of the tissues, with anæmia (perhaps hydræmia), and often with signs of renal failure, in which carbonate of iron, freely diluted, is beneficial. And thus if Leamington, with its fine chalybeate, is excellent in the anæmia of the young, so no less Strathpeffer, with its effervescing carbonated chalybeate, may be regarded as congenial to the anæmia with debility of the aged.

Group II.—Dyspepsia in middle life, due to nervous prostration and overwork.

CASE IV.—A lady of nearly 60, after severe domestic trial, began to complain of "rheumatic" pains, indigestion, and loss of strength and colour. She was recommended spinal douches and the chalybeate water, taken hot at noon. The quantity was soon increased to about forty ounces daily, divided into small doses. After a fortnight she left the spa, not without much improvement in health. In this class of cases the peculiarly stimulating effect of effervescing waters is often noticed, exhilaration and even giddiness following their use by delicate stomachs.

Group III.—Chronic malarial affections.

CASE V.—A lady, aged about 45, after much mental strain and daily illness (dysentery and "fevers") in tropical South America, returned home in ailing health, subject to recurring "internal chills," diarrhoea, and general weakness. She was stout, very anæmic, nervous, with frequent indigestion, headaches, and flying pains. For nearly four weeks this lady took the chalybeate, usually hot, and latterly to the extent of forty-five ounces daily. With this were combined occasional douches, sulphur baths, and massage, which no doubt contributed to a striking improvement in nervous, muscular, and digestive tone. For cases of this kind very prolonged use of the water is to be recommended, repeated from year to year, where benefit has been once derived.

The pure or carbonated chalybeates, more especially those of a light and digestible quality, will probably be accorded a wider therapeutic range when they have been systematically put to the test. That the iron is actually absorbed would seem to be certain not only from the fact that the evacuations are hardly ever discoloured, but also from the rapid and obvious tonic effects in many instances.

FACTS AND FIGURES IN CONNECTION WITH THE CLIMATE OF CALIFORNIA.

By JAMES H. PARKINSON, L.R.C.S.I.,
Sacramento, California.

The beauty and grandeur of scenery California is unsurpassed, and there is good railroad communication throughout the State; the hotel accommodation is quite equal to that which people who travel are wont to find away from home. Those who wish to reside permanently will find many places which will perfectly meet the needs of everyday life.

There is, perhaps, no other region where one can travel for hundreds of miles in so equitable a climate as that of the Sacramento and San Joaquin valleys. From Red Bluff in the north to Yuma in the south is 400 miles, and throughout that expanse of country what is true of one portion holds good for all. Northward and southward the surface is more broken, and the climate of different localities varies with the situation.

In order that some idea may be obtained of the relative position

of stations in the following tables, I append the latitude, longitude, and height above sea-level of seven towns in the State.¹

TABLE I.

Stations.	Latitude.	Longitude.	Above Sea-level.
Los Angeles	34° 04' N.	118° 14' W.	334 feet
Oakland	37° 48' N.	122° 17' W.	25 "
Red Bluff	40° 11' N.	122° 15' W.	307 "
Sacramento	38° 35' N.	121° 30' W.	35 "
San Francisco	37° 48' N.	122° 25' W.	60 "
Santa Barbara	34° 25' N.	119° 42' W.	30 "
San Diego	32° 44' N.	117° 10' W.	40 "

The comparative temperatures are well shown in the following table. Those for Europe are taken from Dr. J. H. Bennet's work, *Winter and Spring on the Shores of the Mediterranean*. The temperatures for California are from the Signal Service records and some independent observers, and represent an average of from seven to ten years.

TABLE II.

	Average winter Temp.	Average spring Temp.	Average summer Temp.	Average fall Temp.	Average annual Temp.	Highest Temp.	Lowest Temp.	Above Sea-level.
Florence	44.3	56.0	74.0	60.7	58.8	*	*	Feet.
Mentone	49.0	58.3	73.9	62.5	60.9	85	23	—
San Remo	48.9	57.3	72.4	61.9	60.1	85	25	—
Nice	47.8	56.2	72.3	61.6	59.5	*	*	—
Cannes	49.6	57.4	73.0	61.0	60.2	85	20	—
San Diego	54.6	59.1	66.8	62.6	60.5	101	32	40
Los Angeles... ..	53.6	58.4	67.8	62.7	60.6	112	28	334
Santa Barbara	54.3	59.4	67.7	63.1	61.0	102	31	30
Santa Cruz	51.8	57.7	62.2	59.6	57.8	98	30	25
Monterey	50.9	56.7	61.6	57.1	56.6	90	25	42

Red Bluff	46.8	59.8	79.7	63.2	62.4	110	19	307
Anburn	46.2	56.4	74.3	61.7	59.7	106	18	1,363

* No Record.

It will be seen that the average winter temperatures, except that of Sacramento, are much higher in California. The spring temperatures are about the same in both places. In the summer temperatures California is several degrees cooler, while again in the autumn the temperatures equalise.

In connection with the highest temperature columns it may be stated generally that such elevations are exceptional. High temperatures in California are not oppressive. During the summer months, when harvesting is in active progress, men and animals work throughout the long days under the cloudless skies, with the thermometer at 110° or 120° (in the sun), yet sunstroke is almost unknown. I do not think that this peculiarity has been satisfactorily explained. Many ascribe it to the dryness of the atmosphere, and there would seem to be a foundation for this belief in the history of cases which have occurred in Sacramento.

For the invalid or convalescent a fact of great importance is the universal prevalence of cool nights. During the afternoon the south breeze commences to blow, and very soon the air is pleasantly cool. This breeze arrives at different hours, according to locality: in the coast towns, early in the afternoon; at Los Angeles, about 3 P.M.; at Sacramento, usually about 5 P.M., and continues to blow during the night. It is but rarely, in an ordinary well-ventilated room, that bedclothes can be dispensed with; in fact, during a constant residence of almost five years in this city I can remember just four occasions that I slept without cover.

Table No. III gives some idea of the number of fine days which can be relied on. The figures indicating the days on which rain fell for five of the stations were not at hand. Clear, fair, and cloudy days are estimated on the Signal Service basis, a clear day being one on which cloudiness is three or less in a scale of 10. Sacramento, with 240 clear days, leads every town in the United States at which an observer for the Signal Corps is stationed. I regret that the number of days on which rain fell is not given for all stations, as this is a matter of considerable importance for the invalid.

¹ I am indebted to Sergeant James A. Barwick, the Signal Corps observer at Sacramento, for compiling the tables contained in this article.

TABLE III.

Stations.	Average Annual Number of Days Rain Fell.	Average Seasonal Rainfall.	Average Annual Number of Clear Days.	Average Annual Number of Fair Days.	Average Annual Number of Cloudy Days.
		Inches.			
Los Angeles	—	17.63	171.3	142.4	51.6
Oakland	68.0	24.54	263.9*	—	101.4
Red Bluff	—	27.46	227.7	81.7	55.3
Sacramento	69.6	19.94	240.0	74.9	50.4
San Francisco	—	24.25	146.7	139.0	79.6
Santa Barbara	—	16.92	No record	No record	No record
San Diego	—	11.01	122.3	157.6	85.4

* Clear and fair days combined; they are not recorded separately.

The following table is self explanatory:

TABLE IV.—Average Direction from which the prevailing Winds have been observed to blow. The Averages are from 7 to 15 Years; those in San Diego and San Francisco are Averages from 1871 to 1884, while Los Angeles, Sacramento, and Red Bluff are from 1877 to 1884.

Stations.	January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.
San Diego	NE	NW	W	W	W	W	W	W	NW	NW	NW	NE

Red Bluff	N	N	S	S	S	S	S	S	N	N	N	N
Cape Mendocino	NW	NW	SE	NW	NW	NW	NW	N	N	N	SE	NW

The velocity of the wind is not given, but I may say that in the interior of the State what sailors call a "moderate gale" is practically unknown. I have but seldom seen even a "stiff breeze" in the capital city.

These facts and figures are submitted without extended comment. We who live in the Far West are, perhaps, too apt to boast of our "glorious climate," but those only who have existed for years in less hospitable regions can appreciate what it truly is. For persons of comfortable or ample means California is easy of access, and can be reached in eighteen days from any point of departure in the United Kingdom. The journey can be made in comfort and even luxury. By the Royal Mail and Pacific Mail the trip can be made almost wholly by sea, and for good sailors it is the easiest way to travel.

A CASE OF OSTEO-PLASTIC RESECTION OF THE FOOT BY THE METHOD OF MICKULICZ.

By SIR WILLIAM MACCORMAC, F.R.C.S.
Surgeon, St. Thomas's Hospital.

THE lad whose case I wish to bring before the Society this evening is now 16 years old. On March 12th, 1887, I performed the operation introduced by Mickulicz, of Prague, and Wladimiroff, of Kasan. So far as I know it has not been previously performed in England, and as now more than a year has elapsed since the date of the operation, the Fellows of the Society will be able to estimate the amount of usefulness attained in the limb. The notes were taken by Mr. C. H. James, dresser of the case.

W. B., aged 15, a clerk, much emaciated, with a pasty face and dull, suffering expression, was admitted to St. Thomas's Hospital January 29th, 1887. There is no history of phthisis, and both parents are alive and well. Six months before the boy fell downstairs and sprained his left ankle. He was treated as an out-patient with strapping and plaster-of-Paris splints without improvement. One abscess had formed behind the inner malleolus, which was opened, and another in the sole of the foot. The swelling was very prominent on each side of the tendo Achillis. The sinuses led down to diseased bone, and it was evident the

joint between the astragalus and os calcis was extensively diseased. Two further abscesses presently formed, and the general condition of the patient became much worse. There was now evident that disease was beginning in the ankle-joint. The parents reluctantly consented to an operation, stipulating, however, that the foot must not be amputated. The soft parts covering the bone were much infiltrated and riddled with sinuses, but considering the disease to be limited to the os calcis and astragalus, and involving secondarily the joints adjacent, Sir William decided to perform the following operation.

The patient was placed in the prone position. If it be the right foot, the knife is introduced on the inner border of the foot just in front of the scaphoid tubercle, and a transverse incision extending to the bone is made across the sole of the foot to a point a little behind the tuberosity of the fifth metatarsal bone. On the left foot the direction of this incision will, of course, be reversed.

From the inner and outer extremities of the wound incisions are prolonged upwards and backwards over the corresponding malleolus and their extremities (Fig. 1), united by a transverse

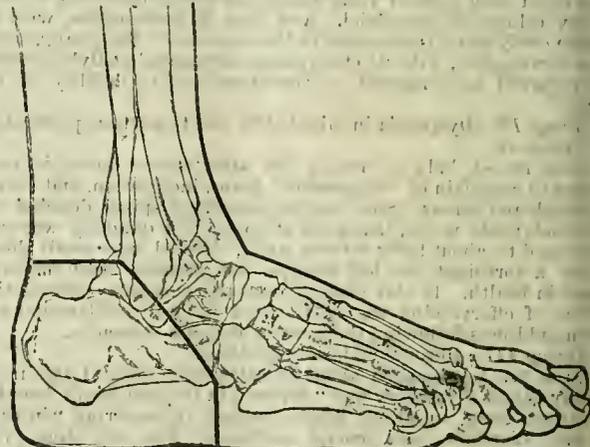

Fig. 1.—Direction of the incisions: Mickulicz's operation.

across the back of the leg, made down to the bone, at the level which it is to be sawn, usually immediately above the joint surface of the tibia. In cases where a larger removal of the tibia or fibula is required, the lateral incisions must be more oblique, and the posterior transverse cut made at a higher level.

The ankle-joint is now opened from behind, the disarticulation completed, and, after flexing the foot, the soft parts are carefully separated in front until the medio-tarsal joint is reached, when disarticulation is effected, as in Chopart's operation. The posterior portion of the foot—consisting of the astragalus, os calcis, and the soft parts covering them—is thus removed. The articular surfaces of the tibia and fibula, with the malleoli, are now sawn off as well as those of the cuboid and scaphoid bones (Fig. 2). The

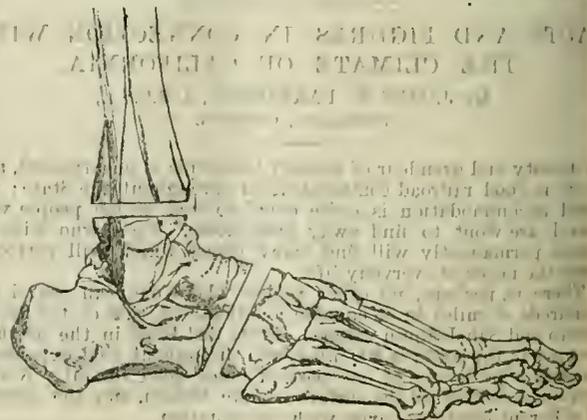

Fig. 2.—Line of section of the bones.

May 5, 1888.]

anterior portion of the foot remains connected with the leg by a loose bridge of soft parts. The blood-supply appears to be ample, or almost directly after the operation blood issued freely from the distal ends of the divided plantar arteries.

All hæmorrhage having been arrested, the foot was brought into a straight line with the leg, and the cut surfaces of bone were sutured together with kangaroo tendon. The attempt to discover and unite the divided ends of the posterior tibial nerve failed on account of the sodden condition of the soft parts. Suitable dressings and a plaster-of-Paris splint were applied, the toes being brought into a position of complete dorsal flexion.

I need not detail the after-treatment; the boy made an excellent recovery, and a firm bony union eventually took place. Sensibility began to return in the sole of the foot in about a month, and this gradually became more complete. In December the boy returned to the hospital to be fitted for the boot he now wears. (Fig. 3.) He can stand or walk with ease and comfort. The left limb is half an inch longer than the right. (Fig. 4.)

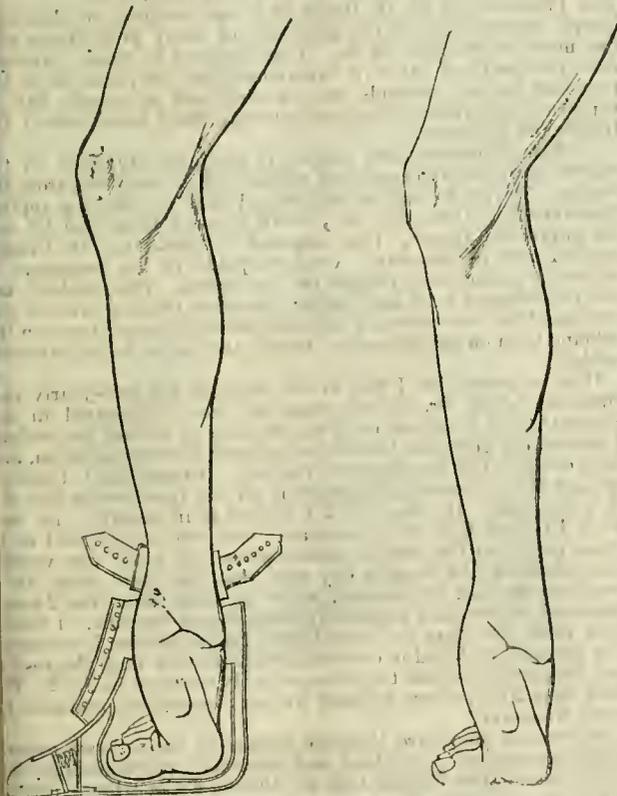

Fig. 3.—Foot fitted with boot. Fig. 4.—Stump after Mickulicz's operation.

The sensibility of the left foot appears to be perfect, showing that the divided nerve must have united. The toes are mobile. I regarded such a result as this, obtained under very unfavourable circumstances, as an exceedingly satisfactory proof of the utility of the operation.

Wladimiroff, of Kasan, in 1872, appears to have been the first to perform the operation, but Mickulicz first published an account of it in Langenbeck's *Archiv*, 1881.

The functional result, as I think this case will show, is an admirable one. An artificial *pes equinus* is procured, the object being to preserve the toes and metatarsal bones, which are sacrificed in other amputations of the foot; these are brought into a straight line with the leg, and the toes bent at a right angle, so that the patient walks on the ends of the metatarsal bones, covered by the thick pads of tissue which invest them (Fig. 4). A broader surface of support is provided than is afforded after either Syme's or Pirogoff's amputation, and there is some elasticity of foot left. In ordinary cases the limb will be longer by nearly an inch, which can be readily compensated for by a thicker sole on the other boot.

As regards indications, it may be at once conceded that the operation will prove better adapted to cases of injury—gunshot

injury more especially—than for those of disease. My experience of this case, however, would tempt me to adopt the procedure again in any case where the bones of the heel and soft parts covering them were extensively damaged or diseased, the anterior half of the foot remaining healthy.

The patient, when shown to the Medical Society, walked with the greatest facility up and down the room, both with and without the boot. There was perfect union at the line of section, and he was evidently very proud of his power to walk so well, and with such ease.

OBSTETRIC MEMORANDA.

CASE OF LABOUR, WITH DOUBLE UTERUS AND VAGINA.

MRS. C., aged 23, sent for Dr. Culpin on September 17th, 1883. Previous to her marriage, she had always had good health, never having had occasion to seek medical advice. Neither the patient nor her husband had ever suspected any abnormality. She had been married sixteen months, and had had one miscarriage when three months pregnant. She now believed herself at the full term of pregnancy. Labour pains were first felt at 2 A.M. on September 17th, and soon after the membranes ruptured. At 10 A.M. Dr. Culpin was sent for. He found a double vagina. The two canals were about equal in size, and the finger entered one as readily as the other. At the end of the right vagina, the os uteri was found dilating, and a foot presenting. At the end of the left was an undilated cervix uteri, and to the right of this the presenting foot could be easily distinguished through the septum, which was entire throughout the whole length of the vagina. There was not any unusual obliquity of the uterus. A sound could be passed into the left cervical canal. Dr. Herman subsequently saw the patient with Dr. Culpin, and confirmed the existence of the state of things described. Delivery was left to Nature until the pelvic extremity of the child had been born, which happened about midday on the 18th. The delivery of the shoulders and head was then accelerated in the usual way; but presented difficulties greater than would have been expected from the size of the child. After delivery, the upper half of the vaginal septum was found to have been torn through. The child was stillborn. Nothing abnormal was noticed about the third stage of labour, or the lying-in. Nothing like a decidua was noticed in the discharges. The patient was delivered of her second child on February 27th, 1888, Mr. Plaister being in attendance. She believed herself to have gone the full term of pregnancy. Mr. Plaister was not sent for until the head had descended well down into the vagina, and was pressing on the vaginal septum. This he pushed to the left side. In the intervals between the pains, he could distinctly feel the left os uteri, and, after delivery, he ascertained that the child had been born from the right uterus. The child was a male, living, weighed 5 lb. 10 oz., and measured 19 inches in length. The labour was a quick one. On March 3rd, Dr. Culpin and Mr. Plaister examined the patient together. The sound entered the left uterus two inches. No decidua was seen by them, or noticed by the nurse. The left cervix uteri had the appearance of that of an unimpregnated uterus. On April 16th, Dr. Herman examined the patient with Mr. Plaister. By bimanual examination the two uteri could be distinctly felt; they moved together. The left uterine body was smaller, rounder, and harder than the right. The sound entered the right uterus for three inches. The vaginal septum had been completely torn through.

In this case the kind of abnormality present was that known as uterus bicornis duplex. There were two distinct uteri, each with its own cervix and vagina, but the two cervixes were united. The researches of Küssmaul show that some abnormality in labour was met with in about half of the cases with this formation. But, as in easy labours an anatomical peculiarity is likely to be overlooked, he thinks this proportion too high to represent the truth, although high enough to show that the occurrence of difficulty is more than a coincidence. The more common sources of difficulty are those exemplified by the first labour in this case: first, that the vaginal septum offers resistance to dilatation, a resistance overcome in this case by spontaneous tearing of the septum, which was partly destroyed in the first labour, completely in the second. Secondly, that the fault in the development of the uterus is apt to lead to irregularity or weakness of pains, and so to protraction of

1 Von der Mangel der Verkümmernng und Verstopfung der Gebärmutter. Würzburg, 1858.

labour. The first labour in this case was lingering, owing to feebleness of pains; and to this cause, and the unfavourable position of the child, with the premature escape of the liquor amnii, the death of the child appeared to be due. Both pregnancies were in the right uterus, and the left uterus did not appear, so far as may be inferred from its condition after delivery, to have at all shared in the development during pregnancy of its fellow. In some cases, the unimpregnated uterus was enlarged during the pregnancy of its fellow; but Cruveilhier saw a case in which, as in this, the unimpregnated uterus remained small and hard.

G. ERNEST HERMAN, M.B., F.R.C.P.

A CASE OF PUERPERAL CONVULSIONS TREATED BY CHLOROFORM.

ON November 23rd, 1887, I was called to see Mrs. G., a young woman about eight months advanced in pregnancy for the first time. She was then in an unconscious condition, having just had a convulsion. She had great œdema of the lower extremities, and passed only a small quantity of blood-stained urine. I went home and fetched some chloroform, and during the time I was gone she had a convulsion about every hour, and stronger than the one before. I at once commenced giving inhalations of chloroform (6 P.M.), not heavily, except when a fit threatened, at which time I gave it freely. She had a strong convulsion at 6.30, the right side being chiefly affected, but the convulsion was cut short by increasing the chloroform. From 6 P.M. to 10 P.M. I kept her under chloroform, only the above mentioned convulsion taking place. At 10 I went home for some more chloroform, and whilst gone she had a convulsion. From 10.30 to 4.30 I gave chloroform without intermission, at which time the child (stillborn) having been born I ceased, there having been no convulsion in that time, nor after I ceased giving it.

When I stopped the inhalation the patient was quite unconscious, and she continued in that state the rest of that night, all next day, and the following night, and recovered consciousness the second morning after the attack. She made a good recovery under ordinary treatment, and is now quite well.

I think this case interesting, from the ready manner in which the chloroform stopped the convulsions, the length of time the patient was under the anæsthetic, namely, ten hours, and the time she was totally unconscious, namely, about forty hours.

Bourton, Dorset.

B. POPE BARTLETT, M.R.C.S.

TETANUS AFTER MISCARRIAGE.

THE patient, a married woman, aged 27, was small, thin and delicate, having suffered from painful ovaries; she had had two children and four miscarriages.

On September 25th, 1887, a miscarriage at three months took place; all went well for three days, when the temperature rose to 102° F. at night; this was found to be due to the presence of a small portion of very adherent placenta, partially decomposed, in the uterus. Under chloroform it was removed, the os having to be dilated by the fingers; the temperature that evening rose to 104°, but was normal the next morning. On October 2nd, two days after its removal, stiffness of the back of the neck was complained of; next day the teeth could only be slightly separated, the masseters being hard and contracted. Spasms on drinking, slight opisthotonos, and the risus sardonius succeeded in the order mentioned; severe and painful spasmodic contractions of the muscles of the back occurred frequently; the patient could swallow only while under the partial influence of chloroform, but later on even this was impossible.

On October 4th a severe general spasm occurred, followed by others; the temperature rose to 102°, and death soon followed. No necropsy could be obtained. Treatment: chloral hydrate gr. 20 every three hours; frequent inhalation of chloroform, and nutrient enemata.

Aylesbury.

CLINICAL MEMORANDA.

CIRRHOSIS OF THE LIVER.

DR. DRUMMOND'S case of cirrhosis of the liver, described in the JOURNAL of February 4th, is of especial interest to me, because I now have a patient, suffering from that disease, who has mani-

festated nervous symptoms, similar in character though not so intense in degree. The history is shortly as follows:—

T. P., a labourer, aged 48, formerly addicted to drink, consulted me in January 1887 for jaundice, etc. He got gradually worse and in March kept his bed. Soon after ascites appeared, he became very restless, and sleep entirely left him. He had delusions and at times got very excited. He lost his memory, and talked in a very rambling manner; his speech became slow and drawing. He remained in bed about two months, when he began to improve. The ascites disappeared, a fact which seems to bear on the remarks of Dr. Wilks in the JOURNAL of February 11th. The delusions left him and he now talks rationally. He can go about a little, but his gait is unsteady and staggering. His memory continues defective, and his speech slow and drawing.

Oswestry.

JAMES T. NEECH, L.R.C.P.E.

THE PROPOSED METHOD OF OBTAINING VACCINE LYMPH WITHOUT PUNCTURING THE VESICLES.

THE introduction by Dr. Grigg of a new method of obtaining lymph entitles him to the gratitude of every practitioner who has much vaccinating to do. I am disposed to think, however, from the results of my own experience, that the rationale of the proposed method depends, not on exosmosis of lymph, but on rupture of the vesicles, and consequently direct admixture of the lymph and glycerine.

A characteristic vaccine vesicle, if carefully examined on the eighth day, is seen to consist of minute ridges, radiating from the centre. Now, it is easy to understand that any friction applied transversely to these lines may break through them and let out the imprisoned lymph, I am disposed to think that Dr. Grigg's method acts in this way. A salient point in his procedure is rubbing a globule of glycerine on the vesicle. The result of my few experiments leads me to infer that this rubbing is a *sine qua non*, and that the success of the new method depends more on the rubbing than on the glycerine, though the latter is an excellent vehicle.

It so happened that I was in the midst of my half-yearly vaccinations when Dr. Grigg's valuable article appeared in the JOURNAL, and I had an early opportunity of testing his method. I applied the glycerine to vesicles on three different children, and in so doing varied the degree of rubbing. In case No. 1, I merely applied the glycerine and spread it on the vesicle with the end of a director. In case No. 2 I rubbed it in gently. In case No. 3 I rubbed it in with moderate force, but not so hard as to cause pain; in this case a minute streak of blood was visible. The result on the seventh day was that the fluid from No. 1 produced no sign of vaccinia, while the fluid from Nos. 2 and 3 produced redness and apparently commencing vaccinia. I would infer from this that to obtain fertile lymph friction is essential. The presence of blood in one case, No. 3, showed that the vesicle had been ruptured, and the same probably occurred in No. 2. The fluid from No. 1, where rubbing was not employed, produced no effect whatever.

Of course, I am aware that the results of one or two experiments are very apt to mislead, and practically prove nothing; but at the same time I think that we should not attribute certain results to such intangible causes as exosmosis and endosmosis, if those results can be explained on merely mechanical grounds. It is difficult to conceive how glycerine could have such an effect on the dense and horny cuticle as to allow the lymph to diffuse through it in a few minutes, unless the glycerine produced actual disintegration of the cuticular structures.

At all events, whatever the way in which Dr. Grigg's method acts, there can be only one opinion as to the great value of his suggestion, and it will without doubt prove a real boon to those who hold the thankless and troublesome office of public vaccinator. FITZJAMES MOLONY, L.K.Q.C.P.I., Public Vaccinator.

Porlock, Somerset.

THE AMERICAN MEDICAL ASSOCIATION.—The meeting of the American Medical Association will begin on May 8th, under the presidency of Professor A. Y. P. Garnett, of Washington, at Cincinnati. An address on General Medicine will be given on the following day by Professor Bartholow, of Philadelphia; an address on General Surgery by Dr. E. M. Moore, of Rochester, on May 10th, and address on State Medicine by Dr. H. P. Walcott, of Boston. The eight sections, which include a "Section on Dental and Oral Surgery," will meet on each of the four days during which the Congress lasts.

VERY LARGE SARCOMATOUS TUMOUR OF THE RIGHT BREAST OF
A FEMALE: SUCCESSFUL REMOVAL.

(Under the care of Mr. VINCENT JACKSON.)

M. E., aged 44, unmarried, was admitted on September 25th, 1887. Her previous personal and family history was unimportant, negative, and barren of causal origin. Eighteen months since the right breast began to enlarge, and it gradually continued to do so until the mamma attained its present unusual dimensions, and it was in consequence of the unsightliness produced thereby, as well as of the weight and dragging of the organ, that she felt constrained to apply for surgical relief.

To the eye there appeared to be a general enlargement of the whole of the right breast; the nipple was not interfered with either in size, appearance, or position. The subcutaneous veins being enlarged were visible, and they arboresced in various directions. With this exception the skin uniformly appeared quite normal, everywhere free and of natural tint, and in no part elevated by underlying bosses.

The weight of the breast was very much added to; this was specially appreciated when with the same hand first the left and then the right mamma was lifted. To the feel all over the impression conveyed was one of semi-elasticity, although here and there a greater resistance to finger pressure was undoubted; the breast moved easily over the underlying thoracic structures. The axilla was void of any enlargement of the axillary glands. The following measurements were taken:

	Right Breast.	Left Breast.
Horizontal ...	15½ inches	10 inches
Vertical ...	14 "	8 "

September 30th. Ether having been given, amputation of the whole breast was performed, the weight, after removal, being 5 lbs. 1 oz.

October 12th. The wound having quite healed, the patient returned to her home. The length of the linear cicatrix by measurement is 11 inches.

REMARKS BY MR. VINCENT JACKSON.—The above case is one of considerable interest, both on account of the large size of the growth involving the right breast and its somewhat doubtful histological character. For a mammary tumour to weigh six pounds is rare, although, of course, not at all a unique circumstance, for Dr. S. Gross records in a foot-note in his work on *Tumours of the Mammary Gland*, that a case is narrated from the practice of Dr. Kremer in which the tumour weighed twenty-two pounds. The growth of the tumour appears to have been

fairly regular from the time it was first observed. Although sarcomata are generally admitted to become in time the most bulky of the mammary tumours, yet they seem frequently to run an irregular course, starting and then growing a little, stopping awhile, then growing again, once more quiescent, and finally, as if with increased energy, rapidly enlarging to a bulk which apparently is only limited by the life of the unfortunate sufferer. The surface temperature of the two breasts to the bare hand was not perceptibly different, but the test of the thermometer was not resorted to.

Dr. Heneage Gibbes on this occasion, as on many previous occasions he has done similar work for me, examined microscopically a portion of the tumour, and I quote as follows from his written report: "I find the morbid growth is of a fibrous character. In some parts it resembles myxomatous growth, in others a homogeneous tissue of a fibrous character is formed. The appearance of cysts is caused by the new growth surrounding the gland acini having absorbed the major portion, leaving only a larger or smaller space, which is lined by epithelium identical with that in a normal gland. I think the growth is of a sarcomatous nature, as it resembles some I have which show a distinct sarcomatous change in parts; but, at the same time, I have similar growths which have been removed from the breast without any recurrence." The illustration taken from a photograph will assist in explaining the previous description.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

LUMBAR HERNIA; RADICAL OPERATION; RECOVERY.

(Under the care of Mr. EDMUND OWEN.)

[Reported by the late Registrar, Dr. PENROSE.]

ALICE J., aged 5½ years, fell down six steps in the autumn of 1886, and soon afterwards complained of pain in the small of the back and in the right foot. She was kept from school, and whilst staying with some friends in the country during the succeeding December an abscess broke above the left hip-bone. After this the child walked better, but the sinus continued to discharge for three months, then the wound closed. Six weeks before her admission into the hospital, the date of which was November 18th, 1887, a painless lump had appeared where the original abscess broke; it was for this that treatment was sought.

On examination it was found that the back was stiff, and that while the dorsal region of the column was unusually straight, some of the lumbar spinous processes were prominent. The lump, which was about the size of a small orange, was just above the left iliac crest, in the interval between the anterior border of the latissimus dorsi and the posterior border of the external oblique—the triangle of Petit. The tumour was resonant on percussion, and its contents could be completely returned into the abdominal cavity; they slipped back spontaneously, moreover, when the child lay on the right side. The sac being emptied, the finger could be invaginated into the abdominal cavity, and at the same time could clearly define the margins of the abnormal aperture, which was about as large as the end of one's thumb. A cough or strain would at once drive the bowel again into the sac, and another cough would still further distend the coverings of the hernia and stretch the painless white scar upon its surface, which marked the spot at which the abscess had burst. The emigrant bowel was probably part of the colon, for hardish masses, which were taken to be faecal, could be felt in it.

Operation.—On January 18th last, chloroform being administered by Mr. Priestley, Mr. Owen made an incision over the tumour until he reached what he thought was the transversalis fascia; he then thrust the sac and its contents within the abdominal cavity without making a special examination of them, and approximated the edges of the latissimus dorsi and external oblique by three deep sutures of strong catgut. The sutures were then cut short; the wound was closed and dressed with blue wool. The child was much collapsed after the operation, but she made an uninterrupted and perfect recovery. Before leaving the hospital she was allowed to run about the ward without a truss or pad being placed over the wound. The hernia is now soundly cured, though there is still some fulness, not to say weakness, in that region.

REMARKS BY MR. OWEN.—A chronic abscess in the situation referred to is of common occurrence, so that, when a surgeon sees a soft, rounded tumour above the back of the iliac crest, and

notices at the same time that there is a stiffness or a curvature of the spine, he is apt to conclude that the tumour is an abscess. Indeed, that error had been committed in this very case. Should the swelling be incised in mistake for abscess, however, the result might be disastrous. Lumbar hernia is rarely met with, at any rate in such a definite form as that in the case just recorded, and I apprehend that an operation undertaken for the cure of a reducible lumbar hernia is quite an exceptional procedure; at any rate, I can find no reference to a similar case.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, MAY 1ST, 1888.

J. HUGHLINGS JACKSON, M.D., F.R.S., Vice-President, in the Chair.

Primary Cancer of the Fallopian Tube.—Mr. ALBAN DORAN exhibited a right Fallopian tube and ovary. The tube was dropsical, and its walls were invaded by a cancerous growth. The ovary was small, but completely converted into new growth. The patient was a married woman, aged 48. For three years she had been subject to a clear vaginal discharge, which sometimes contained membranous fragments. In January, 1887, Dr. Amand Reuth scraped out the interior of the uterus, removing a quantity of red fungous growth. An attack of pelvic inflammation followed, and during the patient's recovery a tumour was detected, rising to the right above the pubes. The tumour grew slowly larger, and the patient lost flesh; fragments of solid matter came away in the discharge. On March 1st, 1888, Mr. Knowsley Thornton removed the tube and ovary; the patient recovered. The uterus was free from malignant disease. A series of sections of the new growth were also exhibited. The tumour-substance was made up of collections of large polymorphous cells, surrounded by trabeculae which were infiltrated with small cells. A few tubules lined with ciliated epithelium were to be seen; they were surrounded by a wide area of large flat cells. The tubules and their surroundings suggested the glands which, as Hennig and Bland Sutton had demonstrated, existed in the Fallopian tube, and further indicated that the cancer originated in those glands. The same collections of large cells (with wide oval spaces caused by vacuolation) and trabeculae, showing small cell infiltration, were to be seen in sections from the ovary. The history of the case, and the small size of the infected ovary compared with the large proportions of the growths in the tube, would appear to prove that the tube was the primary seat of cancer. A cancerous ovary grew very rapidly, and seldom infected the tube till it had become a large tumour. Only three cases of primary malignant disease of the tube had been described. The first, Scanzoni's, was doubtful; in the second, Dr. Senger's, of Breslau, the tumour was sarcomatous; the third occurred in Dr. Martin's practice, and was described by Dr. Orthmann as an instance of truly cancerous papilloma. In the specimen exhibited by Mr. Doran, malignant degeneration of previously innocent papillomatous growths might have taken place; but in any case he believed that the cancer was histologically of glandular origin.

Cystic Disease of the Testis.—Mr. QUARRY SILCOCK showed a specimen of cystic disease of the testis. The body of the testis was the seat of an interstitial fibroid overgrowth, apparently radiating from the mediastinum testis, with an accompanying progressive cystic dilatation of the seminiferous tubules. The cysts, to the naked eye, varied in size from a pin's head to a pigeon's egg, but, microscopically, every stage between a well formed seminiferous tubule and the fully developed cyst was observable. A scrotal tumour was thus formed, which consisted almost wholly of tough-walled cysts, some of these having ruptured, owing apparently to absorption of the intermediate fibrous tissue, so giving rise to multilocular cystic cavities of considerable size. The cystic contents varied, being a clear hydrocele-like fluid in the larger cysts, and a thick glairy fluid or caseous material in the smallest. The specimen was removed from the body of a middle-aged man who died in the medical wards of St. Mary's Hospital, and no history attached to it. The disease appeared to be analogous to some cases of cystic disease of the breast, with general dilatation of the ducts, and to pure cystic disease of the kidney. There was no evidence to the naked eye, or microscopically, that it was in any way connected with the formation of a neoplasm, such as an adenoma or fibroma. The vas deferens appeared to be permeable and healthy. The vesiculæ seminales were not examined.

Congenital Heart Disease in Adults.—Specimens from two

cases of congenital cardiac malformation in adult women were shown by Dr. MONTAGU MURRAY. The first specimen was an example of patent ductus arteriosus, in a woman who died at the age of 26, of malignant endocarditis. During life there was systolic thrill over the pulmonary cartilage, and a systolic murmur loudest over the same place. The patient died with ordinary symptoms of ulcerative endocarditis. She had never been cyanosed, and there had not been any clubbing of the finger-end. At the necropsy the heart weighed 18 ounces; the hypertrophy chiefly affected the left side; vegetations were found on all the valves; the ductus arteriosus was patent, about three-eighths of an inch in length, and large enough to admit a quill. A large mass of vegetation was found in the pulmonary artery, near the opening of the duct. This condition occurring in the adult was rare. The position of the mass of vegetations, the dilatation of the pulmonary artery, the absence of cyanosis and the position of the murmur and thrill seemed to show that blood passed from the aorta into the pulmonary artery, while the absence of any marked hypertrophy of the right ventricle was evidence that there could have been but little obstruction caused in the pulmonary artery by the entrance of the blood. In the second case the aorta arose from both ventricles; the interventricular septum was incomplete; there was stenosis of the pulmonary artery; phthisis and tubercular meningitis were present. The patient was quite well until she reached the age of 21 years, when she had rheumatism and perhaps heart disease. This was followed by attacks of cardiac failure with persistent cyanosis. A systolic murmur was heard at the apex, base, pulmonary and aortic cartilages, in the great vessels, and at the scapula, the patient finally dying of phthisis followed by meningitis; vegetations were found on all the valves after death; the infundibulum was small and the pulmonary valves adherent, so that the opening only measured a quarter of an inch. The ventricular walls were of equal thickness. Attention was called to the age of the patient, and the absence of cyanosis till she reached the age of 21, and to the probability that the pulmonary stenosis was partly acquired. Dr. H. HABERSON referred to a specimen which he exhibited obtained from a child aged 4. The pulmonary artery was atrophied, and a large aorta arose from both cavities, the ventricle being in communication at the undefended spot; the lungs were supplied through a large ductus arteriosus. In the same patient the kidneys were conjoined, lying in front of the vertebral column, forming but one flattened, so-called "horseshoe," kidney with two pelves and two ureters.

Multiple Cancer.—Dr. JOSEPH COATS showed a specimen of multiple cancer of the lungs, bones, brain, etc. There was an old cavity with cancerous walls in the right lung, which was regarded as a primary ulcerating cancer of the lung. There were secondary tumours in the lungs, bones, liver, pancreas, and kidneys. The most extraordinary condition, however, was that in the brain. Here there were cysts of various sizes, numbering no less than twenty-four, the largest about two inches in diameter and the smallest about a quarter of an inch. There was only one instance of a consistent tumour in the brain, and even this was soft and evidently to a large extent cystic. Microscopic examination showed in the lung tumours typically cancerous structure. The tumour which was regarded as the primary one, owing to its size and apparent age, and to the bronchial glands being the only glands affected, showed alveoli resembling in size and shape the normal lung alveoli, but occupied by epithelial cells, the peripheral ones of which had a regular cylindrical shape. In the secondary tumours in the lung the alveoli were less regular in size and shape, and they showed a tendency to cystic development, apparently by colloid metamorphosis of the cells. In the bones it was found that the expanded ends of the femur were largely occupied by cysts in various stages of development, from simple collections of epithelium to large spaces filled with colloid material. The bone was greatly atrophied, being only represented by narrow trabeculae. In the brain the cysts had a definite lining of epithelium. In the case of the semi-solid tumour cysts in various stages of development were visible, much resembling those in the bone. It was regarded as very extraordinary that in the bones and in the brain the secondary tumours should have shown this cystic character. The clinical history of the case was given from notes by Professor Gairdner. P. H., aged 17, was affected with various nervous symptoms, of which the chief were amaurosis, squinting, and nystagmus, but without any definite paralysis or loss of intelligence. In the course of the

[May 5, 1888.]

ase tumours in the bones were observed. The case ended with pulsions.

Primary Cancer of Brain.—Dr. JOSEPH COATS also showed an example of Primary Cancer of the Brain. The tumour was oval in shape, and measured about an inch and a half in diameter. It was situated above the pons and peduncles, apparently growing from the aqueduct of Sylvius, distending it and projecting into the fourth ventricle. The anterior part of the aqueduct was unaffected, the third ventricle normal. Under the microscope the principal constituents were cylindrical epithelium cells arranged in rows and enclosing spaces. Dr. Coats suggested the origin of the tumour from the epithelium of the aqueduct. The clinical history given by Professor Gairdner showed the principal symptoms to have been "weak turns," pain in the head, vomiting, and rigidity of the head. She gradually became very lethargic, and it was difficult to arouse. She underwent progressive emaciation up to death.

Primary Carcinoma of Liver.—Dr. CROOKE (Birmingham) exhibited specimens from a case of primary growth of the liver. The patient was a painter, aged 65, who had been under the care of Dr. Walter Foster and Dr. Simon. The liver, when the patient was under treatment, was uniformly enlarged; there was some jaundice and distinct jaundice. After systematic examination the diagnosis of primary cancer of the liver was given. At the autopsy this diagnosis was confirmed; no other organ or part of the body was affected. The liver, which was uniformly enlarged, weighed 104 ounces; its general shape was unaltered, but its surface was covered by round nodules. On section the growth was diffused in the central part of the right lobe, the central colour being greyish-white, but streaked by lines of fatty degeneration. Throughout the whole of the left and the extremity of the right lobe there was discrete nodular infiltration. Microscopical examination of the growth revealed appearances which illustrated one mode of origin of primary growths in the liver, namely, from proliferation of the liver-cells. Groups of cells were to be met with in the advancing part of the growth, which had very large nuclei, some of which might be observed to be dividing; in other parts a more active division of nuclei might be observed, and the various stages of karyokinesis. With this clear division, vacuolation, and even division of the liver-cells themselves occurred, and thus at the margin of the small nodules of growth columns of liver-cells were formed in which both processes were going on. The bridges between the vacuoles finally became absorbed, while the nuclei became arranged at the periphery; in this way a column of liver-cells was converted into a tubule lined by a highly nucleated protoplasmic border or even filled with proliferating epithelioid cells; a tubule thus formed sprouted in all directions, the nuclei at the same time rapidly proliferating, and thus the adenoid structure was obtained. The stroma of the growth was, Dr. Crooke believed, derived from the peribulbar and intercellular connective tissue. Well-defined blood-vessels were present only in the larger nodules, involving several lobules here Glisson's capsule entered considerably into the formation of the stroma.—Dr. COATS thought the prevalent notion of the growth of secondary tumours was that a cell was transplanted, but if Dr. Crooke's view was correct it would afford a powerful confirmation of the theory that cancer was disseminated by some specific agent.—Dr. CROOKE briefly replied.

Contraction of Orifices of Coronary Arteries.—Dr. TURNER showed the heart of a man aged 52, who had been found dying. The cause of death had been extreme contraction of the orifices of the coronary arteries from atheroma at the commencement of the aorta. The left ventricle was somewhat hypertrophied; the muscles firm and of healthy appearance. Referring to similar specimens previously shown to the Society, and to other cases in which a similar lesion had been the cause of sudden death in cases of angina pectoris, he argued that stenosis of the coronary arteries caused death in all cases by interference with the blood supply to the myocardium, and not indirectly through interference with the nutrition of the nerves, as had been suggested by Dr. Dickinson. He regarded the pain and anxiety of the anginous attack as tending to the recovery of the sufferer by arresting all movement, and thus aiding a restoration of nutritive equilibrium in the heart wall.

Mamma in Dermoid Cysts.—Mr. BLAND SUTTON said that it was by no means uncommon to find in the interior of an ovarian dermoid cyst tags of skin resembling a nipple. Such tags might be associated with a more or less rounded projection, recalling in a striking manner the shrunken mamma of a woman who had

suckled many children. The surfaces of such mammae occurring in ovarian dermoids were dotted over with numerous small pits, indicating the orifices of sebaceous glands, and a crop of hairs usually sprouted from the skin-covered surface. This condition was well illustrated by a specimen preserved in the museum of the Royal College of Surgeons. Standing beside it, in the same collection, was another ovarian dermoid, presenting a mamma of the size of a walnut, furnished with a nipple growing from the cyst wall. The surface was covered with dark-coloured fine hairs; it was made up of fat, covered with skin containing sebaceous and sudoriferous glands. In the museum of the Middlesex Hospital there was an ovarian dermoid cyst of the size of an orange. Standing out from its wall was a mass of fat, covered with skin, and furnished with a nipple. The mamma itself was supported upon a piece of skin-covered bone, lodging three teeth. On section, the interior of the mamma was seen to be occupied by a series of ducts leading to a glandular mass at its base. This specimen had been put up long ago, and the histological features were not well preserved. A recent ovarian dermoid cyst, removed by Dr. Bantock, contained a mamma with a nipple passing from each side to join the cyst wall. The mamma was of the size of a Tangerine orange, and made up chiefly of fat. Lying in the midst of this fat was a series of tubules leading to a glandular mass at the base of the mamma; above, these tubes passed directly into the nipples. When recent, the nipples were widely distended with a fluid resembling very poor milk, but rather more viscid. Under the microscope this fluid had all the characters of milk, and presented even colostrum globules. The microscopical characters of the glandular tissue resembled that of the normal mamma in the arrangement of the ducts and acini, but differed from it in lacking the regular layer of cubical epithelium. These observations were interesting in affording support to the view that mammary glands were modifications of sebaceous glands.

CLINICAL SOCIETY OF LONDON.

FRIDAY, APRIL 27TH, 1888.

Sir W. MAC CORMAC, F.R.C.S., Vice-President, in the Chair.

A Case Illustrating the Advantage of Early Incision with Drainage as Opposed to Excision of Joints.—Mr. WAINWRIGHT described the case. The patient, a boy, aged 3, was admitted to the West London Hospital about two years ago with a large abscess superficial to the periosteum, covering almost the whole of the outer aspect of the left thigh, which was said to have resulted from a fall a fortnight previously. This was treated by antiseptic incision and drainage. A fortnight later, before the incision was quite healed, the right hip began to inflame, and, at the end of another month, distinct fluctuation being detected in four of his joints, it was incised, and a quantity of pus evacuated. Carious bone was then found in the anterior part of the neck of the femur, which was removed by scraping, the joint being otherwise healthy. An antiseptic dressing was applied, and the wound healed in another month, leaving a perfectly movable joint. Meanwhile some thickening, which had existed about the left knee from the commencement, became more pronounced, and that joint became tender and painful—so that, shortly after the right hip had healed, the left knee was freely incised, and the cartilaginous surfaces freed from an overgrowth of synovial membrane, by which they were completely covered, by means of a sharp spoon and scissors. Antiseptic dressing and drainage were used, and the child left the hospital about six weeks later, with a plaster splint on the left knee, the wound having healed. He was admitted about seven months later, and a small exfoliation of bone was removed from a granulation cavity just above the left knee. The sinus then healed, but the knee had become partially flexed, from the splint having been removed by the parents against orders. An effort had since been made to correct this by extension and another plaster splint, but considerable deformity still existed. The knee was now nearly immovable, but all the movements of the right hip were perfect.—Mr. BENNETT said it would be interesting if Mr. Wainwright could say whence the scales came which he described as having been removed from the side of the knee. He thought, on the whole, it was a sort of case by no means rare. The abscess described was such a one as followed inflammation due to injury. In such a case the suppuration in the right hip while the child was lying quiet might be explained on the ground of pyæmia. This was a matter of some importance. He expressed himself as misled by the title of the paper, seeing

that the advantage gained by the operation performed on the knee-joint was the removal of the fungous material rather than simple drainage of the joint. On the whole he questioned whether the condition of the joint which Mr. Wainwright had described was better than would have followed excision. He asked what was the present condition as regarded locomotion.—Mr. LUCAS mentioned a case in which three joints had been affected in succession and required excision. He thought that so far as the hip was concerned he would agree with what Mr. Wainwright had advocated, namely, incision, examination, and removal of any carious bone in the neighbourhood. With regard to the other operation, he felt with Mr. Bennett that the title of the paper was misleading, and he thought that the joint might have done as well with excision. Excision as at present practised was a very different operation from what it used to be. He always clipped away the pulpy material and the synovial membrane as much as could be seen before proceeding to remove the bone. Did the exfoliation come from the neighbouring abscess or the erased joint?—Mr. HOWARD MARSH thought the paper turned on the question as to whether the disease of the joint was tubercular or pyæmic. He had often seen good results, with perfect movement, follow Mr. Wainwright's treatment in pyæmic abscesses in joints in children, but doubted whether this would be the case in tubercular disease. He thought excision was destined to become more rare than heretofore. He himself had been very disappointed with the results obtained from excision of the knee in children; often no bony union followed, and the leg remained flexed and useless.—Mr. PARKER hoped that the possibly misleading title would not be allowed to detract from the excellent results of the arthrectomy carried out by Mr. Wainwright. He himself had not obtained such good movement of the joint after drainage alone.—Mr. BENNETT asked whether Mr. Parker considered multiple abscesses evidence of tubercular disease.—Mr. PARKER said they did not absolutely prove the existence of tubercular disease, but if a child had multiple abscesses, and then disease of the knee, the evidence was in favour of struma.—Mr. SYMONDS said he had examined the child, and thought it was a brilliant result. At the same time he thought that the child was not suffering from tubercular disease. He suggested that the hip disease was due to extension upwards. His own experience was decidedly in favour of the operation. There were, however, a number of cases in which excision was the only operation. The after-results of excision of the knee were very good, and the union often quite solid.—Sir WILLIAM MAC CORMAC said the knee was evidently the seat of strumous synovitis, which Mr. Wainwright had erased with arthrectomy.—Mr. WAINWRIGHT, in reply, said that the title of his paper should have been "early incision with drainage and scraping." What he had done to the knee was an erosion, but not to the hip. The bone removed from the thigh was not carious; it came from about an inch and a half above the knee, and was caused by superficial necrosis of the femur in a granulation cavity. As to the question of pyæmia, the child's temperature never exceeded 101° F., and was usually normal, even when the suppuration started in the hip. It would be strange if such a condition could be compatible with pyæmia being set up in the opposite hip. Probably the knee had been injured at the same time as the hip, and the injury had caused pulpy degeneration of the knee, and necrosis of the femur. He had scraped away a pit from the front of the neck of the femur. The pus was sero-pus, not foetid. As to the result with the knee, probably it would have been as good had excision been performed. The paper was read more for the hip than the knee, and the bad result to the knee was probably due to the fact that the parents took off the splint without permission.

Perihepatitis.—Dr. HALE WHITE began by giving an account of a man, aged 29, in whom the abdomen had been tapped 35 times for ascites, and from whom 790 pints of clear fluid had been drawn off. The tapplings extended over a period of about 20 months, and at times the fluid re-collected at the rate of 2 pints a day. On one occasion 31½ pints were drawn off at one time. The patient had been abroad a great deal, and had had ague, dysentery, rheumatic fever, typhoid, and probably syphilis. He gradually sank from diarrhoea, and at the necropsy it was found that he had general larvaceous disease, granular kidneys, and universal perihepatitis, perisplenitis, and chronic peritonitis. There was never any jaundice, nor was there any evidence of dilatation of the portal vein. For these reasons, and because of the extreme rapidity with which the fluid re-collected, Dr. Hale White maintained that neither pressure on the whole liver nor on

the portal vein could explain the ascites. He examined 40 cases in the Guy's Records, of which 22 were cases of universal and 18 of partial perihepatitis; of the latter, 6 were examples of malignant or tubercular peritonitis. The conclusions at which he had arrived were that universal perihepatitis was, in the great majority of cases, part of a general disease consisting of chronic peritonitis and universal capsulitis of spleen and liver. It was almost invariably associated with granular kidneys, and frequently with gout, syphilis, over-indulgence in alcohol, or disease of the heart or lungs, causing backward pressure. That the cause of the ascites was the general chronic peritonitis seemed proved by the fact that there was no ascites in the very rare cases in which chronic peritonitis was absent. There was never any evidence that the disease could remain latent, or that it tended to recover, so that the prognosis was bad. The cases of partial were probably distinct from those of universal perihepatitis. In the former the thick capsule would not peel off; there was no folding of the anterior edge; the capsulitis of the spleen was not universal, and there was but rarely any peritonitis or ascites. It appeared probable that the universal perihepatitis began equally over the liver, and that the partial was never converted into the universal form. The average age at death of cases of universal perihepatitis was 47½ years, the oldest being 60, the youngest 29. There were 13 males to 8 females. It was suggested that if the author's contention that universal perihepatitis was only part of more general disease turned out to be correct, it would be better to have a new name for that disease. Dr. KINGSTON FOWLER said he had very frequently demonstrated the presence of this membrane on the surface of the liver in cases of ascites of long standing. The same thing was found on the peritoneum elsewhere in cases of chronic peritonitis. He attributed the membrane in some cases to the peritonitis set up by repeated tapping. If peeled off, the membrane was found to be fenestrated. A very similar condition was seen in the pleural cavity when dropsical fluid had been long present, and it was this membrane which often prevented expansion of the lung after the withdrawal of pleuritic fluid by tapping.—Dr. SIDNEY PHILLIPS said he had often remarked how very rapidly the abdomen refilled after tapping in cases of perihepatitis. He said that several varieties had been described, and designated three which occurred. He mentioned the case of a man under his care at St. Mary's Hospital who had jaundice a long time without ascites, but in whom the ascites was very acute a month before death. Being tapped the abdomen quickly refilled. At the *post-mortem* examination a thick band was found blocking up the portal vein. He agreed in discarding the theory that the liver was constricted by the membrane; it was usually enlarged.—Dr. LONGHURST inquired how far the condition described might be due to climatic influence and asked where the patient was when the disease first showed itself.—Mr. LUCAS quoted two cases. The first was one under Dr. Pyle-Smith, in which the abdomen rapidly filled up after repeated tapplings. The patient was a youth with a peculiarly blue complexion, and he diagnosed pericarditis with perihepatitis. In the case there was an inguinal hernia, and they had attempted to drain the peritoneum through the patent tunica vaginalis. This proved unsuccessful in consequence of the blocking of the tube, and the closure of the opening by lymph. The diagnosis was confirmed at the *post-mortem* examination, at which was found an adherent pericardium, with perihepatitis, and a thick membrane was found binding down the lungs. The second case was under Dr. Goodhart. In that case he made an oblique incision through the linea alba for the purpose of drainage, and it succeeded admirably. The patient went out cured, as the fluid did not re-collect. For months it was possible to turn him on his side, and when the wound had nearly closed if a probe was passed in large quantities of fluid escaped. If a tube were kept in, such wound always quickly closed.—Mr. SYMONDS quoted another case under Dr. Goodhart in which an unsuccessful attempt was made to drain the peritoneum, as the tubes became quickly blocked with lymph. He said that they could not wipe over the whole peritoneum with carbolic acid, and nothing short of that would be of use. He was of opinion that surgical treatment in such cases was useless. Possibly Mr. Lucas's successful case was not similar to the one quoted by Dr. Hale White.—Dr. HALE WHITE, in reply, said there might be a general cause at work, but what it was could not be made out. Climatic influence could not be traced.

A Case of Tumour of the Right Ovary in a Child aged 7. Associated with Precocious Puberty.—Mr. R. CLEMENT LUCAS read a paper on this case. The patient was admitted into the Eveling

hospital in December, 1884, for a tumour of the abdomen, and the mother had noticed some time before that the child at times had a dark-stained vaginal discharge. Other signs of puberty were also present, namely, firm breasts as large as oranges, and a mons veneris covered with hair an inch in length. The tumour was firm and slightly lobulated. This extended from the right iliac region within two fingers' breadth of the left anterior superior spine, and from the pubes upwards to one inch above the umbilicus. The child menstruated while under observation on January 7th, and again on January 25th, 1885. Mr. Lucas performed ovariectomy on February 4th, 1885. The tumour was a solid, round-celled sarcoma. The child menstruated again on February 6th, two days after the operation, but from this time it ceased. The signs of puberty also gradually receded, and the breasts again became flat. The child made an excellent recovery, and when seen two years and nine months after the operation was in perfect health, and showed no signs of recurrence.—Mr. HOWARD MARSH said it was not always the case that growing ovarian tumours in children hastened the advent of puberty. Some years ago he performed ovariectomy on a child aged 8, in whom no precocity existed. He thought that this point might be settled by looking up the records of such cases, which were not rare. The nature of the tumour in Mr. Lucas's case as sarcoma, not dermoid, as were most of the cases of ovarian disease in young children.—Mr. MEREDITH mentioned a case to prove that these tumours were not always accompanied by sexual precocity. The patient was a little girl aged 7, from whom he had assisted to remove a dermoid growth of the ovary. She had no sign of precocity. On the other hand, the stimulating effects of ovarian growths on the sexual functions were well marked when they occurred in women after the menopause; in such patients there was often a return of the menstrual discharge.—Dr. ANGEL MONEY said that negative evidence went for nothing in such cases. Other abdominal tumours in children sometimes accompanied similar precocity. He mentioned the case of sarcomatous growth of the suprarenal body in a little girl aged 3, who exhibited many signs of puberty. A similar case had also been recorded by Dr. Dickinson.—Mr. HOWARD MARSH said that it would be interesting to collect a number of cases of precocious puberty, of which he had seen a large number.—Mr. BENNETT asked whether any other members of the child's family had exhibited similar precocity.—Sir WILLIAM MAC CORMAC approved of Mr. Marsh's suggestion, and thought the case pointed to some such association as that indicated.—Mr. WILBERFORCE SMITH asked whether the subsidence of the mammae had still persisted.—Mr. LUCAS, in reply, said that the mammae had since remained small. There was no history of any similar precocity in the other members of the family.

MEDICAL SOCIETY OF LONDON.

MONDAY, APRIL 30TH, 1888.

Sir WILLIAM MAC CORMAC, F.R.C.S., President, in the Chair.
CLINICAL EVENING.

Eclampsia Rotans.—Dr. HADDEN showed two children suffering from eclampsia rotans. The patient with eclampsia nutans whom he intended to show had not come. The first child was nine months old—never had fits, but two of the family died of convulsions. Although the child never had fits, it often looked strange. In the two other cases, there had been nystagmus corresponding to the movements of the head. In the case he was to have shown there was nystagmus, but in a vertical direction. In the child then before the Society there was nystagmus of the one eye only. The movements began ten weeks before the child was seen by him.—Dr. OUTTENSON WOOD asked whether it could be traced to any injury, as was often the case.—Dr. HERRINGHAM pointed out the interesting analogy between these cases and the movements in old age (paralysis agitans), which was also of two kinds. He mentioned the case of an old man who, in addition to tremors of the hands at the rate of five per minute, had a peculiar movement of the head, two and a half per minute, due to an affection of one splenius muscle.—Dr. HADDEN, in reply, said that no history of injury was obtainable. He criticised the designation "eclampsia nutans," and said that the word "nystagmus," signifying to nod, would have been preferable.

Post-Mediastinal Tumour.—Dr. HERON showed a man, aged 50, who, for fourteen years past, had been in perfect health. He now complained of severe pain, radiating from the right clavicle to the level of the tenth rib, in front and behind. For four months past all solid food was vomited, but liquid food could be retained with comfort. No vomiting of blood. Bowels regular; urine

normal. Had been losing flesh since about two months. Distended veins on right side of chest; pupil permanently contracted, with slight ptosis on the same side. Never any difficulty of breathing. Dulness, on percussion, under right clavicle. No history of syphilis.—Dr. FORTESCUE FOX asked if there were any history of strain, or any cardiac symptoms.—Mr. BOWREMAN JESSETT said the history of the case and the interference with the circulation were too rapid to lead one to think of an aneurysm. He suggested sarcoma of the mediastinum.—Mr. TURNER mentioned a somewhat similar case, but the pressure was symmetrical. He summed up the evidence in favour of a neoplasm.—Mr. ADAMS FROST said he could detect no impairment of the movements of the eye, and said that the ptosis, if present, was probably due to pressure on the sympathetic, bearing in mind the condition of the pupil.—Dr. BEEVOY said that, in monkeys, the nerves to the pupil came off with the second dorsal nerve, and suggested that the disease was in that neighbourhood.—Dr. HERON, in reply, said that the eye movement was not impaired, and mentioned that the patient had told him that the drooping of the eye existed when he was a child.

Reduceible Lumbar Hernia Cured by Operation.—Mr. BERNARD PITTS, in the absence of Mr. EDMUND OWEN, showed a child who had been successfully operated upon for lumbar hernia, the details of which are published on page 957.

Osteo-Plastic Resection of the Foot (Method of Mickulicz).—Sir WILLIAM MAC CORMAC showed a patient upon whom he had operated for carious disease of the calcaneo-astragaloid joint, involving the ankle-joint, the details of which are published on page 954.—Mr. BERNARD PITTS said that he had looked upon the operation as the pious observation of a promise not to amputate, but seeing the highly successful result, it was evidently a great deal more.—Mr. BOWREMAN JESSETT asked Sir William what condition he expected to find when the growth of the bone was complete. He mentioned a case of disease of the astragalus and calcaneum, in which he had obtained an extremely satisfactory cure by gouging out the diseased bone, leaving merely a shell.—Sir WILLIAM MAC CORMAC, in reply, said it was not so much in the body of the os calcis as between that bone and the astragalus that the disease was. The operated limb was fully an inch longer than the other, so that there was room for growth.

Functional Contraction of the Right Hand.—Dr. BEEVOY showed a lad who had contused his hand in May last. Five days later he noticed a tendency to closure of the hand, and this shortly became permanently flexed. The flexion was followed by total anaesthesia up to the shoulder, with loss of muscular sense. The movements of the arm and forearm were however intact. He considered it to be purely functional, but had never heard of a similar case in this country as following injury.—Sir WILLIAM MAC CORMAC mentioned that M. Charcot had shown him a case of anaesthesia of both superficial and deep structures following injury.—Dr. HADDEN inquired whether there was any defect of vision, and mentioned an exactly similar case as having been admitted to St. Thomas's Hospital some years ago. Such cases were generally preceded by loss of sensibility. He then alluded to the medico-legal interest of such cases in connection with railway accidents.—Dr. BEEVOY, in reply, said that after the shock of a railway accident the patient might be able to walk home, the symptoms developing subsequently.

Obstructive Jaundice with Enlarged Gall-Bladder.—Dr. HERRINGHAM showed a man, aged 68, healthy and temperate, who was attacked in the second week of March with violent pain in the abdomen. Jaundice followed ten days later. When seen he was deeply jaundiced. The liver projected one inch and a half below the ribs, and the gall-bladder could be felt as a rounded tumour reaching to the level of the umbilicus. The liver was tender. The gall-bladder felt elastic, and there was an indistinct crepitation, suggesting gallstones when it was pressed. No stones have been passed since he came under treatment. The principal complaint is of intense itching, preventing sleep. The diagnosis was obstruction of the bile-duct by a gall-stone. Treatment consisted in opium pills to relieve attacks of pain, a draught of tartrate of soda internally, and lotions, none of which proved of great benefit, for the itching.

Curvature of Spine and Kyphosis.—Dr. HERRINGHAM showed a boy, aged 17, much affected with rheumatism, and possessing a systolic cardiac murmur. His back presented a long kyphotic curve, beginning about the tenth dorsal and ending at the third lumbar. The boy maintains that he has had it ever since he can remember, but his history is probably not very

trustworthy as to this, though it is certain that he has had it for two years. Before that he had had for three years to carry two heavy milk-cans. The case was shown for diagnosis. Dr. Herringham thought the choice lay between rheumatic arthritis, and kyphosis, from the pressure of the weight, and was inclined to the latter.

Tracheotomy for Syphilitic Disease of the Larynx.—Mr. BOWREMAN JESSETT showed a man on whom he had performed tracheotomy five years ago for syphilitic disease of the larynx. He subsequently had to scrape away a large quantity of papillomatous growths, since which time the voice had returned and continued good.—Sir WILLIAM MAC CORMAC asked what had been done to prevent blood trickling into the trachea.—Mr. BERNARD PITTS asked whether tubage had been attempted.—Mr. JESSETT, in reply, said he had used tampons to prevent hæmorrhage as far as possible.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

FRIDAY, APRIL 6TH, 1888.

C. F. MOORE, M.D., President, in the Chair.

Distribution of Enteric Fever in the City of Dublin.—Dr. GRIMSHAW, Registrar-General for Ireland, in conjunction with Sir CHARLES CAMERON, Medical Officer of Public Health for the city of Dublin, brought before the Section a paper on the distribution of enteric fever in the city of Dublin. The authors stated that their attention had been especially directed to the subject in connection with an inquiry which they had recently conducted into the prevalence of enteric fever in the Royal Barracks, and part of the information utilised for their paper had been compiled with the view of throwing light on the barracks inquiry. They showed that while typhus fever had steadily diminished in Dublin for many years, and relapsing fever had been almost absent, enteric fever had remained stationary as to prevalence, not showing any marked tendency to increase or diminish. The death-rates from typhus and enteric fever, and from zymotic diseases generally, had been at the following rates per 1,000 of the population of Dublin during the past eight years:

	1881.	1882	1883	1884	1885	1886	1887
Typhus	0.70	0.30	0.52	0.30	0.18	0.11	0.07
Enteric	0.35	0.40	0.37	0.42	0.42	0.38	0.38
Principal zymotics	2.80	0.81	3.52	3.57	3.47	2.22	5.12

It was also shown that enteric fever was not evenly distributed among the populations of the city and various townships of Dublin—the average death-rate per 10,000 for the whole district being 3.7, which varied from 1.8 in Finglas and Glasnevin district to 3.9 in the city itself. It was pointed out that while the death-rate from enteric fever in England and Wales was 0.25 per 10,000 of the population, and in London only 0.23, or nearly the same, in Ireland the rate was only 0.17 per 10,000. In the Dublin district, however, it was 0.47, or nearly three times the amount. Thus, Dublin, situated in a country with a low enteric fever death-rate, had a higher rate, relatively, than London, situated in a country with a higher rate. It was clear, therefore, that enteric fever had found in Dublin favourable conditions for its spread. The question was, What were these conditions? The greater portion of the Dublin district was supplied by the excellent Vartry water; but it was a remarkable fact that in the only division outside the city where there was not a Vartry water supply, namely, Rathmines, during the past eight years, the enteric fever death-rate was 3.7, or equal to the average for the whole district, and exceeded all the divisions of the district, except the city. Although Rathmines and the adjacent district of Donnybrook were provided with an excellent system of main drainage, such as did not exist in any other portion of the Dublin district, Blackrock and Kingstown, inhabited by the same classes, and supplied with Vartry water, had extremely low enteric fever death-rates. There were also varieties in the geological nature of the Dublin district which had an important influence on the prevalence of enteric fever. Many portions of it were situated on pervious, others on impervious, strata, and enteric fever prevailed most (except in the case of Rathmines, which had a bad water supply) on the pervious strata. The rate of prevalence of enteric fever among the population situated on the pervious stratum was 6.82 per 10,000, while on the impervious stratum it was only 4.6 per 10,000. In the case of the deaths it was found that the enteric fever death-rate on the pervious stratum was at the rate of 1 in 365 of the inhabitants,

while on the impervious stratum it was only 1 in 531. This pervious stratum consisted of a sand and gravel bed formed by an old raised sea-beach, which occupied the centre of the city on both sides of the river Liffey, into which was discharged all city sewage. This gravel bed lay in clay and rock, so that it retained all the fluid filth cast upon it or soaked into its pores in the river, and might be considered to be like a basin of water placed in the middle of the city, over which houses built inhabited by about 80,000 people. The authors believed it to be the great ground for the propagation of enteric fever in Dublin, and pointed out that the only remedies were to be directed towards the prevention of the saturation of the gravel bed with sewage, and the complete isolation of the houses from the foul air contained therein. This must be done by improved drainage, the abolition of privies and cesspits, and the concreting of the basements of all the houses situated in the gravel.—A discussion ensued, in which Dr. J. W. MOORE, the PRESIDENT, LITTLE, and Sir C. CAMERON took part, and Dr. GRIMSHAW replied.

Hypnotism.—Mr. G. M. FOX read a paper in which he traced the history of hypnotism from the days of the notorious Irish Valentine Greatrux, who was specially commissioned by Charles as a "Stroker," and gave an account of the wonderful boy "Keller," Duncan Campbell, the Scotch lad, who had De Foe for biographer, and was the subject of some of Dick Steele's papers in the *Spectator*, up to the advent of Mesmer. Mr. James Br examination of the claims of Mesmerism was detailed, and the fact that many surgical operations of a severe nature were successfully performed by Esdaill, Cloquet, and others was mentioned, together with the views held on the subject by Heinhain, Tuke, Carpenter, and others. The practical question "What therapeutic use can medicine make of hypnotism" awaited an answer, and the author did not much favour the use of the remedy, as it was attended with many dangers, and was not always reliable in its action. Hypnotic sleep had, however, given rest when ordinary remedies had failed, and in the case of a very hysterical woman it not only diminished the pains of labour but also protected the lives of both mother and child, which were endangered by the wildness of the patient's acts. In cases where heart or lung troubles precluded the ordinary anaesthetics, hypnotism might fairly claim a trial, but such cases were few. On the whole, the remedy could not, in our present insufficiency of knowledge of psychology, look for support from scientific medicine.

Glengarriff as a Winter Health-resort.—Mr. EDGAR FLINN, Glengarriff supplied a want long felt in Ireland, where the patient recovering from a long, tedious illness might find a climate mild, equable, and yet invigorating—a climate similar, and many respects preferable, to that of Torquay, Bournemouth, the Isle of Wight—a locality now more easily arrived at, and completely sheltered from the east, north, and north-west winds. There could be no question of the suitability of Glengarriff as a residence for sufferers from bronchial affections, consumptive, and asthmatic patients specially deriving great benefit and relief from a sojourn there. Rheumatic and gouty patients requiring a moderate temperature and a minimum of variability of weather would derive considerable relief during the winter months from a visit to Glengarriff. In February of the present year, when the thermometer at Glengarriff, the thermometer at mid-day in the sun registered as high as 76° F., and in the afternoon never went below 58°, and so mild was the climate in the evenings that persons were enabled to sit in the open air without feeling the slightest discomfort or chilliness.—Dr. JAMES LITTLE, from personal observation, expressed his entire concurrence with Mr. Flinn. Glengarriff compared very favourably, as far as climate and health accommodation were concerned, with the English seaside health resorts, including Torquay, Bournemouth, and Ventnor. Indeed, he thought, making a contrast with Continental resorts also, that Glengarriff lacked the coldness, dampness, gloom, and rain which prevailed during a great part of the year at Pau.—Sir CHARLES CAMERON considered the worst feature of Glengarriff, from a health point of view, was the large rainfall, between 40 and 50 inches. The discomfort of Buxton was the frequent rainfall; it was nothing to that which prevailed at Glengarriff, if the return given was authentic. It would be of great value that meteorological statistics should be accurately known, giving the average number of rainy days, the mean temperature, and the extreme each month.—Dr. J. W. MOORE regretted that there was no meteorological station at Glengarriff, and until there was such a station the place would never be known outside Ireland. It

the establishment of climatological stations that certain places in the South of England came to be known and frequented. The nearest stations to Glengarriff were those at Killarney and Malinbeg. It appeared that the bulk of the rainfall descended in the late summer, throughout the autumn, and in the early winter. Therefore, at the season that Glengarriff was most frequented as a health-resort—namely, spring—the climate must be especially delightful. There was a moderate rainfall, the sky was clear, and the wind, though easterly, was deprived of all its harshness by passing over a considerable extent of water surface. The desirability of establishing a station at Glengarriff should be brought under the notice of the Council of the Meteorological Society, and some suitable person in the neighbourhood ought to be induced to take the observations.—Dr. COSGRAVE said that a patient of his, who had been for the last four weeks at Glengarriff, had written to him, stating that he had been out from morning till night during the whole period without feeling the slightest inconvenience, though when he left Dublin the apex of one lung was affected, and he had great difficulty in breathing. In addition to the advantage of having such a desirable climate within easy reach of Dublin, there was also the advantage that Glengarriff was an exceedingly cheap place, the hotels charging only from £2 to £2 10s. per week for bed and board.—The PRESIDENT remarked that it was also an important fact in favour of Glengarriff that no such violent and sudden changes of weather from east to cold occurred there as in Southern Europe along the Mediterranean shore.—Mr. R. MONTGOMERY said the great drawback to Glengarriff was the difficulty of access and the want of amusements to supplement the picturesque scenery and balmy air.—Mr. G. CLARKE and Mr. J. J. MURPHY made some remarks, and Mr. FLINN, in reply, said he had called the attention of the proprietors of the two hotels at Glengarriff to the necessity of having a regular system of meteorological observation, and they had said they had applied for it five or six years ago, but their request was refused. The rainfall at Torquay was 40 inches in the year, which came very near to that at Glengarriff. Wherever there was a rich scenery, mountainous especially, there was sure to be excessive rainfall.

NORTH OF IRELAND BRANCH.

THURSDAY, APRIL 19TH, 1888.

J. MANSERGH PALMER, F.R.C.S.I., President, in the Chair.

Cases.—Dr. WHITLA showed a case of abdominal aneurysm; Dr. NEILL two children on whom he had operated for congenital guinea-scrotal hernia (radical cure); Dr. J. A. LINDSAY a patient suffering from paralysis agitans.

Specimens.—Dr. O'NEILL exhibited an ovarian tumour successfully removed; Dr. JOHN W. BYERS a multilocular cystoma of the ovary successfully removed; Dr. BURDEN a series of microscopic preparations of tumours.

Injection of Carbolic Acid in Hydrocele.—Dr. ESLEB presented communication on this subject.

Jejunal Enterectomy.—Professor SINCLAIR brought forward a successful case of jejunal enterectomy for the cure of an artificial anus in the right groin, the result of sloughing in a femoral hernia thirteen months previously. About four inches of bowel were removed, and a single row of Lembert's peritoneo-muscular stitches reduced. No wedge of intestine was excised. The specimen was exhibited, and the patient reported as having returned to his work.

Turpentine in Whooping Cough.—Dr. JOHN STRAHAN read a paper on turpentine in whooping cough and some other affections, which he drew attention to the great value of this drug. He regarded it as one of the best stimulants, and his rule was to give under much the same circumstances that hospital physicians prescribed brandy and whisky.—Professor CUMING, Dr. MURPHY, Dr. GREY (Castlewellan), Dr. BYERS, Dr. LINDSAY, Dr. SCOTT, Dr. BURDEN, and the PRESIDENT took part in the discussion on the paper.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.

WEDNESDAY, APRIL 18TH, 1888.

Dr. SMITH, President, in the Chair.

Case of Uterine Fibroid Complicating Labour.—Dr. AYMER, in a paper, contributed notes of a case of labour obstructed by a fibroid tumour of the uterus in the pelvis. The patient, aged 39, and married for four years, was delivered of a stillborn child

three years previously, miscarried at the second month in December, 1881, and January, 1883; and in February, 1884, was in labour at full term. The posterior vaginal wall was pushed so far forward by a round, hard body about the size of a fetal head, that the examining finger could not reach the os. Rectal examination showed it to occupy Douglas's pouch and completely to block up the pelvis. An attempt was made under chloroform to push up the tumour, but without avail. It was then punctured *per rectum* with negative result. The os was now reached, and the head found presenting in the first position. The hand was introduced, and with great difficulty insinuated past the tumour into the uterus, and first one and then another foot seized and turning effected. After steady traction for an hour and a half, a stillborn child was delivered. Opiates internally and regular antiseptic uterine douches were ordered, and the patient got up twelve days after delivery. Since then pregnancy had not again taken place, but the tumour now occupied the whole abdomen, extending four inches above the umbilicus, and having an umbilical circumference of thirty-eight inches. Menstruation was regular every three weeks, lasted four days, and was not excessive. For the past year she had suffered from frequent severe neuralgic attacks in the right iliac region, which were relieved only by hypodermic injections of morphine. Last January the patient was sent to Dr. Thomas Keith, of Edinburgh, who considered the case unsuitable for operation on account of the fixed mass in the pelvis, but suggested electrical treatment.

Specimens and Casts of Cirrhotic Lungs.—Dr. GIBSON showed the lungs removed from a man, aged 32, and zinc-gelatine casts of the same. There was a history of hæmoptysis of two months' duration. The left lung was in a state of chronic interstitial pneumonia and bronchiectasy, while the right showed well-marked compensating hypertrophy. Save the kidneys, which were slightly cirrhotic, the other organs were healthy.

Specimen of "Hammer-toe."—Dr. MACKENZIE BOOTH showed a strongly-marked specimen of "hammer-toe," which he had removed from a teacher of gymnastics, aged 36. The deformity, which was due to contraction of the flexor tendons and the lateral ligaments, had begun twelve years previously after an awkward fall from the horizontal bar, and was operated on nine years ago by subcutaneous division of the flexor tendons, and continued extension. A short time after the operation the contraction recurred, and soon became worse than before, the patient walking on the tip instead of the plantar surface of the third phalanx, and a painful corn resulting on the tip of the toe in addition to that previously existing at the junction of the first and second phalanges. Removal of the toe laterly became necessary on account of the pain and interference with the patient's occupation.

SOUTH-EAST HANTS MEDICAL SOCIETY.

WEDNESDAY, APRIL 18TH, 1888.

JAMES WATSON, M.D., President, in the Chair.

Sacculated Kidney.—Mr. JAMES GREEN exhibited a large sacculated kidney, in which all traces of renal structure had disappeared. A concretion occupied the pelvis. During life the patient had not suffered from any marked symptoms of renal calculus.

Round-celled Sarcoma of Kidney.—Dr. J. O'CONNOR exhibited the specimen. The patient was admitted into the Royal Portsmouth Hospital, suffering from extreme dyspnoea from rapid effusion into the right pleural cavity. The removal of two pints of bloody serum was followed by temporary relief. After death the primary growth was found to occupy the right kidney, and secondary deposits were discovered in the lungs, liver, and peritoneum.

Spindle-celled Sarcoma.—Dr. J. O'CONNOR showed a large nodular growth which had been removed by Dr. Ward Cousins at the Royal Portsmouth Hospital. It covered half the sternum, and extended into the lower part of the neck. It was a recurrent growth, the primary tumour having been removed two years before. The cellular tissue and skin were extensively involved. The wound was nearly closed by freely detaching the skin subcutaneously over the pectoral regions. The patient made a good recovery.

Nephro-Pyelitis and Stone in the Bladder.—Dr. J. O'CONNOR also exhibited the kidneys removed from a boy, aged 10 years, who had been admitted into the hospital for stone in the bladder. A few hours before the time fixed for the operation, he was attacked with all

the symptoms of acute peritonitis, constant vomiting, and almost entire suppression of urine. Renal suppuration was suspected. The abdomen was greatly distended, but there were no localising symptoms. At the necropsy an old abscess was found in the left kidney, the ureter was dilated, and the structure of the entire organ was destroyed. The right kidney was large and much congested. Dr. WARD COUSINS remarked that the patient succumbed from acute septic disturbance. If lithotomy had been performed before the onset of the attack, the operation would probably have been fatal from the advanced disease of the left kidney. At the time of admission the stone in the bladder was found on examination, and the condition of the patient appeared favourable for surgical treatment. The vesical symptoms were not urgent, and the urine contained only a little mucus.

Large Round-celled Sarcoma of Ovary.—Dr. WARD COUSINS exhibited the specimen. The patient was 17 years of age, and the tumour had developed with great rapidity. The first symptom observed was œdema of the right leg. The abdomen measured thirty-five inches in circumference below the umbilicus. The mass was solid, nodulated, and immovable, and appeared continuous with the upper border of the ilium on the right side. The uterus appeared healthy, but firmly fixed to the base of the tumour. After death the right iliac vessels were found much involved in the growth, and they had a very circuitous course through the fibrous structures which fixed it to the pelvis. Secondary nodules were present in many of the abdominal organs, and were scattered also over the peritoneum.

Chronic Phthisis with Atlanto-axoid Disease.—Dr. WARD COUSINS exhibited the specimen. The patient had been many months under treatment with all the characteristic signs of the disease of the upper cervical vertebrae. He could only rest with the head carefully fixed and inclined to the right side. Once only he complained of dysphagia. Deep-seated tenderness was present, but no swelling of the neck. Physical examination of the chest clearly indicated old disease of the lungs, but the thoracic symptoms were only occasionally troublesome. At the *post-mortem* examination the atlas and axis were found in many parts extensively softened and disintegrated. The odontoid process was rough, completely denuded, and surrounded by purulent fluid. A thin collection of pus existed in the anterior surfaces of the three upper vertebrae. Dr. Ward Cousins remarked that the secondary disease of the cervical spine was the result of purulent infection. The extensive disease of the apices of the lungs was of long standing, and the exciting cause of the pyæmic earies.

Calculi Removed by Suprapubic Lithotomy.—The patient, aged 60, was under the care of Dr. WARD COUSINS, in the Royal Portsmouth Hospital, labouring under urgent symptoms of stone in the bladder, attended with fœtid cystitis. On examination a concretion was readily detected, apparently impacted in the vesical wall. There was no history of hæmorrhage. The lithotrite was introduced, but the attempt to seize the stone was unsuccessful. Three calculi were then removed by the suprapubic method. They were detached by the point of the finger from the wall of the bladder, which was very thick and vascular. The patient died on the fourteenth day after the operation. The necropsy revealed old renal disease, with dilated ureters, and also the presence of a new growth involving the bladder around the ureteral orifices.—The report on the nature of the growth was postponed until the next meeting.

Early Diagnosis of Typhoid Fever.—Dr. AXFORD made some remarks on the difficulty attending the diagnosis in the early stages of some cases of typhoid, especially instancing cases of typhoid simulating intermittent fever. He then read notes of a case which to all appearance was metritis and parametritis, but which ultimately showed itself to be in reality enteric fever. Miss W., aged 33, had suffered from dysmenorrhœa. Commencing to menstruate on Sunday, November 20th, she was exposed to severe cold on the following day; the flow ceased at once, and severe pain in the uterine and left ovarian region came on, and there was a patch of dulness in this part. There was acute pain of a spasmodic character in the lower part of the abdomen, and the attacks of pain were accompanied by retching. A vaginal examination caused most acute suffering. The os was swollen harder than usual, and very tender, and pushed somewhat forward. On pressing upwards towards the left ovary there was some swelling to be felt, and very great pain was produced. At first the bowels were confined, but early in December there was diarrhœa for a few days, but this was never severe. Typhoid spots were seen about the fourteenth day. The patient was treated by hot fomentations

and poultices, with laudanum and quinine internally. The temperature on the fifth day was 104° F.; it generally ranged from 101° to 103°. In the early stages there was little difference between the morning and evening temperature. Convalescence was established by the twenty-eighth day, and resulted in complete recovery.

Ovarian Tumour and Ascites.—Dr. H. L. K. HACKMAN stated that the first symptom complained of by the patient was a constant desire to micturate. Early in 1887 the left leg became swollen, with tenderness along the femoral vein, and indurated in the left iliac region. The bladder symptoms continued, and soon after marked ascites followed. After careful examination an ovarian cyst was diagnosed, surrounded by peritoneal fluid. The patient refused to undergo any surgical operation. The abdomen was tapped to relieve the distension, and then a well-defined tumour was readily detected. The operation was repeated several times, and the patient at length died from exhaustion. Only a very imperfect *post-mortem* examination was permitted. The abdominal viscera were matted together by adhesions. The cyst was brittle and evidently undergone necrotic changes. It was firmly adherent everywhere, and contained a dirty fluid and much cheesy-looking material. Hackman said that he considered tapping in ovarian disease a dangerous treatment, and he thought the case favourable for abdominal section, but it was impossible to persuade the patient to submit to it.

Aural Inflator and Evacuator.—Dr. WARD COUSINS exhibited an aural inflator and evacuator especially adapted for the Eustachian catheter. By this apparatus the treatment of alternate injection and evacuation of air could be applied to one ear only.

Microscopic Sections.—Dr. F. J. DRIVER exhibited: 1. Round-celled Sarcoma of Kidney. 2. Sections of Heart-Muscle and Kidney in a Case of Phosphorus Poisoning. 3. Sections of Lung and Trachea affected with Chronic Syphilitic Induration.

New President.—Mr. H. B. Norman was unanimously elected President of the Society for the ensuing year.

MIDLAND MEDICAL SOCIETY.

WEDNESDAY, APRIL 18TH, 1888.

W. ROSS JORDAN, M.R.C.S.Eng., President, in the Chair.

Ataxia in a Brassworker.—Dr. HODGEN exhibited a case of ataxia, occurring in a man, aged 31, who was a brassworker. The patient came to the out-patient room at the Queen's Hospital 7 years ago, complaining of tremors and weakness in the legs. There was the green discoloration of the teeth characteristic of his occupation. His gait was staggering, and he suffered much from static ataxia, being quite unable to walk in the dark, or to stand with his eyes closed. On examination, his muscular sense was found to be much impaired in the lower extremities; there was no loss of sensation. The patellar tendon reflex was exaggerated, and ankle clonus present. His pupils responded to light and accommodation, and the fundus oculi appeared healthy. There was no history of syphilis, nor of gastric or other crises. The patient had continued under observation for two years without much progress for better or for worse.

Specimens.—Mr. LAWSON TAIT exhibited the following specimens: a Sarcomatous Kidney, weighing one pound two ounces removed from a child three years of age; a Dermoid Tumour of Ovary, with a long twisted pedicle, and adherent to the ascending colon; a large Cystic Kidney, removed from a woman aged 52. Mr. E. L. FREER showed a case of Dupuytren's Contraction in a man successfully treated by multiple incisions.

Treatment of Spinal Curvature.—Mr. FREER also read a paper on "The Treatment of Curvature of the Spine," and demonstrated the mode of applying the divided plaster cuirass.

PRESENTATIONS.—Mr. William L. Thomas, M.R.C.S.Eng., has been presented with a purse of money and an address, on retiring as Medical Officer to the Weald of Sussex Lodge of Odd Fellows. Mr. Robert Francis Symmons, M.R.C.S.Eng., of Colchester, has been presented with a purse, containing upwards of £100, by his patients and friends, as a mark of esteem and goodwill.—At the presentation of certificates to the successful lady members of the Pontpool Ambulance Class by Dr. Lawrence, of Usk, Dr. E. Stanbury Wood, who had conducted the class, was asked to accept a valuable gold pencil case, bearing a suitable inscription, from the twenty-one members of his class.

REVIEWS AND NOTICES.

FUNCTIONAL NERVOUS DISEASES; THEIR CAUSES AND THEIR TREATMENT. By GEORGE T. STEVENS, M.D., Ph.D., formerly Professor of Ophthalmology and Physiology in the Albany Medical College. New York: D. Appleton and Co. 1887.

In this book there is a great deal of what is good mixed up with the products of a specialist's exaggeration. Its thesis is thus expressed by the author: "Difficulties attending the functions of accommodating and of adjusting the eyes in the act of vision, irritation arising from the nerves involved in these processes, among the most prolific sources of nervous disturbances, and more frequently than other conditions, constitute a neuropathic tendency."

All physicians and ophthalmologists will agree with the author that headache, migraine, and facial neuralgia are very frequently caused by disorders of accommodation, and especially by hypermetropia and insufficiency of the ocular muscles.

The chapters relating to these functional nervous disturbances are the best in the book. The author, taking consecutive cases of migraine, shows that, by correcting disorders of vision, 83.6 per cent. were cured, 12.4 per cent. improved, and 4 per cent. not red. Similar results were obtained in cases of neuralgia. If the author had stopped here he would have written a very instructive and practical treatise, but he goes much farther. He asserts that sciatica and lumbago are also occasionally due to ocular disturbance. He shows that the majority of cases of chorea occur in children who have hypermetropia or other disorder of accommodation. This may be so in America, but, even taken with the successful cases of the author who cured the chorea by correcting the vision, it by no means proves that "chorea is emphatically a nervous trouble...depending upon ocular conditions" (100).

Similarly epilepsy and insanity are believed to be associated with derangements of accommodation, and to be curable by attention to the visual disturbance.

In spite of the author's imposing array of 2,692 cases, and even making considerable allowance for the fact that functional neuroses are more common in America than in England, we do not agree with him in his conclusions.

We will add one more quotation, p. 130: "1. In such families (with high degree of refractive errors) there is an extraordinary prevalence of nervous disorders, including migraine, neuralgia, insanity, and organic lesions, such as apoplexy and paralysis. 2. Consumption and Bright's disease are rife in these families. 3. The higher the grade of refractive anomalies, the greater is the proportion of these last-named diseases."

The author is clearly an expert ophthalmologist, and the supplement to his book, giving the methods of detecting and treating functional disorders of the eyes, is an excellent summary.

The account of the work which we have given will serve to show into what errors of judgment too great specialism may occasionally lead an otherwise able observer. It is right we should state that, in spite of what we judge to be its faults, the memoir received the highest honours from the Académie Royale de Médecine of Belgium in 1883.

THE NEW JUDGMENT OF PARIS. A Novel in two volumes. By PHILIP LEFARQUE. London: Macmillan and Co. 1888.

Medical men, like other hard-worked folks, are none the worse sometimes for a little intellectual as well as physical recreation. Those of them, therefore, who desire agreeably to divert their attention for a few hours from the routine of duty, will find in the perusal of the volumes under notice a congenial and refreshing pastime. To any of our professional brethren who are wearied and jaded by professional work, we can confidently recommend a course of PHILIP LEFARQUE as a tonic and stimulant. They in turn may safely prescribe it to their patients as a wholesome and efficacious restorative in cases of weariness or depression of spirits.

A medical journal is scarcely the place in which to give an exhaustive or critical review of a novel. We, however, gladly spare a brief space in our columns for the notice of this book, as we have good reason for knowing that it is the production of one of our own cloth, and we believe that it is the maiden effort

in the direction of romance of a physician well known and respected for his literary and artistic attainments.

That there are many cultured medical men is a fact which cannot be denied, and although there are numerous isolated instances of talented doctors who have distinguished themselves by their contributions to general literature, it must be confessed that our calling as a profession is not famed for its imaginative or romantic productions. Whether this is due to want of leisure, or to the intrinsically engrossing nature of its duties, or to the practical and materialistic line of thought which it entails, it is needless at present to discuss. The fact remains that doctors, as a rule, are not novel-writers. This is perhaps to be regretted as medical men in reality have opportunities of observing and studying human nature under varied aspects, and of coming in contact with incidents and scenes which should provide them with a rich soil for the cultivation of romantic and imaginative works, and which, if properly utilised, might provide us with more wholesome and intelligent reading than the insipid publications so frequently met with.

Of the details of this book we do not propose to speak. We can only express our opinion that it is cleverly written, that the literary style leaves nothing to be desired, and that the characters and incidents of the story will be found to be interesting and psychologically instructive. There is nothing strictly medical in the book unless it be that one of the chief personages is a fashionable doctor, whose character is admirably drawn. He represents a type, unfortunately too common, of man whose style of practice we deplore but are helpless to prevent. Dr. Bland is the astute, worldly-minded individual, who, without being criminally culpable, or even placing himself beyond the pale of the profession, sails close to the wind and succeeds in gaining the confidence and money of the public in greater abundance than the respect of his own colleagues.

NOTES ON BOOKS.

Shepherd's First Aid to the Injured. Revised and Rearranged by ROBERT BRUCE, M.R.C.S.—This shilling handbook of the St. John Ambulance Association has been carefully revised and much improved. The illustrations will very greatly assist the reader in following the practical descriptions of improvised splints and stretchers. A very useful chapter on Conveying Injured, by Mr. John Furley, will be found invaluable by those lecturers who are instructing ambulance classes of men engaged in factories and mines. No manual can be found equal to this for the purpose for which it is intended, that is, to give some plain rules to non-professional persons, which will enable them to render immediate aid in many of the cases of accident and illness which occur in our daily life.

Royal University of Ireland. The Calendar for the Year 1888.—Examination Papers, 1887. A Supplement to the University Calendar for the Year 1888. (Dublin: Printed for the Royal University by Alexander Thom and Co. 1888.)—The Royal University of Ireland has this year published the Calendar proper and the examination papers in separate volumes. The innovation will be a great convenience to students preparing for its examinations, who will find in the bulky volume of 560 pages, which contains all the papers set during 1887, matters of absorbing interest.

The Calendar of the Pharmaceutical Society of Great Britain, 1888. (London: Printed for the Society.)—The new volume of the Calendar of the Pharmaceutical Society contains the usual classified lists of members, associates and apprentices, and abstracts of Acts of Parliament affecting the interests of pharmaceutical chemists and others engaged in the drug trade.

JAMBUL FROM THE DUTCH INDIES.—Dr. J. A. Quanker, of Amsterdam, records in the *Weekblad* a case of diabetes in which he administered an infusion of jambul with great success. The specimen employed was imported from Dutch India, where the plant, *Syzygium jambolona*, is called by the natives *Dioctet*, and is to be found everywhere in the gardens. The drug appeared to exert so beneficial an effect that the strict diabetic diet was relaxed without increasing the sugar. It is not clear whether this is the same plant as *Eugenia jambolana*.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1888.

SUBSCRIPTIONS to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the West Central District Office, High Holborn.

The British Medical Journal.

SATURDAY, MAY 5TH, 1888.

THE DUTIES AND THE DIFFICULTIES OF EDUCATIONAL WORK.

We have often urged in these columns the necessity of providing special classes or day schools for those children whose feeble constitution or low brain-power renders them unfit for education in the ordinary classes of our public elementary schools. This subject is ably discussed in the last two numbers of the *Journal of Mental Science*, and reference is there made to the auxiliary schools which have been established in several of the more important German towns, mainly through the efforts of Herr Kielhorn, these schools being intended for children who are unable to bear the strain of the ordinary curriculum. Those children who after two years' trial have been shown to be quite unable to follow the instruction given in the classes of the national schools are drafted into these special schools, where, all the pupils being on about the same intellectual level, it becomes possible to place them under the charge of a specially trained teacher, who instructs them in classes not exceeding twenty members, so that some care may be devoted to their individual capacity and requirements. This withdrawal of the feeble and more backward children from the national schools enables more care to be given than to the ordinary children working in the curriculum, a heavy incubus and tax upon the teachers' time being thus removed. It is manifestly unwise in the interests of society, and unjust to the weakly children to leave them practically uneducated, allowing them to be sent out into the world to meet the many dangers which await the weaker members of the community, tending to draw them towards pauperism or criminality if left untrained and unprepared. Dr. Shuttleworth, of the Royal Albert Asylum, Lancaster, advocates the introduction of a similar system in this country. No systematic effort has thus far been made among us for the special training of those children whose weak mental capacity renders it impossible for them to keep pace with the requirements of "the code."

A similar movement has been made in Norway, where it is said that the ratio of the "abnormal" children in public elementary schools bears a ratio to the ordinary school children of 0.4 per cent. This ratio appears much

lower than that suggested by our own experience in England. The requisite funds are provided through the School Board, and the annual cost is about £6 15s. each pupil. Such auxiliary schools are at work both in Christiania and in Bergen. Dr. Shuttleworth has suggested that an experiment might be made with some central school or special department of a school for exceptional children. Such school department would have a distinct sphere of usefulness, apart alike from the common school and the imbecile institution. An important hiatus in our English educational system is thus pointed out. The subject is ripe for practical consideration and action. A satisfactory solution of the problem has been found by our Continental neighbours, and we must be prepared to do likewise. It is not fair to throw ordinary National Schools, which have to depend for their success in a large degree upon the results obtained at examinations, that they should be burdened by a number of feeble children, and it is unjust to neglect such children. Sufficient scientific knowledge exists among us for the selection of the "special children" by those whose studies have led them to overlook children with care. It seems to us unnecessary to wait two years' failure in school has demonstrated the feeble brain-power of the children. Selection might be made by the occasional visit of a medical inspector, acting in conjunction with the opinion of the teacher and managers. The subject is within the scope of the Royal Commission on the blind, dumb, and deaf, who, from exceptional circumstances, require special methods of education. We believe they have already received some evidence as to this class of children.

A very temperate article in the current number of the *Educational Times* refers to what sounds something like a declaration of war between the National Union of Elementary Teachers and the Education Department. The causes of quarrel are principally two—payment by "results," and the "cast-iron system" which ignores every consideration of humanity." Two heavy indictments, but of different significance. They both, however, have some foundation in certain points within the cognisance of our profession. Results of education, as the bellicose schoolmaster points out, are not simply to be tested by scholastic examination, but partly by results seen in appearance, in conduct, in accuracy and quickness of brain-action. Some tangible results of education must be looked for; let the schoolmasters say what in their opinion are the visible results of their best work. Members of our profession often have to work long and hard without reward or recognition, contented that good always follows good work. A medical practitioner does not take as the standard of his work the amount of money it will bring him, but is bound to do the best he can in the discharge of his professional duties. We cannot echo the sentiment contained in a letter from the President of the Teachers' Union, as quoted in the article we have noticed, when he says: "I advise the teachers of the country to leave overt acts as to the moral training of our children to their parents, their ministers, and the magistrates. Neither of them have to enter in a punishment book the deterrent good they do to their own disparagement."

5, 1888.]

this advice seems very shocking; still, I hold it to be policy." We cannot ourselves recommend that a "safe" be placed before loyalty to the honourable traditions of the profession. We greatly sympathise with elementary teachers in the unwise attempts of certain magistrates to the power of maintaining discipline in schools by means of corporal punishment; children may not like it, the remedy is not to be used. As long as such means are found necessary in higher schools and in families, it is only just that moderate and reasonable means of punishment be left in the hands of teachers. We agree with the *Educational Times* in their opinion that "more stringent discipline is needed in an elementary school than in a higher school." There is too much laxity nowadays about corporal punishment.

IRISH PRISON SURGEONS AND CONSULTANTS.

Arbitrary conduct of the Irish Prisons Board towards, and interference with the powers and duties of, prison surgeons, has obliged us more than once to comment on its proceedings. In the inquiry and report of the Royal Commission on Prison Discipline, better relations appeared to have been established, and it was hoped that further attempts to curtail the independence of the medical officers of prisons would not have been

The question asked by Mr. Murphy in the House of Commons on April 17th—which, with Mr. Balfour's reply, was noted in the *JOURNAL* of April 21st—shows that such hopes were vain, and that the Board is again endeavouring *ultra vires* to interfere with the rights of the medical officers.

It appears that the Prisons Board issued a circular to governors of prisons, directing them, after consultation with the medical officers, to forward a list of medical practitioners—regarding qualification and religion—to be called in from time to time in consultation.

It was asked whether the power to call in additional medical assistance was not given by the 105th Rule of Local Prisons Regulations. This was a mistake—and a very natural one—for the 105th Rule professes to give the power. But the 105th Rule is a verbatim extract from the 53rd Section of the 40 and 41 Chap. 49 (the Prisons Ireland Act), so that the power of calling in a consultant is statuteable, and necessarily involves the choice by the person on whom it is conferred of the consultant to be called in.

In England, the mistake of confounding the provisions of an Act of Parliament with the rules made by the Prison Commissioners could not occur, because, in the rules for local prisons, the provisions taken from the Acts are printed in Roman characters, and the rules in script type. In the Irish rules, however, the provisions from the Acts and the rules made by the Board are printed in similar type, numbered consecutively, and presented to the world as made by the Board and approved by the Lord-Lieutenant.

Advantage of the mistake was taken to furnish Mr. Balfour with his reply; and the only explanation of his answer which we can arrive at is, that his informant confused the appointment of wardens with that of medical officers, so that a specious reason might be given for an autocratic action on the part of the Board.

Mr. Balfour is reported to have replied that "The appointment of medical officers required the sanction of the authorities, and it seemed to him to be certainly within the spirit of the rules that some effective control should be exercised as to the election of consulting physicians."

There is a grave error in the first statement: the appointment of medical officers does not require the sanction of the authorities; the latter part is a mere *sequitur*; and, finally, there is no such office as that of consulting physician, nor any election thereto.

As it stands the reply is incomprehensible, but what is intended to be expressed appears to be that the power of calling in consultation being conferred by the Board, it is natural that the authority giving that power should also have the right of controlling the exercise of it. But, as the power is not given by the Board, that body has no more right to control or to interfere with its *bonâ fide* exercise than the junior clerk in its office has.

The Act of Parliament is specific. Section 53 says: "He (the medical officer) "may in any case of danger or difficulty, which appears to him to require it, call in additional medical assistance; and no serious operation shall be performed without previous consultation being held with another medical practitioner, except under circumstances not admitting of delay, to be recorded in his journal." Now it is clear not only that the medical officer may call in additional medical assistance, but that he is constituted the sole judge of when it is requisite; and it is a recognised principle of law that a power conferred carries with it, unless expressly stated to the contrary, a discretion to the person so empowered as to when and how and by whose means he shall exercise that power.

The effort of the Board to regulate or assume an authority to approve of the practitioners to be called in may seem a small thing to cavil at; but when it is remembered that there is in existence an uncancelled circular of the Board directing, in distinct opposition to the provision of the Act, that additional advice is not to be obtained, except in urgent cases, without the sanction of the Board, and that the Board has taken it on itself to specifically order that certain practitioners are not to be called in again because they have refused to accept a fee of one guinea in place of the ordinary consultation fee of two guineas, or because they have compelled the Board to pay money legally and equitably due, or for other trivial reasons, the matter assumes larger proportions.

But the real objection lies in its being only one of a number of persistent attempts to take away the independence deliberately conferred on the prison medical officers by the Acts of Parliament. The medical officer is intended and ought to stand independent between the prisoners and the discipline authorities.

His duty to the Government requires that he should himself obey the rules, and not suffer them to be relaxed on medical grounds, unless the health of a prisoner is suffering or is likely to suffer. His duty towards the prisoners is not merely to treat them when sick, but to see that neither their lives are endangered or their healths injured by discipline, diet, labour, or confinement. If he fails in either he is liable to punishment, but to discharge his duties efficiently he must be to a great extent independent.

The tendency of modern prison legislation has been towards more humane treatment and greater care of prisoners, both mentally and physically; and with this object in view the Prisons Act has removed the appointment of medical officers from boards of superintendence and the Prisons Board, vesting it in the Lord Lieutenant; and they have conferred much more extensive powers directly on the medical officer. Thus, in addition to the duties imposed by 7 Geo. IV, c. 74, *sec.* 72, the Prisons (Ireland) Act increases his duties and defines them more clearly, and then it places the health of the prison in his charge; makes him responsible for its sanitary condition, warmth, ventilation, quality of provisions, etc.; authorises him to give such directions as he may think proper for the treatment, not of the insane alone, but for that of any prisoner whose mind is likely to be injuriously affected by the discipline; and in case of death of a prisoner, directs him to report particulars of the illness, etc., "together with any special remarks that appear to him requisite."

At any time to reduce the medical officers to a position of subservience to the Board would be a policy most detrimental to the best interest of the service and the welfare of the prisoners. But at the present it is singularly inopportune. Wild charges are made of an intention on the part of the Government to destroy the health and lives of prisoners claimed to be political. So long as the prisons are served by independent medical men, who can, without fear or favour, exercise the powers conferred in the Act, it is felt that such charges are absurd and incapable of fulfilment. But once let the medical officer become the mere servant of a department, then public confidence is shaken, and the possibility, nay the probability, of a prisoner being done to death will be entertained. That, even in case of such subserviency any intentional cruelty or injury would be sanctioned or permitted, we do not for a moment believe, but the position of a medical officer would become intolerable. He dare not act without orders: he would be liable to censure for this, blame for that; precious time would inevitably be lost in ascertaining the will of the Board, and in many cases irretrievable injury would be done, and even fatal mischief have resulted, before the opinion or permission of the Board could be obtained.

The grounds, therefore, of objection to the illegal action of the Board are not even primarily the injustice or hardship of interfering with and curtailing the statutable rights of the medical officer; they lie chiefly in the interests of the public, and enormously so in the interests of the prisoner.

It would be difficult to conceive why the Board should seek to deprive the doctors of their rights, were it not that the Board appears to mistrust its officers, and more especially the medical ones. It probably suspects that they give a preference to those medical gentlemen who discharge their duties when absent. There is no evidence that this is the case; but even if it were, we see nothing objectionable in it; on the contrary, the man who has some experience of the peculiar circumstances of prison life, from having acted as the medical officer's substitute, is the one best suited to appreciate the relaxations of discipline or changes in diet requisite in particular cases.

We trust the matter may not be allowed to rest, and that members of Parliament will closely watch the action of the Board, and prevent by gradual encroachments its acquiring supreme authority.

Nor is there any need for such encroachment. The work of the Irish prison surgeon has been well done. The reports of the Board, year after year, show a remarkably small mortality, which is mainly owing to the medical officers' attention to the sanitary state of the prisons and their care of the sick prisoners; on the other hand, discharged prisoners testify publicly to their efficient discharge of duty.

With such testimony from both parties, it seems particularly hard that these officers, whose responsibilities are serious, whose work is arduous, and whose salaries are inadequate, should have been publicly slighted by being twice passed over for promotion; and that now injury should be added to insult.

It would be far better for all parties concerned if the Prisons Board adopted the sensible policy of trusting their medical officers. If their powers are large, they must act with a full sense of the heavy responsibility such powers involve; for no good cause to try and curtail those powers, lowers the sense of responsibility; and when the conviction of being distrusted is added, all heart for or interest in their work is taken away. Were the Board capable of appreciating advice, we would say: Trust your officers fully, and do not hamper them in the discharge of their duty. If an officer is proved unfaithful or careless or negligent by all means apply to the Lord Lieutenant to get rid of him; but until he is so proved unfit for confidence, trust him fully; and we venture to say on behalf of the medical officers that they are not and will not be found unworthy of such confidence.

A CONVERSAZIONE will be given by the Medical Society at its rooms, 11, Chandos Street, Cavendish Square, on Monday May 7th, after the annual oration, to be delivered by Sir Joseph Payrer, M.D., K.C.S.I., at 8.30.

At the meeting of Convocation of the University of London on Tuesday next (May 8th), a resolution will be moved, at the instance of the annual Committee, empowering it, in conjunction with the Committee appointed at the instance of Sir Philip Magnus in 1885, to take steps to represent by suitable witnesses the views of Convocation to the Royal Commission appointed to inquire into the condition of the higher education in London.

May 5, 1888.]

LORD RANDOLPH CHURCHILL, M.P., will preside at a Special Festival Dinner, to be held at the Hôtel Métropole on May 12th, in aid of the scheme for the extension of St. Mary's Hospital, mentioned in the JOURNAL on April 21st (p. 865).

H.R.H. THE DUCHESS OF ALBANY has graciously consented to distribute the certificates to ladies who have passed the examination allowing the lectures on Domestic Hygiene, by Dr. A. T. Schofield, at the Parkes Museum, Margaret Street. The ceremony will take place at 3 P.M. this day (Saturday).

THE SIR GEORGE BURROWS MEMORIAL PORTRAIT. We are asked to state that the subscription list for this portrait will be closed on May 15th. Intending contributors are, therefore, requested to send their subscriptions without delay to any member of the committee, or to the hon. treasurer, Sir Dyce Duckworth, M.D., 11, Grafton Street, Piccadilly, W.

THE SOCIETY OF APOTHECARIES.

MISS MACDONALD has obtained the diploma of the Society of Apothecaries. Subsequent to the admission of Miss Garrett in 1865, regulations were adopted by the Society which had, up to this date, prevented the further admission of ladies to this examination. These, it will be seen, have now been relaxed.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE surgical lectures to be delivered by Mr. Thomas Bryant at the College will be three in number, and will be given in June. The hour for their delivery has been, as our readers should note, altered to 5 P.M. The subject of two of the lectures will be the Causes, Effects, and Treatment of Tension in Surgical Cases, and that of the third lecture will be the Surgical Treatment of Injuries of the Cranium.

THE CROONIAN LECTURE.

THE Croonian Lecture of the Royal Society will, as we have previously stated, be delivered this year by Dr. Kühne, Professor of Physiological Chemistry in the University of Heidelberg, on May 28th, in the theatre of the Royal Institution, Albemarle Street. Professor Kühne, who will speak in German, has chosen for the title of his lecture "*Ueber die Entstehung der vitalen Bewegung* (On the Source of Vital Movement)."

ROYAL COMMISSION ON UNIVERSITY EDUCATION IN LONDON.

WE are enabled to announce that the Earl of Selborne will be the Chairman of the Royal Commission on University Education in London, and that the other members of the Commission will be the Right Hon. J. T. Ball, lately Lord Chancellor of Ireland; the Right Hon. Sir James Hannen; the Hon. George Brodrick, Warden of Merton College, Oxford; Dr. Weldon, Head Master of Harrow; Professor Stokes, M.P., President of the Royal Society; and Sir William Thomson, LL.D., F.R.S., with John Leyburn Goddard, barrister-at-law, as Secretary. The Commission will be signed by the Queen at the next Council meeting.

DONDERS MEMORIAL FUND.

As the subscription list to this fund must shortly be closed, it is requested that all who still wish to subscribe will send in their names to the Honorary Secretaries, Messrs. Gerald Yeo and Brailey, on or before Monday, May 14th. It is to be hoped that some of our countrymen may be able to attend the ceremony at Utrecht on May 28th. Donders's 70th birthday falls upon the day pre-

vious, but since that is Sunday, the ceremonial of presentation is deferred until Monday. It is needless to say that all who can attend from this country will be most heartily welcomed. It is expected that the total amount of the fund will exceed £2,000, of which some £250 will be from this side of the Channel. A programme of the ceremony will be published.

THE GERMAN EMPEROR.

As we go to press, we are glad to learn, by special telegram from Charlottenburg, that His Majesty is daily gaining strength. The highest temperature on Wednesday night (the 2nd instant) was 101.4° F., the lowest on Thursday morning was 99° F. There is still an abundant purulent discharge. The local condition is unchanged.

RABBITS IN AUSTRALIA.

THE *Australasian Medical Gazette* states that the Minister for Lands in New South Wales, in whose department the administration of matters relating to rabbits has recently been placed, has communicated with the Governments of the other colonies, asking whether they will co-operate with the mother colony in the appointment of a Commission to advise on the subject. Considerable doubt was felt as to whether it would be possible to constitute a Committee which would command general respect, since the inquiry would involve much travelling to make investigations on the spot, and a consequent expenditure of much time. Our contemporary suggests that a more effective body might be constituted by appointing a Committee consisting of a human pathologist recommended by the Council of the Royal College of Physicians, London, a veterinary surgeon by the governing body of the Royal Veterinary College of London, a pupil of Pasteur, and one educated under Drs. Virchow and Koch.

MEDICAL SELF-HELP.

THE quarterly report which we published on April 21st of the Medical Sickness, Annuity, and Life Insurance Society shows in bright colours the excellent results of mutual co-operation among medical men to secure for themselves provision against sickness, accident, or temporary or permanent disablement from those maladies, accidents, and misfortunes which so often strike down practising medical men unexpectedly, and deprive them for a time at least of the means of continuing to earn an income. This Society provides for each subscriber a claim to weekly payments of from £2 2s. to £4 4s. a week, in addition to lifelong maintenance payments in case of permanent disablement or in old age. The last quarterly report states that the Society, although only four years in existence, has now 855 members, and an annual income of about £10,000, exclusive of interest on its invested funds, which already amount to upwards of £22,000. It is paying out upwards of £1,500 a year to members who have suffered from sickness or accident, and two insurance claims have fallen in, and during the year been promptly met. All the departments of the fund show a handsome surplus, and the singular and indeed altogether unprecedented economy of the management is shown by the fact that although in view of the wholly mutual character of the organisation, and the honorary services of its Council, only 10 per cent. had been reserved for management (which is about half the usual estimate), the actual outlay for the year has been 3½ per cent. of the premium income. The investments are all in the hands of trustees, and the first-class securities show an improvement of about 10 per cent. since the date of investment. The success and prosperity of this fund has been continuous and unflinching from the first. It is proving of the utmost benefit to a great number of professional men, not only by affording them the means of securing themselves from inconvenience at times when

income ceases and expenses increase, but by relieving them of anxiety of mind and of the sense of insecurity which so often darkens long years of professional life. Reports and forms of proposal for this Society may be obtained from the Secretary, Mr. Radley, 26, Wynne Road, Brixton, London. S.W.

MALIGNANT SYPHILIS.

DR. KOPP states in the *Münchener Medizinische Wochenschrift* that, out of nearly thirteen thousand cases of skin and venereal disease under his own observation, he only detected four cases of malignant syphilis. This form he recognised as manifesting itself by very early and regular development of what, in ordinary syphilis, would be considered as tertiary symptoms, especially in the skin, with severe constitutional disturbance. In these characteristics the variety in question resembled the great epidemic at the end of the fifteenth century. As the phenomena in the latter case indicated that syphilis, when it appeared in countries and amongst races where it was hitherto unknown, always assumed a severe type, so Dr. Kopp concludes that malignant syphilis in a European in the nineteenth century implies that the patient's ancestors happen to have been free from that disease. He advised great care in the administration of mercury, and found that the cases did best under a course of quinine and iron, nourishing diet, and plenty of fresh air, iodide of potassium being administered when the patient showed distinct signs of improvement.

IDIOPATHIC NEPHRITIS IN CHILDREN.

DR. STEPHEN MIRCOLI states, in the *Centralblatt für d. Med. Wissenschaften*, No. 40, 1887, that between August and September, 1885, he observed fourteen cases of primary nephritis amongst children between the ages of 3 and 10, in a town of 3,000 inhabitants. The illness began with high fever, which disappeared at the end of the third or fourth day; then very firm œdema developed. Convalescence began in the majority of cases at the end of the second week. Three children died. In the kidneys from one of these fatal cases Dr. Mircoli discovered the appearances seen in diffused acute nephritis, and also numerous little specks, which, when strongly magnified, appeared of an elongated oval form, and consisted of collections of germs resembling groups of pneumococci. The germs were arranged either in balls or in chains, and were most abundant in the outer part of the cortex, then in the glomeruli, then in the midst of the blood-vessels around the tubuli uriniferi, and most sparingly in the tubuli themselves. The germs had caused the formation of thrombi in the vessels of the cortical and medullary part of the kidney, causing either obliteration of the lumen or dilatation of the vessel. Dr. Mircoli could not explain the nature of the micro-organisms, and he most rightly took care to note in his report of these cases that he could find no germs in the kidneys of the two other fatal cases. At the time of this epidemic of nephritis in children, none of the zymotic diseases which most frequently cause inflammation of the kidney were prevailing in the same district.

PROFESSOR SEEGEN ON DIABETES MELLITUS.

PROFESSOR SEEGEN'S paper, "On Diabetes Mellitus in regard to recently acquired knowledge regarding Sugar-formation in Animals," is to be found in the *Zeitschrift für Klin. Medicin.*, Bd. xiii. The chief results of his investigations are formulated in the following theses: 1. The formation of sugar is a normal process, going on in the liver uninterruptedly. 2. The daily amount of sugar formed in the liver is very considerable. 3. This sugar is continually "converted" in the body; but where and in what way this occurs has not hitherto been explained. 4. Sugar or carbohydrate taken as nourishment do not participate in the formation of sugar within the liver. 5. Albumen and fat are the materials from which the liver forms sugar. 6. The formation of glycogen,

in contrast to liver-sugar, is intimately related to the kind of nourishment taken, and is greatest when cane-sugar is taken. How do these facts agree with those derived from clinical observation of diabetes mellitus? The latter occurs in two forms; in the first of these (the light form), the patients are usually well-nourished, belong to the middle period of life, and voracity, thirst, and polyuria are only seldom excessive; in the second, or severe, form the patients are usually young, lose flesh rapidly, and have great voracity and thirst, with an excessive amount of urine. The main distinction between these two forms lies in this, that patients of the first class only excrete sugar when they take sugar or carbohydrates in their food; the symptoms of diabetes cease when these are discontinued. In the second class of patients, the sugar excretion is scarcely influenced by the avoidance of carbohydrates in the food. Seegen is of opinion that these two different forms represent two distinct pathological processes. In the first, the excreted sugar is derived undoubtedly from the sugar ingested, and the diabetes must be regarded as the result of incapacity of the liver cells to dispose of the carbohydrates in the normal manner. In the second form, it must be assumed that the normally formed liver-sugar is excreted. The whole body, or more or less of its elements, has not the capacity to "convert" the sugar conveyed in the blood; hence the graver prognosis in this form than in the other. The ultimate cause of diabetes is still unknown, but the author is of opinion that nervous derangements very frequently underlie this disease.

CHLOROFORM-WATER AS AN ANTISEPTIC.

PROFESSOR E. SALKOWSKI has an article on this subject in the current issue of the *Deutsche Medicinische Wochenschrift*. He has used chloroform for some years to preserve urine from decomposition (a few drops added to a specimen preserve its acid reaction apparently for any length of time), and has lately examined the action of chloroform-water upon former ferments, and on some pathogenic bacteria. Chloroform well shaken up with water, in the proportion of 1 to 200, dissolves perfectly at the ordinary temperature, and it was found that such a solution prevents the occurrence of all fermentations which are dependent on the vitality of micro-organisms; for example, alcoholic fermentation, ammoniacal urine-fermentation, the fermentative decomposition of hippuric acid, lactic acid fermentation, and the bacterial decomposition of albumen; while it has no influence upon unorganised soluble ferments (enzymes), and therefore does not affect the action of ptyalin, pepsin, trypsin, invertin, diastase, etc. The latter fact was known already. Of course, in this use of chloroform, care must be taken that it does not escape by evaporation; the bottle should be well corked or stoppered. Thus used chloroform is convenient for revealing the presence of minimal quantities of ferments, the actions of which are only developed after some months; for the observation may be continued as long as desirable, without the intervention of any micro-organisms, and chloroform, while it can be removed from a liquid when desirable, does not injure the nutrient substratum. This is well shown in milk shaken up with a little chloroform and kept in a closed vessel. After some months the casein and fat separate, but a clear albuminous fluid remains, just as in sterilised milk. Solutions of cane or grape sugar shaken up with yeast do not ferment, but the sugar is inverted by next day, the inverting ferment of yeast being a soluble ferment, and therefore unaffected by chloroform. Albuminous liquids are sterile with chloroform-water, and even meat in small pieces may be thus preserved without essential alteration, though a certain degree of rancidity may be perceived after a time from the gradual oxidation of fat. But chloroform has a powerful disinfectant and destructive action upon bacteria already present. A putrid meat infusion is rendered sterile by it

a few hours; and the same destructive action is exerted upon the bacillus anthracis (though not on the spore-form) and on the comma bacillus. The chief use of chloroform as a disinfectant probably lies in the preservation of solutions of the soluble salts, the action of the latter not being influenced by it, but various other uses suggest themselves, both pharmaceutical and therapeutic. Chloroform-water is well tolerated by the system. In a supplementary note Professor Salkowsky writes to the effect that most of the ethylic chlorine compounds possess antiseptic properties, and that chloroform, from its superior volatility, is the best as a respiratory antiseptic.

ORBITAL SYPHILIS.

Dr. MACERK observes, in the *Wiener Klinik*, that orbital syphilis is rare, but may be observed in the inherited as well as the acquired form of the disease. It usually begins in the roof of the orbit, being first recognised by severe pains, which are constant, but worst in the evening and at night. The lid swells, and the eyeball may become unusually prominent. Symptoms of paralysis of the recti or oblique often appear. These symptoms develop slowly, and are of long duration; as a rule, a clear history of syphilis, or symptoms of that disease in other parts of the patient's body, is at hand. Orbital syphilis must be promptly treated, as the eyeball may suddenly become involved, or the process, which is essentially periostitis of the bony boundaries of the orbit, may extend into the cranial cavity, attacking the meninges and the brain itself. The cure, which consists in the administration of the ordinary antisymphilitic drugs, is always slow. Dr. Macerk intends to publish a complete series of histories of cases of orbital syphilis which have come under his observation and treatment.

ABDOMINAL SECTION FOR RUPTURED UTERUS.

Dr. GARRIGUES, of New York, performed abdominal section for rupture of the uterus, last January, and contributed a paper on the subject to a medical society, which is published in the *Philadelphia Medical News*, March 3rd. The patient was a multipara, aged 35. She fell in labour at term, a few days after a bad fall. About twelve hours after the pains began her medical attendant, Dr. McCauley, reduced an extreme left lateral obliquity of the uterus. Four hours later the waters broke, but the head did not advance. An hour later crampy pains occurred, without shock, and the vagina was found full of clots. Abdominal section was performed; the placenta was free in the peritoneal cavity, with a quart of dark blood and lumps of meconium. The child was large, dead, and ensanguined. The rent comprised the whole anterior wall and part of the posterior; it went down too low to allow of Perro's operation. The rent was sewed up on Schröder's principle, by thirty-seven antisepticised silk ligatures, deep and superficial. The abdominal cavity was washed out with warm water, the uterine cavity with a hot solution of bichloride of mercury (1 in 5,000). Unfortunately the patient lived in a lodging-house of very low grade, and was badly nursed, being allowed on one occasion to get out of bed. She died of peritonitis four days after the operation.

INFANTILE OPHTHALMIA AND SUBSEQUENT BLINDNESS.

It has been calculated that at least 30 per cent. of the cases of total blindness existing in the United Kingdom (that is to say, about 7,000 of the 22,000 blind persons enumerated at the last census) have resulted from the neglect of purulent ophthalmia in infancy. The Ophthalmological Society of the United Kingdom, about three years ago, appointed a deputation, comprising Mr. Nathaniel Hutchinson, Sir W. Bowman, Mr. J. Tweedy, Dr. McKeown, Dr. Abercrombie, and others, which waited upon the Registrar-General and the Local Government Board, and urged

that registrars when registering births, and relieving officers when issuing orders for the parish midwife, should, at the same time, issue a printed slip containing the necessary warning. The Registrar-General did not, however, see his way to imposing on registrars this additional duty. Another, but unfortunately equally unsuccessful, effort has recently been made by the Committee of the Bradford Eye and Ear Hospital to enlist the co-operation of the central authorities. The Committee deserve great credit for their efforts to spread the warning in their own town, and the local registrars deserve thanks for their voluntary co-operation in distributing the printed slips. Taking 1,000,000, as a rough estimate of the number of births annually in the United Kingdom, about £30 would be sufficient to defray the cost of printing the same number of the slips already referred to.

ABDOMINAL SECTION ON A NEW-BORN CHILD.

The *Journal of the American Medical Association* for January 14th describes a singular case of what may be termed radical cure of congenital umbilical hernia in a new-born child. Dr. Dunlap, of Springfield, Ohio, attended on October 2nd, 1887, at the birth of a healthy female child. There was a large umbilical hernia, which included the intestinal canal from close below the duodenum to the sigmoid flexure and the great omentum. The sac was formed by the tissues of the umbilical cord; its neck was so narrow that the hernia was irreducible. Dr. Dunlap therefore enlarged the neck of the sac by incision. A fresh difficulty was then encountered. Owing to the absence of the intestines from their normal position, the abdominal cavity was so contracted that they still could not be properly reduced. "I therefore," writes Dr. Dunlap, "made an opening commencing in the umbilicus, running up two inches, and then began stretching the walls of the abdomen with my fingers; then catching portions of the bowels and forcing them down into the cavity, while assistants, with hooks passed through the cut edges of the walls of the abdomen, held them firmly up. In about twenty minutes I succeeded in forcing them in and closing the wound with five sutures and ligatures to the cord close up to the natural skin." No anæsthetic was used. The child neither struggled nor screamed, nor did any signs of shock follow the operation. A small teaspoonful of castor oil was given, and the bowels afterwards acted freely. Ten days later, when Dr. Dunlap read the case before the Medical Society of the District of Columbia, the child was suckling and sleeping well, the stitches were out, and the cord was separating in a satisfactory manner. The earliest age at which ovariectomy has ever been performed is one year and a half, on patients at which tender period of their existence Dr. Schwartz and Dr. Küster have successfully operated.

MICRO-ORGANISMS IN THE FEMALE GENITAL TRACT.

MUCH has recently been written about gonococci and streptococci in the vagina, uterus, and Fallopian tubes. Professor Bumm claims to have established pathological laws of high importance, relating to the infection of these parts by micro-organisms. He states that the gonococcus does not in itself cause suppuration, but by damaging the epithelium facilitates the admission of pyogenic streptococci. This is seen in inflammation of Cowper's gland in gonorrhœa, which ends in resolution or in cystic degeneration of the gland when gonococci alone have entered its duct; but should streptococci enter the gland, suppuration becomes certain. Gonococci, Bumm declares, readily ascend as high as the tubes, whilst the pyogenic micro-organisms are slow to follow; hence the comparative rarity of pyosalpinx in proportion to the frequency of gonorrhœa. Superficial observers have detected hosts of micro-organisms in the normal tract, after death. But Dr. Winter has made a series of careful experiments in this direc-

tion, embodied in a communication to the current number of the *Zeitschrift für Geburtshilfe und Gynäkologie*. He concludes, first, that the normal tube contains no micro-organisms, and, as a rule, no contents of any kind. Secondly, the uterine cavity in health contains no micro-organisms, and in half the cases which he examined, no germs were found in the neighbourhood of the os internum. The cervical secretion of every healthy woman abounds in micro-organisms, and so does the vagina. In short, the genital canal of a healthy woman contains micro-organisms in the vagina and cervix, from which the uterus is free, and the boundary between the part bearing and the part free from germs lies about the os internum.

ERGOT IN SUBINVOLUTION.

SOME very interesting observations were recently made by Dr. Emile Blanc on the effect of ergot in involution of the uterus after labour. A fairly large number of women who had gone through normal labour were divided into three categories. Forty of them were left to Nature; forty were treated with daily hypodermic injections of Yvon's solution of ergotine (1 cc. = 1 gramme of ergot) during the first five days after delivery; and the remaining twelve were similarly treated for ten days. Daily external measurements were then made in all the cases to ascertain the size of the uterus, and on the fifth and tenth days its internal measurement was taken by means of the uterine sound. It was found that the administration of ergot during the first five or ten days failed to produce any favourable effect in hastening the process of involution, but that, on the contrary, it seemed to delay the normal retraction of the uterus. Ergot is nevertheless an exceedingly useful agent in the treatment of secondary hæmorrhage, and its action is more marked the less the interval of time that has elapsed since the confinement.

COCAINE IN LITHOTRITY.

IN a case in which an attempt to perform lithotripsy proved futile on account of the extreme irritability of the bladder and the prostrate condition of the patient, Dr. Philip injected into the bladder sixteen grains of cocaine dissolved in twelve fluid ounces of water at a suitable temperature. After a few minutes, during which the patient was moved into different positions to ensure the anæsthetic coming into contact with all parts of the wall of the bladder, it was found possible to proceed. The patient felt no pain whatever, and the surgeon was enabled to do his work quietly and completely. The anæsthetic condition of the bladder lasted about twenty minutes. The experiment, having proved so successful, was repeated on five subsequent occasions with the same happy result. It was noticed, however, that the effect produced by the last two injections was less marked and did not last as long as after the others. No untoward symptoms followed at any time, but it is recommended to adapt the dose of the drug to the degree of vesical irritation, and never to use the higher strength before trying the effect of a weaker one.

THE EFFECT OF OPIUM ON THE FÆTUS IN UTERO.

IT is a curious fact that while therapeutists are thoroughly alive to the danger of giving opium to young infants, they have not apparently considered what effect is likely to be produced on the unborn fœtus by its administration to the mother. Dr. Ruth, of Muscatine (Iowa), has recently investigated the subject, and has arrived at the conclusion that it not infrequently causes convulsions in the fœtus analogous to those produced in the infant. Bartholow states that opium kills by paralysis of the respiratory muscles, and more rarely by paralysis of the heart. The fœtus has, of course, for the time, no respiratory function, and this may account for the small number of deaths from administering opium to pregnant women when labour is not threatened or in progress; will also account for the relaxed condition and feeble hold upon

life that children have when born while the mother is under the influence of an opiate. Given what we know of the effect of opium on infants, it is obvious that the moment a child is born whose blood is charged with opium, so soon do the influences of paralysis of the respiratory muscles manifest themselves. Opium is the stoek remedy in cases of threatened abortion, but it probably does more to bring about the very contingency that it is sought to avert, while it seriously imperils the infant's chances of a separate existence. The foregoing observations may possibly afford an explanation of the preference which has of late been given to chloral in cases of threatened abortion.

SCOTLAND.

LECTURESHIP OF BOTANY, UNIVERSITY COLLEGE, DUNDEE.

MR. PATRICK GEDDES, F.R.S.E., late Assistant to the Professor of Botany in Edinburgh University, has, at the request of the authorities at University College, Dundee, consented to deliver the summer course of lectures on botany in the College.

GLASGOW MATERNITY HOSPITAL.

WE are glad to be able to record what is said to be the first completely successful case of Cæsarean section performed in Glasgow. The operation was performed at the Maternity Hospital by Dr. Murdoch Cameron nearly three weeks ago. Both mother and son are alive and well, and the latter has been appropriately christened "Cæsar Cameron."

GLASGOW EAR HOSPITAL.

AT the annual meeting of the subscribers of the Ear Hospital, the medical report was read, and showed that the hospital was in a flourishing condition and increasing in popularity. In the out-door department there were 789 new patients, an increase of 83 patients over the previous year; and in the indoor department there were 57 admissions, an increase of 5. As a means of diffusing knowledge of ear disease among students and practitioners the hospital had been utilised during the past year, to an unprecedented extent. At the last annual meeting it was reported that 13 students attended Dr. Barr's course of lectures. During the past year 75 names were enrolled, including medical men from both town and country.

INTERNATIONAL EXHIBITION, GLASGOW.

THIS exhibition, which is to be opened on May 8th by their Royal Highnesses the Prince and Princess of Wales, promises to be one of the most interesting as it is the largest exhibition of recent years. It will doubtless form a special attraction to members of the Association at the forthcoming Glasgow meeting in August next. The press view of the exhibition took place on April 21st when over one hundred journalists, representing the daily press of the United Kingdom and also some Continental and American papers, came to Glasgow and visited the buildings. They were hospitably entertained by the executive, and fortunately were favoured with beautiful weather. They were evidently much impressed with the architectural beauty of the buildings, their magnificent situation, and the interesting nature of the exhibits. Not the least interesting feature of the exhibition to professional men will be the large and magnificent display of historical and archaeological treasures now being arranged in the Bishop's Palace on the slope of Gilmorehill.

GRADUATION CEREMONY, UNIVERSITY OF GLASGOW.

THE graduation ceremony took place on April 27th in the Butcher's Hall, the Vice-Chancellor presiding. There was a large attendance of students and their friends. Besides the honorary and other

degrees conferred, the general University prizes were awarded, and then the Vice-Chancellor delivered an eloquent address on the general idea of knowledge and of the higher education on which such an institution as a University is based. The idea was that there was not only no discord, but no hard and fast distinction, between the various departments of human knowledge; that each department upon and could be rightly apprehended only in its organic relation to the rest. Although limitation was the necessary condition of success in either study or work, there was no incompatibility between knowing a wide range of subjects in their leading features and some one subject with the completeness of those who make it their principal occupation. It was this combination which created a truly cultured mind and an enlightened, educated public.

FAITH HEALING.

At the last monthly meeting of the Parochial Board of Dunoon, a sad case of insanity was reported. A woman, who, some time ago, was delivered of her fourth child, had since been affected with puerperal mania. It was stated that a local clergyman, with one of his sons, visited the woman, and prescribed the faith-healing cure. The woman was accordingly prayed over, and anointed. The cure, however, failed, and the poor woman went mad, and is now an inmate of Lochgilphead Asylum, suffering from religious mania. The case was severely commented on by several members of the Board, and a committee was appointed to investigate the matter, and report to a future meeting.

EDINBURGH ROYAL INFIRMARY.

Last week this admirable institution was subjected to a wholly unwarranted attack in regard to a case admitted to its wards. A woman who had been sent in from the country to be treated for supposed ovarian disease, very shortly after her arrival was delivered of triplets. This fact was made the basis of a highly-colored descriptive article in a local newspaper, which detailed all the circumstances of the case in a manner that is unusual in the lay press. It is not as yet generally known who has been the guilty party in producing so sensational a version of a very simple incident, and in giving his *canard* so successful a flight.

EDINBURGH MUSEUM OF SCIENCE AND ART.

The original design of the Edinburgh Museum of Science and Art, so inseparably associated with the name of its distinguished founder, the late Professor George Wilson, has at length, after the lapse of many years, been fully carried out. The new addition consists of a large west wing, which completes the symmetry of the building externally, and gives it additional internal accommodation amounting to at least a third of its previous area. The new galleries it provides are to be dedicated in part to works of art, chiefly from Italy, to a collection illustrating the arts and manufactures of savage races, and to maps and model sections showing the results of the geological survey of Scotland.

EDINBURGH UNIVERSITY.

The summer session commenced on Tuesday, May 1st, when the various professors and teachers who hold summer courses met their classes, and delivered introductory lectures. In the Botany Department, at the large lecture hall in the Botanical Gardens, a great gathering of students and teachers assembled to listen to Professor Bayley Balfour's inaugural address, on his induction into the duties of the Chair. The new Professor was very heartily received, and listened to with great attention by his large audience. In the department of Physiology, Professor Rutherford delivered a short address introductory to the work of the practical physiology courses that are held during the summer session. In his address he adverted to the fact of his absence for twelve

months from the post of duty, and to the satisfaction with which he again met his students, completely restored by his visit to a southern climate. He also referred to the ability and conscientious thoroughness with which his teaching duties had been performed in his absence by his friend and former assistant, Professor Hayercraft, of Birmingham. In all the departments, and in the wards of the Royal Infirmary, the opening lectures were attended by a plethora of students, from which it would appear that the new session shows no falling off in the numbers coming forward for the Edinburgh degree.

THE SANITARY WORK OF A GREAT CITY.

In the course of a lecture delivered on this subject to the Philosophical Society by Mr. Peter Fyfe, sanitary inspector, some of the provisions of the Burgh Police and Health Bill were discussed. Glasgow, it was stated, was supplied from the country with about 35,000 gallons of milk daily from 1,175 farms, many of which were dangerous to the community from defects of structure and the nature of their water supply, yet all that could be done by the sanitary officials of the city was whenever a case of infectious disease was known to exist at any of the farms, at once to stop the milk supply from that farm. The new Bill provided no such central authority as medical and scientific inspectors as England had possessed for years. The Bill only applied to burghs and populous places, while the country was left to feed the towns from amid insanitary conditions which, through ignorance and carelessness combined, many of its landlords or farmers would not remove. The lecturer insisted that, besides compulsory notification of infectious diseases by medical men, there should be more power in the hands of local authorities of removal and isolation. This would entail great expense and difficulty from the want of hospital accommodation and the increased work of disinfection. There should also be more summary power of compelling landlords to remove nuisances. But the most difficult problem of all was what was to be done for the people who were condemned to live in such conditions as were pictured by the words "348 to the acre." Such a state of things went on from day to day in some districts of the city. Nay, during the night little knots of humanity were found huddling together at the rate of 4,400 to the acre, or 10 persons in 11 square yards. To give some idea of the atmosphere in which many of the population nightly sleep, he had caused two samples of air to be taken for analysis. No. 1 was taken at 3.40 A.M. from a single apartment house measuring 700 cubic feet, and in which four adults and three children were sleeping; the amount of carbonic acid gas was certified by Dr. Wallace to be 21.9 in 10,000 volumes of air. No. 2, taken in somewhat similar conditions, contained 14.1 in 10,000 volumes. In the first case the carbonic acid gas was five times and a half, and in the second case three times and a half, what it should be. What could the sanitarian do to decrease the chances of disease in such homes?

SCARLATINA AND COW DISEASE.

DR. J. B. RUSSELL, Medical Officer of Health for Glasgow, has issued a report on the outbreak of scarlatina at Garnethill. After a careful house-to-house visitation of the district he found that there were ninety-five cases in all, and that each of these cases obtained milk from the one dairy. All the cases had fallen ill since March 15th. The milk was, therefore, the obvious medium of infection. Further investigation led to the suspicion that the milk in this dairy had come from a farm at which there had been a case of scarlet fever. The son of the farmer who brought in the milk was seized on March 23rd with the first symptoms, and the byreman on March 24th was seized with sore throat. No other person had been ill. With the view of answering the question, Did the milk derive its infection from the cow? as in the Hendon case in 1886, Dr.

Russell and Mr. McCall, veterinary surgeon, carefully inspected the stock. Two cows were found with scabbed sores on the teats. One of these was miserably thin and mangy-looking, casting its hair and skin; the other was in good condition, not casting its hair, and the sores on the teats bled freely. These cows were removed to the Veterinary College for observation on March 31st. Owing to the state of the law no inoculation experiments were possible, and consequently the field of observation was much restricted. This much, however, Dr. Russell says, is certain: a calf fed on the milk from these cows was almost at once seized with a highly febrile illness, which nearly killed it, but from which it is now recovering with loss of hair and copious casting of the skin. The cow which was not casting hair or skin when removed is now doing so freely. Dr. Russell's object in making the present report is not to draw premature inferences or make rash statements, but to show that he has in hand a question of immense importance both to the consumer and producer of milk, and to obtain permission of the local authority to buy these cows and otherwise make a certain expenditure of money on the question.

IRELAND.

HOW DISEASES ARE SPREAD.

A MAN named Sproule having died at Athlone recently from fever, his wife was cautioned against holding a "wake" over the remains. She however persisted in doing so, and ten persons were found "waking" the deceased. A summons has been issued against Mrs. Sproule by order of the guardians.

NATIONAL LYING-IN HOSPITAL, HOLLES STREET, DUBLIN.

At a meeting of the President and Council of the Royal College of Surgeons in Ireland, held on April 19th, it was resolved, on the recommendation of the committee of inspection, to accept from candidates for the diplomas of the College the certificates issued by this hospital.

WOMEN'S AND CHILDREN'S HOSPITAL, CORK.

THE work done at the hospital during the past year has been much greater than in any previous year since its foundation, and this has been carried out at a greatly reduced averaged cost. The system of sending out nurses to private cases, inaugurated in 1886, has been carried out during the past year with marked success, and the probationer nurses have in all cases given the greatest satisfaction. In addition to the public wards there are private rooms attached to the hospital, which have been largely availed of by many ladies resident in the country. During the close of the year the severe epidemic of measles which universally prevailed in the South of Ireland materially interfered with the work of the hospital. The disease having found its way into the wards, it was deemed necessary during the continuance of the epidemic to close the children's ward, so as to limit as far as possible the spread of the disease.

THE SANITARY CONDITION OF CORK.

THE prevalence of infectious diseases in Cork has been for a number of years a matter of anxiety to the corporation, and it has been shown that the existence of enteric fever and some other zymotic diseases is, in a great measure, traceable to the defective sanitary condition of the sewers in consequence of the want of ventilation. The medical officer of health, Dr. Donovan, and the City engineer have recently furnished a report to the Public Health Committee on this subject, which states that sewers several miles in extent are in almost all cases unprovided with ventila-

tors of any kind, for the ordinary street gullies are trapped, as in the words of Dr. MacCabe in a report made in 1877 on the prevalence of enteric fever in Cork during that year, "Here he says, "we have conditions all favourable to the development of enteric fever—unventilated main sewers, trapped gullies, tide pressure twice a day, compressed sewer gas, with no possible outlet except through faulty drains, and sink-traps within the houses, and faulty traps and valves of water-closet basins." Even if the traps and valves of water-closet basins are constructed what may be termed scientific plumbing principles, yet the tide and atmospheric pressure at the mouths of the sewers will, many instances, force the gas through those traps and valves in the interiors of the dwelling houses, where, mingling with the confined air of the room, it frequently becomes dangerous, if not fatal in its effects. Dr. O'Farrell, late inspector of the Local Government Board, in December, 1886, among other suggestions recommended that all the main sewers should be ventilated to their highest levels, and that they be provided with side entrance man-holes, and not less than twenty ventilators for each mile of sewers; but financial difficulties prevented the matter being carried out. What is known as the "open grid" system is thought to be the best of the kind; and it has been resolved that a sum of £750 shall be borrowed from the Government for the purpose of carrying into effect a complete system of sewerage ventilation throughout the city.

DWELLINGS FOR THE POOR IN DUBLIN.

THE Dublin Corporation, whatever shortcomings may be charged against it, has done a great public service. It has built and about to let dwellings for the poorer classes, which will accommodate 730 individuals. The work in this direction has hitherto been done by a public company, which, with the aid of the Corporation, has taken possession of squalid corners, and built up there its suitable homes for those who could only pay small weekly rents. The undertaking, besides conferring a great benefit on the poor and on the general community by the removal of horrid rookeries, has proved a marked financial success. Now the Corporation itself has followed the example, and we hope it will continue to pursue it. In 1881 the leases of some old tenements, one of the worst streets in the city fell in; and it was determined to clear away the tumble-down houses, to erect new buildings, to open a new street, and to erect tenement blocks. These blocks are substantially built in red brick. The total accommodation provided is as follows:—5 shops, 9 treble-roomed dwellings, 6 double-roomed dwellings, 65 single-roomed dwellings, and 10 beds for casual lodgers, making in all habitations for about 700 persons. All the rooms are 9 feet high, except the basement rooms, which have a height of 11 feet. The length and width vary from 12 by 20 to 14 by 13 feet. Each floor is supplied with water supply, scullery trough, and dust receptacle, whence the contents pass into the yard bins, which are emptied by the servants of the Corporation. The roofs are flat and asphalted, and give a surface of 16,250 feet. They are to be used as playgrounds, and they are of course, properly protected. One of the blocks is set apart for lodgers, who will be accommodated at 4d. a night each, and provided with a bath for an additional penny. There is a supply room 32 by 11 feet, and 13 feet high. The rents will vary from 1s. 6d. to 2s. per week for a single room; from 3s. to 4s. for two rooms; and from 4s. 9d. to 5s. for three rooms. The whole cost of the buildings has been £25,000. Sir Charles Cameron, the superintendent medical officer of health, has carried out the scheme with characteristic energy, and it is certain that it will prove remunerative. The Corporation deserves the highest credit for this enterprise. If it only continues in the same path, it will do much to improve the physical and moral health of the Irish metropolis.

PARLIAMENTARY BILLS COMMITTEE.

NOTIFICATION OF INFECTIOUS DISEASES.

At a meeting, on Thursday, April 26th, of the Subcommittee appointed to draw up reasons for opposing the compulsory notification clauses in the Public Health Prevention of Infectious Diseases (Hastings) Bill—present, the Chairman (Mr. Ernest Hart), Mr. Bridgwater, Dr. Alfred Carpenter, Dr. Grigg—Dr. Carpenter handed in the following returns:—

Voluntary Notification.

Town.	Population.	Zymotic Death-rate.	Zymotic Deaths.	Scarlet Fever.	Non-certified.
1883.	—	2.6	2,426	789	3.46
Brighton.....	112,954	1.7	197	29	3.0
Cardiff.....	93,463	4.8	456	122	4.4
Hull.....	181,225	3.5	654	45	5.6
Leeds.....	327,324	4.9	1,476	487	2.3
Lymouth.....	75,509	2.0	153	2	1.6
Wolverhampton.....	78,307	3.3	304	40	2.4
1884.	868,847	3.85	3,240	725	3.2
Brighton.....	118,186	2.2	260	10	3.1
Cardiff.....	104,580	2.3	263	20	2.2
Hull.....	196,855	2.5	558	67	4.4
Leeds.....	345,090	2.7	925	115	1.7
Lymouth.....	77,125	2.8	174	14	1.2
Wolverhampton.....	80,847	2.5	202	16	1.5
1887.	922,673	2.5	2,382	242	2.3

Dual Notification.

Town.	Population.	Zymotic Death-rate.	Zymotic Deaths.	Scarlet Fever.	Non-certified.
1883.	—	2.3	1,941	262	3.1
Birkenhead.....	90,870	2.2	204	10	4.6
Bolton.....	108,068	4.3	378	15	2.4
Blackburn.....	110,498	3.1	363	48	4.3
Bradford.....	209,564	2.4	518	33	2.6
Leicester.....	132,773	4.0	544	62	2.0
Salford.....	197,153	4.2	843	139	4.7
1884.	618,926	3.36	2,850	307	3.4
Birkenhead.....	97,703	3.2	311	88	2.2
Bolton.....	112,354	3.2	359	37	2.4
Blackburn.....	116,844	4.4	509	158	3.1
Bradford.....	224,517	2.9	640	98	2.8
Leicester.....	143,153	3.1	153	5	2.5
Salford.....	218,668	4.4	969	156	4.0
1887.	913,229	3.5	2,941	542	2.1

DR. CARPENTER observed, in commenting on the above:—It is said that, where dual notification has been in existence for a certain number of years, there has been a marked decrease in the amount of zymotic disease in those towns; that the death-rate has gone down; that the number of deaths has materially diminished in consequence of dual notification; and that, in consequence of that diminution of the zymotic death-rate, it is only right that dual notification should be extended all over the country. I have (he continued) examined the returns published by the Registrar-General; and in those thirty-eight towns which he publishes there are six towns where there is no dual notification—namely, Brighton, Cardiff, Hull, Leeds, Lymouth, and Wolverhampton. Those six towns have a population of 922,000 people. In 1884 those six towns had a zymotic death-rate of 3.85. Taking the 900,000 people in them, they had 2,400 deaths from zymotic disease, and 725 of those from scarlet fever. In 1887 the number of zymotic deaths had fallen from 2,400 to 2,382, and the zymotic death-rate from 3.85 to 2.5, without dual notification. The scarlet fever cases had gone down from 725 to 242. Another point in connection with the return is that the non-certified deaths had fallen from 2 to 2.3. Those are the facts with regard to the only six towns where dual notification is not in existence. Now take out of the same list six towns that correspond in numbers

and population as near as I can to those I have just mentioned. Instead of having a population of 922,000 these six towns have a population of 913,000. They are: Birkenhead, Bolton, Blackburn, Bradford, Leicester, and Salford. The first four are the first in the list, then I have to pick out two others to get them near to the population. Now what is the case with regard to the zymotic death-rate in those six towns in 1884 (and the other years correspond)? In that year it was 3.36. In the non-notification towns it had in 1887 come down to 2.5, but in these towns it has risen to 3.5. The number of deaths from zymotic disease in the dual notification towns in 1884 was 2,850, and in 1887 there were 2,941; there is an increase of zymotic deaths, not a decrease, as in the voluntary notification towns. The number of scarlet fever cases had gone up from 307 in 1884 to 542 in 1887. Then I come to a town like London. London in 1880 had a population of 3,644,000. The zymotic death-rate in London in 1880 was 3.73; in 1887 it had come down to 3. Then I take Kensington, a large district in London, where they have no notification except that which is voluntary, and it is very well looked after. I find in Kensington in 1880 the zymotic death-rate was 2.9; that of 467 deaths 105 were from scarlet fever. In 1886 the zymotic death-rate had come down to 1.6, and that of 280 deaths (against 467 in 1880) 11 only were from scarlet fever (against 105 in 1880). What inference do I draw from these facts? A very important town is Edinburgh. It is said in Edinburgh the success of the principle has been most marked, but what do I find in Edinburgh with regard to scarlet fever? In 1884 in Edinburgh there were reported 1,205 scarlet fever cases, with 42 deaths. In 1887 (three years afterwards) when the system is said to be working so excellently well, there were reported 2,487 cases, with 145 deaths. In the very place which is quoted against us as being the one which ought to recommend it to other towns, actually the number of deaths and the number of cases of scarlet fever have risen year by year. It is the same in Dundee and Aberdeen with regard to the spread of scarlet fever. What is the reason for that? The reason is that in those towns there are individuals who are now perfectly aware that if scarlet fever is in their shop, in their lodging house, in their public-house, in their business as a tailor or whatever it may be, and it is communicated to the authority, there is a tendency to close that place of business, and the result is just this, that the disease, when it is not likely to be fatal, is not treated by a medical man. They do not employ a medical man (in my own neighbourhood I know it to be so), and the consequence is these mild cases of scarlet fever (which are such a source of danger) distribute the disease more abroad, and, as a consequence, there is a spread of disease from dual notification, and not a repression. Well, then, I argue that our object is not notification, it is prevention; and that it is not so much disclosure that is required as it is to prevent the spread of the mischief; and that if a person, say a shopkeeper, has got scarlet fever in his premises, and that shopkeeper's children are taken care of by a qualified medical man, who will advise him how to isolate them, you are very much less likely to have an extension of the disease than in having these mild cases treated by herbalists and druggists, by which means the disease is spread much more generally than before. Now you will say, Have you any other grounds to support it? Yes, I have. In some of the towns I have got evidence from, one finds that the number of deaths that are reported show, in those towns, a high mortality compared with the number of cases reported. That means to me that the cases are not all reported, and that where you have in other towns a possibility of getting at any information, as in Kensington, as to the number of cases, you find the mortality is not so high as it is reported to be from Edinburgh and Aberdeen. Here is an argument that I hold against the notification being thrown upon the medical man. I have another argument, and, to my mind, it is a very strong one. Our great object is to get the people themselves to take measures for the purpose of repression; but in towns where this dual notification is in existence, the people do not have anything to do with it. It is supposed to be all on the shoulders of the inspector for the local authority, and the result is that there is nothing done by the people themselves. Our great object is to bring it home to the people, and to spread a knowledge of sanitary matters amongst them. If we do not get the notification given by the people themselves, they think it has nothing to do with them. I want to know by what right an Act of Parliament is to be set aside in the way that the dual notification Act is? In no case do they summon the other party—the occupier. But why should the medical man, as in Croydon, be singled out as the one man who had failed to comply

with a certain Act of Parliament, while 99 other persons who do not comply are left alone? It seems to me a wrong principle.

The following document was then discussed, and ordered to be circulated as amended:—

MEMORANDUM OF REASONS

Why the British Medical Association objects to the Penal Clause against Medical Men as proposed in the Notification of Infectious Diseases Bill, 1888.

The promoters and objectors agree upon some of its principles, namely, the necessity for the enactment of compulsory notification which shall equally apply to the whole of the kingdom.

They agree that when a medical practitioner is employed to treat a case of infectious disease, it is his duty to make its nature clearly known to his employer, or to the person legally in charge of the case.

They are agreed that this information should be conveyed to the local authority for use by the State.

They are agreed that the information, if conveyed by the medical attendant, should entitle the latter to a fee from the local authority.

They disagree as to the means whereby that information shall reach the local authority. The objectors base their objections to the independent action of the medical attendant upon its being the establishment of a new crime, if failure to perform the duty is to be penal that it is an interference between the relations of employer and employed, which the State has no right to claim.

Medical men object to doing an invidious duty which ought by law to devolve upon the employers, and them alone. They do not object to disclose the facts if the law takes proceedings against the true defaulter, and they do not object to act as the employer's agent, when the latter requests the medical attendant to do so.

They believe that repression and prevention can only be effective by the act of the people themselves; that to relieve them of the duty of notification either by themselves or their agent is to lead them to believe that the doctor is the person to secure repression, although this effect can only be produced by the proper disinfection and isolation, which must be carried out by the householder himself, and not by the doctor.

The proposed plan is encouraging the people to think that it is a question for the doctor and for the local authority, but not for themselves, by which course sanitary knowledge among the people is impeded.

That it proposes to enact a clause which past experience has shown will be a dead letter as to one part of its dual action, namely, that which imposes a duty on the householder. That such legislation is contrary to the principles of justice, and is likely to lead the people to think they can set aside the clauses of an Act of Parliament when it suits their convenience to do so; that there is no moral or legal obligation on their part to conform to it, and that in this view they are upheld by the act of the local authority—a vicious course which must be contrary to equity and good government. Although so-called dual notification is at present enacted in forty-six towns, the obligation upon the householder is, it is alleged and believed, nowhere enforced.

The objectors believe that a penal medical clause defeats the object sought for, inasmuch as it leads to the employment of irregular, unqualified, and non-registered practitioners for the treatment of mild cases of an infectious character; and so the disease is spread because skilled aid is not sought. It should be remembered that such mild cases are apt to be the most potent and efficient agents in the spreading of epidemic disease. The skilled adviser would advise efficient methods of personal disinfection and isolation. Thus hotelkeepers, innkeepers, dressmakers, tailors, some retail tradesmen, lodging-house keepers and others, who would be seriously injured in their business by the visits of official persons, and their businesses possibly put a stop to for a time, avoid such visits and altogether evade such notification by employing quacks and herbalists instead of legally qualified medical practitioners, upon whom alone the responsibility of notification at present really virtually falls under the operation of the dual clauses. The objectors believe that there is no harm in secrecy if proper measures are taken to repress disease, and to ensure that it does not spread to other people, discovery being used only to avoid extension.

The penal clause as drafted in this Bill can only reach the carc-

less, and will not reach those who dishonestly fail to notify. The careless will be equally reached by the clauses proposed by the British Medical Association.

It is not shown that zymotic disease is materially lessened in districts in which it is penal against the doctor if he does not notify; but statistics indicate that these diseases are as prevalent in those districts as in others in which notification is voluntary. It is contended that the plan proposed by the British Medical Association would be more efficacious, though possibly giving little more trouble to the medical officer of health.

The British Medical Association proposes that notification shall be compulsory on the householder or person in charge of the patient, but that he may employ the medical attendant as his agent, and that when so employed the latter should be entitled to a fee from the local authority for the certificate given.

The British Medical Association contends that the enactment of this clause would procure much more satisfactory results than that in the proposed Bill. The compulsory clause puts the whole profession in a false position.

That, until medical officers of health are forbidden to engage in general practice, it may easily cause friction as placing the reputation of practitioners at the mercy of a professional rival, inasmuch as an error on the part of the ordinary medical attendant might be used for malicious purposes under the cloak of zeal for the public good, whereas diagnosis is especially difficult in some forms of infectious disease.

For these reasons, the British Medical Association urges upon the Government the propriety of not assenting to the proposed penal clauses against medical men.

On the notice of the CHAIRMAN, seconded by Dr. BRIDGWATER, it was agreed to forward copies to the promoters of the Bill, to the President of the Local Government Board (Mr. Ritchie), and to other members of Parliament.

PUBLIC HEALTH CLAUSES OF THE LOCAL GOVERNMENT BILL.

A SUBCOMMITTEE of the Parliamentary Bills Committee of the British Medical Association and a delegation from the Society of Medical Officers of Health appointed to consider the public health clauses of the Local Government Bill, met at the offices of the British Medical Association on Wednesday, May 2nd.

Present: Mr. Ernest Hart in the chair; Mr. W. H. Michael, Q.C., Dr. Alfred Carpenter (Croydon), Dr. Woodforde (Reading); Dr. Wilson (Leamington), Dr. Fosbroke (Bidford), Dr. Armistead (Shelford, Cambridge), Mr. Shirley Murphy (London), and Mr. George Turner (London).

The CHAIRMAN stated that he was informed that all were agreed as to the general principles and objects to be attained, which were to secure that the County Councils to be constituted by the new Local Government Bill should have attached to them medical officers of health, and that the necessary powers for making such appointments efficient should be transferred from the existing health authorities.

The Chairman laid on the table the following documents: (1) A Report, dated August, 1871, of the joint committee of the British Medical and Social Science Associations, adopted at the annual meeting of the British Medical Association at Plymouth, in which the reasons for desiring the establishment of County Councils, and the appointment thereto of medical officers of health of adequate skill, having authority over large areas, were laid down in detail. He thought it desirable that this document should now be reprinted, in order to point out that the Association had consistently urged upon successive Governments, from that date, the creation of such an organisation as that which was now the subject of impending legislation, together with the creation of medical officers of health in connection with such councils. It was to him a matter of melancholy recollection that this report was drawn up partly by himself, with the aid of Dr. Stokes, Dr. Rumsey, Dr. William Farre, Dr. Sibson, Dr. A. P. Stewart, and others of hardly less eminence and weight in the Association, few of whom now survived to see the fruit of their labours recognised as of legislative imminence. (2) There were also laid on the table Two Reports prepared by Dr. F. Bond, medical officer of health for the Gloucestershire combined district, headed "The Local Government Board in its relation to Medical Officers of Health and Sanitary Organisation in general;" and (3) on behalf of the Parliamentary

s Committee, the following Draft Memorandum, due to the kindness of Mr. W. H. Michael, Q.C., in which the object in view and the reasons in support of it are briefly condensed:

DRAFT MEMORANDUM.

In order to secure efficiency in local government administration, to obtain the greatest public advantage it is essential that qualified medical officers of health should form part of the staff of all sanitary authorities.

The great advance made of late years in the knowledge of medical hygiene is mainly due to the special training of medical officers who have devoted themselves to the study of the causes and the best means of arresting the spread of preventable diseases. It is only by securing the services of such highly-trained and experienced officers that adequate skill can be obtained in order to carry out the provisions of public health statutes.

Under the Local Government Bill there is at present no adequate provision to insure such appointments. These can only be secured by making the area of the appointment of a medical officer of health sufficiently large to justify the payment of an adequate salary in return for the devotion of the whole of the time of a highly trained officer to the exclusion of private medical and surgical practice.

However competent, the full value of the service of a medical officer of health cannot be obtained without the cordial co-operation of the members of the medical profession practising in the district to which he is appointed.

Medical officers of health should be attached to and appointed to County Councils, for districts large enough in area, population, and rateable value to occupy their whole time and attention, and to superintending inspectors should be, as at present, appointed to the Local Government Board.

Where one County Council is self-contained, the medical officer of health would report to and be exclusively occupied by the care of the district under the government of such Council.

Where a County Council contains within its area several District Councils, one or more medical officers of health should be appointed by such County Council. In such a case all medical officers of health so appointed should, in addition to reporting to the County Council from which they received their appointment, report also as to all work required to be done or executed within the area of a District Council to such District Council. Should such reports not receive proper attention, or sanitary work remain unattended to, power should be given to the County Council, upon the report of the medical officer of health, to execute such works and recover their cost from the defaulting District Council.

A letter was read from Mr. Finch Heneage, M.P., giving the wording of an amendment which he proposed to move to Clause 3, page 37, as follows:

"The appointment, control, and dismissal of medical officers of health, and the power to unite two or more sanitary districts under one officer of health, together with any other powers now vested in the Local Government Board under the Public Health Act of 1875."

The amendments on the same subject proposed by Dr. BOND are as follows:

15*. "There shall be transferred to the Council of each county, on and after the appointed day, the powers at present vested in the urban and rural authorities of such county for the appointment, remuneration, and removal of medical officers of health, such powers being in addition to those relating to the same matters which are hereinbefore transferred to County Councils from the Local Government Board; and the County Council shall, in the execution of such powers, have full authority to determine the number of medical officers of health which it may consider necessary for the efficient sanitary supervision of the district under its control, and to assign to them severally such duties and relative positions as they may deem necessary."

Add to Section 45 (E) "the power given to urban and rural sanitary authorities respectively by Sections 189 and 190 of the Public Health Act shall not be transferred to District Councils but to County Councils as hereinbefore provided."

Add to Section 118 (7) "except in the case of medical officers of health, who shall become officers of the Council of the county in which the sanitary authorities to whom they are severally attached exercise their jurisdiction."

Mr. W. H. MICHAEL, Q.C., suggested amendments as follow:—
"Sections 189, 190, 191. Power to prescribe the qualification of

medical officers of health, to appoint such officers, to sanction the appointment of the same person as medical officer of health for two or more districts, and to prescribe the amounts to be paid by each district towards the expenses, salary, and charges of such officer of health."

The above amendments were discussed and ultimately adopted.

A delegation, consisting of the above gentlemen, with the addition of Mr. Sibley, subsequently waited on Mr. Stansfeld, M.P. (the author of the Public Health Act), and discussed the subject with him prior to official proceedings of a more formal character.

ASSOCIATION INTELLIGENCE.

NOTICE OF QUARTERLY MEETINGS FOR 1888.
ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Meetings of the Council will be held on July 18th, and October 17th, 1888. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before each meeting, namely, June 27th, September 26th, and December 28th, 1888.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No member can be elected by a Branch Council unless his name has been inserted in the circular summoning the meeting at which he seeks election.

FRANCIS FOWKE, *General Secretary.*

COLLECTIVE INVESTIGATION OF DISEASE.

THE Report upon the CONNECTION OF DISEASE WITH HABITS OF INTEMPERANCE, which was presented to the Section of Medicine in the Annual Meeting of 1887 will shortly be published in the JOURNAL.

Reports upon the two remaining inquiries, namely, that into DIPHTHERIA, and that into the GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES, are in preparation, and will be published as soon as ready.

The following inquiry only of the first series remains open, namely, that on the ETIOLOGY OF PHTHISIS.

A fresh inquiry into the ORIGIN AND MODE OF PROPAGATION OF EPIDEMICS OF DIPHTHERIA has been issued.

Memoranda upon these subjects, and forms for recording observations, may be had on application to the Secretary of the Collective Investigation Committee, 429, Strand, W.C.

BRANCH MEETINGS TO BE HELD.

STAFFORDSHIRE BRANCH.—The third general meeting of the present session will be held in the Bell Library and Medical Institute, Cleveland Road, Wolverhampton, on Thursday, May 31st. The chair will be taken by the President, Mr. W. D. Spanton, at 3 o'clock in the afternoon. The following papers will be read:—Dr. C. A. McMunn: Excretion of Reduction Products of Hamatin in Disease. Dr. Alfred H. Carter: Observations on the Practical Management of Chronic Diseases of the Heart. Mr. E. Hurry Fenwick, London: The Electric Illumination of the Bladder and Urethra, and its Value in the Diagnosis and Treatment of Obscure Vesico-Urethral Diseases. Dr. McMunn will show a simple method of adapting a photographic camera to the microscope.—T. VINCENT JACKSON, Wolverhampton.

SOUTH EASTERN BRANCH.—A meeting of the Executive Council of this Branch will be held at the Bridge House Hotel, London Bridge, on Thursday, May 10th, at 3.15 P.M.—CHARLES PARSONS, M.D., Honorary Secretary, 2, St. James's Street, Dover.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT.—The annual meeting of the above District will be held at Canterbury, on Thursday, May 24th, at 8 P.M., in the chair. Anyone wishing to send papers, etc., should communicate at once with the Honorary Secretary, W. J. TYSON, Folkestone.

EAST YORK AND NORTH LINCOLN BRANCH.—The annual meeting will be held at the Infirmary, Hull, on Wednesday, May 30th, at 1.30 p.m. Gentlemen who intend to make any communication, or to propose any resolution, are requested to inform the Secretary not later than May 20th.—B. P. HARDEY, Honorary Secretary, 80, Spring Bank, Hull.

METROPOLITAN COUNTIES BRANCH: SOUTH LONDON DISTRICT.—The annual meeting will be held at Bethlem Royal Hospital, St. George's Road, S.E., on Tuesday, May 8th, at 5.30 P.M. The chair will be taken by Dr. Frederick Taylor, Vice-President of the District. Business: To read the minutes of the last meeting. Election of Vice-President, representative member of Council. Com.

mittee, and Secretary for the ensuing year. All the present officers are eligible for re-election. Dr. Savage, Resident Physician to Bethlem Hospital, will give a demonstration on Cases of Insanity in the Wards of the Hospital. All medical practitioners will be welcomed. There will be a Committee meeting at the same place at 5 P.M. Gentlemen desirous of reading papers, exhibiting specimens, etc., at future meetings, are requested to communicate with R. PERCY SMITH, Honorary Secretary, Bethlem Royal Hospital, S.E.

SOUTH-EASTERN BRANCH: EAST SURREY DISTRICT.—The next meeting will be held at the Greyhound Hotel, Croydon, on Thursday, May 10th, at 7 P.M. T. A. Richardson, Esq., of Croydon, in the chair. Dinner at 6 P.M.; charge 7s., exclusive of wine. The following papers have been promised. Dr. Goodhart: On Certain Innominate Febrile Conditions and Antipyretics. Mr. Bruce Clarke: On the Treatment of Stricture by Electrolysis. Dr. Philpot: On the Local Treatment of Eczema. Members desirous of contributing papers will please communicate with the Honorary Secretary, P. T. DUNCAN, M.D., Croydon.

NORTH OF ENGLAND BRANCH.

The spring meeting was held at the Infirmary, Sunderland, on April 25th.

Cases.—Mr. MORGAN showed a little girl who had suffered from a severe attack of cancrum oris, resulting in great destruction of the cheek, and distortion of the mouth.—After some remarks by Dr. LAWRENCE and Dr. EMBLETON, Mr. MORGAN said that he intended to repair the deformity by operation.—Dr. HUME showed a patient on whom he had performed the operation of inguinal colotomy with a good result.—Dr. MURPHY showed a man on whom he had performed the operation of gastrostomy about seven months ago. The patient's condition improved so much after the operation that there was a hope that the original diagnosis of cancer might be given up.—Drs. WATSON, GIBSON, and EMBLETON discussed these cases, and Drs. HUME and MURPHY replied.—Dr. MURPHY showed a girl with closure of the jaws from cicatrix, caused by accidentally inhaling flame. It was suggested in the discussion (Mr. MORGAN and Dr. HUME) that if the adhesions did not give way on stretching under chloroform, that they should be divided, and, if necessary, the strong bands of scar dissected out, and also a piece of fresh mucous membrane might be transplanted to the surface of the wound.

Specimens.—Mr. MORGAN showed some of the parts from a case of tubercular peritonitis simulating cystic disease of the ovary. The case raised a discussion on the question of diagnosis and treatment, the surgeons thinking it desirable to explore the abdomen in doubtful cases, and, as far as possible, cleanse the peritoneum, whilst Dr. DRUMMOND, as a physician, urged the advantage of general and local medicinal treatment.—Dr. DRUMMOND showed a tumour of the brain, removed after death. The interesting feature of the case was that there was no optic neuritis, although other symptoms were present which established the diagnosis.—Dr. DRUMMOND also showed the parts from a case of intestinal obstruction, in which there were pendulous growths of the structure of a cylindroma. He also exhibited a spleen with many infarcts of uncommon appearance, and a liver full of adenomatous growth.

Congenital Gastric Fistula.—Dr. HUME read notes of a case of congenital fistula of the stomach cured by operation.

Quack Advertisements.—Mr. MORGAN moved the following resolution on quack advertisements, which was seconded by Dr. EASTWOOD, and carried: "1. That inasmuch as the evidence is before us that the newspaper notices, the pamphlets, books, and handbills issued by advertising quacks on the subjects of 'Nervous Debility,' 'Courtship and Marriage,' 'The Philosophy of Life,' and such like, are most injurious in their effect and most debasing in their moral tendency, suggestive of impurity, and giving false notions of health, it is the duty of this meeting of the North of England Branch of the British Medical Association to warn the public, and especially the young, against those who pretend, under the garb of philanthropy and religion, to minister in some secret way to the physical and moral well-being of their fellow men. And further, to point out that 'health, energy, and manly vigour' are best maintained, and if lost through vicious habits, best recovered, by self-restraint and purity of life. 2. That this resolution be printed, and a copy sent to each of the mayors in the district which our Branch covers, asking him to take such steps as he may deem right and practicable to have these advertisements suppressed within his jurisdiction; and also to the chairman of each bench of magistrates with the same request; and, secondly, to each newspaper proprietor in the said district, drawing his attention to the evil, and asking him, as a respectable journalist, to refuse insertion of such advertisements; and, thirdly, to allow such resolution to be publicly advertised, as our warning to the public against this baneful thing."

Over sixty members were present at the meeting.

Dinner.—Afterwards the members and their friends dined together at the Queen's Hotel, Sunderland.

JAMAICA BRANCH.

The usual bi-monthly meeting was held at the Public Library on April 4th, the Hon. J. C. PHILIPPO, president, in the chair. There were ten members present.

Multiple Mammary Tumours.—Dr. J. LESLIE COX read a paper on a case of Multiple Mammary Tumours. The patient was shown.

Removal of Foreign Body from Male Bladder.—Dr. T. H. SAUNDERS read a paper on the removal of a pipe-stem from the bladder of a man.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.

The April meeting of this branch was held in 198, Union Street, Aberdeen, on Wednesday, April 18th, at 8 P.M., the president, Dr. SMITH, of Kinnairdy, being in the chair.

New Member.—The minutes of last meeting having been read and approved, Dr. James Crevie, Newburgh, was balloted for and admitted a member of the Branch.

Petition against Proposed Horse and Carriage Tax.—Dr. WIGHT moved that the Branch petition the House of Commons against the taxation of horses of medical practitioners, as proposed by Mr. Goschen in the Budget, and recommend individual members to use their influence with members of Parliament to attain the above object. Dr. Wight further proposed that the petition should take the form suggested by Mr. Ernest Hart at page 761 of the current volume of the JOURNAL.—This motion was seconded by the PRESIDENT, and unanimously adopted by the meeting.

Post-Graduate Course.—Dr. EDMOND, the convener of last year's Post-Graduate Course Committee, made a statement regarding the advisability of a course for 1888, and wished to elicit the feeling of the Branch on the matter.—Dr. GARDEN proposed that a year should be missed, and no counter motion having been proposed, the motion was declared to be carried.

GLOUCESTERSHIRE BRANCH.

An ordinary meeting was held at the Gloucester Infirmary on April 17th, 1888, at 7.30 P.M., under the presidency of Dr. CURRIE.

The minutes of the last meeting were read and confirmed.

Next Meeting.—It was proposed by Dr. BATEN, and seconded by Mr. WADDY: "That the half-yearly meeting be held in June at Gloucester." Carried.

Therapeutical Society.—It was proposed by Mr. WADDY, and seconded by Dr. SOUTAR: "The Branch having heard the offer of Dr. Percy Wilde, of Bath, to bring the subject of the aims and object of the Therapeutical Society before this Association, this Branch accepts his offer." Carried.

Communications.—Dr. SOUTAR read a paper on Epilepsy.—Dr. BROWN showed the Temperature Charts of a Case of Hysterical Pyrexia.

BATH AND BRISTOL BRANCH.

The fifth ordinary meeting of the session was held at the Grand Pump Room Hotel, Bath, on Thursday evening, April 19th, Dr. G. F. BURBER, President, in the chair. There were also present thirty members.

New Members.—The following gentlemen were elected members of the Association and the Branch:—Messrs. B. R. T. Trevelyan, M.R.C.S.E., Bristol General Hospital; W. R. Ackland, M.R.C.S., L.D.S., Rodney Cottage, Clifton; and A. Pring, L.R.C.P., 4, Arlington Place, Clifton.

Diphtheria.—The evening was devoted to a discussion on Diphtheria, which was opened by a short, practical paper by Dr. A. B. BRABAZON, medical officer of health for Bath, who pointed out the lines on which the discussion should be developed. He was followed by Drs. CROSSMAN, DAVIES, J. BROOM, STOCKWELL, BONVILLE FOX, and E. FIELD, and Messrs. TUCKETT, HINTON, WAUGH, POLLARD, and R. J. H. SCOTT, who spoke severally on the etiology, the distinctive features, and the treatment of the disease.

SOME of the medical societies in the United States, following the lead of the Georgia State Medical Society, are agitating for the removal of all customs duties now levied on surgical instruments and medical apparatus and supplies.

PROCEEDINGS OF COUNCIL.

a meeting of the Council, held in the Council Room of the Association, 429, Strand, London, on Wednesday, April 18th, 1888; sent:—

- Dr. T. BRIDGWATER, President of the Council, in the chair,
 C. Holman, Reigate, Treasurer
 J. W. Baker, Southport
 H. Barnes, Carlisle
 G. B. Barron, Southport
 J. S. Bristowe, F.R.S., London
 H. T. Butlin, London
 A. Carpenter, Croydon
 Surgeon-General W. R. Cornish, London
 J. Ward Cousins, Portsmouth
 G. W. Crowe, Worcester
 A. Davidson, Liverpool
 J. L. H. Down, London
 George Eastes, London
 J. H. Galton, Upper Norwood
 Bruce Goff, Bothwell
 O. Grant, Inverness
 W. C. Grigg, London
 T. W. Grimshaw, Carrick-ines
 James Hardie, Manchester

- Mr. T. R. Jessop, Leeds
 Mr. H. R. Ker, Halesowen
 Dr. W. G. V. Lush, Weymouth
 Dr. J. McIntyre, Odiham
 Mr. F. Mason, Bath
 Dr. W. W. Moore, Brighton
 Mr. W. Jones-Morris, Portmadoc
 Dr. F. Needham, Gloucester
 Dr. C. Parsons, Dover
 Dr. R. Saundby, Birmingham
 Dr. A. Sheen, Cardiff
 Mr. S. W. Sibley, London
 Dr. W. Strange, Worcester
 Mr. T. Sympton, Lincoln
 Mr. J. Taylor, Chester
 Dr. T. W. Trend, Southampton
 Mr. F. Wallace, London
 Dr. E. Waters, Chester
 Mr. C. G. Wheelhouse, Leeds.
 Mr. A. Winkfield, Oxford

the minutes of the last meeting having been printed and circulated, and no objection having been raised, were put and confirmed. Read letters from the Registrar-General, of which the following copies:

February 29th, 1888. Sir,—I am directed by the Registrar-General to acknowledge the receipt of your letter of the 1st instant, and to state that he regrets that, for the reasons fully stated in his former communication of November 19th, 1887, he is unable to comply with your request that tabulation of causes of death shall be extended in the way proposed by you. regards the suggestion made by the Registrar-General that the information you wish for could probably be obtained by you from the hospitals of the country; this was, of course, no more than a passing suggestion, and the Registrar-General regrets that it should have been one which, as it appears, did not in your judgment meet the case. I am, Sir, your obedient servant,
 W. OGLE, M.D., Superintendent of Statistical Department.—The General Secretary, British Medical Association, 429, Strand, W.C.

February 29th, 1888. Sir,—Enclosed in the letter forwarded by you to the Registrar-General, which has been answered officially, was a letter addressed to me personally inviting me to have an interview with the signatories of that communication. Will you be so good as to say that I shall be happy to receive a gentleman who wishes to see me, at any convenient time, and to convey to the Registrar-General any remarks which he may wish to make on the subject which the letter refers. I take it, however, that the object of such an interview would be to insist upon the importance, from a medical point of view, of information asked for. As, however, the Registrar-General does not in the contest this value, of which, of course, the medical signatories are far more competent judges than himself, but has based his refusal to extend his tabulation of causes of death upon perfectly different grounds, I hardly think the proposed interview and discussion would be of much service. I am, Sir, your obedient servant, W. OGLE, M.D., Superintendent of Statistical Department.—The General Secretary, British Medical Association, 429, Strand, W.C.
 Resolved: That a reply be sent to the Registrar-General in the following words:

To the Registrar-General of Births, Deaths, and Marriages in England.
 Sir,—We are desired by the Council of the British Medical Association to acknowledge and thank you for your communications, dated February 29th, signed by Dr. William Ogle.

We understand that you are unable to comply with our request on account of the necessity of avoiding any increased expenditure in your department, and we refrain from pressing the matter at the present moment. But we sincerely trust that the time is not far distant when you may see your way to providing the detailed statistics of cancer which we have suggested.—We are, Sir, your obedient servants.

Resolved: That the proposed by-laws of the Perthshire Branch, in recognition of that Branch as a Branch of the British Medical Association be and it is hereby confirmed by this Council; that in notifying this resolution the Council of the Association desire to express to the Perthshire Branch their high sense of the mutual benefits that this union should necessarily insure.

Resolved: That the 319 candidates, whose names appear on the circular convening the meeting, be and they are hereby elected members of the British Medical Association.

Resolved: That the Financial Statement for the year ending December 31st, 1887, as certified by the auditors as correct, be received and approved, and published in the JOURNAL in accordance with By-law 26.

Resolved: That the minutes of the Journal and Finance Committee of to-day's date be received and approved, and the recommendations contained therein carried into effect.

The minutes of the Journal and Finance Committee contain the accounts for the quarter ending March 31st, amounting to £5,979 16s. 3d. Report of the auditors for the quarter, and a recommendation that the Editor's salary be increased by £250, the Manager's by £150, and the Assistant Secretary's by £100, and an honorarium of £100 to the Manager.

The Treasurer reported the investment of £2,000 in Nottingham Corporation 3 per cent. inscribed Stock.

Resolved: That the President of Council, the Treasurer, and the General Secretary be empowered to seal power of attorney authorising the London and Westminster Bank to receive the dividends.

Resolved: That the minutes of the Premises Committee of April 17th be received and approved, and that the recommendations contained therein be carried into effect.

The minutes of the Premises Committee contain communications from the Hunterian Society, stating that, in consequence of new arrangements by the London Institution, their medical library would remain there.

The President of the Council placed before the Council letters from Dr. Prosser James and Dr. McDonell.

Read minutes of the Committee appointed to consider the subject of Relative Rank.

The minutes of the Committee appointed to consider the subject of Relative Rank, contain the reply of the Secretary of State for War to the communication of the President of Council on behalf of the Association.

Resolved: That the correspondence be referred to the Parliamentary Bills Committee, and that Surgeon-General Cornish be added to the Parliamentary Bills Committee.

Resolved: That the minutes of the Branch Organisation Committee of April 17th be received and approved, and the recommendations contained therein carried into effect.

The minutes of the Branch Organisation Committee contain recommendations that copies be struck off of the map of the Branches, and one sent to each Honorary Branch Secretary.

Resolved: That the minutes of the Scientific Grants Committee of April 17th be received and approved, and the recommendations contained therein carried into effect.

The minutes of the Scientific Grants Committee contain particulars of seventeen applications for the scholarship vacated by Mr. Watson Cheyne, and a recommendation that Dr. Ralph Stockman, Edinburgh, be appointed to the vacancy for one year.

Resolved: That the President of Council, the Treasurer, and Mr. Sibley be a Committee to draw up the Annual Report.

Resolved: That the arrangements for the Annual Meeting be approved and confirmed.

SPECIAL CORRESPONDENCE.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

"Phthisiogenic" Pleurisy.—Vaginal Antiseptics.—Orthosyphon Stamineus.—Treatment of Typhlitis.—Telepathic Remedies.

In a clinical lecture at the Hôpital de la Pitié, Professor Jaccoud recently made some interesting remarks on a case of dry diaphragmatic pleurisy, and on the possible connection of such cases with tubercular phthisis. The case was extremely severe at the outset, and the patient breathed with great difficulty, and suffered much pain. On examination, it was found that the affection was localised at the postero-lateral part of the left side of the chest in communication with the diaphragm. The severe symptoms soon gave way to local treatment, and recovery was rapid. At the end of eight days the only traces left of the pleural inflammation consisted in a slight fibrinous exudation indicated by some want of resonance, harshness of breath-sounds, and retraction of the two intercostal spaces in the lower posterior part of the chest in inspiration. Dr. Jaccoud attaches special importance to the persistence of this exudation after apparent recovery, as it may lead to pleuritic adhesions, and, on account of the close connection between pleurisy and pulmonary phthisis. It is generally supposed that only pleurisy of the apex can lead to tuberculosis of the lungs. This is quite a mistake. Any pleurisy, no matter where located, may precede and pave the way for tubercles. Moreover, as Dr. Jaccoud already stated in 1882, the essential character of "phthisiogenic" pleurisy is that it occupies the lower region of the pleura at its antero-lateral part, and generally on the right side. In a case of pleurisy of this description the patient recovers rapidly, with, perhaps, some loss of strength; this is the first stage. But after some weeks, or perhaps months, he again falls ill; a pneumonic patch is discovered at the seat of the pleuritic adhesions, and the patient is obliged to take to his bed. The pneumonic patch soon breaks down, and leads to what is

known as caseous pneumonia. This is the second stage. Lastly, should the patient survive for a few months there may be a third stage, represented by more or less generalised pulmonary tuberculosis. Dr. Jaccoud thinks that the connection between these pleuritis ending in adhesions and the formation of a pneumonic focus, which is, after all, tuberculous, may be explained by the fact that the portion of lung bound by the adhesions to the chest-wall has lost its power of expansion, and participates little or not at all in the respiratory process. On the other hand, the blood circulates perfectly in this region of the pulmonary parenchyma, the vessels are compressed by the pleuro-costal adhesions, stasis becomes frequent; consequently there is a diminution of the nutritive action, extremely favourable to the multiplication of the bacilli, which have already taken up their abode in this part of the lung, while direct examination of the apices shows that these are still quite free from microbes. Dr. Jaccoud draws the following practical conclusions from the above facts: Pleurisy may as readily lead to pulmonary phthisis when it affects the lower parts of the pleural cavity as when it is in the apex. This is particularly the case as regards dry pleuritis ending in adhesions situated in the antero-lateral parts on the left side, such pleuritis being more often "phthisiogenic" than any other. On the appearance of such symptoms active measures must be taken notwithstanding their apparent mildness and the rapid recovery of the patient. Every effort must be made to prevent the formation of adhesions, particularly by extensive blistering of the side of the chest. This will often succeed. The inhalation of compressed air is also very useful if it is continued during several weeks.

The *France Médicale* of March 3rd publishes an article by Dr. F. Verchère on vaginal antiseptics, of which the following is an abstract:—Vaginal and uterine cleanliness is one of the greatest achievements of modern times, and, thanks to it, gynecology has become surgical and effective. For a few days before operation or childbirth vaginal aseptics must be established and maintained. The author passes in review the various liquids employed to obtain vaginal aseptics, carbolic acid, boric acid, bichloride or biniodide of mercury, etc. Carbolic acid, in order to be efficacious, must be used at a strength of 40 in 1,000, when it becomes too irritating to the mucous membrane of the vagina and uterus; boric acid, on the contrary, is not energetic enough. There remain the mercurial solutions, which are the best; above all Van Swieten's solution. For vaginal injections it may be used pure, but for intra-uterine injections it is better to employ a weak solution of about one-third of the liquid to two-thirds of water. The surgeon or accoucheur should not trust to the patient, but should give the injections himself twice a day for four or five days before the confinement or operation. Between the injections occlusion must be maintained by means of a pad of iodoform wool, which should remain *in situ* night and day. Should the odour of iodoform be disagreeable to the patient, ground coffee, Tonka bean, etc., should be used to disguise it. After operation, the antiseptic measures must be continued with the same care until healing is complete. After delivery, the iodoform pad is not necessary, and may be replaced by iodoform gauze.

Dr. Frochard recommends, in the *Gazette des Hôpitaux*, of March 1st, a powerful diuretic, *orthosiphon stamineus*, in the form of Java tea, in treating gravel and arthritis. He records the following cases. I. H., aged 60, had passed gravel in his urine for a year. An infusion of Java tea (five grammes to the litre) was prescribed daily. The urine gradually became clear and abundant. II. F., aged 52, for six months had suffered every three weeks from nephritic colic, followed by the expulsion of large calculi. Java tea was prescribed in the same way as in Case I. In the next two months he had only one attack, and during the five months which had since elapsed he had not suffered at all. III. M., aged 46, had suffered since 1883 from ascites due to cirrhosis of the liver. For a month he took Java tea, at first five grammes, and then ten grammes in a litre of water. The abdomen diminished in size several centimètres weekly. The drug is perfectly harmless. Dr. Frochard has only used it in the form of Java tea, and pills obtained direct from the importer, M. Périnelle.

M. Bouchard recommends the following treatment for typhlitis: Sootie pain by a morphine injection, if very sharp at first; if not, a thick layer of Neapolitan ointment with belladonna, covered by a large, very hot poultice. Aseptic rectal injections twice a day, with at least one litre of water, to which are added five grammes of borate of soda, and two or three teaspoonfuls of tincture of benzoin, mixed with camphorated alcohol. The injections must

be given very slowly. Absolute rest is indispensable. No purgatives, or, if any, only those of the mildest kind, such as magnesia in water, etc. Only the lightest diet, which will leave no deposit for intestinal fermentation, should be allowed. Milk and alkaline drinks may be given in small quantities at a time; later on, milk thickened with yolks of eggs. If at the end of a fortnight some thickening can still be felt round the cæcum, a small blister should be applied.

Professor Bernheim, of Nancy, writing in the *Revue Hypnotique* observes that, since recent experiments have led the medical profession to believe in remedies which can act at a distance, experiments on that subject should be made in a more serious and conscientious manner. Substances having a definite action should be chosen and enclosed in numbered tubes by a person not present at the experiments, the names of each being put in sealed envelopes bearing corresponding numbers with those on the tubes. New substances should be chosen for subjects who have already been submitted to those experiments, in order to prevent their first impressions being recalled. The various phenomena should be noted immediately after they are observed. The envelopes should be opened only after the experiments are terminated and the subject has gone away. If, after all these precautions have been taken the effects produced agree with the known action of the drug, the presence of something more than the influence of suggestion in telepathic medicine will be proved. Professor Bernheim's own experiments on a young girl considered susceptible to the action of telepathic medicine have given negative results.

Acute Quinine Poisoning.—Rare Form of Congenital Syphilis.

DR. L. ROSENBUSCH, of Lemberg, in a recent number of the *Przeglad Lekarski*, reports a case of acute quinine poisoning which he had observed in the hospital of that city. After the administration of a gramme of the sulphate of quinine, the patient was attacked with shivering, tinnitus aurium, severe headache, cold and pains in the extremities, palpitations, and vomiting, with great prostration. An hour later the patient became unconscious, the temperature rose to 39.7° C., the pulse was 158 and compressible the pupils contracted, but reacting to light, the tongue dry. The skin of the face and the whole body presented a uniform redness resembling that of scarlet fever, and composed of many small confluent patches. The likeness to scarlet fever eruption was the more striking as the neck and the thighs were very deeply coloured. Respiration was difficult. Castor-oil, caffeine, and cold compresses to the head and the cardiac region were ordered. On the following day the temperature was only 36.5 C., the pulse 108, with considerable arterial tension. The patient had a restless night and was delirious; the bowels acted towards the morning the rash became paler, the pupils regained their normal size, the tongue became red and coated with yellow patches. Sensation of tearing and trembling in the extremities were complained of. Bromide of sodium was given. The rash and all the other symptoms just described disappeared in two days, and only a slight pigmentation of the skin remained. The patient had stated that, five years ago, he had a similar attack after taking two powders, each containing half a gramme of sulphate of quinine. On that occasion the rash disappeared the next day. Dr. Rosenbusch points out that this case is specially interesting by reason of the high temperature (39.7° C.), which had never before exceeded 38.7° C.; also on account of the great resemblance of the rash to that of scarlet fever, from which at first it could hardly be distinguished. The absence of throat symptoms and the sudden occurrence of a diffuse and uniform blush over the whole body were the chief features which differentiated the affection from scarlet fever.

At a recent meeting of the Royal Society of Physicians of Buda Pesth, Dr. Róna showed a baby two months old which was affected with congenital syphilis of a particularly interesting type. Some days previously Dr. Róna had observed the following symptoms in the child: coryza (which had already been present in the first week after birth); mucous patches on the lips; a papule as large as a pea on the left cheek; broad condylomata and ulcers around the anus; pseudo-paralysis of the two upper and right lower extremities, due to considerable swelling of the lower ends of both the arms, the ulnæ and radii, and the lower end of the right femur. The metatarsal bones and the first phalanges of the middle fingers were swollen to such a degree that the palm of the hand was as convex as the back. The spleen was enlarged; the liver and

ts unaffected. Hence in this case the skin, the bones, as well as the spleen, were the sites of syphilitic affection. The syphilitic affection of the epiphyses and the enlarged spleen were quite common symptoms of congenital syphilis, but the rare and interesting feature in the case was the periostitis of the small ulnar bones, an occurrence quite unknown even to the most experienced pædiatric specialists. After five mercurial inunctions the symptoms began to disappear. The child is the tenth of its parents. The father acquired syphilis in 1879-80, and the mother presented the first syphilitic symptoms in 1885.

BERLIN.

[FROM AN OCCASIONAL CORRESPONDENT.]

Health of the Emperor.—The Withdrawal of Professor von Bergmann.

The condition of our Emperor-King continues to occupy men's minds here to the exclusion of almost everything else. The official reports—meagre and somewhat Sphinx-like as they are—are eagerly scanned, and in the absence of any information as to the essential points of the situation, we try, though with indifferent success, to comfort ourselves with slight falls in the illustrious Emperor's temperature and passing improvements in his general condition. Even those who professed to share the optimistic views of the foreign physicians no longer blind themselves to the fact that the present reign is too surely destined to be very short. In the meantime, His Imperial Majesty is considerably better, and eats fairly well, taking solid food with hearty relish. Dr. Leyden takes a great point of his taking grape instead of cane sugar as the reason for this injunction the Professor appears to serve *in petto*. The morning temperature is now out normal, but in the evening it has risen to 102° F. since April 25th inclusive. Before that the evening temperature had been 103° on several occasions, and once reached 104°. The temperature is always taken in the mouth with a "half-minute" thermometer, which was given

Sir Morell Mackenzie by an eminent surgeon during his last visit to England. The instrument which is generally used here is a rather coarse affair, which has to be kept in for ten minutes before a trustworthy register of the temperature can be got. When the Emperor returned to Berlin, Dr. Wegner, who is rather what the French call *perruque* in his ideas, insisted—either to the annoyance of the august patient—on using the ordinary German thermometer to which he was accustomed instead of the new-fangled English importation. It was only after repeated trials with the two instruments—one being kept in the mouth for half a minute and the other in the axilla for ten minutes—and finding that they invariably registered the same temperature, that the Leibartz would give way on this point. All the physicians are now, however, unanimous in their approval of the "short time" thermometer, and it alone is used in the case.

You have already learned, no doubt, that a few days ago the prolonged "tension" among the Kaiser's medical advisers came to a crisis, which ended in Professor von Bergmann withdrawing from the case. He has been replaced by Professor Bardeleben, the head of the surgical staff of the Charité, whose name, I am given to understand, much better known in England than that of von Bergmann. Bardeleben, who is considerably the senior of his brother professor, is a man of great judgment and experience, and it has been a matter of some surprise that his advice was not asked before. At the stage which the case has now reached, however, the change of surgeons is of very little practical consequence. The event has, I need hardly say, made an immense sensation here, not only in professional circles, but among the general public. I hardly think, however, that much sympathy will be felt in England for Dr. von Bergmann, who, though he may possibly have good grounds for complaint against Sir Morell Mackenzie, has, in this particular instance at least, put himself out of court by the aggressive attitude which he took up, apparently without any special provocation on the part of his English colleague. I do not mean to imply that he is personally responsible for the scandalous attacks on Mackenzie and Hovell, which appeared in certain ultra-patriotic German papers, but if he did not directly inspire them he has never, so far as I know, disowned them. Considering that these attacks did not concern matters of opinion, but were statements of concrete facts the truth or falsehood of which was within Dr. von Bergmann's knowledge, this reticence on the part of the distinguished surgeon can only be interpreted as an endorsement of the charges there

made. When the alleged facts are absolutely denied in the most public manner by the persons accused, Professor von Bergmann has no right to shelter himself behind a *soldisant* superior code of professional ethics, and refuse to take up the challenge thus openly given.

It is a somewhat suspicious circumstance, moreover, that this virtuous resolution of the Professor should be announced just at this particular time. He did not appear to be so scrupulous a few weeks ago, when, at the Langenbeck Memorial Festival here, his speech was understood to contain a covert attack on Sir Morell Mackenzie, which was received with the fullest appreciation by the audience. I happen to know also that, whether he has "inspired" the press or not, he has been in frequent communication for a long time back with the Berlin correspondent of a powerful English newspaper, whose "candid friendship" towards the English specialist has been obvious to the most casual reader.

I dare say there have been faults on both sides, but when the whole miserable business comes fully before the medical world, as it is sure to do one of these days, I think it will be seen that Sir Morell Mackenzie has had such an amount of provocation that, after all, he may well, like Lord Clive, "stand astonished at his own moderation."

GLASGOW.

[FROM OUR OWN CORRESPONDENT.]

Meeting of Glasgow University Council.—Opposition of the University Authorities to the Universities Bill.—Queen Margaret College.—Typhus Fever in "Tinkler" Wigwams.—St. Mary's Industrial School Epidemic.—The Scotch Education Department and Leaving Certificates for Secondary Schools.

THE annual meeting of the University Council was held on April 25th, and was characterised by the largest attendance for very many years. It soon became evident, however, that the expected discussion on the Universities Bill was not the cause of the unusual attendance, but that the large number was the result of the beating up for votes on the part of indefatigable candidates for the vacant clerkship of the Council. Three candidates were put forward, one by the University Council Association, but his name and that of another were withdrawn after the first vote, as soon as the enormous majority was evident in favour of a strictly non-party man, Mr. Arch. Craig, LL.B., for whom 392 voted. As soon as this vote was over, two-thirds of the meeting trooped away. On the question of approving the arrangements made by the University Extension Board for the extension of university teaching, Dr. McVail expressed a strong objection to the scheme. He maintained it was completely inadequate because the university element in the certificate proposed to be granted would be reduced to a minimum, and there was no provision for accepting any of such certificates as qualifying for the degree in the University. He refrained from proposing an amendment because he hoped that they would soon find themselves working under a new Universities Act, with a different University Court, and a Senate reduced from its position of dictation and universal control. In the discussion that followed on the Universities Bill there was nothing of marked importance elicited. The Committee of Council had suggested that general approval of the Bill should be expressed, coupled with a desire for a fuller definition of the meaning and conditions of affiliation, and for an increased grant. An attempt was made, on a motion moved by Principal Douglas, seconded by Sir William Thomson, to get the Council to express an opinion in favour of restricting the Commissioners to investigation and report on the question of affiliation with a view to legislation, on the ground that the subject had not yet been sufficiently matured by discussion. This however was defeated by a majority of 81 against 63. The falling off, however, in the attendance from between 450 and 500, when a small piece of patronage came up for disposal, to less than 150, when the reform of the University was under discussion, is not a favourable comment on the claim of the Council for increased power in the administration of the University. Subsequently a motion was carried objecting to the interference with the patronage of bursaries as proposed in the Bill. Owing to the lateness of the hour two motions by Dr. J. R. Wolfe were postponed to next meeting. They proposed that a representation be made to the University Court to consider, with the managers of the Royal Infirmary, how, by endowing chairs of clinical medicine and otherwise, the clinique of that institution might be utilised for the University, and to consider the disadvantageous position of extra-mural teachers in

medicine, in respect that they are not represented among the Examiners for Degrees, and to report in which way this disadvantage can best be removed. Should it be necessary when next meeting comes round for these motions to be brought up, considerable support is promised for them.

The authorities of Glasgow University are directing all the force of their attack on the new Bill to the affiliation clauses, and to the proposal to give the Court power to review, *ex proprio motu*, the decisions of the Senate. These are the portions of the Bill to which the University Court itself, at a recent meeting, took strong exception. They also expressed the opinion that the Court, as proposed, was too large for business purposes, and recommended that only one assessor, instead of two, should be appointed by the Crown, on whom the title of Dean of Faculties should be conferred, with a view to maintaining that historical office. The deep dislike entertained to the Bill by many of the Senate is shown in a letter addressed by Professor Dickson to the University member of Parliament, Mr. J. A. Campbell. Professor Dickson offers a most uncompromising criticism to the whole Bill, objecting to the proposals bearing on the General Council, because "they are understood to have emanated from a self-constituted association," formed of scarcely one-fifth of the whole body of graduates, and representing those mainly resident in Glasgow and vicinity, because they limit the freedom of choice of the Council in its representatives, and because of the proposal for a Standing Committee of Council. He objects to the size of the proposed Court and to its extended powers of review, and speaks of affiliation as "an unknown quantity under a metaphorical name," finally characterising the Bill as "legislation at haphazard," and as "a perilous experiment." There is no doubt that the Senate will use all its influence to have all the affiliation clauses removed from the Bill, and the question referred to the Commissioners simply for consideration and report; and the Senatorial breast is animated with no little hope that in this attempt they will be successful.

Queen Margaret College closed its fifth session on April 30th, when the prizes were distributed by Sir J. N. Cuthbertson. The total number of students was 242.

Dr. Russell gives another example, in his latest report on the health of Glasgow, of the conditions which maintain typhus. It is that of a one-apartment house from which five cases were removed. The house was inhabited by two families, consisting of fourteen persons. The parents of the first family were 44 and 41 years of age, and they had a family of four girls, of ages 16, 11, 9, and 7 years, and three boys, of ages 13 and 3 years, and 16 months. The parents of the second family were 35 and 24 years of age, and had two children, one a boy of 4 years and a second boy of 5 days. The mother of this family was a daughter of the first. Her age is 24, and her mother's 41, and both were suckling infants. There was besides an illegitimate child, aged 2 years, of a grown-up daughter of the first family. The people belonged to a class known in Scotland as "tinklers." They had no furniture but a table and some soap-boxes, one bed and shakedown, and a very scanty supply of cooking or feeding utensils. The complicated indecencies of life in these circumstances, Dr. Russell remarks, may be evolved by anyone's imagination. The existence of such circumstances depends in this case on the will of the parents who choose to revert to the savage state. Ought the habits of the wigwam, he asks, to be permitted in the midst of a city? If they are, the smallest penalty is the expense of treating typhus and maintaining people in the reception-house.

St. Mary's Industrial School remains free of disease, and only five of its patients remain in hospital. A total of 310 cases are at present in Belvidere, of which 168 are cases of scarlet fever, 52 of enteric fever, 34 of measles, 25 of typhus, 19 of whooping-cough, 6 of erysipelas, and 5 undefined. There is also a solitary case of small-pox—that of an actor, who left Sheffield on April 1st, remained in Edinburgh fulfilling an engagement till the 8th, and then came on to Glasgow. It is a mild case. A fortnight ago the total number of cases of fever in hospital was 344, and at the corresponding period of last year they were only 254.

The Scotch Education department has now offered to secondary schools placed under their inspection leaving certificates of three grades: one aiming at the standard maintained in the senior local examinations of the university, or the examination preparatory to the three years' course; a second corresponding to the junior local examination or the medical preliminary; and an honours certificate for the benefit of such schools as aim at still higher standards. The examinations will be held in the third week of June.

CORRESPONDENCE.

TO CORRESPONDENTS.

OUR correspondents are reminded that prolixity is a great bar to publication, and, with the constant pressure upon every department of the JOURNAL, brevity of style and conciseness of statement greatly facilitate early insertion. We are compelled to return and hold over a great number of communications chiefly by reason of their unnecessary length.

THE SANITARY CONDITION OF HAILEYBURY COLLEGE

SIR,—I trust that you will allow me space for a few remarks under this head, and for the statement of some facts which do not appear in your commissioner's report, in fairness to the authorities of the College and to the parents of the many boys at school there. For the sake of clearness I shall follow the order of Mr. Bailey Denton's report.

1. *Sanitation: External Arrangements.*—There are no water closets "in the Master's house;" there are two in houses "Assistant Masters." This correction may appear a mere quibble, but it will be appreciated by those who know Haileybury and are acquainted with the relative position of its several buildings.

Internal Arrangements.—Dormitory ventilation. In fairness to the College, it should be known that the method of ventilation referred to was originally adopted as one which then held a position of considerable prestige, and only after its adoption had been commended by a sanitary authority of acknowledged position. Although now somewhat discredited, it may still be regarded a fair "system," as anyone who examines the dormitories under conditions would, after noting the low percentage of carbon dioxide present in the air of all the rooms, admit. But the advantage originally claimed for the "system," namely, that practically converted each set of dormitories into one large apartment, and ventilated them as such, constitutes its essential drawback; because it the more readily admits of the conveyance of infection (should there be such in one dormitory) to the rooms above. [As a matter of fact, none of the recent cases held such relationship to any of the others as would be explicable on this hypothesis.]

It was on account of this special feature in the ventilation that I, as medical officer of the school (not "the medical officer of health") stated in my report to the Council for 1887—in which Mr. Bailey Denton gives partly as mine and partly as my own—"The system of ventilation which exists in most of the school dormitories cannot be considered as satisfactory, or as accordance with the otherwise good system of sanitation obtaining in the school. I believe that it could be greatly improved but a small outlay, and that without any material alteration of the buildings. I hope shortly to be able to draw up a detailed memorandum on the subject." In the same letter (dated April 9th, 1888) in which I supplied Mr. Bailey Denton with this information, I added that the Council had, immediately on receiving this presentment, agreed to the undertaking of such alterations in this respect as were recommended; and that the actual carrying out of these changes was now held over only in order to await the detailed report of the sanitary authority to whom the question had been committed in connection with an investigation into the recent cases of diphtheria.

In the same letter I also stated to Mr. Denton that, on my representation, it was, some time ago—and quite independently of the late illness—arranged that the Tobin's tubes in the school house should be heightened, and that this work had been postponed until the Easter holidays simply in order that it might be carried out in conjunction with other structural alterations and repairs which were due at that time. This work, with other minor details, has been completed; but, in justice to parents and others interested in the College, these facts should, I think, have been made public simultaneously with the criticisms referred to.

As regards the condition of some of the ditches between Hford Heath and Haileybury, it should be known that these will become pure as soon as the new sewage farm, now in process of arrangement for this district, is completed. Many of the boys at Haileybury must often pass these ditches, as, at times, they go others for miles round; but, it is not the case that they "constantly play" in Little Amwell. It may be added that the College has, in successive years, spent very considerable sums in acquiring property in its immediate neighbourhood, simply in order that it might improve and have control of the drainage, etc.

II. *Water-supply*.—The present position of the well may not exactly such as would be chosen were it now proposed to sink new well for the College. Whether its contents are, or ever have been, prejudicially affected by its position is another matter. On this head it should be noted that:—

1. Not only does the well for a large part of its depth pass through a dense and practically impermeable clay, which would naturally allow impurities to be washed away over its sloping surface more readily than to penetrate its mass, but that all the evidence of repeated examinations, made under the most various conditions, at all times of the year, at short intervals, and, again, after pumping the well dry, is quite against the entrance of fluid to it, except from the one point, at the very bottom, whence the water issues from the chalk. As a result of the numberless examinations made during the last quarter of a century there has never been found the slightest trace of soakage through any part of its walls.

2. There is certainly no permanent contamination of the well-water, from sewage or otherwise. In such a case, successive analyses could not have given such results as “a phenomenally pure water,” “a most excellent water,” “of the highest degree of purity.” In his last report, dated April 24th, 1888, Dr. Stevenson again describes the water as “of the highest degree of purity.”

3. After long-continued heavy rain the well-water is apt to become yellow in colour. Examinations of the well under these conditions prove that there is no leakage through the well-walls. Other chalk wells in the district exhibit a similar phenomenon, and the conclusion is that this yellow matter enters at the bottom of the well after percolating the chalk and thick superjacent strata, the filtration through the chalk being naturally less rapid and less effectual under the pressure resulting from a heavy and long-continued rainfall. [I do not know the “authorities” who aver that this vegetable matter percolates “laterally from the sea.” Inasmuch as the Ordnance data show that the bottom of the well is some sixty feet above the level of the river Lea, such lateral percolation from this source is obviously impossible.] Analyses of the water at these times show the yellow matter to be a vegetable, and peaty in character. Dr. Stevenson, for example, analysing the darkest sample which could be collected after awaiting very heavy rainfall for the purpose, states that the organic matter “is of a peaty character, and does not appear to be due to sewage matters”—a conclusion obvious from the figures disclosed by the analysis. This would rebut the suggestion that surface contamination (due to the proximity of “urinals and various gulleys down which sewage is thrown”) was the cause of the irruption of organic matter referred to. Moreover, after flooding all the drains with carbolic acid and other substances, no trace of contamination has been obtainable in or about the well.

It should also be noted (as showing that the authorities were not blind to the possibility of risk, nor careless as to its prevention) that Messrs. Allen and Hanburys, analysing similar (discoloured) samples of water in February, 1886 (again after heavy rain), state that “the softening process” [which is applied to all the well-water before distribution] “has reduced the vegetable organic matter to a very small amount. It is now a satisfactory water, and is fit for drinking and domestic purposes.”

I think it will be admitted, therefore, that

(a) There is no permanent contamination of the usually “most excellent” well-water.

(b) That the occasional discoloration noticed after heavy rain is not derived from surface contamination of the well, or from lateral soakage into it. That it is due to a temporary irruption of vegetable organic matter, and is not dependent on sewage pollution. That the College authorities were justified in relying on the analyses which showed that this vegetable matter, when it did find its way into the well-water, was effectually removed by the Porter-Clark softening process, before the water was distributed throughout the College; and

(c) That the authorities have taken every reasonable precaution—by frequent examinations of the well itself, and by regularly-repeated analyses of its water (both before and after softening, always under various conditions—to keep themselves posted as to the state of the water-supply, and forewarned with respect to any possible impairment of its quality.

III. *Milk-supply*.—The Council will doubtless take action in the direction suggested by your commissioner, if they are not anticipated in this matter by Mr. Wells himself. Of course, as regards the recent cases of diphtheria, the same argument which Mr. Bailey Denton quotes, from my letter to him, as opposed to

the idea of the water-supply being the *fons et origo mali*, applies with at least equal force to the milk also. I prefer not to commit myself to any theory with respect to the origin of the diphtheria until we have all the facts obtainable at our command. These are being very patiently and thoroughly collated by Dr. G. Turner, to whom the investigation of the subject was entrusted by the Council at my suggestion. His full report will, I hope, be completed shortly. Meanwhile, I can conscientiously state that all the evidence before us unites in exonerating the College from the suspicion of any such local defect in sanitation as could be considered responsible for an outbreak of epidemic disease.—I am, etc.,

CHAS. EDWD. SHELLY, M.B. Cantab.,

Medical Officer to Haileybury College.

** The above letter appears to us to be somewhat of an admission of the facts described in our commissioner's report, although Dr. Shelly apparently does not concur in the remarks made therein as to the possibility of the College well being or becoming polluted owing to its position. The best way for Dr. Shelly to strengthen his case as to the immunity of the well from suspicion will be to send us for publication Dr. Stevenson's last analysis, with his notes and remarks thereon, which, we presume, are by this time in the possession of the College authorities. We will gladly publish them.

THE NATIONAL PENSION FUND FOR NURSES.

SIR,—Now that the subject of the Pension Fund is under discussion, there are many nurses who would be glad to have their own opinion on the matter made public, and who would be grateful to you if you would make it known through your paper.

In the first place, surely the word “pension” is misleading; the dictionaries define it as “an allowance made without an equivalent.” Of course, no nurse would be so unreasonable as to expect her services to be so rewarded, but there certainly is a very widely spread feeling of disappointment that the terms of the Pension Fund are such as to render it almost an impossibility for nurses to join it.

So much has been written in the *Hospital* about the “duty of making provision for the noble women who are devoting their lives to the nursing of the sick,” that the first feeling on receiving the prospectus was one of surprise that the provision was to be made almost entirely by themselves.

It is true that very young nurses will find the terms comparatively easy, but the vast number, who have already spent many years of their lives in this work, will find it difficult, if not impossible, to spare regularly from £20 to £40 per annum out of a salary which, in the case of nurses, never exceeds £40, and is in most instances considerably less.—I am, etc.,

A NURSE.

** We believe that self-help and self-respect will be found to be the dominant principles by which the great body of nurses are animated. At the discussion at the Society of Arts in October last, when the Fund was first instituted, the founder emphatically stated that the Pension Fund was one of providence, and was not eleemosynary. Nurses were then, and are now, wanted to join the fund by paying into it at least one-eighth of their earnings year by year. All who do this may, we believe, rest assured that those who have already shown so much liberality and interest in the cause of nurses by promoting this Fund will take steps to conserve the best interests of every nurse who entrusts her savings to their care. There are necessarily a large number of nurses who have already devoted many years of their lives to nursing, and who have no reserve, who will, as our correspondent points out, “find it difficult, if not impossible, to spare regularly from £20 to £40 per annum out of a salary which, in the case of nurses, never exceeds £40, and is in most instances considerably less.” The managers of the fund, with the object of meeting such cases, we believe notified that nurses so placed, and who are desirous of being assisted to help themselves should apply to the Secretary, 38, Old Jewry, E.C., for a special form of application to be filled up and returned with as little delay as possible. With reference to some statements which have been published, and are being circulated, intimating that the payments required are from an actuarial point of view excessive, it is right to say that they are effectually refuted by the report of Mr. King, the well-known actuary, and that the comparisons therein made are based on palpable error.

THE LOCAL GOVERNMENT BILL AND SANITARY ADMINISTRATION.

SIR,—In a leading article in the JOURNAL of April 28th you have pointed out a defect of the most dangerous kind in the Local Government Bill, namely, the careless provisions made for the appointment, tenure, and duties of the medical officer of health. It may seem from the Bill itself that little attention has been given to this department, and that old provisions have been inconsiderately thrown into the new Bill to take their chance there.

I sincerely hope that the medical profession will make its voice plainly heard on this matter, for I am sure that we should carry the public with us; indeed, I can scarcely doubt that when the attention of the Government is drawn to their defects the clauses in question will be fully reconsidered. Sir Lyon Playfair's speech on this subject on the second reading displayed his usual ability and knowledge, and must do good service; other speeches, I trust, will follow his lead. It was my intention to secure an opinion on this subject at the recent special meeting of the West Riding Quarter Sessions, but we did not reach the sanitary clauses. The Quarter Sessions stand adjourned for May 8th, but time presses, and it is possible that even then these clauses may not be reached. Our chairman, Colonel Spencer Stanhope, has, however, expressed his own opinion to me in the terms of the enclosed letter, which he permits me to publish, and which I therefore now enclose for that purpose.

The views which we hold could not be better or more tersely expressed.—I am, etc.,
T. CLIFFORD ALLBUTT.
Athenæum Club, Pall Mall, S.W., May 1st.

"DEAR DR. CLIFFORD ALLBUTT,—As you suppose, the Quarter Sessions did not find time to discuss the sanitary question. I think the adjourned session of May 8th will have to be adjourned again, as I believe the deputation to Mr. Ritchie will be later than that.

"I think that sanitary matters will fare worse under the Bill than they do at present, and I think medical men should raise an independent protest against Part III (Sir Lyon Playfair has, I see, spoken on the second reading).

"The proposal is that sanitary work shall be done by a District Council, which will be elected by the cottagers in rural sanitary districts, divided into wards for the purpose of election of one councillor.

"Practically speaking all ratepayers rated above £4 per annum will thus be disfranchised, as they will have a vast majority of smaller ratepayers to outweigh them. I do not think it would be possible to have a more ignorant council than that which will probably result from this proposal, and I should think that vaccination and all compulsory sanitation will in most cases be opposed by them.

"It is these clauses to which, in my opinion, public attention should be directed. The powers of the County Council can be increased after they have come into action.—Yours very truly,

"W. SPENCER STANHOPE.

"Cannon Hall, Barnsley, April 24th."

** The views here urged are those first brought forward by the State Medicine Committee of the British Medical Association, and forcibly urged by them upon the Royal Sanitary Commission and the Government, when the resulting Public Health Act was framed. It will be seen that the Parliamentary Bills Committee, acting in concert with the Society of Medical Officers of Health, whose co-operation they have courted, are now engaged in framing clauses to carry out the object stated (see report, p. 276). The Memorandum of the State Medicine Committee in 1871—a most valuable document, drawn up with the aid of Dr. Stokes, Dr. Farre, Dr. Rumsey, Dr. Sibson, and Mr. W. H. Michael, Q.C.—has been reprinted; and further memoranda on the existing situation have been prepared by the Parliamentary Bills Committee, with the aid of Mr. W. H. Michael, Q.C., and of Dr. Bond, of Gloucester. Medical officers of health and others interested in this highly important question are invited to apply for such copies of these documents as they may require for their own use and that of members of Parliament and others. They will be forwarded post free. Communications on the subject, by way of criticism or suggestion, should be addressed to Ernest Hart, Esq., Chairman of the Joint Subcommittee on the Public Health Clauses of the Local Government Bill, at the offices of the Association.

RESECTION OF THE PYLORUS FOR CANCER.

SIR,—A mortality of 70 per cent. of cases in which pylorectomy has been performed—to say nothing of the number of cases of cancer of the pylorus in which surgeons have commenced to operate with a view of resecting the pylorus, but have had to abandon the operation for some more expeditious method of relieving symptoms (such as duodenostomy or jejunostomy) from which the patients suffer—is more than sufficient reason for classing this procedure among the most severe and fatal operations in surgery. The reasons for this high rate of mortality are not far to seek. First, patients are rarely seen until the disease has existed so long that they are reduced to a state of approaching inanition or starvation, and the neighbouring mesenteric glands are more or less affected; and, secondly, the length of time occupied in performing the operation is such that the patients, who are invariably in condition not well adapted for prolonged operations, run great risks of immediate death due to shock, the result of the operation, or more remote death from exposure to infection. These dangers may be diminished in proportion to the shortening of the time consumed in the operation, and by inducing patients to submit to operation at as early a stage of the disease as possible.

Dr. Senn, of Milwaukee, in his admirable address entitled *Experimental Contribution to Intestinal Surgery*, with Special Reference to the Treatment of Intestinal Obstruction, read in the Surgical Section of the Ninth International Medical Congress at Washington last year, has given us the results of numerous experiments made by him on dogs and cats; and although, so far as I know, he has not published any experiments of resection of the pylorus on these animals, yet, from his description of operations such as gastro-enterostomy and resections of portions of the intestines, I think a great deal can be learnt which may enable us to reduce the time occupied in the performance of pylorectomy very considerably.

In reading Dr. Senn's very able paper, I was at once struck by the simplicity of the operations he suggested, and I can see the reason why, with some slight modifications, the same method should not be adopted for uniting the duodenum and stomach after excision of the pylorus.

I would suggest, then, supposing the preliminary steps of the operation to have been performed, and the cancerous pylorus with a portion of the stomach and duodenum to be brought out of the abdomen in the usual way, that the incision for the removal of the cancerous mass from the stomach should be somewhat of the shape: ~, so as to allow the end being fashioned to fit into the duodenum. Two plates of decalcified bone, of the same shape and about a quarter of an inch in width should be prepared, as recommended by Dr. Senn, with double holes in them or four places, about an inch apart, through which loops of aseptic silk should be passed through and tied so as to form loops on the back; then long threads of silk or carbolised catgut with needles corresponding in number to the loops, should be tied together and fastened securely to the loops on the bone. Each plate of bone being accurately adapted to the mucous lining of the stomach along the cut edges, the needles are passed through the entire thickness of the stomach walls, and the edges inverted so as to bring the two plates covered with the stomach walls accurately together. The corresponding sutures on the two plates are then tied; in tying the sutures, the centre one should be tied first, then the end ones, and finally the intervening threads.

The end of the stomach, which is to become the intussusceptum, is to be lined with a soft pliable rubber ring, made of a rubber band transformed into a ring by fastening the ends together with catgut sutures. This ring must be the length of the circumference of the end of the stomach, and about half an inch wide; the lower margin is stitched by a continuous catgut suture to the lower end of the stomach, which effectually prevents the bulging of the mucous membrane. Then a few carbolised catgut sutures are threaded, each with two needles. The needles are passed from within outwards, transfixing the upper portion of the rubber ring and the entire thickness of the wall of the stomach, and equidistant from one another. The cancerous pylorus should now be removed with scissors from the duodenum, all bleeding points being caught up and ligatured with fine catgut. The needles which are attached to the threads passing through the rubber ring and wall of the stomach are now passed through the peritoneal, muscular, and connective tissue coats of the duodenum at corresponding points about one-third of an inch from the margin, and when all the needles have been passed, an assistant makes equal traction

e threads, and the operator assists invagination, by turning in the margins of the end of the duodenum evenly with a director, and by gently pushing the end of the stomach completely into the duodenum. The invagination accurately made, the catgut sutures are tied only with sufficient firmness to prevent disinvagination, and vomiting occurs.

The invagination effects accurate, almost hermetical, sealing of the visceral wound. After a few days the rubber ring becomes detached and passes by the bowel, and the decalcified bone becomes absorbed.

The importance of this subject must be my excuse for the length of this communication, but it will be evident if the above method of performing the operation can be carried out with equal safety and efficiency as by the adoption of the Czerny-Lembert suture, there must be a material saving of time, with a proportionate less risk to the patient.—I am, etc.

16, Upper Wimpole Street.

FRED. B. JESSETT.

TEA AND TEETH.

SIR,—Having seen in a recent number of the JOURNAL an article on the old question of the harm in excess of tea-drinking, I write to allude to a point that does not appear to be touched upon. Some years since, when on duty at recruiting stations in the north of England, I took observation on the great amount of disease and loss of the teeth existing amongst the class of men suffering themselves. It became a cause of rejection of itself in great numbers. As far as my inquiries went I was led to trace it to the excessive tea-drinking indulged in by the working classes in the manufacturing towns, and this went on all through the day, whether with food or not. In fact, instead of five o'clock tea being the invention of the upper classes, it was found to exist to an injurious extent in the working classes long before that time. Tea seems to have a peculiar tendency to cause hyperemia in the tooth-sacs, leading to inflammation and, eventually, abscess of the fang, with, of course, dentalgia at every stage. Whether this special tendency was due to theine or tannin having an elective affinity for dentine it is not possible for me to say. It would be curious to know if medical men, practising in such manufacturing districts, had observed the deterioration of the teeth to be coincident with tea-drinking.

W. T. BLACK, F.R.C.S.E., Surgeon-Major.

CHIANTURPENTINE IN CANCER.

SIR,—I observe that in his lecture on diseases of the tongue, reported in your issue of April 21st, Mr. Christopher Heath refers to the treatment of cancer by the use of Chian turpentine, and says that he has employed the drug as an adjuvant to surgical treatment, but without having seen any benefit from it. In illustration of this opinion Mr. Heath mentions the case of a patient who came to me after having been operated upon by him, and who after operation had a return of the disease. The patient, Mr. Heath adds, died under the treatment, and in about the same time, without having received the slightest benefit.

Will you permit me to say that when this patient came to me he did not look as if he could live more than three or four weeks, instead of three or four months, the period for which he did live? The case was a hopeless one. It was one of recurrent cancer of the stump of the tongue and the floor of the mouth, the growth filling the mouth up to the level of the teeth. As Mr. Heath did not see the patient after I saw him, I cannot think him justified in contending that the sufferer received no benefit, and I am sure he will admit this when I say that after treatment by Chian turpentine there was an evident arrest of the growth, and a large portion of it sloughed away, so that the gums and the root of the tongue could be seen; and, as I have often observed in such cases, after taking the Chian turpentine for some time the enlarged submaxillary gland broke up and discharged freely. The immediate cause of death was hæmorrhage; a slough, separating from the stump of the tongue, exposed an artery which during one night bled to the extent of twenty ounces, the patient refusing to allow medical assistance to be obtained for the purpose of arresting the hæmorrhage.

Out of regard for your space I will not now discuss the general use of Chian turpentine as a palliative, and in some instances a remedial agent in cases of cancer. I will only say that generally speaking recourse is had to this agent only when the disease portends a fatal issue, and not at the commencement, when, as my own practice and the experience of others convince me, a bene-

ficial effect is capable of being produced. Even when the use of the knife is clearly desirable, the drug might be concurrently employed; indeed, in cases of the tongue and mouth I know that it is not useless, as I have seen several cases of cure, some of them recurrent cancer after operation.—I am, etc.,

Birmingham.

JOHN CLAY.

NAVAL AND MILITARY MEDICAL SERVICES.

ARMY MEDICAL DEFENCE FUND.

SIR,—In the JOURNAL of April 14th you say that the time has come when the medical officers of the army will have to offer, in the defence of their own interests, the most strenuous opposition to the changes which are now in contemplation. In order to do this effectually I would suggest the formation of an Army Medical Defence Fund, with a paid secretary, and a committee formed of pensioned officers of the department, the officers now in the service subscribing a small sum for the purposes of the committee.

The committee would endeavour to interest members of Parliament, issue printed letters and circulars setting forth the grievances of medical officers, and endeavouring to induce editors of professional as well as non-professional journals and newspapers to bring the subject before their readers.

One of the most effective ways of bringing pressure to bear on the authorities is to stop the supply of candidates, and this may be done by issuing a notice of the grievances of the department, which should be posted in every medical school in Great Britain and Ireland, setting forth that the service is not worth entering till the grievances complained of are redressed. I was a member of the Indian Medical Defence Fund, and we issued such a notice to every medical school in the kingdom, with the result that the number of candidates fell off to such an extent that at one or more of the competitions there were not men qualified to fill the vacancies which were before eagerly sought after. After this very great concessions were made and the status of the service was greatly improved, the committee being told that, but for their interference, all this would have been granted long before. This, of course, we believed!

If this idea meets with approval, I shall be very glad to give any information I can as to the mode of working the agitation. I need hardly say that the names of subscribers to the fund would be known to the committee and secretary only, and that merely a small sum of money would be necessary, which might be obtained by the secretary issuing a circular to every member of the service, setting forth the object of the committee and the amount required.—I am, etc.,

JAMES IRVING, M.D., Surgeon-General
Fowey, Cornwall, April 16th. Bengal Army, retired.

CHAIN OF RESPONSIBILITY IN MILITARY HOSPITALS.

REFERRING to a late instance in which the chain of responsibility for an incorrect diagnosis in a military hospital was stretched to its utmost, a correspondent points out that the said chain is very clearly and fairly laid down in paragraph 111 of the Army Medical Regulations, defining the duties of medical officers in hospitals as follows:—"They will invariably draw the attention of the medical officer in charge to all serious and important cases in their wards, immediately on such coming under their observation; and will, in all cases of professional doubt and difficulty, seek his advice, and consult with him as to the course to be pursued, but it must be clearly understood that each medical officer will be held personally responsible for the proper treatment of patients under his care."

This judicious regulation is, with reference to the fact that, while the medical officer in charge diagnoses, as far as possible, the nature of each case on admission, such diagnosis is necessarily subject to revision on a fuller investigation in the wards. Consultation by the whole hospital staff is often necessary in obscure cases, and should always be carried out, both for the patients' sake and for the mutual support and safety of the medical officers.

AIDE-TOI, LE CIEL T'AIDERA" takes exception to the action of an "Administrative Officer" in the appeal of two medical officers who had to sign on a mixed board in India under their juniors in the army. Instead of saying "Don't kick up a row," the "Administrative Officer" ought to have taken up the cudgels on behalf of those under him against the unjust Indian order. He contrasts this *laissez-faire* attitude with the vigorous action under similar circumstances of, say, a Commanding Royal Engineer. The Medical Department must learn to fight: its own battles or submit to be sat upon.

THE NAVY.

SURGEON H. J. GORDON has been appointed to the *Ganges*.

THE MEDICAL STAFF.

BRIGADE-SURGEON THOMAS RUDD, M.D., is promoted to be Deputy Surgeon-General (ranking as Colonel), *vice* R. W. Clifton, retired. Dr. Rudd's previous commissions are thus dated: Assistant-Surgeon, August 1st, 1857; Surgeon, November 18th, 1871; Surgeon-Major, March 1st, 1873; and Brigade-Surgeon, March 13th, 1883. He served with the 8th Hussars during the Indian mutiny in 1857-58, and was present at the capture of Kotah, battle of Kotaria and Koolahana (mentioned in despatches, medal with clasp). He also served in the Afghan war of 1878-80 (medal).

Surgeon-Major G. W. McNalty, M.D., F.R.C.S.I., is promoted to be Brigade-Surgeon (ranking as Lieutenant-Colonel), *vice* T. Rudd. He entered as Assistant-Surgeon, April 14th, 1863; became Surgeon, March 1st, 1873; and Surgeon-Major, April 1st, 1874. He was (says *Army List*) with the British Ambulance, B Division, during the Franco-German war from October, 1870, to March, 1871, and was present at the siege of Paris; accompanied the 22nd Prussian Division in the operations before Chartres and Orleans, and was present at several engagements (received the thanks of General von Wittsch, commanding the Division, for attending wounded on the field, German steel war medal). He subsequently proceeded to Le Mans and Connerre (French bronze cross for anaesthetising wounded French). Served in the Ashantee war in 1873-74. Was in medical charge of the Headquarters Staff, and present at the battle of Amoaful, battle of Ordahsu, and capture of Coomassie (mentioned in despatches, promoted Surgeon-Major, medal with clasp). Was Chief Surgeon and Commissioner of the National Aid Society in the Russo-Turkish war in 1876-77, and was present at the siege of Plevna. Served in the Afghan war of 1878-80, and was present with the expedition into the Lughman valley and in the engagement at Saiddabad; accompanied Sir Frederick Roberts in the march to Candahar, and was present at the battle of Candahar (mentioned in despatches, medal with clasp, and bronze decoration). Served in the Egyptian war of 1882 as personal assistant to the Principal Medical Officer with the Indian Contingent, and was present at the battle of Tel-el-Kebir (medal with clasp, 4th Class of the Osmanieh, and Khedive's star).

Surgeon-General JOHN IRVINE, M.D., Honorary Physician to the Queen, has been granted retired pay. His commissions are dated: Assistant-Surgeon, March 15th, 1850; Surgeon, October 2nd, 1857; Surgeon-Major, November 16th, 1859; Deputy Surgeon-General, November 8th, 1876; and Surgeon-General, June 1st, 1883. He served throughout the operations with Havelock's column in 1857 in medical charge of the Royal Artillery (Maude's), including the actions of Futtehpoore, Aoung, Pandoo Nuddee, Cawnpore, Oonao, Buserut Gunge, Mangawarra, and Alumbagh, relief and defence of the Residency at Lucknow (mentioned in despatches); with Outram's force in the Alumbagh from November, 1857, to March, 1858, and at the siege and capture of Lucknow by Lord Clyde (medal with two clasps, and a year's service).

Deputy Surgeon-General JOHN TULLOCH, M.D., is also granted retired pay. He entered as Assistant-Surgeon, June 7th, 1854; became Surgeon, February 13th, 1866; Surgeon-Major, March 1st, 1873; Brigade-Surgeon, November 27th, 1879; and Deputy Surgeon-General, May 2nd, 1883. He served with the 10th Regiment in the Indian campaign of 1857-58, including the suppression of the mutiny at Benares, capture of Atrawlea, advance to Lucknow, and actions at Chanda, Umeerpore, Sultampur, and Douraha, siege and capture of Lucknow, relief of Azimgurh, and operations near Jugdespore (medal with clasp).

Brigade-Surgeon W. J. WILSON, M.D., is granted retired pay. His commissions bear date: Assistant-Surgeon, April 1st, 1861; Surgeon, March 1st, 1873; Surgeon-Major, April 1st, 1876; and Brigade-Surgeon, March 28th, 1887. Dr. Wilson was with the Southern Afghanistan Field Force during the war in 1880-81, and during the campaign in the Soudan in 1885 he was in command of a bearer company (medal with clasp, and Egyptian bronze star).

Surgeon-Major S. G. WHITE, M.D., also has retired; having applied prior to January 1st last, he is granted the honorary rank of Brigade-Surgeon. He entered the service as Assistant-Surgeon, October 1st, 1860; became Surgeon, March 1st, 1873; and Surgeon-Major, November 2nd, 1875. He served with the Royal Artillery in the Hazara campaign of 1868, including the expedition against the tribes on the Black Mountain (medal with clasp). He was also in the Afghan war of 1878-80, and was present in the engagements at Ahmed Kheyl and Urzoo near Ghuznee (medal with clasp).

ARMY MEDICAL RESERVE.

THE undermentioned Surgeons-Major to be Surgeons-Major (ranking as Lieutenant-Colonels): FRANCIS BONNEY, 3rd Battalion East Surrey Regiment (late the 1st Surrey Militia); E. A. RAWSON, 8th Battalion King's Royal Rifles (late the Carlow Militia); O. B. STONEY, M.B., 3rd Battalion Prince of Wales's Lincaster Regiment (late the Klog's County Militia).

THE undermentioned Surgeons to be Surgeons-Major (ranking as Majors): ANDREW CLARK, 4th Middlesex Volunteers; WILLIAM HALL, F.R.C.S.E., 5th Lancashire Artillery Volunteers.

THE undermentioned Officers to be Surgeons (ranking as Captains): SURGEON W. H. B. CROCKWELL, Manchester Division Volunteer Medical Staff; SURGEON T. W. RICHARDSON, 1st Volunteer Battalion Norfolk Regiment (late the 1st Norfolk Volunteers); Acting-Surgeon R. B. PORTER, M.D., 2nd Lancashire Volunteers; Acting-Surgeon R. T. A. O'CALLAGHAN, 1st Flintshire Engineer Volunteers; Acting-Surgeon F. J. WALKER, M.B., 1st Volunteer Battalion Lincoln Regiment (late the 1st Lincoln Volunteers); Surgeon A. D. MACDONALD, M.D., 3rd Volunteer Battalion King's Own Scottish Borderers (late the 1st Dumfriess); Acting-Surgeon JAMES TURTON, 1st Volunteer Battalion Royal Sussex Regiment (late the 1st Sussex); and Acting-Surgeon J. A. MACKENZIE, M.B., 4th Lancashire Volunteers.

THE INDIAN MEDICAL SERVICE.

SURGEONS-MAJOR H. DE TATHAM, M.D., Bombay Establishment, has been allowed to retire. He entered the service as Assistant-Surgeon April 1st, 1867, and became Surgeon-Major twelve years thereafter. He was engaged in the Abyssinian war in 1867-68, and has the medal granted for that campaign.

The retirement of Brigade-Surgeon EMANUEL BONAVIA, M.D., Bengal Establishment, already announced in the *JOURNAL*, has received the sanction of the Queen.

Surgeon G. B. IRVINE, Bengal Establishment, has passed the examination in Hindustani by the lower standard.

THE VOLUNTEERS.

THE undermentioned gentlemen have been appointed Acting-Surgeons in the regiments specified: ROBERT DENMAN, 2nd Volunteer Brigade Southern Division Royal Artillery (late the 1st Dorset); Acting-Surgeon J. W. BEATTIE from the 1st Northumberland Artillery to the 1st (late 5th) Durham; and J. M. WHYTE, M.B., 1st Volunteer Battalion Royal Highlanders (late the 1st Perth).

MEDICO-LEGAL AND MEDICO-ETHICAL.

A HARD CASE.

AN appeal is being made to the profession on behalf of Mr. H. C. Bayfield, L.R.C.P., who has been subjected to heavy cost (amounting to £106) in defending an unfounded charge brought against him under the following circumstances: On February 26th, 1886, an attempt was made to poison his wife's mother by introducing landanum in tea prepared for her use. The police made exhaustive inquiries, and on their own responsibility, and entirely in opposition to Mr. Bayfield's wish, took the parlourmaid into custody on the charge. Fully persuaded in his own mind that the girl was not guilty, Mr. Bayfield supplied her with legal assistance. As may be remembered, the cook confessed to the crime. The parlourmaid, who was acquitted, then brought an action against Mr. Bayfield for £200 damages for false imprisonment. The case, of course, was decided in Mr. Bayfield's favour but the plaintiff having no means he was left to pay his own costs, which, as we have stated, amount to £106 on the solicitor's bill alone, to say nothing of the very heavy incidental expenses.

The following subscriptions have been received:—

	£ s. d.		£ s. d.
Henry James, 31, Sisters Avenue	3 3 0	J. Ince, M.D., Parntingham, Kent	1 1
Mr. Bellamy, 17, Wimpole Street	2 2 0	T. C. Hayes, M.D., 17, Clarges Street	1 1
J. Williams, M.D., 11, Queen Anne Street	2 2 0	Professor Chiene, Edinburgh	2 2
Mr. Pitts	1 1 0		
Hy. Whiting, Esq., Lavender Hill, S.W.	2 2 0		14 14

Subscriptions will be received by Ed. Bellamy, F.R.C.S., 17 Wimpole Street; R. F. Frazer, L.K.Q.C.P., etc., Lavender Hill; Tandy, L.R.C.P.Ed., 43, Cedars Road, Clapham; Joseph Sutcliffe, L.R.C.P.Ed., 641, Wandsworth Road; Fredk. Hunter, L.R.C.P., Haycroft House, Lavender Hill.

THE LAW AS TO INFECTION.

TAYLOR v. SPALDING.

THIS case, tried before Mr. Baron Huddleston and a special jury raised some important questions of public health law interesting to medical practitioners and the public. It was an action brought by a lodging-house keeper at a seaside resort to recover damage on the ground that the defendant, who had on June 16th, 1887, taken rooms in her house for herself and four children, had imported the infection of scarlet fever into it, and so caused the house to be shut up for a considerable time. In May the defendant's cook had an illness resembling scarlet fever, but attributed to drain-poisoning. The children were, however, sent away, but the day after their return developed sore throat. The medical man did not consider that the children had scarlet fever, and looked upon the disease as diphtheritic. The children quickly regained their health, and it was not until June 25th that one of the sons, who had not been previously ill, sickened with scarlet fever. The defendant's family left the house which was shut up for six weeks, disinfected, and re-papered, but scarlet fever again broke out among fresh visitors.

Mr. BARON HUDDLESTON said that the questions which he should leave to the jury would be: 1. Did the infection which communicated the scarlet fever to the son originate in connection with the sickness in defendant's house? 2. Did the defendant know or ought she to have known, that there was any danger of infection from any of her children at the time she answered the question of the plaintiff's daughter on that subject? 3. Was there on the part of the defendant a wilful concealment of the risk of infection? If the learned judge said, the first question was answered in the negative there would be an end to the plaintiff's case; if, however, in the affirmative, then the question arose as to whether there was at law an implied warranty on part of a person taking lodgings that he was free from infectious or contagious illness. Upon that he had no hesitation in holding that there was no such

y 5, 1888.]

and warranty in cases where the person taking lodgings was aware of the danger of infection, and even in cases where *scienter* was clear, he had his doubts unless there was evidence of fraudulent concealment of the fact. In cases of express warranty, however, there would be no doubt, but here there was a plea in the statement of claim. The judge considered that the parties ought to come to terms, and the case was settled out of court upon terms which did not require.

MEDICO-PARLIAMENTARY.

THE HORSE TAX.

Our last announcement of the following petitions have been lodged by 11 men against this tax: By Mr. H. Bass, from Great Haywood and Sany Mr. Yerburch, from Chester; by Sir H. Fletcher, from Shoreham, and Southwick; by Sir E. Lechmere, from the president and members of the Worcestershire and Herefordshire Branch of the British Medical Association; by Mr. L. Fry, from Walter E. Horland and others; by Mr. A. Reynolds, from members of the profession in the district of Alton; by Mr. J. Lands, from Aberayron and Lampeter; by Mr. Stanley Leighton, from Wrexham; by Mr. A. Egerton, from Eccles, Swinton, Pendlebury, and Walkers; by Sir W. Lawson, from Maryport; by Mr. Haldane, from Haddington; by Mr. J. Kennaway, from Dr. Southcott, Axmouth; and by Mr. W. Lowther, from Kirkby Stephen.

HOUSE OF COMMONS.—Monday, April 30th.

Medical Officers.—Sir H. FLETCHER asked the Secretary of State whether it had been customary to grant medals, gratuities, and other rewards, to the medical officers and establishments employed on board hospital ships in time of war; and whether it was the case that the medical officers who served on board hospital ships in the Abyssinian, Ashantee, Egyptian, and Soudan campaigns received medals, including those who served on board the Indian hospital ship *Cesarewitch* at Suakim.—Mr. E. STANHOPE replied to both questions in the affirmative.

Epidemic of Pneumonia in Fermoy Barracks.—In reply to Dr. STANHOPE, Mr. E. STANHOPE said that, probably on account of the variable weather, lung disease had been rather prevalent in the barracks of Ireland, and, in the weekly return to April 20th from the 1st Dragoon Regiment at Fermoy, it was shown that there had been thirteen admissions for pneumonia, and one death. The general state of the barracks was reported to be satisfactory, and no other than the weather had been assigned for the outbreak. Further inquiry had, however, been ordered.

Tuesday, May 1st.

Vaccination of Infants.—Mr. RITCHIE, in answer to Mr. W. STANHOPE, said his attention had been drawn to the two inquests referred to by the hon. member. As regards the case of the child in the Greenwich Infirmary, the verdict of the jury at the inquest was not that the child died from being vaccinated when six days old, as stated in the question, but from being accidentally suffocated while at the mother's breast. The child died in the infirmary thirteen days after the vaccination, and, according to the statement of the medical officer of the guardians, was perfectly healthy at the time of the vaccination and at the time of being brought to the infirmary. A *post-mortem* examination showed, however, that the child had one lung in a state of collapse, probably at the time of birth, and had other congenital malformations; the jury, having this evidence before them, added to their verdict a rider to the effect that the child was, in their opinion, in an exceptionally delicate state of health, and that its vaccination was much to be regretted. As he had already stated, however, the cause of death was accidental suffocation. As regards the case of the child born at Queen Charlotte's Hospital, it was vaccinated when five days old, as was the practice in that hospital unless the mother objected. In this case the mother was aware of the rule, and did not object. The child, when discharged from the hospital, was certified by the physician to be in good health. The child died when just over a month old. The coroner stated that death was not due to the vaccination, but to injury to the vaccination wound, followed by inflammation, which was probably of an erysipelatous character.

Small-pox at Sheffield.—Mr. RITCHIE, in answer to Mr. PICTON, made an exhaustive inquiry into the circumstances of the epidemic of small-pox at Sheffield by one of the Board's medical inspectors still in progress, and added, in reply to Mr. VINCENT, that the epidemic had been so far suppressed that the town could be said to be clear of small-pox.

Employment of Retired Officers M.S.—Mr. E. STANHOPE, in

reply to Dr. TANNER, said retired medical officers would be employed from time to time as their services became necessary. When so re-employed their remuneration was limited by the Royal Warrant to a sum of £150 a year beyond their retired pay, and their service did not count towards increase of retired pay. He might add that this re-employment during peace was entirely at the option of the retired officer. If a retired officer were called out for service in a time of national emergency, the conditions of employment would be altogether different.

Wednesday, May 2nd.

The Early Closing Bill.—Sir WALTER FOSTER, in seconding the motion for the second reading of the Bill on general grounds, with reference to the effect on the health of the population, referred to the public health question involved. As long ago as 1845 the Commissioners reported that the health of those persons who were compelled to work in the vitiated atmosphere of shops and private dwellings was greatly injured. Twenty years ago he himself had undertaken an inquiry into this subject, and he had ascertained that confinement in factories and workshops largely tended to the increase of lung-disease among the persons, especially the females, employed in them. The decennial report of the Registrar-General showed that while the death-rate among the agricultural class was as 644, that among the shopkeeping class was as 877. In the same report it was shown that, taking the death-rate of fishermen, who lived in the purest air, at 198, that of agricultural labourers was 237, that of persons employed in grocers' shops was 283, and that of persons employed in drapers' shops was 430. No figures could be more eloquent than these, which showed the necessity of this Bill for the purpose of securing the health of the population.—After a lengthy discussion the House divided, and the Bill was lost by a majority of 183.

UNIVERSITY INTELLIGENCE.

CAMBRIDGE.

At the congregation on Thursday, Edwin Cooper Perry, M.A., late Fellow of King's College, Senior Classic 1880, assistant physician at Guy's Hospital, was admitted to the degree of M.D. A grace proposing the purchase of the site of the Perse School, adjoining the new Chemical Laboratory, was carried.

GLASGOW UNIVERSITY.

EXTENSION BOARD.—This Board has appointed the following lecturers on scientific subjects:—Magnus Maclean and John G. Kerr, M.A., on Natural Philosophy and Mathematics. Patrick Geddes and A. Somerville, B.Sc., on Botany and Zoology. Yule Mackay, M.D., and Bruce Young, M.B., on Anatomy. J. McGregor Robertson, M.D., and W. Snodgrass, M.B., on Physiology. G. G. Henderson, M.A., B.Sc., on Chemistry or Mineralogy. D. Forsyth, M.A., B.Sc., on Physical Geography. J. H. Fullerton, M.A., B.Sc., on Geology. It has been further intimated that each course of lectures will cost about £50, but where there may be difficulty in raising this sum, the Board will endeavour to meet the requirements of each case as far as possible.

UNIVERSITY OF DURHAM.

FACULTY OF MEDICINE.

EXAMINATION FOR Degrees in Medicine and Surgery, Easter Term, 1888.—At the First Examination for the Degree of Bachelor in Medicine, the following candidates satisfied the examiners:

In Elementary Anatomy, Elementary Physiology, Chemistry and Chemical Physics, Botany and Medical Botany.

A. W. Latimer, College of Medicine, Newcastle-upon-Tyne; W. Turnbull, College of Medicine, Newcastle-upon-Tyne; J. D. Wardale, College of Medicine, Newcastle-upon-Tyne.

In Elementary Anatomy and Elementary Physiology.

A. C. Baea, St. Bartholomew's Hospital; R. C. Brown, College of Medicine, Newcastle-upon-Tyne; A. J. Dale, College of Medicine, Newcastle-upon-Tyne; W. M. Davison, College of Medicine, Newcastle-upon-Tyne; J. P. Iredale, College of Medicine, Newcastle-upon-Tyne; E. W. Kirkman, Sheffield School of Medicine; F. W. Standish, College of Medicine, Newcastle-upon-Tyne.

In Chemistry with Chemical Physics, Botany with Medical Botany.

F. H. Alderson, Middlesex Hospital; H. A. Claridge, Queen's College, Birmingham; C. V. Dingle, College of Medicine, Newcastle-upon-Tyne; E. W. Diver, University College; C. P. Felvus, College of Medicine, Newcastle-upon-Tyne; F. E. France, College of Medicine, Newcastle-upon-Tyne.

Tyne; E. Gane, St. Bartholomew's Hospital; R. McCoull, College of Medicine, Newcastle-upon-Tyne; J. P. Molyneux, Owens College; A. B. Wear, College of Medicine, Newcastle-upon-Tyne; G. E. M. Wood, Guy's Hospital; J. Wood, Owens College.

In Chemistry with Chemical Physics.

T. A. Collinson, M.R.C.S., L.S.A., College of Medicine, Newcastle-upon-Tyne; A. Jervis, L.R.C.P., M.R.C.S., St. George's Hospital; J. S. Tew, M.R.C.S., L.S.A., University College; A. A. D. Townsend, Queen's College, Birmingham.

Old Regulations. Botany only.

L. A. Baine, College of Medicine, Newcastle-upon-Tyne.

Chemistry only.

W. J. Burleigh-Robinson, London Hospital, and College of Medicine, Newcastle-upon-Tyne; N. Raw, College of Medicine, Newcastle-upon-Tyne.

At the Second Examination for the Degree of Bachelor in Medicine, the following candidates satisfied the examiners.

Second Class Honours.—A. Gane, St. Bartholomew's Hospital.

Pass List.—J. Arnott, College of Medicine, Newcastle-upon-Tyne; R. C. Benington, L.R.C.P., M.R.C.S., L.S.Sc., St. Thomas's Hospital; G. B. S. Darter, St. Thomas's Hospital; A. E. Davis, College of Medicine, Newcastle-upon-Tyne; E. Gane, St. Bartholomew's Hospital; J. L. Joyes, Middlesex Hospital; F. B. Rutter, London Hospital; H. L. Rutter, London Hospital; A. J. Swallow, St. Thomas's Hospital; A. M. Wilson, St. Thomas's Hospital.

At the Examination for the Licence in Sanitary Science, the following candidates satisfied the examiners.

F. Eastes, M.D., M.R.C.S. Eng.; J. P. Williams-Freeman, M.B., M.R.C.S. Eng.

OBITUARY.

HORACE TURNER, M.R.C.S. ENG., L.S.A.

THE death of Mr. Horace Turner, of Norwich, at the age of 39, occurred on March 27th under peculiarly melancholy circumstances, the deceased gentleman having contracted diphtheria whilst attending his patients. He was a student of University College, and formerly house-surgeon at University College Hospital, house-physician at the Middlesex Hospital, and resident medical officer of the Female Lock Hospital. He had been in active practice in Norwich for about fifteen years, where he held some local appointments. He was medical superintendent of the Bethel Asylum and surgeon to the Jenny Lind Infirmary. He was a member of the Norwich Medico-Chirurgical and Meteorological Societies. He leaves a wife and four children.

CHARLES GOODWIN, M.R.C.S. ENG., L.S.A.

NORWICH has lost another of its most respected practitioners in the person of Mr. Charles Goodwin, who died on March 22nd at the age of 76. The deceased, who was the son of a solicitor of that city, studied at St. Bartholomew's Hospital. He was formerly house-surgeon to the Norfolk and Norwich Hospital. Having filled the post of senior surgeon to the Norfolk and Norwich Eye Infirmary, he subsequently held the position of consulting-surgeon to that institution. He was a Justice of the Peace, and occupied many influential positions in connection with local charities, taking a keen interest in all that concerned the welfare of the city.

WILLIAM ALEXANDER, M.D. EDIN.

WE have to announce the death of Dr. William Alexander, who died somewhat suddenly at his residence at Blackwell Lodge, Halifax, on April 13th, at the ripe age of 81. Dr. Alexander was the son of Dr. Gervase Alexander, and grandson of Dr. Robert Alexander, of Hopwood Hall, and for two centuries the Alexanders have practised as medical men in the Halifax district. The deceased gentleman was born in 1806, and educated at Hipperholme Grammar School, and afterwards at the University of Edinburgh. He took his degree of M.D. in 1830, and commenced practice in his native town, where for many years he enjoyed a large and lucrative connection. He was elected a Fellow of the College of Physicians in 1869, was a member of the Council of the University of Edinburgh, honorary physician to the Halifax Infirmary for nearly half a century, and on his retirement two years ago was appointed consulting physician to that institution. He was a member of the magisterial bench. He was the author of several works, including *The Spa Water and Sea-bathing at Scarborough*, *The Adulteration of Food and Drinks, etc.*, *The Sanitary Condition of Halifax, etc.* By Dr. Alexander's death Halifax has lost one of its best known and most respected citizens.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

BELFAST WATER SUPPLY.

THE public mind of Belfast is at present much exercised alarming statements which have been made before some of public boards and in the press regarding the alleged contamination of the water supply by sewage matter, surface water, and other impurities. On April 9th a meeting of the Public Health Committee of the Town Council was held to consider the statement of Councillor Finnegan. This gentleman states that a few weeks ago, as he was walking near one of the reservoirs of the Water Commissioners, he was surprised to see a number of dead fish lying about. Seeking for a cause for this remarkable fact, he examined the sources of the reservoir, and found that a tunnel constructed some time ago for the purpose of draining off polluted water proceeding from the Oldpark Mill and adjoining meadow had become leaky, and was discharging into a watercourse leading to the reservoir. He further stated that at one portion of the waterworks there was a metal pipe carried over the reservoir at a height of only two feet, that this pipe contained sewage matter and that at the time of his examination matter of a foetid and disgusting character was escaping into the reservoir.

These extraordinary statements naturally excited the utmost astonishment and alarm. The question is being thoroughly examined by the Water Commissioners, the public health officer and the borough analyst, and is still under consideration. The results hitherto made public are mainly negative. The public health officers and the borough engineer visited the waterworks and were unable to verify the statements made. They saw dead fish, and deny that sewage matter finds its way into public reservoirs. They decline, however, very properly to press any opinion regarding the quality of the water until they obtain the results of the examination of the borough analyst, whom six specimens have been sent. Mr. Macassey, the engineer of the Water Board, states that the water escaping from one of the culverts, and alleged to be very foul, is only discoloured by a little iron rust. Councillor Stewart, M.D., who took a sample of the leaking matter, finds that it contains nothing worse than face water.

It is also clear that the very high death-rate which has prevailed in Belfast during the past winter is not directly attributable to impurity of water, the chief sources of mortality having been measles and whooping-cough, typhoid fever not having prevailed to any abnormal extent. While we should deprecate public panic until the alleged facts are more thoroughly investigated, the public attention now directed to the water supply of Belfast can hardly fail to exercise a salutary influence. That supply has certainly been inadequate in point of quantity during the recent period of drought, but it is only fair to the Water Commissioners to recognise the efforts which they are now presenting to give the town a thoroughly satisfactory supply. The engineering works at present in progress can, however, be completed for some time, and it is eminently desirable that in the interval which must elapse until then every precaution should be taken to preserve the great and growing population in Belfast from the manifold evils resulting from defective or impure water supply.

NOTIFICATION OF INFECTIOUS DISEASE.

OFFICIAL STATEMENT BY THE CHAIRMAN OF THE SELECT COMMITTEE OF THE HOUSE OF COMMONS.

THE Select Committee of the House of Commons, consisting of Mr. George Hastings (Chairman), Dr. Farquharson, Mr. Harcourt, Mr. Mayne, Mr. Powell, Mr. Sexton, Mr. J. L. Wharton, and Mr. Williams, sat to consider the clauses in the Kingston Improvement Bill, on Wednesday, April 25th, when Dr. Biddle, Dr. Corbet, Dr. Paradise appeared on behalf of eighteen members of the medical profession to oppose the notification clauses, so far as they provide for the compulsory notification of infectious diseases by medical men, and urged the arguments which have already been stated in these columns in favour of the limitation of compulsion to the occupier of the house.

The Chairman stated that it was not necessary for the committee to address the Committee in support of these clauses, but the

tee were anxious that in giving their decision with regard to retention of these clauses in the existing form, he should say few words, for which publicity was desired. He pointed out that the Committee had now sanctioned the insertion of these clauses in many Bills dating from the year 1882, because they believed them to be framed and to have acted for the benefit of the whole community, the medical profession included. After giving some examples of the well-known evils following from the total absence of notification, he proceeded to speak as follows: Zymotic disease is like fire—you can put it out very easily and quickly at its commencement, but allow it to spread, and it very soon gets beyond your control. I venture to say that a very large proportion of zymotic diseases in this country are caused by the absence of notification where the disease breaks out in the locality. According to the statement of the President of the Local Government Board, made in the House of Commons a very few weeks ago, there are upwards of fifty boroughs in the United Kingdom that have this system of notification of disease in force. I ask, what proof is there that in any one of those places any mischief has followed? We have had two instances given to us to-day; one in Croydon where it has been in existence four years, during which time one case of prosecution is recorded; one other in Croydon, where for some reason or other—we know nothing of the facts—a medical man has been convicted for not complying with the Act. I think that really proves the ease for notification. In other towns you have had this Act in force for years, and only two cases for complaint have arisen, which proves that the Act is administered with perfect satisfaction both to the public and the medical profession. In Edinburgh the medical profession stands very high, exercising immense influence in the city and university through their own high attainments. They were at first opposed to the Act, but are now completely reconciled to it, and admit that it does a great deal of good, and according to a statement sent to me by Dr. Littlejohn, there is not a single medical practitioner in the city of Edinburgh who is now in any way opposed to the working of this system of notification. It has been said that all that could equally be done if the duty was left wholly upon the householder. I totally differ from that opinion, and I must act upon my own conscientious conviction in the matter. Is it to be proposed that if a man is gaining his living by keeping a lodging-house he will willingly send notice that infectious disease is in his house? And do we not know that one of the most common causes of the spread of a scarlet fever is through people contracting it in lodging-houses, where its existence has been carefully concealed, and they have gone out from those places and spread it broadcast? To leave it to the occupier to notify is, in my opinion, to do away with the utility of the Act, so much so that if it were left to them I should be in favour of striking out the clause altogether, for that would be simply a delusion and a snare. There is one great town in Great Britain which did adopt that very provision, which is the town of Greenock, where they imposed notification only on the householder, and I have the authority of the medical officer of health of that town for saying that the system of notifying by the householder proved a complete failure. No one notifies unless they want to do so for some reason of their own, and if they do not want to notify they simply leave it alone, and there is no remedy either for the medical officer or the sanitary authority of the borough. He has placed these facts upon record, and has printed them, and no one can doubt the result. I am very well aware that the British Medical Association has expressed an official objection to these clauses, but we all know how these votes are taken. I had the honour of being present at one of the discussions of the Association on this question, and the majority against was exceedingly narrow. I would not do the medical profession at large the dishonour of thinking that they, or purely private reasons of their own, are in favour either of concealment of disease or of the spread of zymotic disease amongst the community. I am quite sure that, when these provisions have been made—as they will be made by Parliament—universal, and applicable to the whole community throughout Great Britain, that the medical profession will within three years themselves acknowledge that no wiser piece of legislation has ever been made.

Mr. Powell: Being connected intimately with the borough of Bradford, where the notification of infectious disease is enforced by these clauses, I wish to bear witness to the salutary operation of the Act in preventing the spread of disease, saving many valuable lives, and giving entire satisfaction to the whole population of that great borough.

The following letter has been addressed to the Right Honourable C. T. Ritchie, Bolton, February 20th, 1888.

SIR.—Some time ago a series of queries, anent the notification of infectious disease, was sent by your Board to medical officers of health. The medical officer of health for Bolton, without consulting either the medical men of Bolton, or the Town Council, forwarded his replies to you. The medical men of Bolton wish you to know that the action of our medical officer of health has been repudiated by vote of the Town Council, and emphatically condemned by 98 per cent. of the medical practitioners in Bolton. The opinion of the latter body is set forth specifically in the subjoined protest, unanimously adopted at a meeting of the profession held on February 2nd, 1888. At that meeting I was instructed to forward this protest to you, and to ask for its careful consideration.—I am, Sir, your obedient servant,

NORMAN MCLISEE.

Query 2. We assert that the removal is carried out most capriciously. In some cases, where isolation is carried out satisfactorily, the patient is nevertheless hustled off to the Fever Hospital. In other cases, where removal was urgently required, the sanitary authorities have refused to take action. In our view a preference in removal is given to persons of the better class, and to persons outside the borough. Moreover, serious hardship is often inflicted on members of the working class. The wives are threatened and terrorised; the husbands are stopped from their work, or they are compelled to find lodgings elsewhere. Thus, the family is either papered or its resources seriously crippled at the hour of its utmost need. All this is done without any compensation whatever.

Query 3. We object to compulsory notification by the medical attendant, as an infringement of the confidential relations which subsist between patient and practitioner. Speaking from an abundant clinical experience, we emphatically assert that compulsory notification does often lead to the concealment of infectious disease; and as the medical officer of health is not, and never has been, in general practice, we hold that his opinion on this question is absolutely worthless.

Query 4. We agree that notification should be compulsory, but that the compulsion ought to rest on the householder. The proposal to provide an isolating hospital we hold to be simply preposterous. It would inevitably lead to the spread of infectious disease.

Query 5. The medical officer of health states that he restrains scarlet fever. In point of fact, the number of deaths from that disease in 1887 was double that of 1888. Again, his percentages are wrong; for in the first half of his favourable decade, many zymotic patients were removed to the workhouse. Some of them died there, and their deaths were registered as deaths occurring out of the borough.

Query 6. The proposal to give the medical officer of health and his inspectors power to enter any house in which infectious disease is believed to exist we characterise as most unwarrantable. We deem it probable that, if such a power were ever attempted to be enforced, it would in most cases be strenuously resisted. It may also be added under this head, that medical men not resident within the borough, as well as illegal practitioners, are not seldom preferred to attend cases of infectious disease in the borough, because they are not required to report. Generally we consider it, in the highest degree doubtful whether the action of medical officers of health, with respect to persons, has any tendency to restrict the spread of infectious disease.

HEALTH OF ENGLISH TOWNS.—During the week ending Saturday, April 28th, 5,781 births and 3,400 deaths were registered in the twenty-eight large English towns, including London, which have an estimated population of 9,398,273 persons. The annual rate of mortality per 1,000 persons living in these towns, which had been 21.9 and 19.9 in the two preceding weeks, further declined to 18.9 during the week under notice. The rates in the several towns ranged from 14.7 in Bolton and in Hull, and 16.1 in Brighton and in Newcastle to 24.3 in Wolverhampton, 24.8 in Manchester, and 25.9 in Blackburn. The mean death-rate in the twenty-seven provincial towns was 20.0 per 1,000, and exceeded by 2.5 the rate recorded in London, which was only 17.5 per 1,000. The 3,400 deaths registered during the week under notice in the twenty-eight towns included 328 which were referred to the principal zymotic diseases, against 359 and 364 in the two preceding weeks; of these, 143 resulted from whooping-cough, 48 from scarlet fever, 38 from measles, 35 from diphtheria, 34 from diarrhoea, 23 from "fever" (principally enteric), and 7 from small-pox. These 328 deaths were equal to an annual rate of 1.8 per 1,000; in London the zymotic death-rate was 1.9, while in the twenty-seven provincial towns it averaged 1.7 per 1,000, and ranged from 0.0 in Birkenhead and Preston, and 0.4 in Brighton and in Sunderland to 3.0 in Oldham and 3.4 in Cardiff. Measles caused the highest proportional fatality in Leicester, Bradford, and Bristol; scarlet fever in Oldham, Blackburn, and Cardiff; whooping-cough in Wolverhampton, Halifax, Manchester, and Salford; and "fever" in Leicester. The 35 deaths from diphtheria in the twenty-eight towns included 22 in London and 3 in Oldham. Of the 7 fatal cases of small-pox recorded during the week under notice in the twenty-eight towns, 5 occurred in Sheffield, 1 in London, and 1 in Bristol. The Metropolitan Asylums Hospitals contained 21 small-pox patients on Saturday, April 28th, of which 3 had been admitted during the week. These hospitals also contained 967 scarlet fever patients on the same date, against 1,002 and 961 at the end of the two preceding weeks; there were 79 admissions during the week. The death-rate from diseases of the respiratory organs in London was equal to 4.2 per 1,000, and was below the average.

HEALTH OF SCOTCH TOWNS.—In the eight principal Scotch towns, 839 births and 530 deaths were registered during the week ending Saturday, April 28th. The annual rate of mortality in these towns, which had been 20.8 and 21.2 per 1,000 in the two preceding weeks, declined again to 21.0 during the week under notice, but exceeded by 2.1 per 1,000 the mean rate during the same period in the twenty-eight large English towns. Among these Scotch towns the lowest rates were recorded in Greenock, Aberdeen, and Leith, and the highest in Glasgow and Paisley. The 530 deaths in these towns during the week under notice included 49 which were referred to the principal zymotic diseases, equal to an annual rate of 1.9 per 1,000, which slightly exceeded the mean zymotic death-rate during the same period in the large English towns. The highest zymotic rates were recorded in Perth and Paisley. The largest proportional fatality of measles occurred in Glasgow, and of whooping-cough in Glasgow and Aberdeen. The 5 deaths from diphtheria recorded in these towns during the week included 4 in Glasgow. The mortality from diseases of the respiratory organs in these towns was equal to 4.5 per 1,000, against 4.2 in London.

THE LOCAL GOVERNMENT BILL: SANITARY ADMINISTRATION.

DR. PAUL Q. KARKEEK (Medical Officer of Health for Torquay and St. Mary's church) writes: I foresee that the proposed new county medical officer may possibly turn out a doubtful blessing. If this officer be chosen by the County Council, there is a probability of all the evils now ascribed to local influences being perpetuated. Some protégé of a local magnate, or a raw boy with a new diploma in sanitary science, or perhaps a difficult man to work with, may get appointed, and turn out to be a round peg in a square hole, or worse.

I venture to suggest that these county medical officers be deputies of the Local Government Board sent into a county or division to work, and answerable to the Board, although advising the County Council. Let them form a "Sanitary Service of the Local Government Board," just as the "Army Medical Department." Such men, if impracticable or unsatisfactory in any way, could be removed by the Board, or admonished, advised, etc., and they would carry more weight from the fact of their being the representatives of the Board. But if the officer be elected by the County Council, he would be then for ever subject to social and other influences, and answerable only to a few local magnates, whom he might keep in with. In fact, he might do what, how, and when he liked. The nearest resemblance I can point out to my idea of a county medical officer is that very active, independent set of men called, I think, surveyors of taxes, though I should be sorry to see the county medical officer so unpopular. If my idea of a Sanitary Service be adopted, very many probable evils will be avoided and many advantages follow.

ROYAL SURGEON writes: With reference to your leading article of April 28th, allow me to suggest that the appointment of sanitary officers should be vested neither in the County nor the District Councils, though the former proposition is obviously the less objectionable; but that such offices should be filled by a competitive examination open to all qualified medical men of a certain age and standing. This course would put an end to the familiar and, too often, successful attempts to secure these appointments for ill-qualified persons, by backstair influence and petty party and religious intrigues. The ratepayers would have the best guarantee that the best man was selected, while aspiring candidates would have an opportunity of gaining the object of their ambition by honourable competition with their fellows, instead of having, hat in hand, to solicit the votes of village magnates, while if successful they would enter on their duties unhampered by obligations to their village patrons.

HUMAN AND CALF LYMPH.

MANCHESTER, judging from the course and similarity of the vesicles obtained from calf lymph to those of humanised lymph (taking as a standard the calf lymph used at the Animal Vaccines Establishment of the Local Government Board), the protection would appear to be almost certainly the same, but there exist no statistics in Great Britain to prove it. With reference to his second question, "Manchester" will find a full account in the Report of the Medical Officer of the Local Government Board for 1882, page 34; also a shorter account in the JOURNAL for June 28th, 1884. As regards the private vendors of lymph mentioned in "Manchester's" letter, we have no opportunity of expressing an opinion.

TEXTBOOKS ON HYGIENE.

H. J. T. will find advice as to books to read for the diploma in Public Health at page 49 and at page 724 of the current volume of the JOURNAL.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen, having conformed to the by-laws and regulations, and passed the required examinations, were admitted Licentiates of the College on April 26th.

H. P. Ainsworth, Guy's Hospital; **V. Allen**, St. George's Hospital; **J. N. Anwyll**, St. Bartholomew's Hospital; **J. W. Applegate**, St. Bartholomew's Hospital; **J. E. Appleton**, St. Mary's Hospital; **C. H. Ashford**, St. Bartholomew's Hospital; **T. Austen**, Charing Cross Hospital; **H. T. S. Aveline**, Bristol; **J. L. Aymard**, Guy's Hospital; **G. A. Ballingall**, Edinburgh University and St. George's Hospital; **A. M. Barford**, St. Bartholomew's Hospital; **H. Barnett**, Cambridge University and St. Thomas's Hospital; **H. N. Baron**, King's College; **J. C. Barr**, St. Mary's Hospital; **L.**

Beckett, London Hospital; **D. T. Belding**, St. Bartholomew's Hospital; **E. S. Bell**, St. Thomas's Hospital; **R. Bird**, St. Bartholomew's Hospital; **A. H. Blunt**, St. Thomas's Hospital; **S. A. Bontor**, St. Bartholomew Hospital; **R. F. Bour**, University College; **R. W. Boyce**, University College; **G. Braide**, Manchester; **R. J. Braye**, London Hospital; **H. Bristowe**, St. Thomas's Hospital; **E. H. Brock**, Guy's Hospital; **F. Brooke**, St. Mary's Hospital; **J. D. Brown**, St. George's Hospital; **H. Cappe**, University College; **A. E. Chambers**, Manchester; **F. Chand**, Newcastle-upon-Tyne; **R. S. Charsley**, Westminster Hospital; **C. H. Clifton**, University College; **T. Clifford**, Newcastle-upon-Tyne; **J. G. Colby**, St. Bartholomew's Hospital; **C. Collier**, London Hospital; **F. Collins**, University College; **E. Cooper**, Charing Cross Hospital; **F. Corbridge**, London Hospital; **J. K. Couch**, Middlesex Hospital; **J. J. Coulter**, London Hospital; **A. E. Cox**, St. Thomas's Hospital; **H. C. F. Crisp**, London Hospital; **J. D. Cruickshank**, Guy's Hospital; **G. W. B. Dani**, St. George's Hospital; **B. A. Daniell**, Dublin; **C. S. Dowdell**, University College; **C. W. Edwards**, Middlesex Hospital; **W. S. Fenwick**, London Hospital; **H. S. Fremlin**, Westminster Hospital; **O. B. Flux**, King's College; **P. G. Gilmour**, St. Bartholomew's Hospital; **P. D. Goldsmith**, Toronto University, Ontario; **A. Goulston**, St. Thomas's Hospital; **F. Gray**, Charing Cross Hospital; **T. J. Head**, London Hospital; **E. M. Hearn**, Guy's Hospital; **F. Heasman**, St. Bartholomew's Hospital; **S. M. Hewthwaite**, St. Bartholomew's Hospital; **G. A. Heberden**, St. George's Hospital; **W. M. Helsham**, St. Thomas's Hospital; **P. Hicka**, St. Bartholomew's Hospital; **H. Hill**, Bristol; **F. S. D. Hogg**, St. George's Hospital; **W. S. Holford**, St. George's Hospital; **F. K. Holman**, Guy's Hospital; **T. Hudson**, Bristol; **A. H. W. Hunt**, Westminster Hospital; **J. A. Hutcheon**, Middlesex Hospital; **A. W. L. Jones**, St. Bartholomew's Hospital; **R. Jones**, London Hospital; **H. R. Kenwood**, London Hospital; **J. Ker**, St. Thomas's Hospital; **W. B. Lane**, St. Bartholomew's Hospital; **W. Lockyer**, St. Thomas's Hospital; **K. McLaren**, St. Bartholomew's Hospital; **W. J. Maillard**, Guy's Hospital; **W. L. Mathias**, St. Thomas's Hospital; **G. H. Metcalfe**, Guy's Hospital; **S. C. H. Moberly**, St. Bartholomew's Hospital; **J. C. Molson**, London Hospital; **S. G. * Approved by Examining Board.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH, AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the April sittings of the examiners for the Triple Qualification, held in Glasgow, the following candidates passed respective examinations:

First Examination.

W. P. Lonergan, F. Rawlings, junior, A. J. D. Reid, J. C. Ferguson, W. A. Davies, J. Suley-Wheeler, J. T. Hislop, and J. C. Sturdy, of the Glasgow Medical School; **C. E. Lester**, of the Edinburgh School; **J. McCullor**, of Queen's College, Belfast; **P. B. M'Laughlin** and **P. F. Goldfrey**, of Dublin Medical School; **W. Ramsay**, of the Liverpool School.

Second Examination.

M. M. Campbell, J. Steele, T. McMillan, J. Smith, J. Kerr, of the Glasgow Medical School; **W. E. Toyne**, E. E. Craster, and A. G. Ginders, of Edinburgh Medical School; **J. W. Chapman**, of Queen's College, Belfast; **H. Stedman**, Miami, U.S.A.; **H. C. Pauli**, of the Leeds School; **A. Bull**, of the London School.

Final Examination (and admitted L.R.C.P.Ed., L.R.C.S.Ed., and L.F.P.S.Glasg.)

C. Carruthers, E. Brooks, A. Nicholson, A. F. Criaan, D. Buchanan, J. Brown, J. F. Fergus, M.A., G. A. Bannatyne, R. W. Roberts, J. T. Haworth, Steele, and J. Kelly, all of the Glasgow Medical School; **C. F. de Mell**, Bombay and Glasgow Schools; **E. Carter**, of the London School; **V. Vanderstraaten**, of Ceylon Medical College.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates having passed the Qualifying Examination in Medical Surgery, and Midwifery have received certificates entitling them to practise in the same, and have been admitted as Licentiates of the Society.

Andrew, Bennet Harvey, 33, Tyrwhitt Road, St. John's, S.E. **Cooke**, Montague Percy, Fern House, Landkey, Barnstaple. **Eyton-Jones**, John Arthur, Wrexham, North Wales. **Goldsmith**, Perry David, Campbellford, Ontario. **Macdonald**, Isabella Macdonald, Windmill House, Arbroath. **Merrall**, Harry, 102, Victoria Terrace, Bury, Lancashire. **Nall**, Joseph, Whaley Bridge, near Stockport. **Reichardt**, Ernest Noel, St. Bartholomew's Hospital. **Valentine**, Thomas Harcourt Ambrose, Green Lane, Adlestone.

The following candidates passed the Surgical portion of the examination.

W. Evans, of St. Bartholomew's Hospital; B. P. Johnson, of the Liverpool School of Medicine; W. De la Motte, of the London Hospital; J. S. Part, of Westminster Hospital; P. de C. Potter, of Owens College, Manchester; J. A. Smith, of the Leeds School of Medicine; O. T. Stephenson, of the Liverpool School of Medicine.

The following candidates passed the Medical portion of the examination.

J. Brown, of the Middlesex Hospital; J. M. Cochrane, Toronto; A. J. De Butte, of St. Mary's Hospital; S. H. Secombe, of Guy's Hospital.

Primary Examination.—The following candidate passed the sole examination.

C. M. Given, of the Liverpool School of Medicine.

The following candidate passed in Anatomy and Physiology.

P. M. Swales, of St. Bartholomew's Hospital.

The following candidates passed in Anatomy only.

P. Cadel, of Guy's Hospital; J. M. Fry, of Westminster Hospital.

The following candidates passed in Chemistry, Botany, and Terrestrial Medicines.

E. Atkins, of St. Bartholomew's Hospital; H. Massingham, of the London Hospital; J. T. R. Miller, of St. Thomas's Hospital; W. L. G. Morgan, of St. Thomas's Hospital; H. B. Shillingford, of Guy's Hospital.

MEDICAL VACANCIES.

The following Vacancies are announced:

COATS HOSPITAL, Manchester.—Junior Visiting Surgeon. Salary, £60 per annum. Applications to the Honorary Secretary.

BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon. Salary, £150, and £30 extra for cab hire. Applications by May 10th to A. Forrest, Esq., Secretary.

DOMSBURY DISPENSARY.—Physician. Applications by May 15th to the Secretary.

STOL ROYAL INFIRMARY.—Honorary Assistant Physician (to out patients). Applications by May 5th to the Secretary.

RY DISPENSARY HOSPITAL.—Junior House-Surgeon. Salary, £60 per annum, with board and residence. Applications by May 5th to the Honorary Secretary.

BYDON GENERAL HOSPITAL.—House-Surgeon. Salary, £100 per annum, with board and residence, increasing to £120. Applications by May 11th to the Honorary Secretary.

STURFOUR BRITISH HOSPITAL, Paris.—House-Surgeon. Applications to the Secretary, Rue de Villiers, Levallois, Paris.

LYWELL UNION, Whitford District.—Medical Officer and Public Vaccinator. Salary, £42 per annum, and fees. Application by May 10th to P. Harding Roberts, Esq., Union Offices, Holywell.

LYWELL UNION.—Medical Officer to the Workhouse. Salary, £40 per annum. Applications by May 10th to P. Harding Roberts, Esq., Union Offices, Holywell.

HOSPITAL FOR DISEASES OF THE THROAT, Golden Square.—Resident Medical Officer. Salary, £50 per annum, with board and lodging. Applications by May 26th to the Honorary Secretary.

HOSPITAL FOR EPILEPSY AND PARALYSIS, [32, Portland Terrace, Regent's Park.—Assistant Physician and Registrar. Applications by May 14th to H. H. Graham, Esq., Secretary.

LONDON TEMPERANCE HOSPITAL.—Registrar and Chloroformist. Salary, £50 per annum. Applications by May 5th to the Secretary.

MONKWEARMOUTH DISPENSARY AND ACCIDENT HOME.—House-Surgeon. Salary, £80 per annum, with board and lodging. Applications by May 5th to T. R. Blumer, Esq., Honorary Secretary, Avenue House, Monkwearmouth, Sunderland.

NATIONAL LYING-IN HOSPITAL, Holles Street, Dublin.—Two Assistants to the Master. Applications to Dr. Roe, 13, Lower Fitzwilliam Street, or at the Hospital.

NEWPORT AND COUNTY INFIRMARY.—House-Surgeon. Salary, £100 per annum with board and residence. Applications to J. K. Stone, Esq., The Infirmary, Newport, Mon.

STAFFORDSHIRE INFIRMARY.—House Physician. Salary £100, with board, washing, and apartments. Applications by May 23rd to the Secretary.

ST. WEST LONDON HOSPITAL, Kentish Town Road.—Senior Resident Medical Officer. Applications by May 7th to the Secretary.

RISH OF BARNET, ETC.—Medical Officer of Health. Salary, £443 per annum. Applications by May 14th to H. M. Turner, Esq., 66, High Street, Watford.

RISH OF LOCHS, Stornoway.—Medical Officer. Salary, £140 per annum, with free house. Applications by May 16th to Mr. H. M. L. Ross, Inspector of Poor, Lochs and Barvas.

GRAY'S INN FREE HOSPITAL, Gray's Inn Road.—Assistant Physician. Applications by May 16th to the Secretary.

GRAY'S INN FREE HOSPITAL, Gray's Inn Road.—Assistant Surgeon. Applications by May 16th to the Secretary.

CITY HOSPITAL FOR DISEASES OF THE CHEST, City Road.—Junior House-Physician. Salary, £50 per annum, with board and lodging. Applications by May 19th to the Secretary.

SOUTH HANTS INFIRMARY, Southampton.—Assistant to House-Surgeon. Board and residence. Applications by May 5th to Dr. Thomas, Anglesea Place, Southampton.

SEAMAN'S HOSPITAL SOCIETY.—Visiting Physician. Applications by May 5th to P. Michelli, Secretary, Seaman's Hospital, Greenwich, S.R.

WARWICK COUNTY LUNATIC ASYLUM, Hatton, near Warwick.—Assistant Medical Officer. Salary, £100 per annum, with board, etc. Applications to the Superintendent.

WESTPORT UNION.—Medical Officer, Achill and Ballycroy Dispensary. Salary, £117 per annum and fees. Applications to Mr. John Corrigan, Honorary Secretary. Election on May 8th.

MEDICAL APPOINTMENTS.

BAILEY T. Ridley, M.D. Edin., reappointed Medical Officer of Health to the Bilston Urban Sanitary Authority.

FOX, E. L., M.R.C.S., appointed Senior House-Surgeon to the Stanley Hospital, Liverpool, vice G. P. Newbolt, M.B., M.R.C.S.

GIDDINGS, George T., M.B., M.R.C.S., appointed House-Surgeon to the London Hospital, vice G. E. Haslip, M.R.C.S., L.R.C.P.

MANNING, P., M.B., M.R.C.S., appointed Junior House-Surgeon to the Borough Hospital, Birkenhead, vice H. Scurfield, M.B., C.M., resigned.

MCLEAN, C. J. R., M.D. Edin., reappointed Medical Officer of Health to the Yeading Urban Sanitary District.

NEWBOLT, G. P., F.R.C.S. Eng., M.B. Dur., late Senior House-Surgeon, Stanley Hospital, Liverpool, appointed Surgeon, No. 2 District, Manchester Ship Canal.

RYE, W., M.B., C.M. Glas., appointed Medical Officer to the Tarbat Parish, Ross-shire.

SAVERY, Frank, M.R.C.S., L.R.C.P. Lond., appointed Senior Assistant House-Surgeon to the Hull Royal Infirmary, vice W. F. Pedler, resigned.

WILLIAMS, W. G., M.R.C.S., appointed Junior House-Surgeon to the Stanley Hospital, Liverpool, vice A. Wood, M.B., C.M., resigned.

THE NEW LARYNGOLOGICAL SOCIETY.—The proposal to establish a society for the study of diseases of the throat and nose, to which we referred some time ago (JOURNAL, January 21st, p. 149), has been received with favour by members of the profession specially interested in these subjects. A preliminary meeting was held on April 27th, at the rooms of the Medical Society, under the presidency of Dr. McNeill Whistler, to whose initiative, seconded by the indefatigable efforts of Dr. R. A. Hayes, of Dublin, the society owes its existence. The following gentlemen, among others, were present: Drs. Whiphram, Woakes, Prosser James, Dundas Grant, Gordon Holmes, J. W. Bond, Coleman Jewell, and Matheson, and Messrs. Lennox Browne, G. H. Bailey, W. R. H. Stewart, G. Stoker, and Arnold Woakes, of London; Mr. Cresswell Baber, of Brighton; Dr. Hunter Mackenzie, of Edinburgh; and Dr. McIntyre, of Glasgow. Letters of apology were read from Mr. Sydney Jones and Dr. Norris Wolfenden. It was stated that there had already been fifty-one applications for original membership, the list including the names of nearly all the prominent laryngologists in Great Britain and Ireland. It was unanimously resolved, that a "British Laryngological and Rhinological Association" should be established, and the first general meeting for the election of officers was fixed for Friday, June 29th. The acting Secretary, Dr. R. A. Hayes, 56, Merrion Square South, Dublin, will be happy to give every information relative to the Association to any gentleman interested in it.

THE CENTENARY OF THE LINNEAN SOCIETY.—The centenary of the Linnean Society will be celebrated on May 24th. A eulogy will be pronounced on Linnaeus, by Professor Fries, the present occupant of the Chair of Botany at Upsala; eulogies will also be pronounced on Robert Brown and George Bentham, both eminent botanists, by Sir Joseph Hooker and Mr. Thiselton Dyer respectively, and on Charles Darwin by Professor Flower. A Linnean gold medal will in future be presented for eminence in botany and zoology in alternate years. This year two medals will be presented to Sir J. Hooker and Sir Richard Owen respectively.

LONDON SLUMS.—The report of the Mansion House Council on the Dwellings of the People presented at its last monthly meeting showed that action taken respecting several streets in the Shore-ditch parish had been successful, and resulted in the almost entire remedy of the insanitary conditions reported, amounting to over 100. Action was also being instituted in regard to insanitary dwellings at Islington and Holborn. Upwards of £200 had been received in answer to the Lord Mayor's appeal, and it was hoped that the receipt of further donations would enable the operations of the Council to be extended.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—Mr. John F. H. Broadbent, of Hertford College, Oxford, has been awarded a scholarship of £50 in classics; Mr. Price, of Pembroke College, Cambridge, a scholarship of £50 in mathematics.

AN OPEN SPACE IN THE CITY.—The gardens skirting the moat of the Tower of London, between one and two acres in extent, have, through the instrumentality of the Metropolitan Public Gardens Association, been thrown open to the public.

THE LATE MR. GEORGE STURGE.—The death is announced of Mr. George Sturge, of Woodthorpe, Sydenham, at the ripe age of ninety years. The deceased gentleman took a warm interest in hospitals, and showed his practical sympathy with them by liberally subscribing to their support. He not long since gave £4,000 to University College Hospital, was a liberal supporter of the London Hospital, and had contributed largely to the North-Eastern Hospital for Children. From its commencement, he substantially assisted the London Temperance Hospital. Two years ago he offered three prizes for the best essays on "The Causes of the Financial Depression in Hospitals." He called attention to the variations in the expenditure on alcohol at the various general hospitals. He was the founder of the "Sturge Convalescent Home" at Folkestone, and was through a course of years engaged in the promotion and continuation of much charitable and philanthropic work. Mr. George Sturge was connected by near relationship with that great philanthropist Joseph Sturge, of Birmingham, and was not distantly related to two or three members of the medical profession. He died, as he had lived, a member of the Society of Friends.

SUTURE OF WOUNDED LIVER.—The *Riforma Medica*, of April 25th, states that Professor Postempski recently stitched up an incised wound of the liver. The operation, which is said to be the first of the kind ever performed, took place in the Ospedale della Consolazione at Rome on April 18th. The abdomen was opened, and the edges of the wound, which was situated in the left lobe, and which was seven centimetres in length and two in depth, were brought together with six catgut sutures, applied by means of extremely fine needles. The hæmorrhage, which had been very free, was at once checked when the wound in the liver-substance was closed. On April 23rd, four days after the operation, the patient's temperature was normal, and he was doing well. Professor Postempski will publish the case in detail in due course.

An attempt to blow up with gunpowder a wooden structure intended for use as an isolation hospital at Trooper's Hill, St. George's, an extensive suburb of Bristol, was made on Sunday night. No patients had yet been sent there, and no great harm was done. There has been, it is stated, a strong prejudice against the use of the site (which was used as a children's playground) for the erection of the building.

DR. CLEMENS LOZIER, of the New York Medical College and Hospital for Women (of which she had been Dean since its establishment in 1863), died recently from angina pectoris. She was the pioneer of the movement in America for the medical education of women, and also a leader in the female suffrage movement.

The *London Gazette* of Tuesday last announces that the Queen has been pleased to direct Letters Patent to be passed under the Great Seal of the United Kingdom of Great Britain and Ireland granting the dignity of a Knight of the said United Kingdom unto John William Tyler, Esq., M.D., F.R.C.S., L.R.C.P., L.M. and L.S.A. Lond., C.I.E.

CLONAKILTY UNION.—The guardians last week passed a resolution allowing £5 a year to the medical officer of the Rosscarbery dispensary district for attending petty sessions at all prosecutions in vaccination and sanitary cases. Dr. Bennett, of Clonakilty district, also receives the same sum for similar services.

MEDICAL HONOURS.—The name of Mr. Charles Williams, J.P. M.R.C.S., of Duffryn, the President of the North Wales Branch appears in the *London Gazette* of April 25th as a Deputy-Lieutenant for the county of Merioneth.

The *Medical Record* (New York) states that a Bill has been passed by the local legislature incorporating an institute for teaching "Christian Science," which appears to be the same craze as faith-healing.

THE VIENNA GENERAL POLICLINIC.—The Minister of Public Instruction of Austria, Dr. v. Gantsch, has given to the Vienna General Polyclinic a subvention of one thousand florins for the year 1888.

At the beginning of the year, there were, according to the *Australian Medical Gazette*, sixty students attending the practice of the Prince Alfred Hospital, Sydney.

At the annual festival of the King's College Hospital, held on Monday, April 30th, subscriptions amounting to £2,200 were announced.

HONOURS TO AN AUSTRIAN PROFESSOR.—The Emperor Austria has conferred on Hofrath Professor E. Brücke, Professor Physiology in the University of Vienna, the Order of the "Ehrenzeichen für Kunst und Wissenschaft." This distinction was created by the Emperor only last year, and has hitherto, far as medical men are concerned, been conferred only on Hyrtl

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.

MEDICAL SOCIETY OF LONDON, 8.30 P.M.—Annual Oration, by Sir Joseph Fayr K.C.S.I.: The Natural History and Epidemiology of Cholera to be followed by a Conversation.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN, 8 P.M.—Dr. Edward Bial On Dental Reflexes and Trophic Changes. Dr. George Cumid ham: On a Statistical Inquiry as to the Results of the Immediate Treatment of Pulpless and Abscessed Teeth.

TUESDAY.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8.30 P.M.—Dr. C. Theodore Williams: On the Results of the Treatment of Pulmonary Consumption by Residence at High Altitudes, as exemplified by Analysis of 141 Cases. Dr. Percy Kidd and Mr. H. H. Taylor On the Value of the Tubercle Bacillus in Clinical Diagnosis.

WEDNESDAY.

BRITISH GYNÆCOLOGICAL SOCIETY, 8.30 P.M.—Specimens will be exhibited Dr. G. Granville Bantock, Dr. Bedford Fenwick, Mr. Law Tait, and others. Mr. Bland Sutton: On Dermoid Tumour. Dr. Richard T. Smith: Cystic Disease of the Cervix and Uterium.

EPIDEMIOLOGICAL SOCIETY OF LONDON, 8 P.M.—Election of Office-Bearers. B. A. Whitelegge: Age, Sex, and Season in relation to Sea Fever.

ROYAL MICROSCOPICAL SOCIETY, 8 P.M.—Dr. A. C. Stokes: New Infus Flagellata from American Fresh Waters.

FRIDAY.

CLINICAL SOCIETY OF LONDON, 8 P.M.—Mr. Charters Symonds: Case of Rupture of the Urinary Bladder, in which the Rent was Sutured. de H. Hall: The Local Application of Cocaine in Acute Pseudomembranous Tonsillitis. Dr. Percy Kidd: A Case of Comp Bilateral Paralysis of the Vocal Cords the Result of Ac Laryngitis. Mr. Thomas Nunn: Necrosis of the Great Cornuoid Bone.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. which should be forwarded in stamps with the announcement.

BIRTH.

WALLER.—On April 27th, at Weston Lodge, 16, Grove End Road, the wife of Dr. Augustus Waller, of a son.

MARRIAGES.

HAMILTON-BODINGTON.—On April 10th, at St. James's Church, Vancouver British Columbia, by the Rev. H. Edwardes, Lauchlan Alexander Hamilton D.L.S., of Winnipeg, Manitoba, Land Commissioner of the Canada Pacific Railway, to Constance Eaton, daughter of George Fowler Bodington M.D., M.R.C.P. Lond., F.R.C.S. Eng., of the City of Vancouver, B.C.

PARRY-HOWELL.—On April 19th, at St. Mary's Church, New Walsingham, Norfolk, by the Rev. G. R. Woodward, assisted by the Rev. E. F. H. George Hales Parry, L.R.C.P., M.R.C.S., L.S.A., of Docking, Norfolk, second son of George Parry, M.R.C.S., L.S.A., Docking, to Sarah Florence only daughter of James Howell, Esq., New Walsingham, Norfolk.

SMITH-PICKERING.—On April 27th, at the church of SS. Philip and James Cheltenham, by the Rev. W. H. Hutchingson, rural dean, assisted by Rev. Percival Smith, brother of the bridegroom, Montagu Square, M.R.C.S. Eng., of 26, Park Place, Cheltenham, son of the Rev. T. Smith Holmwood, Weston-super-Mare, to Ethel, youngest daughter of the Rev. Edward Pickering, chaplain of Port Elizabeth, South Africa.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS respecting editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, Strand, W.C., London.

In order to avoid delay, it is particularly requested that all letters of an editorial business of the JOURNAL be addressed to the Editor at the office of the JOURNAL, and not to his private house.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL, are requested to communicate beforehand with the Manager, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication. CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, forward us with Duplicate Copies.

QUERIES.

FORMULA WANTED.

ENTRY DOCTOR writes: Would any of your readers be good enough to give me a recipe for an "alkaline mixture," containing sodæ bicarb., ammon. arb., zingiber, etc., concentrated so that an ounce added to seven ounces of water would form an agreeable mixture?

PRACTICE IN SPAIN.

RIPATETIC PHYSICIAN would be glad if any member could give him information with regard to the permission to practise in Spanish possessions. Would he M.B.Lond., and M.R.C.P.Lond., be accepted, or is a Spanish diploma obligatory?

MEDICAL BOOKKEEPING.

B. and C.M. asks to be recommended an easy and simple set of books for medical bookkeeping.

ANSWERS.

I. D.—Quite correct.

AVENA.

W. ASPINALL writes: In answer to a question by a member in the JOURNAL of April 28th, 1888, respecting "Avena," your correspondent will find there are many varieties, the chief of which are: *Avena sativa* alba, white oat; *avena sativa nigra*, or black oat; *avena nuda*, or naked oat; grain formerly used to feed horses. There is another vegetable of the same class, called *avena strigosa*, or thistle-pointed oat, or Spanish oat; an annual sown in corn fields. All these varieties were formerly used amongst the sick, at it is scarcely medicinal. I have never before heard of *avena* being prescribed in epilepsy.

PERSISTENT YAWNING.

HENRY SUTHERLAND (Whitehall) writes: If your correspondent, "Ubique," will consider what yawning is due to, he will not be long in finding remedies for its cure. Yawning is caused by an accumulation of carbonic acid gas in the blood of the lungs, which is the result of neglect on the part of the subject to assist Nature in her efforts to properly oxygenate the vital fluid, hence a reflex and spasmodic attempt by a prolonged but unnatural inspiration to do the work which ought to be done by the respiratory muscles of the chest.

This patient is a middle-aged lady, one of a class and at a time of life when exercise is habitually avoided. If she will take a brisk walk for an hour or so every day, and also make use of free exercises which tend to expand the chest, she will soon cease to complain of this troublesome affection.

MEDICO-PARLIAMENTARY SUBJECTS.

GEORGE CORDWENT (Milverton) writes: Several questions raised and discussed at the recent meeting of the Parliamentary Bills Committee, invite criticism. Permit me space to direct attention to two of them.

In what consists the necessity of a medical coroner appointing a lawyer as his deputy? A coroner and his deputy do not sit at the same inquest. The work of coroner is so little complex in its points of statute law, that a reasonable and cultured mind can have no difficulty, so far as those are involved in such inquiries as come within his office; on the other hand, most of those inquiries present features demanding much pathological knowledge in the coroner, some chemical knowledge also; by these only in occasional cases an essential evidence be brought out before the jury; the causes of death must be inquired into of course by those who best know the laws of organic life. What lawyer, as such, could, as readily as a medical man, cause to be developed essential evidence in death doubtful as caused by apoplexy or inn, or in death attended or preceded by special convulsions? What lawyer would not unfavorably compare with a medical coroner in inquiry as culpable interference or attributed neglect in a case of fatal child-birth? Medical evidence would be called certainly, and may be duplicated, but that the coroner should be as fully able to appreciate the evidence if conflicting, as should a law judge be able to appreciate points of law, and lay his views distinctly and fairly before the jury. In cases of questionable cause of death, will the public be content to depute decision to an individual, will it still be preferred to retain an unimpeachable mode by jury which has retained its public sanction more than one thousand years? And now, where representative elections are more than ever promoted by the Government, and suited to popular taste, will freeholders be content to be deprived their longest traditional right and a nominee of the Crown appoint their migratory magistrate, who ought to be familiar with the habits of the people of his district, and whose duty it is to inquire whether a death among them occurred by fair or felonious means? That *post-mortem* examinations could be more completely done than has been frequent is evident, but as that evil is markedly lessening, it would be insulting to supersede the practitioner in attendance, and injurious to remove from him the stimulus of conscientious liability to be called any day to give precise evidence on a point of pathology. As to "assessors" being added to a coroner's inquiry, the country should never submit for inquests to be burdened with the further expense of an anomaly. How can a medical coroner be other than an "assessor?" A court is a court of inquiry, not of prosecution; he sits to develop competent evidence, or sees that it is done, and is himself essentially an assessor.

I am past any personal interest in this matter, and to that extent have advantage not possessed, I fancy by many experimental legislators. I would add that, in my experience, the attributed want of competence in inquest juries has now become a buffoon tradition; if errors occasionally occur they are not more frequent than those which happen in the higher courts of law, as shown by daily applications for amended trials.

As regards alarmist views as to spread of disease by personal propagation, would it not be of vast individual and commercial service before proceeding therewith an effort towards penalties, if we endeavoured to find out something more definite than our present slipshod acceptance of spread of epidemics by propagation from person to person, by which preconceived admissions we less industriously seek a probably more frequent cause. Till recently cholera was thought infectious, so diphtheria; yet if it be so by possible inhalation, I am certain instances of this must be extremely rare; every case of cholera many I have seen has occurred in childhood or quite young adults, and its origin has clearly been due to intense or continued exposure to privy gas,

if such a phrase may be used for distinction. Is roseola infectious? Is typhoid fever infectious? And if rubella be doubtfully so, the first two cases in a rural district are often miles apart, and this, as other epidemics, often subsides even more quickly than it invades. I have seen several cases of endemic small-pox rearing as it were to propagate. A cosmic cause must give a condition essential to the speed of an epidemic, by intensifying or elaborating pre-existing elements. If this be true or approach a truth, ought we not to modify our views in regard to spread of epidemics by personal propagation.

NOTES, LETTERS, ETC.

HOMŒOPATHIC FORMULARIES.

DR. F. A. CASTLE (Editor of the *American Druggist*, and member of the Committee of Revision and Preparation of the *Pharmacopœia* of the United States of America) writes: In the JOURNAL of March 10th, p. 545, you comment upon a recently published report of The Temperance Hospital, for 1886-87. The existence of this institution has long been known on this side of the ocean, and there has been a justly general desire for information respecting the forms adopted for the administration of medicines which would be consistent with the claim which is made that alcohol is not used.

I have several times addressed letters of inquiry to the hospital, requesting information on this subject but, thus far, have never been favoured with an answer. Can you give any information on this subject?

You are aware, of course, that alcohol is the menstruum for a very large proportion of the drugs used in medicine, and tinctures, fluid extracts, and wines would appear to be almost indispensable. If, however, the managers of the Temperance Hospital have succeeded in preparing a special pharmacopœia or formulary in which alcohol is replaced by something equally serviceable, they would be doing something which would give very general satisfaction in making their formulary more public.

** We believe that the tinctures at the Temperance Hospital are prepared with glycerine instead of alcohol in some such proportion as 1 in 3. As, however, we have no authentic information, we can only agree with Dr. Castle, that an authoritative statement of the precise form of the various non-alcoholic preparations in use at this hospital is greatly to be desired.

A CASE OF DISTRESS.

DONATIONS received since April 17th.

	£ s. d.		£ s. d.
Arthur E. Durham, Esq. ...	5 5 0	G. Kveritt Norton, Esq. ...	1 1 0
Dr. F. de Havilland Hall ...	1 1 0	J. E. Kenyon, Esq., Bradford ...	0 10 0

Further donations towards the relief of the family will be gratefully received by Dr. G. C. Jonson, 16, South Eaton Place, S.W., or by Dr. John M. Bright, Forest Hill, S.E.

PLACENTA PREVIA.

MR. W. M. KNIFE (Melbourne, Derbyshire) writes: The following note of a few cases of placenta previa may be interesting. 1. Primipara, strong pains, violent hæmorrhage, but labour over in a few minutes, the placenta being expelled with child; good recovery. 2. Second labour, patient phthisical, repeated hæmorrhage, turning easily performed, child expelled after three quarters of an hour, and placenta twenty minutes afterwards; atony of uterus and draining hæmorrhage, in spite of every effort, uterus relaxing repeatedly, and death nine hours after the flooding ceased. 3. Multipara, tiring, good recovery. 4. Separation of placenta round cervical zone failed to arrest hæmorrhage and turning, successful recovery. Several cases of partial placenta previa also treated by rupture of membranes. Barnes's bags are very useful before os is dilated.

PROFESSOR VERNEUIL ON THE CAUSATION OF CANCER.

DR. C. R. DREYSDALE, Senior Physician Metropolitan Hospital of London, writes: In a debate upon cancer in the JOURNAL of April 7th, Professor Verneuil is reported to have quoted with approval the results of some statistics collected by M. Reclus, which showed that cancer was all but unknown among persons whose food was exclusively vegetable. He also mentioned that when he was interne in Lisfranc's wards in 1844, there were nothing like the number of cases of cancer in the same number of patients as there are at present in his wards; indeed, that there were four times as many cases of cancer now as there were forty years ago. This Professor Verneuil attributed largely to the carnivorous diet of the present generation.

Everything that falls from the lips of such a distinguished and learned surgeon as M. Verneuil deserves the greatest attention. Is there not, however, another reason why cancer is far more fatal now than it was forty years ago, and another reason why so great a celebrity as M. Verneuil sees more of it in his wards? In 1844, in London the death-rate was 24 per 1,000, and now it is 19.8, and a similar falling off in the death-rate has taken place in France, where the birth-rate now is only 26 per 1,000, against 32 per 1,000 in the United Kingdom. Hence France, in modern days, contains far more elderly people than she did forty years ago; and as cancer is rare in youth, may not this account more easily than the vegetable diet hypothesis for the greater proportion of the cases seen by M. Verneuil than formerly?

Again, the learned professor is so well known and appreciated as the light of French surgery, that, in these days of railways, persons in the provinces can far more easily betake themselves to Paris than they could in former days. France, I have said, has the most adult population in Europe; out of 100,000 of her population there are 14,700 between the ages of 30 and 40,

REMARKS

ON

THE ELECTRICAL TREATMENT OF
DISEASES OF THE UTERUS.*Read before the Brighton and Sussex Medico-Chirurgical Society.*BY SIR T. SPENCER WELLS, BART., F.R.C.S.,
Surgeon to the Queen's Household.

I HAVE had, perhaps, a longer and more varied experience than most men in dealing with uterine diseases, especially those which are characterised by overgrowth. I have so constantly had to regret the inefficacy of medical treatment; and the results of surgical operations, though sometimes brilliant, have often come so short of my desires that I have for many years past fallen into a frame of mind readily disposed to listen to any suggestion of a mode of treatment which offered a reasonable chance of success, and avoided the risks and perils attending the bolder practice. So, when reports reached me from Paris of what Dr. Apostoli was teaching and doing, they came with a welcome ring.

Electro-therapeutics were no novelty to me. More than thirty years ago I had put galvanism to the test, and had gathered in various ways evidence of its potency both in destroying and repairing tissues. What I had learned of the treatment of ulcers by galvanism was published in 1849 by Golding-Bird, and may still be read in an appendix to his book; but his son and Mr. Nunn are the only surgeons, so far as I know, who have made much use of the practice.

Not long afterwards I tried the galvanic stem pessaries of Simpson in amenorrhœa, and have used them until now with occasional good result. I knew also what Radford had done with galvanism in the treatment of uterine hæmorrhage, and what Simpson had taught as to the influence of galvanism on uterine contraction in labour. I have repeatedly made use of the galvanic cautery in various ways, and have very often removed masses of epithelioma, or the cervix uteri itself, by a platinum wire heated by a battery and used as an *écraseur*, with very satisfactory results. Quite recently, with Dr. Goddard, of Highbury, I removed a cervix uteri without the loss of one drop of blood. My attention was later on attracted to the electrical work of the French and American surgeons in reference to fibroid tumours of the uterus. This was so little satisfactory that it dropped out of notice. Our English experiments were not more encouraging, and surgical enterprise seemed destined to throw into the shade all less dazzling endeavours.

In the meantime, taking up the idea of the wonderful influence of galvanism upon the nutrition of tissues, Apostoli was unobtrusively resolving the problem of its right application in the treatment of abnormal growths and exudations. His published observations were so interesting, and the reports of eye-witnesses were so confirmatory, that in the autumn of 1886 I determined to see and judge for myself. I went to Paris, and was received frankly and cordially. Dr. Apostoli explained to me his views, and demonstrated his mode of procedure. He threw open the records of his daily practice, and gave me the opportunity of verifying his diagnosis, and witnessing his treatment of the cases actually under his care. Besides this, he mustered for my inspection about sixty of the patients who had passed through his hands. I heard many of their histories in their own words, and could contrast for myself their actual condition of good health and activity with the symptoms reported in the early notes of their attendance, and the deformity represented in the plaster casts of their bodies, taken before the tumours had been influenced by the galvanic current. I spent many laborious hours in what I may say was a rigidly sceptical examination of the evidence before me, seeking for weak points in the system and the resolution of theoretical objections.

The conviction was irresistible that, though the method might not have reached its point of perfection, the work, so far as it went, was good. If the women were not radically dispossessed of

their tumours, they were symptomatically cured. Nothing but prejudice could have turned the back upon the facts; and it would have been unjust not to put the matter to further proof. This I have unhesitatingly done. If I have hitherto been silent, it was because I did not wish to prejudge the case. But I have not been inactive, for I wished that if the utility of the method could be made as manifest here as elsewhere, it should be advocated impartially, and presented to the profession upon reasonable grounds.

The uterine diseases which come under Dr. Apostoli's care range through all degrees of fibroid development. He has to deal, as we all do, with simple cases of sub-involution, general hypertrophy of the organ, with metritic deposits all round, polypoid excrescences in the cavity, thickening, more or less irregular, of the walls, and sub-peritoneal outgrowths expanding into abdominal tumours. Practically all these cases group themselves into two classes: first, those which give no trouble and may be left alone; and secondly, those which threaten health and life by loss of blood, or, by mechanically interfering with the organic functions, cause a multimiform series of distressing symptoms.

In the treatment of these conditions, instead of scraping and cauterising the cavity with a curette, or caustics, or fire, Apostoli does the same thing with a pole of the galvanic battery. We give ergot, or mercury, or iodine, or bromine in the hope of altering the nutrition of the diseased mass; he sends a disintegrating current through it. We castrate to cut short a woman's sexual existence; he seeks to quiet down neurotic sensibility, and induce regularity of ovarian function. Where we proceed to a root and branch extermination, he proposes a denutritive paralysis of the uterine substance. Time will show whether, and how far, he surpasses us in his results.

But the novelty at present is not so much in the fact of electricity being used, as in the mode of using it. Others have tried the same means, but not in the same way; former methods were uncertain, dangerous, and insufficient. The point that Dr. Apostoli has arrived at is this: he has studied the effect that certain currents will produce, he measures the intensity of those currents, and he has found the means of safely directing them, of proper force, through the diseased tissues, to ensure the partial if not complete disorganisation of these tissues with the desired coincident relief of suffering, and often with restoration of general health.

It is the continuous galvanic current which is generally brought into action. For this purpose the operator must be provided with an apparatus which will guarantee him an unflinching current of at least 250 milliamperes, or electro-therapeutic units. I may say, in passing, that it may probably be found convenient to speak of milliamperes as "units" of current strength—10, 20, or 60 milliamperes, for example—would be 10, 20, or 60 units. In practice at the hospital or the surgeon's residence a battery of Leclanché cells answers admirably. It is enduring and easily manageable. For work at the patient's home a portable battery of the bisulphate of mercury is convenient, but it requires great care and frequent renewal. An indispensable accessory is the galvanometer. With a fractional deviation it gives a measure of the intensity of the current passing. The graduation should rise to 250 units or milliamperes, though this intensity is rarely wanted. Before every operation the perfect working order of battery, galvanometer, and conducting wires should be ascertained. As it is a characteristic point in the Apostoli practice that the galvanic current should be carried either into the cavity of the uterus or into the substance of the tumour, appropriate sounds and trocars are essential. To avoid loss of power by action on the metal, the sounds are made of platinum. For punctures with a negative current steel trocars are equally good, but when it is intended to transmit a positive current, a certain length of the sharp end of the trocar must be of gold. All that portion of the sounds and trocars passing through the vagina from the handle of the instrument to the mouth of the uterus or point of puncture must be insulated. Before every examination or operation the closest attention should be given to antiseptic precautions, both as regards the patient, the operator, and the instruments. During the whole course of the treatment vaginal irrigations, with sublimate or phenol, are never to be neglected.

The labours of Apostoli have expanded and given a definiteness to our knowledge of the special power of galvanic currents in the treatment of uterine diseases, and of the mode of applying the currents in a way which I may thus resume.

In the first place, we have learnt from him better to under-

stand the double action of the uninterrupted, continuous, galvanic current. The one action is purely local, and coincident with the flow; the tissues immediately in contact with the pole which delivers it are decomposed; the bases and acids of the substances and fluids acted upon are set free, and, according to their nature, produce cauterisation of the surrounding parts, independent of any thermic influence. This effect is local, immediate, and visible. The second action is due to the interpolary passage of the current. It is a trophic action influencing the nerves, vessels, and lymphatics, followed by molecular changes, so as to modify the nutrition of the tissues through which the current goes, and varying according to the pole employed. The effect of the direct and of the secondary counter-current is durable, and, whatever may be our interpretation of it, it is remedially of far more importance than the mere galvano-chemical cauterisation.

Secondly, though the coagulating power of the current passing from the positive pole was known from the writings of Ciniselli and A. Tripièr, we have had disclosed much more since as to the distinctive character of the action of the currents from the two opposite poles. It was with the positive current that Apostoli began his attack upon uterine fibroids, because of the more striking nature of the hæmorrhagic symptoms, and it was the speedy relief of this grave trouble by the production of a hard, dry eschar, and resisting cicatrix, which encouraged him to persevere. The eschar resulting from the alkaline caustic action at the negative pole is just the contrary, softening and liquefying, and tending to promote discharge and hæmorrhage. Logically enough, its dissolvent powers were applied to the opposite class of cases, where there was no hæmorrhage, and the object was rather to reduce the bulk and solidity of compact masses of fibroid material. Experience has proved this to be as good in practice as in principle. The positive pole is therefore designated as "anti-hæmorrhagic" or "hæmostatic," while the words "hæmorrhagic" or "denutritive" are applied to the negative pole.

Thirdly, Apostoli has taught us a much more satisfactory way of utilising these currents in uterine diseases. His predecessors had used currents which were generally uncalculated and ineffective. They were often not strong enough to do much good, yet at other times sufficient to bring about mischievous results. They were brought into play in an ill-judged fashion, and, when used by means of puncture, the punctures were made through parts which ought to have been left untouched. Now the operation is performed under such control as to be a matter of measurable certainty. A strong and regular current is at command. By means of the galvanometer a knowledge of the exact intensity of the current employed is insured. The dosage can be regulated in proportion to the cauterising and trophic effects considered necessary. A current of high intensity can be made to traverse the fissures offensively, and brought out through the abdominal integuments in a dispersed fashion, without more than a temporary blush, and made to complete the circuit through the cutaneous electrode imbedded in wet clay. Than this clay nothing as yet has been found more effectual. Then, by insisting upon the intra-uterine introduction of the current by means of the uterine sound, or its direct interstitial application through the inattaçable trocar, a certainty of action is obtained which was otherwise out of reach. The whole performance is thus strictly at the will and under the control of the operator, who, granted his mastery, wants no other guide either as to the dosage, direction, or duration of the current than the facial expression of the patient, or her declaration of tolerance.

Fourthly, other important points upon which we have clear and definite information are the modifications which this treatment requires according to the varying nature of the cases, and the successively changing circumstances of each case as the treatment is going on, and the wide range of uterine affections to which it is adaptable. Given a tumour and a current, there is no such thing as reciprocal automatic action. At every step of the process of cure, deliberation, judgment, and promptitude of resource are challenged. One day there is an unaccountable power of endurance, another an exaggerated sensibility, one day a perplexing structural resistance, another an easy flow of current, all which have to be taken cognisance of, and throw an ever-recurring strain upon the mindfulness of the surgeon, enough to baffle book-guided novices, and make inestimably valuable the more than five years' experience to which we can recur for counsel. A field, too, is opened up for exploration among the infinitely multi-form presentations of disease of the female generative organs, untraversable by the limited powers of any one man, but to

which Apostoli has pointed the way. This will be the work of the coming generation.

Lastly, there are several interesting questions upon which the work of Apostoli has thrown a new ray of light, such as the dangers and difficulties of the procedures; their being a cause, or the reverse, of subsequent sterility; the practicability of applying the treatment in cases where the uterus is impenetrable; the permanence of the benefits derived from the treatment in the mitigation of the symptoms and the reduction of the tumours; the relation of the menopause to the production or dispersion of fibroid enlargements. It would take up too much of your time if I were to consider these in detail, and it is needless, as Apostoli himself is here, on the invitation of your President, to give any required information.

But, admit that there may be danger in treating our patients by electricity. Is this a reason for rejecting it? What surgical operation is free from risk? Would common sense sanction our leaving disease alone till science has reached completion and skill infallibility? The danger lies not in the method but with the operator, and the moral is, that no man should undertake this work till he has qualified himself to do it well.

Then, as to the permanence of cure, where cure there has been one can only say that though five years and a half is but a short term to form estimates upon, when we are assured that during that time the return of symptoms, or the necessity for further measures has been quite exceptional, it argues well for the future and the objection of the possibility of relapse becomes of little weight.

Again, when Apostoli tells us that some of his patients now under treatment are women in whom the tumour developed after the menopause, no trace of such a growth having previously existed, what are we to say to the principle of Hegar's operation? To say the least, it would limit castration in the treatment of uterine disease to the cases where loss of blood is the prominent symptom in younger women. I might go on much further, but I think I have said enough to show that whatever may be, or may not be, the merits of Apostoli's method, we have made since he began his work a distinct scientific advance. And coupling this specific information we have thus acquired with our previous diagnostic tact and pathological exactitude, it appears to me that we are in a better position, even supposing that circumstance hinder the personal practice of the method, not only to discuss the abstract principles upon which it is based, but as consultant to pronounce upon its respective applicability to the cases submitted for our opinion.

There are conditions of fibroid tumours in which it would seem to me almost idle to suggest electricity. A polypoid growth from the mucous surface of the uterus projecting into the cavity, or perhaps through the os, can be so easily and expeditiously taken away that I should not think of any slow or gradual process. Neither does it appear very probable that a subperitoneal outgrowth from the body or fundus of the uterus could be in any great degree affected by any current that could be made to reach it. Myotomy would be the work of minutes, and the risk scarcely worth mentioning. Even large solid tumours, the removal of which means the removal of a great part of the uterus have been successfully removed by me and by others, and success has increased with experience. But the risk must be always great, and there are tumours so large, or with such intimate connections, that no prudent surgeon would meddle with them. Here, surely, is the occasion for the electrician to show his power. His method is a new resource for a desperate condition and should be welcomed as such. It has been successful in such cases, if not completely so yet to a degree which has rendered life enjoyable. No weak prejudice should stand in the way of recommending a trial under experienced guidance.

Where the object is mainly to suppress hæmorrhages, electrical treatment has decided advantages over other practices. Should the tumour be growing, but not advanced beyond the limits of reasonable surgical interference, balancing the comparative risk, should be disposed to put the matter to the test; since in case of failure, the more hazardous operation of removal can still be done. In my opinion, with the option before her, it would be neither wise nor charitable to give a patient strong advice in favour of an immediate cutting operation.

Experience seems to show that there is a group of cases, numerous as they are troublesome, of chronic metritis with enlargement and surrounding deposits, which may be cited as pre-eminently eligible for electric treatment. They are, as regards

the patient, painful and exhausting. To the judicious surgeon they are exasperating by their rebelliousness, and in some rash hands they have opened the way to practice more lamentable than the disease. It will be one of the crowning merits of electro-therapeutics if proved to be equal to bring relief to these patients. Recent reports give good reason to hope that this end may be realised by a careful use of the positive galvanopuncture.

We have not, I am inclined to think, taken heed enough of the work of Tripiet and Apostoli in reference to various disordered states of the uterine appendages. The soothing effect of the vaginal or uterine bipolar application of the induced current in some distressing forms of ovarian neuralgia and vaginismus is said to be marvellous and enduring.

As a last word, I may say that we are face to face with an important revival; and though some American surgeons have gone before us in its acceptance, nowhere more than in our own country has there been shown an open-minded readiness to weigh fairly all the evidence which Dr. Apostoli has to set forth in support of his system.

In London we have heard, through the medical journals, of some failures, of one death, and of more than one accident, probably due to the inexperience of the practitioners. But we have far more encouraging reports from Edinburgh: and if some member of this Society who combines sufficient knowledge of electrical science with practical experience of the diagnosis of uterine diseases, and of the treatment by other methods, will carefully put to practical test the conclusions already arrived at by Dr. Apostoli, I am very hopeful that the result will not be disappointing.

THE ELECTROLYSIS OF FIBROIDS.

By W. E. STEAVENSON, M.D. CANTAB., M.R.C.P.,

In charge of the Electrical Department at St. Bartholomew's Hospital; Physician to the Grosvenor Hospital for Women and Children.

WHAT takes place when an electric current is passed through a fibroid tumour? Does any change take place in the substance of the tumour or only at the points of application of the electrodes? An interesting paper on this subject was read by Dr. J. Inglis Parsons before the British Gynecological Society on March 14th and 28th of this year. The human body contains about fifteen elements combined in different proportions to form the several issues. These elements, arranged in an electro-chemical series, are as follows:

Electro-negative.	Electro-positive.
Oxygen	Hydrogen
Sulphur	Iron
Nitrogen	Manganese
Fluorine	Magnesium
Chlorine	Calcium
Phosphorus	Sodium
Carbon	Potassium
Silicon	

But each element in the series is electro-negative to the one which follows it, and electro-positive to the one which precedes it.

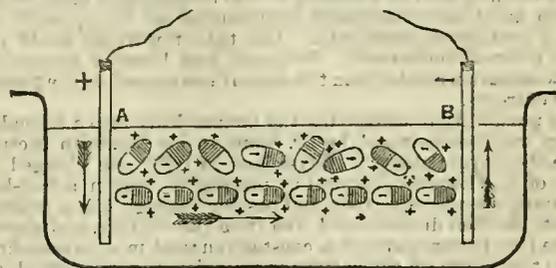

In the electrolysis of animal tissues the electro-negative elements are freed or appear at the positive electrode forming at once new chemical compounds, and the electro-positive elements are liberated or undergo similar recombinations at the negative electrode.

It would require a most accomplished analytical chemist to decide what actual changes take place at the relative poles, but what we know is that oxygen and chlorine are liberated at the positive pole and give an acid reaction; and that potash and soda are formed, and hydrogen liberated, at the negative pole. Some of the most likely bodies to be found in the substance composing fibroid tumour are: Albumen, which contains C H N S O; mucin C 52.2, H 7.0, N 12.6, O 28.2 per cent.; gelatine (C 50.4, H 6.8, N 18.3, S+O 24.5 per cent.); keratin (C 50.3-52.5, H 6.4-7.0, N 16.2-17.7, S 0.7-5.0, O 20.7-25.0 per cent.) (Hermann's *Physiology*), and the saline solutions of the body containing potassium and sodium phosphates. In these compounds "the molecules of the simpler bodies, as OH, CH₃, NH₂, C₆H₅, occur in the most varied and intricate combinations." "Of these complex substances"

which occur in the human body, "only a few can be obtained in a pure condition; the remainder cannot, either because they are too unstable, or because they are not crystallisable; with regard to the majority, we do not therefore know even their composition by weight, much less their constitution. The greater the number of atoms which combine to form a compound, the greater becomes the complexity of its composition, so that elementary analyses are insufficient clearly to indicate its formula. The formulæ of the substances are for this reason unknown to us" (Hermann's *Physiology*).

All we can say with regard to the electrolysis of these bodies is that the oxygen and sulphur have a tendency to be liberated at the positive pole, and the hydrogen and potassium would traverse the space between the two electrodes, and appear upon the surface of the negative electrode.

The fact that elements are only liberated at the surface of the electrodes is explained by the theory of Grotthüss, which is, that the molecules of any electrolyte, under the influence of an electric current, turn themselves so that their electro-negative constituent is directed towards the positive pole of the battery, and their electro-positive constituent towards the negative pole. The molecule nearest to the positive electrode yields up its electro-negative constituent, and it escapes free, but the electro-positive constituent acts upon the next molecule in the direct line between the two electrodes, attracting its electro-negative constituent, and again repelling the electro-positive atom or atoms. This action, continued in each contiguous molecule, forms a direct chain of decompositions and recombinations across the substance being electrolysed, until the negative pole or electrode is reached, and then the last molecule of the chain having yielded up its electro-negative constituent in the direction towards the positive pole, and there remaining no further molecules for the electro-positive element to split up, it is therefore discharged free at the negative pole. Such is the theory of Grotthüss, propounded in 1805, and, as applied to water, it is explained by the accompanying diagram:

A is the positive electrode, and B the negative one. In the upper line the molecules are seen arranging themselves so that the electro-negative element, the oxygen, is turned towards the positive electrode (A). In the lower line the molecules are arranged in a chain across the liquid. The atom of oxygen nearest the positive electrode is then liberated as free gas, and the two atoms of hydrogen combine with the atom of oxygen directed to it in the next molecule, and form a new molecule. This action extends throughout the chain, and ultimately the two atoms of hydrogen of the last molecule, having no further molecules to split up, are liberated as free hydrogen gas at the negative pole (B). Therefore the volume of gas liberated at the negative pole is double that liberated at the positive pole. No appreciable action or change can be seen or detected at any point across the fluid; the gases are liberated only at the points of contact with the electrodes. A similar diagram would explain the electrolysis of hydrochloric acid; only for the oxygen (the electro-negative atom) would have to be substituted one atom of chlorine, and for the two atoms of hydrogen only one would be liberated by the decomposition of each molecule, because chlorine and hydrogen combine in equal volumes to form hydrochloric acid gas. This is the case with a simple compound composed of two elements, and constitutes primary electrolysis. When the compound is more complex, what is called secondary electrolysis takes place. This would be the case in a solution of sodium sulphate Na₂SO₄. We should obtain at the anode, from the splitting up of the water, an equivalent of oxygen O, and also an equivalent of free sulphuric acid H₂SO₄, while at the cathode we do not obtain sodium Na, but we have instead of it hydrogen H, and in the solution we have also caustic soda NaHO. This results also from the secondary splitting up of

the water (Sprague, *Electricity*. 1884). When we are dealing with mixed electrolytes, such as the substances composing animal tissue, the decompositions which take place are still more complicated.

It is difficult, in the present state of our knowledge, to say how many secondary electrolyses take place in the passage of the current through the body. That it meets several elements presenting different states of polarity towards each other is certain, but whether chemical change takes place at the points of junction of each of these heterogeneous bodies it is at present impossible to determine. As a rule, electrolysis does take place between any two substances of different electro-chemical polarity at the point where they touch one another, if they are capable of conducting electricity. If in the treatment of a uterine fibroid we use an external potter's-clay electrode, a water rheostat to regulate the current, and an intra-uterine electrode, we know that electrolysis takes place at four points: (1) in the cells of the battery; (2) in the water in the rheostat; (3) between the clay and the skin of the patient; and (4) at the point where the internal electrode touches the mucous membrane of the uterus.

That electrolysis does take place in the tissues is probable from the fact that storage of electricity takes place in a patient subjected to the electrolytic treatment. The patient becomes a secondary battery, and is capable of giving off a current in an opposite direction to the one used from the battery. We have demonstrated this to be the fact on several occasions at St. Bartholomew's with patients under treatment for uterine fibroids. Immediately after the application of electricity has been discontinued we have disconnected the rheophores from the battery and united them to each other, still keeping them connected to the electrodes in contact with the patient; a reverse current has immediately been shown on the galvanometer, at first about 12 milliamperes, but rapidly decreasing to 8 and 4. No storage of electricity could take place unless some decomposition of the fluids contained in the tissues electrolysed had taken place. The liquids bathing the cell elements of the tissues must have become split up, and their constituents accumulated on the opposite surfaces of contiguous tissue cells. It is this only which could produce a polarisation current. Becquerel and Faraday have shown that polarisation results from the depositions caused by the passage of the currents.

This possibility of converting the human body into a secondary battery was demonstrated by Dr. Stone in his Lumleian Lectures before the Royal College of Physicians in 1886. He charged the porter of St. Thomas's Hospital by placing his feet in a foot-bath containing a leaden electrode, and passing through him a constant current; he then disconnected him from the battery, and showed that he (the porter) gave off a constant current in a reverse direction to that given by the battery from which he was charged, and Dr. Stone asserted that he would continue to give off such a current, gradually diminishing in intensity, for about four hours (see *JOURNAL*, vol. i, 1886, pp. 812, 813).

In the recent discussions on the electrolysis of fibroid tumours it has been asked: If the passage of an electric current has an effect upon the tumour, how is it that the normal structures, such as the bladder, muscles, skin, adipose tissue, etc., which are included between the two electrodes, are not also affected? It is quite possible that they are affected; that in them the normal tissue-changes always in progress are accelerated, and that assimilation or "progressive metamorphosis" is encouraged. This from analogy would appear to be the case; for when a galvanic current is applied frequently to an atrophied and palsied muscle very often its nutrition is improved and its bulk increased; and Dr. Apostoli has drawn attention to the extraordinary increase of subcutaneous adipose tissue which takes place in the abdominal walls of patients subjected to the electrolytic treatment.

Dr. Poore has said,¹ "it is probably impossible to pass a galvanic current through animal tissues without setting up some electrolytic action, and we are unable to say what part such action may play in the ordinary phenomena caused by the galvanic current." I have elsewhere said,² "it is probable that changes are induced in the ultimate tissue cells of a part exposed to a constant current of electricity, analogous to the chemical action produced in the electrolysis of water. If the current is weak, the process does not go so far as splitting up the watery parts of the cells into oxygen and hydrogen, but produces some sort of activity in the

cell not present there before. It increases or alters the character of the secretion of the cells composing secreting glands, as evidenced by the increase of saliva and metallic taste in the mouth, produced by the application of a continuous current of electricity anywhere in the neighbourhood of the salivary glands. This probable increased cellular activity, the quickening of the building up and destruction of cells never ceasingly going on in the living body, is sufficient to account for the increased demand for blood required for these changes, and the resulting increased supply afforded by the dilatation of the capillaries. The capillaries do not dilate by any power possessed by the constant current to cause muscular relaxation, but secondarily through nervous influence excited by the demand produced in the cells for more blood. The action of the constant current upon muscular tissue if anything beyond, besides inducing these probable changes in the ultimate muscular elements leading to increased activity in the ultimate cells, increased nutrition, and therefore increased tone (as it is called), is probably to induce contraction rather than relaxation. In considering these changes in the cellular element of the body and in the blood-supply, the osmotic power of electricity must not be forgotten. It has been found that if two fluids of different densities be divided by a porous diaphragm and an electric current be made to pass through them, osmosis takes place in the direction of the current." That is from the positive to the negative pole. "If the current passes from the lighter to the denser fluid the natural osmotic action is increased; but if the current passes in the reverse direction, the osmotic action is reversed; the denser fluid passing through the diaphragm into the less dense. The osmotic power of electricity probably explains the influence of galvanism in causing the absorption of fluid effused into joints, or serous cavities, when applied in such cases."

The theory suggested by Dr. Inglis Parsons, that the electric current has a modifying influence on the cells of tumours which from their lower vitality could not recuperate themselves so well as the normal cells of the body, is also not altogether improbable. In fact, it may be that in the tumours subjected to a current of electricity a "retrograde metamorphosis" is set up.

The tumours do not disappear so rapidly or so completely as we have been led to expect, or perhaps as British gynecologists suppose would be the case. I do not think that the electrolytic treatment will supplant the necessity for abdominal section or removal of the uterine appendages in such cases as those in which these operations would be appropriate, but I do think that in the use of electricity we have a means of treating fibroid tumour which is superior to any we have formerly employed, short of their entire removal. I have treated a large number of cases, and in nearly all the symptoms have been relieved, in many the tumours have decreased in size, and in some the decrease has been considerable. The hæmorrhage has usually been arrested; the dysmenorrhœa has been relieved; the pain and discomfort have decreased; the rectal and bladder troubles have also been lessened, and the patients able to get about and walk with much less difficulty. All these favourable symptoms are probably due to the relief from pressure caused by a slight diminution in the size of the tumour. Nearly all the patients I have operated upon have expressed themselves as feeling better—better in health and better in spirits. In those whose tumours were accompanied by menorrhagia no doubt the improvement in health was greatly due to the arrest of the hæmorrhage. That adventitious tissue does decrease and get reabsorbed under the electrolytic treatment, I feel sure, and have been able to observe it in several cases of stricture of the urethra.

NOTES OF A CASE OF HYDROSALPINX A NEW MODE OF ELECTRICAL TREATMENT.

By G. APOSTOLI, M.D.,
Paris.

THE case of which I am about to give the particulars seems to me to be of great interest. It opens up a new question in therapeutics, and will serve as a prelude to a complete memoir which shall shortly publish on the electrical treatment of salpingitis. In this paper I confine myself to a full and exact report of the case and a statement of the conclusions that may be drawn from it.

¹ *Electricity in Medicine and Surgery*, by G. V. Poore, M.D., p. 233. 1876.

² *Electricity and its Manner of Working in the Treatment of Disease*, by W. E. Steavenson, M.D., pp. 24, 25. 1884.

SUMMARY OF CASE.

Patient, 25 years old, general good health. Three full natural pregnancies; abortion at two months on September 21st, 1887, twenty days after a violent fall on the back, followed by incessant pain, excessive menorrhagia, general derangement of health, with sharp pains in the right iliac fossa; no antiseptic precautions. Came to clinic on October 27th, 1887, with indications of a threatening pelvic peritonitis. Swelling of the whole upper part of the vagina, with fluctuation on the right side.

On October 27th first galvano-puncture, negative, on the left side, vaginal; 100°; 5 minutes. Remained in bed for forty-eight hours, with some relief on the following days.

November 8th. Second galvano-puncture, negative, vaginal, in the *cul de sac*, right side, one centimètre; 140°; 5 minutes. Two days later spontaneous opening of a cyst, and discharge of fluid, without either pus or blood. Cessation of all pain and diminution of swelling.

November 18th. First appearance of menstruation since abortion; flow continued freely for three days; pain on left side only. Since then local condition has become natural, and all symptoms have disappeared. The periods of December and January natural; health good, and allowing of regular work at the sewing machine.

DETAILS OF CASE.

Mrs. T., domestic, aged 25, came to the clinic of Dr. Apostoli on October 22nd, 1887.

History.—Native of the Vosges, was married when 20, came to Paris a year afterwards, and has lived there since. No account of hereditary disease; no disease during childhood; menstruated at 2 years; no infantile leucorrhœa. Menstruation has since been regular, but painful, the pains preceding the flow, continuing the whole time, and then disappearing; quantity moderate; time three days, and no leucorrhœa. Had no illness before her marriage, and was always able to do her work regularly. Has had three children, with natural labours, at full term, at 21, 22, and 23½ years. Each time kept her bed for ten days after delivery, but had no milk for her children. Menstruation recommenced six weeks after the first two confinements, but not till three months after the last. During the time of marriage menstruation has not deviated from its natural characters, and has been less painful. Her good health has been uninterrupted; she has carried on her work regularly up to the month of July, 1887, has had no leucorrhœa, and conjugal relations have caused no suffering.

In July of 1887 her fourth pregnancy began, and for the first time gave her trouble, from severe pain in the body, though not causing her to give up work. On September 2nd, at the second month of pregnancy, she had a violent fall in the street, on her back, after which she had constant pains in the back and lower parts of the body. This pain increased day by day till September 15th, making her work very difficult. A little discharge of blood was seen on the 19th and 20th, and on the 21st there was an abortion. The patient affirms that there was no other cause for this accident, and it was evidently owing to the fall twenty days before. The pains lasted for three hours. The expulsion of the contents of the uterus was complete, and followed by profuse menorrhage. She had no medical assistance, and took no antiseptic precautions. She kept her bed for eight days, rising only occasionally for a short time, and used injections of warm water. There was a pretty copious bloody discharge for four days, and this was supplanted by profuse leucorrhœa, which lasted for a month. On October 5th she began again to attend to her household duties, and continued them till the 20th. Immediately after a miscarriage, for the first time in her life, she felt a severe pain in the right iliac fossa. This confined her to bed, and prevented her from doing any work for a fortnight. After a short respite the pain became worse, and she was obliged to give up on the 21st. The pain never ceased, but there were moments of exacerbation, brought on especially by sitting down. It spread over the whole of the right hip, but was never felt on the opposite side, nor the lumbar region.

The patient lost flesh, strength, and appetite; her countenance showed how much she endured, and, on October 20th, she was so prostrated that she sought relief at the clinic.

Actual Condition, October 22nd, 1887.—Woman somewhat under medium size, very pale, with a distressed look; walks with difficulty, and complains of severe pain in the right side of the body. Lymphatic temperament, without hysteria. She is in a state of feverish excitement, with high temperature. On eight

successive evenings has had a rigor about bedtime, and lasting for an hour. There is complete sleeplessness, loss of appetite, constipation, and foul tongue.

The abdomen is tender under pressure, especially on the right side, where, in the region of the broad ligament, there is evidently a phlegmonous deposit.

Local Examination.—The uterus is very low down, almost touching the vaginal orifice. The anterior *cul de sac* only is normal, all the others being obliterated, and the parts very tender to the touch. The uterus has on each side a large exudated mass. These encroach upon the posterior *cul de sac*. Though apparently the result of the same inflammatory action, they are in some respects different in character. On the right side the projection into the vaginal space is more marked, more tender, and more elastically resistant than on the left. It has almost the form of a hen's egg, with a rounded surface, the least pressure upon which causes intolerable pain. The evidence of fluctuation on the right side is very clear. The swelling on the left side is less defined, less prominent, and not so painful. It is not so elastic and resisting as the tumour on the right side. Both swellings are amalgamated with the body of the uterus, and the whole mass seems to be adherent to the walls of the pelvis, for no movement can be made of any part.

The condition of the patient is serious, the symptoms indicating the setting up of an acute pelvic peritonitis. I therefore put off any local operative treatment.

October 24th. The patient is worse, and eagerly demands relief. It was, however, decided that we should wait before making any application, but by the 26th the pain was so much increased that the patient had been rolling on the floor; walking was nearly impossible, and it was with difficulty that she was conveyed to the clinic.

October 26th. *Diagnosis.*—There is no sign of general peritonitis being really present, but it seems imminent. Taking into consideration the accession and increase of pain, the local conditions, the manifest renitenency on the right side, together with the unmistakable fluctuation and the high temperature (38.5° C.), there can be no doubt as to the existence of a peri-uterine phlegmonous supuration.

Treatment.—At the urgent request of the patient, I with some hesitation decided upon the treatment by galvano-puncture in its most modified form. Hoping that it was not too late to expect an arrest of the threatening inflammation by this means, I proposed to make the slightest possible tentative puncture on the left side, so that I might judge by the effects there produced whether it would be possible or proper to do the same thing on the right side.

October 27th. After chloroform and a vaginal injection of weak solution of sublimate, I made a vaginal negative galvano-puncture on the most prominent point of the swelling of the left side, in the lateral *cul de sac*, with a very small steel trocar, entering only 1 centimètre, with a current of 100 milliampères, for five minutes. The trocar was one specially made for the purpose, and not larger than the point of a subcutaneous injecting syringe. The puncture caused no bleeding. I again used the antiseptic irrigation, and placed a tampon of iodoform gauze in the vagina. The patient was put to bed at the clinic, and there she remained for two days.

During this time she was in a state of great excitement, almost constantly delirious, moaning incessantly, with green vomiting and a temperature varying between 38 and 39° C. The delirium had all the characteristics of that produced by chloroform, with alternations of agitation and quiet, during which she was scarcely conscious.

By the evening of the 28th, the delirium had all passed away. She slept well during the night, and woke up in the morning of the 29th refreshed and better. There was a complete transformation. She got out of bed without assistance to be examined and dressed, stood up and walked about free from pain and difficulty. The abdomen was much less tender, and bore such pressure as would have been intolerable the day before.

The vaginal tampon was not stained. On examination, no change was found in the state of the right side, but on the left side there was a great change for the better, less tenderness, less swelling, and the space was freer. Contrary to advice, the patient was imprudent enough to return home on foot, a distance of three kilomètres (about two miles). On arrival she was obliged to go to bed, and all the night suffered much pain in the right side. The next morning she was easier and returned to the clinic.

walking with less difficulty. The pain was less, the tampon was clear, and there was no unusual discharge from the vagina. The injections were continued, and for several days she remained under observation, with gradual amelioration.

November 8th. On this day I made a second vaginal galvanopuncture, under chloroform, with the same trocar, to the depth of a centimètre and a half, in the centre of the right *cul de sac*, and used a current of 140° for five minutes. In order to insure the coaptation of the tumour with the wall of the vagina, and to give myself the certainty of making my puncture exact, I caused an assistant, during the whole time of the operation, to press downwards slightly with his hand in the right iliac fossa. There was no escape of fluid after the puncture, and the injection and tampon were used as before.

As on the former occasion, the patient remained in bed for two days at the clinic. There was no delirium, but she suffered some sharp pains in the right iliac region. They were sufficiently bad to prevent sleep, but she could take some nourishment, and was less feverish than before.

November 10th. Since the morning the patient has become more calm, and the shooting pains are less frequent. In making the vaginal toilet, which has not been done since the operation, the tampon was found dry and unstained. The abdominal tenderness has subsided, and there is no trace of distension. Examination shows that structural retrogression is going on; the vaginal sensibility remains much the same. The dressings were replaced as usual.

In spite of remonstrance she persisted in going to her home, and was much fatigued by the journey. Unable to keep about, she was obliged to lie down, and, while quiet in her bed, she suddenly found herself drenched by a fluid, clear and transparent as water, which ran from the vagina, without being accompanied with any pain. The patient says this liquid was without smell, unmixt with blood, somewhat serous, and continued flowing for several minutes without washing away the tampon. From this moment she found complete relief. Her former pains ceased, and she had no more suffering. A good night followed, and in the morning she felt so well that she rose and dressed without fatigue, and was not in any way inconvenienced when driving down to the clinic.

November 12th. There is a great change in her appearance, her complexion is clearer and she declares herself well in all respects. She has no further symptomatic troubles. Locally the transformation is not less remarkable; two facts are especially to be noted. The sensibility of the two *culs de sac* has disappeared to such a point, that this woman, who two days ago could scarcely bear to be touched, particularly on the right side, can now submit to a thorough vaginal examination, accompanied with external pressure, without a word of complaint. The anatomical change is quite as complete, for in place of a resistant tumour as large as a fowl's egg, there is nothing now remaining on the right side but a fibrous substance, a little irregular on its surface, not one third of the original size, unresisting, not at all tender, and fixed to the uterus.

The conditions, both symptomatic and anatomical on the left side, have undergone a similar change. The tampon, which had been in place since the 10th, on being removed before examination, had no blood stains upon it, but was found saturated with about two spoonfuls of serous fluid. A new light was thus thrown upon the question of diagnosis; the tumour, supposed to be a collection of pus, was after all a serous cyst of the Fallopian tube.

November 15th. The patient goes on improving both locally and generally, she walks easily, and all the functions are regular. Absorption has taken place, and the *culs de sac* have their natural depth. The punctures, made on either side on the same horizontal line, are now only to be found near the centre of the posterior *cul de sac*, in consequence of the general contraction of the vaginal mucous membrane. The uterus, although attached behind, is in some measure movable. Same local treatment.

November 17th. The improvement continues; though she cannot resume her full outdoor occupation, she manages to do her household work.

November 24th. Her visits have been suspended because menstruation began on the 18th, for the first time since September 21st. The appearance was preceded by two hours of sharp pain. The flow continued for three days, freer than usual, and the pain lasted all the time. Comparing the present period with those of early years, she finds that instead of having pains all over the abdomen, they are now confined to the left iliac region, with none

on the right side. A feeling of weariness obliged her to lie down occasionally during the three days. But, since the cessation of the period, she finds herself as well as before it began. She thinks she is a trifle fatter, and she looks well. There is some tumefaction of the upper part of the vaginal mucous membrane and the points of puncture have resumed their original place in the lateral *culs de sac*.

November 29th. Much the same; but though her strength is returning, and she is gradually mending, she cannot manage more than her home work.

December 3rd. Examination shows:—1. That the uterus is higher up, and that the neck is slightly turned forward. 2. Diminution of the bilateral peripheral exudation, and complete absence of tenderness under pressure. 3. The two punctures are no longer found on the sides of the uterus, but are actually in the posterior *cul de sac*. 4. The hinder part of the uterus is attached to the sacrum. The sound passes for 6½ centimètres, and causes a little pain.

The patient is completely free from all the symptoms caused by her malady; has no pain, walks well, has no sensation of weight in the body, eats well, digests perfectly, grows fat, and has regained her strength and healthy look.

December 27th. Menstruation came on, for the first time without pain, on the 20th. The duration was five days, and the quantity rather more than usual. She has resumed conjugal relations, interrupted since September 1st, without inconvenience. For the last fortnight she has worked five hours a day at her sewing machine, with one pedal for the right foot; and, though the movement fatigued her, she was not obliged to give it up.

January 15th, 1888. Since the 1st of this month she has worked all day at the machine, and, notwithstanding the extra exertion has not been in any way troubled.

January 27th. This month the period was rather later than usual, but she had no difficulties, and was able to do her machine work regularly, though away from her home in a factory. Menstruation lasted three days, less abundantly and without pain.

February 10th. Since the last report the patient has been free from all troublesome symptoms. Independently of her declaration—and she is generally very truthful—the following fact is a clear proof of her full restoration to health: she has been able to go through her day's work at the machine, from 7 o'clock in the morning till 7 in the evening, regularly and without fatigue or interruption, even during the last two menstrual periods, in December and January. In fact her condition is so satisfactory that she declares herself better than before her last pregnancy, and free from the little miseries which she then had to endure.

Local Condition.—1. No reasonable pressure on the abdomen gives her any pain.

2. The uterus is natural as regards form and consistence, little low down, and retroflexed; the neck of right form and without ulceration.

3. The vagina is everywhere in its natural state, and there is no peri-uterine swelling.

4. The uterus is still adherent by its posterior surface, but admits of some movement.

5. Under strong pressure the sides and back part of the uterus show a little sensibility, especially when the finger touches deep-seated nodule, about the size of an almond, lying to the right side and a little behind the organ. This is probably the tube slightly hypertrophied.

With the finger in the rectum, pressure on the back of the uterus is not painful, and, even in spite of the retroflexion, it is easy to trace the form and the upper border. On either side the tube and ovary may be made out distinctly a little enlarged more so on the right than the left side. Both sides are a trifle more tender than natural. The ovary on the left side is very plainly felt; that on the right side forms a conglomerate mass with the Fallopian tube.

Conclusions and Observations.—Without anticipating the extended memoir which I intend to publish on the electrical treatment of salpingitis, I may sum up in a few words my observation on this case. Other facts, to be produced at a future time, will give full confirmation.

1. In gynaecology fever and inflammation are not to be regarded as absolutely contraindicating the methodical and proper application of the galvanic current.

2. Inflammation of the uterus and its appendages, when not in the stage of suppuration, may be advantageously treated by the galvanic current. This current, though admissible in the first

stages of congestion and inflammation, I consider ought not to be used when suppuration exists, unless it be brought into action in the form of an electrical cauterisation, for the purpose of making a safe and certain outlet for the matter through the vaginal wall.

3. A galvano-caustic puncture is a valuable means by which we may gain two ends: first, to check the outbreak of inflammatory action or to stop its progress; secondly, to give an easy exit to a collection of fluid, by the falling of an eschar, in any case where the cavity containing such fluid is accessible through the upper part of the vaginal wall.

4. Every inflammatory exudation presenting itself in the vaginal *cul de sac* may be treated by means of the galvano-puncture, except under the condition which I shall hereafter mention.

5. This method may be easily and harmlessly employed for the treatment of certain cases of salpingitis and hydrosalpinx, on account of the close relation between the tumours and the vaginal wall.

6. In making every galvano-puncture, all the rules which I have hitherto laid down concerning the seat of the puncture, its depth, the size of the trocar, the antiseptic precautions, the repose of the patient, etc., must be scrupulously observed.

7. Two negative galvano-punctures, vaginal only, were sufficient in one case of hydrosalpinx to bring about very quickly an important anatomical change, and complete symptomatic cure.

A CASE IN WHICH RUPTURED TUBAL PREGNANCY OCCURRED TWICE IN THE SAME PATIENT.

By LAWSON TAIT, F.R.C.S.,

Professor of Gynaecology in Queen's College, Birmingham; President of the Birmingham and Midland Counties Branch.

On May 10th, 1885, Mrs. E. R., aged 25, was sent to me by Mr. W. P. Whitcombe, Victoria Road, Aston, suffering from urgent abdominal symptoms. The history was to the effect that she had been ill from a short time before Christmas. She thought it was pregnancy. Menstruation had been suspended for three months. In April she had a period, and again early in May, and at the latter time she complained of violent pains in the lower abdomen, and on the 9th she had an attack of fainting with vomiting, the pain being referred to the lower abdomen. When I saw her she looked extremely ill and anemic. A large ill-defined mass existed on the right side of the uterus intimately associated with the organ, and the roof of the pelvis was fixed. There was no difficulty in diagnosing the case to be one of ruptured tubal pregnancy. I opened the abdomen on the 11th, and found the belly full of blood-clots and bloody serum. I removed the right Fallopian tube, which was occupied by a pregnancy of about the third month, and in its walls a large rent had occurred, through which the foetus and placenta were partly protruding. Some points of bleeding from the intestine required touching with perchloride of iron. I inserted a drainage-tube, and the patient made an easy and rapid recovery. The case is published in a short paper on Ruptured Tubal Pregnancy, in the JOURNAL of December 19th, 1885.

About eighteen months after this operation, she was confined of a child, at the full term, being attended by a midwife, and there was nothing remarkable about the labour.

About fifteen months after this confinement she again became pregnant, and her husband states that during the period of this pregnancy (which she thought had turned four months), she had no symptoms of note, but only complained at intervals of slight pain in the abdomen, but not sufficiently severe to induce her to call in medical assistance. The only point on which he lays any stress was, that she stated that she felt the child very plainly, more so, it seemed to her, than at the same period in any previous pregnancy.

Mr. Whitcombe was sent for to see her in the forenoon of March 14th, but he being from home, the patient was seen by his assistant shortly before 1 o'clock on that day. She was lying fully dressed in bed, her knees drawn up, and was complaining of great pain in the hypogastrium. She was extremely pale and almost senseless, and had had some vomiting. Mr. Hall was informed at only half an hour before she had been cleaning her fireplace,

and, in the act of stooping, was seized with acute pain and a feeling of faintness. Stimulants were at once administered, and every effort made to restore her without avail, and the patient died shortly after 5 o'clock, clearly from internal hæmorrhage.

Mr. Whitcombe made a *post-mortem* examination, and has been kind enough to give me the following particulars: He found the abdomen full of blood-clots and fluid blood; a large clot was adherent to a portion of the placenta which protruded from the uterine wall, and when this clot was separated it had a quantity of villous placental tissue adherent to it. All the organs were very anæmic, and there could be no doubt that the hæmorrhage was the cause of death. Mr. Whitcombe was good enough to bring me the preparation, and aided by my assistant, Mr. Teichmann, I am enabled to give the following report of the appearances presented.

There can be no doubt that the specimen represents an interstitial tubal pregnancy of the left side. The cavity in which the foetus is situated is separated from the true uterine cavity by a strong septum of uterine tissue springing from each side of the uterine walls. The under surface of this septum and the rest of the uterine cavity is lined by hypertrophied mucous membrane (decidua). The stump of the right Fallopian tube is attached to what appears to be the lower angle of the uterus, but which is really the much displaced upper angle. This displacement, however, is only apparent, and arises from the enormous development of the left cornu of the uterus. A fine probe may be passed from the true uterine cavity into this stump. The left Fallopian tube, on the contrary, communicates with the cavity in which the foetus and placenta lie, and the rupture has taken place in the upper and back part of the left uterine corner. In this case we have the almost incredibly strange instance of a woman suffering from tubal pregnancy twice, with the still stranger fact of her having a normal pregnancy between the two occurrences. From the first of her disasters she was saved by prompt surgical interference, and she might even have been saved the second time, but there can be no doubt that the poor woman's doom was sealed before medical assistance reached her, and there was no time then to effect the interference which was necessary. All the appearances of the preparation point to the fact that the woman's estimate of the period of her pregnancy was correct, and we have therefore an indication that the interstitial form of pregnancy does, as we might have expected it would, take a longer time to arrive at the period of primary rupture than do those cases in which the pregnancy occupies the free part of the tube. In these latter we have no evidence as yet of any instance going beyond the twelfth or thirteenth week before primary rupture. It may be noticed here I am introducing a new phrase in using "primary rupture." I do so because I am becoming convinced that unless we make such a distinction as I am about to indicate we shall still continue some of the elements of confusion which exist about this interesting displacement.

It is perfectly clear that in all cases of tubal pregnancy, when the ovum is growing, the tube must burst, and that it bursts in two directions, either into the peritoneal cavity or into the cavity of the broad ligament. In the free part of the tube this rupture takes place, as I have said, about the twelfth or thirteenth week. In the interstitial form, the case before us shows that the rupture may be deferred to a later date. The primary rupture into the peritoneal cavity seems to be almost necessarily fatal alike to mother and child; but when the rupture occurs into the cavity of the broad ligament, it may be followed by a continuance of the development of the child, and these only are the cases in which the child is permitted to reach a viable period.

In a recent number of the *New York Medical Record*, a case is reported by Dr. Taft as being one in which no rupture had taken place. But the description given makes it perfectly certain that this was a case where the primary rupture had taken place into the cavity of the broad ligament. In this group of cases a secondary rupture at any period is possible, and therefore it is that the adoption of the terms, used strictly to indicate relative dates, will become very useful. This secondary rupture was most clearly demonstrated in Nonat's celebrated case as given by Bernutz, a case which, on account of the occurrence of this secondary rupture, is full of the greatest interest (see my *Ingleby Lectures*, 1887). This secondary rupture probably also explains such an occurrence as that in Jessop's case.

Connected with the case I am now discussing there are many important points worth alluding to, some of which are new, and others, though quite familiar, are worth noticing on account of

the confusion which still seems to exist in the mind of the most recent writers on this subject.

The patient was rather an intelligent woman for her class, who, having undergone the terrible experience involving her first operation, had obtained a fairly full knowledge of the nature of the accident, and what had been the condition as a consequence. Yet, with this dreadful experience, and the knowledge of it when the same condition recurred, so little did she suffer that, up to the moment of rupture, knowing she was pregnant, she never thought of asking for medical assistance, and this was the case also in her first tubal pregnancy. There were no symptoms whatever to draw attention to her state until the rupture occurred; indeed, there were no symptoms even calling for examination.

The strangest thing of all to me is that, in the enormous experience I have now had of tubal pregnancy, I have never but once been called upon to make an examination until the rupture had occurred, and in that case there was neither history nor symptoms which enabled me to do more than determine that there was tubal occlusion; not, indeed, until the rupture occurred and the abdomen was opened was a diagnosis possible. Under these circumstances, I think I may be excused for maintaining a somewhat sceptical attitude concerning the correctness of the diagnoses of those gentlemen who speak so confidently of making certain diagnosis in cases of tubal pregnancy before the period of rupture, and who speak with equal confidence of curing the cases by a puncture either simple, medicated, or electrolytic.

The great bulk of the utterances in these directions may stand very well in "society discussions" or in "library papers," but they will not stand the test of bedside experience. Upon these points I have been much misrepresented, and am glad to have an opportunity of clearly stating my views; but I wish to state that after the period of rupture a diagnosis can be, and has in my own experience been, made correctly in the majority of instances.

Another point in connection with this interesting case is the fact, made abundantly clear by the preparation, that, no matter what the symptoms had been previous to rupture, physical examination could not have permitted any diagnosis other than that of normal pregnancy of about four months and a half.

This is my solitary experience of interstitial tubal pregnancy, but it so closely resembles a number which I have seen in museums that I take it to be quite typical of its class. I am, therefore, disposed to believe that from physical examination interstitial tubal pregnancy could not be diagnosed, and I can imagine no symptoms which would help us to recognise it before rupture.

If we were to assume that in such a case as this a diagnosis could be made, much ingenious speculation might be indulged in as to what would have been best to do for the patient. If a correct estimate of the relation of parts could have been made, clearly what ought to have been done was to dilate the cervix, divide the septum freely, and empty the cornual cavity. To have attempted to destroy the child would not have benefited the patient one bit. The placenta would have gone on growing; and, even if it had not, putrescent material would have been left, which must have burst into the peritoneal cavity. At the time of rupture, if surgical assistance could have reached the woman with sufficient promptitude, she might have been saved by a hysterectomy; and, from the appearances at the *post-mortem* examination, there is no doubt that this could have been easily accomplished.

THE VIENNA MEDICAL FACULTY.—The prospectus of the Vienna Medical Faculty for the summer semester shows that 192 lectures, courses, and demonstrations will be held during this semester by 19 ordinary professors, 36 extraordinary professors, and 70 *dozenten* and assistants. During the past semester, there were 6,157 students in the different faculties, distributed as follows:—(1) Theology, 225 ordinary and 17 extraordinary students; (2) law, 1,927 ordinary and 256 extraordinary students; (3) medicine, 2,287 ordinary and 836 extraordinary students; (4) philosophy, 438 ordinary and 358 extraordinary students. A comparison of these numbers with those of the winter semester of last year shows an excess of students in the law faculty and an increase among the extraordinary medical students. The number of the ordinary medical students, on the other hand, shows a slight decrease. The extraordinary students were this year, for the most part, foreigners, of whom 109 were Americans, 39 Russians, 36 Englishmen, 28 Prussians, 11 Swiss, 16 Roumanians, 12 Belgians, 7 Greeks, 5 Australians, and 4 Turks.

AN ADDRESS ON THE VALUE OF PRACTICAL STUDIES.

Delivered at the opening of the Summer Session in the School of Practical Physiology, Edinburgh, May 1st, 1888.

By WILLIAM RUTHERFORD, M.D., F.R.S.,
Professor of Institutes of Medicine in the University of Edinburgh.

GENTLEMEN,—Before proceeding to the ordinary work of the session, I should like to direct your attention to some ideas regarding the value of Practical Studies. A short discussion of that subject may be of service to you who are still on the threshold of a life of study. It may help you to perceive the principle that has led your teachers to develop methods of practical study, and to extend them in all the departments of natural science and in those of medicine.

We can acquire a knowledge of Nature in two ways: in a direct way by observing Nature by means of our own senses, and in an indirect way by listening to and by reading an account of the observations of others. All natural science springs from the observation of Nature. To assist our observation various instruments have been invented, and various experimental methods devised to induce Nature to reveal her secrets. The facts so discovered and the laws deduced from them have been marshalled in the orderly array that forms the characteristic feature of science.

The first and obvious duty of the student is to gain a knowledge of what is already known. He is not immediately concerned with the advancement of science, but with the attainment of a knowledge of its facts and principles, and the methods by which a scientific knowledge of Nature has been gained. The old method of instruction in too many departments of natural and of medical science consisted in the mere absorption of statements made by lecturers and authors, without production of the necessary evidence of their truth, and with imperfect illustration and explanation of the methods by which the evidence has been obtained. The result of such modes of teaching could not be satisfactory. The student's interest in the subject was not sufficiently awakened. The knowledge he gained was superficial, as, indeed it could not otherwise be on a method so imperfect. The mode of instruction now aimed at in all departments of natural science is to bring the student as directly as possible into contact with Nature, so that he may have not a mere description or exposition such as may be found in a book, but may, as far as possible, study phenomena directly by the use of his own senses, so that when an object is described he may, if possible, see it with his own eyes, touch it with his own hands, listen to it with his own ears, and, if necessary, smell it and taste it. On such a method of instruction the student is not treated as a mere absorber of the statements of others, but as an independent observer, requiring a demonstration of the truth of what is said, expecting that structure will be shown to him, that the properties of things will be revealed by experiment, that methods of observation and experiment will be demonstrated and explained, and that he will, as far as possible, be allowed to observe and experiment for himself. This practical study of Nature is attractive to all, but especially so to young minds. The mind at any age, but especially in youth, is apt to grow weary of abstract statements, and to lose sympathy with a subject so treated. The young mind is enthusiastic, it is eagerly expectant, and keenly on the outlook for new impressions. It is not satisfied with mere descriptions of phenomena. It desires to realise them by direct inspection. Such desire is so natural that one can only wonder why so many years elapsed before a serious effort was made to satisfy it. This method of studying Nature by contact with it inspires a confidence that is not otherwise attainable. The mind feels the solid support given by the direct study of phenomena; it feels itself on solid ground, and can advance with firm step. When by this method the student criticises and tests anew the observations made by others, they become to him living impressions printed on his mind in a way they never can be by merely listening to, and still less by reading descriptions of them. The student soon comes to feel that this practical method of study is the surest way to acquire definite

nd accurate knowledge of scientific facts. But in his eagerness o learn the facts, he is apt to lose sight of another mental process that is being cultivated while his category of facts is growing; he is apt to overlook the fact that a great and leading object a practical studies is to quicken and increase the power of making accurate and independent observations.

To any student of Nature the exercise of such power is important, but it is doubly so to a student of medicine. The practice of medicine largely consists in an exercise of observing power. The correct diagnosis of disease requires this power to be acute and highly trained. It not infrequently happens that the early stage of a disease passes undetected because the physician has failed to observe some symptom that is imperfectly developed, and, therefore, apt to escape attention, unless his power of observation be acute and highly trained. It is often the case that a practitioner does not sufficiently use the ophthalmoscope, the laryngoscope, the microscope, and other appliances which would help him in the diagnosis of disease, but of which he cannot with confidence avail himself, because in his student days he had no opportunity of learning how to make reliable observations with such instruments.

I need scarcely remind you how greatly men differ in their power of observation. If you listen to travellers giving an account of the impressions they have received in the countries and cities they have visited, you will find they vary very much in the sense they have made of their eyes; some men let few things escape their notice, others have only vague impressions of what they have witnessed. Some men have that power of precision which enables them to fix their attention firmly on an object until they have thoroughly scrutinised it, and have obtained from it a deep and lasting impression. Such men apply their minds thoroughly to the subject on hand. They proceed methodically; they avoid flitting rapidly from one subject to another, knowing that by such utterly methodical an abiding impression is not attainable. On the other hand, there are many whose minds have no firm grasp; their eyes are open but they fail to see; their impressions are vague and indefinite; they hesitate to describe what they have seen because they cannot exactly recall the impressions. The usual explanation is that the mind was not firmly fixed on the object, and the mental vision was not steadily turned towards it.

We shall not require to travel very far to have such experience of the difference in men's powers of observation. It is soon obtained when a number of observers put their eyes to the microscope: all may be looking at objects precisely similar, but if the different observers be called upon to describe what they see, we quickly find great differences in observing power. I assure you, gentlemen, that this is a subject of great moment to every one of us—especially great to those who intend to pursue medical science and practice. Your power of observation must be carefully and widely trained. You must strive to fix the mind so firmly on every object your teachers place before you that the power of acute and accurate observation may grow steadily; it is sure to grow steadily if you will only refuse to be satisfied with impressions that are vague and indefinite. The power of precise and accurate observation depends far more on the mind than on the organs of sense. Most men's eyes are good enough, the relative acuteness of their vision is mainly the result of a mental cause.

Again, in relation to the exercise of the power of observation, there is a principle of no small importance from an educational point of view. There are some practical studies which from their nature must be undertaken by the student working in an isolated manner; practical anatomy is one of these. As you know, it is necessary in the dissecting-room for each student to pursue his own way without reference to his fellows. He works out the subject with a book of reference by his side, and with the help of teacher at intervals. There are several other subjects, of which practical physiology and practical pathology are illustrations, in which a collective system of study is adopted. On that system the teacher treats his pupils like a regiment, directing them all to perform the same operations and to observe the same facts at the same time. That system has been to so great an extent originated and developed in this university that it might almost be called the Edinburgh method of practical teaching. This method has now been adopted in a number of other schools, yet I have heard it severely criticised by teachers in the South, who prefer the system of isolated study, on the plea that a student who is quick in thought and movement ought not to be hampered and held back by those less rapid, and that self-reliance is fostered by isolated effort. Well, gentlemen, I believe our regimental system

of practical teaching has for you great advantages that far outweigh any drawbacks. Taking work with the microscope as an illustration, it is for you and still more for the teacher a great saving of time to be collectively told how to prepare an object for the microscope, and how to observe its several characters. You save a great deal of time by keeping your eye at the microscope while information regarding the object is not being sought for in a book, but is reaching you through another organ of sense which more than any other stimulates the mind and keeps it vividly awake.

Microscopic study is apt to proceed very slowly if information is being searched for in a book. But it proceeds smoothly and quickly if the information come through the ear. To you who have so much to acquire in a limited period, any method that economises your time is important. But our regimental system has another great advantage that isolated study never can have; it creates at once a congenial mental atmosphere; each hourly section of our class becomes a miniature scientific world, in which one mind reacts upon another, and stimulates it by sympathetic rivalry. In such an atmosphere the observer is at once thrown on his guard, for he knows that the same object is being looked at by many eyes, and that the accuracy of his description is being keenly scrutinised. Such an atmosphere seems to me of great value to young minds, for we all know that a characteristic feature of youth is desire for sympathy and love of generous rivalry. That mental glow we call "enthusiasm," which in youth is so readily kindled and fanned by the sympathy of other minds, is an invaluable help in study; it lightens labour, it carries the mind up different paths to high attainments, and induces it to forget its fatigues; therefore, it is our duty to do what we can to enable you to foster a spirit so helpful.

At the same time, gentlemen, I must guard myself against misapprehension in thus commending to you what I have termed the regimental system of practical study. That system must not be pushed too far. It is particularly suitable for beginners, and should for them be adopted in all subjects that permit of it. But for the advanced student the method of isolated study is preferable, in subjects characterised by elaborate practical details, requiring much time and thought for their execution, and for the full apprehension of their significance.

But practical studies carry with them another advantage especially important to students of medicine, namely, cultivation of the power of manipulation. You have all, no doubt, felt how rapidly manipulative dexterity is cultivated by the practice of dissection, and you know that, from a surgical point of view, it is nearly as important to acquire a dexterous use of the knife as it is to gain a knowledge of anatomy. Not a few medical practitioners make no use of the laryngoscope, because the use of a mirror at the extremity of a handle and the management of the light thrown upon it require considerable manipulative dexterity. Many a practitioner would refuse to perform such operations on the eye as iridectomy and extraction of the lens because he may have had no opportunity of practising such operations on dead eyes, under the supervision of a teacher. And I have heard not a few medical men bitterly complain that in their student days there were no arrangements by which on suitable models they could acquire the manipulative dexterity so essential in many obstetrical operations. It is a matter of common observation that men differ greatly in manipulative power. Some men are clever with their hands, quick and precise, and delicate in movement, accomplishing a practical result fluently; in others the hands accomplish their task with difficulty, there is lack of precision, and the result may be failure. Such difficulties are always diminished, and sometimes entirely overcome, by practical studies.

The Medical School of Edinburgh can lay claim to no small share in the development of practical teaching. In former years the development was denounced as a needless innovation by those who were victims of the curious popular delusion that the old times were good enough, and required little improvement. Believe me, the Medical School of Edinburgh goes far better now than it did twenty years ago; some of us have often turned the eye back to our student days and have marvelled at the change. Practical teaching has been developed in nearly every department, and every year adds something to its efficiency, for though much has been accomplished, we have to keep in mind that the principles and methods of education are problems full of difficulty and perplexity, and that a perfect system can only grow by degrees. But while pointing out the great development of practical

teaching in Edinburgh, I would not have you suppose that in this respect we stand alone. Many teachers have gone from this to other medical schools and have carried with them our methods, and have planted them there. And indeed all the medical schools of England and Ireland, as well as those of Scotland, have been making rapid progress in the attempt to raise the standard of attainment in every student of medicine by providing him with increased facilities for study in every department. To those of us who are familiar with the results both of the old and of the new systems of medical education, the great benefit of the newer method is apparent.

But although we have taken the right way in bringing the young mind more and more into direct contact with Nature, we must ask you not to fall into the error of supposing that a practical mode of study can ever supersede the older method by means of lectures. It would be impossible for one mind to observe independently all the facts of any science, even if it had all the means at its command. How much more impossible must it be for any one of you to observe independently the great mass of facts in the many sciences you have to learn within a limited period of time. In practical studies salient points have to be selected and many others omitted. The systematic lecture must always remain as a systemised exposition in which facts and principles are arrayed, not in the order that might be necessary for practical study, but in the order required to produce a lucid conception of the subject. Both methods are necessary to enable the mind to gain a definite knowledge of detail, and a sufficiently wide conception of any science that deals with physical nature.

I have now seen a good many years of student life, and have watched the results of a good many educational experiments, and as the result of the experience, the advice I offer you is to attend all the practical classes you can. Give no heed to their being compulsory or non-compulsory, for with their help you can obtain a kind of education which you never can find in books or get from lectures; and when you leave the university and pass into medical practice you will find the opportunity gone.

NOTES OF A CASE OF CHOLECYSTOTOMY: RECOVERY.

By RUTHERFORD MORISON, F.R.C.S., M.D. Edin.,

Late Visiting Medical Officer, Hartlepool Hospital, Newcastle-upon-Tyne.

H. P., aged 45, married, was the mother of six living children, and had had four miscarriages. The patient was an active, intelligent-looking woman, with nervous complexion and features, black hair and bright brown eyes. She was in good condition, though thinner than formerly. She had been occasionally intemperate. The organs, with the exception mentioned below, were healthy. Menstruation had been irregular lately, and for the last four years profuse. The tongue was furred, appetite poor, and bowels irregular.

She had never felt well since a miscarriage, her last pregnancy, eight years ago, and had had pain in her right side from that date. So far as she could judge, the pain had always been of the same nature as that of which she now complained. The attacks of pain started in the right side over the liver, and extended to the right shoulder and epigastrium. They were accompanied by vomiting and shivering, and made her so ill that she was obliged to stay in bed. Latterly the attacks had increased in number and severity, so that three or four days of each week had been spent in bed. The bad fits always terminated by diarrhoea. Exercise brought on these attacks.

The lump was first discovered by herself four years ago. It was tender then, and had remained so throughout, but was worse sometimes than others. She said that it became decidedly less and not so sensitive after the purging.

Examination discovered a round, hard swelling in the position of the gall-bladder, about the size of an orange, and moving freely up and down with respiration. Puncture with a hypodermic syringe showed its contents to be the ordinary opalescent mucous fluid of a distended gall-bladder.

The operation was performed on February 29th, the tumour being exposed by a vertical incision through the abdominal parietes, immediately over it, from two to three inches long. After placing a couple of small sponges behind the distended gall-bladder, an aspirator needle was introduced at the fundus, and six ounces of opalescent fluid removed. The front wall of the

gall-bladder was now drawn forwards by two pairs of ordinary artery forceps, and opened sufficiently between them to admit easily my forefinger. Between fifty and sixty small round stones the largest being no bigger than a pea, were scooped out with a finger, and washed out with a Higginson's syringe. The gall-bladder was sponged dry, the bile-ducts explored without finding anything, and the sponges removed from the abdominal cavity.

The only serious difficulty in the operation occurred at the time. One of the sponges was lost amongst the intestines, and before I could find it I was obliged to enlarge the incision. In the future the sponges shall be under my control with ligature forceps. The difficulty of finding them has to be experienced and believed. The edges of the thickened gall-bladder were now fixed to the abdominal wall, including the peritoneum, by a continuous suture, the edges of the wound brought together above and below with interrupted sutures, a rubber drainage-tube laid in the bladder, and the wound dressed with carbolic gauze and wood-wool pad. The operation throughout was conducted with antiseptic precautions.

The after-progress was uneventful. The patient got up on the ninth day, and went home some distance by rail on the seventeenth day. The wound was entirely healed at the end of six weeks, and her health is now as good as it ever was, and better than it has been for years.

A CASE OF TRAUMATIC CEPHAL-HYDROCELE

By F. A. SOUTHAM, M.B. Oxon., F.R.C.S.,

Assistant-Surgeon to the Manchester Royal Infirmary; Lecturer on Clinical Surgery in the Owens College.

As cases of traumatic cephal-hydrocele—the term now applied to a tumour formed by an accumulation of cerebro-spinal fluid beneath the scalp, occurring as a complication of simple fracture of the vault of the skull—are somewhat rare, the following instance is perhaps worthy of record.

The patient, a male child, aged 6 months, was admitted into the hospital under my colleague, Mr. Heath, on December 28th, 1887, suffering from an injury to the head, the result of a fall down a flight of stairs the previous evening. The mother stated that when taken up the child was in an unconscious state, and

remained so during the night. On admission the following morning he was sensible, though somewhat drowsy; there was right ptosis, with slight conjugate deviation of the eyeballs towards the right side; the pupils were equal, neither contracted nor dilated. On examining the head a fracture was found running obliquely across the parietal and occipital region on the right side, causing a deep oval, gutter-shaped depression, two inches and a half in length, one inch in width. There was no bruising of the skin, and

swelling beyond a little puffiness of the tissues of the scalp over and around the seat of fracture. In the course of a few days the child became bright and lively, the deviation of the eyeballs and the ptosis disappeared, and on January 8th he was discharged from the hospital apparently quite well, no swelling being perceptible in the region of the fracture, the depression of which was still evident.

Four days later, on January 12th, the child was brought to my out-patient room, when I saw him for the first time, and on examining the head a distinct swelling was apparent immediately over the seat of fracture. The swelling was oval in shape, about two inches in length, one inch and a quarter in breadth, and slightly constricted at its middle, its long axis running parallel with the direction of the fracture; it was raised about three-quarters of an inch above the level of the surrounding surface, and was soft and fluctuating; it exhibited distinct pulsation synchronous with that felt at the anterior fontanelle, was partially reducible on pressure, and became fuller and more tense when the child cried; the skin covering it presented a normal appearance. The fracture could be felt beyond the anterior and posterior margins of the tumour, and, after partially emptying the latter by external pressure, the depression of the bone beneath could also be distinguished. The child, though somewhat dull and drowsy, presented no other symptoms. The only treatment adopted consisted in applying moderate pressure over the tumour by means of a pad of lint and bandage.

January 19th. The swelling was somewhat diminished in size, and the pulsation less distinct.

January 24th. The pulsation had quite ceased; the tumour was much smaller and softer; it still became more tense when the child cried, and was only reducible after prolonged pressure.

February 15th. The swelling had entirely disappeared and the child appeared to be enjoying perfect health; there was still a marked depression in the bone along the line of fracture.

The condition, of which the foregoing case is a good illustration, was first fully described by Mr. Clement Lucas, in the *Guy's Hospital Reports* for 1876; since that date other instances have been recorded both by himself and other surgeons. Lucas believes that the cerebro-spinal fluid escaping through the fracture in the vault of the skull comes, not as one would suppose, from the subarachnoid space, but from the lateral ventricle, owing to the laceration of brain substance which accompanies the injury to the head involving the ventricular cavity. In two instances he has been able to verify this opinion by *post-mortem* examination, and in two other recorded cases a similar communication has been found to exist.

The present case, to some extent, supports this view, for the leap in-driving of the bone at the seat of fracture would almost necessarily be accompanied by a wound of the dura mater, while from the nature of the injury and the symptoms which the child afterwards presented, it is probable that some laceration of brain substance was also produced. The fact that the swelling did not appear until after an interval of thirteen days also agrees with the period at which the tumour has first shown itself in other cases, and Lucas suggests that the inflammation which follows the injury to the brain is accompanied by softening of the cerebral substance and increased secretion of cerebro-spinal fluid, "so that pressure from within and yielding of the brain-wall together contribute to the escape of fluid from the ventricle;" it accordingly accumulates beneath the scalp in the form of a distinct tumour, which, owing to its communication with the interior of the cranium, presents the characteristic symptoms already described. The absence of any cerebral symptoms at the time the tumour appeared is accounted for by the very young age of the child, for it is a recognised fact that in infants extensive mischief may be going on in the brain, without producing the same marked symptoms which would usually be present in an adult.

The cessation of the pulsation, and the difficulty in reducing the tumour after the twenty-eighth day, were probably owing to the gradual closure of the fissure in the bone cutting off the communication with the interior of the cranium, and the gradual disappearance of the swelling after that date was the result of absorption of the fluid by natural means, assisted by the application of external pressure.

According to Conner (*American Journal of the Medical Sciences*, July, 1884), the prognosis in traumatic cephalo-hydrocele is very unfavourable, half the recorded cases (which up to 1884 were seventeen in number) having terminated fatally from the superinfection of meningitis. The accompanying sketch illustrates the

shape and situation of the tumour, and its relation to the subjacent fracture, the outline of which is indicated by the dark lines.

A CONTRIBUTION TO THE STATISTICS OF STONE OPERATIONS.

BY JOSEPH PROCHNOV, M.D.,
Buda-Pesth.

Nor long ago the excellent work of Sir Henry Thompson, *On the Surgery of the Urinary Organs*, translated into German by Dr. E. Dupuis (Wiesbaden, 1885), came into my hands, and in the last lecture (p. 149) I read the following lines: "It is the sum total of result obtained by employing the two procedures which is to be regarded as the measure of the surgeon's success. And I think I may say that a list of 782 cases in male adults, the mean of whose united ages exceeds 60 years, with 82 deaths, or 1 in 9½ cases, is a result which will be held to justify the selection and adaptation of the method to the case, which has been adopted throughout this series. I venture to say that it is a result which has not, certainly to my knowledge, hitherto been realised."

Professor Kovács, at Buda-Pesth, has recently published his stone operations. It is true that Sir H. Thompson is able to show larger numbers, but the statistical data of Professor Kovács give a result which is a little better than Sir H. Thompson's.

Sir H. Thompson, on 716 patients, performed altogether 812 operations, with 84 deaths (10.3 per cent.). His cases are divided in the following manner:

- 13 female patients:
 - 10 lithotomies, with 1 death.
 - 3 lithotrities — — —
- 15 children:
 - 12 lithotomies, with 1 death.
 - 3 lithotrities — — —
- 2 extractions.

If these 30 cases are deducted, there remain 782 cases of male adults.

- 110 lithotomies, with 39 deaths, 35 per cent.
- 672 lithotrities " 43 " 6.5 "

Total 82 10.5

At the First Surgical Clinic Professor Kovács, on 233 patients, performed 248 operations, with 21 and 18 deaths respectively (8.5 per cent. and 7.25 per cent.). There were:

- 77 sectio perinealis lateralis, with 4 deaths.
- 2 sectio alta " 1
- 168 lithotrities " 16
- 1 extractio calculorum — —

But it must be remarked that among the cases treated by lithotriety there were 3 who died of intercurrent diseases—namely, one patient of 14 years died of apoplexia cerebelli, one patient of 67 years of cholera Asiatica, and one patient of 48 years of pneumonia. If these cases are deducted, as seems to be reasonable, the mortality becomes less.

The cases of Professor Kovács, classified in the same way as Sir H. Thompson's, give the following result:

- 13 female patients:
 - all 13 lithotrities — —
- 115 children (namely patients under 20 years)
 - 70 lithotomies, with 2 deaths.
 - 75 lithotrities " (4) 3 "
 - 1 extractio calculorum — —
 - and 2 sectio alta " 1

(The two cases of sectio alta are cited separately, because Sir H. Thompson did not mention any cases of sectio alta amongst the lithotomies of male adult patients.)

These 131 cases deducted, there remain 117 male adults treated by lithotomy and lithotriety—namely:

- 7 lithotomies, with 2 deaths, 28.5 per cent.
- 110 lithotrities " (12) 10 " (10.9 per cent.) 9 per cent.

Total 117 (14) 12 (11.9 per cent.) 10.2 per cent.

Consequently, from this combination, it is clear:

1. In the female patients lithotriety was performed without a death.
2. In children—namely, patients under 20 years—lithotomy (sectio perinealis) was performed 70 times, with only 2 deaths;

consequently, 1 death to 35, namely, 2.8 per cent. Lithotripsy was performed 45 times, with 3 deaths, because, if the one that died of apoplexia cerebelli be omitted, the mortality is 6.6 per cent.

3. In the list of male adults—namely, patients over 20 years—there were 7 lithotomies, with 2 deaths, a result which, in spite of the small number of cases, is better than Sir H. Thompson's, the mortality being only 28.5 per cent. Of the 110 lithotripsy cases, 10 died, omitting the two patients who died of intercurrent diseases, giving a mortality of 9 per cent.

Thus lithotomy and lithotripsy were performed on 117 male adults, with 12 deaths—a mortality of 10.2 per cent.; consequently the result is about 0.3 per cent. better than Sir H. Thompson's result, which is 10.5 per cent.

CLINICAL MEMORANDA.

FUGITIVE OEDEMA OF EYELIDS.

A SISTER OF MERCY consulted me on March 1st of this year. Her history was that she had not menstruated for four months. (She was 46 years old.) She had been subject all her life to stomach and head troubles, and she had had many attacks of erysipelas of the face and head; the last attack of erysipelas was six years ago. She had always had a puffiness of the face, often the headache. Her friends often used to say, "Hav'nt you a touch of erysipelas? Your face is so swollen." Her present condition began in December, 1887. The swelling of the eyelids was much worse in the morning, and was sometimes so marked that she could not see out of them until she had bathed them and been about for a time. There was a discharge from the eyes at times, which glued the lids together. The swelling kept coming and going; it generally lasted two or three days, and returned when she got another headache.

She was a big-faced woman, with a large, loose frame. Her face and brow were covered by drops of sweat. There was quite a cushion of oedematous tissue overhanging each upper eyelid. There was nothing which would indicate eczema. She was free from any organic disease of the heart or kidneys. The legs were not swollen.

REMARKS.—Such cases as the one given above are not uncommon. We often find those who are the victims of periodical headaches present a condition of fugitive oedema of the eyelids. In one instance the swelling was limited to one orbit, and looked as if the man had been stung by a wasp. We also find many women during the menopause who have localised swellings of the hands and arms—swellings which are tender, pit on pressure, are preceded by pain, but pass away after a few hours of exercise.

TOM ROBINSON, M.D.

9, Princes Street, Cavendish Square, W.

A CASE OF HIP-JOINT DISEASE WITH PERIPHERAL NEURITIS AND EPILEPSY.

T. C., aged 15, was seen by me on December 20th, 1887. For the last three years he had suffered from disease of right hip-joint. The lower limbs were stretched out at full length in the bed. On the right thigh there were six openings which occasionally discharged pus, three on the outer and three on the inner side. Both feet were "dropped," so that the upper part of each foot was nearly on a straight line with the front of the leg. A rule placed along the left leg and foot lay only half an inch above the surface of the leg. On the sole of the right foot the arch was deep, and on the upper part of this foot there was a slight rounded prominence. He could dorsiflex the toes and feet to a small extent. The skin from the knee down was dry, scaly, and cracked; its condition somewhat resembled ichthyosis. The nails of the feet were kept closely cut to prevent them growing into the flesh, otherwise they presented no trophic changes. The knee-joints were ankylosed. The legs were very hyperæsthetic, so that the boy would not allow them to be washed, and complained of the weight of the bedclothes. His feet could not be bent into their normal position. There was no anæsthesia. Two months before I saw him he had had severe cramps in his legs. The knee-jerks were well marked. The plantar reflex was present on both sides. The peroneal nerves were not tender. There was no difficulty in passing urine or feces; no bedsores. Three months before I saw him he commenced to have "fits." He "screached," lost consciousness, and was convulsed in them. He never bit his tongue or passed his urine in those fits. There was no aura. He died on February 17th, 1888, from exhaustion. There was no necropsy.

REMARKS.—The dropped feet, the trophic changes in the skin and joints, and the hyperæsthesia were due to peripheral neuritis. Dr. Gowers says that nerves near suppurating joints may become inflamed. The nerves on the left side were involved, and this was an instance of "sympathetic neuritis." The nutritive changes in the skin are interesting. Irritative lesions of nerves are specially liable to be followed by trophic changes. It is well known that peripheral irritation sometimes produces epilepsy. Londonderry. E. DONALDSON, B.A.T.C.D., L.R.C.S.I., etc.

THE SIGNIFICANCE OF BLOOD-PRESSURE IN RENAL DISEASE.

WHILE I thoroughly appreciate and agree with the whole tenor of Dr. Broadbent's remarks on the significance of the blood-pressure in acute renal disease, I feel that on one point I must differ from him. After well describing the course of the variations of tension usual in that disease, he points out, what is certainly true, that failure to develop increased tension generally means inability or defect of the heart, and is, therefore, of unfavourable prognostic import. But he goes on further to remark that "the low tension is not always so caused; there is sometimes diminished resistance at the periphery; the capillaries and arterioles are relaxed, and allow the blood to slip through them as in pyrexia, and the pulse is not only weak but short. It is not easy to understand why this should be of bad augury, and it is only by observation that this conclusion has been reached."

The correctness of the observation I can confirm, but the explanation seems both unnecessary and deficient in probability. Putting nerve influence on one side, the three principal factors in the production of arterial tension are heart power, peripheral resistance, and mass of blood to be propelled. With peripheral resistance increased, heart muscle developed, and tissue was going on at nearly normal rate, we have the most typical example of high tension, as seen in men who, although suffering from chronic granular kidneys, are struggling to do the work of health. If, however, as is apt to occur in more acute conditions, the heart does not develop power in proportion to resistance, we find the pulse still persistent but not so hard. Persistency of the pulse, shown by the sphygmogram, commonly spoken of as the trace of high tension, does not necessarily indicate raised tension, nor even absolutely increased peripheral resistance; it only shows that the resistance is increased relatively to the propelling force, and is found not uncommonly to co-exist with great softness or compressibility.

Shortness of pulse is, however, a different affair, and is on seldom found in conjunction with the increased peripheral resistance common to all forms of Bright's disease. Any interference, however, with the mass of blood to be propelled may, at any rate for a time, take away both the tension and the persistence, leaving the pulse both weak and short. We see this after bleeding sometimes after purging, and I think it possible that in Dr. Broadbent's case the course of the disease had so interfered with the mass of the blood as to produce shortness, as well as compressibility, of the pulse, and that the condition may, therefore, be explained without calling on the hypothesis that the capillaries and arterioles were "relaxed." The heart was very weak, and there was increased tissue change to produce excess of excretory matter, and, therefore, of resistance, so that there was no likelihood of any increase of tension, and I suppose that the disturbance, both mass and quality of blood, produced by the large dropsical effusion, and the extreme albuminuria would, like either bleeding or purging, be sufficient to produce the shortness of the pulse. I make this suggestion merely for the sake of putting this case on all fours with others which on any different hypothesis are very difficult to explain.

While compressibility of pulse is not uncommon in the late stages of chronic renal disease, such shortness as to be suggestive of diminished peripheral resistance is chiefly met with in cases in which some intercurrent malady, such as paralysis, has so altered the patient's general condition as to food and waste and blood production, that the mass of blood to be moved is lessened. As a fact, we do see men whose pulses have formerly been so tight as to burst their arteries, leading an invalid semi-vegetable existence, with pulses beating shortly in slack arteries, the peripheral resistance no doubt still being sufficient to oppose the passage of a quantity, but, the quantity being no longer there, the amount propelled is well within that which can be resisted.

This is, I think, the true explanation of these somewhat rare

ases in which the pulse is slack where we should expect it to be persistent, and it may possibly apply to the one so well described by Dr. Broadbent.
Halifax.

SURGICAL MEMORANDA.

A CASE OF INFANTILE INTESTINAL OBSTRUCTION.

On October 8th, 1888, Mrs. H. gave birth to her first child. Its bowels not acting at the end of twenty-four hours, a dose of castoril was given by the mouth, which was repeated next day, and a small soap suppository inserted. These were repeated on the third day. Afterwards it was discovered that the rectum was all but occluded just above the sphincter. Just before this there was a quantity of most offensive material vomited, which was so very isagreeable that the babe was removed from its mother. Repeated trials failed to force a passage into the bowel. The skin was rapidly changing colour, and collapse seemed to be setting in. On the sixth day I succeeded in passing a small probe through the pex of the inverted cone in the rectum, and afterwards the blades of a small pair of dressing forceps, which were gradually expanded through this opening a No. 10 gum elastic catheter was passed to the extent of four inches. A brass syringe, charged with an emulsion of castor-oil and warm water, was attached to the other end of the catheter, and about two ounces injected. This had the effect of distending the bowel, and allowing the catheter to slip higher up still. By perseverance in this method, the hole of the catheter was passed into the bowel, and the distal end could be felt near the ascending colon. About six ounces of the above emulsion was then injected, and the catheter withdrawn. Eight hours afterwards the babe passed a free motion of feconium. In eight hours more it passed another copious motion, which smelt very strong, and looked dark olive-green. The little patient looked exceedingly ill. The skin was mahogany-tint, and very shrivelled; the bones of the head had sunk; the hands and feet cramped; the lips and tongue dark purple. The nurse then gave it a warm bath, and afterwards wrapped it well up in wadding, and applied it with a bottle of milk and water, which it sucked greedily. It was then carried back to its mother, who had not seen it for sixty-four hours, and never expected to see it again. The babe soon resumed breast-feeding, and for some time did well. I merely bring this case before the profession to show that these cases of infantile occlusion of the rectal end of the bowel are not always so bad as to require colotomy. There was an undoubted stricture of the bowel, about an inch and a half from the anus. This was overcome by, first, a probe, and afterwards dilatation of the blades of a small pair of dressing forceps, and the whole tract of colon distended by enemata introduced through a long gum-elastic catheter, which enabled the latter to slip along to near the ascending colon. Whether the emulsion passed through the ileocolic valve into the ileum, and so released a possible intussusception, I cannot say. Treves says (*Intestinal Obstruction*, page 38) that enemata do not pass this valve.

Springfield House, St. Leonard's-on-Sea.

THERAPEUTIC MEMORANDA.

THE ACTION OF ANTIPYRIN IN MIGRAINE THAT OF AN ACID.

INCE my paper on the treatment of the paroxysm of migraine by acids appeared in the JOURNAL of January 14th, 1888, I have several times been asked whether I could explain the good effects of antipyrin in the same kind of headache.

I was at first inclined to think that its action as a nerve sedative was sufficient to account for its effects, and that it perhaps acted like bromide potassium; there was, however, some difficulty in accepting this view, for several fellow-sufferers, who, like myself, had found that bromides were of comparatively little use, yet found that antipyrin acted like a charm.

I therefore repeated my experiments with antipyrin, and found that it quickly and decidedly increased the acidity of the urine, a fact which I had overlooked in my previous experiments with acids, probably from taking too small a dose to overcome minor disturbing influences.

I now find that a dose of twenty grains raises the acidity of the urine within the first hour after taking it, and the rise con-

tinues and increases for some four, five, or six hours more, and one drachm taken in three doses causes a very distinct rise in the acidity of the twenty-four hours, and a decided fall in the uric acid excretion. Further, in experiments on myself, antipyrin caused the pleasant feeling of well-being, which I have noticed in my paper on Epilepsy in the *Neurologisches Centralblatt* of March 1st, 1888, as one result of taking acids. I should therefore have no doubt that the rise in acidity it occasions is sufficient to account for the action of antipyrin in curing any case of migraine which is due to uric acid.

Another instance of the same thing is probably to be seen in the good results which some have obtained in these headaches with chloride of sodium (see note in JOURNAL, vol. ii, 1887, p. 528) as this drug also raises acidity, and acts as an acid.

I have not myself made use of antipyrin in the treatment of migraine, for my results with acids are completely satisfactory; and I frequently hear from other people of their obtaining good results. I notice also that somewhat smaller doses of acid than those I have recommended appear often to be sufficient.

REPORTS

OF

HOSPITAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN, IRELAND, AND THE COLONIES.

QUEEN'S HOSPITAL, BIRMINGHAM.

CASES OF NERVOUS DISEASE.

(Under the care of Dr. C. W. SUCKLING.)

Tabes Dorsalis, with Rapid Development of Ataxia.—In the following case the ataxia developed so rapidly that the disease in this instance deserves to be called acute. The patient, up to within a fortnight of his admission, was walking about in charge of a team of horses; while, when admitted, he was totally unable to stand. Moreover, the inability to stand came on in a single night. H. B., a carter, aged 33, was admitted in February, 1887, complaining of loss of power in the legs. He stated that five years earlier he had a sore on the penis, but no rash or throat affection. Five months before admission he found that he staggered when standing up and washing his face. Later on he noticed numbness in his feet and a sensation like "walking on wool," with shooting pains at intervals. The symptoms rapidly increased, but he was able to walk by the side of his horses until a fortnight before his admission, when he suddenly found himself unable to stand. He had been out all day, walking perfectly well without any difficulty, but the next morning he was unable to stand, the ataxia thus developing within a few hours. When admitted he was quite unable to stand without support, swaying in all directions. He could move his legs about freely and with considerable force, but could not properly control the movements. There was no vertigo. The muscular sense was greatly deficient, both in the upper and lower extremities. There was a separation of tactile and painful sensations. When pricked with a pin contact was first felt and then pain. The knee-jerk was lost on both sides, the plantar reflexes were also lost; the other reflexes were normal. There was myosis, but the pupils responded to light and accommodation. There was nystagmus when the eyes were directed strongly to the right or left or in an upward or downward direction. Diplopia was also observed when looking upwards. The fundus oculi on both sides was normal. After admission the ataxy rapidly increased, and he soon found that he could not hold his pen to write, and he complained of loss of control over the movements of the little and ring fingers of the right hand, with numbness; his writing was almost illegible. The patient was at first treated with iodide of potassium, but the symptoms increased while he was taking large doses of this drug. Nitrate of silver was therefore given, and in a few days he expressed himself as being better, the numbness and loss of control over the fingers had disappeared, and his writing was much better. The girdle pain and shooting pains in the legs were also relieved, but he still remains unable to stand. There were no crises of any kind.

Hemiplegia with Hemianesthesia due to Cerebral Hemorrhage.—A. P., a woman, aged 59, was admitted in March, 1887, suffering from loss of power on the right side. The only feature of interest

in the family history was that her father suffered from gout, and that one of her brothers is gouty. A few days before admission, while standing, her right arm began to tingle, and in a few minutes she lost all power and feeling in the right leg and arm, and also lost her power of speech. On admission, it was found that the right arm and leg were completely paralysed; the lower facial muscles on the right side were also weak, and the tongue was protruded to the right. There was also complete anaesthesia of the right side of the face, right arm and leg, and of the right half of the trunk to the middle line. No hemianopia or affection of the special senses was observed. There was cardiac hypertrophy with accentuation of the aortic second sound and a hard pulse, the arteries being very atheromatous. The urine contained a trace of albumen, but was otherwise normal.

The patient improved slowly, and in a fortnight could move her leg fairly well, but the arm remained almost completely paralysed. The anaesthesia to some extent had cleared up from above down in the upper extremity, sensation being quite lost on both surfaces of the hand, but having returned slightly in the forearm, and to a still greater extent in the arm. Painful impressions could be easily distinguished, but tactile and thermal sensations were completely lost. The anaesthesia formerly present in the right side of the face had also disappeared, and on the trunk and right leg was much diminished, sensation reappearing in the leg also from above down. The muscular sense was still completely lost in the right upper extremity, but was only slightly impaired in the leg.

On April 14th it was noticed that the anaesthesia of the lower extremity was clearing up rapidly, and remained only along the outer surface of the dorsum of the foot, where she could not feel a pin prick, or a light touch.

On April 19th she complained of pain in the right elbow and wrist joints, which were found to be slightly swollen.

May 15th.—The patient got up, and could walk unaided, but with considerable dragging of the right foot. The power of movement had returned to a considerable extent in the right arm. In the lower extremity she could feel and localise a very light touch, and sensation was now recovered in the right half of the abdomen, but was still impaired in the pectoral region. She was still unable to perceive the exact position of the arm or leg. The recovery of sensation was far in excess of the recovery of motion.

REMARKS BY DR. SUCKLING.—Hemianæsthesia is far more commonly due to hysteria than to coarse organic lesion of the brain. Still, it is not infrequently observed in severe cases of hæmorrhage. The clot in the above case is, in all probability, in the internal capsule, and due to rupture of the lenticulo-striate artery. The sensory fibres of the internal capsule occupying its posterior third are evidently damaged. All forms of sensation were impaired, the loss of muscular sense being very marked. The sensory portion of the internal capsule is supplied by the posterior cerebral artery and not by the middle cerebral, so that, in cases of hemiplegia accompanied by hemianæsthesia due to a vascular lesion, the case is always one of hæmorrhage, obstruction of the middle cerebral artery by a thrombus or an embolus not affecting the sensory portion of the capsule.

ST. BARTHOLOMEW'S HOSPITAL.

A CASE OF TUMOUR OF THE LOWER JAW: ENUCLEATION: REMOVAL OF THE LEFT HALF OF THE LOWER JAW.

(Under the care of Mr. WALSHAM.)

M. W., a woman, aged 25, was admitted on July 12th, 1881, having been sent to Mr. Walsham by Mr. Harrison, of Braintree. The patient, who appeared in perfect bodily health, stated that about nine years ago, whilst cracking a nut, she broke her second left molar tooth, and about two years afterwards noticed a swelling of the jaw in that region, which then began to be painful. The swelling and pain had gradually increased, and had been attended with a discharge from an ulcerated opening in the gum. On examination there was found on the left side a swelling of the lower jaw, extending from the anterior bicuspid tooth backwards nearly as far as the angle, and downwards to the lower margin of the bone. It projected both externally on the cheek, and internally into the floor of the mouth. In the situation of the second left molar tooth, which was absent, there was an ulcerated opening leading into a cavity extending from that point downwards and forwards towards the bicuspid teeth. A small quantity of puriform fluid

exuded from the opening, and a fleshy granulation was seen at the entrance of the sinus.

On July 16th Mr. Walsham made an exploratory examination under gas, and a piece of the tumour was removed, and appeared on microscopic examination, to have the structure of a sarcoma.

On August 3rd an incision was made through the skin and periosteum, along the lower margin of the jaw, extending from a little to the left of the symphysis nearly as far back as the angle; the periosteum was separated from the outer table, and sufficient of the latter was removed with bone-scissors to expose the tumour which was found expanding the bone around it. The tumour was next enucleated with the aid of a raspator, leaving a smooth-walled cavity in the interior of the jaw. At the situation of the second molar tooth, however, the tumour had formed for itself a smaller loculus, and as at this spot the growth did not shell out so readily, Paquelin's cautery was swept over the interior of the cavity. After all the growth had been removed, the ulcerated aperture at the situation of the second molar tooth was found to communicate with the cavity in the interior of the bone. It appeared, therefore, that the growth had commenced at this situation, and, expanding the bone, had protruded into the mouth through the socket of the tooth.

The growth is described in the notes as having the microscopical characters of a sarcoma, but beyond this, and that it was of a papillary nature, the detailed account of its minute structure is unfortunately not given.

The patient made an excellent recovery, and returned to the country on September 20th, with the wounds in the mouth and below the jaw completely and soundly healed. Nothing more was heard of her till February 25th, 1886, four years and a half after the operation above described, when she was again admitted into the hospital with a large tumour of the left side of the lower jaw. In the meantime she had married, and had three children. She had enjoyed perfect health till two years before, when she noticed a return of the swelling about the site of the former operation. The lower jaw on the left side was now found expanded by a tumour, which had fungated at one spot into the mouth, and was infiltrating the cheek. It extended along the alveolar margin of the jaw, and prevented the teeth from being completely closed. There were no enlarged glands, and the patient's general health was good.

On March 5th Mr. Walsham excised the left half of the lower jaw in the usual manner, and a portion both of the mucous membrane of the cheek and of the masseter muscle, which were to some extent infiltrated. The patient made a rapid recovery, and was discharged March 30th with the wound soundly healed. When last heard of, January 25th, 1888, there had been no return.

REMARKS BY MR. WALSHAM.—The specimen was examined by Mr. Bowlby, and shown by him at the Pathological Society; it is now contained in the hospital museum. The microscopical examination of the tumour after removal of the jaw clearly showed it to have the structure of those growths for which Mr. Eve has proposed the term "multilocular cystic epithelial tumours." Such tumours appear to be the result of the ingrowing of the epithelium of the gum consequent upon an increase of the blood-supply attending certain injuries, the irritation of decayed teeth, and the like. They are generally of slow growth, frequently do not return, and show little tendency to involve the lymphatics or to become disseminated. The small portion of growth removed for microscopical examination before the first operation was thought to have a sarcomatous structure; but, as the growth after enucleation does not appear to have been examined with sufficient care, it is questionable whether from the first it was not a multilocular cystic epithelial tumour. Its clinical character, moreover—namely, slow growth, its origin in connection with a broken tooth, the absence of any glandular enlargement and of any tendency to general dissemination—bear out this view. The growth had already attained some size when it first came under my notice, and had perforated the bone in places, and consequently some outlying portion probably escaped extirpation. The propriety of an early and thorough removal of the growth whilst it is yet confined within its bony case cannot, I think, be too strongly insisted upon.

ACCIDENT TO DR. REID, ROTHESAY.—While driving through Rothesay on April 25th, Dr. Reid met with a severe accident, but is, we are glad to learn, now recovering.

PADDINGTON GREEN CHILDREN'S HOSPITAL.—Miss Augusta Forbea has been appointed Matron of this hospital.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MAY 8TH, 1888.

Sir E. H. STEVENING, M.D., President, in the Chair.

On the Results of the Treatment of Pulmonary Consumption. Residence at High Altitudes, as exemplified by an Analysis of 1 Cases.—Dr. C. THEODORE WILLIAMS offered a contribution on his own practice of 141 cases of phthisis treated in sanatoria lying in altitude from 5,000 to 9,000 feet, in the Alps, the Rocky mountains, and the South African Highlands, during the last nine years, in order to deduce certain practical rules therefrom. The 141 cases had been tabulated for statistical purposes under the following headings: Sex. Age. The length of illness before the commencement of mountain residence. Hæmoptysis. History and nature of cases. State of the lungs. Medicine and diet. Length of residence at high altitudes. The Alpine climate was then compared with that of Colorado and the South African Highlands. The results of this treatment had been tabulated under the heads: General—referring to the general health, vigour, and weight—local, including the conclusions arrived at from the examination of the lungs. The general results were divided into (1) cured 41.13 per cent., where the restoration to health was complete, (2) greatly improved 29.78 per cent., (3) improved 11.34 per cent., (4) deteriorated 17.02 per cent., thus giving a total of 82.25 per cent. improved and 11.34 per cent. deteriorated, including 13.47 per cent. deaths. The local results of the 141 cases yielded improvement, greater or less, in 74.82 per cent. (including arrest in nearly 44 per cent.), and deterioration in 21.5 per cent., and a stationary condition in 3.59 per cent. Among the first stage cases there was improvement in 91 per cent., and arrest of disease in 63 per cent., with deterioration in nearly 7.5 per cent. Cases of unilateral first stage gave 92 per cent. improved and 70.5 per cent. of cures, and cases of bilateral affection yielded 87.09 per cent. of cures and 48.38 per cent. of arrests. In the second and third stage cases there was improvement, to a greater or less extent, in 68 per cent., arrest in 10 per cent., and deterioration in 46 per cent. Single cavity cases gave better results than cavity cases with the opposite lung involved, and left lung cavities showed a greater tendency to change, either for better or worse, than the right lung cavities. The following conclusions were arrived at: 1. That prolonged residence at high altitudes produced great improvement in the majority of consumptive patients, and complete arrest of the disease in a considerable proportion, such arrest being in a greater or less degree permanent. 2. That in order to secure these advantages, patients must be free from pyrexia and all acute symptoms, and must possess sufficient lung surface to adequately carry on the process of respiration in the rarefied atmosphere. 3. That the influence of the climate seemed to promote a change in the lungs, either of a curative or destructive character, and to oppose the process of necrosis. 4. That residence at high altitudes caused enlargement of the thorax, hypertrophy of the healthy lung-tissue, and development of pulmonary emphysema around the tubercular cavities, and that this expansion of the chest was accompanied by diminution of the pulse and respiration rate. 5. That it was probable that the arrest of consumptive disease was partly owing to the pressure exercised on the tubercular masses by the increasing bulk of the surrounding tissue. 6. That the above local changes were accompanied by general improvement, shown in the cessation of all symptoms and the gain of weight, colour, and of muscular, respiratory, and circulatory power. 7. That consumptives of both sexes benefited equally by mountain residence, but that the age of the patient exercised considerable influence on the result. 8. That the high-altitude treatment seemed to be specially adapted in cases where heredity and family predisposition were present. 9. That the climate was useful in cases of hæmorrhagic phthisis, and that hæmoptysis was of rare occurrence at the mountain stations. 10. That mountain climates were most effective in arresting phthisis when the disease was of recent date, but they were also beneficial in cases of longer standing. 11. That the special effects of high-altitude residence on the healthy and diseased were common to all mountain ranges of elevations of from 5,000 feet and upwards. 12. That to ensure the full advantages of high-altitude residence, a period of at least six months was necessary in the majority of consumptives. In cases of long standing and of extensive lesions, one or two years were often requisite to produce arrest of the disease. 13. That, in addition to the above

examples, mountain climates were beneficial in (1) cases of imperfect thoracic and pulmonary development; (2) in chronic pneumonia without bronchiectasis; (3) chronic pleurisy where the lung did not expand after removal of the fluid; (4) spasmodic asthma without much emphysema; and (5) in anæmia. 14. That they were contra-indicated in the following conditions: (1) Phthisis with double cavities, with or without pyrexia; (2) cases of phthisis where the pulmonary area at low levels hardly sufficed for respiratory purposes; (3) catarrhal phthisis; (4) cretanic phthisis, or phthisis where there was great irritability of the nervous system; (5) emphysema; (6) chronic bronchitis and bronchiectasis; (7) diseases of the heart and greater vessels; (8) affections of the brain and spinal cord, and conditions of hypersensibility of the nervous system; and (9) where the patients were of advanced age, and where they were too feeble to take exercise.—Dr. BOWLES wished to call attention to a point which was very common in the Alps, and produced pathological changes, namely, sunburn. It did not seem at first sight to have much to do with phthisis, but he considered that it might be found to throw some light upon it. Snow was a potent factor in producing the effects of sunburn, as might be seen in any collection of snow walkers in the high Alps, as contrasted with those who walked in the lower levels; some of them felt a stinging sensation in the face almost as soon as they got upon snow, and developed a condition almost like erysipelas. He had noticed that the freckles on a face were almost unaffected, and from that indication had painted his own face brown before going on the snow, and had by that means succeeded in avoiding being burnt. He had been interested to learn subsequently that that was a plan adopted for a similar end, by the natives of North Africa and Sikkim.—Dr. HERMAN WEBER was specially interested in Dr. Williams's figures, as he had compiled somewhat similar tables himself in 106 cases which he had sent to high altitudes. His results were not quite as satisfactory as those of Dr. Williams, but very nearly so, for they showed nearly 40 per cent. of cure, and nearly 40 per cent. of improvement, more or less. He had, however, sent a larger proportion of patients in the first stage (namely, 70 out of 106) than Dr. Williams. Of his cases, 55 per cent. had gained weight, 38 per cent. had remained stationary, and only 7 per cent. had lost weight. He was not inclined to attribute very much importance to this last group of figures, as it was largely dependent on the opportunities of nourishment before leaving England; nor did he attach value to altitude, except as making open air and exercise easy. At Frankenstein, for instance, which was less than 2,000 feet above sea level, he thought they got quite as good results as in the high Alps, or even better.—Dr. DE HAVIDLAND HALL had been sorry to hear nothing from Dr. Williams about laryngeal phthisis. He should be glad to know if Dr. Williams agreed with the general opinion that no gain was to be got for that from high altitudes, unless in the cases in which the laryngeal mischief was merely catarrhal.—Dr. J. E. POLLOCK thought there was something to be learnt from figures in this matter, and was grateful to Dr. Williams for what he had put before them. He had himself, a good many years ago, collected and tabulated a series of 13,500 cases which had been under his observation at the Brompton Hospital. Altitude was only one of the many agents which might tend to cure phthisis, and on what all the others were he had still a great deal to learn. The cases Dr. Williams had selected to send to the Alps were just the cases that would do well in London also. The cases where there was pyrexia had been excluded, and he must draw their attention to this, for really it seemed to him that this was half the battle. The cases with a chronic first stage did well in England also. The cases with a limited cavity in one lung lasted longer in England than those in any other stage of any other form of phthisis; they were checked by the consolidation, and might live through twenty-five or thirty years. And, lastly, the cases of scattered deposit often remained unchanged for a long while. They had often heard of a rich man's gout, and a poor man's disease. Dr. Williams had been talking to them about was emphatically a rich man's phthisis. What these people were suffering from, who would indulge themselves in their weighing machines and their toboggans, and support their doctors and their parsons, was a very different thing from the malady of *les misérables* with which we all had so much to do nearer home.—Dr. A. TUCKER WISE remarked that in the Alps appetites improved and spirits rose in all who could enjoy the sun and take wholesome exercise, and there was very little annoyance from the lesser colds and coughs. The cold aseptic air acted as a sedative to the cough, and the rooms were often not heated above 50° F.

The action of the sun's rays helped to change the white corpuscles of the blood into red, and to develop hæmoglobin. The ozone was beneficial. He had noticed that those who perspired readily did not have the usual dyspnoea of a high altitude.—Dr. EWART had no doubt that the poor would improve even more than the rich if they could go to equal comforts in high altitudes; it was difficult, or in fact impossible at present, that they should go. The question they had to consider was what was the best way of improving phthisis in rich men. They suffered here from luxurious living: in the Alps they got physical and mental rest. They got complete change and a fresh spring of hope. If anyone doubted it, it would be best for him to go to see the patients whilst they were out there, or at least to hear their evidence when they came home. He had himself been greatly improved by four winter visits to the Alps, and the comparative want of vigour and freshness in the Riviera had struck him much. Nevertheless, much discrimination was wanted in choosing the cases to send to the Alps.—Dr. HUGGARD had not met with a condition of hypertrophy of healthy lung-tissue in the Alps, such as Dr. Williams had mentioned. He had found the chief change in the chest was increased capacity for movement, a greater maximum of expansion in inspiration or smaller minimum after expiration. He could not agree with what Dr. Bowles had said as to the probable effect of snow in the cure, for the consumptives did equally well in Mexico and Colorado and the Andes, where there was no snow. It was a remarkable fact that phthisis was completely absent from Mexico, although it was a crowded city.—Dr. QUAIN was very much obliged to Dr. Williams for his statistics, but he could not help saying that to him they were absolutely valueless. He had heard not a word of the constitutional symptoms and dyspepsia of these patients, and he was inclined to think they got well because they could not help it; they would have got well anywhere. One point went strongly against his sending anyone to the Alps, and that was the most unfriendly fashion in which Switzerland had forbidden English physicians to practise there, under pain of imprisonment. That was a genuine grievance, and needed speedy attention.—Dr. C. T. WILLIAMS begged to thank the meeting for their kind reception of his paper, and for their various criticisms and suggestions. He was glad to find Dr. Weber, on the whole, confirmed his statistics. Before he could quite believe all that was said of Frankenstein as a health-resort for phthisis, he wanted to see more statistics about it, and asked where he could find them. He had found, as Dr. Hall had expected, that laryngeal phthisis was not benefited at all by treatment at high altitudes. The hypertrophy of healthy lung-tissue he had mentioned was a conclusion to which he had been led by the absence of any other hypothesis to explain the physical facts of increased nausea, chest capacity, and breathing, as measured by the spirometer. He acknowledged great debts to Dr. Pollock, but ventured to doubt if even he could show him so many cases of arrest, although he admitted for his own part, of course, that he had selected his cases. He referred to many tables on the walls with a view of showing that many groups of cases treated at the English coast, or on the Riviera, or by sea-voyage, did not show equally good results with those treated at high altitudes.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, MAY 2ND, 1888.

JOHN WILLIAMS, M.D., President, in the Chair.

Specimens.—Mr. DORAN: Glandular Structure in the Substance of a Primary Cancer of the Fallopian Tube.—Dr. GALABIN: Microscopic Section of Tube from a case of Tubal Gestation at fourth or fifth week.—Dr. GRIFFITH: (1) Microscopic Section of Oviduct of Frog, showing Tubular Glands; (2) Microscopic Section from a case of Interstitial Gestation, showing Mucous Follicles in the Muscular Wall of the Fallopian Tube.—Dr. HOBROCKS: Completely Inverted Uterus removed by Operation.—Dr. GRAILY HEWITT: Invalid's Compendium.—Dr. GODSON: Auvard's Nipple Shield.—Dr. ARMSTRONG (Liverpool): Alpha Enema Syringe.

Cyst Connected with Uterus, and Simulating Enlargement of that Organ.—Dr. CULLINGWORTH described the case of a woman, aged 23, admitted into hospital on November 23rd, 1886, with an abdominal swelling which had been observed for five months. The catamenia were regular, but during her last pregnancy they had continued to the seventh month. The swelling fluctuated distinctly, and reached upwards as high as half way between the

umbilicus and the ensiform cartilage. A soft *bruit*, synchronous with the radial pulse, could be heard, especially towards the left iliac region. The uterus lay high in the pelvis, and was intimately connected with the tumour; no fetal heart sounds could be heard. She left hospital, but returned on December 20th, sudden abdominal pain having followed an attack of profuse metrorrhagia, and the abdomen, which had been very tense, became soft as the pain set in. She was pale and collapsed when readmitted; high temperature followed. By December 26th she had greatly improved. A distinct, firm, elongated, movable tumour could be felt in the lower part of the abdomen. Ascitic distension of the abdomen took place. On January 19th, 1887, Dr. Cullingworth performed abdominal section. Six pints of ascitic fluid were cleared away, and there were evidences of recent peritonitis. The uterus, or what appeared to be the uterus, was enlarged, as at the fifth month of pregnancy. Douglas's pouch was obliterated by adhesions. The right ovary (as large as a hen's egg) and the tube were found to be covered with recent lymph; they were ligatured and removed. The left ovary was normal. The omentum was enormously thickened. Nothing like a ruptured cyst was detected. The patient died, with symptoms of catarrhal pneumonia, eleven days after the operation. At the necropsy the uterus was found to be of normal size, and what had appeared to be the enlarged uterus proved to be a thick-walled cyst, containing a quantity of thick, opalescent, jelly-like fluid, in which were some portions of tissue, like softened parchment. The left Fallopian tube ran along for some distance in the wall of the cyst, but did not anywhere communicate with it. No fetal remains could be found. A thickened patch of tissue on the cyst-wall was carefully examined, but Dr. T. HARRIS (Manchester), who examined it when fresh, could find no evidence that it represented degenerated placental tissue. The specimen had been referred to a committee after its exhibition before the Society in April. Their report was now read; the parts were minutely described, and it was concluded that it was impossible to say whether the tumour was a cyst which had grown, possibly, from the left broad ligament and extended to the right between the uterus and rectum, thus becoming adherent to the surrounding parts, or whether, on the other hand, it was the product of an inflammatory process with pseudo-cystic walls. The cyst had completely separated the posterior part of the uterus from its peritoneal coat. Douglas's pouch lay behind the cyst, obliterated by adhesions.—Mr. BLAND SUTTON believed that the cyst really represented hydatid disease.—Dr. HORROCKS thought that the thickness of the middle muscular coat negated that supposition.—Mr. SUTTON considered that the presence of a layer of muscle fibre supported his view.—Dr. CULLINGWORTH regretted that the fluid from the cyst had not been examined; he was inclined to agree with Mr. Sutton's theory.—Mr. ALBAN DORAN admitted that the cyst occupied the position noted by Freund and others in their recorded cases of hydatid disease of the pelvis. But hydatids were usually much disseminated, and none were discovered at the necropsy on Dr. Cullingworth's case.—Dr. HEWITT had seen a case where a hydatid tumour was found in the same situation as in Dr. Cullingworth's specimen.

The Glands of the Fallopian Tubes and their Function.—Mr. BLAND SUTTON endeavoured to show that the mucous membrane of the tubes in the human subject was, contrary to the current opinion, glandular, and that the tubes themselves had a function beyond acting as simple passages for ova. Their structure had been so thoroughly investigated by competent histologists that the question was merely a matter of interpretation. The homology of the various parts of the human uterus and the avian oviduct was described, and the function of those parts considered. Thus the infundibulum and the albumen segment of the oviduct corresponded with the Fallopian tube and its fimbriae. The shell-forming segment and the uterus proper were homologous. The vagina was the homologue of the isthmus and the oviducal portion of the cloaca. The nature of a gland was considered, and comparison made between the epithelial diverticula of the oviduct, the uterus, and Fallopian tubes, in order to show that the so-called rugæ of these tubes were really glandular diverticula, whose function was to secrete an albuminous material comparable to the albumen of an egg. From this substance the embryo obtained pabulum by means of the chorionic villi.—Mr. ALBAN DORAN stated that Hennig had shown, about fourteen years ago, that there were glands in the Fallopian tube, but had not convinced authorities in respect to his theory. Mr. Sutton had more

oroughly demonstrated the glandular nature of the tubal mucous membrane, but sceptical scientists might demand more practical evidence, in the shape of microscopic preparations and accurate diagrams, than could be afforded by his undoubtedly able arguments alone.—Dr. GRIFFITH insisted that in discussing the function of the highly specialised mucous membrane of the human oviduct the glands found in the oviducts of many lower vertebrates should have been taken into consideration by Mr. Atton.—In reply, Mr. SUTROX admitted the value of studying the oviduct in the lower vertebrates, but when it came to be a question of structural peculiarity in a mammal, the oviducts in lower forms afforded little that was trustworthy. Doubtless the opinion that the rugae of the tube were glandular in function had occurred to many; but they lacked the boldness, or perhaps rashness, to express it.

Hemiplegia occurring Nine Days after Parturition; Death: Autopsy Post-mortem Examination.—This case was recorded by C. E. F. SCUGAL (Huddersfield). A patient, aged 37, was confined on August 21st, 1887, of her seventh child. All went well till August 28th, when she complained of numbness and tingling in the first, second, and third fingers of the left hand. At 1.30 p.m. on August 29th the nurse noticed that amongst other symptoms the patient's mouth was slightly drawn to the right. At 10 p.m. she was found as follows: complete paralysis of the left arm and paresis of the left leg, slight divergent strabismus of the right eye, and the mouth slightly drawn to the right side. There had been a little difficulty in swallowing, which had now passed away. Consciousness and speech were unaffected; there was no pain in the right side of the head. The skin was moist, temperature normal, pulse 96; no loss of sensation could be detected. Three and a half grains of calomel pill was given, to be followed by two ounces of Esculap water every two hours till diarrhoea was produced, and a draught containing iodide of potassium and citrate of potash was prescribed. By 1 p.m. the left leg was completely paralysed. In the course of the next day drowsiness came on; the bowels were opened by enemata. Later on numbness and increased pain in the right side of the head were served; the temperature rose to 99.2°; the pulse was irregular rhythm and power, varying from 72 to 84. The secretion of milk had quite disappeared by August 31st. The patient became comatose and died at 2.15 on September 1st. The brain alone was examined after death. A clot was found in a vein on the surface of the brain corresponding in position to the right middle meningeal artery, and another in a vein corresponding in position to the right middle cerebral artery. These clots were distinctly *ante mortem*. There was no sign of thrombi in the sinuses. The brain, pons, and medulla exhibited no trace of extravasations or of any other morbid appearance.—After some observations by Dr. MORGAN HANDFIELD-JONES on a case in his own experience, Dr. GRIFFITH NAPLIER observed that puerperal hemiplegia was practically due to thrombosis, embolism, or reflex influences, the first cause being the most frequent.

A Case of Extirpation of the Uterus for Primary Carcinoma of the Body.—This communication was read by Dr. LEWERS. The patient was aged 58, and had had one child. She had been subjected to uterine hæmorrhage for ten months, accompanied ultimately with watery discharge, severe pain radiating to the thighs, and emaciation. On vaginal examination, February 26th, 1886, the vaginal portion of the cervix was found normal; a hard lump was felt posteriorly, apparently in the supra-vaginal part of the cervix. The uterus, examined under chloroform, was freely movable, the body evidently enlarged. Through the speculum no blood-stained discharge was seen issuing from the os. The fundus was then passed, and afterwards small fragments of a soft material appeared in the discharge. On March 1st, 1886, vaginal extirpation of the uterus was performed. The perineum was incised, to gain room. The bladder was separated from the uterus, the utero-vesical reflexion of peritoneum being, at this stage, left intact. Douglas's pouch was then opened to a small extent with scissors, and the aperture enlarged by laceration effected with the fingers. The utero-vesical fold was then torn through from below, the size of the uterus prevented the operator from passing his fingers along the back of the uterus and over the fundus, so as to use a guide to the cutting through of that fold. The ends of the anterior and posterior incisions were united laterally, by cutting, first, through the mucous membrane only. The lateral attachments of the cervix were tied on each side by silk ligatures passed with the aid of an aneurysm needle from behind forwards. The cervix was cleared as high as the level of the internal os. Each

broad ligament was transfixed and tied in two halves, stout silk ligatures being employed. The broad ligaments were then cut through, and the uterus separated; on account of its bulk it could not be retroverted and brought out fundus foremost. The peritoneal wound was closed with silver sutures, the ends of the broad ligaments being adapted between the edges of the wound. A small drainage-tube was introduced into Douglas's pouch; it was found loose in the vagina two days later. The vagina was filled with eucalyptus gauze sprinkled with iodoform. The patient made a good recovery. The uterus was found to contain a papillary growth occupying the right side of its cavity, and separated from the healthy mucous membrane by a sharp line of demarcation. She continued in good health for several months; at length a lump could be felt in the upper part of the vagina, followed by secondary deposits in the lumbar glands. She died in hospital sixteen months and one week after the operation. Dr. Lewers considered that the patient had enjoyed ten months of renewed health and comfort, owing to the operation which had prolonged her life.—The PRESIDENT was glad that Dr. Lewers had not published his case until able to give a complete account of it. Total extirpation of the uterus for cancer of the cervix was not justified, because supra-vaginal amputation was less dangerous, and furnished as good results; recurrence, when it took place, appeared in the cellular tissue around the cervix, and not in the uterine stump. The scanty data at our disposal did not put us in a position to judge the value of total extirpation for cancer of the body. The mortality was high, and recurrence, in most instances, so early that it remained doubtful if, in the majority of cases, life were prolonged. Still, it could not be doubted that a longer or shorter respite from suffering was given in all cases which recovered from the operation.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

THURSDAY, MAY 3RD, 1888.

J. W. HULKE, F.R.S., President, in the Chair.

Melanotic Sarcoma.—Mr. C. HIGGINS gave an account of a case of this affection. The chief point of interest was that the appearance of the growth simulated to such an extent an opaque and displaced lens as to be taken for one by more than one of those who examined it. The eyeball was eventually excised, and found to contain a mass of melanotic sarcoma. The patient died with a greatly enlarged liver seven months after the removal of the eyeball.

A Point in Connection with Artificial Eyes.—Mr. McHARDY pointed out that a sinister appearance almost invariably associated with the wearing of an artificial eye was very largely, if not indeed entirely, obviated when such a patient wore spectacles or eyeglasses glazed with odd lenses, so that the lens in front of the artificial eye had something like 3 D greater refracting power than that before the natural eye. The extra lens power before the artificial eye produced an optical delusion regarding the level and size of the latter; and the excess of lens power, which usually was about 3 D, could be varied according to the distance at which the lens was placed in front of the artificial eye.—Mr. TWEEDY thought there was nothing new in the suggestion; he had adopted the practice for many years, and believed he owed the idea to Mr. Lawson.

Primary Tuberculosis of the Choroid.—Mr. McHARDY read the notes of a case of local tubercular choroiditis occurring in a child aged 6, with negative family history. He closely watched the intra-ocular condition during four weeks, and then enucleated. The constitutional symptoms which had preceded enucleation immediately subsided after removal of the eye, and had not returned in the five months that had since elapsed. The specimen showed that complete detachment of the retina had occurred at the time of enucleation; that the main intra-ocular tumour was in the choroid, and that the two smaller masses in the retina were all definitely tubercular so far as the microscopical appearances without the presence of bacilli would reveal. He regretted that inoculation had not been practised, urged the importance of early enucleation in analogous cases, and remarked that the literature of the subject pointed to the infrequency of local intra-ocular tuberculosis, to the not invariable, but very usual, failure to find the Koch bacillus therein, and that successful tubercular inoculation from such masses had been effected even when the Koch bacillus had eluded detection.—The PRESIDENT did not remember to have seen a single instance

of primary tubercle of the choroid.—Dr. HILL GRIFFITH asked how it was proved that the growth was not a sarcoma? He had enucleated an eyeball for sarcoma, and found a detachment of the retina which was not present immediately before the enucleation. The improvement in the constitutional state might have been the result of the relief from pain.—Dr. SHARKEY thought that the diagnosis of primary tuberculosis of the choroid could not be sustained in this case without further history. It was a well recognised fact that tubercular peritonitis was frequently cured, as attested both by clinical and pathological evidence, the latter being extremely strong. It was much more likely that this was a case of tuberculosis of the peritoneum and subsequently of the choroid.—Mr. CARLESS described the methods of staining adopted in the search for bacilli, and alluded to some points in the clinical history of the abdominal ailment.—Mr. MCLARDY, in reply, pointed out that the appearances did not at all agree with those seen in sarcoma. There was no pain about the eye, but the tumour grew very rapidly, and hence probably the relief of the symptoms after the enucleation. He quite agreed that there was a doubt as to the nature of the original abdominal affection.

Functional Eye Symptoms in Hysteria and Allied Conditions.—Dr. HILL GRIFFITH read an abstract of a paper on this subject. He classified the cases into the following groups: 1. Hysterical blindness, mostly monocular; 2. Amblyopia of one eye, with achromatopsia and hemianæsthesia (Charcot); 3. Same group with absence of hemianæsthesia; 4. Blepharospasm as sole eye symptom. This symptom was common in all the groups; 5. Hysterical conjugate deviation of eyes; 6. Neurasthenic asthenopia, symptoms bilateral. He was in favour of the theory of changes in the centres of vision rather than in the retina, as the cause of contraction of the field of vision.—Mr. JESSOP asked if he had met with the concentric spiral cases described by Mr. Priestley Smith, in which it had been shown that a neutral tinted glass enlarged the field. He asked if any change had been noted in the ordinary fields, that is, in relation of green to white, etc.—Mr. ERNEST CLARKE objected to all the cases being grouped under one heading, some being evidently due to fraud, others to true hysteria, and others possibly were central.—Dr. GRIFFITH agreed that the fields of vision were always affected. He thought it was difficult to draw the line between fraud and self-deception.

On the Removal of Staphyloma of the Cornea.—Mr. TATHAM THOMPSON read a paper recommending that a curved needle threaded with horsehair should be passed through that portion of the staphyloma which it was intended to remove; it afforded a ready means of steadying the eye whilst the elliptical incisions were being made, and of removing the portion after they were completed. The edges of the wound usually adapted themselves readily: the parts were then well flushed with a weak solution of perchloride of mercury, and tolerably firm pressure applied to keep them in apposition. The results obtained were very satisfactory.

Specimens.—The following card and living specimens were shown:—Dr. W. J. COLLINS: Photographs and Drawings of some Rare Affections of the Eyelids: 1. Spontaneous Symmetrical Œdema of both Eyelids in a Boy without obvious cause of rapid onset and slow subsidence; 2. Spurious Ptosis due to Paralysis of Frontalis Muscle on one Side; 3. Bilateral Hysterical Ptosis.—Mr. S. H. A. STEPHENSON: Case of Double Optic Neuritis after Measles.—Mr. J. B. LAWford: Pathological Specimens: 1. Pigmentation of Retina chiefly along the Larger Vessels; 2. Colouring Matter (? Blood Pigment) in Cornea; 3. New Tissue Formation in Choroid.—Mr. BRATLEY: 1. Case of Destructive Ulceration of Eyelid in an Infant, probably Syphilitic; 2. Case of Nipple-like Detachment of the Retina.—Mr. JESSOP: New Form of Stereoscope.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.
THURSDAY, MAY 3RD, 1888.

F. W. SALZMANN, M.R.C.S., President, in the Chair.

Electrical Treatment of Diseases of the Uterus.—Sir SPENCER WELLS read a paper on this subject, which is published in full at p. 995.—Dr. APOSTOLI said he had but one word to add to what had been said by their illustrious master, Sir Spencer Wells. In the month of August, 1885, he (the speaker) wrote as follows: "If the electrical treatment of fibroid tumours of the uterus is not destined to altogether replace the knife, yet it ought, when its safety and efficiency are taken into consideration, to be counted a most useful auxiliary to surgery; whether it is to be used only for women upon whom it is not advisable to operate; or whether

it will delay, for all, for a time at least, or perhaps render unnecessary, an operation which is always dangerous." These words remained true to-day. After an experience of nearly six years during which time more than 500 patients had been treated, and more than 6,000 applications of electricity had been made, he was able to confirm what he wrote three years ago, and to say that his method was not in itself dangerous. It was also necessary, however, to state that it might become full of danger in inexperienced hands, and, if antiseptic precautions were not carried out, or the rules which he had laid down were not attended to. These rules were as follows: 1. Never to employ large doses suddenly but always gradually, and according to the amount of tolerance which was shown by the uterus. 2. In all suspected or recognised inflammations of the uterine appendages it was necessary to redouble the precautions and to lessen the doses. He repeated his method was almost constantly efficacious in relieving symptoms. The electrical treatment did not pretend to make a radical cure of fibroid tumours of the uterus; it was content to diminish their bulk, to relieve the patients, and to make them feel well. In the presence of an operation such as that of hysterectomy always difficult and accompanied by great danger, and of that of oophorectomy, an operation not always possible nor always efficacious, the electrical treatment, in its simplicity, in its freedom from danger, aspired legitimately to place itself before all gynaecologists as a means of treatment of fibroid tumours of the uterus, palliative in the first place, but also one which allowed us to assure our patients that they would almost certainly remain in good health.

—Dr. PLAYFAIR said that few subjects in gynaecology had of late years caused more interest than Dr. Apostoli's work, and he was glad to find it made the subject of public discussion, so that the experience of those who had been working at it should be learnt. There could be no doubt that any means of treating certain classes of fibro-myomata which would prevent or postpone the formidable and mutilating operations of hysterectomy and removal of the uterine appendages would be an enormous gain, even if the results fell far short of those claimed for his methods by Dr. Apostoli; and great credit was due to him for his energetic work, which had thoroughly roused the interest and attention of the profession. Being anxious to see for himself what Dr. Apostoli was doing, he (Dr. Playfair) had visited Paris at the end of last summer, and had not only been received by Dr. Apostoli with great courtesy but had had free access to his carefully-reported cases, and opportunities of personally investigating and examining many of his patients. One thing he was perfectly satisfied of, that although Dr. Apostoli might be an enthusiast, and possibly given to overestimate the value of his treatment, he was at least an honest and convinced enthusiast. Certainly in this he did not stand alone, for without enthusiasm in medicine no progress was ever made. They did not need to go beyond that room for an example in point, for had Sir Spencer Wells not been an enthusiast in ovariectomy, in the face of the most unfair and prejudiced opposition where would be the great name and world-wide reputation he had achieved for himself? As to the criticisms on Dr. Apostoli's method, all he had heard were based on mere theory or on second-hand gossip. To this sort of objection no sensible man would give a moment's attention. What was wanted was careful and unbiassed personal investigation and accurately recorded facts, without prejudice either for or against. If Dr. Apostoli's treatment was subjected to tests such as these and found wanting, then by all means let it be condemned, but not condemned untried and unheard. Since October he (Dr. Playfair) had been endeavouring by numerous trials to form an estimate of its value. In so short a time no very positive conclusion could be arrived at, especially as to permanency of results, but he had at least had a fair opportunity of testing it. He had not used it in anything like the number of cases in which he might have tried it, as he selected his cases, and did not wish to use it indiscriminately. With the permission of the Society he would say a few words: (1) as to the cases in which it was applicable; (2) as to its possible dangers; (3) as to its application, and the difficulties connected with it. 1. The cases in which it had been most talked of were those of fibro-myomata, attended with hæmorrhage, and certainly this was its most important and promising application. Now out of the cases of this kind he had treated most had been benefited; in some the hæmorrhage had been entirely checked, but in one or two he was bound to say that no appreciable result on the hæmorrhage had followed. It was impossible in such a meeting to enter into details, which he might possibly publish elsewhere, but such was the fact. Perhaps he might fairly say that in three cases out of four the hæmorrhage

results had been distinctly good. The action of the positive current in this way was, no doubt, that of a chemical cautery, and he was inclined to think that the failures were due to the difficulty of bringing the sound, in certain cases, into accurate apposition with the uterine cavity. Some more perfect mechanical appliances in this direction were certainly required. With regard to non-hæmorrhagic fibroids, the number in which any interference was needful was very small. Indeed, it was only when pressure symptoms were well marked that it was justifiable to do anything. He had, therefore, only treated two cases of this kind. In one a large tumour had practically entirely disappeared, but with a very serious amount of constitutional disturbance presently to be referred to. In the other, then under treatment, the patient, whose tumour was impacted in the pelvis, and who had not micturated for a long time in consequence of pressure on the urethra, was already able to pass her own water. The cases in which he had found the most remarkable and satisfactory results were those of severe dysmenorrhœa, and bad chronic endometritis, with profuse glairy discharges. In them the results were really very remarkable, and some cases of both kinds, which had resisted years of treatment, had apparently been perfectly cured after only three or four applications of the electro-negative currents. Thus, three cases of intense dysmenorrhœa were treated, the patients writing of themselves as follows: (a) after four applications, "entirely free from pain;" (b) "quite painless;" (c) "hardly any pain." Of the application of the continuous current to absorb inflammatory deposits, and of the faradic current to relieve pain, he had not had sufficient experience to offer an opinion. The faradic current he had found very useful in restoring the menstrual discharge in one case of amenorrhœa of seven years' standing in another it had failed. 2. With regard to the alleged dangers, he believed them to have been greatly exaggerated. Dr. Keith's experience was of itself sufficient to prove this. Unquestionably, however, like all potent agents, electricity might do serious mischief if rashly employed by those unskilled in its use. He had only seen two cases in which the slightest irritation or mischief had followed its use. One was a case of pelvi-peritonitis with pelvic exudation, in which he was conscious that he had used it too soon, and a fresh but not serious exacerbation had followed. The other was the case of fibroid above referred to. This was a dense fibro-myoma he had watched for ten years, steadily growing. It nearly filled the pelvic cavity, and reached above the umbilicus. He had made six electro-negative punctures in Douglas's pouch. These were followed by pyrexia, accompanied by a profuse purulent offensive discharge from the uterine cavity at intervals of two or three days. The tumour had entirely disappeared, but the constitutional disturbance had certainly been considerable. That there were certain risks must therefore be admitted; he did not, however, believe them to be prohibitive, and time would probably show us what they were, and how they were to be avoided. 3. As to the alleged difficulties, they certainly were not of a nature to prevent any well-instructed gynecologist from adopting the practice. He must protest strongly against the statement that had been made that this class of work should be carried out by a professed electrician. Anything more absurd he had never heard. The manipulation of the apparatus, so far as the electricity was concerned, offered no difficulty at all. Any intelligent student could learn it in half an hour. The selection of proper cases, however, the passage of the sound, etc., required a profound gynecological knowledge, as Dr. Apostoli had well remarked; and beyond any question this method of treatment never could be widely and indiscriminately employed. If not carefully used, and in suitable cases only, much mischief would most certainly follow.—Dr. AVELING said he was sure all who, like himself, were employing electricity for the treatment of uterine tumours, would feel fortified in their opinions, and encouraged to proceed in their work, by the fact that Sir Spencer Wells sympathised practically with them. All would remember the remarkable paper which Dr. Keith published in the JOURNAL a short time since, in which he said he should consider himself guilty of a criminal act were he to advise any patient to run the risk of her life by hysterectomy, before having given a fair trial to electricity; "even," he adds, "if he were sure the mortality would not be greater than that which hysterectomy has given in his private practice—under 4 per cent." No one could say Sir Spencer Wells and Dr. Keith had taken to the electrical treatment of tumours because they were afraid of operating. Their exploits in abdominal surgery were known to all over the world. Their support of electrical treatment was therefore all the more valuable. The galvanic battery was, as

already pointed out, used by Sir James Y. Simpson forty years ago for the discussion of a uterine fibroid, and one of the most healthy signs of the electrical method was the gradual development of it since that time, every step enabling the operator to employ it with greater safety and efficacy. The two greatest modern improvements had been the use of the galvanometer, and the substitution of the dispersing abdominal electrode for the dangerous abdominal galvano puncture, two points insisted upon by Dr. Apostoli. The speaker said it was quite amusing to observe the flutter of excitement which the recent rapid advancement of electrical treatment had caused among some distinguished abdominal sectionists. From their uncompromising opposition and their abuse and ridicule, one was almost inclined to think these gentlemen feared their occupation was gone. They need not be alarmed; there would always be a place for hysterectomy and oophorectomy, as there seemed every reason to believe there would be for electrical treatment. An endeavour was now being made to determine what that place should be. If it were proved that it could cure a patient symptomatically—could stay hæmorrhage, relieve pain, and diminish bulk, in fact could remove the symptoms which brought the patient to the medical man for help—how many would propose and how many submit to the more fatal and radical operations? Complaint had been made that we were acting empirically, and were all in the dark as to the action of the galvanic current on tumours. This might to a great extent be granted, but it was no argument against its use. Who knew how quinine cured intermittent fever? If clinical experience proved that a patient having a uterine tumour could by electricity be relieved of her symptoms, and her existence rendered useful and comfortable, we were bound to employ the galvanic current, and might contentedly wait until science explained what was the effect of the caustic action of the pole, and how the catalytic interpoler current acted in producing atrophy of the tumour. Dr. Aveling stated that he had used the electrical treatment in several cases, and had met with such satisfactory results that he intended to continue its employment. He had met with no symptoms resulting from it to give him the least anxiety. He believed that most of the accidents reported were due to ignorance, carelessness, or impatience. Sir Spencer Wells had not mentioned the use of a rheostat in his paper. A water-rheostat was a great comfort to the patient. It obviated the succession of shocks caused by adding or taking off cells, while increasing or reducing the intensity of the current. A useful dispersing electrode was one made of a flat coil of copper wire, placed between a layer of moist spongio-piline and amadou. An important practical point was that the skin of the abdomen should be thoroughly saturated with warm water before using electricity. Dry epidermis was a potent non-conductor. The clay was difficult to keep sufficiently moist, and was dirty. Later in the discussion Dr. Aveling dissented from the opinion that the interpoler current was inert, and asked Dr. Parsons whence he thought the ions were derived which arrived at the poles during the passage of the current.—Dr. INGLIS PARSONS congratulated Dr. Apostoli on his success. He was not, however, able to agree with Dr. Apostoli's theory of an interpoler action. There were no scientific proofs that any change occurred between the poles. The speaker had tried several experiments, thinking to prove the theory, but had found it untenable. The first of these was on the web of a frog's foot. At the negative pole a collection of hydrogen gas occurred, at the positive a coagulation, but between the poles the circulation proceeded as before, and no change in the tissues could be found under the microscope. A similar result took place when a current of 250 milliamperes was passed through a small fibroid for one hour and a half soon after its removal from the body. Sections made by Dr. Rutherford showed destructions of all tissues, except the fibrous, in contact with the poles, but no interpoler alteration could be discovered. The principle also held good with saline solutions. If three glasses filled with a standard solution of iodide of potash were connected by damp cords, and a current were passed through for several hours, the solutions in the end glasses containing the poles were decomposed, while that in the centre, or interpoler, glass remained unchanged. Not only was there no interpoler decomposition, but the transport of elements from one pole to the other had apparently no effect; but the latter action required further investigation. These results corresponded with Dr. Parsons's clinical experience at the Chelsea Hospital for Women. If a tumour could be punctured it soon disappeared. He had cured a case in this way that was not amenable to surgical treatment. Nothing remained of the tumour but a diffused mass

one-third the size of the original. This probably consisted of fibrous tissue, which, as he had shown, was not decomposed by the current. The patient left the hospital three months ago, and was seen recently with no return and in good health. With regard to hæmorrhagic cases, he found that unless the electrode was brought into direct contact with the whole of the bleeding surface the hæmorrhage would continue. In a case now under treatment the electrode was passed only half the full distance into the uterus, and the hæmorrhage continued, even after twelve applications. But as soon as it was passed the full distance, the hæmorrhage commenced to diminish. This was no doubt due to the fact that the action of the current was chiefly at the poles. With regard to dosage, he found a distinct difference between those cases where the current passed first through the uterus, and those where it passed directly into the tumour. In the latter case a much larger dose could be used even with susceptible patients. To one he had given as much as 250 milliampères every other day for thirty minutes, with a most successful result. If the current passed through the uterus, the restrictions laid down by Dr. Apostoli must be strictly followed.—Dr. HERWOOD SMITH, in answer to the President's invitation, said he had but little claim to speak on the subject, as he had no personal experience of Dr. Apostoli's treatment, nevertheless, as they were all present that evening to learn, he thought that some questions might elicit some instructive answers. He wished to know the way the electric current was intended to act, whether as a disintegrating force or as an escharotic. If the latter, then any cautery would do to start to destructive action, as had been the case in some of the cases reported; namely, one by Dr. Holland, and that just mentioned by Dr. Playfair, where evidently the curative process was proceeding by the sloughing away of the tumour. If the current acted as a disintegrating or decomposing process, in what way was the *débris* thrown off or absorbed, as fibrous tumours were exogenous, not endogenous growths, and their vascular and lymphatic systems were at the circumference of the tumours? How then was the disintegrating process, which was commenced round the needle which was thrust into the middle of the tumour, placed in relation to the vascular system at the circumference of the tumour? Then, in cases of subinvolution with chronic endometritis and menorrhagia, what was the action of the current on the lining membrane of the uterus, and did it produce any escharotic or other effect on the membrane and on the uterine follicles, or did it by its stimulus induce greater tonicity of the uterus, and so lessen the hæmorrhagic tendency?—Dr. ELDER (Nottingham) said that his first duty was to thank the President and members of the Society for allowing him to take part in that important discussion—a permission which he would be wanting in gratitude to Dr. Apostoli for his kindness to him during a recent visit to Paris, if he had not gladly taken advantage of. The necessarily short time at his disposal would be best occupied by first alluding to three of his most successful cases under this treatment, and then generalising upon the other cases which had been under observation. Case I.—Mrs. F., aged 37, came with a history of flooding for two years and severe pressure symptoms, totally incapacitating her for housework. A solid uterine growth filled the pelvis and reached midway between the umbilicus and the xiphoid cartilage. Treatment was commenced at the end of July by galvano-punctures (negative), and continued at intervals, usually of a week, till Christmas, with the following results. The growths had decreased by quite a third, so that her clothes, which on her first visit were fastened by connecting tape, now overlapped; the periods had become normal as to time and quantity; the pressure-symptoms disappeared, and she was able to do her work as beforetimes. From time to time she had been seen, and the improvement was maintained. Case II.—Mrs. W., aged 48, consulted him for flooding of five months' duration due to an interstitial myoma in the posterior wall. The uterine cavity measured four inches; seven intra-uterine applications of the galvano-positive electrode caused disappearance of the tumour, arrested the hæmorrhage, and reduced the length of the cavity to three inches. Case III.—Mrs. M., aged 35, had suffered for several years from bouts of flooding, which during the past twelve months had laid her up for weeks together, and totally disabled her for work. The uterine cavity measured $3\frac{1}{2}$ inches, and a uterine growth occupying the right iliac fossa and reaching above to a level with the anterior inferior iliac spine could be well defined. Treatment by galvano-positive intra-uterine applications was begun in January, and continued once a week till now, with the result of bringing about menstrual regularity, removing pressure symptoms,

and also restoring the patient to very good health. In all, the treatment had been employed by him in forty cases, including some examples of subinvolution, endometritis, peri-uterine exudation, etc., without danger to the patient, unless in a case which would again be alluded to, and with only one distinct failure to relieve more or less the symptoms for which the patients consulted him. The failure occurred in a lady suffering from a uterine myoma, in whom complete removal of the tubes and ovaries had not arrested the draining, nor had the galvano-positive applications any better effect. The only case which gave him any anxiety was that of a middle-aged woman enfeebled by long-continued hæmorrhage and pressure symptoms due to a large uterine growth. In September of last year, after the third galvano-puncture, she persisted in walking home, a distance of a mile, on a very wet night, and took a chill. Some four months afterwards she died of septicæmia; but whether after this interval and with the utter neglect of common-sense precautions on the part of the patient this casualty could fairly be laid to the charge of the treatment must be left to fair, impartial judgment. So far as his experience of this treatment had gone, he believed it to be not only a distinct advance on the treatment of myomata by rest, diet, drugs, etc., but one which would in most cases supersede removal of the appendages and hysterectomy and our plain duty in all cases where its application was possible was to offer to our patients this alternative.—Dr. TRAVERS asked what was meant by "tolerance of the uterus."—Dr. APOSTOLI replied that where there was a simple fibroma of the uterus in a healthy woman the uterus was made more tolerant than where there was inflammation of the annexes, or where the uterus was irritable. In the latter case much more care was needed in applying electricity. It was best to begin with small doses and short sittings. If he could introduce a sound, he employed that first.—Mr. SKENE KEITH said that although sufficient time had not elapsed since Dr. Apostoli began this treatment for them to pass judgment upon it, yet he could say, from an experience of nearly 3,000 applications, that the results—and some of these results had already stood the test of 8 or 9 months—had been such that Dr. Keith, whose mortality after hysterectomy appeared to be the smallest of any operator, had not found it necessary to advise either that operation or even the less serious one of removal of the ovaries since his visit to Dr. Apostoli last year. Since June Dr. Keith and himself had had under treatment 92 cases of distinct fibroid tumours of the uterus, in fact, everyone where there where symptoms had been treated; and, without entering into details which would be published later on, he might say that, on the whole, the results had been extremely satisfactory. Of those 92 women, 76 had had more or less of the ordinary treatment without receiving any marked benefit. The great disadvantage of this treatment was the length of time it took, though often not longer than a visit to a watering-place, and the amount of work which fell on the physician or surgeon. On the other hand, one great advantage was that, when necessary, it could be carried out in the out-patient room of any hospital, and that the patient could attend to her ordinary duties exactly the same as usual. They had already heard of operation being required when this treatment had failed. This might be so, but he would ask that a distinction should be made between Dr. Apostoli's and various methods of treatment which went by his name. For example, a friend had told him (the speaker) that he had not read Dr. Apostoli's papers; another thought that he had made a discovery when a patient told him that he (Mr. Skene Keith) had moved the sound over the surface of the uterine cavity. Need he say that their results had not been brilliant? The practice of Sir Spencer Wells of publishing every case of ovariectomy had been followed by Dr. Apostoli in the thesis of Dr. Carlet, published in 1884. They had had full details of about 100 cases, and it was by such means that the value of the electrical treatment of fibroids had to be decided. Dr. Keith regretted much that he could not be present, but he (the speaker) had his authority for saying that so long as they could get the results they had had by electricity, he had no intention of advising any patient to run the risk of dying after hysterectomy, or after removal of the ovaries for fibroid.—Mr. WILLOUGHBY FURNER inquired as to which pole of the battery should be used in a case of uterine fibroid that did not bleed.—Dr. APOSTOLI replied that the positive pole should be used in hæmorrhagic cases, on account of its hæmostatic properties. In non-hæmorrhagic forms the negative pole should be employed, as being more active.—Dr. INGLIS PARSONS made some further remarks of

be electrolytic action in these cases, and on his own experiments in this direction.—Sir SPENCER WELLS made a few concluding remarks.

Electrical Apparatus.—Messrs. MAYER and MELTZER exhibited a battery for the electrical treatment of fibroids and other uterine diseases. The battery, which is 14 in. by 10 in. by 10 in., is arranged so that the fluid cannot be spilt if carried with ordinary care. The battery is supplied complete with Dr. Aveling's abdominal electrode, platinum-pointed sound, and trocars. Messrs. Mayer and Meltzer also exhibited specimens of electric lamps, Dr. Heywood Smith's speculum lamp, etc.

BRITISH GYNÆCOLOGICAL SOCIETY.

WEDNESDAY, APRIL 25TH, 1888.

ARTHUR W. EDIS, M.D., F.R.C.P., President, in the Chair.

Hermaphroditism.—Dr. FANCOUR BARNES exhibited a case in which the determination of the sex appeared to be doubtful. The individual was the third child in a family of eleven, and was now nineteen years of age. Up to the present she had been reared up as a girl, and her tastes were decidedly feminine. His reasons for believing the sex to be masculine were—(1) the appearance of the head; (2) the *timbre* of the voice; (3) the non-development of the breasts; (4) the undoubted existence of a well-developed prepuce and glans penis; (5) the imperfectly-formed urethra running down from the tip of the glans and passing into the bladder; (6) the utter absence of anything like uterus or ovaries; and (7) the appearance of the perineum. The thighs and lower abdomen were covered with masculine hairs. Hair had grown on the arms, and especially the forearms; and there were traces of moustache and beard, which were evidently shaved. The head was somewhat bald. Maternal impressions were alleged as a possible cause. The last born of the same family appeared to be similarly affected.—Mr. LAWSON TAIT, Dr. ROUTH, Dr. HEYWOOD SMITH, and Dr. R. BARNES made some remarks.

Kolpo-hysterectomy for Malignant Disease.—Dr. F. A. PURCELL exhibited the uterus and appendages which he had removed through the vagina for epithelioma of the cervix. The growth as removed by the galvanic *écraseur*. As a portion of the disease appeared to be left behind, he proceeded to the total removal of the uterus, which was accomplished without loss of blood. Both ovaries and the Fallopian tubes were also removed. The patient made a most satisfactory recovery, and was up and walking about by the twenty-second day.—The PRESIDENT pointed out that the patient was only twenty-five years of age, and the specimen showed clearly enough the nature of the growth. Under such circumstances total extirpation seemed justifiable.

A Method of treating Incontinence of Urine in the Female in cases hitherto considered to be beyond the Resources of Surgery.—Dr. WILLIAM ALEXANDER (Liverpool) read notes of two cases in which he had successfully treated this condition. The first was a married woman, aged 35, who had had two miscarriages and no children. She ascribed her illness to her having been compelled by her occupation to remain for long periods without emptying the bladder. The urethra was quite patulous, admitting with ease the index finger, and sphincter power was lost. In other respects she was a strong, healthy woman. He first released the upper or anterior surface of the urethra from its connection with the pubic arch. A slit was made into the rectum through the exposed vaginal and rectal walls. The urethra was then denuded in front and laterally only, except a small piece around the orifice, and drawn through the slit in the rectal wall, to which it was stitched in front and at the sides, but not behind. The labia minora and clitoris—in fact, everything in front of the urethra—were denuded up to the middle of the labia majora. The vulvar orifice was then completely closed by the labia being united in the middle line with numerous fine silkworm-gut sutures. The urethra was thus pressed well back and firmly supported in its place, and the rectal wall at the same time held forwards by the stitches that passed through it. The result had been a complete success. A diagram showed that there was only one external aperture instead of three. The urethra opened into the rectum, and just behind the urethra was a small fissure through which any uterine or vaginal secretion found its way into the bowel. On passing the finger into the rectum, the opening of the urethra could be felt with difficulty just above the internal sphincter; the difficulty of feeling it arose from the way in which the folds of the rectum covered it over. The folds were so disposed that it would appear very difficult for gas to pass from the bowel into

the bladder. The patient could hold her urine for upwards of four hours, and had to get up only two or three times during the night. The second case was that of a patient, aged 50, whose urethra had completely disappeared from sloughing, an unsuccessful attempt having been made to cure a cystocele some two years before. A somewhat similar operation had been successful in her case also.—After some remarks by Dr. GRANVILLE BANTOCK and Dr. AVELING, Mr. LAWSON TAIT said that the first time he saw the vulvar orifice closed on account of the destruction of the anterior and posterior walls of the vagina was by Sir James Simpson, in 1862, and he happened to be able to trace the woman's history afterwards. It was one of prolonged misery. What was reported as a "mild diarrhoea" amounted to irritation so excessive that the patient ultimately induced someone to undo the result of the operation. A patient on whom he had operated seven years ago had also had the operation undone for the same reason. In spite of that, he was attempting to close a third, in the hope that the condition of irritation might not be common to all these unfortunate creatures. If he found that the rectum would tolerate a mixture of faeces and urine, he would agree in the performance of Dr. Alexander's operation. He suggested it would be better to divert the ureters into the rectum.—Dr. MANSELL-MOULIN said it was obvious from the diagram that the bladder, vagina, and rectum intercommunicated with each other at the seat of operation. The patient, therefore, was in no way benefited by Dr. Alexander's operation beyond what she would be by the simple closure of the vulvar orifice, and an opening made into the rectum. In either case the urine necessarily passed into the vagina.—Dr. ALEXANDER replied.

REVIEWS AND NOTICES.

HUNTERIAN LECTURES ON CERTAIN DISEASES OF THE JAWS. Delivered at the Royal College of Surgeons. By CHRISTOPHER HEATH, F.R.C.S. London: J. and A. Churchill. 1888.

THE author has been so long and so well known as the most established authority on surgical affections of the jaws, that we are not surprised at his making use of his large store of material for the Hunterian Lectures, and there is no doubt that these lectures will form the best modern reference on the subjects treated in them. But the author's position as the editor of the largest and best work in recent days on the practice of surgery, and his vast field of observation at one of the most important metropolitan hospitals, may have led us to hope he would have devoted his practical mind to some new region of surgery in these lectures. However, there is much in them that is indicative of the author's thoroughness, though it does not seem that there is much that is new to record in this branch of surgery.

The first lecture includes cystic diseases of the jaws, and, as with the other lectures, deals with the pathology and treatment of the disease, making excellent use of the store of specimens to be found in other museums besides that of the College of Surgeons. The second lecture considers the other tumours of the jaws, and one kind comprises the diseases of the temporo-maxillary articulation, and the very troublesome and unsatisfactory class of cases where the jaw has become closed by disease in the joint, or by contracted scars or other similar complications outside.

The deformities produced by these diseases are certainly ugly, and the pictures often very repulsive, and for that reason perhaps the subject is not attractive; but, if the surgeon can relieve these conditions successfully, he will be the greater benefactor. The causes and the pathology of the disease are here specially treated of; but there are certain points in the treatment we should have expected to find comment upon. For instance, we miss in these lectures any reference to the steps which should be taken in performing some of the greater operations, and such reference would be advisable in any such work as this may become for a surgeon or student in the future. The question of preliminary tracheotomy, and the best apparatus or means to prevent suffocation during operation, are important matters; the case recently reported in the JOURNAL (April 21st), where a recurring sarcoma of the upper jaw was removed, shows this very clearly, and Mr. Morris's remarks are very much to the point.

It is a pleasure to find that the experience and the opinions of the older race of surgeons and anatomists are brought prominently forward; for we cannot but feel the justice of some remarks

in the JOURNAL, recently made, that students are nowadays made to trust too much to the opinions of modern authorities, and to overlook the work and the judgment of able surgeons and pathologists who lived before the days of Listerism and bacteria. We do not mean to make light of what is now being done in these directions; but it is quite possible to make too much of it. It is also refreshing to find that Hignmore's work is still continued by able successors in the same classical Sherborne; for we find that one at least of the recent cases, sent to the author for operative treatment and pictured in these lectures, was under the care of Hignmore's present representative in the practice. The illustrations are numerous, the type good, and the writing clear and forcible, as we should expect from the author.

TRANSFUSION. By C. E. JENNINGS, F.R.C.S., M.B. Third Edition. London: Baillière, Tindall, and Cox. 1888.

This little book, which has reached a third edition, discusses an important subject to the general practitioner and to the surgeon, and we look into it with some interest to see what the author's experience will lead him to recommend. There seem to us to be two distinct points to be inquired into: first, the simplest and safest means of transfusing; and, secondly, the kind of fluid to be transfused in particular cases. Each of these subjects is capable of careful consideration; and the author has succeeded, we think, in selecting a practical and simple method of transfusing, or, more correctly, injecting into the veins fluid which is artificially prepared. The method he adopts is practically what has been recommended before him, and may be described as the syphon method, in contradistinction to the force-pump method, which has always appeared to us as dangerous and unscientific. Moreover, as he rightly points out, a simple apparatus is the only one available in the majority of cases, and where skilled assistants are not within call. He is right, too, in insisting upon complete arrest of hæmorrhage as a preliminary to any transfusion. But we want fuller evidence than he gives of the utility of transfusing simple saline fluids, though there is no doubt they act as a charm for a time. But will their influence be lasting enough for Nature to work the cure? Anyhow, they are not open to the objection of blood-transfusion, as it must be done very often in general practice, or as we have seen it done in hospital practice. Roussel's ingenious apparatus is too elaborate, too costly, and too liable to be out of working order to be of real service in the majority of instances.

As to the character of fluid transfused, we confess to not feeling convinced by the author's arguments that he has made out his case for the simple saline and alcoholic solution, as against that of milk with saline and stimulant, and more, we think, remains to be done in this latter direction. The one or two cases he gives are not sufficient, though they are interesting and valuable. It does not seem to us that the work does itself justice as a manual on transfusion, but here and there we find a summary of the author's opinions on certain important matters, as on pages 21 and 63.

The appendix constitutes half the book, and gives cases, other papers on the subject written by the author, a number of experiments performed on animals, under different circumstances, by the author and others; and extracts from medical journals, including those referring to the injection of milk. These latter we have already referred to as inconclusive.

The little book is interesting as calling attention to a very important subject. In many parts it is objectionable in its style, and not scientific in its method, and the attempt at a popular and rather flashy style detracts from its influence. Very much is assumed, but not proved; but we shall be glad to see that further experience supports the sanguine hope which others before the author have felt and expressed, that benefit is to be obtained from the transfusion of nutritive as well as stimulating fluids, when a patient has been drained by hæmorrhage, whatever the cause.

MR. W. H. ALISON TEBBS, of Auckland Hospital, New Zealand, has been awarded a Scholarship of £40 in Chemistry and Physics at the Westminster Hospital Medical School.

PRESENTATION.—Dr. Cobbold, the late Medical Superintendent of Earlswood Asylum, has received from the members of the medical staff of that charity a gratifying testimony of their esteem and regard, by the presentation of a handsome spirit stand, claret jug, and salver. Dr. Cobbold, in acknowledging the gift, spoke of the great changes that had been effected in the five and a half years during which he held office, and referred to matters in which he had been enabled to improve the position of the staff.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS, IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

GREEN'S HYPODERMIC SOLUTIONS.

ALTHOUGH the introduction of tabloids, gelatine discs, and the like for the extempore preparation of hypodermic solutions at the bedside has of late years met with considerable favour, many practitioners still prefer to employ solutions. Messrs. Green and Co., of Tower Chambers, Moorgate Street, E.C., have submitted to our notice a number of such solutions, for which they claim the following advantages: that they are of uniform strength; that they are clear and neutral; and that they will not undergo decomposition under varying climatic surroundings. These claims, as far as we have been able to test them, are well founded. The solutions are certainly neutral and clear, and in our hands have retained their condition when subjected for a prolonged period to widely different conditions as to temperature and light. We are informed by Messrs. Green that this result is effected by the use of an antiseptic hydrocarbon as a preservative.

Messrs. Green's list of solutions includes aconitine, apomorphine, atropine, caffeine, ergotin, morphine, sparteine, pilocarpine, etc. They are all of convenient strength, the morphine especially so, a grain of the alkaloid being contained in 12 minims of the solution. Thus, a half, one-third, a quarter, and one-sixth of a grain of morphine are all represented by an even number of minims and no calculation is required in order to administer these doses.

FRY'S TRUSS.

MR. CORRIE JACKSON (17, Poland Street, W.) writes: Shortly after the meeting of the Medical Society in December last, referred to by Mr. Walter Pye in his article in the JOURNAL of April 5th, the truss invented by Mr. Fry, of 13, Ivydale Road, Nunhead, was brought to my notice. I fitted one, with the best results, on a patient who had had a large double scrotal hernia of forty years' duration, for which he had been under treatment for three weeks in hospital for strangulation, all other trusses proving painful and ineffectual.

A great feature in Fry's truss is that it can be worn by the patient whilst lying on his back; in the case mentioned no other truss could be worn in that position.

Contrary to Mr. Pye's experience, I found that considerable pressure was obtained against the apertures by the action of the elastic webbing and taper-shape of the pad. I believe this truss would afford very efficient relief in cases of inguinal, femoral, and scrotal hernia on account of the ready adjustment of the pad.

ROYAL COLLEGE OF SURGEONS.

AN ordinary meeting of the Council was held at the College on the afternoon of Thursday, May 10th.

The minutes of the quarterly Council held on April 12th were read and confirmed.

Mr. E. Hurry Fenwick was introduced, and the President handed him the Jacksonian prize for the past year (a cheque for £12 15s. 2d., being the amount of one year's dividends received from the Jacksonian Fund), together with the instrument declaratory of the award thereof. Mr. F. A. Southam was also introduced, and the President handed him an instrument declaratory of the appreciation of the Council of the merits of his dissertation for the Jacksonian prize. Mr. J. A. Marston was introduced, and after signing the necessary declarations, etc., was admitted a Fellow of the College.

A Report from the Committee on Extension of the College Premises, recommending the Council to authorise the expenditure of about £400 in alterations of the library and other portions of the building, and also recommending that, with a view to expediting the completion of the redecoration of the library which is contemplated, it be closed during the month of August as well as September, accommodation being provided for readers during August, was approved and adopted.

A Report from the Committee of the two Colleges, on "the Internal Arrangements and the requisite Fittings of the Rooms and Theatre in the New Building on the Embankment," was read, approved, and adopted.

A motion "That the annual meeting of the Fellows of the College for the election of members of the Council be held at the College on Thursday, July 5th, at 2 o'clock, P.M., precisely," was agreed to.

A letter was read thanking the Council for their resolution of condolence in reference to the death of Mr. T. B. Curling.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1888.

MEMBERS to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the West Central District Office, High Holborn.

The British Medical Journal.

SATURDAY, MAY 12TH, 1888.

THE DEVELOPMENT OF BRITISH HEALTH RESORTS.

As has been said and written during the last year or two regarding the development of the health resorts of this country, and at this season it seems opportune to inquire what may chiefly be aimed at in this direction, and what is clearly ill-considered and chimerical. It can hardly be denied that in the matter of popularising sanatoria and rendering them thoroughly attractive, we have still much to learn from our Continental neighbours. Some of the most noted resorts in Europe have their natural advantages either of scenery, position, or resources, and in many cases art has been admirably utilised to supplement Nature. The gay Kursaal, with its daily round of amusements, the pleasant parks and trim gardens, the admirably appointed *établissements des bains*, the excellent music—these are but parts of the ordinary stock in trade with which Wiesbaden and Carlsbad, Homburg and Vichy so successfully attract their crowds of annual patrons. But of such attractions our British resorts are for the most part singularly destitute. They may have beautiful scenery, valuable mineral waters, excellent air, but these important advantages do not save them from being in many cases intolerably dull. Our error is twofold: we make the theoretical mistake of regarding health resorts as places solely for definite medical treatment, forgetting that amusement and mental distraction are not only desirable to all, but absolutely indispensable to the sick; and we fall into the practical error of assuming that sanatoria can provide sufficient recreation without organisation and co-operation. We need to realise, first, that a health resort has not fulfilled all its duty when it has built fine hotels, secured an ample water-supply, and cleansed its drains; and, secondly, that adequate distraction and amusement cannot safely be left to the accidents of individual enterprise, but require united and municipal effort. A health resort must first be healthy, and secondly attractive. It must aim at securing as many as possible of the conditions which check disease and promote recovery, and it must provide ample and varied relaxation for convalescents and their companions. Nor should it be forgotten that the presence of every invalid entails on an average the presence of two or three others, friends or attendants, who are not invalids. A health resort which provides sufficient occupation and amusement for this latter class will have gained an additional claim to consideration.

While we are still far behind France and Germany in enterprise of this kind, it would be unjust to ignore the great progress which is being made. Southport shows what a pleasant resort can be constructed upon the barest of sandhills, and Bournemouth is a witness of how a pine forest can be transformed into one of the most attractive of sanatoria. Bath, Leamington, and Droitwich are proving that enterprise is not hopelessly dead at the English spas, and here, as always, well-directed effort is reaping its due reward. No British resort has hitherto, so far as we are aware, adopted the plan so general on the Continent of imposing a fixed tax upon all visitors for the development of the locality on the lines indicated in this article. Such an impost would be a novelty in this country, and perhaps somewhat repugnant to our prejudices, but a nation that still tolerates tolls upon bridges cannot consistently rebel against a *Kur-tax*. The advantages of such an arrangement need hardly be pointed out.

After all has been said, it may be urged that Continental resorts surpass us in point of climate, and that as long as our summers and autumns are prone to be sunless and damp, so long will those who have the means migrate to more favoured regions. Granting this argument some weight, it by no means disposes of the entire question. There can be little doubt that at the holiday season our climate is far more promotive of health than that of many of the most famous sanatoria. From July to October includes the period at which our various classes seek their annual holiday. During July and August sea-bathing is one of the chief ends pursued; and it may be confidently asserted that no marine resorts in the world equal those of Great Britain. Scarborough, Hastings, Brighton, Eastbourne, Ilfracombe, Cromer, Whitby, Llandudno, Tenby, and Barmouth constitute a list that might easily be enlarged, and one to which no Continental country can afford an adequate parallel. Another large class of holiday-seekers is composed of those who require mineral waters and baths, which are usually associated. Now, with one important exception, this country is well provided with natural mineral springs, and it can hardly be denied that in summer or early autumn Harrogate, Buxton, and Moffat are more desirable resorts than the German or Austrian baths. Unfortunately, our springs are deficient in waters aerated with carbonic acid gas, and hence our sulphur and saline waters are apt to prove somewhat heavy and indigestible. It has been proposed, and in places successfully attempted, to have some species of natural water artificially aerated.

But, to recur to our original position, it is not, we think, any natural deficiency in our health resorts which dooms many of them to insignificance, so much as lack of enterprise and blindness to those attractive accessories which make the fortune of many of the Continental sanatoria. It must be owned that as a nation we are not successful in organising those minor enjoyments and lighter graces which are yet indispensable to a well-rounded existence. We "take our pleasures sadly," and thereby are great losers. Probably that incapacity for small enjoyments, that inability to be easily amused which so strongly characterises us, is a lingering relic of the old Puritan prejudice against every species of pleasure. Such a prejudice is happily almost a thing of the past. From the medical point of view it was an error to be deplored, and

such errors, even when ostensibly abandoned, are apt to leave traces behind in the poise and adjustment of the national mind. We must not be ashamed to amuse the sick, and both sick and healthy may with advantage occasionally devote some serious thoughts to those arts which promote the best and most advantageous utilisation of leisure hours and holiday seasons. It is only a crude philosophy which can condemn such efforts as unworthy of our best endeavours and most serious attention.

This JOURNAL has taken many opportunities of pressing these views upon the attention of those most interested in their success, and the subject is one to which Mr. Ernest Hart referred in some detail in his "Letters from Carlsbad." It is gratifying to us to know that some good results are likely to follow. At the beginning of another season we again invite attention to a subject of national as well as professional importance.

TEACHING SCIENCE AND SCIENTIFIC TEACHING.

IN teaching science, a double aim is sought—to impart knowledge, and to give mental training; both objects are of great importance to the student. It is frequently a subject of regret to see how soon physiology, anatomy and chemistry are forgotten by the student who has passed his examinations in those subjects, although he may have worked industriously at them in his earlier years. We cannot but think that this is in part due to failure in training the student to think and argue for himself about what he sees in the laboratory and the class-room. Observing facts does not necessarily imply thinking about them; to make logical comparisons and analogies between objects seen, to trace out under wise supervision the sequences of events as demonstrated by what is seen does compel thinking. Questions asked as to the action of different groups of muscles, and as to the muscles, the nerves, and the nerve centres which produce certain visible movements; such methods tend to produce efficient thinking, and add a practical interest to physiological and anatomical studies. In the hospital some students are too apt to be satisfied with detecting physical signs; a systolic apical *bruit* is detected over the heart, and the hasty inference is drawn that the mitral valve is diseased, and that this constitutes a diagnosis justifying at once the prescription of digitalis and iron. The *bruit* is a very important piece of initial evidence, and suggests the hypothesis of possible mitral disease, and the necessity of looking to all the physical conditions of the heart and the circulation in the pulmonary and systemic systems, as well as in the various viscera. A successful observation should stimulate thought, and lead to further observation. A patient complains of pain in the chest; on listening no friction is heard, and no abnormal dulness is found; the hasty conclusion may be drawn that no pleurisy is present, the student neglecting to take the temperature and to look for all the signs of pleurisy. Such habits of want of thoughtfulness lead to bad practice. Every observation should be followed by thought as to its significance and its relations to our knowledge; such mental habits may be

inculcated in teaching science. It is not only in clinical work that the need for correct thinking is seen; in the examination room we have frequently seen candidates fail to answer simple questions, not necessarily through ignorance, but because they were unpractised in continuous and regular habits of thought.

MR. PEARCE GOULD has resigned the office of Surgeon to the London Temperance Hospital.

THE Guy's Hospital Biennial Festival Dinner will take place on Wednesday, July 4th; and Dr. P. H. Pye-Smith, F.R.S., will be the chairman. The annual distribution of prizes will be made in the afternoon of the same day at the Hospital.

DR. AUGUST WEGNER, Generalarzt of the First Class, and Physician in Ordinary to the German Emperor, has been ennobled. This gives him the right to place the *particule nobiliaire* "von" before his name.

DR. MATTHEWS DUNCAN will preside at the half-yearly dinner of the Aberdeen University Club (London), which will be held at the Holborn Restaurant on Wednesday next. The honorary secretaries of the Club are Dr. R. W. Burnet and Mr. R. M. Routledge (1 Elm Court, Temple).

THE Burial Reform Association has resolved to memorialise the Home Secretary to inquire into the condition of cemeteries and the mode of burial adopted. At the annual meeting to be held next Monday at Grosvenor House, the Duke of Westminster in the chair, it is proposed to put the sanitary aspect of the question to the front. Sir E. H. Sieveking, M.D., Dr. Hubbard, Dr. Danford Thomas, Mr. Ellice-Clarke, C.E., Mr. F. Seymour Haden, F.S.A., and Mr. Wollaston Pym, are among those who have promised to take part in the proceedings.

ST. GEORGE'S HOSPITAL.

WE understand that it is proposed to present a testimonial to both Dr. Wadham and Mr. Holmes, whose periods of office as physician and surgeon respectively to St. George's Hospital have recently expired. Dr. Dickinson is the treasurer, and the subscription to each testimonial is not to exceed one guinea.

RABBITS IN AUSTRALIA.

A TELEGRAM from Sydney states that the conference upon the means of dealing with the rabbit pest has resulted in the selection of an island where M. Pasteur's and other methods of extirpation will be thoroughly tried. The liability of other animals and birds to infection by the same means will also be tested.

INTERNATIONAL OTOLOGICAL CONGRESS.

THE next International Congress of Otolology will be held at Brussels from the 10th to the 16th of September next under the presidency of Dr. Ch. Delstanche. Gentlemen wishing to be present are requested to communicate before May 15th with the Secretary, Dr. Ch. Goris, 143, Rue Royale, Brussels.

MEDICAL DEVOTION.

ANOTHER instance of the heroic and praiseworthy services so often rendered by medical men, in times of disaster and special danger has come to our notice in an account of the terrible disaster which recently occurred at the St. Helen's Colliery at Workington, where, as the result of an explosion, many lives were lost and others injured. Drs. Dudgeon and Ormrod were, it is stated, early on the scene, and, while Dr. Dudgeon was attending to the injured Dr. Ormrod went down the pit with the rescue party; and though

the after-damp was very oppressive, the whole of the workings were explored. Again and again they made the descent, bringing up the dead and injured, and imperilling their own lives in doing so. Every possible help was given to the injured and suffering. Dr. Ormrod has, we believe, had experience of many colliery explosions.

METROPOLITAN COUNTIES BRANCH: WESTERN DISTRICT.

Members are requested to call the attention of our members resident in the Western District of the Metropolitan Counties Branch to the fact that at the next meeting, which will be held on Wednesday, May 16th, at St. George's Union Infirmary, Fulham Road, London, the chair will be taken at 8.15 by Dr. Charlton Bastian, F.R.S., Vice-President of the District, when a short paper will be read by Mr. Butlin on "The Treatment of Chronic Ulcers of the Tongue." Demonstrations will be given by Mr. Noble Smith and Mr. H. W. Webster. This District Branch, which has an ample constituency, promises a programme of considerable interest for its summer proceedings, and the attendance of all members and their friends is invited.

THE GENERAL MEDICAL COUNCIL.

It seems probable that the General Medical Council will not have much business before it during the next session, which commences on Tuesday, May 22nd. Official notification of the appointment of two new members, Dr. G. Y. Heath, representing the University of Durham, and Dr. Hector C. Cameron, representing the Faculty of Physicians and Surgeons of Glasgow, will be received. Reports of the various committees—the Finance, Pharmacopœia, Statistical, and Income and Expenditure Committees—will be presented, as well as a report from the Education Committee, which may possibly give occasion for some discussion. The Executive Committee will meet on Monday, May 21st, to arrange the order of business.

THE MAGNESIUM LIGHT IN PHOTOGRAPHY.

PROFESSOR DR. HERMANN COHN, Breslau, is of opinion that the "lightning powder" used of late (consisting of magnesium powdered and chlorate of potash in equal parts) is disadvantageous for the following reasons: 1. On account of the dangerous character of this powder it cannot be made in large quantities and stored for use, but must be carefully prepared for use as occasion requires. 2. It is not easy to set on fire at the precise moment desired, even with the electric spark. Fuming sulphuric acid will do this, Dr. Cohn has been told, but this is not a desirable substance to deal with, as its vapour would damage any delicate apparatus in the vicinity. 3. It is not always desirable to have a double illumination. 4. The light should be "photochemical." Professor Cohn obviates all these inconveniences by using simple magnesium powder, which is then blown through any flame in use by means of a simple little apparatus (which may be obtained for 3s. from Herr Pusch, Breslau, Schmiedebrücke 46). Armed with this and a small benzine lamp, anyone can produce a momentary and brilliant illumination, and this may obtain photographs anywhere and at any time. Magnesium is only about one-twentieth of a grain, and a grain or two amply suffices. For medical photographers nothing can be simpler than Professor Cohn's magnesium-benzine light.

A THRILLING INCIDENT.

DR. A. C. DUTT calls attention to the following circumstance reported in the *Indian Daily News* (Calcutta), which is of interest not only for its personal aspects, but as an example of successful treatment of snake-bite. A number of snakes, principally cobras, were sent to Dr. Vincent Richards for experiment. Dr. Richards

took out one of the cobras with the object of getting some of its poison in a watch-glass, which he had ready for the purpose. He held the snake in his right hand, and was moving his left hand in front of it, when the snake bit him severely on the forefinger of the left hand. Dr. Richards, fortunately for himself, preserved his presence of mind; he killed the snake, and with a knife laid the finger open to the bone above the wound, and applied permanganate of potash; he then applied a ligature to the finger and another to the forearm, and drove off for medical help. Dr. Macleod and Sir Benjamin Simpson reopened the wound and thoroughly cauterised it with nitric acid. Ordinary dressings were then put on. More than two months have passed since the accident, and Dr. Richards is doing well.

THE GERMAN EMPEROR.

WE received the following telegram from Charlottenburg on Thursday morning: "Last Saturday, immense, sudden increase of pus took place, twice as much as any day previously, but no increase of fever occurred. It is probable, therefore, that the abscess which formed a fortnight ago broke down. The discharge of pus is now lessening, and the Emperor is gradually recovering strength." We learn, on what appears to be trustworthy authority, that in Professor Senator's opinion the disease is undoubtedly laryngeal cancer, complicated with extensive suppuration. New swellings are continually becoming developed in the trachea, so that the cannula has to be frequently changed.

THE PARKES MUSEUM OF HYGIENE,

HER Royal Highness the Duchess of Albany presented on Saturday last, at the Parkes Museum, certificates to the ladies who had passed an examination following a course of lectures on domestic hygiene given by Dr. Schofield on behalf of the National Health Society. Sir Douglas Galton, who opened the proceedings, spoke of the need which was felt by friends of hygiene and workers in sanitation at this critical point, when further progress of the sanitary education of the nation required earnest and concentrated effort, and expressed a strong belief that, if all the different sanitary and health associations were combined, ample funds for the endowment of a grand national college of hygiene, with affiliations in the chief localities of the empire, would be at once available. Lord Wantage proposed and Mr. Ernest Hart seconded a vote of thanks to the Duchess of Albany, which was cordially passed. A letter from Miss Florence Nightingale, expressing her deep sympathy with the objects of the Museum, especially with the ceremony that day, was read; it contained the following passage: "Without women there can be no domestic hygiene. The first principles and work of sewerage, water-supply, and ventilation must, without the housewife, almost remain a dead letter. But let her be practically interested in how to keep air, earth, and water pure, and to admit light in her house, and the health and life-giving machinery is complete."

MEETINGS OF GERMAN ASSOCIATIONS.

THE sixty-first German Scientific and Medical Congress will be held in Cologne from September 18th to 23rd. Dr. Laudahn, representing the section of Neurology and Psychiatry, will receive announcements of intended papers.—The second Congress of the Anatomical Society will take place in Würzburg from May 20th to 23rd. The following papers and addresses are announced:—Gegenbauer: On Cœnogenesis. Bardeleben: On the Position of the Female Pelvic Organs. His: On the Origin of Nerve Fibres (with demonstrations). Kollmann: On the Skeletal Hand in Vertebrates; also On Cœlom and Nephridium in Vertebrates. Von Brunn: Membrana Præformativa and Cuticula Dentis. H. Virchow: The Spinal Cord in Anthropoidea. Th. Kölliker: On the

Simple Deposition of the Intermaxillary, with demonstrations *contra* Biondi. Lehoucq: The Finger-skeleton in Pinnipedia and Cetacea. Bonnet: Stump-tailed Dogs, in regard to the Transmission of Acquired Peculiarities. Born: On the Formation of the Valves, Orifices, and Septa of Mammalian Hearts, with demonstrations. Rabl (Prague): On the Origin of Connective Substances. Several interesting demonstrations are announced, in addition to the above.—The German Gynaecological Association will hold its second meeting in Halle from May 24th to 26th. About twenty-three members have promised papers, amongst which are the following,—Winckel (Munich); On the Facilitation of the Delivery of the Head in Foot-presentation. Dohen (Königsberg): The After-birth Period. Schwartz (Halle): (1) The Treatment of Extra-uterine Pregnancy; (2) Atony of the Non-puerperal Uterus. Ahlfeld (Marburg): (1) On Placenta Prævia and Uterine Incision; (2) On some Intra-uterine Fœtal Movements not hitherto described. Olshausen (Berlin): On the Mechanism of Delivery in Cranial Presentation.

BOWER AND KEATES INDEMNITY FUND.

THE Committee of the Bower and Keates Indemnity Fund are now, after several unavoidable delays, in a position to wind up the affairs with which they have had to deal. After paying Messrs. Bower and Keates's bill of taxed costs and all the expenses connected with the appeal to the profession, etc., a balance of about £500 remained. Some time ago the Committee issued to every subscriber a circular regarding the disposal of the surplus, and suggested that part should be given to help other practitioners who had been attacked and had vindicated themselves at considerable cost, and that part might be given to some of the medical charities. The subscribers having left the power of disposal in the hands of the Committee, we believe they have advanced so far in the distribution as to vote £100 to Mr. Ralph Hodgson, late of Lewisham, who was successful in clearing himself from charges brought against him by a servant; in the case of Gibson and Wife *v.* Jeffries and Hills, £50 to the defendants; and a like sum to Mr. Brown, of Wandsworth, in the case of Lennard *v.* Lennard, Brown, and Allatt. The Committee have still about £300 remaining, and they propose to meet in a month to decide as to its distribution and to close the accounts.

A CASE OF SPLENECTOMY.

In the *Annali Clinici dell' Ospedale degl' Incurabili in Napoli* for May and June, 1887, Professor Agostino Casini has recorded a case in which he successfully excised a "wandering" and hypertrophied spleen. The patient was a woman, aged 22, who for four years had suffered from frequent attacks of malarial fever, sometimes accompanied by jaundice. Three years before she came under the care of Dr. Casini she became conscious of uneasy dragging sensations in the abdomen, and noticed a tumour in that region which steadily increased in size, whilst her general health became gradually worse. On examination the belly was seen to be enlarged, especially on the left side. A smooth, rounded, rather hard swelling was felt occupying the fore part of the cavity; it extended upwards nearly to the margin of the ribs, downwards to the pelvis, and laterally to a line passing downwards from the anterior axillary border. The tumour was freely movable, and was not adherent to the abdominal parietes. It could be rotated so that its upper edge was directed forwards perpendicularly to the wall of the belly, the anterior surface thus becoming the inferior, and the posterior the upper. On the rounded margin a notch could be distinctly felt. The mass could be moved upwards and to the left, so as to be almost covered by the ribs; displacement towards the right, on the other hand, caused a feeling of dragging and stretching on the left side. There was some fluid in the abdominal cavity. On April 20th Professor Casini opened

the abdomen in the middle line, and removed the spleen. There were some adhesions to the kidney, and especially to the pancreas, which formed part of the pedicle. The latter gave a good deal of trouble, and had to be tied in a number of separate pieces, a portion of the pancreas, which could not be detached, being seized between the blades of a pair of forceps, and crushed off; the stump of the pancreas was then stitched up, and, after careful cleansing of the peritoneum, the abdomen was closed. Very little blood was lost in spite of the difficulty which had been felt in securing the vessels of the pedicle. The spleen weighed 3 kilogrammes and 100 grammes (6½ lbs.). The temperature on the first and second day was 100.4° F., after which it fell to a point little above normal. On the seventh day the sutures were removed from the abdominal wound, which had healed by first intention. A few days later a small abscess formed in the abdomen on the left side above the level of the umbilicus; the patient, however, soon afterwards passed a quantity of pus in her urine, and continued to do so for some little time, the swelling meanwhile gradually disappearing. Towards the end of May she was discharged cured, and six months later she was still in perfect health. This makes the ninth splenectomy that has been performed in Italy, the first having been done in 1874. Of these operations five had a fatal result; the remaining four, which have all been performed since 1881, have been successful.

DR. APOSTOLI AT BRIGHTON.

AT the last meeting of the Brighton and Sussex Medico-Chirurgical Society, held on Thursday, May 3rd—Mr. W. F. Salzmann, President, in the chair—Sir T. Spencer Wells read a paper "On the Electrical Treatment of Diseases of the Uterus." After the paper, which will be found reported in full on another page, Dr. Apostoli, who was very well received, made some remarks in French. An animated discussion then followed, sustained by Drs. Playfair, Aveling, Inglis Parsons, Heywood Smith, George Elder (Nottingham), Travers, Skene Keith, and Mr. W. Furner. As will be seen from our report, most of the speakers were decidedly in favour of Apostoli's method. Various questions on the subject were replied to by Sir Spencer Wells and Dr. Apostoli. There were over sixty gentlemen present, amongst others, as visitors, Mr. Morse (Norwich), Dr. Beaumont (Southampton), Drs. Colgate and Farnell (Eastbourne), etc. The members present included the Vice-Presidents, Mr. Noble Edwards and Dr. Withers Moore, the Treasurer, Mr. Hodgson, and the Honorary Secretaries, Mr. Cresswell Baber and Dr. Mackey (acting for Dr. Whittle).

THE DEATH OF MR. WALTER SHIRLEY.

THE distressing circumstances attending the death of Mr. W. Shirley, until recently M.P. for the Doncaster Division, have naturally attracted a good deal of attention. He was admitted into the London Hospital, and died within twenty-four hours, *post-mortem* examination showing that the immediate cause of death was suppurative peritonitis. A painful impression was created by the statement that he had previously applied to St. Thomas's Home and Hospital and had been refused admission. We have received from the Resident Assistant Physician the following explanation of the reasons which led to this refusal:—"On April 30th, at 11 P.M., Mr. Shirley, accompanied by his landlord and a policeman, applied for admission to St. Thomas's Home. He was seen by Dr. Edmunds, the medical officer of the Home, and subsequently, at Dr. Edmunds's request, by Dr. Hawkins, the resident assistant physician of the hospital. It appears that he had left his residence in the Temple to take lodgings in Newington. In Newington he had been seen by a local practitioner, who had recommended his admission to St. Thomas's Home. The appearance of the policeman on the scene was due to the fact that Mr. Shirley, on his way to the Home in a cab, had

imped out and invoked the assistance of the police to protect him from being taken to an asylum. Dr. Edmunds and Dr. Hawkins found Mr. Shirley to present such marked signs of mental aberration as to render him unfit to be admitted to Home Hospital, the rules of which forbid the admission, except in cases of extreme urgency, of such cases. Extreme urgency was certainly not apparent. Mr. Shirley walked about with much activity, conversed freely, had a good pulse and a clean tongue; his mental condition rendered it in the highest degree undesirable that he should be introduced into a ward containing a number of persons to whom rest was precious. His physical condition after his journey to the hospital showed nothing incompatible with his return to Newington, under the care of his medical attendant in that locality. Admission was therefore refused. At the same time a letter was sent to his medical attendant, giving the reasons which prevented his admission; and a telegraphic message was ordered to be despatched to his nearest known relative notifying his condition."

SWISS LAWS AND ENGLISH PATIENTS.

In the discussion at the Royal Medical and Chirurgical Society on the treatment of phthisis by residence at high altitudes, Dr. Quain made some very pertinent remarks. He dwelt with some emphasis on the recent action of the Swiss Government, which has rendered to English practitioners, however well qualified, liable to fine and imprisonment for attending his own countrymen within the Republic. This unfortunate state of the Swiss law led Dr. Quain to hesitate before advising patients to go to health resorts where they would be so ruthlessly deprived of the advice of English medical men. There was, he said, good reason to believe that not a few of his colleagues in London held the same opinion. His recent decision of the Swiss authorities is the more remarkable inasmuch as they must be aware that Swiss medical men can practise in England without let or hindrance, and could now even be placed on the *Register* for foreign practitioners, which confers every privilege possessed by an English practitioner, provided that the Swiss were willing to reciprocate by giving English practitioners a like privilege in Switzerland.

A VICTIM TO THE CHLOROFORM HABIT.

Two points at least furnishing matter for reflection arise out of the death from inhalation of chloroform reported this week. The case ceased, a midwife, aged 42, had, it appears, been in the habit for at least ten years of inhaling large quantities of chloroform; in fact, she claimed to be—at any rate it was claimed for her at the quest—that she was the champion chloroform taker of the world, and that she would take a pint of chloroform in the day. It will be safe to assert that a very considerable quantity of this illicit allowance was never really taken, or inhaled by her at all, but wasted on the atmosphere around her. As everyone conversant with the subject is well aware, it is not the amount of chloroform, but the proportion of it to air, that constitutes the chief source of danger in inhalation. The first point, however, to which we would refer is whether we may infer from this case that a system may become habituated to, and so more tolerant of, chloroform vapour; we do not think such an inference can be made; we have no evidence as to the degree of concentration of the vapour she was wont to inhale, and her death would prove that she certainly had not attained to complete toleration, whilst it is well known that many fatal results from chloroform inhalation have occurred in persons who had previously and sometimes repeatedly taken chloroform without any ill effect. Our second reflection is as to how it happened that this woman was able to purchase such large quantities of so potent a drug; some chemists may sell it to medical men, or by their instructions; and it is to be regretted that the opportunity was not afforded to the jury of

making a strong presentment on the subject on the present occasion. The unfortunate woman could never have acquired the habit had it not been for the laxity of some person or persons in selling chloroform to her.

WEIL'S DISEASE.

WITHIN the last two years, another disease, bearing a man's name, has been described and discussed. We have already Bright's, Addison's, Graves's or Basedow's, Raynaud's, Friedreich's, Thomsen's, and Menière's diseases, besides Argyll-Robertson's pupils, Colles's fracture, and several surgeons' amputations. There are numerous objections to the practice of employing men's names to distinguish diseases. The taunt of the Psalmist against the heathen calling their lands after their own names does not apply to the present case, as the names in question, surnames of distinguished observers, are invariably attached by others to the diseases which these observers first described without the aid and convenience of nomenclature. Nevertheless, the practice is objectionable; it implies the glorification of men through disease, and, as part of a system of nomenclature, is faulty. Weil's disease is so-called for the usual reason—that is to say, it was first described by a physician of that name. About thirty cases have been noted, including those first detailed by Dr. Weil only two years ago. Dr. Fiedler has since written on the new disorder in the *Deutsch. Archiv*, vol. xlii, part 4, page 281. His paper has already been fully condensed in the May number of the *American Journal of the Medical Sciences*. Fiedler concludes that the disease, first described by Weil in 1886, is not an abortive form of typhoid fever, as Dr. Weil has suggested. It is a distinct, acute infectious or toxic affection. The disease begins suddenly, without prodromal symptoms, but often with a chill. The constant symptoms are fever, headache, gastric disturbance, jaundice, and muscular pain, especially in the calves. The fever has a typical course, and lasts eight or ten days. Relapses have been observed. The spleen and liver are generally but not always swollen; the liver often becomes tender on pressure. Nephritis is often observed; herpes and erythema occur at times. The prognosis is generally favourable. Weil's disease is generally seen in hot weather, and men in the prime of life are the most subject to it. The cause is quite unknown, but butchers appear most liable to the disease, judging from the scanty statistics already at the disposal of the physicians who have studied Weil's disease.

EXTIRPATION OF CONSTRICTED PORTION OF THE LIVER.

DR. LANGENBUCH describes, in the *Berliner Klinische Wochenschrift*, No. 3, 1888, the case of a woman, aged 30, who had suffered for eight years from abdominal pain, most marked when she lay down: when lying on the back, palpitations and a feeling of fear came on. In the upper part of the abdomen a swelling, the size of a fist, could be felt. It was hardly perceptible externally, and extended from the ensiform cartilage to within two and a quarter inches of the umbilical level. The swelling was smooth, tough, and elastic; its inner border was thick. Percussion impaired, the dulness being continuous with that corresponding to the area of the liver. Echinococcus or, more probably, constriction of liver, caused by clothing, was diagnosed. An exploratory incision was made, and a large mass of liver-substance, cut off by a deep constriction from the left lobe of the liver, was discovered. The position of the constricted mass explained the high degree of pain and discomfort which it caused, strongly contrasting with the trifling inconvenience observed when the right lobe is similarly affected. The mass in this case pressed the pyloric portion of the stomach, the duodenum, pancreas, aorta, with several great nerves and ganglia of the sympathetic against the vertebral column. The mass of liver was amputated, several pedicles being

made out of the bands of connective tissue which still united it to the main part of the liver, and carefully ligatured. Hæmorrhage occurred on the evening of the operation, the abdominal cavity was opened up again, clots removed, and a vessel ligatured. The patient recovered for a time. Gradually ascites set in, with œdema. Dr. Langenbuch was uncertain whether the ascites should be attributed to the high degree of hydræmia present in this case, or to diminution of the area of the portal circulation. The abdomen was twice tapped, when the patient is said to have recovered completely.

PHYSICAL INSTRUCTION.

MADAME BERGMAN ÖSTERBERG, who has for some years acted for the London School Board as superintendent of physical training, and in supervising and training the teachers, has given evidence before the Royal Commission on education. Madame Österberg, as the result of her experience, gives her opinion that the present drill does not develop children physically, it simply sharpens their attention. The recommendation is made that the training of special teachers should comprise an elementary course in anatomy, physiology, and hygiene, and that special inspectors should supervise these subjects. The health of girls appears to suffer from neglect of such training, especially in towns, and improvement has been obvious under training upon the Swedish system. In schools it has been found that where mistresses at first grudged the time given to physical exercises, they have never afterwards regretted the time so spent. Exercise must, of course, be modified in the case of children who are underfed or starving. Mr. Alexander, of Liverpool, advocates that teachers should qualify themselves in giving gymnastic exercises, and that children should commence such practice when 8 years old. He also proposes that children should be taught to play under competent supervision, and that gymnastic apparatus be provided in every school; he considers that the use of some such apparatus quickens the circulation, and that other exercises aid development, while free exercises are enough for health. It is much to be hoped that the report of the Royal Commission will give some recommendations for physical training and attention to the hygiene of primary schools.

ULCERATIVE OR INFECTIOUS ENDOCARDITIS IN DOGS.

M. MATHIS, of the Lyons Veterinary School, has recently published some cases of infectious endocarditis in dogs, which appear to be of interest to medical men from their similarity to cases occurring in human beings. The first case described is that of an old bitch, which had been operated on for a tumour of the udder. All went well till a week after the operation, when the animal managed to tear away a ligature which had been placed on the mammary artery. This was followed by violent hæmorrhage, which was checked by the actual cautery. From that time the bitch refused her food, the wound ceased to granulate, and the respiration became rapid and difficult; there was also violent palpitation of the heart. A week later she died. The heart was found filled with whitish clots, easily broken down, looking more like jelly than fibrin; these were adherent to the walls of the heart and especially to the mitral and tricuspid valves, which were ulcerated. In the second case a bitch, which had just dropped a litter of puppies, had to walk through a large puddle of water which came up to her middle. She was immediately afterwards attacked by violent fever (40.5° C.), the pulse being 145, and the heart beating very violently; the breath was short, and the mouth hot and dry. She fell into a somnolent state, the dyspnoea and palpitation gradually increasing, till death ensued seventy-two hours after the commencement of the attack. Clots and valvular ulcers were found in the heart. In the third case, where there had been

a good deal of uterine hæmorrhage a trocar had been inserted into an old hæmatoma situated at the fundus of the vagina of a bitch five years old. Soon afterwards dyspnoea, palpitation, and pyrexia came on, death rapidly ensuing. Some very distinct ulcers of a reddish-grey colour were found on the auriculo-ventricular valves; from these ulcers a micrococcus was obtained and cultures prepared; these succeeded very well in broth, but developed less quickly in gelatine, and not at all in agar-agar. The juice of all the organs served for sowing the cultures. Intra-venous injections of the culture did not succeed in developing the disease in healthy animals, a certain predisposition being apparently required. Thus, in two of the three cases described there had been exhausting hæmorrhage, while the third occurred in the puerperal state. The clinical characters of this disease may be said to be sudden invasion causing extreme depression, dyspnoea and violent palpitation, no physical signs to account for these being discoverable by auscultation or percussion.

SCOTLAND.

DR. W. SCOTT LANG has recently been appointed to lecture on surgical pathology at Surgeons' Hall, and commenced the course by giving an introductory lecture on May 2nd.

SOUTHERN MEDICAL SOCIETY, GLASGOW.

ON May 3rd Dr. McIntyre read notes of laryngeal cases illustrating difficulties of diagnosis and treatment. He specially referred to the frequency with which the larynx was the seat of reflex irritation from other parts, such as the nasal mucous membrane or from the presence of nasal polypi, and described the more recent methods of treating such cases.

OPENING OF THE GLASGOW EXHIBITION.

THE great social event of the week has been the opening on Tuesday last of the Exhibition by their Royal Highnesses the Prince and Princess of Wales. The event was most successful. Glasgow visited so seldom by Royalty, was *en fête*. In the most brilliant sunshine, the miles of gaily-decorated streets and the dense crowds of holiday-makers made a sight well worth seeing. The Exhibition and grounds were in apple-pie order, and nothing occurred to mar the beauty of one of the most brilliant ceremonies that have ever occurred in Glasgow.

DISCUSSION ON TRACHELORRHAPHY.

At the last meeting of the Glasgow Obstetrical and Gynaecological Society, Dr. Park introduced a discussion on trachelorrhaphy; he criticised and traversed the conclusions of Nøggerath. He thought subinvolution and hypertrophy were not only directly but remotely sequent to lacerations of any considerable extent; but that, while that was so, these frequently yielded to treatment, and trachelorrhaphy was only called for in intractable cases. The discussion was an animated one, and was engaged in by Drs. Sloan, Oliphant, Pollock, Turner, Stark, and Nairn.

MEDICO-CHIRURGICAL SOCIETY, GLASGOW.

At the meeting of the Medical Section on May 4th, Professor W. T. Gairdner showed a young child with a peculiar deformity of its arms, affecting chiefly the muscles, causing abduction of the arm, with flexion of elbow and inversion of forearm. It was supposed to be due to some central nervous lesion. Dr. Middleton showed a patient with congenital cardiac disease, due probably to communication between the auricles or ventricles, but without any blueness of skin. Professor Gairdner showed a heart from a case in which an auricular systolic murmur was heard during life, while the *post-mortem* examination revealed no lesion.

at a perforation of one of the anterior segments of the aortic valve. Professor Gairdner said this was the first case that had come under his observation that appeared to support Austin Flint's theory of the causation of the presystolic murmur. Professor Gairdner and Dr. Middleton showed a heart from a case in which systolic and diastolic murmurs were heard during life, while the *post-mortem* examination revealed extreme mitral stenosis as well as aortic and tricuspid lesions.

DEATH OF DR. H. C. MACEWEN.

This talented physician has just died at the early age of 27, from phthisis caught in the discharge of his professional duty, and the very outset of his career. After a most distinguished course as a student, first at the University of Glasgow, and afterwards of Edinburgh, he graduated in 1885, and then proceeded to Vienna, to continue his studies of special branches. On his return to Glasgow he entered the Royal Infirmary as house-physician, here he resided for a year, and only left a month ago to fill a vacancy on the staff of the Belvidere Fever Hospital. He had hardly been three weeks in his new post when he was seized with his fatal illness. He first complained of sore throat on April 15th, and he died on May 3rd, deeply regretted by all who knew him.

GLASGOW BOUNDARIES COMMISSION.

The report of this Commission, which has just been issued, will in many respects have a very great influence on the health and sanitary conditions of the inhabitants of Glasgow. The Commission recommends the inclusion within the city of all the presently separate suburban police burghs and of certain portions of the counties of Lanark and Renfrew, built upon and inhabited, but still extra-burghal. This means the addition of about 180,000 inhabitants and of about 8,500 acres to the present city, giving a total population of about 724,000, and an acreage of 14,600 to the extended city. In making these additions the Commissioners have been largely guided by the sanitary and drainage necessities of the various districts and by the common interests of the city and districts in regard to the spread of infectious diseases and the treatment and removal of these diseases and of all other unsanitary conditions. They regard it as of the utmost importance that the whole urban area should be under the charge of one chief medical officer, with an adequate staff and appliances in the various districts, and that that officer should be responsible to the central authorities, consisting of representatives of every part of the extended city. It is to be hoped that a report based on such enlightened considerations for the health of the inhabitants may speedily be made the basis for Parliamentary procedure.

GLASGOW UNIVERSITY.

The summer session of the various Glasgow medical schools opened last week. The interruption to the ordinary course of work by the opening of the International Exhibition on May 8th seems, however, to have deterred many students from entering promptly for the classes. At any rate the enrolments at the University are as yet in many cases considerably below those of last year. The agitation aroused by the Universities Bill seems to have opened as the Bill slowly progresses in Parliament. It will be rather difficult to form a just estimate of the dominant opinion regarding the Bill so far as Glasgow University is concerned, as fewer than four petitions have already gone up from various bodies connected with the University, and expressing views of no little divergence. That of the Senate seeks to have the affiliation clauses wiped out, and the clauses relating to the powers of the Court and Senate amended, so as to leave the present powers of the Senate in educational matters intact; while the petition of the Council Association, representing the views of "about a thousand

graduates,.....comprising clergymen, medical men, lawyers, and others," specially singles out the affiliation clauses and those restricting the powers of the Senate for approval, though it expresses the opinion that the affiliation proposals are defective in that they do not expressly confer on the University Court any share in the management of the affiliated colleges. The Council itself asks only for a definition of affiliation, incorporation, etc., disapproves of the transference of the patronage of bursaries, and petitions for an increase in the financial grant; while the University Club takes the senatorial view that the Commissioners should have affiliation referred to them merely for consideration and report. On May 3rd the unusual spectacle was witnessed of the Principal and a deputation from the Senate, consisting of Professors Leishman, Veitch, Stewart, and Jack, appearing before the Town Council to show cause why the Council should not petition in favour of St. Mungo's College Bill, as the promoters of the Bill had desired them to do. The deputation addressed the Council for an hour and a quarter, and at the close the Lord Provost intimated that the statements made would be carefully considered before a decision was arrived at.

ASPHALTE PAVEMENTS AND THE PUBLIC HEALTH.

The vapour of tar has been supposed to be beneficial in a number of disorders, but Dr. Edmund J. Mills, of the Glasgow Technical College, has written a short note on the injurious effects of tar vapours so copiously discharged on our streets while asphalt road-mending is going on. It is said that the injurious effects of these fumes is perfectly well known at tar works, where the pitch is always cooled down in a closed chamber prior to casting in blocks. Casual inquiries have convinced him that the operations of road repair in Glasgow have been, during the last three weeks, the cause of a great deal of totally unnecessary illness, the leading symptoms of which are nausea and giddiness. He himself has been three times prostrated in this way, and has been thereby debarred from pursuing his ordinary professional work until these repairs cease. In view of the serious inconvenience from which many more must have suffered, it is to be hoped that the use of pitch in the future may be dispensed with, as the operation of road-mending can, if desired, be conducted without any offence whatever to the public health.

THE CONSUMPTION OF METHYLATED SPIRITS.

At a meeting of the Edinburgh Town Council held last week, an important communication was presented by the chief constable of the city referring to the great and increasing use of methylated spirits as a beverage among the poorer classes. This trade in a most noxious material is largely carried on on Sundays, when the ordinary liquor traffic is prohibited in Scotland under the Sunday Closing Act. The head constable's report is as follows: "I think it my duty to bring prominently under the notice of the magistrates and council the fact that on Sundays within the city a considerable trade has arisen among certain druggists for the sale of methylated spirit to persons who consume it as a beverage. In consequence of numerous complaints, I have had observation kept upon the shops of a number of druggists who were reputed to carry on this Sunday trade, and the result of that observation shows clearly that a very considerable traffic goes on every Sunday. The class of persons who purchase the spirit is about the lowest we have in the city, and their appearance ought to be sufficient to denote to the druggist the purpose for which they are making their purchases. No questions, however, are asked as to what the methylated spirit is wanted for, and in not a few cases the purchaser did not even require to ask for any specific article, but simply placed an empty bottle on the counter with the price of the quantity wanted, and it was at once supplied. The whole facts go to show that the druggists are perfectly well aware that

the spirit is bought to be drunk, but without specific evidence to prove this knowledge on their part there is little hope of securing a conviction for a contravention of the Act. The spirit is known amongst its users by a variety of names, among which are 'finish,' 'dynamite,' 'polish,' etc. The trade is an increasing one, and I am certain it is doing a vast amount of mischief; but as the law stands, the police are powerless to deal with it. I have never been able to find any objection which would hold good to the prohibition of the sale of methylated spirit on Sundays, and if the corporation can see their way to make any representation likely to effect this, they would do a public service."

ROYAL SOCIETY OF EDINBURGH.

At the last meeting of the Royal Society, several papers of medical interest were communicated to the Fellows. Dr. Woodhead and Mr. Irvine read a paper on the secretion of carbonate of lime by animals. Dr. Bruce then communicated a paper on his recent interesting case of a brain in which the corpus callosum was entirely absent. After fully describing the actual condition of parts in the cerebrum, which was in many particulars curiously abnormal, he entered into a discussion of the views held by Professor D. J. Hamilton, of Aberdeen, who communicated his doctrine of the non-commisural character of the corpus callosum some twelve months ago. This doctrine has found little favour in Dr. Bruce's eyes from the first, and in his paper he largely developed his antagonism to the new doctrine. Several other interesting papers, mostly on zoological subjects, followed; among them a valuable paper on the distribution of marine life on the west coast of Scotland, and one describing the crustacea of the Firth of Forth by Mr. W. E. Hoyle.

IRELAND.

THE WATER-SUPPLY OF LISBURN.

A REPORT has been issued, in which the sanitary officers of Lisburn give a startling account of the impurity of the water at present supplied to the inhabitants. Confidence is felt that now, when attention has been drawn to the matter, the necessary improvements will be instituted by the lord of the soil, Sir Richard Wallace, who has always shown generosity and public spirit in the management of his property.

POLLUTION OF THE RIVER LEE, CORK.

THE Cork City Engineer has recently reported to the Public Health Committee that at Macroom the river Lee is subject to pollution, and it is intended that immediate steps shall be taken to compel the guardians of Macroom to prevent any further contamination of the water which supplies the citizens of Cork.

LADIES AT IRISH EXAMINATIONS.

At the recent examination under the Conjoint Scheme, Miss Thoms, of London, outstripped the other twenty candidates and came out first. At the Royal University, Miss Fleury, of the London School of Medicine for Women, made brilliant answering at the third year's examination. She was one of six candidates who—out of 80—were recommended to compete for honours. The result of this further test has not yet been made known.

TESTIMONIAL TO SIR GEORGE OWENS, M.D.

On Friday, May 4th, a purse of one thousand sovereigns, an album, and a claret jug, with an address, were presented to Sir George Owens, M.D., as an acknowledgment of his services to the public. Sir George Owens has devoted much time to the duties of the various public bodies of which he is a member, and he has earned the approval of a large section of the community.

THE ROYAL COLLEGE OF SURGEONS AND THE QUEEN.

THE President and Council of the College of Surgeons announce that a portrait of the Queen will be unveiled at the College on May 22nd. His Excellency the Lord Lieutenant and Prince Edward of Saxe-Weimar will be present on the occasion. The President (Mr. Corley) will give a banquet on the evening of the same day, when His Excellency the Marquis of Londonderry and other distinguished guests will be present.

AMALGAMATION OF SCHOOLS.

A REQUISITION is being signed by Fellows of the College of Surgeons, asking the President to convene a special meeting to consider the question of the amalgamation of one or more private schools with that of the college. The subject was brought up at the annual meeting last year by Mr. Thomson, and was defeated by a narrow majority. There are no less than five medical schools in Dublin, two of them being proprietary. The waste of power which results is very obvious, and it would be a clear gain to medical education if there could be more concentration of teaching.

ELECTION OF EXAMINERS, ROYAL COLLEGE OF SURGEONS IN IRELAND.—The annual election of examiners took place at the College of Surgeons last week. Messrs. O'Grady, Mapother, R. L. Swan, and A. Benson retired by rotation. The following were appointed to the Conjoint Board of the College of Physicians and College of Surgeons:—Anatomy: John Barton and Thornley Stoker. Surgery: William Thomson and C. B. Ball. Physiology and Histology: J. A. Scott. Midwifery: H. G. Croly. Ophthalmology: H. R. Swanzy and F. Devaine. To the Conjoint Board of the College of Surgeons at the Apothecaries' Hall:—Anatomy: F. A. Nixon and C. H. Robinson. Surgery: L. H. Ormsby and H. G. Croly. Physiology: Coppinger. Medicine: M. A. Boyd. Chemistry: H. C. Tweed. Midwifery: J. J. Cranny. The last-named gentlemen will all take place in any other examinations at which their services may be required. Dr. Hayes was appointed an examiner in Medicine and Dr. Minchin in Chemistry.

COLLEGE OF STATE MEDICINE.—The introductory lecture of the inaugural session of the College of State Medicine was delivered by Mr. Brudenell Carter on Wednesday, May 2nd, the subject being "The Aims and Objects of State Medicine." Sir Joseph Fayrer, in introducing the lecture described the character, scope, and objects of the institution which that day had begun its active existence. It was proposed that the College should be a training institution for those who desired to be specially qualified to guard the public health, or to fill any of those public offices which required sanitary knowledge, and also for those who held commissions in the Volunteer Medical Service and who required a knowledge of ambulance work; that, in fact, the College should do for the members of the medical profession very much what Netley has now for many years past done for the military.

TESTIMONIAL TO MR. JOHN BROADBENT.—At the last meeting of the Manchester Medico-Ethical Association, an illuminating address was presented to Mr. John Broadbent, surgeon, who has held the office of honorary secretary for the last ten years. The address, which was signed by Dr. Henry Simpson, President, and Drs. A. Wahltruch and Frederick H. Collins, honorary secretaries in the name of the Association, expressed a high appreciation of the manner in which Mr. Broadbent had discharged the duties of the office for so long a period.

BEQUESTS.—Mr. Richard Benyon, of Englefield Park (the President), has given £500 to the Royal Berkshire Hospital, Reading. Professor Leone Levi has given 100 guineas to the Great Northern Central Hospital, on condition that one of the beds in the new building shall be named "The Leone Levi Bed."—Mr. Henry Clarke has given £100 to St. Mary's Hospital.—Mr. William Speke, J.P. and D.L. of Portledge, Bideford, has bequeathed £100 to the Taunton and Somerset Hospital.—The Royal Maternity Charity has received £100 under the will of Mrs. E. Douglas.—Sir Edwin Saunders (the senior Trustee) has given £50 to the Dental Hospital of London.

PARLIAMENTARY BILLS COMMITTEE.

IRISH LUNACY LAW.

The following is the report of the Subcommittee of the Parliamentary Bills Committee of the British Medical Association on the above.

There were present at the Subcommittee Mr. Ernest Hart, Mr. Bridgwater, Dr. Alfred Carpenter, and Dr. Mickle, who drafted the report.

Resolutions in relation to Irish lunacy law passed in the section of Psychology at the annual meeting of the British Medical Association in Dublin, August, 1887, and referred to the Parliamentary Bills Committee by the Council of the Association; "It was moved by Dr. Yellowlees and seconded by Dr. Savage:—

"That this Section of the British Medical Association, having had under consideration during the meeting in Dublin the Irish lunacy laws and their practical working, and having strongly felt their grave defects when compared with those of England and Scotland, conclude to bring this subject under the consideration of the Council, in the hope that they will take such steps as to bring under the attention of the Government the urgent need of better regulations and further legislation in regard to this matter." The chief defects are the following:

"1. The modes of admission of patients into asylums, which often involve injustice and injury to the patients, and great danger to the public.

"2. The defective powers possessed by the medical superintendent for the proper and efficient management of the asylums, for example, his having no power to engage or to dismiss the attendants, on whose loyal discharge of duty the welfare of the patients so greatly depends.

"3. The want, in the majority of asylums, of assistant medical officers, so that the medical superintendent is unable to give the necessary time to his strictly medical duties, and large asylums containing some hundreds of lunatics may be left entirely without resident medical supervision when the superintendent is absent."

1. The modes of admission of (pauper) patients into asylums in Ireland.

One mode of admission is provided for under the General Rules and Regulations for the Management of District Lunatic Asylums in Ireland, made by the Lord-Lieutenant and Privy Council (Nos. 15, 16).

A declaration (stamped) is made before a magistrate that the person (for whom admission is sought) is destitute and insane. With this is a certificate by a magistrate and clergyman or poor-law guardian, that they have inquired into the case, and believe the person aforesaid to be a lunatic in destitute circumstances. Another certificate required is a medical one, that the individual concerned is insane and a fit subject for speedy admission into the district asylum. The applicant for a lunatic's admission to an asylum must also enter into an engagement to remove the lunatic whenever called upon to do so by the inspectors of lunatic asylums or the board of governors. These prescribed procedures and forms having been duly complied with, and application for admission of the lunatic made, the latter may be admitted on the authority of the board of governors of the asylum; three governors; the resident medical superintendent (or, in his absence, the visiting physician) having also the power to admit the case at once should he deem it to be urgent, and report afterwards to the board of governors, and obtain its sanction at the next meeting. A form containing a few particulars must be filled in by the lunatic's friends. So far as it goes, it is believed that this mode of admission is signed on fair and just lines, both as regards the public, the lunatic, and those who send him to, or receive him in, an asylum. But it has met with several objections: it has been said to cause unnecessary delay, trouble, and expense, application having to be made for the form at the asylum, and the form, after being filled in, having to be returned to the asylum before the patient can be admitted. Yet, in these days, when it is thought to be so necessary to safeguard the liberty of an alleged lunatic, and when it is desirable that the whole procedure, in placing a lunatic under care and control should be most carefully carried out, and the checks upon carelessness or negligence therein should be efficient, the above-mentioned objections will, perhaps, hardly be considered to tell against this particular method of admission into asylums, and, in fact, in some points they refer to provisions that are commendable.

With this, however, we would link the suggestion that whilst in ordinary cases of alleged lunacy it is desirable to avoid undue precipitancy of action in placing the subjects thereof in asylums, yet some provision is necessary for securing promptitude in placing urgent and dangerous cases under proper care and control; and some modification of the ordinary mode of procedure is needed in these latter cases, and can easily be devised.

Another objection to the above mode of admission is that it does not provide absolute authority for the immediate admission of dangerous lunatics. And this flaw might well be met by an amendment to the effect that the magistrate might have power to order the immediate admission of lunatics dangerous to themselves or to others.

But the mode of admission under which, in fact, most lunatics (more than two-thirds) are admitted in Ireland is the procedure under the Act 30-31 Vic., cap. 118, sec. 10. This is as follows:—The alleged lunatic having been brought before two justices, and it having been proved to their satisfaction that such person was discovered and apprehended under circumstances denoting a derangement of mind and a purpose of committing some crime for which, if committed, such person would be liable to be indicted, the said justices shall call to their assistance a medical officer of the dispensary district, who shall examine such person; and if he shall certify that such person is a dangerous lunatic or idiot, it shall be lawful for the justices, by warrant, to direct that the alleged lunatic shall be taken to the lunatic asylum for the district or place. But any relation or friend may, thereafter, take such lunatic under his own protection and care if he shall enter into sufficient recognisance for the peaceable behaviour or safe custody of such lunatic, before two justices of the peace, or the Chairman of the Court of Quarter Sessions of the county, or a judge of a superior court at Dublin.

That the magistrates may be duly satisfied that the alleged lunatic was found and taken under circumstances denoting a derangement of mind and a purpose of committing some indictable crime, it appears to be necessary that the alleged lunatic should be apprehended, be taken before two justices, and that a deposition should be sworn concerning his conduct and acts, and justifying the required opinion and conclusion on the part of the justices as to the existence of such derangement and purpose. The justices also, although they are required to see and examine the alleged lunatic, and be satisfied that he is lunatic and dangerous, are not bound to give any reasons for their coming to that conclusion, except the recital of those mentioned in the deposition. Then, again, the form of medical certificate and statement of particulars relating to the case are meagre in their requirements.

However desirable in a few dangerous and criminal cases this mode of admission may be, it is obviously unsuited for the vast majority of patients. And while adapted only for dangerous or criminal cases, it is inseparably linked with the most incongruous provision that any relative or friend may get the dangerous or criminal lunatic, who has been sent to an asylum by this mode, out of the asylum by becoming bail for his good behaviour and safe custody—behaviour and custody of a dangerous lunatic which such friend or relative is, in reality, unable to secure, but with regard to which failure to secure, it is believed, the recognisances entered into are never forfeited, thus depriving the public of any real protection by the feebly deterrent influences of the provision concerning bail.

It is submitted that what is required in Ireland is: either a modification and expansion of the mode of admission to asylums, first described above; or else such changes as will, as nearly as possible, make the modes of admission the same there as they are in Great Britain, or in one or other part thereof.

2. The defective control of medical affairs over the asylum staffs in Ireland.

According to the Act already mentioned (30 and 31 Vic., cap. 118, sec. 2), the Governors of the Asylums in Ireland appoint all the servants and attendants. Obviously, it would conduce to the welfare of the asylums and their inmates if the selection was left to the medical superintendents, and if engagement or dismissal of members of the staff should primarily rest with them, subject to the approval and confirmation of the board of governors.

3. The absence of the post of assistant medical officer in many asylums in Ireland.

It is understood that only about 9 asylums out of 22 in Ireland have a second medical officer. Where the asylums are of any but very small size, the desirability of having an assistant medical officer is too obvious to require any comment.

LUNACY ACTS AMENDMENT BILL.

At a meeting of the Subcommittee appointed to consider the report submitted by Dr. Mickle on the above Bill, present Mr. Ernest Hart (Chairman), Dr. Bridgwater, Dr. Carpenter, Dr. Mickle, and Dr. Grigg,

It was proposed by Dr. BRIDGWATER, and seconded by Dr. GRIGG:—

"That the report now made be received and placed on the minutes, and that a copy be forwarded to every member of Parliament and to the Branches, with a request that they communicate the same to their members, and ask their support to the suggested amendments in the House of Commons, and that a special request be forwarded to all the medical members of Parliament, asking them to consider the same, and if they approve to put notices in accordance therewith on the papers of the House."

RECOMMENDATIONS OF PARLIAMENTARY BILLS COMMITTEE OF THE BRITISH MEDICAL ASSOCIATION ON LUNACY ACTS AMENDMENT BILL.

Sect. 4, subsections 1, 2, p. 3, and Section 9, pp. 6 and 7. It is suggested that partly in modification and partly in substitution for these provisions in non-paper cases, the justice should see the alleged lunatic before signing an order of admission. At present, the provisions of these Sections leave room for much delay, so that a lunatic may be certified and yet his case only decided upon a fortnight later; and though when certified he might be extremely insane, when examined by a justice he might have recovered, and hence the certifier be placed in an extremely equivocal position, open to misunderstanding and attack. It is desirable to make it compulsory for the justice to see the alleged lunatic before signing an order for his admission.

Sect. 12, subsection 2, p. 9, line 21, for "may" read "shall;" and in line 22-3 omit "or whether making such visit or not;" and thus secure personal examination by the justice. Also in

Form 12, p. 51, Schedule, line 4, after "practitioner" to insert "and having personally examined A.B."

It is felt to be desirable that the existing requirement that the justice who signs the order of admission of a pauper lunatic to an asylum shall personally see and examine the alleged lunatic before signing such order should not be discontinued under the present Bill.

Sect. 20, subsection 5, p. 13, for "practitioner" to read "practitioners," and to omit "not being an officer of the workhouse;" and in line 4, for "examines" to read "examine." Also in

Subsection 7, p. 13, lines 23 to 25, to omit "for each day or part of a day, after the first day and before the notice is given during which the alleged lunatic remains in the workhouse."

These suggestions are made to secure remuneration for the medical officers of workhouses, except where they have contracted to do all the duties for a fixed salary; and modification of the severely punitive clauses with regard to them.

Sect. 28, subsection 4, p. 18, line 10, to omit "a special report," and the words following it to and including the word "with" in line 13, and to make the necessary alterations in this and subsequent subsections to harmonise with this alteration.

The medical certificate of unsoundness of mind sent periodically is thought to be sufficient.

The large amount of extra routine work imposed on the medical superintendent of an asylum will for a time absorb his whole attention to the detriment of his other numerous and important duties. Imperfectly recovered lunatics will constitute a serious danger to the community when at large, and the tendency of this Section will be to set many patients at liberty before recovery has become sufficiently established.

Sect. 36, p. 22. It is suggested that this Section be omitted. If this Section be not omitted, it is suggested that the person making application for discharge of a patient under this Section should give adequate security for the payment of all necessary expenses; and that persons be disqualified to sign any medical certificate under this Section who hold to the applicant under this Section the same relations as the persons disqualified to sign under Section 8 hold to the "petitioner" for an order for reception of an alleged lunatic into an asylum, or under single care, etc.

It is to be anticipated that under this Section vexatious and wholly unnecessary proceedings will sometimes be instituted, and that it is likely to lead to the discharge of persons who are in an unfit state for discharge.

Secs. 40 and 41. It is suggested that these Sections be omitted; or failing this, to omit Section 41, and the part of Section 40 following the word "be" in line 18, p. 25.

The correspondence of patients in private asylums is thought to be already duly protected, inasmuch as all letters to certain persons and authorities must be forwarded, unopened; and any letter written by a private patient, and not forwarded to the person to whom it is addressed, must be endorsed to that effect by the medical superintendent or proprietor, and laid before the Visiting Commissioners, or Committee of Visitors, as the case may be, at their next visit.

Sect. 50-55, p. 32, *et seq.* It is suggested that the provisions of the Bill be so altered as not to subject the registered lunatic hospitals to special restrictions and disabilities.

Sect. 60, page 35, line 27. It is suggested to omit the words "wholly or in part belonging to the county or borough;" so that the services of medical officers in any two or more county or borough asylums should count accumulatively towards pension, as if all such service had been in one asylum; each such county to contribute its appropriate share.

It is also suggested that officers and servants in county and borough asylums should be entitled to claim pensions, as a right, after a certain length of service with good conduct; and that the medical officers should be placed, as regards this matter, on a footing analogous to that of members of the Civil Service (First Class, 22 Vic., cap. 29, sec. 4).

MEDICAL SOCIETY OF LONDON.

THE annual meeting of the Medical Society of London took place on Monday, May 7th. The Oration was delivered by Sir Joseph Fayrer, K.C.S.I., on "The Natural History and Epidemiology of Cholera." The orator alluded to his own considerable experience of cholera in India and elsewhere, reviewed the history of the epidemics of the disease which have devastated the various regions of the habitable globe at different epochs, and discussed its appearance in the sporadic, endemic, and epidemic forms. He alluded to the ignorance which prevailed as to the real nature of epidemic influence, and proceeded to consider the influence of meteorology on the production of epidemics. He pointed out that the word cholera was as a rule only applied to the disease in its fully-developed condition, although it presented many phases varying in gravity from simple *malaise* to collapse and the coma of the worst forms of fever. He maintained that under certain circumstances English cholera was indistinguishable from its Asiatic congener, and quoted the opinions of various authorities to the effect that Asiatic cholera, *Damietta cholera*, and British cholera differed only in severity and not in kind. Various local outbreaks were quoted as tending to show the influence of some factor or factors apart from contagion and local insanitary conditions. He showed that the severity of the disease was not always greatest in proportion to density of population, and that its geographical distribution was a phenomenon of meteorological significance rather than of condition connected with human intercourse. He then discussed the correlation of season and the spread of cholera, pointing out how in India the seasonal prevalence varied according to the district, consequent to some extent on the fluctuating level and stagnation of subsoil water. The periods of cholera abeyance and cholera prevalence offer curious differences in the various provinces, the disease being very general in one district in a given year, while others are comparatively exempt. He argued that the theories of contagion and diffusion by human intercourse did not explain the movements of cholera epidemics, since neither the frequency, the direction, nor the rapidity of the spread of the disease bore any relation to the development of means of communication. He then criticised the alleged transport of disease by contagion, and showed that in many instances the disease had already occurred before the vehicle of contagion had arrived. In the same direction, he recalled the peculiar predilection of the disease for certain districts, streets, and even houses. Moreover, in Bengal, for example, the course of the disease was upwards, that is, not with but rather against the rivers and main lines of traffic.

Passing on to the consideration of the etiology of the disease, the orator reviewed the various theories that had been suggested to account for it, and expressed himself as unable to convince himself that any of them satisfactorily or conclusively explained all the phenomena exhibited by epidemics, or that either or any theory was to be accepted to the exclusion of the others. Alluding to the present tendency to trace all diseases to a specific cause, he insisted on the necessity for not losing sight of the possibility of poison, autogenetically developed, giving rise to disease. He added that although the primary cause was still a mystery, local conditions undoubtedly permitted and favoured the occurrence and spread of the disease. He declined to accept the water theory as a sufficient explanation of all cholera outbreaks, and was led to seek the explanation in causes of a wider and more general character. He maintained, therefore, that until contagion in every form was entirely disproved authorities were justified in adopting measures which, while avoiding all oppressive or coercive interference with personal liberty, took reasonable precautions against possible sources of infection, and gave full effect to all known practical measures against the importation or diffusion of disease. The orator then discussed coercive measures and their results, dwelling upon the rigours and hardships of quarantine and the great suffering and incalculable damage to commercial interests which had resulted from the contagion theory as interpreted in other countries. After giving some tables bearing on the mortality of the disease at different epochs, Sir Joseph proceeded to discuss the precautionary measures, general and special at present employed against cholera, and wound up with fifteen conclusions based on the knowledge of the facts and phenomena of the disease which have so far been recorded. These were to the effect (1) that cholera has always been present in India, but that isolated cases occur there and elsewhere; (2) that its prevalence varies according to the year and the season of the year; (3) that

May 12, 1888.]

cholera does not visit all the places within an epidemic area; (4) that meteorological changes produce sudden alterations in the activity and intensity of an outbreak; (5) that the rate and direction are not influenced by facilities of communication; (6) that cases are more frequent and more severe at the commencement than in the continuance of an outbreak; (7) that hygienic measures afford the greatest but not an all powerful safeguard against cholera, and that it is important to check diarrhoea in time of epidemic; (8) that cordons and quarantine have utterly failed to prevent the spread of cholera, but on the contrary have done harm; (9) that epidemic districts present peculiar dangers to new comers, from which residents have a better chance of escape; (10) that in case of attack of bodies of men, removal is the best course; (11) that attendants on the sick do not suffer more than others; (12) that certain agents, impure water, articles of diet, etc., may cause diarrhoea and then cholera; (13) that fatigue, anxiety, etc., are powerful predisposing causes; (14) that observations tend to negative the idea of a specific poison; (15) that one attack confers no immunity. The orator concluded with an eloquent appeal to authorities to secure the removal of conditions likely to favour the occurrence and spread of the disease, observing that epidemics were not a necessary though a constant condition of men's existence, and were amenable to the laws of hygiene and common sense.

After the annual oration, the usual *conversazione* took place, the music being furnished by the band of the Coldstream Guards, under Mr. C. Thomas. The pictures were lent by Messrs. Boussod, Valadon, and Co., and by Messrs. J. and W. Vokins. There was so on exhibition a number of photographs by the new colour process, by Mr. Mayall; Robertson's writing telegraph, etc. A very large number of Fellows and their friends were present, and were received by the President, Sir William MacCormac.

THE LOCAL GOVERNMENT BILL AND PENSIONS OF ASYLUM OFFICERS.

ASYLUM officials are invited to attend a special meeting of the medico-psychological Association, to be held at Bethlem Hospital, on May 16th, at 6 P.M., to discuss the pension clauses of the Lunacy Acts Amendment Bill, and the clauses of the Local Government Bill affecting Asylums.

Among the many indications of the keen interest felt by those most affected in the operation of the Local Government Bill, would it become law, is the action recently taken by the Committee of Visitors of the Derby County Asylum. The following resolution passed at their meeting on May 5th, Sir Henry Every, Bart., in the chair.

That in the opinion of this Committee it is desirable that all existing officers should have an assured right to a pension on a scale not lower than that provided by the rules relating to Her Majesty's Civil Service.

A similar resolution was passed by the Committee of Visitors of the West Riding Asylum, Wakefield, on April 26th last, and to the same effect was adopted by the Committee of the South Yorkshire Asylum, Wadsley, on April 30th.

The following petition was unanimously signed by the staff of officers, attendants, and resident servants of the Derby County Asylum, and forwarded to the President of the Local Government Board, on May 2nd.

To the Right Honourable Charles Thompson Ritchie, M.P., President of the Local Government Board.

The petition of the undersigned officers, attendants, and servants in the Derby County Asylum, humbly sheweth—

That our position at present as regards prospect of pension is unsatisfactory, owing to its uncertainty, and to the extreme inequalities which prevail; whilst the new County Government Bill no clause appears which is likely to remedy its state of things; that our duties are irksome, depressing, and trying to temper and to health; that they involve more or less continuous responsibility, anxiety, and bodily risk; that the hours of duty in an asylum are long, and the pay in most cases is by no means proportionate; that a prospect of pension is one of the greatest inducements to long and faithful service.

We therefore pray that, in our interest and for the advantage of the public, you will insert in the County Government Bill a clause which will ensure to us a fixed scale of pension similar to that which is granted to civil servants under the 1st Vict., cap. 26, with the same qualifications and additions as therein specified.

We further pray that you will insert in the County Government Bill a clause which will enable officers, attendants, and servants, when they are transferred, often happens, from an asylum in one county or borough to an asylum in another county or borough, and when their approved service has been of not less than three years' duration (as proposed in the Police Constables Superannuation Bills of 1885 and 1887) to reckon such transferred service as continuous service which shall be counted (for the purpose of computing their pension, gratuity, or allowance, or gratuity) for length of service as if all such asylums had constituted only one asylum (see Section 60 of the Lunacy Acts Amendment Bill, 1888, which only applies to asylums in the same county). And your petitioners will ever pray, etc..

UNIVERSITY OF LONDON.

THE annual meeting of Convocation took place at the University Buildings on Tuesday, May 8th. Dr. FREDERICK JOHN WOOD was re-elected chairman. The Clerk of Convocation, Mr. H. E. ALLEN, LL.B., B.A., was reappointed.

Dr. T. B. NAPIER and Mr. W. J. SPRATLING presented the report of the Annual Committee, and moved its reception, which was agreed to.

Dr. T. B. NAPIER next moved:

"That the Annual Committee, jointly with the Special Committee already appointed on December 8th, 1885, for the consideration of the scheme for the constitution of the University, be empowered to take steps with reference to the representation, by suitable witnesses, of the views of Convocation to the Royal Commission appointed to inquire into the condition of the higher education in London, and for that purpose to adopt such measures and make such communications to the Senate as shall seem desirable."

In moving this resolution, the proposer gave a lucid historical account of the present movement for the furtherance of university education in London, and criticised adversely the part which the University and King's Colleges had taken in the matter. Mr. SPRATLING seconded the resolution. Sir JULIAN GOLDSMID considered the movement furthered by University College in favour of the formation of the proposed Albert University was decidedly retrograde. He had used some influence to prevent it, and, being unable to attain his end, had, with several other persons, resigned his position in the College. It was not desirable to have two universities in London. He thought that Convocation ought to be well represented before the Royal Commission, and he cordially supported the resolution. Mr. T. E. SCRUTTON urged that University and King's Colleges had not started their movement in favour of the Albert University until they found that the Senate of the University of London was opposed to their interests. Mr. T. TYLER and Mr. B. H. COOPER addressed the house, and the resolution was carried unanimously.

Mr. J. ANSTIE, Q.C., presented the report of the Special Committee for the Consideration of the Regulations for the Examinations for the Degrees in Laws, and moved its reception. This proposal was seconded by Dr. J. B. BENSON, and, after a long debate, was carried unanimously.

ASSOCIATION INTELLIGENCE.

NOTICE OF QUARTERLY MEETINGS FOR 1888. ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Meetings of the Council will be held on July 18th, and October 17th, 1888. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before each meeting, namely, June 27th, September 26th, and December 28th, 1888.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No member can be elected by a Branch Council unless his name has been inserted in the circular summoning the meeting at which he seeks election.

FRANCIS FOWKE, General Secretary.

COLLECTIVE INVESTIGATION OF DISEASE.

THE Report upon the CONNECTION OF DISEASE WITH HABITS OF INTemperance, which was presented to the Section of Medicine in the Annual Meeting of 1887, will shortly be published in the JOURNAL.

Reports upon the two remaining inquiries, namely, that into DIPHTHERIA, and that into the GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES, are in preparation, and will be published as soon as ready.

The following inquiry only of the first series remains open, namely, that on the ETIOLOGY OF PHTHISIS.

A fresh inquiry into the ORIGIN AND MODE OF PROPAGATION OF EPIDEMICS OF DIPHTHERIA has been issued.

Memoranda upon these subjects, and forms for recording observa-

tions, may be had on application to the Secretary of the Collective Investigation Committee, 429, Strand, W.C.

BRANCH MEETINGS TO BE HELD.

STAFFORDSHIRE BRANCH.—The third general meeting of the present session will be held in the Bell Library and Medical Institute, Cleveland Road, Wolverhampton, on Thursday, May 31st. The chair will be taken by the President, Mr. W. D. Spanton, at 3 o'clock in the afternoon. The following papers will be read:—Dr. C. A. McMunn: Excretion of Reduction Products of Hæmatin in Disease. Dr. Alfred H. Carter: Practical Considerations on the Nature and Treatment of Chronic Cardiac Disease. Mr. E. Hurry Fenwick, London: The Electric Illumination of the Bladder and Urethra, and its Value in the Diagnosis and Treatment of Obscure Vesico-Urethral Diseases. Dr. McMunn will show a simple method of adapting a photographic camera to the microscope.—T. VINCENT JACKSON, Wolverhampton.

EAST YORK AND NORTH LINCOLN BRANCH.—The annual meeting will be held at the Infirmary, Hull, on Wednesday, May 30th, at 1.30 p.m. Gentlemen who intend to make any communication, or to propose any resolution, are requested to inform the Secretary not later than May 20th.—E. P. HARDEY, Honorary Secretary, 80, Spring Bank, Hull.

MIDLAND BRANCH.—The annual meeting will be held at Nottingham on Thursday, June 14th, at 2 p.m. Members desirous of reading papers, exhibiting cases, etc., are requested to communicate with the Secretary before May 24th. Candidates for election by the Branch Council must send in their forms of application by the same date.—W. A. CARLINE, M.B., Honorary Secretary, Lincoln.

METROPOLITAN COUNTIES BRANCH: WESTERN DISTRICT.—The next meeting will be held on Wednesday, May 18th, at St. George's Union Infirmary, Fulham Road, Brompton, S.W. The chair will be taken at 8.15 p.m. by H. Charlton Bastian, Esq., M.D., F.R.S., the Vice-President of the District. Business:—Minutes of preceding meeting. A short paper will be read by H. T. Butlin, Esq., F.R.C.S., on the Treatment of some Chronic Ulcers of the Tongue. A Demonstration will be given by Noble Smith, Esq., F.R.C.S., on the Treatment of various Curvatures of the Spine. A few Cases of Clinical interest will be introduced by H. W. Webster, M.D., Medical Superintendent of the St. George's Infirmary.—C. ARTHUR PATTEN, Honorary Secretary, Marpool House, Baling.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT.—The annual meeting of the above District will be held at the Kent and Canterbury Hospital on Thursday, May 21th, at 3 p.m., Dr. Parsons, of Dover, in the chair. The dinner will take place at 5 p.m. at the Royal Fountain Hotel. Agenda:—Usual business of annual meeting. Mr. Raven: Tendon Reactions in Health and Disease. Mr. Brian Rigden: Notes on a recent Epidemic of Measles. N.B.—Anyone wishing to send papers, etc., should communicate at once with the Honorary Secretary, W. J. TYSON, 10, Langhorne Gardens, Folkestone.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.—The May meeting of this Branch will be held in 191, Union Street, Aberdeen, on Wednesday, May 16th, at 8 p.m., the President, Dr. Smith, of Kinnaird, in the chair. Business:—Minutes, nomination of new members, etc. Ballot for the admission of Dr. Ligertwood, Methlick. Professor Ogston: Intubation of the Larynx. Dr. Mackenzie Booth: Otological Memoranda; (1) Hyperacousia after Trauma of Membrana Tympani; (2) Recovery of Hearing after prolonged Eustachian Obstruction and Tympanic Catarrh. Exhibition of Specimens.—Dr. Gordon: Abscess of Liver. Dr. Mackenzie Davidson: Jessop's Refraction Ophthalmoscope. Professor Ogston: Composite Photograph.—ROBERT JOHN GORDON and J. MACKENZIE BOOTH, Honorary Secretaries.

OXFORD AND DISTRICT BRANCH.

A MEETING of this Branch was held at the Radcliffe Infirmary, at three o'clock, on Friday, April 27th; the President, Mr. CHEATLE, was in the chair, and about thirty members attended.

New Members.—Mr. D. Iles, of Fairford; Dr. Mair, Mr. Watson, Mr. Hickman, and Mr. Palmer, of Newbury; Mr. G. Mallam, of Oxford; and Dr. Ball, of Wantage, were elected members of the Branch.

Alteration in By-Laws.—Some alterations in the by-laws, proposed by Dr. DARBISHIRE, were carried.

Member Proposed.—Mr. Oates, of Bampton, was proposed as a member of the Branch.

Cases and Papers.—Mr. BLOXSOME showed a very successful case of Macewen's Operation.—Dr. BATT showed a most interesting and marked case of Pseudo-Hypertrophic Paralysis in a Boy.—Dr. COLLIER showed a specimen of Thoracic Aneurysm; there were no physical signs during life.—Mr. W. LEWIS MORGAN showed a good specimen of Tubercular Disease of Testis.—Mr. WINKFIELD showed a specimen of Round-celled Sarcoma of the Testis.—Dr. BROOKS read a paper on the Uses of Antipyrin.—Mr. DOYNE showed an Optometer.

METROPOLITAN COUNTIES BRANCH: SOUTH LONDON DISTRICT.

THE annual meeting was held at Bethlem Royal Hospital on May 8th, at 5.30 p.m. There were present about thirty members and visitors.

The minutes of the previous meeting were read and confirmed.

Election of Officers.—In accordance with a resolution passed at the last meeting of the Council of the Branch, the present officers of the District were re-elected for the ensuing year, namely:—**Vice-President:** Dr. Frederick Taylor. **Representative on Council:** Dr. Savage. **Committee:** Mr. Howell, Mr. Brindley James, Dr. Oswald, Dr. Pitt, Mr. Johnson Smith, Mr. Sangster, Dr. Verdon. **Honorary Secretary:** Dr. Percy Smith.

Dr. Savage then conducted the members and visitors through the wards of the hospital, and gave a clinical demonstration on several cases of insanity.

Vote of Thanks.—A vote of thanks to Dr. Savage for his interesting demonstration was subsequently carried unanimously.

SPECIAL CORRESPONDENCE.

BERLIN.

[FROM AN OCCASIONAL CORRESPONDENT.]

The Health of the Emperor.—The Bergmann Incident.—The German Press on Sir Morell Mackenzie.—The True History of the Present Crisis.

DURING the past week there has been a slight improvement in the Emperor's condition, which of course has been made the most of in the official bulletins. The most favourable feature in the case is, that His Majesty has no difficulty whatever in swallowing, and is therefore able to take plenty of nourishment. His appetite is, however, capricious, and it is in this respect that Sir Morell Mackenzie's continued presence beside him is so especially valuable, for His Majesty will obey the advice of his English physician when he will not listen to any one else, and will eat in deference to Sir Morell's wishes, even when he has no appetite.

The Bergmann catastrophe still continues to be hotly discussed, both in professional circles and in the general press. Public opinion seems, on the whole, to be against our "leading surgeon," as Bergmann is usually called here, not so much because he retreated from a position which circumstances had probably made untenable, but because he was unwise enough to make the situation which he himself had created the basis of a further attack on Sir Morell Mackenzie. At the last meeting of the Berlin Medical Society, the following letter was read:¹

"In der Nummer 1426 des BRITISH MEDICAL JOURNAL vom 28 April, 1888, wird mit folgenden Worten auf Seite 933: 'As Dr. von Bergmann has not contradicted this statement, it may be accepted as true,' die Behauptung vertreten, dass, weil ich zu persönlichen und sachlichen Angriffen schweige, ich die Richtigkeit derselben zugebe. Wenn das BRITISH MEDICAL JOURNAL nicht ein Blatt wäre, dessen wissenschaftlichen Werth ich ausserordentlich hochschätze, könnte ich zu diesem Schlusse auch schweigen. So aber muss ich mich gegen denselben verwahren. Ich schweige, nicht weil ich Unrecht habe, sondern weil ich, wie jeder ehrenwerthe britische und deutsche Arzt, Vorgänge am Krankenbette meiner Patienten nicht öffentlich bespreche.

"ERNST VON BERGMANN."

It had, I believe, been intended by some of Professor von Bergmann's friends to make that meeting the occasion of proposing a vote of confidence in him, but when his letter was read it was received with dead silence. After the meeting the letter was freely discussed, and no one seemed to have a word to say in Bergmann's favour. If he had merely said he had a defence but that was not the time to publish it, such a course would have met with general approval, but his indirect attack on his English colleague was thought to be in very bad taste. The general opinion seemed to be that Bergmann ought not to have attacked Mackenzie before the Medical Society, because that was not a place for the ventilation of personal grievances, but solely for the discussion of scientific topics, and also because Mackenzie could not defend himself before the Society. Much the same view of the matter is taken in the general press. The *Vossische Zeitung* of May 4th says: "The meeting heard Professor von Bergmann in silence and with astonishment. His explanation did not make a favourable impression.....Bergmann made use of the Society to attack a distinguished man who enjoys the absolute confidence

¹ A translation of this will be found in Sir Morell Mackenzie's letter at page 1032.

the Emperor. It is quite possible that the editor of the English professional journal (the BRITISH MEDICAL JOURNAL, to wit), wounded in his national feelings by the German papers attacked Bergmann of his own accord. But it is also possible that the learned and able editor was influenced by Mackenzie, which has yet to be proved; and in that case Bergmann has other means of defending himself than that which he has chosen. Mackenzie would not think of attacking Bergmann at a meeting of the British Medical Association, and Bergmann should not attack a foreigner with reference to a matter which was not before the meeting of the Berlin Medical Society."

In dealing with the same subject another paper says: "Professor von Bergmann draws a fine distinction between an honourable medical practitioner and one that is not honourable. According to him, a doctor who talks publicly about things occurring in the sick-room to a number of different people through whose nose means this talk is inserted in a newspaper, such a man is dishonourable; but if a doctor demands, in accordance with the German Press Laws, that incorrect statements concerning himself shall be corrected and signs his name (in accordance with the law), such a physician is not dishonourable." Then there is the *Freisinnige Zeitung*, which says: "It is remarkable in any case that at a very moment when Professor von Bergmann demands the greatest reticence from the physicians in attendance, the 'efficients' press is able to publish the contents of his correspondence respecting the august patient. If one physician publicly attacks another, we consider his conduct more honourable if he signs his name, than if he attacks his colleagues through the *ptilia*."

These quotations will suffice to show that the independent public opinion of Germany is entirely misrepresented by the "elegant facts" from the *reptile* section of our press, which certain of your newspaper correspondents have so perseveringly collected for the edification of your English *gobemouches*. By the way, I suppose that I should explain the expression *Reptilia*, used above to designate the German Tory papers. This addition to the political vocabulary owes its invention, like so many others, to the genius of our Iron Chancellor. There is a very large sum of money in the hands of the Prussian Government, owing to the confiscation of the property of the King of Hanover. This money Bismarck, with his characteristic cynical frankness, said he would keep for himself and the payment of spies in foreign countries and of parliamentary scribes at home, and he gave it the significant name of the *Reptile Fund*. In this way, certain papers which are commonly supposed to receive subventions (the *Kölnische Zeitung*, the *ev. Zeitung*, the *Post*, and the *Hambürger Nachrichten*), have come to be known among opposition journalists as the *Reptilia*. The fact that Mackenzie is bringing an action against one of them, which recently used the term "dishonest" in speaking of him, and claims 10,000 marks as damages, this being the legal price here for the luxury of applying that epithet to an opponent.

As there has been an incredible amount of misrepresentation as to what occurred on that fatal 13th of April (when the present Emperor in the Emperor's malady began), I think you may like to see a brief account of what actually took place. You may rely on the accuracy of the information which I am about to give. On the night of Wednesday, April 12th, Dr. Howell noticed that His Majesty was breathing somewhat noisily, but plenty of air entered his lungs; he shifted the tube a little so as to make it lie more comfortably, and at 10 o'clock on Thursday morning, when Drs. Wagner and Krause, together with Sir Morell Mackenzie, were in attendance, a fresh tube was put in. After Drs. Wegner and Krause, Sir Morell Mackenzie, not being entirely satisfied with the result of things, went into Berlin to see if some tubes which he had previously ordered were ready. Finding that they were not, he had an impromptu tube made of lead, which, of course, could be readily bent to any curve that might be desirable. On his return to Charlottenburg, it being then 3 p.m., Sir Morell Mackenzie dispatched a groom belonging to the palace (called officially a *Reitknecht*, but in the papers, not quite correctly, a *Dispatchenreiter*) with a letter to Professor von Bergmann asking him to "come as early as possible." This expression, which has been made so much of by Sir Morell Mackenzie's assailants, meant in reality nothing more than that, as everything was in readiness, it was desirable that the Professor should be in attendance without delay. In writing a *Reitknecht* Sir Morell Mackenzie only did what he is in the habit of doing on much less important occasions; in fact, when he arrived at Charlottenburg he was told that when he wanted

anything (for example, a book from Berlin, change for English money, etc.), he was always to send a *Reitknecht*. The dispatch of this messenger, therefore, whose ride *ventre à terre* to Berlin has been described with the lurid eloquence of Carlyle as a historical event of "epoch-making" character, was in reality nothing out of the ordinary course of things. Professor von Bergmann was summoned as a matter—not of necessity—but of professional courtesy; and it is Sir Morell Mackenzie's declaration to that effect (made in reply to totally unfounded attacks) that has made him so angry. When he arrived, instead of standing by while Sir Morell Mackenzie introduced the tube, Bergmann quickly pulled out the cannula then in the trachea, and tried to introduce a fresh tube. It went in, *but no air came out*. He then thrust his finger deeply into the wound, and afterwards pushed in a second cannula. Still no air came out, but blood began to flow freely, and repeated attacks of violent suffocative cough came on. Bergmann then sent for his assistant, Dr. Bramann, who was waiting outside, and the latter inserted a small tube (No. 8 German scale). This tube was several sizes smaller than the one Sir Morell Mackenzie had suggested using at San Remo, when he was overruled by the German surgeons. The bleeding continued for some hours, and during Friday and Saturday the Emperor complained of soreness in the throat. At 6 p.m. on the latter day, he had a shivering fit, followed by a rise of temperature. An abscess situated at the sides and back of the trachea near the lower end of the tube soon afterwards burst, and pus has been discharged in greater or less abundance ever since. This is a plain unvarnished narrative of the facts as they occurred. I prefer to make no comment on them, but professional men will no doubt draw their own inferences from them. The retirement of Professor von Bergmann has removed the one discordant element in the counsels of the Emperor's medical advisers, among whom the most perfect harmony now prevails.

Volatile Bases in the Blood.—Bacillary Pseudo-tuberculosis.
M. WURTZ publishes, in the *Compte Rendu des Séances de la Société de Biologie*, of January 20th, some notes on the presence of volatile bases in the blood, and in the air exhaled from the lungs. To collect and isolate the volatile bases which pass from the blood into the expired air, M. Wurtz stirred up in it a 1 per cent. solution of oxalic acid, using a special apparatus. This apparatus is so constructed as to avoid error arising from the projection of saliva or solid particles. When a sufficient number of cubic metres of air has passed into the apparatus, the solution of oxalic acid is saturated with pure carbonate of lime, free from chloride or sulphate, as the solution is neutralised by adding a drop or two of lime water, which immediately precipitates the oxalic acid. Then filter; neutralise exactly by a trace of chlorhydric acid; evaporate *in vacuo*. Various chlorhydrates are thus obtained, amongst which chlorhydrate of ammonia, which predominates; and a certain proportion of an organic base determined by M. Wurtz, by the following reagents precipitated by Bouchardat's reagent, also by double ioduret of potassium and of mercury. A soluble chloroplatinate, crystallising in short needles, is formed. This chloroplatinate seemed to have the same crystalline form as that of one of the bases of the blood isolated by soluble chloraurate. M. Wurtz was not able to analyse or to experiment on the physiological effects; this he intends to do on future occasions.

A communication from MM. Charrin and Roger, on bacillary pseudo-tuberculosis, was read before the Académie des Sciences, on March 19th, 1888. A guinea-pig died suddenly in Professor Bouchardat's laboratory. At the necropsy the liver and spleen were found covered with granulations similar to those of tuberculosis. MM. Charrin and Roger isolated a mobile bacillus from those organs which develops in gelatine, gelose and potato, but does not liquefy gelatine. The skin of rabbits was inoculated with this bacillus, and a local tumour was produced, followed by adenopathy. The animals died on the third day: the liver and spleen were full of granulations, and in a fifth of the cases similar granulations were found in the kidneys and lungs. The same results are produced when the peritoneum is inoculated. A sero-fibrinous pleurisy results from inoculation of the pleura. In addition to the above lesions. In the guinea-pig the disease gives

rise to local lesions. The microbe is pathogenic to the mouse, but has no effect on the dog, cat or ass. The disease discovered by MM. Charrin and Roger, like that of MM. Malassez and Vignal, is inoculable in series. This characteristic does not suffice to prove the tuberculous nature of a disease, but to indicate its parasitic nature.

VIENNA.

[FROM OUR OWN CORRESPONDENT.]

Operative Treatment of Empyema of the Antrum.—Innervation of Hepatic Vessels.

DR. S. LINK, of Lemberg, in a recent number of the *Przeglad Lekarski*, relates two cases of operative treatment of empyema of the antrum. Miculicz was the first who successfully performed the operation proposed by Zuckerkandl. He has operated in four cases. With a specially constructed drill he perforated the thin part of the wall of the maxillary sinus below the inferior turbinate bone, and thus gave issue to the contents through the nose. Dr. Link has in two similar cases performed the same operation, with an equally good result. The first was that of a woman, aged 32, who suffered from severe pain in the upper maxilla owing to a carious tooth. After the extraction of the tooth, pus was constantly discharged from the alveolus. On examination Dr. Link detected in the alveolus, corresponding to the left upper wisdom-tooth, a fistula through which the mouth communicated with the maxillary sinus. On dilating the fistula a considerable amount of atheromatous material escaped into the cavity of the mouth. With the view of closing the fistula, Dr. Link performed the above-mentioned operation under chloroform. A large quantity of sour-smelling fluid escaped from the nostril. The antrum was then washed out with a 10 per cent. emulsion of iodoform and glycerine, and stuffed with iodoform gauze. The tampons were removed after twenty-four hours, and the cavity was washed out every day by means of the syringe devised for the purpose by Miculicz. After eight days the fistula in the alveolus was closed, and after three months the patient wrote to the author that she had very seldom occasion to syringe out the cavity, that the pain had ceased, and that there was very little discharge. The second case was that of an artilleryman, aged 22, belonging to a tuberculous family. After the extraction of the second upper right molar tooth, which was carious, an abscess formed beneath the internal angle of the right eye, which burst later on, and was followed by a fistula in the cheek, from which there was a constant discharge of pus. The fistula communicated with the maxillary sinus, into which a probe could be passed through the alveolus of the tooth which had been removed, or through the natural opening of the right nasal cavity beneath the lower turbinate bone. Miculicz's operation was performed on November 26th. On syringing out the cavity, a fluid similar to that in the first case escaped. The maxillary sinus was afterwards scraped out with a sharp spoon which was passed through the external fistula; a drainage-tube was introduced, and the right nasal cavity was stuffed with iodoform gauze. The tampon was removed after twenty-four hours, and the maxillary sinus was then daily washed out with a solution of salicylic acid. The drainage-tube was removed after six days, and two days later the fistula in the cheek and the alveolus had closed. On washing out the cavity, which was now done daily through the artificial opening, the injected fluid returned quite clean. A deep retracted scar was left below the internal angle of the right eye, at the spot where the fistula had been before. The author then discussed the advantages of this method as compared with that of Störk, and stated that he had found a new diagnostic sign which consisted in the fact that by percussing of the hard palate it could be recognised whether the maxillary sinus was empty, and whether its contents were fluid or solid.

At a recent meeting of the Imperial Royal Society of Physicians of Vienna, Dr. Pal made a communication on the innervation of the hepatic vessels. Claude Bernard was the first to formulate the hypothesis of hepatic nerves, though their existence had not been directly proved. Dr. Pal had tried to decide this problem in the following manner. He ligatured below the anastomosis of the hepatic veins with the portal vein all those blood-vessels which conveyed blood to the liver, such as the thoracic part of the aorta and the ascending vena cava. On irritating the peripheral part of the splanchnic nerve, considerable increase of the blood-pressure was produced; the same was also observed when

the ascending cava was ligatured above the implantation of the hepatic veins, but in this case to a lesser degree. Experiments which he had made with the view of determining the rapidity of the out-flowing blood showed that the liver pressed out blood on irritating the splanchnic nerve, thus proving the presence of vaso-constrictors in the liver.

EGYPT.

[FROM AN OCCASIONAL CORRESPONDENT.]

Economies in the Sanitary Service.—Professor Virchow on Bilharzia.—The Medical School and Hospital.—Foundation of a Medical Society.—Out-Patients.—The Alexandria Hospital.

ECONOMY is just now the order of the day in Egypt. To provide means for cutting drainage canals and thereby supplement and complete the irrigation scheme from which so much has been expected, the finance authorities are resolved on reducing expenditure in all departments of the State to the lowest possible figure. A Commission of Economy has consequently been very busy lately examining budgets in the various administrations, and amongst other retrenchments has recommended that a reduction of £7,500 should be effected in the Services Sanitaires. This department, with a totally insufficient budget of £100,000, is supposed to carry out the following duties: Registration of births and deaths throughout Egypt; vaccination; the issuing of permits for burial; examination of, and report on, all medico-legal questions; recruiting; medical inspection of government employes; medical charge of prisons; sanitary supervision of country in general; charge and maintenance of 21 hospitals containing 1,735 beds; the same as regards several newly established dispensaries, which latter seem to promise well for the future civilisation of the country. Out of the above mentioned sum no less than £28,000 is devoted to the scavenging and watering of Cairo and Alexandria, one item of expenditure in the former city being £7,000 for cost of water alone; there remains, therefore, about £70,000 to meet the above requirements, besides others too numerous to mention, such as veterinary supervision, sanitary engineering, maintenance of foundlings, etc., and from this meagre allowance it is now proposed to subtract about 10 per cent. in order that visionary irrigation may be prevented from ruining the land. This is certainly very hard on the officials of the Sanitary Department, who have one and all worked with zeal and energy, and are admitted on all sides to deserve well of the country. The Economy Commission also holds this opinion, for it has recommended the fusion of the Tanzim in the Services Sanitaires, the Tanzim being that section of the Public Works Department which gives permission for the erection of new buildings, and which also has charge of road making and public gardens. For these purposes a sum of £60,000 is allowed annually for Cairo alone, a sum which the Commission with justice looks on as too large, considering the results obtained, and considering also that no less than 54 engineers and 26 writers are now employed in obtaining these results at a cost to the State of over £12,000.

Professor Virchow, who had been for some time up the Nile, lately returned to Cairo, and devoted his immense influence towards stimulating the authorities to a systematic examination into the *habitat* of the bilharzia hæmatobia and the manner in which that parasite makes its entry into the human body. There is no doubt that the distoma is abundant in Egypt, but what remain to be ascertained are the localities where it undergoes its development and attains to maturity. If these could be determined, something might possibly be done towards reducing the evil, or perchance the pest might even be stamped out altogether. Dr. Fouquet, of Cairo, has had great success in the treatment of the bilharzia by means of the extract of male fern. He has communicated to *La France Médicale* a detailed account of fifteen cases in which perfect cure had been the result. This seemed to interest Professor Virchow very much, for, in common with most authorities, he had been under the impression that treatment was of little avail when once the parasite had established itself in the urinary tracts.

The great pathologist visited with unwearied diligence the whole of the medical and sanitary institutions of Cairo, and appeared much struck with the new installation of the medical school, and with the arrangement of the Government hospital at Kasr-el-Aini, which of late years has been much improved under the able management of Dr. Milton. Amongst the cases which attracted the attention of the Professor was one of a native girl

who was being supplied with a new upper lip from her arm, the limb being immovably fixed in the necessary position by means of a plaster-of-Paris apparatus. Perfect union had taken place by the first intention, but during the process there had necessarily been some difficulty in feeding the patient, till it was discovered that she possessed the power of swallowing fluids quite easily through the nose. For the Professor's edification she was given a cup of water, which she applied to one nostril, quietly sniffing up her contents without even closing the other nostril, and with apparently the greatest ease in the world.

A new medical society has lately been started in Cairo under the presidency of Dr. Salem Pacha. The second meeting took place a few nights ago, when Professor Virchow delivered an address in the German language, his eloquent utterances being, at the close of each period, translated into equally eloquent Arabic by the President. It is hoped that this Society, so auspiciously inaugurated, may do much to cement and solidify the *entente cordiale* amongst the members of the medical profession practising in Egypt, whom, unfortunately, national and other jealousies have hitherto done much to keep separate and antagonistic.

The out-patient department at Kasr-el-Aini has increased of late in an almost alarming manner. Last year no less than 30,000 cases were treated—that is to say, there was a daily average attendance (excluding Fridays) of about 100 patients, for whom upwards of 17,000 prescriptions were dispensed. This, of course, increases the drug bill of the Sanitary Administration, whose budget, however, is unfortunately not an elastic one.

Dr. Greene Pacha hopes soon to secure the services of another English medical man, whom he proposes to place in charge of the Government hospital at Alexandria, in order that that institution may be raised to the level of Kasr-el-Aini, a *desideratum* which, under present circumstances, is absolutely hopeless. Dr. Keatinge, who has done good service with the Egyptian army, and who is well acquainted with Arabic, is the gentleman proposed for the post.

SWITZERLAND.

[FROM OUR OWN CORRESPONDENT.]

Camphorated Carbolic Acid.—Professor Forel on Hypnotism.

In the *Correspondenzblatt für Schweizer Aerzte*, No. 7, 1888, p. 229, Dr. Th. Schneider, of Basle, recommends camphorated carbolic acid as an "elegant, reliable, and very convenient antiseptic preparation." As is well known, when one part of crystallised carbolic acid and three parts of powdered camphor are shaken up together in a test-tube, a colourless limpid fluid is produced. This mixture does not possess either the characteristic odour or the anæsthetic and caustic properties of carbolic acid, while the antiseptic power of the latter remains intact. When placed on the tongue the compound causes but a very slight burning sensation. It has no effect on polished steel.

At a meeting of the *Gesellschaft der Aerzte in Zürich*, Professor Forel read an interesting paper on hypnotism. Having recently made experiments on seventy-two persons, he had succeeded in inducing more or less deep hypnotic sleep in as many as fifty-two. He had never observed the slightest injurious effects from hypnotisation by modern improved methods, whereas, several years ago, when using an old bad method consisting in fixation of a bright shining button, he had seen in a neurotic woman a severe hysterical attack, with subsequent delirium, which, however, yielded to faradisation. On the whole, he believes that any injurious effects of hypnotic experiments are caused by the employment of bad methods, as well as by some want of skill and experience. Like Liebeault, Professor Forel teaches that the hypnotic state is simply an artificially-produced sleep, modified in so far that the hypnotiser is enabled to influence the course of the "subject's" dreams. The hypnotisation itself consists in actually sending to sleep, and, as far as the person experimented upon is concerned, its success depends solely upon a certain power of falling asleep easily, and a corresponding willingness to submit to the hypnotiser's will. Any disappearance of nervous symptoms under the influence of hypnotism is to be explained exactly in the same way as the cessation of pain (for example, toothache, sciatica, etc.), which, as is well known, often follows sudden violent fright, etc. In other words, "it is to be attributed to cerebral inhibitory processes caused by intensive dreams." "A deep-rooted morbid irritation cannot be removed by hypnotisation." The author mentions a case of obstinate neuralgia in an otherwise healthy nurse,

which was permanently cured by hypnotic suggestion. A marked improvement also took place in a case of chronic alcoholism where a disgust towards spirits had been "suggested during the hypnotic sleep." On the other hand, no satisfactory results could be obtained in a case of epileptic insanity in a boy. Referring to Professor Forel's communication, Dr. von Monakow, of Zürich, stated that he had lately treated two women by hypnotic suggestions. One of them was suffering from brachial neuralgia, the other from hallucinations. In both, the morbid symptoms disappeared for a time, but returned after a certain interval (for example, a fortnight) to yield again temporarily to the same procedure, and so on.

NEWCASTLE - UPON - TYNE.

[FROM OUR OWN CORRESPONDENT.]

The Infirmary.—*The Medical Officership of the Workhouse Hospital.*

A quarterly meeting of the governors of the Infirmary was held last week, when it was announced that the Corporation of Newcastle had increased their annual subscription from 160 guineas to £300, and that there was an increase in the subscriptions for the quarter over that of any previous year.

The board of guardians have at last definitively settled the appointments of medical officer and master and matron, and both appointments have been ratified by the Local Government Board. Mr. T. A. Dodd, assistant-surgeon to the Infirmary, has received the post of consulting medical officer after a close fight with Mr. W. G. Black. The appointment is a popular one with the profession, and could not have fallen into better hands. Mr. Dodd has been in practice for some time, and has held the assistant-surgery of the Infirmary for about ten years, so that both in age and experience he is well qualified for the post.

MANCHESTER.

[FROM OUR OWN CORRESPONDENT.]

The Owens College Medical School.—*Professor Sinclair's Introductory Address.*—*The "Sweating System."*

THE summer session in the Medical School of the Owens College was opened on May 1st, and already we believe the entries are ahead of those in any previous session, so that, as far as numbers go, the present summer session bids fair to be the most successful in the history of this Medical School.

Professor Sinclair, the newly-elected Professor of Obstetrics in the College, gave his introductory lecture on Thursday to an audience who accorded him a most hearty welcome. The Professor gave an interesting account of the evolution of gynaecology, and he secured the wrapt attention of his audience from beginning to end by the marked literary tone of the address, combined with the effective historical account of the subject. We understand that clinical work will form an integral part of the teaching of Professor Sinclair.

Much interest is being exhibited by the authorities in the investigation of the "sweating system" in this neighbourhood, and already reports have been made to several municipal authorities thereon.

SHEFFIELD.

[FROM OUR OWN CORRESPONDENT.]

Working Class Representatives on the Board of the Rotherham Hospital.—*Small-pox Hospitals and Schools.*—*Small-pox in Sheffield.*

THE working men of the town and neighbourhood contribute in a most praiseworthy manner to the Rotherham Hospital. Some little feeling has found expression that they are insufficiently represented on the management. The weekly board called a meeting of the representatives of the working men subscribers, and, in consequence of the frank and courteous manner in which the chairman and other members met the delegates, it is hoped any irritation will have been dissipated. The question of hospital management is recognised as a difficult one, and the increase of working class representatives, whose time for such work is necessarily limited, is one requiring care and wisdom. The hospital has received a notable and valuable addition in a new ward for twenty beds, erected at a cost of about £1,200, with every modern requisite. It was opened in January last. It was suggested by one of

the working men representatives that the opening of this new ward would render necessary an increase in the medical staff. During the last year, however, the daily average of in-patients was only 19.1, and, therefore, it may well be affirmed that more such wards will have to be added before it becomes necessary, or, indeed, desirable, to add to the honorary working staff, which already consists of three members.

The Mexborough School Board are proceeding with their plan of erecting a school close to the small-pox hospital, in spite of the remonstrances of the medical officer of health. The playground will be adjacent to the hospital.

The small-pox epidemic may almost be regarded as ended. The number of deaths from this cause during the last week was only five. Attercliffe has been the district where the disease has chiefly lingered. Here many people have unfortunately persistently set their faces against revaccination, pinning their faith to Mr. Herring. If Attercliffe had only adopted the prudent and sensible course adopted elsewhere, the disease would have died out ere this.

CORRESPONDENCE.

THE CHARTERS OF THE ROYAL COLLEGE OF SURGEONS.

SIR,—The Fellows and Members of the College must not allow of any lull in their agitation for those rights for which they have so long striven. A sharp eye must be kept on the petition of the College for a new charter. The last that was heard of the matter was on April 23rd, when Viscount Cranbrook, in reply to Lord Sudeley, said that he did not think that the petition of the Royal College of Surgeons for a supplementary charter, though it raised points of some importance, could be properly referred to the Commission about to be appointed to consider the question of a new university. Care must be taken lest the Fellows and Members should be hoodwinked by the expression "supplementary," which practically, though not technically, implies a new charter; in short, it signifies precisely what the Fellows do not wish to be sanctioned by law until they have been allowed a voice in the matter. Let them remember and think on their claims calmly and deliberately, else they may not be awakened to energy till within three weeks or a fortnight of the next meeting—too short a period for independent thought. Let not everything be left for a few well-known bold and disinterested leaders. Again, July is drawing near; let the Fellows and Members think whom they will select as worthy to represent them and to further their views on the Council; and may the provincial Fellows exert themselves, so as to add at least one more of their number to the Council. It is noteworthy that the Council have thought that prudence advised them not to notice the Members' petition to the Privy Council, or to attempt any reply to the statement made by them to the Lord President.—I am, etc.,

F.R.C.S.

SIR MORELL MACKENZIE AND PROFESSOR VON BERGMANN.

SIR,—At the meeting of the Berlin Medical Society last Tuesday a letter from Professor von Bergmann to the following effect was read: "On April 28th the BRITISH MEDICAL JOURNAL made these remarks: 'As Professor von Bergmann has not contradicted this statement it may be accepted as true;' that is to say, because I am silent in the face of a statement of facts and of personal attacks it shows they must be well founded. If the BRITISH MEDICAL JOURNAL were not a journal whose scientific value I prize very highly, I might still remain silent in the presence of such an accusation, but under the circumstances I must defend myself. I am not silent because I am in the wrong, but because I, like every honourable British or German physician, do not talk publicly about what goes on at the bedside of my patients."

The observations which you made on Professor Bergmann were,

I suppose, called forth by the letter which Mr. Howell addressed to the *Cologne Gazette* demanding a rectification when charged by that newspaper with "having done serious injury to His Majesty by having forced deleterious matters down into his lungs." In Germany, before taking criminal proceedings against a journal for making a false statement, the Press Laws require the aggrieved person to demand a *rectification* (*Berichtigung*), and *such demand must be signed*. I have never given any information to the press except such as was permitted by august personages, with a view of contradicting the false and exaggerated reports which certain people have delighted to spread.¹

Further, neither I nor Mr. Howell have ever attacked a colleague under the veil of anonymity, nor openly, except when acting in self-defence. On the other hand, Professor von Bergmann is known to be in close relationship with Dr. Fischer, the Berlin correspondent of the paper (*Cologne Gazette*) which libelled Mr. Howell so cruelly. It has, in fact, been stated over and over again in the German press that this attack could only have come from Professor von Bergmann. The English public have seen that Professor von Bergmann is on such intimate terms with the Berlin correspondent of the *Times* that he has shown that person a private letter of mine to him. The *Kreuz Zeitung*, an organ which likewise receives its inspirations from Professor von Bergmann, and could only have obtained its pretended information, directly or indirectly, from him, described me as "*at my wil's end*" (*rathlos*); then, when, in accordance with the German Press-Laws, I wrote a letter demanding a rectification, and pointed out that Professor von Bergmann did not even introduce the cannula, the professor is hurt at my candour and poses as a "whole-souled" man who "*does not speak publicly of what goes on in the sick room*." This is really too much like the Gracchi denouncing sedition.

The medical profession in England will be glad to hear that I have received an immense number of letters from medical men in all parts of Germany expressing their satisfaction at the treatment which I have pursued in the case of His Majesty, and it is on the pressing advice of eminent members of the profession in Berlin (members of the Berlin Medical Society) that I now defend myself in the JOURNAL against the attacks of Professor von Bergmann.—I am, etc.,

MOBELL MACKENZIE.

Charlottenburg, May 8th, 1888.

WANTED AN ADDRESS.

SIR,—The late Dr. John Murray published in the *Medico-Chirurgical Transactions* for 1873 the cases of three children in one family who suffered from a most extraordinary condition of the gums with the development of subcutaneous tumours in various parts of the body. The parents of the children S. kept a greengrocer's shop near the Liverpool Road. The children had been under care at various hospitals, and their cases had excited great interest. I should be very much obliged to any of your readers who may be able to give me any information as to the present condition of these patients, and should be especially glad of an opportunity of seeing them again.—I am, etc.,

15, Cavendish Square, W.

JONATHAN HUTCHINSON.

TEA AND TEETH.

SIR,—It seems a pity that the writer who contributes to the JOURNAL of May 5th some speculations on a subject of dental pathology did not first make himself acquainted with some of the fundamental facts of the subject. He might have learnt from any dental manual that no such structures as "tooth-sacs" exist in relation with fully formed teeth; and that teeth are covered with enamel, not dentine. Reference to a work on chemistry might have further taught him that to write of "theine or tannin having an elective affinity for dentine" is pure nonsense.

This writer represents a considerable class who seem to look upon the teeth as mysteries worked by miracle, whereas they are, in fact, extremely simple structures compared to more highly organised parts, and their maladies proportionately easy to under-

¹ Whilst, however, Professor von Bergmann was in attendance, the minutest details from the sick chamber were published in the *National Zeitung*, a paper which received its information from Professor von Bergmann. Not only was the state of the pulse given, but the frequency of the respiration was published; not only was the exact food and drink stated, but the medicine and even the surgical measures proposed by Professor von Bergmann, but not carried into effect, were described. Neither I nor my English colleagues have ever given any information as to food or medicine, much less as to the frequency of respiration. Any details on such matters published in English papers have been taken from German sources.—M. M.

tand and explain. The main predisposing causes of tooth decay (aries) are, first, innate structural defects in enamel and dentine, rendering them easily acted upon by agents; and, secondly, vitiation of the secretions of the mouth, whereby these agents (acids and micro-organisms) are developed and lodged on and about the teeth. Excessive tea drinking, in so far as it might tend to produce the latter effect, should certainly be looked upon as a remote cause of dental disease.—I am, etc.,
H. S.
London, May 5th.

SIR,—About 2,000 of the population here work in the cotton factories; they not only take strong tea at their morning, mid-day, and evening meals, but many of them a cup at 6 A.M. when going to their work, and numbers also carry cans of tea with them which they drink during the day, heating it on steam pipes. They almost without exception have bad teeth, many having lost nearly all their teeth at puberty, and in not a few instances the disease, whatever be its cause, appears to be hereditary, children during the period of teething losing their first teeth before the latter ones appear. The decay begins in or near the fangs, having no resemblance to specific disease; in fact, syphilis is almost unknown in his particular district.—I am, etc.,

E. B. FENNELL, M.B., B.Ch.

Barrowford, Lancashire, May 7th.

INCISION AND EXCISION OF JOINTS.

SIR,—May I be allowed to correct a clerical error in the report of my remarks on Mr. Wainwright's paper, read before the last meeting of the Clinical Society. I was arguing in favour of Mr. Bennett's view that the suppurating hip-joint which recovered after incision was the result of acute inflammation, possibly septic in nature; and I mentioned a case in which three joints in succession had been affected, requiring incision. The printed report says, "Mr. Lucas mentioned a case in which three joints had been affected in succession requiring excision." This quite alters the direction of my contention, which was to the effect that acute suppurating joints would recover after simple incision, but that chronic pulpy joints would require a more radical operation to bring about complete cure.

The case alluded to is now before me. A child, aged 3 years and 9 months, was seized five days before admission with shivering, sickness, and headache. She was admitted as a medical case in a fretful, typhoid condition, complaining of general tenderness. A few days later a swelling connected with the left shoulder was noticed, and about three weeks after an abscess was opened antiseptically. The temperature fell to subnormal, but soon rose again. After another interval of three weeks, owing to pain and swelling about the right hip, it was thought advisable to apply a double hip-splint. A week later an abscess was opened behind the right trochanter. Irregular temperatures continued, and, after a fortnight's interval, an abscess was found connected with the left hip, which was also opened. All these joints recovered, and the wounds healed, but some shortening was noticed on the right side before the child left the hospital.—I am, etc.,

R. CLEMENT LUCAS, B.S., F.R.C.S.

Surgeon to the Evelina Hospital for Children, etc.

Finsbury Square, May 5th.

MEDICAL DECLARATIONS RE ALCOHOL.

SIR,—The annexed circular has been sent to more than 2,000 of the leading medical men of the United Kingdom, and a very large number of valuable endorsements has been received. Our Council would, but for the great expense involved, have sent a similar circular to every practitioner in the kingdom; but, as this is impossible, may I ask that this important matter may be brought under their notice through your columns, and that all may thus have an opportunity of appending their names before the list is published? If, as soon as possible after reading this, each one who approves of these declarations will send me a post-card, addressed "Dr. Ridge, Enfield, Middlesex," with the simple statement, "I endorse Declaration I, II, and III" (any or all, as the case may be), with his name and qualifications, it will be much appreciated.—I am, etc.,
J. JAMES RIDGE.
Enfield.

Carlton House, Enfield, Middlesex. February, 1888. DEAR SIR,—You are doubtless aware that during the last fifty years three medical declarations respecting alcohol have been issued. The first of these, issued in 1839, was to the following effect:—

Declaration I.—"An opinion handed down from rude and ignorant times and imbibed by Englishmen from their youth, has become very general, that the habitual use of some portion of alcoholic drink, as of wine, beer, or spirit, is beneficial to health, and even necessary to those who are subjected to habitual labour. Anatomy, physiology, and the experience of all ages and countries when properly examined, must satisfy every mind, well-informed in medical science, that the above opinion is altogether erroneous. Man, in ordinary health, like other animals, requires not any such stimulants, and cannot be benefited by the habitual employment of any quantity of them, large or small; nor will their use during his lifetime increase the aggregate amount of his labour. In whatever quantity they are employed, they will rather tend to diminish it. When he is in a state of temporary debility from illness or other causes, a temporary use of them, as of other stimulant medicines, may be desirable; but as soon as he is raised to his natural standard of health, a continuance of their use can do no good to him, even in the most moderate quantities, while larger quantities (yet such as by many persons are thought moderate) do, sooner or later, prove injurious to the human constitution, without any exceptions. It is my opinion that the above statement is substantially correct."

This document was signed by Sir Benjamin Brodie, Dr. W. F. Chambers, Sir James Clarke, Bransley Cooper, Dr. D. Davies, Sir J. Eyre, Dr. R. Ferguson, Mason Good, Dr. Marshall Hall, Dr. J. Hope, C. A. Key, Dr. R. Lee, Herbert Mayo, R. Partridge, Richard Quain, Dr. A. T. Thomson, R. Travers, Drs. Andrew and Alexander Ure, and in all by seventy-eight men of distinction in the profession.

The second medical certificate was promoted by John Dunlop, Esq., in 1847, and was signed by upwards of 2,000 physicians and surgeons. Their testimony was as follows:—

Declaration II.—"We, the undersigned, are of opinion: 1. That a very large portion of human misery, including poverty, disease, and crime, is induced by the use of alcoholic or fermented liquors or beverages. 2. That the most perfect health is compatible with total abstinence from all such intoxicating beverages, whether in the form of ardent spirits, or as wine, beer, ale, porter, cider, etc. 3. That persons accustomed to such drinks may, with perfect safety, discontinue them entirely, either at once or gradually, after a short time. 4. That total and universal abstinence from alcoholic liquors and beverages of all sorts would greatly contribute to the health, the prosperity, the morality, and the happiness of the human race."

Among the signatories to this document in London were those of Dr. Addison, Dr. Niel Arnot, J. Moncrieff Arnott, Esq., Dr. B. G. Babington, Dr. Beattie, Sir J. Risdon Bennett, Dr. A. Billing, Dr. John Bostock, Dr. Golding-Bird, Dr. Black, Dr. R. Bright, W. Bowman, Esq., Sir B. C. Brodie, Sir W. Burnett, Dr. G. Budd, Sir G. Burrows, Dr. W. B. Carpenter, Dr. W. F. Chambers, Sir J. Clark, Dr. Copland, Sir J. Eyre, Dr. A. Farre, Dr. Robert Ferguson, Sir W. Ferguson, Sir J. Forbes, R. D. Grainger, Esq., Dr. Guy, Dr. Marshall Hall, Sir H. Holland, Sir Aston Key, F. Kiernan, Esq., W. B. Langmore, Esq., Dr. P. M. Latham, Sir J. McGrigor, Bart., Dr. J. A. Paris, Dr. Peacock, Dr. Pereira, Dr. Pettigrew, Dr. Prout, Dr. Toynebee, Dr. Wilks, Erasmus Wilson, Esq., Dr. Forbes Winslow, and many others of equal note.

In the provinces the following signed with many others:—Professor Adams, Dr. Aitken, Professor Alison, Dr. S. Begbie, W. Braithwaite, Esq., Dr. Buchanan, Dr. P. Crampton, Professor Curran, Dr. Keith, Sir H. Marsh, Dr. Q. E. Paget, Professor Pirrie, Professor J. Reid, Professor Syme, T. P. Teale, Esq., Dr. Andrew Wood, Dr. Wylie, etc.

The third declaration was issued in 1871 to the following effect:—

Declaration III.—"As it is believed that the inconsiderate prescription of large quantities of alcoholic liquids by medical men for their patients has given rise, in many instances, to the formation of intemperate habits, the undersigned, while unable to abandon the use of alcohol in the treatment of certain cases of disease, are yet of opinion that no medical practitioner should prescribe it without a sense of grave responsibility. They believe that alcohol, in whatever form, should be prescribed with as much care as any powerful drug, and that the directions for its use should be so framed as not to be interpreted as a sanction for excess, or necessarily for the continuance of its use when the occasion is past.

"They are also of opinion that many people immensely exaggerate the value of alcohol as an article of diet, and since no class of men see so much of its ill effects, and possess such power to restrain its abuse, as members of their own profession, they hold that every medical practitioner is bound to exert his utmost influence to inculcate habits of great moderation in the use of alcoholic liquids.

"Being also firmly convinced that the great amount of drinking of alcoholic liquors among the working classes of this country is one of the greatest evils of the day, destroying—more than anything else—the health, happiness, and welfare of those classes, and neutralising to a large extent the great industrial prosperity which Providence has placed within the reach of this nation, the undersigned would gladly support any wise legislation which would tend to restrict within proper limits the use of alcoholic beverages, and gradually introduce habits of temperance."

This third declaration was signed by most of the leading consulting and hospital physicians and surgeons of the day.

It is now 17 years since the last declaration, 41 years since the second, and 49 since the first, and during this long period a vast amount of experience has accumulated, both as to the effects of alcohol, and as to the practice of abstinence, so that there should be no difficulty in determining whether the above declarations are correct or not.

It has seemed to the Council of the British Medical Temperance Association highly desirable, both for the credit of the profession and the advantage of the public, that these declarations should be reviewed, and their statements confirmed or denied, according to the judgment of the medical authorities of the present day.

I beg, therefore, respectfully to submit these declarations to your notice, and ask you to be kind enough to sign and return the enclosed form, if your experience and observation enable you to endorse them.—I am, etc., J. JAMES RIDGE, Honorary Secretary British Medical Temperance Association.

BEQUESTS AND DONATIONS.—Mr. George Cope, J.P., of Woolton, Liverpool, has bequeathed £5,000 to the Woolton Convalescent Institution.—The Baroness de Stern has given £1,000 to the London Hospital.

NAVAL AND MILITARY MEDICAL SERVICES.

CLASS BLACKBALLING.

SIR.—With reference to the announcement in your issue of April 28th that an extraordinary general meeting would be held at the Junior United Service Club on May 7th, to vote concerning the rejection of four officers at a former ballot, your readers will be glad to hear that the four gentlemen, two of whom were medical officers of the army, were elected almost unanimously. The "clique" who amuse themselves by blackballing medical officers made a most ridiculous and feeble display, and it is quite evident that the great majority of the members are determined to permit no class prejudices to operate in the working of the club. The meeting was a large and representative one, and, it is hoped, will do much to eradicate the objectionable practice which has prevailed for some time past of blackballing officers for no other reason than that they belonged to the medical profession.—I am, etc.,

A CORRESPONDENT.

THE DIRECTOR-GENERAL AND THE RESERVE OF MEDICAL OFFICERS.—In a lecture on "Field Medical Organisation," delivered to the West Kent Tactical Society, on May 4th, the Director-General, Sir Thomas Crawford, M.D., K.C.B., referred to the objects of the Reserve of medical officers. He stated that the scheme was under consideration and drafted, two years ago, before the present discussion of the rank and privileges of army medical officers commenced, and that there was no intention of employing the officers of the reserve to the prejudice of the officers of the regular army.

ARMY MEDICAL POLITICS IN INDIA.—A correspondent sends us a cutting from the Indian *Pioneer*, from which we see the press in that country fully grasps the points at issue between the War Secretary and the Medical Department. The questions of the reductions in the active list, the restrictions placed on retirement, and the proposed increase of the periods of foreign service, are all cleverly handled. The full significance of the Army Medical Reserve Warrant is also realised, and pronounced to be a shabby endeavour to inveigle medical men in the auxiliary forces to place themselves and their practices at the disposal of the War Office—for, literally, nothing!

THE NAVY.

STAFF-SURGEON ROBERT GRANT, M.A., M.B., has been promoted to the rank of Fleet-Surgeon. His commission as Surgeon is dated May 7th, 1868, and as Staff-Surgeon, June 7th, 1879. While Surgeon of the *Flora*, he served on shore with the 88th Regiment during the Kafir War, 1877; was specially promoted for services when in charge of small-pox patients of *Zoadicea*, 1879; as Staff-Surgeon, he lauded during the Zulu war, and accompanied the Naval Brigade to Port Durnford (mentioned in despatches, medal); Staff-Surgeon of *Orion* during Egyptian war, 1882 (medal, Khedive's bronze star); Staff-Surgeon of *Orontes* during naval and military operations in the Eastern Soudan, 1884; was Medical Officer in charge of Transports, and accompanied the Royal Marine Battalion in action at Tannich (mentioned in despatches for his admirable arrangements for the sick and wounded, clasp).

Fleet-Surgeon **MAXWELL RODGERS, M.D.**, has been promoted to be Deputy Inspector-General. His previous commissions are dated: Surgeon, December 28th, 1857; Staff-Surgeon, December 8th, 1868; and Fleet-Surgeon, March 6th, 1860. He served as Assistant-Surgeon in the *Belleisle*, and attended on the wounded during the operations at the Pelhe forts in 1858 (China medal); was Acting-Surgeon of the *Assurance* during an outbreak of cholera and fever on board in 1865, when in the River Danube and Black Sea; Fleet-Surgeon of the *Monarch* at the bombardment of Alexandria, July 11th, 1882, and at the occupation of Port Said (Egyptian medal, clasp, Khedive's bronze star).

Inspector-General **T. J. HARRAN** has been placed on the retired list. He entered the service as Surgeon, July 27th, 1850; became Staff-Surgeon, April 4th, 1853; Fleet-Surgeon, June 8th, 1871; Deputy Inspector-General, April 1st, 1881; and Inspector-General, March 19th, 1886. He was (says the *Royal Navy List*) Assistant-Surgeon of and employed in charge of *Harlequin's* boats in attack on Lagos, November, 1851 (mentioned in despatches), and in several subsequent expeditions into the rivers and lagoons adjoining against the expelled chief Kosoko; also employed repeatedly in boat cruising in *Harlequin's* boats, for suppression of slave trade on the West Coast of Africa. Assistant-Surgeon of *Viper* in the Black Sea during the Crimean war, repeatedly in action; took part in the battle of Eupatoria; operations on the coast of Circassia, including the capture of Kertch, and the expedition in the Sea of Azov, night attacks on sea defences of Sebastopol, capture of Kinburn, and subsequent operations in the Gulf of Dupleir (Crimean and Turkish medals, Azov and Sebastopol clasps). Assistant of the 1st Battalion Surgeon of *Roscaevan*, flagship of the Hon. Sir F. W. Grey on the Cape of Good Hope and West Coast of Africa Station, 1857-60, and landed at Assension to attend yellow fever cases of *Trident* in 1859. Surgeon of *Brisk*, 1861-63, employed at the Cape of Good Hope and East and West Coasts of Africa; accompanied Commodore Wilmut in December, 1862, on a mission to the King of Dahomey, considered then a perilous enterprise; absent from ship six weeks. Selected for service with Royal Marine Battalion which proceeded to South Africa in 1879. Employed as Deputy Inspector-General at Haslar, and in charge of Malta hospitals, 1881-1886, when promoted to Inspector-General and

appointed to Plymouth Hospital (Sir Gilbert Blane's Gold Medal); J.P. of Queensland.

The following appointments have been made at the Admiralty: F. W. FOSTER, to be Surgeon and Agent at Walton-on-the-Naze; T. A. SKENE, M.B., to be Surgeon and Agent at Cove Bay.

THE MEDICAL STAFF.

BRIGADE-SURGEON HENRY KNAGGS has been granted retired pay. Entering as Assistant-Surgeon, April 22nd, 1858, he became Surgeon, March 1st, 1873; Surgeon-Major, April 1st, 1873; and Brigade-Surgeon, April 16th, 1884. During the Bechuanaland Expedition, under Sir Charles Warren in 1884-85, he had charge of the hospital at the base.

Surgeon-Major **Alexander BREBNER, M.D.**, is also granted retired pay. His commissions bear date: Assistant-Surgeon, April 14th, 1863; Surgeon, March 1st, 1873; and Surgeon-Major, April 28th, 1876. He was with the 55th Regiment during the Bhootan campaign, in the North-West Frontier of India, and was at the recapture of Dewangiri in 1865 (medal with clasp).

Surgeon **H. G. CHRISTIAN, M.B.**, has resigned his commission, which bore date March 6th, 1880.

Surgeon **V. E. HUNTER**, serving in Bengal, has passed the examination in Burmese by the lower standard.

ARMY MEDICAL RESERVE.

The following is substituted for the announcement in the *Gazette* of April 24th, 1888 (*vide* JOURNAL, April 25th): Surgeon **FREDERIC EDWARD MANNY, F.R.C.S.**, 3rd Volunteer Battalion the South Staffordshire Regiment, to be Surgeon-Major (ranking as Major).

The undermentioned officers to be Surgeons-Major (ranking as Majors): Surgeon-Major **ROWLAND HILL COOMES, M.D.**, 3rd Battalion the Bedfordshire Regiment (late the Bedford Militia); Surgeon **ERNESTER SHEED**, 2nd Volunteer Battalion the Essex Regiment (formerly the 2nd Essex Volunteers); Surgeon **HENRY GEARY DYER**, 4th Volunteer Battalion the Hampshire Regiment (late the 4th Hampshire Volunteers).

The undermentioned officers to be Surgeons (ranking as Captains): Surgeon **WALTER CULVER JAMES, M.D.**, F.R.C.S.E., the Honourable Artillery Company of London; Surgeon **WILLIAM JOHN NAISMITH, M.D.**, F.R.C.S.E., Artillery Yeomanry Cavalry; Acting-Surgeon **ALFRED LINGARD**, 3rd Middlesex Artillery Volunteers; Acting-Surgeon **ROBERT CLARK**, 5th Lancashire Artillery Volunteers; Surgeon **WILLIAM CHALMERS COWAN**, 1st Forfarshire Artillery Volunteers; Surgeon **WILLIAM COATES**, the Manchester Division Volunteer Medical Staff; Acting-Surgeon **QUINTIN CHALMERS, M.D.**, 5th Volunteer Battalion the Highland Light Infantry (late the 10th Lanarkshire Volunteers); Acting-Surgeon **WILLIAM DUNCAN, F.R.C.S.**, 1st London Rifle Volunteers; Acting-Surgeon **WILLIAM BROWN MOIR, M.D.**, 2nd Volunteer Battalion the Highland Light Infantry (late the 6th Lanarkshire Volunteers).

THE INDIAN MEDICAL SERVICE.

SURGEON F. C. CLARKE, Bengal Establishment, is appointed to the officiating medical charge of the 6th Bengal Cavalry, *vice* Surgeon-Major P. F. O'Connor, M.D., granted furlough. This cancels Surgeon W. R. Clark's appointment to the 6th Bengal Cavalry, previously notified.

Surgeon **W. R. CLARK**, Bengal Establishment, is appointed to the officiating medical charge of the 17th Bengal Cavalry, *vice* Surgeon-Major W. E. Griffiths, granted furlough.

Surgeon **E. HUDSON**, Bengal Establishment, is appointed to the officiating medical charge of the 11th Bengal Infantry, *vice* Surgeon C. Vaid, transferred temporarily to civil employ.

Surgeon **W. A. SYKES**, Bengal Establishment, is appointed to the officiating medical charge of the 18th Bengal Lancers, *vice* Surgeon A. W. Dawson.

Surgeon **E. C. HARE**, Bengal Establishment, is appointed to the officiating medical charge of the 1st Punjab Infantry, *vice* Brigade-Surgeon J. Duncaan, M.D., appointed to Shaikh Budin during the ensuing season.

Surgeon **W. CONRY, M.B.**, Bengal Establishment, medical officer 13th Bengal Lancers, has leave of absence for one year on private affairs.

Surgeon **G. B. IRVINE**, Bengal Establishment, is appointed to the officiating medical charge of the 1st Battalion 2nd Gorkhas, *vice* Surgeon-Major D. P. Macdonald, M.D., granted leave out of India.

The services of Surgeon **H. ADEY**, Bombay Establishment, are placed at the disposal of Government for employment in the Civil Department.

Surgeon **T. D. C. BARRY**, Bombay Establishment, is appointed to the officiating medical charge of the 20th Native Infantry during the absence of Surgeon-Major J. Macgregor, M.D., or until further orders.

Surgeon-Major **J. LUCAS**, Bombay Establishment, is appointed to the officiating medical charge of the 27th Native Infantry during the absence of Surgeon H. Adey, or until further notice.

Surgeon **CHARLES MATRIAS**, formerly of the Indian Medical Service, died on April 13th at Penally, Pembrokehire, aged 70.

The undermentioned probationers for the Indian Medical Service, having completed a course of instruction at the Army Medical School and being reported qualified, have been appointed Surgeons on the Bengal Establishment, their commissions as such bearing date October 1st, 1887, the day of their joining the Army Medical School:—A. E. ROBERTS, D. M. DAVIDSON, F. P. MANNARD, J. C. LAMONT, A. H. NOTT, A. COLEMAN, W. W. WHITE, D. T. LANE, M.D., R. C. MAOWATT, W. H. E. WOODWRIGHT, W. J. BUCHANAN, J. CLOSS, M.D., J. M. MACNAMARA, M.D., and H. M. BRABAZON.

THE VOLUNTEERS.

The undermentioned gentlemen have been appointed Acting-Surgeons to the corps specified:—C. L. FRASER, 1st Berwick-on-Tweed Artillery; Acting-Surgeon **R. K. TAIT**, from the 1st Newcastle and Durham Engineers, to the 17th Division Submarine Miners Royal Engineers; **EDMUND VAUDREY, M.B.**, 1st Volunteer Battalion Derbyshire Regiment (late the 1st Derby).

Surgeon and Hon. Surgeon-Major **H. MEAD**, of the 2nd West Riding Artillery, has resigned his commission, which was dated July 3rd, 1872; he is permitted to retain his rank and uniform.

Surgeon and Hon. Surgeon-Major **J. WILLIAMS**, of the 1st Volunteer Battalion South Wales Borderers (late the 1st Brecknock), has also resigned, with permission to retain his rank and uniform; his appointment was dated April 15th, 1862.

Acting-Surgeon **A. R. WADE** is appointed Surgeon to the 2nd Battalion Hampshire Regiment (late the 2nd Hampshire); and **MR. W. J. HARNETT** is appointed Surgeon to the 22nd Middlesex (Central London Rangers).

Surgeon E. T. PRIOR, of the 4th Volunteer Battalion Norfolk Regiment (late 4th Norfolk), has resigned his commission, which was dated July 30th, 87.
Mr. H. J. JOHNSON is appointed Surgeon to the London Division of the Volunteer Medical Staff, and Mr. J. OLIVER, M.B., Surgeon to the Leeds Division.

B. F.—There is every reason to believe that the effort at promotion in the family party at the headquarters of the Army Medical Department which was rumoured, and which is referred to by our correspondent, has been frustrated.

SPREADING THE NET FOR VOLUNTEER SURGEONS.

A CAUGHT BIRD," himself ensnared into the Medical Staff, expresses his surprise that any volunteer surgeons could be caught by such a naked pinch of salt as the Army Medical Reserve Warrant seeks to place on their tails. He thinks they, in joining the so-called Reserve, incur obligations scarcely realised, or they would pause. They will not be able to back out of these obligations when summoned upon to do duty anywhere in a factitious "national emergency."

THE QUALIFICATIONS OF VOLUNTEER MEDICAL OFFICERS.

EDICUS asks: Can a practitioner holding only the L.S.A.Lond. be appointed acting-surgeon of a volunteer regiment? If so, is it not time for the Volunteer Medical Association, and have the same inserted in the Volunteer Medical (?) Regulations? I have looked through the Volunteer Regulations, but cannot find any reference as to the necessary medical qualifications. I ask this question as I know of a case wherein a practitioner having only the L.S.A.Lond. has been nominated for this appointment, his name being sent to the War Office for confirmation of appointment.

. A certificate of proficiency is only granted to a volunteer medical officer who is registered under the Medical Act of 1858 as qualified to practise medicine and surgery in Great Britain and Ireland" (Army Form, E 564; Volunteer Regulation, 1887, Part I, sec. ii, para. 144). Volunteer medical officers have been appointed who have only one qualification, and the certificate of proficiency has been withheld by the War Office in such cases. Officers are now required to become proficient within one year of their appointment.

THE ARMY MEDICAL RESERVE.

FRASER STOKES (Surgeon, the London Rifle Brigade) writes: As a volunteer medical officer, I have read with interest your leading article upon this subject in the JOURNAL of April 28th. Since the issue of the Warrant I have been hesitating about joining, but at present have not done so, there being many adverse opinions to the scheme. Doubtless, as your article states, volunteer medical officers are quite prepared to make great personal sacrifices, together with volunteers of all ranks, when real national danger unfortunately comes about, but it is entirely another matter to ask them to risk private professional ruin when the emergency may be not national at all."

With this I entirely agree, but it seems to me that if the War Office wishes to see this Army Medical Reserve become a success, and be thoroughly well taken up, it should make the Warrant more adapted to the position and occupation of the man whose services it is seeking to enlist. For instance, if we were to guarantee that volunteer medical officers should be placed in large of troops only in those barracks situated in the immediate neighbourhood of the towns in which they reside, and at the same time to allow them to devote some part of the day to the supervision of their own private practices, I believe the scheme would be warmly supported. As matters stand at present it would appear, for example, that an officer resident in London is able to be ordered to Portsmouth or Chatham, and kept there for an unlimited period, during which time his private practice must be seriously damaged. Perhaps the War Office will see fit to so modify the Warrant as to make it more adapted to the professional life of volunteer surgeons.

. We fear the writer of the above hardly grasps the absolutely necessary conditions of a Reserve which shall be other than a merely bogus one. In any national emergency, "real or factitious, the military authorities would very soon show they care nothing for the private practice or personal convenience of a reservist who is bound under penalties to fulfil a contract. He must go where ordered—the "London resident" to Chatham, or, for that matter, to Regent's Park or Trafalgar if required. If he repents and refuses at the last moment, we doubt not he would discover he was under the penalties of the volunteer and other enactments. Crude and unworkable as the Warrant is, it could certainly not be made more impracticable by guaranteeing reservists they should only have such duties as suited their private interest or convenience. If the writer is in any doubt on this subject, then, we say, do not join the Reserve.

PLEA FOR HONORARY RANK.

TEN YEARS writes: I think the familiarity with which medical officers of long service and high position are treated by young military officers is very humiliating and humiliating. I have seen Senior Surgeons-Major, Brigade Surgeons, and administrative medical officers of the highest position addressed without any prefix to the surname by officers young enough to be their sons. In civil life such a thing would not occur. Military officers respect military rank only, and treat Dr. Browne, the Surgeon-General, as they would Dr. Browne, the Surgeon, not condescending to inquire what their respective ranks may be.

There is no doubt that socially we have lost position since the abolition of a regimental system. We are a large body of officers, brought in intimate contact with military officers, and dependent on them for all that constitutes social life in the army. We have no messes, and no means of making, as a rule, any return for hospitality. Naturally, regiments look down on a body of officers without any position, and we sink lower every day in the social

scale. This cannot be denied; it is evidenced by the neglect of regiments to make us honorary members of their messes, and by the exclusion of medical officers from regimental entertainments. I do not say every regiment excludes us, but the number of those that do is steadily increasing. We are growing more unpopular every day. There is a strange want of independence amongst us. Many an act of grave injustice has been done medical officers; for instance, sweeping us with one stroke out of our regiments, but a Director-General resigning his chair, no matter how snubbed and insulted, has never been known. A short time ago the "aiguillette" was taken from honorary surgeons to the Viceroy; any other body of officers would have resigned the degraded position, but I have not heard that any one of those gentlemen has acted with becoming spirit and independence, a public insult to the Department should be publicly resented. The position of a medical staff officer is intolerable to men of gentlemanly feeling; snubs, slights, and humiliations are daily served out to us with an unsparing hand. The remedy is obvious—honorary rank. There is a slavish respect for military titles in the army, and no matter who the persons are, they rise at once to weight and consideration when granted military titles. I need only point to paymasters and Commissariat officers. Can any one deny that their position in the army has been marvellously improved by honorary rank?

We are deeply indebted to you, Sir, for fighting our battles, but we are a numerous body, and, I think, should do something for ourselves. We should establish in London a Medical Staff Defence Association, appoint a paid secretary; plenty of medical officers on retired pay suitable for the post. I shall be happy to subscribe liberally. The medical officers of the Indian Service adopted this plan, and got their grievances redressed. I do not see why we should not do the same. Our position is bad, and will, unless we exert ourselves to improve it, become intolerable.

MR. STANHOPE'S MEMORANDUM.

A SENIOR SURGEON-MAJOR, writing from India, says the alterations in the terms of retirement foreshadowed in Mr. Stanhope's memorandum have produced positive consternation among the Medical Staff serving in that country. He asks: Can it be possible that the British Government, hitherto distinguished for its absolute good faith, would deliberately break its contracts with its servants? It is surely impossible.

MEDICO-LEGAL AND MEDICO-ETHICAL.

PRESCRIBING CHEMISTS AND COMPOUNDING DOCTORS.

M. R. C. asks if it is competent for a L.K.Q.C.P.I., in face of the declaration, to superintend a medical hall publicly opened for sale of medicine and for compounding prescriptions; the hall to be the property of unqualified persons, who would have in it a capable though unqualified hand to do all work, and merely superintended by the L.K.Q.C.P.I.

. We have referred this question to Mr. James R. Upton, Solicitor to the British Medical Association, who replies as follows: Whether L.K.Q.C.P.I.'s superintendence would constitute "covering" would entirely depend on the extent of the supervision he exercised. If complaint were to be made to the General Medical Council, the tests that would be applied to the facts laid before them would be (1) was the employment of the unqualified assistant in substitution for the services of L.K.Q.C.P.I., or under circumstances in which due personal supervision and control were not, or could not, be exercised by him? and (2) did L.K.Q.C.P.I. do any act to enable the unqualified person to practise as if duly qualified (see the JOURNAL for March 31st last, at p. 714)?

A BONE-SETTER.

T. W. writes: I have been attending a woman, aged 70, suffering from fracture of the neck of the femur. I put a long splint on, but was obliged to remove it on account of bedsores caused by incontinence of urine. I was going to mould a leathern splint for it when I was superseded by a bone-setter, who said it was out of joint, and the leg never had been broken. I have been severely handled by many of my patients for my ignorance. Have I any redress at a court of law, and should not our Branch take it up seeing that it would benefit the profession?

. The only means of obtaining redress that we can suggest would be an action claiming damages for slander. Before attempting to bring such an action, it is important to have clear proof of the exact words used. If they impute ignorance of his profession to a medical man they would clearly be actionable, but the amount of damages awarded would depend on the view taken by the jury.

CORONERS AND MEDICAL WITNESSES.

NEMO asks: What discretionary powers, if any, has the coroner in regard to the calling in or not of the medical man in attendance on the deceased before death?

. If the coroner previous to the inquest considers medical evidence at an inquest is necessary, he can subpoena a medical man to attend. Should, however, the inquest have been commenced and no medical evidence forthcoming, it is within the power of the coroner or the jury to adjourn for the attendance of a medical witness. The jury have also the power to call additional medical evidence, and to name the medical man they desire to attend should they not feel satisfied with the medical evidence that may already have been given.

The Skinners' Company have given a donation of ten guineas to the Parkes Museum, Margaret Street, Regent Street, to aid in maintaining and extending its work of practically teaching the laws of health.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

ENGLISH URBAN MORTALITY IN THE FIRST QUARTER OF 1888.

THE vital and mortal statistics of the twenty-eight towns dealt with by the Registrar-General in his weekly return are summarised in the accompanying table. During the three months ending March last, 76,127 births were registered in the twenty-eight large towns, equal to an annual rate of 32.5 per 1,000 of their aggregate population, estimated at nearly nine and a half millions of persons. In the corresponding periods of the three preceding years, 1885-7, the birth-rate in these towns was 35.3, 34.7, and 32.9 respectively. The birth-rate in London last quarter was equal to 32.2 per 1,000, while in the twenty-seven provincial towns it averaged 32.8, and ranged from 22.7 in Brighton, 26.5 in Huddersfield, and 28.3 in Bradford to 37.4 in Norwich, 37.7 in Newcastle-upon-Tyne, 39.5 in Preston, and 43.9 in Cardiff.

The 51,659 deaths registered in the twenty-eight towns during the first three months of this year were equal to an annual rate of 22.1 per 1,000, against 22.7, 24.4, and 22.0 in the corresponding quarters of the three years 1885-7. In London the rate of mortality was 22.0 per 1,000, while in the twenty-seven provincial towns it averaged 22.2 per 1,000. The lowest rates in these provincial towns were 18.0 in Bradford, 18.1 in Hull, 18.5 in Brighton, and 19.0 in Sunderland; the highest were 27.1 in Preston, 28.8 in Plymouth, and 29.0 in Blackburn and in Manchester. During the quarter under notice, 5,637 deaths were referred to the principal zymotic diseases in the twenty-eight towns, equal to an annual rate of 2.41 per 1,000; the zymotic death-rate in these towns in the first quarter of the five preceding years averaged 2.38 per 1,000. The lowest zymotic rates in these towns last quarter were 0.75 in Halifax, 0.97 in Sunderland, 1.01 in Newcastle-upon-Tyne, and 1.04 in Brighton; while they ranged upwards in the other towns to 3.01 in Nottingham, 3.31 in Plymouth, 3.74 in Blackburn, and 5.39 in Sheffield. The 5,637 deaths referred to the principal zymotic diseases included 2,335 which resulted from whooping-cough, 858 from scarlet fever, 618 from measles

from "fever" (including typhus, enteric, and simple and ill-defined forms of continued fever), 499 from diphtheria, 396 from diarrhoea, and 393 from small-pox. The 2,335 fatal cases of whooping-cough registered in the twenty-eight towns during the quarter under notice were equal to an annual rate of 1.00 per 1,000, and, with the exception of 1886, when the rate was also 1.00, exceeded that recorded in the first quarter of any year since 1882. This disease was proportionally much more prevalent in London than in the aggregate of the provincial towns: for while the whooping-cough death-rate in London was as high as 1.52 per 1,000, it did not average more than 0.56 in the twenty-seven provincial towns, among which it was highest in Norwich, Salford, Leicester, and Wolverhampton. The 618 fatal cases of measles were equal to an annual rate of 0.26 per 1,000, a lower rate than in any quarter of any year since 1878. The rate of mortality from this disease in London last quarter was 0.22 per 1,000, while it averaged 0.30 in the twenty-seven provincial towns, among which it showed the highest proportional fatality in Bolton, Blackburn, Birmingham, Nottingham, and Plymouth. The death-rate from scarlet fever was equal to 0.37 per 1,000, and exceeded that recorded in the March quarter of any year since 1884; in London the rate of mortality from this disease was equal to 0.39 per 1,000, and slightly exceeded the mean rate in the provincial towns, among which scarlet fever was proportionally most fatal in Manchester, Sheffield, Birkenhead, Oldham, and Blackburn. The number of scarlet fever patients in the Metropolitan Asylums Hospitals, which had been 2,049 at the beginning of the year, steadily declined to 1,037 at the end of March. The admissions into these hospitals, which had risen from 466 to 2,908 in the four quarters of 1887, declined to 1,037 during the first three months of this year. The 538 deaths referred to different forms of "fever" in the twenty-eight towns last quarter were equal to an annual rate of 0.23 per 1,000; this rate was below the average of the corresponding quarters of the five preceding years, although it exceeded that recorded in the first three months of any of the three previous years. In London the fever death-rate was 0.23 per 1,000, and corresponded with the mean rate in the twenty-seven provincial towns, among which it was highest in Cardiff, Derby, and Nottingham. The rate of mortality from diphtheria was equal to 0.21 per 1,000, and although showing a slight decline from the rate in the preceding quarter, was higher than in the

quarter of any year on record; in London the death-rate from diphtheria was equal to 0.29 per 1,000, while it did not average more than 0.15 in the provincial towns, among which this case showed the highest proportional fatality in Preston, Huddersfield, Norwich, and Oldham. The rate of mortality from diarrhoea was 0.17 per 1,000, and was below the average. During the first three months of this year, 393 deaths resulted from small-pox in the twenty-eight towns; of these, no fewer than 318 occurred in Sheffield (against 3, 45 and 230 in the three preceding quarters), also 15 in Bristol, 13 in Manchester, 13 in Leeds, 9 in Nottingham, 8 in Blackburn, and 6 in Oldham. Only 9 cases of small-pox were under treatment in the Metropolitan Asylums Hospitals at the end of March, and 38 cases of this disease had been admitted during the quarter, against 7 and 30 in the two preceding quarters.

The rate of infant mortality in the twenty-eight towns, measured by the proportion of deaths of children under one year of age to 100 registered births, was equal to 147 per 1,000 during the quarter under notice, against 154 and 145 in the corresponding periods of the two preceding years. While the rate of infant mortality was 143 per 1,000 in London, it averaged 150 in the twenty-seven provincial towns, among which it ranged from 114 in Sunderland, 119 in Huddersfield, and 122 in Bristol, to 177 in Wolverhampton, 178 in Preston, 199 in Plymouth, and 203 in Blackburn. The causes of 1,054, or 2.0 per cent of the deaths registered in the twenty-eight towns during last quarter were not certified, either by registered medical practitioners or by coroners. The proportion of uncertified deaths in London did not exceed 0.9 per cent., while it averaged 3.0 in the twenty-seven provincial towns, and ranged from 0.8 in Wolverhampton, and 1.0 in Birkenhead to 4.1 in Halifax, 5.5 in Sheffield and in Liverpool, and 5.8 in Hull.

MEDICAL OFFICERS OF HEALTH AND THE LOCAL GOVERNMENT BILL.

A SPECIAL meeting of the Birmingham and Midland Branch of the Society of Medical Officers of Health was recently held for the purpose of considering the Local Government Bill, presided over by Dr. A. BOSTOCK HILL, President, who said he thought the present moment was favourable for effecting the reform in the position of medical officers of health which they had so long been fighting out for. There were a great many medical officers of health engaged at salaries which made it absolutely impossible for them to do any sanitary work at all. There were a large number getting salaries of £5 and even £3 a year—a sum which did not pay a professional man even for the time expended in collecting statistics for his annual report. The payment of such a small salary, in fact, was practically an intimation from his employers that the less sanitary work he did the better. A large number of the present officers would become the officers of the district councils; but under the new system, there would probably be an amalgamation of the smaller areas, so that a salary could be paid which would enable a man really to do good sanitary work. Reference was made to the recent meeting of the Society held in London.—Dr. AGG suggested that the impending change afforded an opportunity of effecting still larger reforms in the system of sanitary administration. For instance, vaccination ought to be included in the work of the sanitary authorities. Small-pox was as much a matter for the sanitary administration as other zymotic diseases. The Bill was a comprehensive and far-reaching measure, and those were special reasons that the utmost care should be bestowed upon the construction of its details. Putting aside the omission of the adjustment of the shortcomings of our poor-law system, it was surprising how little, as the Chairman had noted, the Bill proposed to effect in the reconstruction and adjustment of our "tumbledown" piecemeal sanitary legislation, beyond renaming the local authorities and the introduction of County Councils. The Bill took no notice whatever of those sanitary requirements which such competent authorities as Farr, Acland, Simon, Rumsey, and the Councils of the British Medical and Social Science Associations have declared essential to the satisfactory working of our sanitary organisation. Her Majesty's Government had no excuse for ignoring these essentials, since they were duly brought officially before them as long ago as 1868, in the "Memorandum of State Medicine," the "Memorial of the Joint Councils of the British Medical and Social Science Associations, appointed to consider the better administration of the laws relating to Registration, Medico-legal inquiries, and the improvement of the Public Health;" and in 1869

in the "Minutes of Evidence in the first Report of the Royal Sanitary Commission." No mere renaming or grouping of the existing sanitary authorities could be satisfactory. The conditions of sanitary science and progress in the large centres of population and combined districts might be considered fairly satisfactory, but the very reverse held in the numerous small districts; there the hindrances to effective sanitary work and to the officials were greatest and most powerful. No doubt the former might be left as separate organisations or centres; but adjoining small districts ought to be grouped around their largest town into a sanitary district or area with a definite minimum population (about 100,000 or 150,000, this latter corresponding to the approximate Parliamentary divisional basis), under the care of a properly qualified medical officer and his staff, who would each devote their whole time and energies to the work, with life tenure of office during "good conduct," and at adequate remuneration; these four were the long recognised essential defects of our legislation. There were two other points he would allude to. From the experience of the 30 odd towns having compulsory notification of infectious disease, there was every reason that that important provision should now be extended by the Bill (or a separate one to follow it) to the whole country, all the new authorities being compelled to forego themselves with suitable hospital accommodation; lastly, there was the urgent necessity of the abolition of the antagonism between the practical working of the Education Acts and the Public Health laws in the matter of the constant diffusion of infectious diseases by schools. All pecuniary loss to the elementary schools by the non-attendance of children from infected houses ought to be done away. The Bill, so amended, would meet the most pressing and acknowledged defects of our present sanitary disorganisation.—Dr. A. HILL thought the object of the meeting should be limited to that taken by the Metropolitan Society—namely, the desirability of the medical officers of health holding their appointments direct from the County Councils.—Dr. PAGE, in accordance with the Chairman's suggestion, proposed: "That this branch of the Society of Medical Officers of Health wishes to express the opinion that the election of medical officers of health should be in the hands of the County Council."—Dr. A. HILL seconded the motion.—Dr. FENTON said that he agreed with the proposal so far as it affected the small rural appointments, but he thought that in boroughs of a moderate size matters might remain as they were. He had, during his time, proceeded against the Mayor and other members of the Town Council, but he had nothing to complain of in the way he had been treated.—Dr. UNDERHILL, while having no personal grievance, supported the motion, and, with regard to the amalgamation of districts, said that they must sink their personal interests out of regard to the general interests of sanitation.—Mr. HOLLINGSHEAD said he could not vote for the motion. He had no reason to complain of want of support from the authority of his district.—The PRESIDENT said that he was exactly in the same position as Mr. Hollingshead, being officer to two local authorities. There were, however, some flagrant instances of medical officers of health of the highest ability losing their positions through having incurred personal hostility in the discharge of their duty.—Dr. A. HILL said if county medical officers were appointed, they could only supervise the work of the districts. Local officers would still be required for the details of the works. The motion was carried.

HOSPITALS FOR INFECTIOUS DISEASES.

THE principle that the spread of infectious disease is to be controlled most effectually by the isolation of the first cases attacked has been so frequently exemplified, that of late years it has become more generally recognised and acted upon by sanitary authorities; but with some authorities exaggerated considerations of expense and false notions of economy have asserted themselves, and the warning that a comparatively small initial expenditure in making some small hospital provision may be the means of protecting a locality from much sickness, misery, and pecuniary loss has too frequently been ignored. The Public Health Act, 1875, leaves the matter entirely within the discretion of the local sanitary authorities, but the Medical Department of the Local Government Board have, with much success, availed themselves of every suitable opportunity of influencing local authorities in the right direction.

A further effort has just been made by the Central Department to bring the subject under the attention of those local authorities who have not provided their districts with hospital accommoda-

tion, by the issue of a short memorandum¹ on the subject, signed by Dr. G. Buchanan, together with some carefully prepared plans of small hospitals. In that memorandum it is pointed out that too often the provision of isolation hospitals is put off until some infectious disease is immediately threatening or has actually invaded a district, and that it cannot be too clearly understood that such hospitals, to fulfil their proper purpose of sanitary defence, ought to be in readiness beforehand. During the progress of an epidemic, it is of little avail to set about hospital construction. The mischief of allowing infection to spread from first cases will always have been done, and this mischief cannot be repaired. Thus hospitals provided during an epidemic are mainly of advantage to particular patients; they have little effect in staying the further spread of infection. Moreover, hospitals provided under such circumstances, to be of any use, must be large and costly, and their construction can seldom be of a kind that is suited in after times for the isolation requirements of their districts.

Large villages and groups of adjacent villages will, it is pointed out, commonly require the same sort of provision as towns. Where good roads and proper arrangements for the conveyance of the sick have been provided, the best arrangement for village populations is a small building accessible from several villages; otherwise the requisite accommodation for (say) four cases of infectious disease in a village may be got in a suitable four-room or six-room cottage at the disposal of the sanitary authority; or by arrangement made beforehand with some trustworthy cottage holders, not having children, that they should receive and nurse, on occasion, patients requiring such accommodation.

In towns hospital accommodation for infectious diseases is wanted more constantly, as well as in larger amount than in villages; and in towns there is greater probability that room will be wanted at the same time for two or more infectious diseases which have to be treated separately. The permanent provision to be made in a town should consist of not less than four rooms in two separate pairs; each pair to receive the sufferers from one infectious disease, men and women of course separately. The number of cases for which permanent provision should be made must depend upon various considerations, among which the size and the growth of the town, the lodgment and habits of its population, and the traffic of the town with other places, are the most important. There is no fixed standard, therefore, by which the standing hospital requirements proper for a town can be measured. Furthermore, it is to be remembered, that occasions will arise (as where infection is brought into several parts of a town at one time) when isolation provision, in excess of that commonly sufficient for the town, will become needful.

For a town, the hospital provision ought to consist of wards in one or more permanent buildings, with space enough for the erection of other wards, temporary or permanent. Considerations of ultimate economy make it wise to have permanent buildings sufficient for somewhat more than the average necessities of the place, so that recourse to temporary extensions may less often be necessary. And in any case it is well to make the administrative offices somewhat in excess of the wants of the permanent wards; because thus, at little additional first cost, they will be ready to serve, when occasion comes, for the wants of temporary extension.

Some very useful plans, illustrating the sanitary requirements of small hospitals for infectious diseases, are arranged on sheets accompanying the memorandum. In all the plans proper standards of space are observed, namely, not less than 2,000 cubic feet of air space, 144 square feet of floor space, and 12 linear feet of wall space to each bed; means are provided for the adequate ventilation and warming of wards, and for securing them from closet emanations and the like. Places for washing and disinfection, and for a mortuary are indicated. An interval of 40 feet is everywhere interposed between every building used for the reception of infected persons or things and the boundary of the hospital site; and this boundary, it is recommended, should have a close fence of sufficient height, and the 40 feet of interval should not afterwards be encroached on by any temporary building or other extension of the hospital.

In determining the locality where an infectious hospital should be placed, the wholesomeness of the site, the character of the approaches, together with the facilities for water-supply and for slop and refuse removal, are matters of primary importance.

¹ To be purchased, either directly or through any bookseller, from Eyre and Spottiswoode, East Harding Street, Fleet Street, E.C.; or Adam and Charles Black, 5, North Bridge, Edinburgh; or Hodges, Figgis, and Co., 104, Grafton Street, Dublin.

The memorandum does not fail to emphasise the caution which recent experience as to the spread of small-pox from hospitals has shown to be necessary. "Sites," it says, "for hospitals designed to receive small-pox require a very much larger space about them than sites for other infectious diseases hospitals. Small-pox hospitals, as we know them, are apt to disseminate small-pox, and their sites should, therefore, be placed outside of towns, and should, indeed, be sought at places as far distant from any populated neighbourhood as considerations of accessibility permit. It has been suggested that small-pox hospitals may be so constructed as not to be dangerous to neighbouring habitations; that this can be done by a system of passing through a furnace all outgoing air from infected wards and places: but this suggestion has not yet been carried into effect in England."

We commend the memorandum to the serious attention of all those sanitary authorities that have not provided their districts with the primary defence against epidemics which isolation hospitals constitute.

PUBLIC HEALTH ADMINISTRATION IN BRADFORD.

A MEETING of the medical practitioners of Bradford was held recently for the purpose of presenting an address to Dr. Hime on the approaching termination of his five years' engagement as medical officer for the borough. There was a large attendance. The address, which was elaborately illuminated on five pages, and handsomely bound in book form, with a suitable inscription, signed by eighty-six medical men, congratulated Dr. Hime on the good work which, in conjunction with the sanitary authority, he had been able to accomplish during his five years of office; on the cordial relations subsisting between himself and his medical brethren, which had enabled him to secure their active co-operation in carrying out the by-laws for the control of infectious diseases; on the greatly diminished death-rate, and the fact that Bradford now occupied a favourable position among the healthiest towns in England.

CHOLERA IN CHILI.

ACCOUNTS reach us of the fearful ravages of cholera, which has prevailed during the last three months in Chili. The *Chilian Times* of March 17th says: "Last week there occurred here 96 cases and 39 deaths, against 105 cases and 38 deaths in the previous returns. This brings up the total for the twelve weeks ended last Saturday, according to the defective returns of the Board of Health, to 3,338 cases and 1,357 deaths, which is nowhere near the mark. Dr. Gacitua estimates that from 4,500 to 5,000 persons have died in Valparaiso of cholera from the time of the appearance here of the disease on December 25th last until the 3rd instant. As the epidemic shows no signs of disappearance yet, a recrudescence of the disease having coincided with the introduction of fruit and *chicha* (grape cider), the probabilities are that the cholera will linger on until, as happened last year, it is temporarily placed in abeyance by the arrival of winter, by which time it may be taken for granted that Dr. Gacitua's highest estimate of victims will have been reached, and perhaps exceeded."

HEALTH OF ENGLISH TOWNS.—In the twenty-eight large English towns, including London, which have an estimated population of 9,398,273 persons, 5,834 births and 3,367 deaths were registered during the week ending Saturday, May 5th. The annual rate of mortality, which had declined from 21.9 to 18.9 per 1,000 in the three preceding weeks, further fell to 18.7 during the week under notice. The rates in the several towns ranged from 12.7 in Portsmouth, 15.1 in Birkenhead, and 15.8 in Sunderland to 24.8 in Plymouth, 26.3 in Preston, 27.6 in Manchester, and 28.1 in Salford. In the twenty-seven provincial towns the mean death-rate was 19.8 per 1,000, and exceeded by 2.3 the rate recorded in London, which was only 17.5 per 1,000. The 3,367 deaths registered during the week under notice included 146 which were referred to whooping-cough, 45 to scarlet fever, 38 to diarrhoea, 32 to "fever" (principally enteric), 31 to diphtheria, 25 to measles, and 12 to small-pox; in all, 329 deaths resulted from these principal zymotic diseases, against 363 and 328 in the two preceding weeks. These 329 deaths were equal to an annual rate of 1.8 per 1,000; in London the zymotic death-rate was 2.1 per 1,000, while it averaged 1.6 in the twenty-seven provincial towns, and ranged from 0.0 in Portsmouth and in Plymouth, and 0.4 in Sunderland to 2.8 in Sheffield and in Norwich, 3.5 in Blackburn, and 5.3 in Salford. Measles caused the highest

proportional fatality in Bristol, Preston, Bradford, and Nottingham; scarlet fever in Salford and Blackburn; whooping-cough in Norwich, Manchester, London, Blackburn, and Salford; and fever" in Manchester and Salford. Of the 31 deaths from diphtheria recorded during the week under notice in the twenty-eight towns, 15 occurred in London and 3 in Manchester. The 3 fatal cases of small-pox included 8 in Sheffield, 2 in Bristol, in Oldham, and 1 in Hull. The number of small-pox patients in the Metropolitan Asylums Hospitals on Saturday, May 5th, was 1, of which 2 had been admitted during the week. These hospitals also contained 920 scarlet fever patients on the same date, against 961 and 967 at the end of the two preceding weeks; 10 cases were admitted during the week, against 91 and 79 in the two previous weeks. The death-rate from diseases of the respiratory organs in London was equal to 3.5 per 1,000, and was considerably below the average.

HEALTH OF SCOTCH TOWNS.—During the week ending Saturday, May 5th, 888 births and 493 deaths were registered in the eight principal Scotch towns. The annual rate of mortality, which had been 21.2 and 21.0 per 1,000 in the two preceding weeks, further declined to 19.5 during the week under notice, and exceeded by 0.8 per 1,000 the mean rate during the same period in the twenty-eight large English towns. Among these Scotch towns the lowest rates were recorded in Perth and Dundee, and the highest in Edinburgh and Glasgow. The 493 deaths in these towns during the week under notice included 35 which were referred to the principal zymotic diseases, equal to an annual rate of 1.4 per 1,000, which was 0.4 below the mean zymotic death-rate during the same period in the large English towns. The highest zymotic rates were recorded in Aberdeen and Glasgow. Eight fatal cases of diphtheria, 7 of whooping-cough, and 5 measles occurred in Glasgow; but no zymotic disease was fatally prevalent in any of the other towns. The mortality from diseases of the respiratory organs in these Scotch towns during the week under notice was equal to 4.4 per 1,000, against 5 in London.

THE POWERS OF THE REGISTRAR OF DEATHS.

Y. Z. asks: Has a registrar of births and deaths power to give a certificate of death in cases not seen by a medical man if there are no suspicious circumstances? My reason for asking is the following case, which has occurred this week.

A man called at the surgery to ask me to go at once to see his child. I was unable to do so, but offered to go as soon as I could. This offer the man would not accept (his house is four miles from the surgery), and said if I could not go back with him I was not to go at all. I did not do so. Next day the child died. Speaking casually to the registrar, he informed me he had registered the death as due to inflammation of the bowels. The case had not been seen by any medical man, and it is customary here for the registrar to give certificates in cases similar to the above. Would you kindly tell me whether he has any legal power to do so?

. If the person giving information of a death to the registrar states that the deceased had no medical attendant of any kind during the last illness, and if, upon inquiry, the registrar finds that the case is not one which he should report to the coroner (such as a death caused directly or indirectly by violence, or attended by suspicious circumstances, or when the cause of death is stated to be "unknown," or "sudden"), he must record the best information respecting the cause of death which he is able to obtain from the informant, and may issue his "certificate of the registry of death" in the usual manner.

POOR LAW MEDICAL OFFICERS' ASSOCIATION AND THE PUBLIC HEALTH PREVENTION OF DISEASES BILL.

At a meeting of the Council of the Poor Law Medical Officers' Association, held at their rooms, 3, Bolt Court, Fleet Street, May 1st, it was considered that the time had now arrived when poor law medical officers could cooperate most effectually in the proposed arrangement sought to be made by the medical officers of health. It was proposed to suggest to the central authority that poor law medical officers should be styled "district health officers," and that their duties should include the acting as deputies to those appointed as health officers of counties or large districts.

The subject of the Public Health Prevention of Diseases Bill came also under consideration, and Clause 3, Subsection 5, which makes a distinction in the amount of fees payable under different circumstances, was thought to be very objectionable and derogatory to those holding public appointments, and the Council requested Mr. Barnes to communicate its views upon this subject to Dr. Farquharson, M.P.

In reference to the Lord Chancellor's Coroners Bill, the Council resolved that it is not just towards the medical profession, and will, in many cases, be a hardship on the poor law medical service, if the appointment of coroners, as proposed by the Bill, becomes vested in the Lord Chancellor; and the Council urgently requests all members of the medical profession to oppose in every possible way that clause of the Bill which confers this power on the Lord Chancellor.

UNIVERSITY INTELLIGENCE.

CAMBRIDGE.

ASSISTANT TO THE PROFESSOR OF SURGERY.—It is proposed to appoint an Assistant to the Professor of Surgery, whose duty it shall be to aid in the surgical teaching, and to add to and maintain the surgical collections in the museum. The thanks of the University are offered to Professor Humphry for his generous proposal to provide, out of his own pocket, a suitable stipend for the assistant. Mr. Joseph Griffiths, M.B., is at present doing the work of the new office.

HONORARY DEGREE.—It is also proposed to confer the degree of M.A., *honoris causa*, on Dr. Siegfried Ruhemann, who, for the last two or three years has acted as assistant to Professor Dewar, and has very successfully conducted the teaching of organic chemistry in the University laboratory.

CAMBRIDGE AND LONDON.—The interest taken by London hospital schools in students from the Universities is evidenced by the announcement just made that Charing Cross will offer a scholarship of £50 for competition among Cambridge men who have passed the second M.B., and Oxford men who have passed the first M.B. examination.

OXFORD.

EXAMINATIONS IN MEDICINE AND SURGERY.—1. The Regius Professor of Medicine gives notice that the examination in the several parts of the first examination for the degree of Bachelor in Medicine, will commence on or about Monday, June 25th. The final examination for the degree of Bachelor of Medicine, will commence on or about May 28th, and that for the degree of Master in Surgery on June 7th. The precise days will shortly be notified. Intending candidates are requested to forward their names to the Regius Professor of Medicine, medical department of the museum. 2. The Secretary of the Boards of Faculties gives notice that he will be in attendance at his office in the Clarendon Building, on Friday, May 11th, and Saturday, May 12th, from 9 to 10 A.M., for the purpose of receiving names of candidates for the second examination for the degree of M.B.; and on Friday, June 8th, and Saturday, June 9th, from 9 to 10 A.M., for the purpose of receiving names of candidates for the first examination for the degree of M.B. Names may be sent to him by letter at any time not later than the above-mentioned days.

MEDICO-PARLIAMENTARY.

HOUSE OF LORDS.—Tuesday, May 8th.

The Lunacy Laws.—The Earl of MILLTOWN asked whether it was the intention of the Government to forward and pass into law this session the important Bill for the amendment of the Lunacy Laws, which, having already passed that House on three previous occasions, was sent down to another place on March 22nd of this year.—The Earl of SELBORNE also expressed the hope that the Bill might not be longer delayed in the other House.—The LORD CHANCELLOR said it was difficult to answer the question, because he could not answer for the progress of business in the other House. He agreed that this was a topic quite removed from party politics, and although there was not perfect unanimity, yet he thought they might hope soon to settle it one way or the other.

HOUSE OF COMMONS.—Tuesday, May 8th.

Foreign Medical Practitioners.—Mr. C. WRIGHT asked the Vice-President of the Committee of Council on Education whether the Medical Acts Amendment Bill which passed in 1886, and provided for registering duly-qualified foreign medical practitioners, was now in operation, and whether the requisite forms would be supplied to those practitioners to fill up for registration; and whether he could name the countries that were eligible to claim registration for their medical practitioners.—Sir W. HART DYKE said the second part of the Act had only been applied to New Zealand and Ceylon. In regard to registration of foreign medical practitioners, Sections 11, 12, and 13 of the Act prescribed the exact course to be adopted.

Hospital Accommodation on Transatlantic Steamers.—Sir MICHAEL HICKS-BEACH, in reply to a question by Dr. TANNER as to whether the hospital accommodation on board Transatlantic steamers was not frequently utilised for the accommodation of passengers, officers, or crew, said he was assured by the companies that such was not the case. No such hospital berths could be allocated to other than sick persons, unless on the express sanction of the medical officer of the ship.—Dr. TANNER asked whether

it was not a well-known fact, from all the reports furnished by the emigration officers at Liverpool and Queenstown, that such hospital accommodation was frequently utilised by both passengers and crew.—Sir M. HICKS-BEACH said he was not aware of it.

BURGH POLICE AND HEALTH (SCOTLAND) BILL.

On the motion of the LORD ADVOCATE, it was agreed that the Select Committee on the Burgh Police and Health (Scotland) Bill do consist of twenty-five members: Mr. Anstruther, Mr. Asher, Mr. Baird, Sir G. Balfour, Mr. Barbour, Mr. Barclay, Mr. Bolton, Mr. Preston Bruce, Mr. Caldwell, Mr. Macdonald Cameron, Sir A. Campbell, Mr. R. F. Campbell, Dr. Clark, Mr. Cochran-Ballie, Mr. D. Crawford, Lord Elcho, Mr. Esslemont, Mr. Hozler, the Lord Advocate, Mr. Menzies, Mr. F. S. Powell, Mr. Sinclair, Mr. Mark Stewart, Mr. Webster, and Mr. Williamson, with power to send for persons, papers, and records: five to be the quorum.

THE HORSE TAX.

ADDITIONAL petitions against this tax have been presented by Mr. Hanbury-Tracy, from the medical practitioners of Welshpool and district; by Sir W. Foster, from Northern Counties (Scotland) Branch of the British Medical Association; by Lord Beehive, from a Westmoreland Dalesman doctor; by Mr. S. Leighton, from medical men of Oswestry; by Mr. T. W. Legh, from medical officers in Wigan district; by Viscount Ebrington, from surgeons of Hatherleigh and Black Torrington; by Sir Wilfrid Lawson, from the medical men of Maryport; by the Marquis of Hartington, from Drs. T. Evans and J. Jones, of New Quay; and by Mr. A. E. Gathorne-Hardy, from medical men in Hayward's Heath and district.

OBITUARY.

MARK LONG, M.D., of Ludlow, Shropshire.

WE regret to announce the death of Dr. Mark Long, which occurred on April 28th, in one of the paying wards of Guy's Hospital, at the comparatively early age of 44. The subject of this notice was the eldest son of the late Mr. John Long, engineer of the Limerick Harbour Board. Dr. Long was educated at the Queen's College, Cork, and the Ledwich School of Medicine, Dublin, taking the M.D. of the Queen's University in 1865, and the L.R.C.S.I. the same year. He soon after proceeded to England, and was for ten years in practice in Hackney, in partnership with Drs. Daly and Gibbings. Owing to the delicate health of some members of his family he subsequently removed to Ludlow, where he soon acquired a large and good class practice. The deceased gentleman had a happy way of winning in a remarkable degree the confidence of his patients, and had a genial and pleasant manner. In the zenith of his success, in the autumn of last year, he developed obscure symptoms of disease of the bladder and kidneys, for which he came to London and consulted Mr. Jonathan Hutchinson. The symptoms becoming more acute, he was visited in February of this year by Mr. Clement Lucas, who advised his coming into one of the private wards of Guy's Hospital. Nine weeks ago Mr. Lucas cut down upon the right kidney, letting out eight ounces of foetid pus. The operation was most successful, and a rapid improvement was manifested in his condition, but subsequently grave uræmic symptoms occurred, terminating in convulsions and coma. A *post-mortem* examination justified the operation, the cavity in the kidney having contracted to a third of its dimensions at the time of the operation; the left kidney was quite healthy, but the left ureter was enormously distended, owing to the pressure of a periprostatic abscess. Dr. Long leaves a widow, the daughter of Mr. James Cooper, of Cromer, and four children, two sons and two daughters.

PETER LEONARD, M.D., Inspector-General of Hospitals and Fleets.

DR. PETER LEONARD died at Arbroath on May 2nd. The deceased gentleman was born at St. Vigeans, Arbroath, in 1801, and educated at Arbroath Academy; became a Licentiate of the Royal College of Surgeons, Edinburgh, in 1822; M.D. of St. Andrews in 1851; and M.R.C.P. London in 1859. He entered the navy very early in life, and served in every naval station of the British Empire, except that of the West Indies. In 1833 he published *Records of a Voyage to the Western Coast of Africa and of the Service on that Station for the Suppression of the Slave Trade*. He also wrote a *Naval Medical Journal of Service in South America*, for which he was awarded Sir G. Blaine's gold medal. Dr. Leonard was the first Inspector-General appointed under the Contagious Diseases Act, and he organised the administration of the Act. He was for many years Deputy Inspector-General at Chatham, and afterwards at Haslar, and he received the Greenwich Hospital pension for good service.

PETER ADRIAN VAN DER LAAN, M.D., Lisbon.
DR. VAN DER LAAN, the leading ophthalmologist of Portugal died at his residence in Lisbon on April 20th. He was born a Spanbroek, in Holland, in 1841, and educated at the University of Utrecht, where he took the degree of Doctor of Medicine, the subject of his inaugural dissertation being the disturbances of vision associated with albuminuria. He afterwards studied at Berlin, London, and Vienna, giving his attention chiefly to ophthalmology, under such masters as von Graefe, Liebreich, and Arlt. Being threatened with consumption, he started for Madeira towards the end of 1870, but broke his journey at Lisbon, where he remained for the rest of his life. Wishing to practise his profession in his adopted country, he with rare energy went through the required course of study in the Lisbon Medical School, and successfully passed all the numerous examinations for the degree. He soon acquired a great reputation as an oculist throughout Portugal; during his career he is said to have treated no fewer than 24,000 patients. He was an indefatigable worker, and employed the rare intervals of leisure which his professional engagements allowed him in contributing to medical literature. He died of the disease which had in the first instance driven him southwards, studying up to the very last moment. As the *Correio Medico* says, he died with a medical treatise in his hand on a subject altogether unconnected with the affection from which he was himself suffering.

The *Correio Medico* goes so far as to say that Van der Laan introduced ophthalmology into Portugal, where the pathology and treatment of diseases of the eye were almost unknown before 1870. In addition to his professional attainments, Dr. van der Laan was a deeply-read theologian, a sound classical scholar, and could converse fluently in English, German, and French, besides Portuguese and his native Dutch.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having undergone the necessary examinations for the diploma were, at an ordinary meeting of the Council on May 10th, admitted Members of the College.

H. P. Ainsworth, L.R.C.P. Lond., 26, Norland Square, W.; J. L. Aymard, L.R.C.P. Lond., Vine Lodge, Surbiton; G. Black, L.S.A., 34, Pembroke Road, Walthamstow; J. D. Cruickshank, L.R.C.P. Lond., 10, Dartmouth Terrace, Lewisham; F. K. Holman, L.R.C.P. Lond., Thanington Vicarage, Canterbury; W. J. Maillard, L.R.C.P. Lond., 72, Miskin Street, Cardiff; G. H. Metcalfe, L.R.C.P. Lond., 72, Lee Road, S.E.; B. Moss, L.R.C.P. Lond., 22, Josephine Avenue, Brixton; J. E. Moyses, L.R.C.P. Lond., Arden, Torquay; J. L. Roberts, L.R.C.P. Lond., Eirianfa, Llanrwst, N. Wales; W. C. Swayne, L.R.C.P. Lond., 2, New Street, S.E., Students of Guy's Hospital; J. W. Applegate, L.R.C.P. Lond., 16, Tufnell Park Road; J. B. Appleton, L.R.C.P. Lond., The Lizard, Cornwall; C. H. Ashford, L.R.C.P. Lond., 8, Alfred Place, Plymouth; A. M. Barford, L.R.C.P. Lond., Wokingham, Berks; D. T. Bekling, L.R.C.P. Lond., East Dereham, Norfolk; Robert Bird, L.R.C.P. Lond., Wrattlesley Road, Plumstead; S. A. Bonsor, L.R.C.P. Lond., 29, Castellan Villas, Barnes; J. G. B. Colby, L.R.C.P. Lond., 11, Percy Circus, W.C.; P. G. Gilmore, L.R.C.P. Lond., 24, Carleton Road, N. E. Heasman, L.R.C.P. Lond., Angmering, near Worthing; P. Hicks, L.R.C.P. Lond., Blastow Hall, Kent; A. W. L. Jones, L.R.C.P. Lond., 28, Sutherland Gardens, W.; W. B. Lane, L.R.C.P. Lond., 42, Great Russell Street, W.C.; K. McLaren, L.R.C.P. Lond., La plierne, Kingston Hill; S. C. H. Moberly, L.R.C.P. Lond., 17, St. Thomas Road, Finsbury Park; F. O. Kinealy, L.R.C.P. Lond., St. Bartholomew's Hospital; O. Steinthal, L.S.A., 54, Torrington Square, W.C. E. R. H. Whitehead, L.R.C.P. Lond., 340, Essex Road, N.; H. Williams, L.R.C.P. Lond., 3, Augusta Place, Weymouth, and A. E. Wynter, L.R.C.P. Lond., Templecombe, Twickenham, St. Bartholomew's Hospital; T. Austen, L.R.C.P. Lond., 40, Reedworth Road, Kennington; W. H. Burrows, L.S.A., Western House, Long Lane, S.E.; E. Cooper, L.R.C.P. Lond., Southampton Villa, Southsea; F. Grange, L.R.C.P. Lond., 81, Peckham Rye, S.E.; A. Purvis, L.R.C.P. Lond., 55, Tyrnham Road, Brockley, of Charing Cross Hospital; J. A. Ballingall, L.R.C.P. Lond., Altanton, Blairgowrie, N. B.; J. D. Brown, L.R.C.P. Lond., 83, St. Oswald Road, W.; G. W. B. Daniell, L.R.C.P. Lond., 57, Leinster Square, W.; G. A. Heberden, L.R.C.P. Lond., 18, Milton Chambers; F. S. D. Hogg, L.R.C.P. Lond., 17, Halsey Street, S.W.; W. S. Holford, L.R.C.P. Lond., Worcester House, Sutton; and N. B. Robinson, L.R.C.P. Lond., West Hill Road, Windsworth, of St. George's Hospital; H. Barnett, L.R.C.P. Lond., 17, Oakley Street, S.E.; E. S. Bell, L.R.C.P. Lond., Christ Church Vicarage, Spa Road, S.E.; A. H. Blunt, L.R.C.P. Lond., Market Place, Derby; H. C. Bristowe, L.R.C.P. Lond., 13, Old Burlington Street, W.; A. B. Cox, L.R.C.P. Lond., 37, Harrington Street, Derby; A. Goulston, L.R.C.P. Lond., 26, Peckham Rye; W. M. Helsham, L.R.C.P. Lond., 13, Barton Street, Westminster; O. W. Lockyer, L.R.C.P. Lond., 7, St. Julian's Farm, Road, West Norwood; S. G. Moore, L.R.C.P. Lond., St. Andrew's House, Herford; H. B. Seddon, L.R.C.P. Lond., 1, Queen Anne's Gate, S.W.; R. F. Walker, L.R.C.P. Lond., Vale Cottage, Esher, of St. Thomas's Hospital; H. N. Baron, L.R.C.P. Lond., 57, Great Ormond Street, W.C.; G. B. Flinx, L.R.C.P. Lond., 27, Harley Street; F. V. Peigge, L.R.C.P. Lond., Vernon House, Briton Ferry, South Wales; C. J. Stanley, L.R.C.P. Lond., The Knowle, Streatham, of King's

College; J. C. Barr, L.R.C.P.Lond., 1, Cranmore, Aldershot; F. A. Brooks, L.R.C.P.Lond., 6, Percy Road, Shephard's Bush; N. C. Ridley, L.R.C.P.Lond., Bratton Rectory, Burgh, Lincolnshire; and W. S. Sharpe, L.R.C.P.Lond., Mavis Enderby, Spilsby, of St. Mary's Hospital; R. A. Beaver, L.S.A., Waterloo, Liverpool; E. A. T. Steele, L.R.C.P.Lond., 2, Queen's Terrace, Seacombe, of Liverpool Infirmary; B. R. Sawhuy, L.R.C.P.Lond., 12, Ladbroke Grove, W., of Lahore College, India; L. Beckett, L.R.C.P.Lond.; L. C. E. Calthorp, L.R.C.P.Lond., The Cheal, Hornsey Lane, N.; B. Clark, L.R.C.P.Lond., Coldharbour Lane, Brixton; O. Collier, L.R.C.P.Lond., St. Aubyns, Tiverton; F. Corner, L.R.C.P.Lond., Manor House, Poplar; J. J. Coulton, L.R.C.P.Lond., 47, Bromley Street, E.; W. S. Fenwick, L.R.C.P.Lond., 29, Harley Street, W.; T. J. Head, L.R.C.P.Lond., 23, Queens Down Road, Clapton; R. Jones, L.R.C.P.Lond., Newtown, Montgomeryshire; F. J. Oxley, L.R.C.P.Lond., Drayton Road, Leytonstone; T. W. Robbins, L.R.C.P.Lond., 41, Etchingham Road, Stratford New Town, of the London Hospital; N. D. Best, L.S.A., Lime House, Walsall, Staffordshire, of Birmingham; E. F. Bour, L.R.C.P.Lond., University College; R. W. Boyce, L.R.C.P.Lond., Willoughby Road, Hampstead; H. N. Oappe, L.R.C.P.Lond., 7, Dean Road, Willesden Park; C. S. Dowdell, L.R.C.P.Lond., 25, Rutland Street, N.W.; J. P. Parkinson, L.R.C.P.Lond., 21, Richmond Terrace, Blackburn; W. B. Ranson, L.R.C.P.Lond., The Pavement, Notts.; C. E. Seal, L.R.C.P.Lond., 95, Albert Street, Regent's Park; C. H. Stevens, L.R.C.P.Lond., 21, St. Edmund's Terrace, N.W.; C. H. Clayton, L.R.C.P.Lond., 11, Fairfax Road, South Hampstead, of University College; G. Braide, L.R.C.P.Lond., The Poplars, Warrington; H. Wade, L.R.C.P.Lond., 5, York Place, Manchester; W. K. Walls, L.R.C.P.Lond., 46, Swan Street, Manchester; J. P. Williams, L.R.C.P.Lond., Broomfield, Swinton, Manchester; W. B. Yates, L.R.C.P.Lond., 14, Palatine Street, Manchester, of Manchester; R. S. Charsley, L.R.C.P.Lond., 5, Cowley Street, S.W.; G. C. Cory, L.S.A., 17, Sudeley Street, Brighton; H. S. Fremilt, L.R.C.P.Lond., 1, Margaret Street, W.; C. S. Vines, L.R.C.P.Lond., Abbotsford, Ramsgate, of Westminster Hospital; J. K. Couch, L.R.C.P.Lond., Mansel House, Swansea; M. P. Cooke, L.S.A., Fern House, Landkey, Barnstaple; C. W. Edwards, L.R.C.P.Lond., Mill Hill, Hendon; H. C. Fox, L.S.A., 14, Alfred Place, W.C.; J. A. Hudson, L.R.C.P.Lond., 75, Charlotte Street, W.C.; W. B. Nelson, L.R.C.P.Lond., 1, Shrewsbury Road, W.; A. Primrose, M.B. C.M.Ed., The College, Middlesex Hospital, of Middlesex Hospital; E. H. Gibbon, M.B.Durh., 1, Laygate Terrace, South Shields; E. R. Lyth, M.B.Durh., 39, Brooke Road, N., of Newcastle-on-Tyne; H. Hill, L.R.C.P.Lond., 84, Coronation Road, Bristol; C. T. Hudson, L.R.C.P.Lond., 6, Royal York Crescent, Clifton, and E. Ward, L.R.C.P.Lond., 7, York Place, Clifton, of Bristol.

MEDICAL VACANCIES.

The following Vacancies are announced:

OOMSBURY DISPENSARY.—Physician. Applications by May 15th to the Secretary.

IGHTON, HOVE, AND PRESTON DISPENSARY.—House-Surgeon. Salary, £140, with apartments, etc. Applications by June 2nd to the Assistant Secretary.

ISTOL ROYAL INFIRMARY.—House-Physician. Salary, £100 a year, with board, washing, and apartments. Applications by May 19th to the Secretary.

ESEA, BROMPTON, AND BELGRAVE DISPENSARY, Sloane Square.—Surgeon. Applications by May 17th.

ST LONDON HOSPITAL FOR CHILDREN, Shadwell, E.—Assistant Surgeon. Applications by May 23rd to the Secretary.

ST LONDON HOSPITAL FOR CHILDREN, Shadwell, E.—Surgeon. Applications by May 23rd to the Secretary.

RDON HOSPITAL FOR FISTULA, ETC., Vauxhall Bridge Road. Assistant Surgeon. Applications by May 26th to the Secretary.

LIFAX INFIRMARY AND DISPENSARY.—Senior House-Surgeon. Salary, £80 per annum, with board and residence. Applications by May 22nd to Dr. E. West Symes, Hoop Hall, Halifax.

SPITAL FOR DISEASES OF THE THROAT, Golden Square.—Resident Medical Officer. Salary, £50 per annum, with board and lodging. Applications by May 26th to the Honorary Secretary.

SPITAL FOR EPILEPSY AND PARALYSIS, 32, Portland Terrace, Regent's Park.—Assistant Physician and Registrar. Applications by May 14th to H. H. Graham, Esq., Secretary.

WESTOFT FRIENDLY SOCIETIES MEDICAL INSTITUTION.—Surgeon. Salary, £150 per annum, with extra fees. Applications by May 21st to Mr. J. Hammond, 4, Raglan Street, Lowestoft.

ETROPOLITAN HOSPITAL, Kingsland Road.—Assistant House-Surgeon. Salary, £40 per annum, with board and residence. Applications by May 21st to the Secretary.

ATIONAL LYING-IN HOSPITAL, Holles Street, Dublin.—Two Assistants to the Master. Applications to Dr. Roe, 13, Lower Fitzwilliam Street, or at the Hospital.

IRTH STAFFORDSHIRE INFIRMARY.—House Physician. Salary £100, with board, washing, and apartments. Applications by May 23rd to the Secretary.

WENS COLLEGE, Manchester.—Professor of Surgery. Applications by June 8th to the Registrar.

IRISH OF BARNET, ETC.—Medical Officer of Health. Salary, £443 per annum. Applications by May 14th to H. M. Turner, Esq., 66, High Street, Watford.

IRISH OF LOCHS, Stornoway.—Medical Officer. Salary, £140 per annum, with free house. Applications by May 16th to Mr. H. M. L. Ross, Inspector of Poor, Lochs and Barvas.

DYAL FREE HOSPITAL, Gray's Inn Road.—Assistant Physician. Applications by May 16th to the Secretary.

DYAL FREE HOSPITAL, Gray's Inn Road.—Assistant Surgeon. Applications by May 16th to the Secretary.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road.—Junior House-Physician. Salary, £50 per annum, with board and lodging. Applications by May 19th to the Secretary.

SMALL-POX HOSPITAL, Birmingham.—Resident Medical Superintendent. Salary, £150 per annum, with board, etc. Applications by May 25th to the Chairman, Health Committee, Council House, Birmingham.

VICTORIA HOSPITAL FOR CHILDREN, Chelsea.—House-Physician. Honorarium of £50, with board and lodging. Applications by June 2nd to the Secretary.

VICTORIA HOSPITAL FOR CHILDREN, Chelsea. House-Surgeon. Honorarium of £50, with board and lodging. Applications by June 2nd to the Secretary.

WEST LONDON HOSPITAL, Hammersmith Road, W.—Assistant Surgeon. Applications by May 24th to the Secretary.

MEDICAL APPOINTMENTS.

BLURTON, J. F., M.B.Durh., M.R.C.S., appointed Obstetric and Ophthalmic House-Surgeon at the Queen's Hospital, Birmingham, *vice* R. J. Riley, M.R.C.S.

BRYDEN, F. W. A., M.R.C.S., L.S.A., appointed Assistant House-Surgeon to the Rotherham Hospital.

CUFF, Robert, M.B.Lond., M.R.C.S.Eng., appointed Honorary Surgeon to Scarborough Hospital and Dispensary.

De RENZI, Arthur C. M.R.C.S., L.S.A., late of the New Zealand Shipping Company's R. M. S. *Rimutaka*, appointed Resident Surgeon to the Christchurch Hospital, New Zealand.

HALL, W. W., M.B., C.M., appointed Registrar and Chloroformist to the London Temperance Hospital, *vice* T. F. Pearce, M.D., resigned.

HEWITT, R. J., L.R.C.S.I., etc., appointed Medical Officer to the Ballingarry Dispensary, *vice* M. Fennelly, L.R.C.S.I., resigned.

HILL, J. de Vere, appointed Sanitary Surveyor (Board of Trade) for the port of Liverpool.

HILL, E. B., M.R.C.S., appointed Assistant House-Surgeon to the Birmingham General Hospital, *vice* E. Antrobus, M.R.C.S., resigned.

MELLER, C. B., L.R.C.P., M.R.C.S., L.S.A., appointed Medical Officer of Health for the Borough of Cowbridge, and Medical Officer, Public Vaccinator, and Medical Officer of Health for the Cowbridge District of the Bridgend Union.

NASON, E. N., M.B., M.R.C.S., appointed Resident Surgical Officer to the Birmingham General Hospital, *vice* John Elliott, M.B., resigned.

NICOLSON, R. H., appointed Assistant Medical Officer to the Warwick County Lunatic Asylum, *vice* G. P. Torney, L.R.C.S.I., etc., resigned.

OWEN, A. D., M.R.C.S., L.S.A.Lond., appointed Medical Officer to the Halwell District of Totnes Union, *vice* J. T. Cape, M.R.C.S.Eng., deceased.

PROWSE, A. B., M.D.Lond., F.R.C.S.Eng., appointed Lecturer on Materia Medica and Therapeutics at the Bristol Medical School.

SANCTUARY, T. M.D., L.R.C.P., etc., appointed Assistant Medical Officer to the London Skin Hospital, W.C.

SHAW, W. R., M.D., C.M.Toronto, L.R.C.P.Lond., appointed Resident Clinical Assistant to the City of London Hospital for Diseases of the Chest.

TORNEY, G. P., L.K.Q.C.P.I., L.R.C.S.I., appointed Assistant Medical Officer to the Lincolnshire County Asylum, *vice* J. W. Marsh, M.R.C.S., resigned.

WILLIAMS, P. W., M.B., appointed Honorary Assistant-Physician to the Bristol Royal Infirmary, *vice* A. B. Prowse, M.D.

POST-GRADUATE COURSE IN LIVERPOOL.—It is proposed to give at the Victoria University, during the summer session, a post-graduate course of lectures and demonstrations, commencing on May 16th. The fee for the course is two guineas. Among the lecturers and subjects announced are the following: Mr. Reginald Harrison on Affections of the Bladder and Urethra, including demonstrations with the Electric Endoscope; Dr. Glynn: Some Points in the Pathology and Treatment of Infective Diseases of the Heart; Dr. Carter: On the Practical Examination of the Urine (demonstrations); Dr. Davidson: On the Medical Selection of Lives for Assurance, and on recent Improvements in the Local Treatment of Skin Diseases; Mr. Edgar Browne: Diseases and Defects of the Eye in Childhood; Dr. Ross: On the Anatomy of the Spinal Cord and the Localisation of Spinal Lesions; Mr. Royston: On the Teeth; Mr. Mitchell Banks: On the Anatomy of the Brain in relation to Cerebral Surgery; Dr. Wallace: On Abnormal Tumours; Mr. Paul: Demonstration of a *Post-mortem* Examination made for Medicolegal Purposes, and Ready Methods for the Detection of Common Poisons; Mr. Rushton Parker: Recognition and Treatment of Injuries to the Upper and Lower Limbs; Dr. Caton: On Ptomaines and Leucomaines; Dr. Barron: On Pathogenic Micro-organisms. It is intended that, if possible, June 6th, 20th, and July 11th, shall be devoted to demonstrations of the Different Forms of Insanity in a Lunatic Asylum.

HUNGARIAN MEDICAL WORKS.—The Society for the Publication of Hungarian Medical Works last year completed the twenty-fourth year of its existence. During that time 55 large and 7 small medical works have been published in the Hungarian language, at an average yearly cost of 6,750 florins. Three hundred members have already signified their intention to join the Society.

CENSURE OF A POLICE SURGEON BY A JURY.—Rather too much blame seems to have been attributed by a Deptford coroner's jury to a young surgeon acting for the divisional police surgeon, who, on being called to the police station—which was full of men waiting to be paid, and therefore greatly crowded—failed to detect that a prisoner, who had perforce been placed in a passage outside the cells, was suffering from paralysis in addition to drink. According to the newspaper report, the senior medical officer of Greenwich Workhouse Infirmary, who made the *post-mortem* examination, attributed death to syncope, caused by taking too much beer, combined with the existence of a fatty heart. It is quite possible that the paraplegia, which the young surgeon alluded to promptly diagnosed on a second visit, had come on subsequently to the first examination.

TREATMENT OF MERCURIAL STOMATITIS.—In the *Rivista Clinica e Terapeutica* for February, Dr. E. de Renzi, of Naples, states that he has treated several cases of mercurial stomatitis with corrosive sublimate with satisfactory results. He was induced to try this plan by the consideration that a powerful antiseptic was indicated in a disease characterised by well-marked putrefactive processes. The remedy was prescribed as a mouth-wash, a solution of 25 centigrammes of corrosive sublimate in 1,000 grammes of water being used in that manner in the course of two days. On the first day the foul smell of the breath was removed, and within three days the redness and swelling of the mouth had much diminished. On the fifth day, as a rule, the patient was completely cured.

MEDICINE IN PORTUGAL.—The *Correio Medico de Lisboa* of May 1st states that twelve students will present themselves for their final examination in the Medico-Chirurgical School of Lisbon in July next. The following are among the subjects which the candidates have chosen for their theses; they are of some interest as showing that Portugal is alive to the latest developments of medical science: Radical Cure of Hernia; new methods of Diagnosing Carcinoma of the Stomach; Pathogeny of Tetanus; new Treatment of Chronic Metritis and Fibroid Tumours of the Uterus by Electricity; Uses of Antipyrin; Hypnotism and Suggestion; Massage in the Treatment of Fractures; Anomalous Forms of Typhoid.

DARENTH HOSPITALS.—The Local Government Board have authorised the Managers of the Metropolitan Asylums Board to erect at Darenth a hospital for convalescing small-pox patients, at a cost not exceeding £63,392; and also to cause the Darenth camp buildings used in the last small-pox epidemic to be adapted to infirmary purposes, at a cost not exceeding £2,750. It was resolved to apply to the Metropolitan Board of Works for a loan of £50,000 for the erection of the hospital.

AMBULANCE INSTRUCTION FOR THE POLICE.—Mr. John Furley, Deputy Chairman of the St. John Ambulance Association, presented 104 certificates last week to members of the Metropolitan Police Force, who had shown themselves proficient in the principles and practice of "first aid." The Chief Surgeon of the Force, Mr. A. O. McKellar, spoke in warm terms of the numerous cases of valuable "first aid" rendered by police officers brought to his notice,

WILLIAM HENRY BURKE, M.R.C.S., of Monk Bretton, near Barnsley, who, on February 9th, discharged a revolver at his daughter, aged nine years, in a public-house where he had been drinking heavily during the day, was charged with the murder at the Leeds Assizes, found guilty, and sentenced to death.

On June 12th the University of Bologna will celebrate the 800th year of its existence. This university is said to be the oldest in the world, having been founded by the Emperor Theodosius II in the year 425 A.D.

DR. GARRÉ, hitherto Privat-Dozent in Basle, has become an assistant surgeon in the surgical clinic and Docent in Surgery in Tübingen. Dr. E. Haflter will take his place on the editorial staff of the *Correspondenzblatt für Schweizer Aerzte*.

PRIVAT DOCENT DR. ENGELHARDT, in Halle, becomes Extraordinary Professor of Gynaecology in the University of Iena, in place of Professor Küstner, who has been invited to Dorpat.

THE Commission of the Peace for the town of Belfast has been offered to Dr. Whitla, who has, we understand, declined the proffered honour.

DIARY FOR NEXT WEEK.

TUESDAY.

PATHOLOGICAL SOCIETY OF LONDON, 8.30 P.M.—Mr. J. Hutchinson jun.: Dupuytren's Fracture. Mr. Ballance and Mr. Shattock Note on the Histology of Cancer and Normal Tissues after Sterile Incubation. Mr. Bruce Clarke: Sloughing of Bladder following Cystitis. Mr. Vincent Jackson: Sarcoma of Bladder. Dr. Turner: Necrosis of Kidney. Mr. Fenwick (for Dr. A. Jones): Localised Tuberculosis of Ureters. Mr. Targett: Peculiar Fracture of Skull. Dr. Pitt: 1. Malignant Growths of Bronchial Glands and Pleura; 2. Spinal Cord from Dr. Collier Case of Charcot's Joint Disease. Card Specimens: Mr. Coleman: Polyypus of Umbilicus. Mr. S. Paget: 1. Unusual Fracture of Head of Humerus; 2. Adenoma of the Tongue. Dr. Collier: Curious Fracture of the Larger Pastern Bone of a Horse. Dr. Ormerod: Cancer of Gall Duct; Mr. V. Jackson Stone from a Vesical Diverticulum. Mr. Fenwick (for Dr. Harris): Bilharzian Carcinoma of Bladder. Mr. Stonham: Tubercle of Prostate and Vesiculae Seminales; 2. Cancer of Prostate, Prostatectomy; 3. Melanotic Cancer of Bone; Two Specimens of Cancer of Oesophagus necessitating Tracheotomy; 5. Hematocele with Tunica Vaginalis from Difficult Breech Delivery; 6. Cyst of Peritoneum. Mr. Battle: 1. Duct Cancer of Breast; 2. Very Early Malignant Disease of Testis. 3. Sarcoma of Lower Jaw Associated with Necrosis. Mr. O'Connor: Hydatida of Liver and Spleen. Mr. Lunn: 1. Tabetic Feet; 2. Calvaria, Clavicle, and Lower Jaw from a Case of Osteitis Deformans; 3. Multiple Epiphysitis. Dr. Hebb: Cancer of Thyroid Isthmus; 2. Tuberculosis of Breast.

WEDNESDAY.

COLLEGE OF STATE MEDICINE, Burlington House, 4 P.M.—Professor G. H. Seeley, F.R.S.: On Soil in its Influence on Health.

ROYAL METEOROLOGICAL SOCIETY, 7 P.M.—Mr. G. M. Whipple and Mr. W. H. Dines: Report of the Wind Force Committee on Experiments with Anemometers conducted at Hershham. Dr. William Marcet (President); On the Measurement of the Increase of Humidity in Rooms by the Emission of Steam from the So-called Bronchitis Kettle.

THURSDAY.

HARVEIAN SOCIETY OF LONDON, 8.30 P.M.—Mr. W. Bruce Clarke: The Value of Antiseptics in Internal Urethrotomy.

FRIDAY.

SOCIETY OF MEDICAL OFFICERS OF HEALTH (Crane Court, Fleet Street), 7.30 P.M.—The following papers will be read. Mr. C. A. Watts Parkison: Notes of an Epidemic of Poemonia. Mr. J. F. J. Sykes: Verification and Certification of Deaths. Mr. F. J. Lloyd: On the Powerlessness of the Public Health Act for the Closure of Wells Supplying Contaminated Water.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d which should be forwarded in stamps with the announcement.

BIRTHS.

HOOKE.—On May 7th, at Cirencester, the wife of Charles Hooker, of a daughter.
KNOWLES.—On May 7th, at 5, Ashford Road, Maidstone, the wife of John Knowles, surgeon, of a daughter.
NAPIER.—On May 5th, at 3, Beaufort Gardens, S.W., the wife of A. D. Leitch Napier, M.D., F.R.S.E., of a son.

DEATH.

SHEEHY.—On April 30th, at 4, 'Claremont Square, N., Myra, wife of W. H. Sheehy, L.R.C.P.Lond., aged 29.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS respecting editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivered of the JOURNAL, etc., should be addressed to the Manager, at the Office, 42 Strand, W.C., London.

In order to avoid delay, it is particularly requested that all letters on editorial business of the JOURNAL be addressed to the Editor at the office of the JOURNAL, and not to his private house.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL, are requested to communicate beforehand with the Manager, 42 Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication. **CORRESPONDENTS** not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

QUERIES.

D., in practice, wishes to know what books are usually read for the London College of Physicians final.

NERLEY asks which would be the best sea voyage, lasting about three months out and home, for a phthisical patient whom he wants to be at sea, starting middle of May.

ESERINE.

writes: 1. When and by whom was this name first applied to the active principle of the Calabar bean? 2. Where is the earliest mention of it to be found? 3. What is the derivation of the word?

ANSWERS.

Y. Z. should put himself in communication with the Registrar of the General Medical Council, W. J. C. Miller, Esq., 299, Oxford Street.

LECTURES AT THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.
A. JOHN INCE.—The lectures at the Royal Colleges of Physicians and Surgeons are always noted in the Diary for the next week, which is published weekly.

MEDICAL BOOKKEEPING.

D. writes: In reply to your correspondent, "M.B., C.M.," let me recommend him to try the "A. B. C." system of medical bookkeeping. It is infinitely more simple, accurate, and rapid than any other system with which I am acquainted, and before I adopted it I had tried a number. It is suited to any size or class of practice, and can be commenced at any time. I believe it is much used now, and it will certainly revolutionise the bookkeeping of doctors, doing away with the wearisome rudgerery and the immense losses which have been general among them. The publisher is Mr. Allsop, Saltire, near Leeds.

MBYSES writes: When I remember many of the horrors I endured over the lay books and ledgers of others in years gone by, I am thankful that necessity, the mother of invention, has stimulated me to devise a *multum in parvo* for my own use and comfort. All one wants in ordinary practice is as follows:—

1. Loose leaves to be fastened together as they increase by a clip, on which can be pencilled down every day names and memoranda.
2. Prescription book for recipes like to be repeated or wanted again at some time (one in five, say, at most), at least, that is my experience.
3. Silverlock's, or Smith's *Monthly List*, with column in same page of aggregate fees opposite each name, which can always be verified at a glance.
4. Ledger, in which the sums for each month are simply entered, under the proper name with member of family also if preferred.

This system answers all practical purposes, and saves a mint of time to the busy practitioner, let alone worry.

D. writes: If "M.B.," "C.M." will refer to Sections 565-5 of the *Medical Digest* and appendix. He will find a clue to all the various plans which have been recommended in the *JOURNAL* since 1880, excepting the last, which appeared in June, 1886.

CONSTITUTIONAL SYPHILIS.

ONE writes: In answer to the question of "Hermes," the impregnation must have taken place before the syphilitic eruption appeared; had it occurred after, the mother would have aborted a syphilitic ovum of two or three months' gestation. In the supposition assumed the child will not be syphilitic; but now constitutional syphilis has declared, four or five abortions will result—if there be so many pregnancies—each successive gestation being more prolonged, until in time a living birth results. This, in my experience, will be the course whether mercury be given, or time only assuages the acuteness of the evil. To procure abortion on mere supposition of syphilis would be criminal; if acute syphilis exist in the fetus it is certain to be aborted.

R. J. BRYDEN (Gravesend) says, in answer to "Hermes": I attended in her confinement, about a month ago, a person whose husband a year previously had given her syphilis. She came to me suffering from bad "secundaries," and, although under proper treatment, the disease was very obstinate; yet, after three or four months course of mercury, she got much better. She had sore throat, with severe ulceration of one of the tonsils. The hair fell out, and her skin presented a marked psoriatic eruption, etc. I quite expected to see a syphilitic fetus, but she went the full term, and was delivered of a healthy child, and it has remained so up to the present time of four weeks. She got very weak and exhausted during the labour, so I used the creeps, and she afterwards made a rapid recovery.

This case proves that the child need not of necessity be syphilitic. It is absolutely necessary for the mother to take mercury, and there is no justification in such a case to procure abortion or induce premature labour.

AVENA.

A. DE WATTEVILLE writes: The answer given by Dr. Aspinall to "Member" in your last issue will no doubt have satiated his hunger for botanical knowledge, but hardly satisfied his therapeutic curiosity. What he wants to know is that there is an American concoction known as "tinct. avena sativa" (with New York), reputed to be "a powerful nerve stimulant, tonic, etc.," and recommended for the cure of paralysis, writers' cramp, epilepsy, chorea, cholism, insomnia, nerve exhaustion, etc. "Member" will probably be tempted (and wisely) to ask himself how this American tincture of common oats can differ so much from the Scotch decoction, or porridge, as to acquire so marvellous therapeutic properties ascribed to it by its promoters?

P.S.—Since writing the above, I came across the following report (*New York Medical Journal*, April 21st, 1888) by Dr. H. Smith, Professor of Chemistry Yale College:—"I have separated from the preparation ('Scotch oats tincture') a considerable quantity of morphia."

GRADUATION IN AUSTRALIA.

BEN DOWN asks whether a student, who is obliged to go to Australia, can qualify in the colony, and, if so, what qualifications are available, where, and at what?

* The universities of Sydney (New South Wales) and of Melbourne (Victoria) grant degrees in medicine after a curriculum has been kept and certain

examinations passed. In both properly attested certificates of attendance on lectures at a recognised school are accepted as proof *pro tanto* of attendance on lectures and examinations required by its by-laws. A degree in Arts, or some similar literary or scientific certificate is required by the University of Sydney. The University of Melbourne requires matriculation in it, or in some university recognised by it. The total fees for education and graduation at the University of Sydney amount to £171 12s., but of this only £12 is payable to the University, the remainder being for hospital practice and systematic classes. Fuller particulars will be found in Bruck's *Australian Medical Directory*, Sydney: Australasian Medical Gazette Office. London: Baillière, Tindall, and Cox. 1886.

A TONIC PILL.

A. H. C.—Richardson, of Leicester, prepare a sugar-coated pill, No. 95, containing 1 grain each sulphate of quinine and sulphate of iron, and 1-8th of a grain of nuxvomica, which is an excellent combination. This is probably the pill referred to.

TREATMENT OF PALMAR PSORIASIS.

VICTUS asks to be recommended treatment for so-called "psoriasis palmaris," which has baffled all recognised methods for the past two years.

. The effect of macerating the skin in its own secretions might be tried by the use of india-rubber gloves. If this fails, the hard epidermis might be softened and removed by the application of Beiersdorf's salicylic gutta-percha plaster, and stimulating remedies applied subsequently. Valuable indications will be found in the larger works on skin diseases recently published.

PRACTICE IN AMERICA.

M.D., M.R.C.S.E. (Philadelphia, Penn.) writes: In reply to "Stars and Stripes," and at the same time correcting a grave mistake of "Yankee's" in his reply to "Stars and Stripes," I would say that an English graduate will have no difficulty whatever in securing the proper registration in any of the States of the Union. The examination required is simply formal, as the examiners themselves will tell you. "Yankee," unlike the original Yankee, remarks that it would be hard for an Englishman to pass. This is an intentional error (I feel like saying lie), since anyone who knows the relative standing of the profession in both countries will bear me out in my assertion. It would be no advantage for an English graduate or licentiate to possess an American M.D. It would be to him less than "thank'ee for nothing." And should he desire one (M.D.) he would have little trouble in securing it. "I speak whereof I know," since I am graduate of England and America.

THE "MEDICAL DIGEST."

A COUNTRY DOCTOR writes: If "A Member" (*JOURNAL*, April 21st, p. 856) will have his BRITISH MEDICAL JOURNALS bound, which any bookbinder will do for half-a-crown a volume, he will find the *Medical Digest* more useful to him than the new editions of textbooks on medicine, surgery, or midwifery.

THE LETTER OF THE LAW AT THE GENERAL MEDICAL COUNCIL OFFICE.
SURGEON-MAJOR (Indian Medical Department).—The Registrar of the General Medical Council is bound by law to keep his *Register* correct, and for this purpose sends letters of inquiry as to change of address to the addresses given by the persons registered. If these letters are not answered, it is held to be the duty of the Registrar to remove the name from the *Register*. Registered persons are required to take care that their addresses are correctly given. Our correspondent appears to have great cause of complaint against the India Office, and probably, if representations were made in the proper quarters, the difficulty would be overcome.

NOTES, LETTERS, ETC.

DISEASE OR TOXÆMIA.

SURGEON P. H. FOX (Castlebar) writes: I have been much impressed by Dr. Alfred Carpenter's most interesting paper on "The Difficulty in Diagnosis between Symptoms produced by Disease and those produced by Drugs," which appeared in the *JOURNAL* of March 24th, 1888; and, as the subject is one of great importance to military as well as to civil surgeons, I beg to offer a few remarks, and to give a brief description of a case in point. I have had some experience in these cases, and, as Dr. Carpenter so well remarked, it is not always easy to distinguish between "dead drunk," cerebral compression, and narcotic poisoning. In fact, when called suddenly to see a patient in a cell or barrack-room suffering from intense coma, it is often almost impossible to arrive at a correct diagnosis; and, unless there happens to be some person present who can give a satisfactory history of the case, the real cause of the comatose condition cannot be determined. The following is the latest case which I have had bearing on the subject.

Private J. H., Royal Welsh Fusiliers, aged 20, was found in a most intense state of coma in his barrack-room on the morning of March 26th, shortly after the "rouse" was sounded. His comrades and the non-commissioned officer in charge of the room were interrogated, but nothing could be elicited which would in any way account for the man's condition. They merely stated that he was a most temperate man, drank nothing the day before, never had fits, went to bed apparently in good health, and at "rouse" they found him in his present condition. I had him conveyed to the hospital on a stretcher, where I made a most careful examination.

The pulse, temperature, and respirations were normal; the heart and lungs were also healthy. I passed a catheter and drew off a few ounces of urine, which I found to be normal in every respect. There was no smell from his breath, no oedema or swelling, no wounds or other marks of violence on his head or on any part of his body; yet there he lay, perfectly unconscious. Slapped in the face with a wet towel, he opened his eyes and gazed vacantly for a moment or two; and then, closing them gradually, he went on to sleep as before. The pupils were slightly dilated, but sensibly to light. There was neither congestion of the countenance nor suffusion of the eyes. In this state the patient remained for two nights and three days, having slept sixty hours without partaking either of food or drink.

Medically speaking, the only thing I did for him was this. Finding the ordinary means of resuscitation ineffectual, I plied him with enemata, drew off his urine, and blistered the nape of his neck. After a good deal of yawning

REMARKS

ON

THE TREATMENT OF CARBUNCLES
AND BOILS.

By SIR PETER EADE, M.D., F.R.C.P.,

Senior Physician to the Norfolk and Norwich Hospital.

THE very valuable papers by Mr. Page and Mr. Rushton Parker recently published in the BRITISH MEDICAL JOURNAL aptly recall attention to the subject of the local treatment of carbuncles as well as boils, and I think yet a few more words may well be said on this matter.

The contribution of Mr. Page refers chiefly to the treatment of carbuncle in its advanced stages, and especially to the method of then treating it by incision and scraping away as far as possible the sloughing and diseased mass which gradually forms in the course of this disease. It is doubtless in these later stages that this method of procedure by abrasion or scraping appears most applicable, because it is then that the soft, boggy material exists in considerable quantity, and the size of the peculiar "core" or slough is then such as to make its removal desirable for every reason. In all three of Mr. Page's cases the carbuncle had reached a very forward stage, the diameters of the swellings being four, five, and eight inches respectively, and in all the disease having existed for from two to three weeks. The results appears to have been in all of them highly satisfactory.

Mr. Parker's cases carry these views as to the desirability of surgical interference still further, and press upon consideration the question of always treating carbuncles and boils at all their stages by removal or destruction.

These views are, of course, in direct opposition to the opinion expressed by Sir J. Paget as to the propriety of non-interference in these cases, but they strongly confirm the recommendations given by the late Mr. James Startin (BRITISH MEDICAL JOURNAL, vol. ii, 1866) in a most practical paper on this subject.

Many years ago I devoted considerable attention to these diseases, and I published several papers (see *Lancet*, 1869 and 1874, and BRITISH MEDICAL JOURNAL, 1876) advocating the free use of caustics for their destruction. Then, as now, all evidence went to show that a carbuncle (like a boil) was mainly a local disease, and that its career could be cut short at almost any stage, from its earliest one of a pimple with an open apex, through that of a solid papule, to the fully-formed condition of a pulpy mass with its characteristic cribriform and discharging openings.

The several cases so recently published show once more what are the true theoretical principles on which we should act, and also how effective is the knife or the spoon in removing the disease and relieving the patient. I would urge that they forcibly inculcate the duty of considering in every case whether prompt surgical interference is not called for, not only when the disease is large and fully formed, but also when smaller, yet slowly but surely advancing in its well-known course, and is certainly involving the patient in a prolonged illness attended with much pain and general suffering, as well as the possibility of some danger to life.

That the disease is not only local, but is due to the presence (or products) of a micrococcus, is now practically established (see Mr. Watson Cheyne's Lectures, 1888, etc.), and there is now little doubt that the multiplication and spread of a mass of germ-growth (? *staphylococcus pyogenes aureus*) from the centre or original pimple in a circular form outwards and outwards is the essence of the disease.

Like anthrax and malignant boils generally, carbuncle is in its early stages undoubtedly curable through local destruction or removal. But it seems that a necessity for increased strength of the destructive agent steadily increases as the period of its existence is prolonged. At first the pimple may be almost certainly destroyed by continuous soaking with a solution of boracic acid, salicylic acid, or other mild antiseptic. At a little later period it

may usually be aborted by inserting freely into its central or cribriform openings some strong solution of carbolic acid in water or glycerine, or by adopting one or other of the methods suggested by Mr. Startin (JOURNAL, vol. ii, 1866). But when it has become large and solid, and much surrounding tissue has been infiltrated with the growing germs and their products, the disease appears to be chiefly susceptible of surgical treatment by partial or entire excision, or incision with scraping away of the boggy material, as recommended and practised by Mr. Page.

In cases where this severer form of treatment is either declined or thought inexpedient, there is then nothing for it but such careful expectant treatment as Sir J. Paget recommends; although my own experience shows that even in the later stages the free application of oil or glycerine of carbolic acid, alone or upon a poultice, or inserted into the openings, has a marked effect in penetrating and rapidly improving the condition of the sloughy mass, and apparently in hastening its separation.

None of the usual local caustic applications are otherwise than painful, for the spreading growth is always excessively tender, but nevertheless, in many cases, it is well worth while to submit to the pain of the application in the early stages, rather than incur the risk of one, two, or three months' severe and, perhaps, dangerous illness. But in some other cases it is almost imperative to try and abort or destroy the nascent growth, as, for example, in carbuncle commencing upon the face or upper lip, which is, perhaps, its severest form. A few years ago it happened that a well known surgeon in this county was attacked with a carbuncle of the lip, which was treated in the ordinary way by poultices and the other usual methods of soothing and expectant treatment. This gentleman was severely ill, and in considerable danger of his life for several weeks. He was compelled to leave his home and to relinquish practice for several months; and when he returned, the whole side of his face was deformed and distorted from the contraction of cicatricial tissue, and his face and chin were reddened and disfigured for life.

Very shortly after this I was asked to see another medical man in whom the same form of the disease had begun, and was rapidly spreading. It began at the right side of the upper lip, and had extended nearly to the middle line, and the lip was swollen, tense, and very painful, whilst several small openings had already formed. Remembering the other recent and unfortunate case, which I quoted to the patient, I persuaded him to allow me freely and frequently to insert a strong carbolic glycerine solution into every part of the swelling where a hole permitted it. The process was disagreeable and somewhat painful, yet the good result obtained encouraged us to persevere, and in three or four days we had the satisfaction of finding that the increase of the growth was quite stopped, that the tension and swelling were steadily subsiding, whilst bright red granulations (such as carbolic acid will often produce in the base of a sloughing tissue) began to show themselves.

In two or three weeks from the commencement of the attack this gentleman was absolutely well, quite free from deformity, and almost free from any cicatrix, the result exhibiting a marked and gratifying contrast to that in the case of his professional brother.

Boils are not identical with carbuncles, for they have a different size and aspect, a different life-history, and an entirely different duration; but they are evidently closely akin, alike local and "fungoid," and the theory of their treatment must be the same, however modified in practice by their lesser importance. And they are markedly contagious, for there is strong reason to believe that what is commonly called a "crop of boils," and is often attributed to some blood-fault, is essentially the result of auto-inoculation, and that each successive boil is due to the implantation in the skin of fresh seeds or germs from the preceding one. It is well known that a nascent boil may be easily aborted by a point of some strong caustic. The same result may be more easily and pleasantly obtained (as in the earliest stages of carbuncle) by soaking the commencing pimple frequently with a solution of salicylic acid; and I had the satisfaction a short time since of thus entirely stopping the progress of "a crop of boils" in both husband and wife, who had clearly infected each other, by the adoption of this very simple and painless process.

The whole tenour of our increasing knowledge of both carbuncles and boils appears to me strongly to point not only to the certainty of their local and parasitic nature, but also to the desirability of their destruction and removal at the earliest stage at which they come under our observation.

ABSTRACT OF
CLINICAL LECTURES
ON
CARCINOMAS OF THE BREAST WHICH
REQUIRE AN OPERATION.

By N. C. MACNAMARA, F.R.C.S.,
Surgeon to the Westminster Hospital.

LECTURE I.

SIR B. BRODIE, in his lecture on the treatment of scirrhus tumours of the breast, observes, "that terrible as is the fate of persons suffering from carcinoma, and desirable as it may seem to remove such tumours, we must remember that the larger proportion of those operated on die within two or three years afterwards, and, in many cases, instead of the operation stopping the disease, it actually seems to hasten its progress." This opinion was formed some fifty years ago by one of the ablest surgeons England has produced; and the question is whether there is reason to suppose that recent improvements in surgery enable us to modify our ideas on this subject. Sir B. Brodie commences his lecture on the treatment of scirrhus of the breast by stating that, from a clinical aspect, carcinomas in this situation may be divided into two classes: those in which the tumour in the course of a few months reaches a large size, the whole of the gland being converted into a malignant growth; and secondly, slowly-growing tumours, which in their early stages appear as if embedded in the substance of the gland. The peculiarity of the rapidly-growing carcinomas is that the diseased action seems to involve simultaneously the whole of the epithelial structures of the affected gland; its progress is remarkably rapid, neighbouring glands as well as distant organs of the body being speedily implicated, so that the patient usually succumbs to the disease within twelve months of its first appearance.

For instance, Mrs. M., aged 38, first came under my care in the Westminster Hospital on November 4th, 1886. Her family and previous history were good. She had had eleven children, and had weaned her baby just before being admitted into the hospital on account of a submammary abscess on the left side. The abscess was opened on November 12th, and the patient left the hospital on December 1st; the wound had then healed, and the breast, although indurated, appeared otherwise to be healthy. On February 3rd, 1887, Mrs. M. was readmitted. Her left breast was then fixed to the chest-wall, and projected uniformly forwards; it was extremely painful; the skin was of a dusky red colour, in places dimpled and attached to the gland. The breast felt tense but elastic; the axillary glands were enlarged. The patient urged me to operate, and, as she was suffering intense pain I did so, removing the whole of the diseased structures. Mrs. M. left the hospital in March, having made a good recovery from the operation; but within six months she returned, with recurrence of the carcinoma in her left side, and evidently in a dying condition, and that within nine months from the time when the abscess formed in her breast.

With reference to these rapidly-growing cancers, the opinion expressed by Sir B. Brodie was correct; he states that "an operation never succeeds, but it rather hastens the progress of the disease." This form of carcinoma is usually preceded by mastitis or by injury to the gland, but such cases hardly form 5 per cent. of instances of cancers of the breast we meet with in practice.

With reference to the second class of cases mentioned by Sir B. Brodie, and in which the cancer has first appeared as a hard lump in the breast, and has since grown in the course of twelve months or more to about the size of a pigeon's egg, I think these tumours should be subdivided into two classes in which the scirrhus has been first observed after the cases in which the scirrhus has been long observed probably for some 50 years of age, the catamenia having probably ceased for some two or three years, and those in which the "change of life" had lately ceased for some two or three years, and in which a carcinoma has commenced before the change of life has taken place.

Supposing a patient with a densely hard tumour in the breast, which has long existed for two years, and

during that time has grown to be as large as a pigeon's egg, the skin over the tumour being dimpled and fixed to the mammary gland; there is a suspicion of the axillary glands being enlarged, and the patient has lately experienced a considerable amount of pain in the part. In such a case, if the individual is upwards of 50 years of age before the tumour had been noticed, the menses having ceased for some time, I should hesitate to perform an operation, but caution the patient against allowing her to do anything else to rub or press upon the breast. My reason for forming this opinion would be based on the experience I have gained as to the results which in such cases follow an operation, as contrasted with those which are observed when the disease has been allowed to run its course. The mammae, at the period of life when I have supposed the tumour to have developed, are slowly undergoing atrophic changes, and it is not unreasonable to hope that a morbid growth forms in them, it may with the breast, unaided, pass into fibrous tissue and so become converted into a cicatrix. For instance:

I was asked by Dr. Potter to see a patient suffering from scirrhus of the right breast; the woman was then 52 years of age, and had ceased to menstruate for about five years; she had for some time noticed the lump in her breast, regarding which she sought for my opinion; this was in 1879. The tumour was about the size of a pigeon's egg; the skin over it was dimpled and adherent to the growth, some of the axillary glands were enlarged. It is now nearly 9 years since I first saw this patient; she is still in excellent health, the breast has become converted into a dense cicatrix and the axillary glands appear to have undergone similar changes.

We have another patient attending the hospital at present. She observed a nodule in her right breast when she was 55 years of age; it had been in existence for a considerable time and she did not think it had increased in size lately; the skin, which was adherent to the growth subsequently ulcerated; the woman had been under observation for seven years, and, although she has suffered much from pain in the part she is now in very good health and well able to do her work in life: I do not think this would have been the case had I excised the breast seven years ago.

Cornil and Ranvier, writing on cancer, remark that "the certainty of their dissemination is in proportion as the disease is longer standing;" this is not my experience in the class of cases above referred to. On the other hand, Sir B. Brodie was right when he remarked that "if you are doubting about the expediency of an operation, and the disease be in an indolent state, the recollection of such cases as these, where the patient has lived with scirrhus of the breast unaltered for many years, should be sufficient to incline you to reject it." I would, however, restrict this observation to the class of patients who are advanced in life before the tumour develops; such cases form, perhaps, 10 per cent. of all the slowly growing cancers of the breast which are met with in practice. This opinion, as I have already remarked, is founded on my own experience, and I have no desire to fortify it by referring to statistics of cancer of the breast, for I think that if applied to a subject of this kind, are often misleading. Probably few surgeons were better able to appreciate this fact than Sir B. Brodie; and it is quite possible he may have had the matter prominently brought to his notice, with regard to the treatment of carcinoma of the breast; for Sir Charles Bell had written forcibly on the advantages to be derived from excision of the gland when affected with cancer. Sir Charles, in his Edinburgh lectures, taught that excision failed in the greater number of cases because the operation was delayed too long; on the other hand, Dr. Alex. Munro, of the same school, published a paper in which he stated "that of nearly sixty cases of cancer he had seen extirpated, only four were free of the disease at the end of two years." In reply to this, Sir Charles remarks it was natural that Dr. Munro should have formed so bad an opinion of excision of the breast for cancer, because he was only a consultant, and, therefore, saw none but far advanced cases of the disease. Sir Charles observes "before applying for this kind of assistance, private surgeons are usually consulted, who generally retain the patient under their own management if the case does not appear to be desperate, or if any reputation is likely to be got from an operation." In order to prove the correctness of this idea, Sir Charles quotes the following from a paper written by his friend Dr. Hill, of Dumfries: "He was the more readily induced to do this from knowing that no fallacy or mistake could occur in the relation, Mr. Hill having been so exact as to keep a register of every case." The statement which Sir C. Bell thus endorses as being accurate shows to what remarkable purposes figures may be turned in reference to the sur-

gical treatment of disease; for Mr. Hill asserts that he had not only extirpated eighty-eight genuine cancers, all of which except four had ulcerated, with only two deaths, but that of seventy-seven such cases, sixty-six continued free of cancer as long as they lived, so that "the different patients lived as long after extirpation of the cancer as, according to the bills of mortality, they would have done had they never had any cancer, or undergone any operation." Sir Charles in this way disposes, to his own satisfaction, of his friend the "late justly esteemed" Dr. A. Munro. I have no desire to follow his example, and attempt to strengthen my opinion regarding carcinomas of the breast which should be operated on by referring to figures, for "everyone knows how easy it is to twist statistics to suit any moral which the manipulator is anxious to enforce."

Excluding cases of cancer which have advanced beyond hope of relief and those whose health is seriously compromised by some other disease, Sir B. Brodie avoided operating on rapidly-growing carcinomas, as well as on those very slowly-growing tumours above referred to. He was also disposed to hesitate in operating when the skin and axillary glands as well as the breast were affected with cancer in younger persons. There seems good reason why he should have formed this opinion, because fifty years ago the death-rate directly following an operation for excision of the breast was hardly less than 16 per cent., and if the glands were removed it rose to 25 per cent. With a risk of this kind from the operation, and the certainty that by far the larger proportion of those who survived excision of the glands would die of cancer within two years, Sir B. Brodie was right in declining to operate unless in exceptional cases of this kind. Thanks, however, to drainage, anaesthetics, and antiseptics, we may now take a more favourable view of the risks incident to excision of the breast; the death-rate from this proceeding has diminished of late years, and the pain from the subsequent dressings has been greatly alleviated, so that we are not only justified, but it is our duty to remove a large proportion of carcinomas of the breast, although the skin and axillary glands are diseased; we may thus hope to prolong life, and we have good reason to believe that we shall also save our patient much suffering. It is true there are a certain few cases of rapidly-growing carcinomas of the breast, and some very slowly-growing tumours we had better leave to run their course, but these do not form more than 12 or 15 per cent. of all the cases of scirrhus we meet with, and their existence cannot justify practitioners abstaining from excising the affected gland in the large majority of cases, especially in the early stages of the disease, a subject to which I shall return in my next lecture.

MODE OF FIXATION OF THE SCAPULA, SUGGESTED BY A STUDY OF THE MOVEMENTS OF THAT BONE IN EXTREME FLEXION OF THE SHOULDER-JOINT: ITS BEARING UPON FRACTURE OF THE CORACOID PROCESS.

By W. ARBUTHNOT LANE, M.S., F.R.C.S.,

Assistant-Surgeon to Guy's Hospital, and to the Hospital for Sick Children, Great Ormond Street.

In the *Guy's Hospital Reports*, 1886, page 332, I showed that during the movement of flexion of the shoulder-joint, the scapula rotates around a transverse axis, or, more accurately, around an axis whose direction is, on the whole, obliquely inwards and forwards. While the scapula is performing this movement, that portion of it which is most fixed as regards the clavicle is the acromion at its articulation with that bone, and next to that the coracoid process of the scapula. The lower extremity of the scapula glides outwards, forwards, and then upwards, over the convex outer surface of the thorax, while its upper margin is carried backwards and somewhat upwards from its relative position to the clavicle in the pendulous attitude of the arm.

The coraco-clavicular ligaments oppose and limit this separation of the two bones, and the coracoid process is prevented from moving upwards and backwards by its coming in contact with the under surface of the clavicle.

I also pointed out that in those labourers who have to carry loads upon the head or trunk, in order to keep their heavy burdens in place by their arms, the shoulder-joints are retained in a position of extreme flexion, the scapula being fixed upon the clavicle by the opposing surfaces of clavicle and coracoid process;

that in such labourers an arthroclavicular joint is developed in this situation, and that the perfection at which the joint arrives depends entirely upon the strain exerted upon the arm, and therefore upon the opposing surfaces of coracoid process and clavicle while the shoulder-joint is in a position of complete flexion (this condition is even more marked when the load exerts a direct as well as an indirect pressure upon the clavicle).

In some cases I have found this joint remarkably well developed, the articulating surfaces on the coracoid process and clavicle being eburnated, and the capsule surrounding them strong and well defined. In that paper in the *Reports* I suggested that this apposition of the coracoid process of the scapula and clavicle was the developmental factor which determined the separation of a portion of the tendon of the pectoralis minor to form the coraco-humeral ligament, that tendon originally passing superior to the coracoid process, as a large portion of it does in occasional instances. In the same manner it has possibly destroyed a portion of the subclavius, which may have formerly extended outwards as far as the acromion. In porters I have seen the subclavius arising by fleshy fibres from the capsule of this joint, rendering it obvious that during one lifetime the extent of the origin of that muscle can be considerably altered. As it does not bear directly upon the point I wish to illustrate here, I will only mention the similar joint formation and other pressure changes, identical in character with the above, and associated with them, which develop between the clavicle, rhomboid ligaments, and the underlying first rib and cartilage.

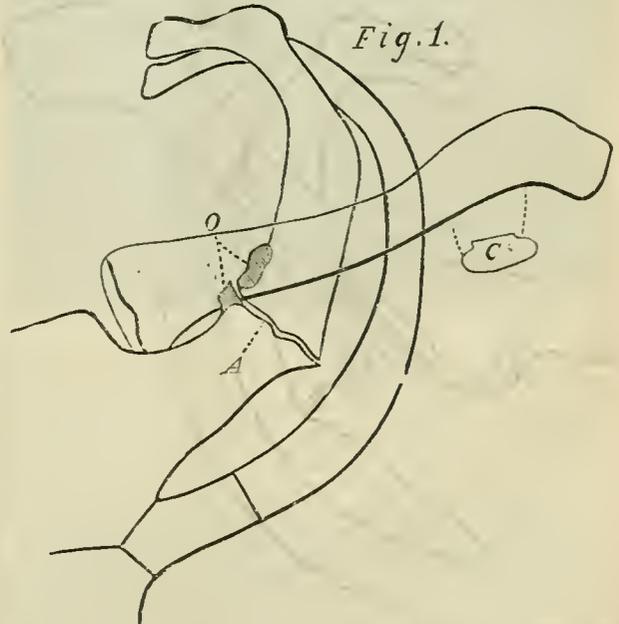

Fig. 1 represents the upper two costal arches, the clavicle, the extremity of the coracoid process, and the half of the manubrium of the left side of the body of a labourer. On the upper surface of the coracoid process C the articular facet, by which this bone articulates with the under surface of the clavicle, is represented as a slightly elevated plane. The dotted line indicates the position of the capsule of the acquired coraco-clavicular joint. A points to the arthroclavicular joint which has developed in the outer portion of the ossified first costal cartilage. O indicates the position of facets on the first costal cartilage and on the anterior extremity of the first rib, which articulate with a corresponding articular surface on the under surface of the clavicle, and form with it what I call the chondro-clavicular articulation.

In Figs. 1, 2, 3 and 4 I have represented the chondro- and coraco-clavicular joints as they existed in a labourer who carried loads upon his left shoulder.

The movements of the scapula with regard to the clavicle during flexion of the shoulder-joint are very briefly and somewhat inaccurately described by anatomists, and I am describing them here, as a knowledge of them suggests a very important practical point in the surgical treatment of that joint.

The circumstance which I wish to call attention to is this—namely, that in complete flexion of the shoulder-joint the scapula is rendered fixed by the coracoid process impinging upon the under surface of the clavicle, and that while the shoulder-joint is

completely flexed the humerus may be rotated, completely adducted, and very extensively abducted without the scapula accompanying it in its movements.

Surgeons are all familiar with the difficulty they experience in fixing the scapula when they wish to break down adhesions which have formed between the humerus and that bone, and many means have been devised to obviate this difficulty. I will illustrate this by quoting a few lines referring to the treatment of synovitis of the shoulder-joint from Holmes's *System of Surgery*, vol. ii, page 393: "But, if adhesion remain between or about the surfaces, difficulties in restoring motion are met with in the shoulder-joint which are not present to the same extent in other joints. They are due to the mobility of the scapula, which, when we attempt to make passive motion for the stretching or the tearing of the new material, moves with the bones, and we have no *point d'appui*, as in other joints. But the difficulty can to some extent be overcome if the patient be put under the influence of an anæsthetic, by giving the scapula into the charge of an assistant, who stands at the side of the patient opposite to that of the affected joint. If now, while he grasps this bone with both hands, and fixes it against the ribs with his fingers on its borders, the humerus be slowly brought away from the side, and then rotated upon its own axis, the adhesions may be gradually loosened after one or two attempts if the assistant be able to hold the scapula firmly. Unfortunately, the patient himself will not, as a rule, carry out active motion carefully."

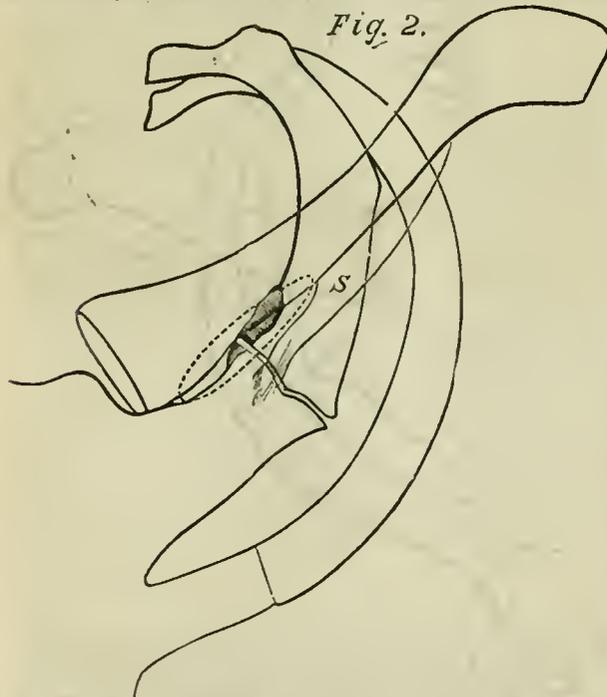

Fig. 2.—The dotted line indicates the limits of the chondro-clavicular joint and its relations to the subclavius muscle (S) and sterno-clavicular articulation. The outer end of the clavicle has been displaced upwards and backwards, in order to show this new joint.

The writer very wisely inserts the proviso, "if the assistant be able to hold the scapula firmly;" and in my experience the assistant was never able to do so to my satisfaction. By means of the method I suggest, not only can the surgeon and his assistant completely fix the scapula, and rotate the humerus readily when the scapula is fixed, but the patient can readily arrange that his relations or friends shall carry out the definite and simple instructions of the surgeon, and a very important part of the subsequent treatment can in this manner be secured.

It is obvious from the above description of the movements of the shoulder-joint that the coracoid process is brought into forcible contact with the under surface of the clavicle only in extreme flexion of the shoulder-joint; and that if the force exerted in bringing these bones into apposition be great, the coracoid process may sustain a strain sufficient to break it. Such an acci-

dent might then ensue by the exertion of a sudden or considerable strain upon the trunk of an individual hanging by his arms, or by a heavy fall forwards, the arms being at the time completely flexed at the shoulder-joints, and, therefore, stretched directly forwards. In either case it is very likely that fracture of the coracoid process would be accompanied by dislocation of the head of the humerus.

The coracoid process would, therefore, be broken by indirect and not by direct violence, but, according to surgical authors, the coracoid process is not broken in this manner. For instance, in Holmes's *System of Surgery*, vol. i, page 953, I find the following: "Fracture of the coracoid process is an extremely rare accident, and only produced by severe direct violence; it is usually accompanied by other injuries, as dislocation of the humerus in the cases reported by South and Holmes, or by fractures of other parts of the scapula." I would ask how it is that fracture of the coracoid process by direct violence is so frequently associated with dislocation of the humerus? It seems difficult to understand. The writer goes on to say that "Two cases of fracture of this process have come under my notice. In both the fracture was caused by a fall forward from a slight height with the arms stretched forward, etc." Again I would ask in what manner does he suppose that the coracoid process could have been influenced by direct violence when the shoulder-joint and arm were in the position he describes?

It is obvious that he refutes in a very practical manner the assertion he had just made by the two cases which he has brought forward to illustrate and verify it, since it would be almost impossible to fracture the coracoid process by direct violence under the circumstances related.

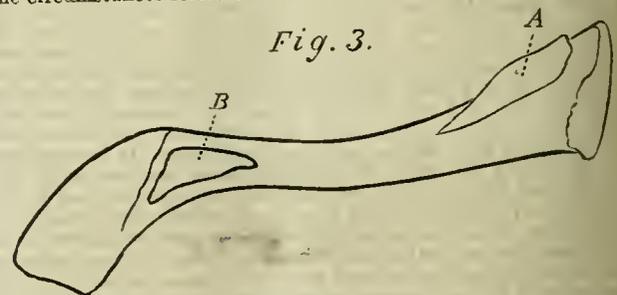

Fig. 3 represents the under surface of the left clavicle; A the facet on the clavicle which enters into the formation of the chondro-clavicular articulation; and B the facet forming the clavicular portion of the coraco-clavicular articulation.

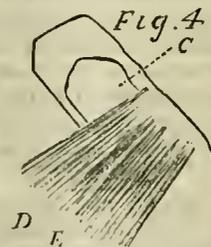

Fig. 4 represents the upper surface of the left coracoid process, C indicating the raised flat facet on this surface of the bone, which articulates with the facet B on Fig. 3. D and E point to the trapezoid and conoid ligaments respectively.

The extreme rarity of this fracture illustrates another point in which I am interested, namely, the relative frequency of fractures of the various bones. In 325 bodies whose bones I have thoroughly examined in the dissecting-room, I found no undoubted instance of fracture of the coracoid process, though I have looked for it very carefully. In the same number of subjects I found that a considerable proportion presented fractures of the acromion, that portion of the scapula being broken more frequently than any other bone in the body. Yet in the statistics of the fractures of the upper extremity, treated at the Middlesex Hospital during ten years ending 1879, comprising a total of 1,084 fractures, there are six fractures of the coracoid process, and only ten fractures of the acromion.

The reason of the incompatibility of this last statement with the results of my experience in the dead subject is obvious from

the comparative difficulty in detecting a fracture of the acromion. I have in many instances of so-called simple contusion of the shoulder of the living subject been able to satisfy myself of the presence of an ununited fracture of the acromion or of fracture of the outer third of the clavicle.

This is another instance of the extreme inaccuracy of the published statistics of the relative frequency of fractures of the various bones. In a paper in the *Guy's Hospital Reports*, 1886,¹ I have described in full the frequency of fractures of the acromion, first costal arch, and outer third of the clavicle, and I am merely referring to it here as bearing upon the rarity of fracture of the coracoid process. It is also obvious that the force required to produce a fracture of the coracoid process must be great as compared with fractures of the acromion or clavicle.

A NOTE ON THE RHYTHM AND CHARACTER OF CERTAIN TREMORS.

By R. NORRIS WOLFENDEN, M.D.(CANTAB.),

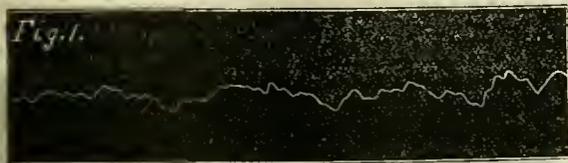

Physician to the Hospital for Diseases of the Throat;

AND

DAWSON WILLIAMS, M.D.(LOND.),

Fellow of University College, and Assistant-Physician to the East London Hospital for Children, Shadwell.

THE voluntary contraction of a muscle in man is maintained by a series of nervous impulses, which reach the muscle at a certain definite and fairly constant rate. Under ordinary circumstances in health, the fine vibration thus produced is imperceptible to the casual observer; but if even a steady hand be attentively watched, it may be seen to be constantly vibrating. By the use of suitable apparatus a graphic representation of this vibration may be obtained; the general character of such a tracing is fairly represented by Fig. 1, which was obtained by one of us from his own forefinger.

The rhythm of muscular contraction for the muscles of the forearm was set down by Beaunis (*Physiologie Humaine*, 1876, p. 273) at 10.5 per second, and he added the remark that these vibrations were much more "pronounced in senile tremor and alcoholic trembling, which are only exaggerations of the physiological state."

Horsley and Schäfer (*Journal of Physiology*, vol. v) have recently found from experiment that the rhythm of muscular response to electrical excitation of the nerve centres is the same, whether the excitation be applied to the grey matter of the cerebral cortex of the motor region, the corona radiata, or the spinal cord (but not to the peripheral motor nerves); and that with all the rates of excitation higher than ten, the rhythm of muscular response is maintained at a fairly uniform rate of about ten per second. The rhythm in the case of voluntary and reflex contractions is essentially the same as that got by excitation of the nervous centres. In the case of epilepsy they obtained sometimes a slower rate, due to summation in the cells of the spinal cord. This summation on the part of the spinal cord cells explains why in some cases a rhythm was obtained the same as the electrical excitation, or, if not quite equal to that, yet considerably exceeding the normal rhythm. This was due to failure or imperfect performance of the summation process. They think that the spinal cord cells are never capable of originating a rhythm of greater frequency than ten per second, but that cortical cells may originate a rhythm of twelve, thirteen, or even more.

Schäfer (*Journal of Physiology*, vol. v) also has recently shown that a prolonged voluntary action in man is an incomplete tetanus produced by from eight to thirteen successive nervous impulses per second. He concludes that in this case the average rhythm is also ten per second.

That this rate of rhythm is maintained fairly constantly in the various movements constituting the tremor of disease is made

evident by our observations. Mr. Victor Horsley has already figured in the *JOURNAL* (vol. i, 1885, p. 112) a tracing of ankle clonus in a man suffering from caries of the spine, which showed a wave-rate of eight to ten per second, and also a tracing from a well marked case of paralysis agitans made by Dr. Beevor, showing a wave-rate of four or five in a second. Mr. Horsley added that he had found frequent indications of each wave being a compound of two.

The investigation which we now report was directed to the study of the characters, but especially of the rate, of various forms of tremor observed in disease, with the view of ascertaining whether the relation on which they stood to the normal oscillations of health was of a constant character. The analysis of complex movements such as those of athetosis, or even of chorea did not come within the scope of our inquiry.

The apparatus which we employed is represented in Fig. 2. The tracing was taken on an ordinary revolving cylinder (A) driven by

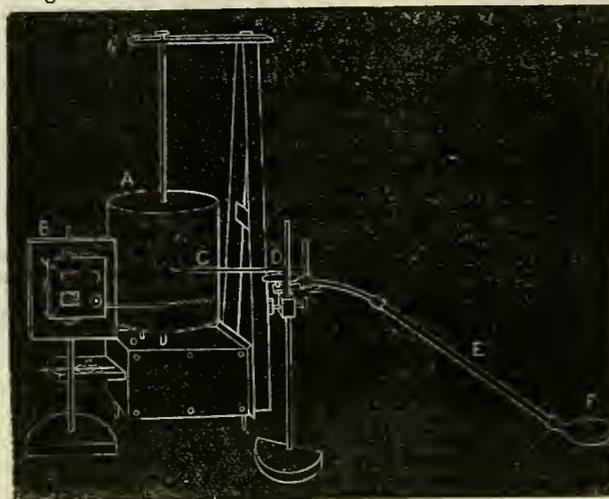

Fig 2

clockwork; the writing lever of the time marker (n) marked half seconds on the same cylinder; a Marey's tambour (D) carrying a writing lever (C) was connected with an india-rubber bag (F)—of the kind used by Dr. Warner in his experiments—by a long piece of glass tubing (E); this rigid tube was introduced in order to prevent as much as possible accidental jarring or shaking of the apparatus, which, especially when the patient has a severe form of tremor, is very prone to occur if the whole connection is by india-rubber. The patient placed the tips of the fingers or the palm of the hand upon the india-rubber bag; each movement was thus transmitted to the tambour (D) and inscribed upon the blackened paper of the recording cylinder by the writing lever (C). This arrangement of the apparatus has the great advantage of permitting observations to be made without difficulty in an ordinary ward; it can be quickly put together and carried from ward to ward by a single assistant.

The first observations were made on cases of exophthalmic goitre (Graves's disease); the exceedingly fine character of the tremor which is present in the earlier stages of that disease can only be studied by obtaining a graphic record of the movements, and, while affording a good test of the applicability of the method to clinical purposes, there seemed to be some probability that a comparison of the tracings with others obtained in other forms of

disease where the tremor is coarser might throw some light on the nature of Graves's disease itself. Fig. 3 is a reproduction of a

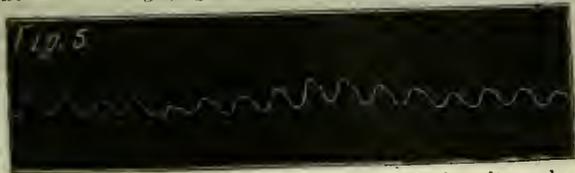

¹ "The Pathology of Pressure-changes in the Trunk and Shoulder-girdle."

tracing taken as above described while the cylinder was revolving slowly. The patient was a young woman, A. C., suffering from well-marked symptoms of Graves's disease in an early stage. The tremor could be distinctly felt when her hand was loosely placed in the hand of the observer. The tracing was taken with her right hand resting lightly on the tambour. The movements occur at the rate of 11 per second, and their amplitude is slight, though varying within small limits. Numerous tracings were taken from this patient, and also from another young woman, E. A., who also presented well-marked symptoms of Graves's disease in the early stage. All the tracings had the same characters, and the rate was practically identical in both patients, the maximum of numerous countings being 11.5 per second in A. C., and the minimum 10.8 per second in E. A. A study of the extended series of tracings from these two cases appears to show that even this slight difference is due to imperfections in the apparatus, and that, within the limits of experimental error, the rate in these cases was almost identical. Fig. 4 is a reproduc-

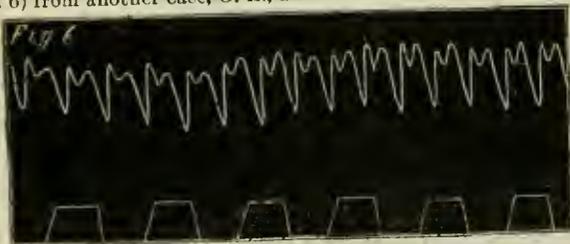

tion of a tracing taken with a more rapidly revolving cylinder. Though the general aspect is, for this reason, different, the rate at which the movements occur (11.3 per second) is almost the same as in Fig. 3, and the two tracings have essentially the same characters.

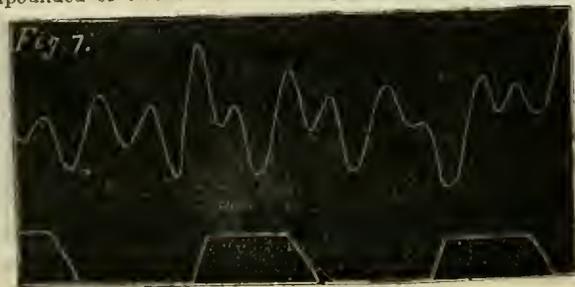

The next tracing (Fig. 5) is from a man, W. H. H., aged 78,

who presented well marked symptoms of paralysis agitans; he was under the care of Dr. Scanes Spicer in the Fulham Infirmary, to whose kindness we are indebted for the opportunity of making this as well as the observations recorded below. Though the tremor was well marked, the patient was still able to do a little light work. The tracing gives a rate of 5.2 per second, but inspection shows that many of the curves give indications of secondary waves. This is beautifully marked in the tracing (Fig. 6) from another case, G. E., an old man, also in the Fulham

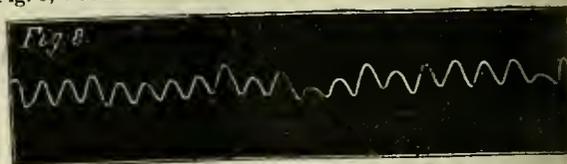

Infirmary, with incapacitating paralysis agitans. Each wave is notched at the summit with singular regularity, and is clearly compounded of two waves. The larger waves give a rate of 5.1

per second; and, as each is double, the true rate is 10.2 per second, which is about the average rate of the oscillations in health, the difference lying in an alteration in the amplitude, and in the fusing of each alternate wave with the one immediately preceding. This point is further elucidated in another tracing (Fig. 7), taken from this case on a more rapidly revolving drum. The lever, as it descends, is caught by the secondary wave, and again thrown up, very much as in a tracing of a "dicrotic" pulse. The tremor of paralysis agitans, which ordinarily gives such a tracing as that reproduced in Fig. 5, is thus seen to be due to a fusion of the waves in pairs as above stated.

Tracings were taken from two cases of disseminated sclerosis. In one, A. D., a woman aged 77, a very uniform tracing, reproduced in Fig. 8, was obtained. The rate is 5.8 per second. A tracing

obtained from another case of the same disease in a woman, A. T., affords evidence of secondary waves, which, viewed in the light afforded by the tracings from the cases of paralysis agitans (Figs. 5, 6, 7), points clearly to a process of fusion. The same effect is extremely well shown in a tracing (Fig. 9) from a case of

lateral sclerosis with tremor of the arms in a woman aged 63. The rate, if the main oscillations only are counted, is 5.2; and, as each oscillation is distinctly double, the true rate is in this case also 10.4. The next tracing (Fig. 10) is from an old woman aged

91, who had well-marked senile tremor. The average of the oscillations is 5.5 per second. Many of the curves, however, are distinctly notched, so that, as in other instances, we here have, in all probability, an effect of regular summation in pairs.

It would be easy to multiply tracings all giving evidence of the same nature, but enough has been advanced to make it clear that the rate of the tremulous movements in these various forms of nervous disorder does not overpass the normal limits observed by Schäfer and Horsley. The general result of our observations is to show that the special characteristics which clinically distinguish the various forms of tremor are to be traced to two causes: in the first place an exaggeration of the amplitude of the normal vibration; and in the second place to the fusion of vibrations, which has the effect of producing a relatively slow tremor, generally of a rate corresponding to half that of the normal vibration.

A NOTE ON FILARIA SANGUINIS HOMINIS:

WITH A DESCRIPTION OF A MALE SPECIMEN.

BY ALFRED GIBBS BOURNE, D.Sc.,
Professor of Biology in the Presidency College, Madras.

OUR knowledge of the adult form of this worm is still incomplete. It was discovered by Dr. Bancroft, in Brisbane, in 1876. It has also been found by Dr. Timothy Richards Lewis, in Calcutta; Dr. Patrick Manson, in Amoy; Dr. Silva Arango and Dr. F. dos Santos, in Brazil. Dr. Bancroft's specimens were described by Dr. Spencer Cobbold. Drs. Lewis and Manson have both given descriptions of their specimens. All these specimens were imperfect, and are

May 19, 1888.]

stated by Cobbold to have all been females. This authority states in his book (*Parasites: a Treatise on the Entozoa of Men and Animals*, 1879) that the male parasite is unknown. This was not, however, strictly correct, as Lewis in the paper (*Quarterly Journal of Microscopical Science*, 1879) referred to by Cobbold, states that he found portions of two specimens: the one was about one inch and a half long, and belonged to a female from which the caudal extremity had been severed, while the other was a fragment of a male worm. Of this latter he says: "It measured half an inch in length, and $\frac{1}{10}$ of an inch transversely; it was thinner than the female, but of considerably firmer texture—so firm, indeed, that whilst endeavouring to make out its anatomy a considerable portion of it was lost by one of the needles used for dissecting snapping, and carrying a portion of the worm along with it. On tearing the helminth across, the severed surface does not present a ragged edge, but an even outline. The male manifested also a great tendency to coil, and it was only with difficulty that it could be separated from the specimen of the female parasite, around a portion of which it had twisted itself. It is unfortunate that its caudal end, especially, could not be found, as the definite decision of the genus to which it should be referred depends in a great measure on the characters which the posterior end of the male worm presents."

Brigade-Surgeon Sihthorpe has had several cases of filarial disease in the General Hospital at Madras, and has always made a search for the adult worm; this has hitherto proved fruitless. Recently, however, after an amputation of a lymphoid scrotum, he found two worms which he had mounted and identified as adult filariæ. He had found embryo filariæ swarming in the patient's blood on the previous evening. He very kindly sent these specimens to me for examination, and I found that one was a female, while the other was a male. The female specimen agrees very closely with Cobbold's figure, but the vagina is everted or protruded. Dr. Smyth, resident surgeon to the hospital, who mounted the specimens, tells me that the eversion took place during mounting; it is probably a normal act during life. The caudal portion is wanting. The male specimen is about an inch and a quarter long; the anterior extremity is wanting, but the caudal extremity is intact, and presents two spicules. The structure of these spicules will doubtless form a valuable specific character. Unfortunately, only one of these spicules remains *in situ*; the other has dropped out in the mounting and lies nearly isolated on the slide. The spicule is broad at its proximal extremity, and gradually tapers until it becomes capillary in character. About half-way down there is a lateral prominence, and when *in situ* the spicule is folded on itself so that this prominence forms the actual free extremity of the spicule, while the broad end and the capillary end lie near to one another.

A description and figures of this specimen, which, with the exception of Lewis's fragment, is, I believe, the first recorded specimen of the adult male filaria sanguinis hominis, will be published in an ensuing number of the *Transactions* of the South Indian Branch of the British Medical Association.

It is interesting to note that in this case, as in Lewis's case, the male and female were found in close contiguity.

EMPHYEMA FOLLOWING PNEUMONIA.¹

By DONALD W. C. HOOD, M.D. Cantab.,

Senior Physician North-West London Hospital, and Physician West London Hospital.

I wish to call attention to those cases in which an inflammatory attack connected with the chest has been followed by anomalous or irregular symptoms. I can of course only hope to touch lightly upon a branch of such a vast subject, and any remarks I may make will relate only to those cases where an acute pneumonia has been followed by purulent effusion.

Is a lung solid with adventitious products or is the pleural cavity charged with fluid contents? This is a problem which we are often called upon to solve; happily it is one in which in the greater majority of cases we shall have, no doubt, no difficulty. On the other hand, we may be called upon to express an opinion where the clinical course has been shrouded in obscurity, where the symptoms from the first are complex and irregular, where our diagnosis is a matter not only of moment but of difficulty.

The ambiguity which arises in those cases where the ordinary well-recognised symptoms of pleural effusion or solidified lung are either absent or profoundly modified have occupied the attention of many clinical observers. It is not easy to realise how completely a chest filled with fluid can simulate a lung solid from pneumonia. But a short time past we had a good instance of this in the case of a woman admitted into hospital suffering from cough and dyspnoea. Her right side was absolutely dull. On this side was the scar due to her breast having been removed for scirrhus. There were symptoms of recurrence of the growth. In this case the entire balance of physical evidence lent much weight to the opinion that the chest was filled with solid mass; an aspirator, however, quickly settled any doubt, and we found the cavity filled with fluid.

The difficulty in diagnosis is much increased if the primary seizure be of the nature of pneumonia, especially if the attack occur on the right side. A young girl, now in hospital, was admitted on February 7th, 1888; she had been ailing about a week, had caught cold and had had a sharp shivering fit. I saw this patient on the afternoon of the day on which she was admitted; her clinical condition was typical of an acute attack of pneumonia; respirations between 40 and 50; *alæ nasi* working vigorously; pulse 130; temperature 104° F.

Beyond some sharp fine crepitation to be heard at the base of the left lung, the physical symptoms were insignificant. She had pain over this side, but no stitch or catch in breathing. The air appeared to be entering both sides of the chest equally well. The following day there was increase in the area over which fine crepitation could be heard, and the lower two-thirds of the left chest was dull; no bronchial breathing could be detected; there was no expectoration, though frequent cough.

From this time the patient was severely ill, so ill that an accurate, careful examination of the chest was impossible. The lower part of the right lung was implicated in the attack, the constitutional symptoms being extreme.

On January 14th, seven days after admission, a thorough examination was made. The left side was dull, with tubular breathing and bronchophony. The apex-beat of the heart could not be felt, but the heart-sounds were heard loudest to the left of the median line. There had been no hectic, no shivering, the temperature gradually falling, and the general condition of the patient had improved. She pronounced herself as feeling much better. Nevertheless the breathing was still rapid and embarrassed. At this time the general condition of the patient suggested the presence of fluid within the chest, though a physical examination almost directly negatived such a view.

On January 17th the girl was seen again. She expressed herself as being much more comfortable, had slept well, and had taken food with appetite. The temperature was now normal, but both pulse and respiration were still rapid. Cough was very frequent, almost paroxysmal, but without expectoration. On this day I distinctly heard the heart-sounds loudest to the right of the median line. An aspirator was used, and a pint of sweet pus withdrawn. Subsequently a free opening into the chest was made by my colleague, Mr. Durham, about two pints of pus being removed. The patient has made an uninterrupted recovery.

Another case, bearing on the matter under our notice, occurred to me in the case of a patient admitted under my care into the West London Hospital, on March 5th, 1886, suffering from an attack of pneumonia of ordinary intensity. There was nothing irregular in the clinical course, and the normal physical symptoms of pneumonia were present. There was a rather free expectoration of rusty and blood-stained sputa.

On the seventh day after admission the general state of the patient was satisfactory. The attack had run an ordinary course, and on the morning of this day the temperature was 99°. The percussion note at the lower part of the right chest was toneless, that is, it was more dull than is usually the case from pneumonic consolidation. The cough was irritating and paroxysmal. We had noticed the ordinary cough of pneumonia giving place to one which was paroxysmal and without expectoration. Such a cough may be caused by the presence of a small quantity of fluid within the chest. A hypodermic syringe revealed the presence of fluid, and a small quantity, namely four ounces, was removed, and proved to be sero-purulent. It was sweet. The following day the temperature was normal, the cough had gone, and the patient, a few days later, was discharged well.

But lately a child was under my care in the West London Hospital suffering from a slight attack of broncho-pneumonia. The

¹ Abstract of paper read before the Metropolitan Counties Branch, North London District.

illness passed off rapidly; but after all fever and constitutional symptoms had subsided, there remained a very small patch of dullness at the lower part of the right chest. The heart was not displaced, but there was the same paroxysmal cough as I have just referred to. Indeed, so paroxysmal was the cough, that it was suggested that the disease was pertussis, commencing with acute inflammatory symptoms. We determined to explore the dull patch at the base of the lung, and a hypodermic syringe revealed the presence of pus; four drachms were removed. The cough ceased from that moment, and the child was discharged well. Though kept for some weeks under observation there was no return of cough or chest mischief.

Large effusions occurring on the right side of the chest, especially when they simulate solid lung, are doubtless much more difficult to diagnose than when the fluid is on the left side. We do not gain the same help from altered positions of the heart. A large effusion may occur on the right side and the heart beat in its normal position. Of this fact we had striking proof some months past in the case of a poor woman who was admitted under my care. She was sent in for supposed enlargement and disease of liver, that organ being felt below the umbilicus. The enlargement, however, was apparent only, the viscous being displaced downwards by an enormous effusion into the right chest. Although this effusion was sufficient to influence the position of the liver to such an extent, the apex of the heart was found beating in or about its normal position. A free exit was made for the pus which filled the chest, and the liver returned to within two fingers' breadth of the ribs.

An interesting case occurred to me a few months ago in the case of a strong young man admitted under my care into the West London Hospital. The patient stated that three days before admission he had been seized with a severe shivering fit, and since the attack had had pain over the chest, with difficulty in breathing. The constitutional symptoms were of extreme severity; no physical symptoms of importance could be detected on admission. During the first week it was impossible to examine the chest with exactness, as the patient being in a state of delirious mania, it was with the greatest difficulty he could be kept in bed. There was, however, a plentiful crop of herpes on the lip, and an expectoration of rusty sputa, the balance of clinical evidence being largely on the side of pneumonia. The delirious state was followed by a sharp attack of pericarditis, which again prevented a careful examination of the chest; and it was not till after the patient had been in hospital for nearly a fortnight that we were able to estimate the amount of chest mischief.

Briefly, the physical symptoms were as follows: The right chest was found to be dull, and over this region tubular breathing and bronchophony were well marked. On February 15th, being twenty-eight days after admission, the following note was made: "The general strength of the patient has improved, but the lung has not cleared up. The right chest is still dull. Vocal fremitus can be felt on this side, the breathing being tubular. The heart beats in normal position, and the liver is not depressed. The clinical evidence is against the presence of fluid."

A week later the physical symptoms were much the same. The general condition of the patient was good, his temperature gradually falling. The cough was noted as being peculiar, coming on in whooping-cough-like paroxysms, and unattended with any expectoration. A hypodermic syringe detected pus. Subsequently three pints were withdrawn, a free opening being made into the chest, the patient making a complete and rapid recovery. The cough ceased immediately after the pus was removed.

Perhaps nothing has contributed more to the study of medicine as a science than the knowledge gained by an exact investigation into the natural history of individual diseases; in other words—the physiology of pathological processes. We should be in a position to state with confidence the time necessary for the lung, solidified by pneumonia, to become normal tissue. We should know the relation between such a period and the amount of tissue implicated in the attack. Some such exact knowledge would doubtless help us in forming an opinion as to the presence of fluid in the chest, more especially in those cases where the ordinary symptoms are modified or absent.

Dr. Addison, in his 27th aphorism, writes: "When serous effusion is very considerable, giving rise to unequivocal bronchophony, tubular breathing, want of resonance and vocal vibration, physical examination has repeatedly led to a mistaken belief that these signs resulted from a pneumonia or other consolidation of lung." That similar mistakes may occur, even if the fluid be pus, must be admitted.

In the case of the two patients whose attacks I have briefly brought before you, there was nothing in the course of the illness *per se* to indicate, even granting the existence of fluid, that that fluid was pus. They had gone through no process sapping the vital forces. They were strong, in vigorous health, and well-nourished. The attacks were marked by extreme severity at the initial outbreak. There was nothing to indicate a septic influence. There was no hectic, no heavy sweats, no fluctuating temperature. At the time when the first exploratory puncture was made, in the one case it was normal, in the other 90°; in both cases it had been gradually falling. There was no bulging of ribs, no œdema of parietes, no extreme stitch-like pain—nothing, I say, to warrant us in thinking the fluid was purulent. Baccelli's test failed in both instances, for in each whispering pectoriloquy was to be heard with striking intensity. From my own observations I look upon this test as useless, and I have reason for thinking that the vibrations giving rise to the conduction of whispers depend more upon the tension of the fluid than its character. As a general rule tension (that is, distension of the chest) is greater in serous than in purulent effusions: thus we are more likely to hear whispering pectoriloquy in cases of serous effusion. But if, on the other hand, there be a large purulent effusion with consequent great tension, the whispers are as readily conducted as if the fluid were serous.

A paroxysmal cough, more or less of the nature of whooping cough, has been a symptom to which, personally, I owe much help in those cases where the signs of fluid within the chest have been equivocal. My experience is not sufficient to enable me to say with confidence that such a cough, remaining after an acute chest attack has subsided, is invariably indicative or pathognomonic of the presence of fluid. But certainly in nine consecutive cases occurring directly under my own notice such a cough was present, and immediately ceased on withdrawing the fluid from the chest. In all cases the fluid was purulent, and, with one exception, each patient made a complete and speedy recovery, the one exception being a young woman whose attack was evidently septic, and followed a miscarriage.

The case of the little child to which I have very briefly referred was of special interest, the amount of pus removed being but four drachms, this small quantity evidently giving rise to the cough which so closely simulated pertussis.

NOTES ON ANTIPYRIN.¹

By W. TYRRELL BROOKS, M.B.LOND., B.A. OXON.,
Lichfield Lecturer in Clinical Medicine in the University of Oxford.

It is not my intention to make any remarks on the uses of antipyrin as a febrifuge. Antipyrin has been long used for this purpose, long enough indeed for a host of rivals to have arisen, one of which—I mean antifebrin (acetanilide)—bids fair to displace it. I wish rather to bring before the meeting some account of the various diseases for which antipyrin has been used in which it has a more or less specific action, apart from its property of lowering temperature. Antipyrin has been so largely used, during the last year, more especially upon the Continent, that it runs the danger of degenerating into a universal panacea for all ills. So great in fact has been the demand for the drug, that it is believed that the supply has with difficulty kept pace with it, and complaints are now made that the drug is suffering from over-popularity, and that its purity is being sacrificed by the makers to ensure a sufficient quantity in the market.

Antipyrin has been very largely used as an anodyne, and a claim has been made for it by Professors Germain Sée and Lépine that it is a reliable substitute for morphine, whilst in cases where morphine is contra-indicated, such as advanced kidney-disease, acute gout, or certain forms of cerebral irritation, antipyrin may be given freely to allay pain. It has the great advantage over morphine that it does not cause cerebral symptoms; thus there is not any vertigo nor vomiting, and according to Professor Sée the use of the drug is not followed by sleep or nervous stimulation. Professor Lépine, however, considers that antipyrin acts both as an anodyne and a nerve-stimulant, so that though it relieves pain, it at the same time quickens the intellectual faculties of the patient and renders him disinclined for sleep.

Taking his view of the action of antipyrin as an anodyne, we may say that it is diametrically opposed to morphine in that it

¹ Read before the Oxford Branch of the British Medical Association.

acts as an anodyne without depressing the higher brain-centres. In only two cases in which I have given antipyrin has it caused sleep, and in these instances I believe the sleep was rather the result of relief from pain than of any somnolent action of the drug. The fact that antipyrin acts as a nerve-stimulant as well as an anodyne is a decided objection to its employment when we wish to relieve pain and at the same time ensure sleep. The best method in such cases is to follow the antipyrin by a hypnotic, such as chloral.

For the immediate relief of pain the drug should be used hypodermically, and as it is very soluble in water, a fresh solution may be made by dissolving one of the tablets prepared by Burroughs and Wellcome in an equal weight of water.

The dose for an adult of antipyrin used hypodermically to relieve pain is five grains. This has been calculated by Dr. Fränkel of Berlin to be equivalent to one-thirtieth of a grain of morphine. The dose may be repeated if the pain be not relieved. Beyond the pain caused by the injection, and a certain feeling of tension which lasts a few seconds, no bad effects have been noticed. The drug usually gives relief in from fifteen seconds to half a minute, and the effect lasts for some hours (six to eight hours—Fränkel).

As an anodyne antipyrin has been used chiefly in herpes zoster, lumbago, ataxia, hepatic and nephritic colic, acute asthma, acute rheumatism, and acute gout.

If given in sufficiently large doses it appears to give relief in the majority of cases. Dr. Fränkel gave it in all cases in which morphine appeared to be indicated, and did not meet with a single failure. Dr. Jennings, of Paris, however, side by side with many cases successfully treated by antipyrin, mentions a case of acute gout which was uninfluenced by the drug.

If given by the mouth as an anodyne antipyrin must be used in large doses; thus Professor Sée recommends a drachm to a drachm and a half in the twenty-four hours, and Professor Lépine 150 grains divided into two doses.

In rheumatism and gout the drug appears to be both sedative and curative in its action; it not only allays the pain, but in many cases shortens the attack. Professor Sée gave it in fifteen cases of hydrarthrosis which had resisted treatment with the salicylates and also counter-irritation by the actual cautery. In all these cases he found that swelling and pain disappeared in a few days. Dr. Fränkel gave it in thirty-four cases, with the result that in all but two there was amelioration of the symptoms and shortening of the attack. In fifteen cases, however, a relapse occurred. He found that the average duration of acute rheumatism with antipyrin was 25 days, whilst with the salicylate treatment it was 35.2 days. Mr. Raymond Johnson tried antipyrin in four cases of acute rheumatism, with the result that it lowered the temperature in all, but in only one out of the four did it relieve the symptoms. The three cases which were unrelieved by antipyrin yielded to treatment with the salicylates, whilst in the fourth case, where salicylate of soda had failed to relieve the patient, antipyrin readily did so.

To give relief in acute rheumatism or acute gout, large doses of antipyrin must be given, 1 to 2 drachms during the twenty-four hours being a usual dose. As a rule the drug produces free sweating and rapid defervescence. In chronic rheumatism it acts in allaying the pain and shortening the course of the disease. I have given it in a large number of cases of rheumatism, and in the majority I have found it successful. It appears to me to be a remedy which at least should be tried when the salicylates fail or produce disagreeable after-effects, as they occasionally do. Most of the cases recorded in which antipyrin and the salicylate treatment have been used side by side, for the purpose of comparison, yield either to the one or the other, the refractory cases in either section usually yielding to the administration of the other drug. I have not any statistics to prove whether antipyrin is of use in preventing the secondary troubles in acute rheumatism, such as endocarditis.

Antipyrin has been used with great success in nervous disorders, and I believe it supplies us with a specific for many neuralgic and other allied complaints. Its success in the treatment of migraine and cephalalgia is now assured, and one rarely takes up a medical periodical without finding in it the description of various cases which, after being more or less intractable to remedies for years, have yielded to antipyrin.

In Germany and France especially has this drug been used in the treatment of migraine, and to a less extent in England. During the last few months I have used it in the out-patient department and in private practice in such cases with very good results. As

a rule patients return after having taken the remedy, and ask pointedly for some more of the same medicine that they had last time, a fact which stamps its value at once on one's mind.

In treating migraine with this drug, I believe the best plan is to use the remedy as a specific against the attacks, and not to administer it continuously. If the migraine be periodic, or if there be a preliminary aura, the drug should be exhibited as soon as possible before the threatened attack. Thus, if an attack be feared for the morning, antipyrin should be given at night, and if the attack still threatens in the morning, a further dose should be administered. In this way the attack generally is aborted. Even if preliminary warning be absent, the medicine taken as soon as the attack comes on either aborts it, or renders its symptoms less intense. In my experience it is very rare for antipyrin to fail to influence favourably an attack of migraine, and in this I am supported by almost all of those who have noted on this drug.

It is rarely necessary to give large doses to produce the specific effect. I generally give 5 to 7 grains combined with alkalies and a bitter infusion, to be taken when an attack threatens, and to be repeated, if necessary in an hour. I find that somewhat larger doses are recommended (15 to 20 grains), but patients rarely complain that the smaller dose fails.

I have found the drug useful also in those cases of bilious headache, which often occur in patients of full habit, who are addicted to the too frequent use of alcohol. These cases, which generally occur amongst women in a comfortable position in life, yield to the administration of antipyrin; I had the satisfaction of hearing a patient, who has suffered in this way for more than ten years, state that at last a remedy had been found which relieved her. Of course the remedy does not touch the root of the evil.

In some cases of cephalalgia, antipyrin relieves for a time, but at length the patient becomes habituated to the drug, and the relief is less marked. In such cases, either the drug may be increased, or antifebrin or some other of the substitutes for antipyrin may be used.

As antipyrin has so marked an influence over these nervous complaints, it seems natural to suppose that it may be useful in epilepsy.

Fraty concludes that it has a distinct influence over epilepsy akin to that manifested by the alkaline bromides, but he confesses that large doses must be given (1 to 2 drachms daily), and that in a considerable number of cases it has to be given up, owing to the *malaise* it produces.

I have not tried the drug in many cases of epilepsy, but I was not favourably impressed with the result when I did try it. As a sedative antipyrin has been tried in cases of nocturnal emissions, and it has been found that 7 to 15 grains administered on going to bed prevents the emission in many cases. It also acts in diminishing the excessive flow of urine which not infrequently accompanies spermatorrhœa, and which arises from the hyperæsthesia of the nervous system. I would venture to think that this drug may be well worth a trial in those cases which so often are found to exist in young men who have fallen into the habit of masturbation at school, and who, on coming into the world, learn the evils of it, and relinquish the habit, but in whom spermatorrhœa frequently supervenes to a serious extent. I have given it in similar cases with good results, the best plan being to give 10 grains of antipyrin in combination with 10 grains of chloral hydrate at bed time, the patient usually falling asleep shortly after getting into bed, and remaining asleep without disturbance till the morning.

Antipyrin was given by M. Bloch to a neurotic man with a tender spine, who was periodically overcome by attacks of drowsiness, which came on after each meal; these were accompanied by pains in the head and debility. His condition had been improved by the use of *nux vomica* to some extent; but, on the exhibition of antipyrin in 15-grain doses given on waking and at 11 A.M., the drowsiness after a few days disappeared, and the remaining nervous symptoms abated. In this case it acted as a decided nerve stimulant.

The drug has been strongly recommended in cases of chorea by Legroux, who considers it a most rapid, certain, and inoffensive remedy. He administered it in six cases, giving 40 to 50 grains daily. All his cases recovered rapidly in from 6 to 27 days. I have not had the opportunity to use it frequently in chorea, but in such cases as I have used it the movements diminished rapidly. In one child to whom I gave the drug it had to be discontinued, owing to the cardiac depression which accompanied its use.

Antipyrin has been used with success in spasmodic nervous disorders such as hay fever and whooping-cough. Dr. Bloch tried it

in a case of hay fever in which cocaine and the bromides had been given without result. He gave it in 30-grain doses at the hours when the attacks usually came on, and found that the drug aborted the attacks. After taking antipyrin for some weeks the disease disappeared in this case.

Sonnenberger, from an experience of 70 cases in which he used the drug in whooping-cough, concludes that it is a very useful remedy in such cases. He gave it to infants in doses of $\frac{1}{2}$ to $1\frac{1}{2}$ grain three times a day in syrup of tolu or raspberry, increasing the dose to 10 or 15 grains for older children. The remedy must be used systematically to produce a good result in whooping-cough.

In nervous vomiting, especially in the vomiting of pregnancy, antipyrin is useful. If the vomiting be periodic, the drug should be given a few hours before the usual appearance of the attack. In sea-sickness the drug has been lauded as a specific, perhaps only to have its day as most other specifics for this disorder have had. More than one medical man has, however, recorded the debt of gratitude he owes to this remedy in crossing the Atlantic, so that it may be tried in the hope that it may be of use.

Antipyrin has been used as a hæmostatic in cases of pulmonary hæmorrhage by Dr. Olikoff. He made a solution of 15 grains to the ounce in water, and made his patients breathe through this for four or five respirations, repeating the use of it every half hour. In all the six cases tried the hæmorrhage was diminished. As a hæmostatic for general purposes, antipyrin is too costly a remedy to be employed lavishly, though it has been recommended for epistaxis and other forms of hæmorrhage. Herpes zoster and locomotor ataxy have both been successfully treated with antipyrin. In locomotor ataxy it appears to act in alleviating the lightning pains and in giving ease to the patient rather than by altering the course of the malady.

Since antipyrin became a popular remedy, many cases in which the drug has produced disagreeable effects have been recorded, though, as far as I am aware, none of these cases have ended fatally, nor have there been any symptoms which have lasted more than a few hours. The cases which I have collected (more than twelve in number) appear to me to be pure examples of idiosyncrasy. They are usually isolated cases occurring amidst many others in which the same quantity of the drug was administered. They do not appear to depend on the quantity of the drug given, for in one case 4 grains, in another 8 grains, and in a third 15 grains of antipyrin produced symptoms of poisoning, though more than double the dose has been given in many hundreds of cases without bad effects. There is, as far as I can find, no special class of cases in which the administration of antipyrin is likely to bring on symptoms of poisoning; but, as it appears in certain individuals to cause disagreeable symptoms, regardless of dose, we are likely to hear further of this property it possesses from some of the large number of people who are now taking the drug as a preventive against sea-sickness.

The chief symptoms which manifest themselves in cases of poisoning by antipyrin are certain nervous sensations, such as restlessness, loss of memory, a feeling of general expansion of the body, and a sensation of great coldness. These are followed by swelling of the face and the appearance of an erythematous eruption resembling measles—so much like it, in fact, that those who have seen cases of antipyrin rash are careful to warn us to avoid the diagnosis of measles in patients taking antipyrin.

The chief points of difference between this rash and measles are that it appears but slightly on the face, that its chief distribution is on the extremities, that it is non-crescentic in distribution. In many cases it is not accompanied by catarrh of the eyes and nose, but in a few cases catarrh does occur, and when present it must make the differential diagnosis very difficult. Besides these symptoms, antipyrin may cause diaphoresis, feebleness of the pulse, and general collapse. Gastro-enteritis occurs rarely.

The antidote which removes these disagreeable effects most readily is belladonna, given either as the tincture or in the form of atropine used hypodermically (one-seventieth of a grain).

Conclusions.—I would venture to think that in antipyrin we have a drug which, though suffering from a temporary over-popularity, is likely to be of use in practice. Its power of relieving migraine and other forms of cephalalgia is, in many cases, magical. As an anodyne it is particularly useful in those cases where morphine is contra-indicated, especially in advanced kidney disease, acute gout, or in the bronchitis of old people. I do not think that antipyrin is at all likely to displace morphine, as this drug possesses the advantage of being much more powerful bulk for bulk, and hence is more convenient for hypodermic medica-

tion. But a trial of it should be made where morphine cannot be given, or where morphine must be withheld for fear of establishing the morphine habit. In cases of long continued pain in which some anodyne must be given for a period often stretching over years, antipyrin may be found useful as an occasional substitute for morphine when the patient has become habituated to the morphine, and when it otherwise would be necessary to increase the dose of this drug. I regret I have not met with a case in which I could try this, but such cases as locomotor ataxy, or cases of slow paralysis accompanied by spasm of the muscles, would be suitable ones in which to make a trial.

I do not think antipyrin will displace the alkaline salicylates in the treatment of acute rheumatism, but it is undoubtedly useful where the salicylates have failed, or where they are contra-indicated by the disagreeable effects they occasionally produce.

With regard to the objection raised against antipyrin that it not infrequently gives rise to symptoms of poisoning, I believe that such is of little value. I have given the drug in a large number of cases without meeting with any bad effects from it, and few of those who have used this drug most largely lay any stress upon this difficulty. One must be prepared to meet with cases of idiosyncrasy in the administration of this drug as one has to be with cocaine, morphine, quinine, and other drugs.

By far the most serious objection to its extended use, particularly in hospital practice, is expense. At present, its manufacture is in the hands of monopolists, and though the French chemists say they have ascertained its composition and method of preparation, no one at present has sent on the market any of the drug under its proper chemical name, which is dimethyl-oxiquinidin, a name which requires some reflection before being added to a prescription.

I have tried antifebrin as a substitute for this drug in several cases of migraine, and though the effect does not seem so certain as when antipyrin is used, yet in many cases it has acted well. The relative expense of antifebrin is much less than that of antipyrin.

THE USE OF "SALUFER" (SILICO-FLUORIDE OF SODA) AS AN ANTISEPTIC.

By A. W. MAYO ROBSON, F.R.C.S.,

Honorary Surgeon, Leeds General Infirmary; and Lecturer on Practical Surgery at the Yorkshire College.

A PERFECT antiseptic for surgical purposes has yet to be found. It must be at the same time a strong germicide, non-poisonous, unirritating to the skin or to the tissues, inodorous, non-volatile, not destroyed by oxidation, non-corrosive to steel instruments, non-injurious to sponges, and inexpensive. In "salufer" (silico-fluoride of sodium) we have a substance which would seem to fulfil most of these conditions. Mr. W. Thomson, F.R.S.Edin., read a paper before the British Association at Manchester last year in which he explained the results of certain experiments he had made with respect to the antiseptic properties of some of the fluorine compounds. He had tried the effects, on flour paste and on meat chopped into small pieces and mixed with water, of a very large number of chemical compounds, and had found that those which had the most remarkable antiseptic properties were the compounds of fluorine, the neutral fluorides of sodium, potassium, and ammonium, and their fluosilicates. Fluosilicate of soda he found to be the best adapted for use as an antiseptic, it being non-poisonous, inodorous, and sparingly soluble in water. As it had only a very slightly saline taste, he said it might be employed in preserving food without communicating any taste to it. Mr. Thomson stated that a saturated solution which contained only 0.61 per cent. possessed greater antiseptic power for animal tissue than I in 500 perchloride of mercury solution.

For general surgical purposes I have been very well satisfied with perchloride of mercury, which is a most efficient antiseptic, and which is so very conveniently carried in the form of powders, each containing five grains of perchloride and five grains of sal-ammoniac, which quantity, dissolved in a pint of water, makes a 1 in 2,000 solution; but it has the great disadvantages of roughening and cracking the hands, of corroding steel instruments, and of being poisonous. Hence it is dangerous for syringing out large cavities—for example, psoas abscess; for washing out serous sacs—for example, peritoneum and pleura; or for irrigating the interior of the uterus after gynecological operations or in obstetric practice.

It is chiefly to find a safe and efficient antiseptic for such cases as I have during the past few months been using "salufer" most exclusively in my surgical work.

Before describing details of critical cases which incontestably prove the value of any antiseptic, it might be well to mention a few of the uses to which I have put "salufer"; and, unless otherwise stated, a solution of 20 grains to the pint of water is always understood, which proportion seems to be at the same time unirritating and efficiently antiseptic. They are as follows: in washing out the peritoneal cavity after laparotomy, here using 10 grains to the pint; in cases of strangulated hernia; in the radical cure for hernia; in excision of joints; in amputation of the arm, leg, and thigh; in washing out the pleural cavity; in the removal of tumours; in excision of veins; in ligation of blood vessels; in compound fractures; in osteotomies; in washing out the bladder; in washing out the uterus after curetting the interior, and after the removal of septic retained membranes; as a vaginal douche before and after Apostoli's operation for fibroid; in the irrigation of extensive ulceration in the rectum, where a poisonous antiseptic could not have been employed; in washing out the stomach; as an injection in gonorrhoea (10 grains to the pint); as an injection in otorrhoea; in syringing out large pelvic abscesses; as a gargle in hospital and in diphtheritic sore throat; as a nasal douche after removing polypi; for syringing out empyema of antrum; and in many other cases. My colleague, Mr. Wendelack Hewetson, tells me that he has used it extensively in ophthalmic and aural surgery, and that he is well pleased with its use as an antiseptic.

As I have no opportunity of testing "salufer" in obstetric practice, I have asked some of my medical friends to try it, and their reports have been uniformly satisfactory. My brother, Mr. Herbert Hobson, tells me that he has found it most efficient, both in syringing out the uterus and as a vaginal douche.

The following cases, for the notes of which I am indebted to my house-surgeon, Mr. Berkeley G. A. Moynihan, are given more in detail.

1. *Goitre* threatening asphyxia. Division of isthmus by galvanocautery. Skin incision four inches long. Drainage-tube introduced, and wound stitched up with catgut sutures. Tube removed on third day. Antiseptic dressings on third, fifth, and eighth days, the wound being then completely healed. The highest temperature was on the day following operation, being then 99.7° .

2. *Strangulated Inguinal Hernia*.—After the return of the gut a portion of the Omega loops of Treves) the neck of the sac was ligatured with No. 3 catgut. The wound was syringed out and a drainage-tube introduced. Dressing on first, third, sixth, and eighth days, the tube being removed on third day. All but the drainage opening healed by first intention. Highest temperature 99.6° , at every other time below 99° .

3. *Double Osteotomy* for extreme bowing of the tibiae. The right tibia was divided on December 8th, and three-quarters of an inch of the shaft of the bone removed. No drainage-tube introduced. The wound was uncovered for the first time on December 22nd, and found to be perfectly healed. Highest temperature 100.4° , the evening of the day after operation. Temperature never afterwards reached 100° . Left tibia divided on December 29th, and an inch and a quarter of bone removed. On January 11th, when the wound was uncovered, it was found to be perfectly healed. Highest temperature 99.5° . In both cases a catgut stitch was introduced.

4. *Varicocele* of enormous size, said to reach in summer to the knee. At the operation the veins were ligatured in four places, and the intermediate bundles of veins removed. No drainage-tube. On the seventh day the dressing was taken off, and, but for thickening and induration round the veins, the site of the wound could not have been found. Temperature never above normal.

5. *Removal of Enlarged Glands of Neck*.—Incision two inches long; four enlarged glands, two of them caseous, were removed. Small drainage-tube introduced. Dressings on third, sixth, and ninth days; wound healed by first intention. Highest temperature 99.2° .

6. *Radical Cure of Varicose Veins of Leg and Thigh*.—Two veins of the leg and the internal saphenous trunk were doubly ligatured, the ligatures being about half an inch apart, the intermediate portion of vein not being divided. The wounds, which were not drained, were not dressed till the eighth day, running an aseptic course, the highest temperature being 98.8° .

7. *Compound Fracture of Tibia and Fibula*.—About half an inch

of projecting tibia was removed, and the tendo Achillis was divided before the leg could be got into good position. The wound was enlarged for about an inch and a half, and syringed out with five pints of "salufer" lotion. The highest temperature was 100.2° the night after operation, never afterwards reaching 100° ; perfectly aseptic course.

8. *Radical Cure of Varicose Veins of Leg and Thigh*.—Ligatures applied in four places. Dressed on ninth day; course aseptic. Highest temperature 99.7° .

9. *Tubercular Salpingitis: Acute Peritonitis*.—An incision about three inches long was made through linea alba. Acute peritonitis with effusion was found, and as its cause a ruptured Fallopian tube, covered with miliary tubercles. After removing the diseased appendage, the peritoneum was washed out with "salufer" (grs. x ad Oj), and a Bantock's tube introduced. The case ran a perfectly aseptic course.

10. *Removal of Scirrhus of Breast*, of very large size, together with enlarged axillary glands. The whole breast and about six enlarged axillary glands were removed. The wound was of such large size that it was found impossible to bring the edges into apposition along the central part, where a gap of about three inches by two inches was left. Wound dressed on third and ninth day. The whole of wound, with exception of central part, was perfectly healed. Highest temperature 98.6° ; course perfectly aseptic.

11. *Macewen's Operation for Extreme Genu Valgum*.—The angle formed by the tibia, with a line continued down in vertical direction from the thigh, was 75° . Highest temperature 100.2° . Dressing never changed until twelfth day, when the wound was healed.

12. *Pyosalpinx*.—The abdomen was opened by an incision about an inch and a half in length. The distended and totally adherent Fallopian tube was accidentally burst, a large quantity of the most fetid pus escaping. The abscess cavity and the lower part of general peritoneal cavity (the upper being separated off by sponges) were well syringed out with about ten pints of "salufer" lotion (twenty grains to the pint). Keith's drainage-tube introduced. At subsequent dressings the discharge was found to be perfectly sweet. The temperature, which before operation had never been below 101.2° , fell after operation to normal, and has remained so since.

13. *Lipoma of Shoulder*.—Tumour, size of large orange, removed January 25th. Dressed on third day, when the drainage-tube was removed, and on the tenth, when the wound was quite healed. No pus was seen, and temperature normal throughout.

The following are the conclusions to which I have come, after an extensive and varied trial of the fluosilicate.

1. That "salufer" is an efficient antiseptic.
2. That the powder is a strong irritant, even acting as a caustic if dusted on a raw surface, and is, therefore, in that form, unavailable for surgical purposes.
3. That a solution of one grain to an ounce of water is quite strong enough for ordinary purposes, in that strength being apparently unirritating.
4. That a solution of ten to twenty grains to a pint may be safely used to syringe out closed cavities, even where one cannot be certain of all the fluid returning.
5. That the solution is unirritating to the hands, which is no small advantage to those operators whose fingers are easily irritated by the ordinary antiseptic solutions.
6. That the solution acts on the glaze of porcelain after long use, and corrodes steel instruments, but that sponges are unaffected by it. Mr. Thomson kindly suggested to me the addition of bicarbonate of soda to the solution of "salufer" to prevent it corroding steel instruments; this certainly diminishes its action on steel.
7. That a very convenient and comfortable antiseptic poultice may be made by soaking Gamgee tissue or absorbent wool in a hot solution (ten grains to the pint), wringing it free of excessive moisture, applying it to a wound, and covering with gutta-percha tissue.
8. That although for ordinary surgical work I may still employ perchloride of mercury, in all cases where there is danger of absorption, as in syringing out cavities, I shall employ "salufer."
9. That I believe "salufer" will prove to be of great use to obstetricians, it being both safe and efficient.
10. That it acts very efficiently as a deodoriser to the hands. After examining carcinoma of the uterus or rectum, by washing and steeping the hands in a saturated solution, the odour is removed more efficiently than it is by any solution with which I

am acquainted. Messrs. Reynolds and Branson have made some compressed tabloids, each containing forty grains, that is sufficient to make a quart of solution. They have also been good enough to carry out my wishes in making a dressing of "salufer" wool.

In all the cases related this "salufer" wool has been the dressing employed, a layer of gauze wet with the "salufer" lotion covering the wound, and intervening between it and the wool.

TREATMENT OF CONGENITAL HERNIA.

By LEWIS W. MARSHALL, M.D.,

House-Surgeon, Children's Hospital, Nottingham.

MR. TIMOTHY HOLMES called attention, in an address on "Children's Hospitals as Medical Schools," which was published in the JOURNAL of October 30th, 1886, to the absence of statistics in relation to congenital hernia and its persistency. Acting upon his suggestion I kept a record in 1887 of all cases occurring amongst my hospital patients, and at the commencement of this year tabulated them as follows, namely:

No. Cases.	Cured.	Not Well.	No Reply.
41	20	12	9

(all boys)

Each of these forty-one cases was treated by the wool-truss suggested first by Mr. Coates,¹ of Salisbury, and more recently referred to by Mr. Lund. This method commends itself to us because it can so thoroughly be carried out by any mother of ordinary intelligence, and efficient means of support are obtained at a trivial cost.

In analysing the forty-one cases I find that in every instance one of two things was noted, and sometimes both—either a congenital phimosis existed, or an imperfect urethral opening, and sometimes both.

Having recognised for many years that hindrances of this kind were a common cause of hernia in male children, I had not quite realised how very frequently the two co-existed as cause and effect. That they occupy this position is shown by the speedy relief gained by removal of the conditions referred to, either by circumcision—freeing the prepuce from the glans penis by passing a probe round between them, and maintaining this separation, or when necessary by slitting up the urethra.

From the twelve cases entered as "not well," I learn that in all some one or more of these urinary conditions still existed. In one case pertussis was present; in another, obstinate constipation; and in several, malnutrition, with very deficient muscular development.

We may fairly assume, I think, that at least half of those cases in which no reply had been given were cured. In ten of the twelve cases still showing a hernia a phimosis had to be treated more energetically than had been done before, or the urethra was enlarged. Considerable objection is often raised to circumcision, and the simpler method of dilatation has therefore been adopted first in some cases. I am disposed to think that the importance of the size of the orifice of the urethra has been to some extent lost sight of, because cases have not uncommonly come into my hands in which circumcision, having been practised by another surgeon, the difficulty in passing water still remains, and is relieved at once by slitting the urethra. I regret that in the notes no mention has been made of the number of double herniæ, but my impression is that there were not more than half a dozen. All the children were under three years of age.

The practical outcome of this inquiry is that if the primary factor in the production of the hernia is duly recognised and dealt with, the pressure given by the wool-truss is ample to ensure closure of the canal when the nutrition is maintained. As a proof of the importance of this statement in reference to the nutrition may be quoted the fact that "breast" babies always do best. Nothing need be said by me about the best form of wool, etc., because Mr. Pye has so fully described all these details already, and the opinion expressed by him I can endorse.

¹ Vide paper by Mr. W. Pye, JOURNAL, May 23rd, 1887.

Messrs. MANSSELL and Co have forwarded us mezzotint portraits which they are publishing of Sir Andrew Clark, Sir Joseph Lister, and Sir Spencer Wells. The plates, which are 11½ × 9 inches, are in brownish-black upon plate paper 27 × 20 inches. The trial proofs have been approved and signed in each case.

CLINICAL MEMORANDA.

1 SEIZURES CAUSED BY OXYURIDES EPILEPTIFORMULARES IN AN ADULT.

VERMIFORM (March 24th, p. 642, and March

RECENT numbers of the JOURNAL have contained illustrations of the "epileptic attacks." The following case of intestinal irritation and convulsions entitles it to a brief description. It has features of its own which are noted by a man, aged 57, but

In December, 1885, I was first consulted by a man, aged 57, but of a much older as well as somewhat emaciated appearance. He complained that for fully a year he had been sometimes accompanied by an unpleasant odour issuing from the chest, and always followed by unconsciousness. The unconsciousness was at first very brief, the man supporting himself by clinging his bench firmly. Latterly, however, he had on several occasions fallen down, and the body had presented convulsive manifestations, as witnessed by his family and others. He was nervous and irritable from several attacks, Sunday being his worst day. He was not

The family history exhibited no acknowledged disease, but the patient claimed to have been always a healthy man prior to the onset of this affection. After I had very closely examined him, however, as to details regarding his bodily state, he admitted great hesitation—owing to the delicacy of the subject, that he had long been troubled with threadworms, which he tried to get rid of by the use of vermifuge.

Assuming a possible cause in these vermin, I resolved on a course of treatment directed against them upon his other attacks. The result was that, for six weeks afterwards, there was no more convulsive attack, though a few of the *petit mal* seizures. The patient then became careless of treatment, with the effect of again bringing the graver phenomena. The same alternation between improvement and self-neglect has been the man's history since, but on the whole, considerable gain during the past three months.

I may mention that at one stage I prescribed the bromides, but the man's broken down condition quickly increased, and one of the worst epileptoid seizures occurred during their administration, and they were soon withdrawn. By careful observance of dietetic, vermifuge, cathartic, and tonic treatment, the patient produces his ailment to rare attacks of the minor form, but has never been able to get completely rid of them. Whether by more prolonged adherence to treatment he might effect cure, or whether that is too much to hope for, taking into account the difficulty of finally exterminating the parasites in persons well on in life, and also the morbid excitability of the cerebrum acquired by long subjection to special irritation, I cannot affect to say.

TOXICOLOGICAL MEMORANDA.

CHEMICAL NOTES.

A Simple Test to Distinguish the Carbonates from the Bicarbonates of Potassium and Sodium.—A delicate and simple test for distinguishing a carbonate from a bicarbonate will be found in phenol-phthalein. Add a drop of phenol-phthalein solution to a carbonate, and it will be turned to a bright red, but with a bicarbonate there will be no change of colour. I have prepared test-papers which are very convenient; they will detect 1 part of K_2CO_3 in 1,000 parts of water. These papers may be obtained from Mottershead and Co., 7, Exchange Street, Manchester.

Colour Test for Strychnine.—There are many colour tests for strychnine, but I believe the chromate of zinc used in the same way as permanganate of potassium, deserves a place in our text-books, as it is superior to some.

SURGICAL MEMORANDA.

FAILURE TO FIND THE COLON IN LUMBAR COLOTOMY.
In Mr. H. Allingham's valuable remarks on the causes of failure to find the colon in lumbar colotomy, a considerable difference occurs in the tables of statistics quoted as to the presence or absence of a complete peritoneal investment or meso-colon on either side. I think there is one circumstance which has a very important bearing

on this condition, and that is the amount of distension of the bowel, not only of the large intestine itself, but of the whole peritoneal cavity. In the great majority of bodies examined in the post-mortem room, where the intestines are collapsed, and especially in multiparous women, the descending colon is found completely invested by peritoneum, with frequently a mesentery of half an inch or more in length. Now, the effect of gradual distension of the gut by the injection of air is (as can easily be proved by experiment) to cause the bowel as it distends to encroach on its mesentery, shortening and separating its two surfaces, the bowel at the same time coming into close contact with the abdominal wall, and this occurs all the more readily if the parietal reflections of the mesentery are themselves stretched apart by the general distension of the peritoneal cavity. For the peritoneal investment of the hollow abdominal viscera accommodates itself to their varying size more by a sliding or a folding movement than by an actual stretching of the membrane itself.

Diagram showing the effect of distension of the colon on its peritoneal investment.

With regard to the practical application of these remarks, in the operations I have witnessed no difficulty has occurred in finding the bowel in cases where there has been distension, whereas when the bowels have been empty difficulty has occurred, and in the first case on which I operated a meso-colon of two inches in length was found only after opening the peritoneal cavity. In such cases, then, if the gut cannot be distended with air at the time of the operation (a somewhat uncertain proceeding) it would be better, as Mr. Allingham suggests, to open the peritoneal cavity and draw out the bowel.

C. J. BOND, F.R.C.S.,

Honorary Surgeon, Leicester Infirmary.

TREATMENT OF CARBUNCLE.

I HAVE tried the expectant treatment of carbuncle recommended by Paget; but find it so long, tedious, and painful to my patients that I have completely discarded it. The treatment by excision and scraping is too severe to be generally adopted in private practice, although apparently very successful.

I have adopted the following for the last three years, to which I have added the hypodermic injection of cocaine. I inject into the carbuncle hypodermically half a grain of hydrochlorate of cocaine, and wait about five minutes until the skin is quite anaesthetic; then I make a small incision into the centre of the carbuncle with a tenotomy knife, and insert a small sharp piece of potassa fusa, and then push it home. Afterwards a piece of belladonna plaster is cut circular, a little larger than the carbuncle, and placed over it. The plaster serves the double purpose of retaining the caustic, and of alleviating the pain. This is kept on for eight hours, and then it is taken off, and hot linseed-poultices are applied for the same length of time. The result is that the patient always recovers about three days after the commencement of the treatment, which in this way is carried out almost painlessly.

ROBERT MAIN, M.D.

East Isley, Berks.

GYNÆCOLOGICAL MEMORANDA.

CASE OF ENCYSTED SEROUS PELVIC PERITONITIS.

FOR seven weeks E. R., aged 20, single, had complained of pain all over the stomach. The pain, felt more especially on the right side, radiated down the inside of the right thigh as far as the knee. This symptom developed at a menstrual period, on the fourth day of the flow, and the hæmorrhagic discharge continued thereafter for fourteen days, the usual length of time being seven days. The temperature was 101.4° F. Pain was experienced prior to and during the act of micturition. The abdomen, at first slightly distended, gradually became occupied by a distinctly pyriform fluctuating tumour, reaching to above the umbilicus. A plastic deposit in the pelvis could be felt on vaginal examination, close to the cervix on the right side. The abdominal tumour and uterus moved *en masse*.

The cystic swelling gradually lessened in size, and in five months had totally disappeared, the only evidence of pre-existing

inflammatory change being a deviation of the uterus to the right side of the pelvis. The encysted effusion simulated closely an ovarian cyst.

Assistant Physician Hospital for Women, Soho, W.

REPORTS

OF

HOSPITAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN, IRELAND, AND THE COLONIES.

PUBLIC HOSPITAL, GEORGETOWN, BRITISH GUIANA.

A CASE OF TREPHINING FOR CORTICAL BRAIN LESION, GIVING
RISE TO EPILEPTIFORM SEIZURES AND PARALYSIS,
AFFECTING MAINLY LEFT FACE AND
LEFT UPPER EXTREMITY.¹

(Under the care of ARTHUR RANNIE, M.B.)

THAT cerebral surgery is still in its infancy, few who have watched its development of late years will be disposed to deny. As yet but a small number of operations have been placed on record as performed for the express purpose of relieving conditions diagnosed as due to localised disease of the brain or its membranes. It is chiefly, therefore, with the view of adding to the statistics of the subject, that I desire to record the following case which, however, like all other cases of cerebral disease, has some features peculiarly its own.

The patient was a black woman, aged 35, a native of the colony. She was the subject of tertiary syphilis. For about eighteen months prior to her last admission, she had suffered much from intense pain in the head, referred by her to the right frontal and parietal regions. With this pain, which was irregularly intermittent in character, were associated marked tenderness of the scalp over the regions mentioned, and a discharge from the right ear, both symptoms intermitting with the headache. The ear discharge was usually thin and watery, but occasionally became thick, yellowish, and offensive, and was ascertained to be due to catarrh of the external auditory meatus, there being no evidence of disease of the middle ear or of the bony meatus.

She had also suffered much from buzzing and singing sounds in the ears, visual hallucinations, and gloomy dreams. Her whole mental existence became affected, and about a year ago, while being treated in the public hospital for the head pain, her mental condition was characterised by marked exaltation. Since then she had been twice under treatment here for considerable periods of time, her mental condition on those occasions being characterised by gloomy despondency and peevishness, due to the painfully distressing head symptoms above mentioned. The treatment consisted of large doses of the bromide and iodide of potassium, with ferruginous and other tonics, and the application of iodine liniment to the seat of pain. She was last discharged from the hospital about a month ago, at her own request, being considerably relieved.

She was readmitted at midnight on June 5th, 1887. She stated that she had had a fit, causing her to lose consciousness; that she recovered from the seizure very quickly and walked to the hospital at once. On admission, she seemed a little dazed and confused, but otherwise presented nothing worthy of note. A mixture containing iodide and bromide of potassium was prescribed for her. On the morning of June 7th, while at breakfast, she had an epileptiform seizure, lasting two or three minutes, and accompanied by complete loss of consciousness. While she was being put to bed a second seizure occurred, which was witnessed by myself. The left angle of the mouth became retracted and elevated, and this was accompanied by conjugate deviation of the head and eyes to the left side; the left upper extremity then became adducted, the forearm flexed at right-angles with the arm, wrist bent forwards, and fingers flexed upon the palm; left lower limb stiffly extended; the right upper limb was carried above the head and loosely flexed; the right lower limb was stiffly extended during the tonic stage of the seizure. This stage was very short, and was succeeded by clonic spasms affecting mainly the left upper extremity and left facial muscles, the left

¹ Read at a meeting of the British Guiana Branch of the British Medical Association.

leg being but slightly affected, and the right limbs and right facial muscles not at all. Of the left facial muscles, the orbicularis oculi and the muscles which retract and elevate the angle of the mouth were mainly affected. There was moderate and equal dilatation of both pupils during the seizure. The clonic spasms persisted for about a quarter of an hour, when they were checked by the exhibition of 30 grains of chloral hydrate. During the clonic stage the patient largely recovered consciousness, and was able to apprehend to a great extent the meaning of what was said to her, and to execute voluntary movements with her right limbs.

After the effects of the chloral had passed off, there was found to be marked paresis of the left side of the face and of the left upper extremity, as also, though in a much less degree, of the left lower limb. There was slight proptosis of the left eyeball, with slight drooping of the upper eyelid. There was a decided droop to the left side during progression.

On June 8th Dr. Williams, Acting Surgeon-General, saw her in consultation with myself, and it was decided to operate with the view of removing a lesion—probably a syphilitic growth in the membranes—involving the arm and face centres in the right cerebral hemisphere.

The operation was performed by Dr. Williams on June 9th, the patient having had in the meantime four slight seizures. Her temperature before the operation was 101°, and she complained much of severe head pain a little in front of the right parietal eminence. The site selected for trephining corresponded to the right ascending frontal convolution. With an inch trephine an opening was made in the skull, which was found to be much thicker than normal and extremely dense. The dura mater beneath was thickened, and on cutting it a small quantity of puriform fluid ran out; this was found to proceed from the centre of a small degenerating gumma in the dura. As the disease appeared to extend backwards, the trephine was applied again, and a half-circle of bone removed from the posterior edge of the original trephine opening. This was subsequently found to have been unnecessary, as the disease was strictly localised, scarcely extending more than a quarter of an inch beyond the edge of the original trephine opening in any direction. The growth and some portion of the thickened and diseased dura were removed. Beyond slight local inflammation of the inner membranes, giving rise to opacity and thickening, the brain presented nothing abnormal at the site of operation. A little brain tissue was removed during the operation. The wound in the scalp—a crucial incision—was carefully sewn up, only a small opening being left for drainage. The wound was then dressed with sublimated lint. Throughout the operation the wound was irrigated with warm sublimate lotion (1 to 1,000). The patient passed a good night after the operation, had one slight fit, and slept a little. The head pain was relieved, only a slight gnawing sensation being complained of at the site of operation.

On the day after the operation another slight fit occurred, not accompanied by abolition of consciousness. The left limbs were convulsed in the extended position; left facial muscles involved as before. Paretic symptoms decidedly relieved.

June 11th. She had two slight seizures during the night, and fell out of bed.

June 12th. No fits since the day before. She was bright and cheerful, suffered no pain, ate well. There was still marked paresis of the left arm and left facial muscles, more especially of the former.

June 16th. Her temperature, which had been fluctuating between 99° and 101° for several days, suddenly rose to 103°. The wound was dressed for the first time, and found to be nearly healed. A little thick reddish fluid, free from smell, exuded from one of the corners of the wound. It came from the trephine opening, and appeared to consist of degenerated blood. By gentle pressure the trephine opening was emptied of this fluid, and a corner of the scalp wound opened up to allow of free drainage.

June 17th. Temperature this morning 99°. Great improvement in paretic symptoms.

June 30th. The further progress of the case up to this date had been eminently satisfactory. She now walked without the slightest droop, and although motor power in the left upper extremity was still considerably impaired, she was steadily improving in this respect. The left facial muscles were still lacking in tone to some extent. There was no headache and no tenderness of scalp. No further seizures had occurred. Her facial expression was bright and cheerful.

The wound was found to be quite healed at the third dressing, and has given no trouble since then. There has been no tendency to hernia cerebri since the operation.

REMARKS BY MR. RANNIE.—So far as I am aware, this is the second occasion on which the operation of trephining has been performed in this colony for localised disease of the brain or its membrane. In the early part of last year Dr. Grieve, Surgeon-General, operated upon a woman under my care for the relief of coma and limited convulsive seizures, supposed to be due to meningeal hæmorrhage, but which were afterwards found to have been caused by meningitis. The patient was temporarily benefited by the operation, but after a few days the convulsions recurred, and she gradually sank. The temporary relief afforded by the operation was doubtless due to the lessening of intracranial tension.

The main diagnostic features of the case I have just related were the existence of active syphilitic manifestations, the persistent localised head pain and tenderness of scalp, the sympathetic ear discharge, and the limited nature of the epileptiform seizures and subsequent paralysis. Upon the latter mainly the diagnosis of the situation of the disease was based, and the result of the operation tends to confirm, if any confirmation be needed, the doctrines of cerebral localisation.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, MAY 15TH, 1888.

Sir JAMES PAGET, Bart., F.R.S., President, in the Chair.

Morbid Growths Committee.—The report of the Morbid Growths Committee on Dr. Griffith's specimen of tumour in the neck was read by Mr. SHATTOCK. The report stated that the whole of the morbid growth was contained within the vascular system. The occurrence of growths within veins was rare, and the exclusive presence of the growth in the veins was, so far as was known unique. The growth could not be termed an angio-sarcoma, but was a dendritic sarcoma arising from the vessel-walls.

Dupuytren's Fracture.—Mr. JONATHAN HUTCHINSON, jun. exhibited a specimen of Dupuytren's fracture, removed by amputation from a man aged 25. A heavy weight had fallen on the outer side of the foot, breaking both malleoli as well as the fibula about three inches from the ankle. The lower fragment had been separated from the tibia, from which it had pulled off a piece of bone corresponding to the attachment of the interosseous ligament. The astragalus occupied the gap thus formed, and the distance between the malleoli was increased. Dupuytren's might be regarded as an exaggerated form of Pott's fracture; it was so rare that few specimens existed in the museums of the United Kingdom, the best being Sir A. Cooper's at St. Thomas's and Mr. Thomson's in Dublin. Dupuytren stated that it occurred in the proportion of 1 in 200 cases of fracture of the fibula. At the London Hospital it occurred once (possibly twice) to 140 cases of Pott's fracture and 210 cases of fracture of the fibula. Forcible eversion of the foot, which caused the outer border of the astragalus to act as a wedge, seemed to be the usual cause; and generally the interosseous ligament tore off its attachment to the tibia. The upper fragment of the tibia was retained in position by the interosseous membrane, and the extent to which the astragalus rose upwards depended on the exact point at which the fibula was broken.

Histology of Cancer and Normal Tissues after Sterile Incubation.—Further experiments on the infectivity of cancer, by Messrs SHATTOCK and BALLANCE, were described by the latter. After referring to their previous papers on the possibility of maintaining portions of tumour incubated for prolonged periods in the sterile condition, the results of microscopic examination of such portions of tissue were related. The cancer tissues were kept continuously at 100° F., and were found to present certain peculiar appearances which were not observed in healthy tissues thus treated. Zeiss's 1/5th immersion combined with ocular 1 or 3 was used for the examination, and logwood and fuchsin were found to be the most satisfactory stains for showing the nuclear changes. As a typical example, a specimen of mammary scirrhus after eight days' sterile incubation was described. The nuclei of the epithelioid cells were very granular; the nuclear matrix was either slightly stained or colourless. In some of the nuclei there was a distinct network (nucleo-plasm). There were also large distinct granules, nucleoli; the nuclei had a delicate continuous outline, even when

projections of the contained granules gave them a spinous form. In some cases the granules lay free in the cell-protoplasm, but were still connected with the nucleus by thread-like processes. The granules, which varied in size, were round, oval, or comma-shaped. The corpuscles of the fibrous tissue contained a deeply-stained nucleus, and around it the cell protoplasm formed a hazy zone containing granules, which were also found in the fibrous tissue, thickly and uniformly distributed. These appearances were found in numerous carcinomata and in sarcomata. It could not be positively stated that incubation was necessary for the production of this condition, as somewhat similar granules might sometimes be seen in perfectly fresh sections of carcinomata; in some cases the granules in the epithelial cells appeared to have escaped, collecting in the fibrous tissue. The appearances presented by the elements of normal tissue, either before or after incubation, were entirely distinct. The nuclei at first became granular, but well-defined, and presented none of the budlike processes above described as granules. After prolonged incubation the nuclei ceased to stain, and became indistinguishable from the cell protoplasm. In the testicle only did a process occur at all comparable to that observed in cancers; the liberation of spermatozoa was normally accompanied by a disintegration of the nuclei of the epithelium of the nutritive layer; no budding from the nuclei, however, had been observed. Although no explanation could as yet be afforded of the import of the peculiar appearances observed in cancer, it seemed probable that they had an intimate bearing on the local and general infective processes. It was thought by no means improbable that these detached buds (granules) might by their dissemination be one means of conveying infection to the lymphatic glands, and, like the spermatozoa which escaped from the spermatoblastic cells of the testicle, be the *semen* by which the growth was carried forth in other parts of the body. In a previous communication the authors had compared the process to that known as "rejuvenescence" in certain of the protozoa, and it might be that such nuclear particles were capable of subsequent development into cells; or the particles might enter the cells of the organs to which they were carried, and excite in them a tissue process similar to that existing in the primary tumour; if this were so they might be called *cancerzoa*. Or the process might be viewed in relation with the symbiosis of fungi and algae to produce lichen. Sir John Simon, in a private letter, had said: "Substitute for alga a bit of normal human body, say a bit of lower lip; substitute for fungus your amoeba, or whatever else it may be; the cancer which begins in the lip and spreads in its own type through the body is the lichen of that analogy." Gussenbauer (Z. f. Heil., B. ii, 1880) had stated that the secondary infection of lymphatic glands was effected by small granules, presumably derived from the primary tumour, which entered the cells of the glands, and incited them to multiply or to take on the characters of the primary growth. In reply to Dr. PERCY KIDD, Mr. BALANCE said that in some cases fuchsin, and in others logwood, stained the granules best.

Sloughing of the Bladder.—Mr. BRUCE CLARKE showed specimens from a case of sloughing of the bladder which had occurred in a man, aged 36, admitted with retention of urine of three days' duration. A small catheter was passed up a railroad catheter and retained, three or four pints of urine draining away. Much blood passed, and it was conjectured that the bladder contained blood-clot. Though the urethra admitted a No. 10 English catheter five days after admission, the patient was unable to void urine spontaneously, and, in spite of antiseptic precautions, the urine became foul and ammoniacal. A month after admission, perineal cystostomy was performed, but was followed by only temporary improvement; suppuration continued, and he died two months after admission. Examination after death showed that the cæcum was adherent to the upper surface of the bladder, which was gangrenous in its upper part; there was a collection of pus between the bladder and the rectum, but shut off by adhesions from the general peritoneal cavity. The prostate was natural. The urethra had sloughed round the aperture of the wound. There was no stricture; the kidneys were in a condition of tubal nephritis. Sloughing of the mucous membrane, or even, as in this case, of all the coats of the bladder, was not very uncommon in connection with central nervous disease, and in pregnant women sloughing took place from pressure, or in consequence of an acute attack of retention of urine, but he had been unable to find any case which was the direct counterpart of the case described.

Sarcoma of the Urinary Bladder.—Mr. VINCENT JACKSON showed

a bladder with a sarcomatous tumour occupying its interior. The specimen was removed from a gentleman, aged 76, who died two years and a half after the commencement of the first symptom, which was hæmaturia, at first slight and afterwards profuse. The tumour occupied the base of the bladder, covering the trigone and extending forwards to the prostate, the posterior wall of the bladder being unaffected. The growth was single, and although not distinctly pedunculated, yet the attached portion was circumferentially smaller than the free portion. The microscopic examination (made by Dr. Heneage Gibbes) showed that the tumour was made up of rounded cells varying in size in different parts, and a fibrous stroma. Throughout it ran a large number of vessels in direct contact with the cells. In some parts the cells were small and densely packed, and the stroma could only be made out with difficulty; in other parts the cells were large, and the stroma surrounded each cell; other parts were intermediate between these two conditions. The structure of the tumour varied in different parts; that portion containing large round cells surrounded by stroma resembled what had been described as alveolar sarcoma. In other parts it resembled a round-celled sarcoma of the ordinary type, but differed in being much more vascular than they usually were. In the most delicate parts the stroma somewhat resembled that found in myxomata.

Necrosis of the Pyramids of the Kidney.—Dr. TURNER showed the left kidney of an obese female, aged 60, who died with gangrene of the right foot and leg; she had also glycosuria. The papille, with a great part of the pyramids of the kidney, were necrotic, and partially detached from the living tissues, which appeared unchanged up to the line of separation. The organ appeared otherwise healthy. There was no pyelitis. The other kidney and the bladder were normal. There was fatty infiltration of the heart and atheroma of the aorta, but no valvular lesion. Two specimens of similar lesions of the kidney previously exhibited to the Society were referred to. The simultaneous necrosis of all the pyramids was attributed to thrombotic obstruction of the arterioles, due to defect of the general nutrition and to some disturbance of the local nutritive function. The separation of the sequestra instead of their absorption, as in the case of cortical necroses, was attributed to the contact of the necrosed tissue with the urinary secretion.

Peculiar Isolated Fracture of the Skull.—Mr. TARGETT exhibited a portion of a skull showing an isolated fracture of the base of the skull, produced by slight violence applied to the mastoid region; the patient, a boy, died of suppurative meningitis; there was an old history of otorrhœa. The fracture ran through the left petrous bone.

Malignant Growths of Pleura and Bronchial Glands.—Dr. PITT showed specimens from three cases of intra-thoracic malignant growths. The first specimen was from a woman, aged 61, who had been ill for one year, with symptoms of chronic chest disease, and physical signs of fluid in the left pleura. A small quantity of blood-stained fluid was drawn off. She had attacks of hemiplegia, first of one side and then of the other, and died. The necropsy revealed a white cuirass-like growth, involving the whole parietal pleura on the left side, and the pleural cavity contained blood-stained fluid. The lung was capped at the apex by new growth, and collapsed throughout, but unadherent below; the bronchial, aortic, pelvic, and inguinal glands were infected; the other lung and the duodenum contained small growths. The growth was a cylinder-celled epithelioma. Dr. Pitt thought that the history and *post-mortem* appearances rendered it highly probable that the growth was a primary affection of the pleura. He also exhibited two specimens of primary cancer of the bronchial glands.—Mr. SHATTOCK thought that few would agree with Dr. Pitt in believing that a columnar-celled epithelioma could originate in the pleura. There were well-recognised primary sources of such growths within the chest. He would ask Dr. Pitt whether the tracheal and œsophageal glands could be certainly excluded as sources of origin of the tumour? Few competent pathologists, he thought, would believe that a columnar-celled carcinoma could grow primarily from the pleura.—Mr. GODLEE endorsed Mr. Shattock's observations, and supplemented them by observing that the secondary tumours were often large and abundant in number after small primary tumours of the intestine.—Dr. COLLIER mentioned a case of scirrhus cancer of the pleura without any discoverable primary tumour.—Dr. PERCY KIDD had seen cases of carcinoma of the bronchial glands without any primary growths.—Mr. R. W. PARKER suggested that the primary growth might be the growths in the other lung.—Dr. PITT was alive to the obvious difficulties

in accepting the explanation he had put forward; but the distribution clearly pointed to the growth being primarily pleural.

Charcot's Disease.—Dr. PITT also described the microscopic appearances of the spinal cord from the case of Charcot's joint disease described to the Society by Dr. Collier earlier in the session. The membranes were thickened posteriorly; the cord was shortened and distorted. There was extreme sclerosis of the exterior part of the posterior column, and degeneration of Goll's columns. But the most remarkable feature was wasting and degeneration of Clarke's columns on the right side; in places the posterior nerve-roots were degenerated.—Dr. ORMEROD asked whether the ascending cerebellar tract were degenerated.—Dr. PITT replied in the negative.

Card Specimens.—Mr. COLEMAN: Polypus of Umbilicus.—Mr. S. PAGET: (1) Unusual Fracture of Head of Humerus; (2) Adenoma of Tongue.—Dr. COLLIER: Fracture of Longer Pastern Bone of Horse.—Dr. ORMEROD: Cancer of Gall-Duct.—Mr. V. JACKSON: Stone from Vesical Diverticulum removed by Suprapubic Lithotomy.—Mr. FENWICK (for Dr. HARRIS): Bilharzian Carcinoma of Bladder.—Mr. STONEHAM: (1) Tubercle of Prostate and Vesiculæ Seminales; (2) Cancer of Prostate, Prostatectomy; (3) Melanotic Cancer of Bone; (4) Two specimens of Cancer of Oesophagus necessitating Tracheotomy; (5) Hematocele from difficult Breech Delivery; (6) Cyst of Peritoneum.—Mr. BATTLE: (1) Duct Cancer of Breast; (2) Very Early Malignant Disease of Testis; (3) Sarcoma of Lower Jaw associated with Necrosis.—Dr. B. O'CONNOR: Hydatids of Liver and Spleen.—Mr. LUNN: (1) Tabetic Foot; (2) Calvaria, Clavicle, and Lower Jaw from a case of Osteitis Deformans; (3) Multiple Epiphysitis.—Dr. HEBB: (1) Cancer of Thyroid Isthmus; (2) Tuberculosis of Breast.—Dr. PENROSE: Aneurysm of the Heart.—Mr. SHATTOCK: (1) Two Mammiferous Dermoid Cysts of the Ovary; (2) Secondary Duct Cancer of Breast in Ribs.

CLINICAL SOCIETY OF LONDON.

FRIDAY, MAY 11TH, 1888.

W. II. BROADBENT, M.D., F.R.C.P., President, in the Chair.

A Case of Rupture of the Urinary Bladder, in which the Rent was Sutured.—Mr. SYMONDS read notes of the case. The patient was a child, aged 7, who was thrown from Blackfriars Bridge, falling into a passing barge on to her abdomen. She was admitted in a state of extreme collapse, and for some time it was feared she would die. The abdomen was full and tender, chiefly over the hypogastric region, where was a prominence exactly resembling a moderately distended bladder. No urine having been passed for about six hours, a No. 1 catheter was inserted. At first a few drops of clear urine were withdrawn, and then a drain of dark blood. Under chloroform a catheter was again introduced, and a small quantity of dark fluid removed. An attempt was made to pass the catheter through a possible rent in the viscus without success. The abdomen was at once opened, for though the catheter passed easily into the bladder, no reduction was effected in the dull prominence in the hypogastric region. A large quantity of dark fluid (having a faint urinous odour) immediately escaped. The rent was not at once found, but on passing a steel sound into the bladder it protruded just below the apex. There an irregular rent, an inch and a quarter long, was found, involving partly the peritoneal, but chiefly the extra-peritoneal surface. It was Y-shaped. The fold of peritoneum passing from the bladder to the abdominal wall was much lacerated, and the edges of the bladder were much torn. About twenty Lembert's sutures were inserted, the peritoneum was washed out with weak carbolic acid lotion and perchloride of mercury solution, and the abdominal wound closed. A catheter was tied into the bladder. For a time the child did well. Then the catheter irritated her, and was removed. She never fully recovered from her collapse, passing from it into a restless, non-ferverish condition. Fearing an accumulation of urine and inflammatory products, the abdomen was reopened on the sixth day, but nothing was found. Next day urine escaped through the wound, and the child died on the eighth day. At the inspection a collection of pus was found on the left side of the bladder, extending into the left ilio-lumbar region. The peritoneal part of the wound was soundly healed, but the non-peritoneal part was gaping widely, the sutures having torn through. The urine had escaped, and had set up the suppuration. There was no general peritonitis. There was separation of the right sacro-iliac synchondrosis. In reviewing the case, Mr. Symonds said that he considered the best plan would have been to have

closed the peritoneal part of the rupture and the rent in the anterior false drainage-tube into the bladder. The edges of the rent were ragged and bruised, and, though turned in, the muscle did not unite, nor could it be expected to do so. The case, he pointed out, was a good illustration of the necessity of leaving the extra-peritoneal part of the rent open. One point in the diagnosis was important, the prominence representing the bladder was due to the urine, the fluid not having formed a boundary, the pelvic cavity above it the small intestine for part. PRESIDENT called attention to being quite empty of bowel.—The opinion of Fellows on the points at issue, and asked for a record of the point raised by Mr. subject.—Sir WM. MAC CORMAC said that the two cases he had himself Symonds was one of importance. It would be able to suture in self operated upon he had the good fortune. He thought that in both the intra- and extra-peritoneal ruptures would be the better most cases the closure of the entire wound would be the better treatment. The conditions were so far from being healthy, and, of injury that the bladder-walls and urines in the recorded case therefore, disposed to heal.—Mr. BENNETT said that on account of the was an extremely unfavourable one, not only extensive extreme shock, but on account of the irregularity of wounds did laceration of the bladder. Extra-peritoneal parts and provision not heal so readily as those within the peritoneum. It was a disastrous course always to be made, by drainage, to avert the danger, and with sequences of the giving way of the extra-peritoneal wall. MAC CORMAC said extravasation of urine and suppuration.—Sir WM. MAC CORMAC inserted. he had taken it for granted that a drainage-tube was inserted.—Mr. It was a necessary part of the operation in such cases. SYMONDS, in reply, said that the non-insertion of the drainage-tube was a matter of great regret to him, but the wound appeared to him so securely closed that it seemed unnecessary. He thought that it was a most desirable thing to do, especially in such a case, where the lacerated and bruised edges were not unlikely to give way. He did not, however, consider a drainage-tube necessary in a case of intra-peritoneal rupture.

Acute Parenchymatous Tonsillitis, or Quinsy, treated by Cocaine.—Dr. DE HAVILLAND HALL read notes of three cases. Case I.—A labourer, aged 28, was admitted into the Westminster Hospital on September 28th, 1887, suffering from quinsy. He had had two similar attacks in the last five years. On admission, he had been ill four days. The right tonsil and adjacent soft parts were enormously swollen, and he was unable to swallow without the greatest difficulty and pain. On the 30th there was complete inability to swallow, but, after painting a twenty per cent. solution of cocaine freely over the whole of the fauces, the patient was able to swallow some bread and milk. The same night the left tonsil became affected, and the cocaine solution was applied again next day with an equally good effect, and the day following he was able to swallow bread and butter. No suppuration occurred. The patient left the hospital quite well after being in one week instead of four and three weeks respectively, as on the two former occasions. Case II.—A publican, aged 25, was seen in consultation with Mr. Wright at Kennington on October 26th, 1887. When seen, the patient's complexion was dusky; he was suffering from some dyspnoea and great dysphagia. Both tonsils and the soft palate were greatly swollen, and were covered with a viscid secretion, but there was no false membrane. Pulse 120, feeble. Urine, specific gravity 1030, loaded with albumen. The patient's condition was a most anxious one. The throat was swabbed out with a twenty per cent. solution of cocaine, and the application was repeated in ten minutes. Five minutes later, the patient was breathing more easily, and was able to swallow half a pint of egg-milk, and brandy. During the next two days, applications of cocaine were made night and morning, and one on the third day. The patient gradually improved, no suppuration occurred, and a week later the urine was free from albumen, and he was well. Case III.—A porter, aged 39, attended at the Throat Department of the Westminster Hospital on November 16th, 1887, complaining of sore throat and inability to swallow for thirty-six hours. He was previously quite well. The left tonsil and adjacent parts were swollen, and there was a yellow patch on the tonsil. Pulse 88, fair volume. Temperature 102.2°. The urine contained a trace of albumen. A twenty per cent. solution of cocaine was applied, and the patient was soon able to swallow half a pint of bread and milk. Four days later the patient had no difficulty in swallowing and was practically well. In all three cases, as soon as the patients could swallow easily, tincture of the perchloride of iron, with or without quinine, was ordered. Dr. de Havilland Hall pointed out

at cocaine had a twofold action in these cases; it diminished the sensibility of the parts to which it was applied, and at the same time lessened the blood-supply, hence deglutition was much facilitated. He also thought that it checked suppuration. He advised the throat to be sprayed out with a solution of bicarbonate of sodium, ten grains to the ounce, before the cocaine was applied; this means less cocaine was needed, as it appeared that cocaine acted more efficaciously in the presence of an alkali.—After some remarks by Mr. STOKER and Dr. ALEX. MORISON, Dr. SEMON said he had seen cases in which cocaine had been too freely used. Patients obtained cocaine pastilles from the chemist, and used them indiscriminately. A lady suffering from hay asthma, with cough, coryza, etc., being ordered a 10 per cent. solution, procured one of 20 per cent., which she used occasionally for two years to the nostril. One night, after so using it, she awoke from sleep feeling very ill, and with her heart's action very regular. She recovered after a time, and had since then had a wholesome fear of cocaine. Another patient, a gentleman, had severe poisonous symptoms from the use of only the sixth part of a grain. In fact he (the speaker) was of opinion that some patients could not use it. On the other hand, he had seen a patient suffering from tonsillitis, who had had aphagia for twenty-four or thirty-six hours, become able to swallow with some comfort only ten minutes after an application of cocaine to the fauces.—Dr. HALL, in reply, mentioned that last week he had used a 10 per cent. solution of cocaine to the nostril of a young and strong man, who was very strongly affected by it, became faint, and had to lie down for nearly an hour before the effects passed off, although ether and other stimulants were given. He always applied the solution now with a brush, all the cases in which upward symptoms had showed themselves having been when he used the spray. He observed that peri-tonsillar inflammation seemed to take place in some cases when practically no tonsillar issue was left. He thought that cocaine was only of use in parenchymatous tonsillitis; the same good results had not followed its use in follicular tonsillitis.

Complete Bilateral Paralysis of the Vocal Cords, the Result of Acute Laryngitis: Recovery.—Dr. PERCY KIDD read notes of this case. The patient, a pale, thin woman, aged 37, the subject of chronic bronchitis, complained of shortness of breath and loss of voice, which had developed a few days previously. On examination there was inspiratory dyspnoea, with complete aphonia, and harsh laryngeal breathing was audible over the upper part of both lungs. The mucous membrane of the larynx was deeply congested, and there was much swelling of the ary-epiglottic folds, ventricular band, and to a less extent of the inter-arytenoid fold. In the last situation there was a small yellowish mass which could not be detached by coughing. The vocal cords occupied the cadaveric position, and remained motionless during inspiration and phonation. The patient was ordered cold applications to the throat, ice to suck, and complete rest. Four days later she was much better; the dyspnoea had diminished, there was less laryngeal swelling, and the inter-arytenoid fold presented a normal appearance. There was no trace of the small yellow mass, probably a piece of inspissated mucus. The vocal cords had to a great extent recovered their power. On phonation the normal closure of the glottis occurred; but abduction was still very deficient, though not absolutely lost. From that time she rapidly recovered, and in three weeks the larynx was perfectly healthy, and the vocal cords had recovered their functions. The want of mobility of the cords was attributed to paralysis of their muscles from inflammatory infiltration of the intra-muscular nerve filaments and muscular fibres. Reasons were given for the belief that mechanical fixation from abscess, perichondritis, swelling of the inter-arytenoid fold, etc., was inadequate to explain the succession of events.—Dr. SEMON said he had come to the meeting feeling somewhat sceptical as to the possibility of the existence of a bilateral rheumatic paralysis of the vocal records. Such cases, if followed to their termination, generally ended in the discovery of a central cause for the paralysis. He agreed that there were no *a priori* reasons why cold should not affect the recurrent laryngeal nerve as it did the facial, though, being better protected, the former was less liable to such influence. He said that the order of retrogression certainly supported the diagnosis of rheumatic paralysis, but it was the first case on record of bilateral paralysis from that cause. The reasoning which Dr. Kidd had brought forward to prove that the case was not an affection of the laryngeal joints was to him (Dr. Semon) quite conclusive.—Dr. PERCY KIDD, in reply, said he was

extremely gratified to find that Dr. Semon had no more serious argument to allege against his contention.

Necrosis of the Greater Cornu of the Hyoid Bone and of Ossified Portions of the Thyroid Cartilage: Extrusion of Sequestra from an Abscess in the Anterior Triangle of the Neck, following Gummatus Ulceration of the Tongue and Perichondritis of Thyroid and Cricoid Cartilages; Profuse Hæmorrhages; Pneumonia; Phthisis.—Mr. NUNN described this case. The patient, aged 33, was a gentleman who had served with the army in India for a short period. About three years before coming under Mr. Nunn's notice he had suffered from syphilis followed by constitutional symptoms. Tertiary ulceration of the tongue was the chief trouble. The irregular habits of the patient prevented the steady carrying out of any treatment. At the end of fourteen months swelling with tenderness appeared on the right side of the larynx, and a couple of weeks later profuse hæmorrhages, three in number, occurred; ultimately, the sequestra above named were discharged from an abscess which formed in the anterior triangle of the neck near the sternum. The abscess ultimately became a pharyngeal fistula, liquid food escaping during the act of deglutition. Pneumonia set in immediately after the hæmorrhages, and finally the patient died of phthisis. The case was most sedulously watched by Mr. Evans, then of Hobart Place, and by Mr. Edward Semple. After the first hæmorrhage, Sir James Paget was consulted in respect of ligaturing the carotid artery, but the operation was decided against.—Dr. PERCY KIDD observed that the patient was said to have had hæmorrhage from the throat, and yet afterwards tubercular disease of the lung was discovered. Under such circumstances he did not think the lungs could be quite excluded in searching for the source of the hæmorrhage.—The PRESIDENT remarked that in a case closely watched, as this had been, and where the surgeon was actually present, he as thought the source of the hæmorrhage was not difficult to ascertain. It was probably a case of *phthisis ab hæmoptoë*: blood sucked into the lungs originating the phthisis.—Mr. NUNN said, in reply, that when Sir James Paget saw the patient the question arose as to whether the hæmorrhage came from the lingual or the hyoid artery, or some other large vessel. At that time there was only the swelling about the hyoid bone. The hæmorrhages were profuse. The hand-basin was half filled with blood, and the patient quite blanched. When the abscess formed at the front of the neck, and the bone was extruded, then he (the speaker) came to the conclusion that it was the lingual artery which had bled. The lung mischief seemed to have followed the drawing of the blood into the lung.

HARVEIAN SOCIETY OF LONDON.

THURSDAY, MAY 3RD, 1888.

R. S. MAIR, M.D., in the Chair.

Treatment of Spinal Abscess.—Mr. WATSON CHEYNE read a paper on this subject. He said that in these abscesses we had to consider the contents, the wall, and the lesion of the bone from which they started, although the bone lesion could not always be made out. There were three chief types of tubercular disease of the spine: (1) formation of tubercular cavities containing soft, cheesy material; (2) formation of tubercular sequestra, which either lay free in a cavity lined with tubercular granulations, or were not completely separated; (3) a superficial caries of the bone. The first two forms were those which were chiefly associated with marked curvature, while the third form was not necessarily associated with curvature, unless it occurred in conjunction with the others, or spread in along the inter-vertebral discs and destroyed them; but the third form was more extensive; it was chiefly found in adults, and a larger proportion of abscesses accompanied it than in the case of the other two. When the osseous lesion approached the surface, it involved the periosteum and ligaments, and led to the formation of a firm nodule, which, on microscopical examination, was seen to consist of granulation tissue, in which the inflammatory cells were few in amount, but which contained numbers of tubercles. This nodule constantly extended by infiltration of the neighbouring tissue with similar growth, while at the same time the older tubercles which were present in the centre of the mass tended to undergo caseation; the caseous material became infiltrated with exuded fluid, and thus we came to have a central collection of broken-down cells and tissue floating in a variable amount of fluid, and surrounded by a wall composed of new tissue infiltrated with tubercles—in fact, a chronic abscess. The growing

part of the abscess was thus the wall, while the contents were not pus, properly so-called, but broken-down portions of the wall. However extensive the abscess, the wall would be found on examination to present the above appearance, and portions of it inoculated into guinea-pigs set up tuberculosis. The pyogenic organisms did not take any part in the production of chronic abscesses, as shown, among other things, by the fact that they grow rapidly and luxuriantly in the contents of chronic abscesses, while pus in which they had already grown was no longer a favourable nidus for their development. The bad results following the opening of these abscesses where fermentation was not prevented, would be readily understood from their pathology. The entrance of the putrefactive organisms gave rise to the various symptoms of septic intoxication. The pyogenic organisms were able to grow in the contents or in the wall, and cause septi-cæmia or pyæmia, and the chronic osteomyelitis of the bone might be converted into a dangerous acute osteomyelitis. At a later period the continued growth of the pyogenic organisms kept up a state of chronic septi-cæmia, and the profuse discharge led to exhaustion or waxy degeneration. The methods of treatment considered were two in number—those which led to the cure of the abscess without opening it, and those in which the abscess was opened. Reference was especially made to the results obtained by injection of these abscesses with iodoform mixed with glycerine, or with iodoform dissolved in ether; and the method of employment and the results obtained by this plan were narrated, the general conclusion come to being that it would be well to adopt these plans in all suitable cases before proceeding to open the abscess. Details were given of the results obtained by the method of aseptic opening and drainage of these abscesses, the cases referred to having been partly treated by Sir Joseph Lister and partly by the author. Statistics of 56 cases were given, of which 73.2 per cent. healed, and 12.5 per cent. died. These were cases chiefly of psoas abscess, but there were also lumbar, dorsal, and cervical. The cases were most numerous between the ages of 20 and 30: 22 per cent. of these abscesses recurred at periods varying from eighteen days to three years, but the great majority of these cases had again healed, and the patients remained well. As to the causes of death, 4 patients died of phthisis, 1 of exhaustion, 1 of whooping-cough, and 1 of erysipelas which attacked a small incision made in the neck without antiseptic precautions, and which did not spread under the dressings. The latter case was, in reality, a case of cure which died of an accidental attack of erysipelas. The cases in which septic infection of the wound occurred were discussed, and the causes of this occurrence pointed out, and as most of these accidents were avoidable the proportion of successes in future would probably be greater. The average length of time taken in healing was from eight to nine months, but one or two cases lasted considerably longer. In some instances tubercular disease existed elsewhere, and a case was narrated in which a number of abscesses occurred in connection with various bones and which ultimately got well. The progress of a case under aseptic treatment was then described, and the contrast between this course and that followed when the wound became aseptic was pointed out, in the case of a patient whose wound in the first instance followed an aseptic course and healed, but who some time later had recurrence of the abscess, which burst before the patient was admitted to hospital. As to the question when these abscesses should be opened, the conclusion come to was that they ought to be treated as soon as possible, for the chances of absorption were very slight, and if absorption did not occur the abscess-wall grew, and the abscess became larger. It had already been pointed out that in many cases it would be well to employ the methods of iodoform injection for opening the abscess. As to the position of the opening, the most important point was to have it as far removed from sources of contamination as possible; in the case of psoas abscess, either in the lumbar region or in the neighbourhood of the anterior superior spine, in the case of retro-pharyngeal abscesses at the upper and posterior part of the sternomastoid muscle. An important question was what should be done with the abscess wall, which was a very essential part of the abscess. In subcutaneous and small chronic abscesses the author urged that they should be dissected out as if they were cysts, but in these spinal abscesses this was rarely possible, and even scraping the wall thoroughly was dangerous on account of the important structures in the vicinity. Nevertheless, as much of the abscess wall should be removed as possible, and the author had found great advantage in touching the portion which remained

with undiluted carbolic acid. The removal of the diseased bone as advocated by Mr. Treves was seldom feasible, for in the lumbar region the disease was more often a superficial caries of considerable extent than a necrosis, and any attempt to scrape or gouge away the diseased part was impracticable. In the neck this was more feasible, and the possibility of doing good in this way must be borne in mind. With regard to the method of dressing, it must be conducted strictly on the principle of excluding all micro-organisms; that is to say, it must be strictly aseptic. The author was inclined to think that for these abscesses the old carbolic dressings were the best, though he often combined them with the alembroth dressings which had recently come into use. The author objected strongly to imperfect antiseptic treatment in these cases, and more especially to the attempts to remedy the mischief so arising by injecting irritating antiseptic solutions. In conclusion, stress was laid on the fact that the patient was also suffering from disease of the spine, and the treatment necessary in each case must be adopted. As a rule it was best to keep the patient in bed in the recumbent posture, with a light apparatus to prevent lateral movement, and to remind him that he must not sit up. As a rule the general health improved during the patient's stay in bed, and it was not usually seen at the conclusion of the case that any advantage was gained by letting them get about.—Mr. LOCKWOOD said he considered the spinal lesion of the most importance, and the abscess but an accident added to it. Rest in the recumbent posture frequently led to ankylosis and cure. He wished to know whether Mr. Cheyne had experience of cases in which rest had been maintained and the abscess left alone; also whether all these cases were tubercular, because their contents produced tuberculosis in guinea-pigs. The question was also raised as to the occasional origin of the disease in the intervertebral discs. The length of time taken by the abscess to heal was an indication of the progress of repair in the spine. If the abscess required opening, antiseptic precautions were essential.—Mr. CHEYNE, in replying, said that he had no personal experience of the absorption of these abscesses when the patient was placed in bed in the recumbent posture, but he referred to Lacharrière's paper, in which a number of cases of this occurrence were mentioned; for reasons stated in the body of the paper, the author thought this treatment was injudicious. With regard to the views that the occurrence of tuberculosis in guinea-pigs did not necessarily imply that the material introduced was tubercular, he pointed out that the experiments on which such a conclusion was founded had been completely disproved; and that we must look on the occurrence of tuberculosis in guinea-pigs after inoculation as the result of the inoculation of tubercular material. As to whether the disease could begin in the intervertebral discs, he did not deny the possibility of this occurrence, but thought it much more probable that the destruction of the discs was secondary to disease of the bone. As to the point that the length of time taken in healing really implied the length of time for the bone lesion to get well, and that, therefore, the treatment of the bone lesion was more important than that of the abscess, he pointed out that the delay in healing was in all probability mainly dependent on the length of time required for the osseous lesion to get well, but that, however important the treatment of the bone lesion, if the aseptic treatment of the sinus were neglected, the chances of recovery of the bone were very much less. As to the necessity for the spray, he held that it was not essential, but that in many cases it was the most convenient form of irrigation.

Painful Affections of the Feet.—Mr. SYMONDS also read a paper On Some Cases of Painful Feet.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, MAY 4TH, 1888.

C. B. KEETLEY, F.R.C.S., President, in the Chair.

Cases.—The following clinical cases were shown: Multiple Exostoses in three members of the same family, by Mr. BRUCE CLARKE; a case of Nevroid Growth in the Lower Jaw of a Child, by Mr. E. C. VAN BUREN; a case illustrating one cause of failure after Operation for Fistula *in ano*; a case of Complete Iridemia, by Mr. PERCY DUNN; a series of cases of Diseases of the Conjunctiva and Cornea, by Mr. LANG. Pathological specimens were also exhibited by Mr. DUNN.

Cavendish Lecture.—The CHAIRMAN announced the arrangements for the Cavendish Lecture, to be given on Friday evening, June 1st, by Sir William Stokes.

New Members.—Messrs. A. C. A. Alexander, J. M. Barbour, G.

Heaton, A. S. MacCausland, S. H. Moore, B. Nowell, and R. D. R. Sweeting were elected members.

Treatment of Piles by Injection.—Mr. SWINFORD EDWARDS read a paper, in which he gave the results obtained by this method in thirty-eight cases which he had treated at St. Mark's Hospital for Fistula and in private during the last two years. Of these cases, ten were still under treatment; two had been lost sight of; nine, although still under observation, appeared to be perfectly well; and seventeen had been cured. Three had remained well for nearly two years, and fourteen for periods varying between this and six months. In one case only was there a relapse, and this after a year's immunity. The formula used was carbolic acid gr. xii, glycerine and water aa ʒi. The bowels having been well moved, and the piles being extruded, three to five minims or more of the solution were injected by a hypodermic syringe into the centre of each hæmorrhoid. After all were thus treated, they were returned well above the sphincter, and the patient allowed to go home, being instructed to replace the piles at once should they prolapse. The injection might be repeated, if necessary, at intervals of a fortnight; but, in the majority of cases, once appeared to suffice. As an adjunct to this treatment, it was well to order a laxative iron mixture, and an ointment of the subsulphate of iron, to be passed well up the rectum before and after each stool. The advantages of this method were that the patient was not laid up, but could follow his usual occupation during the whole course of treatment, suffered no pain, and ran no risk to life. Its only disadvantage was that at present one could not say how long the cure would last; for this, many more years' experience would be required.—Mr. CHIPPS stated that his small experience of the method (only twenty or twenty-one cases) did not point to any good results. Those cases which he had been able to follow had not at all benefited. The introducer of the method had himself now—in consequence of a succession of bad cases—modified his views as to the advisability of the method in all cases.—Remarks were made by the PRESIDENT, Mr. H. ALLINGHAM, Mr. BENHAM, Dr. ALDERSON, and Mr. BENTON; and Mr. EDWARDS replied.

Hernia of the Bladder.—Mr. KEETLEY read notes of a case in which the bladder was found in the wall of a hernial sac in the course of an operation for radical cure of hernia. The viscus was punctured unintentionally, but the puncture having been carefully closed, and care taken that no urine should be left in the peritoneal cavity, the patient recovered without a bad symptom, and was exhibited. It was believed that similar accidents were not uncommon; and two unreported cases, of which Mr. Keetley had received authentic accounts, were referred to. In each of these two, a portion of the bladder was cut off, in one case with a fatal result.

HUNTERIAN SOCIETY.

WEDNESDAY, APRIL 25TH.

R. CLEMENT LUCAS, B.S., F.R.C.S., President, in the Chair.

Laryngeal Cancer.—Dr. DUNDAS GRANT showed a case of intrinsic epithelioma of the larynx, which he had brought before the Society last year (April, 1887). At present, respiration through the larynx could not be carried on beyond a few moments, the voice was nearly abolished, and there was commencing pain in swallowing. One gland on the left side of the neck was much enlarged and hardened. The spreading out of the thyroid cartilage was distinctly increased. Laryngoscopically the growth was seen to have infiltrated the left ventricular band, and to have extended round the interior of the larynx, so as almost to occlude it. There was no extension upwards into the pharynx. Tracheotomy was performed on July 26th, 1886, when the disease was progressing with obvious rapidity. The immediate improvement in comfort, and the comparative well-being of the patient, added to the retarded progress of the disease since the operation, gave evidence of the unquestionable benefit effected by tracheotomy, and confirmed the opinion of Fauvel, whose statistics showed an average duration of four years in cases of epithelioma of the larynx treated by tracheotomy, against one of one year and four months in those left alone.

Nasal Trephine.—Dr. DUNDAS GRANT then showed the nasal trephine referred to in his paper on Tinnitus Aurium at the last meeting. It was capable of removing cartilaginous or bony outgrowths, and deviating portions of the nasal septum almost instantaneously, and with little or no pain.

Congenital Absence of Iris.—Mr. GEORGE CARPENTER showed, for the PRESIDENT, a case of congenital absence of either iris in a

child 3 years of age. The child had marked nystagmus. The fundus oculi was perfectly healthy. Associated with this deformity there had been talipes equino-varus dating from birth, for which he had been operated upon. His mother had internal strabismus on the left side, nystagmus, complete absence of the iris, together with posterior polar cataract, the fundus oculi being normal. Her occupation was that of a shirt-maker, and she was able to do fine work. The brother and sister of the patient were quite healthy, and there was no history of a similar deformity on either the maternal or paternal side.

Tropho-neurosis.—Dr. STOWEN exhibited a rare case of tropho-neurosis, characterised by chronic ulceration and atrophy of the nails and nail matrices of the hands and feet, in the person of a woman, aged 67, associated with "glossy skin." The disease commenced thirty-seven years previously, within a fortnight of her second confinement, and was at first symmetrical. She had never had acute gout, although several of the phalangeal joints of the hands were swollen and had been tender. Her father was stated to have had gouty manifestations since his early youth.

Paralysis Agitans.—Dr. A. T. DAVIES read notes of a case of commencing paralysis agitans (Parkinson's disease). The disease began in a characteristic manner in the hand, and gradually spread upwards, involving the neck, and downwards to the right leg. The observation of Mr. Parkinson, who, in 1817, first described the "shaking palsy," that the movements occurred in parts not in action, and even when supported, was well illustrated by the case. M. Charcot attributed sudden shock or terror as one of the chief causes of the disease, and this appeared to be the agent in this case. The patient was shown at the meeting.

Skin Affections connected with Rheumatism.—Dr. STEPHEN MACKENZIE read a paper on the skin affections connected with rheumatism. After a passing notice of sudamina and miliaria, so often seen in connection with rheumatic fever, but only indirectly connected with it through the profuse sweating characteristic of the disease, he then dealt with urticaria, showing that, whilst not numerically frequent, there appeared to be some link connecting it with rheumatism, and mentioned a recorded case in which unilateral urticaria and chorea occurred as sequels to rheumatic fever. A few cases of pemphigus have been observed in connection with rheumatism, as also rare cases of exfoliative dermatitis. Coming to the group of erythemata, firmer ground was approached. Erythema circinatum was frequently noticed to concur with acute rheumatism. He had seen erythema papulatum with rheumatic symptoms, and in one case of this affection a murmur resulted, presumably due to endocarditis. With regard to erythema nodosum, he had elsewhere brought forward strong evidence, he thought, that it frequently coexisted with acute rheumatism, which it might precede or follow; that it might give rise to endocarditis when no joint-symptoms were present; and, further, he thought it probable that in some cases it might be the sole expression of rheumatism. He fully dealt with purpura in connection with rheumatism. He thought Schönlein's original description of peliosis rheumatica had been much misread, and that great confusion existed on the subject. He therefore discarded the term. He narrated some cases of purpura with acute rheumatism, occurring during convalescence from acute rheumatism, and in persons who had previously suffered from rheumatism, as well as cases of purpura of great similarity, but without unequivocal arthritis. The general correspondence of the symptoms in the last group with those of the undoubtedly rheumatic group, was, in his opinion, sufficient to justify their being regarded as rheumatic.—Dr. G. N. PITT, Mr. FENDICK, and Dr. A. GARROD took part in the subsequent discussion, and Dr. STEPHEN MACKENZIE replied.

MANCHESTER MEDICAL SOCIETY.

WEDNESDAY, MAY 2ND, 1888.

J. DRESCHFELD, M.D., F.R.C.P., President, in the Chair.

Complete Destruction of Tongue.—Dr. THOMAS HARRIS showed, for Dr. H. SIMPSON, a boy aged 14, in whom there had been complete destruction of the tongue. The boy's friends stated that, eight years ago, ulceration began in the soft palate, and proceeded to almost complete destruction of that part. The affection of the tongue began two years ago with an ulceration in the centre of the organ, and that ulceration gradually spread towards the periphery, and destroyed the whole of the anterior part of the tongue. Eight months ago stiffness of the lower jaw appeared. At the present time only a very small portion of the root of the tongue existed, the whole of the anterior part of the organ having disappeared.

leaving the floor of the mouth irregular and studded with small nodular elevations. The faucial aperture was small and lozenge-shaped, measuring about half an inch vertically and the same transversely, and bounded on either side by thick bands of fibrous tissue. The boy said he could taste very well, but this was found to be true only when he swallowed, since he did not taste either a solution of quinine or of common salt, when these were brushed over the anterior part of the floor of the mouth, until he performed an act of deglutition. It was difficult to obtain a perfect view of the floor of the mouth, in consequence of the boy being able to separate the incisor teeth only half an inch. The boy showed no other evidence of a syphilitic taint; but a brother, about twelve months his junior, exhibits well marked signs of congenital syphilis.

Intussusception of the Bowel: Recovery.—Dr. NESFIELD showed the specimen; it consisted of about ten inches of the ileum, the cæcum, and the valve. The case was that of a married lady, aged 34. On March 10th last, she over-reached herself, and was taken suddenly ill with abdominal pains, a desire to go to the closet, and vomiting. When visited, she was partially collapsed. A tumour was found reaching across the lower part of the abdomen, inclining to the right side, but tender and dull on percussion. After an enema on the third day, she passed a large quantity of blood, and the tumour disappeared; vomiting was frequent, and occasionally stercoraceous. On the eighth day the bowels acted spontaneously. The pulse was slow and the temperature nearly normal. On the seventeenth day the slough came away. Recovery has been slow, but she is now able to move about. Treatment: morphine hypodermically and rectal feeding. Abdominal section was considered, but postponed, the symptoms being at no time sufficiently urgent.

Cystoscopes.—Mr. WHITEHEAD demonstrated different forms of cystoscopes, and mentioned conditions where their use was invaluable.

Peripheral Neuritis.—Dr. BURY read a paper on peripheral neuritis in acute rheumatism, and on the relation of muscular atrophy to affections of the joints.

SOUTH INDIAN BRANCH (MADRAS).

FRIDAY, JANUARY 13TH, 1887.

Surgeon-General G. BIDIE, M.B., C.I.E., President, in the Chair.

Statistics: Compound Fracture.—Brigade-Surgeon SINTHORPE presented an elaborate series of tables embodying the fullest obtainable particulars of all the cases of compound fractures or compound dislocations of the limbs among natives treated in the Madras General Hospital from 1868 to 1886 inclusive. The cases occurred in the practice of ten or twelve different medical officers. There were altogether 115 treated, with 29 deaths. Seven were Mohammedan males, 102 Hindu males, 5 Hindu females, and 1 Syrian male. The injuries were classed as follows:

Nature of Injury.	Admission.	Recovered.	Died.	Ratio Percentage of Death.
Multiple injuries	15	8	7	53.3
Compound fracture of arm	5	4	1	20.0
Compound fracture of forearm	21	18	3	14.2
Compound dislocation of wrist	7	1	—	—
Compound fractures of thigh	9	4	5	55.5
Compound dislocation of knee	1	1	—	—
Compound fractures of leg	63	50	13	20.6
Total	115	86	29	25.2

The causes of the 29 deaths were as follows: tetanus, 13; septicæmia, 2; gangrene and septicæmia, 1; gangrene, 2; shock, 6; exhaustion, 2; acute pneumonic phthisis, 1; no records, 2. It was observed that the mortality from tetanus, which was nearly 1 in 9, was formidable, being greatly in excess of that at Guy's Hospital, which was stated by Mr. Bryant, quoting from Mr. Poland's statistics, to have been 9 in 398 cases of compound fracture, or about 1 in 44.

Excision of Tongue.—Surgeon F. CLARENCE SMITH reported two cases in which he had excised the tongue by Mr. Syme's method, in which ligature was first performed to control hæmorrhage, in the manner suggested by Mr. Jordan Lloyd. This modification of the operation prevented any serious hæmorrhage, and if the

wounds were dressed with some preparation of iodoform, laryngotomy or tracheotomy, with or without occlusion of the pharynx was unnecessary. The only objection was that suppuration followed in the track of ligature, and Surgeon Clarence Smith proposed in future to use a pad over the skin, over which the ends of the ligatures might be tied. In this way he thought the circulation might be effectually controlled, while the puckering of the skin and tissues included in the ligatures would be avoided. In the second case, where the tongue was removed far back, the patient sank from inanition, and it was suggested that in a similar case, where the patient was in a very low condition, it would be better to perform a preliminary gastrostomy.—Surgeon-Major DRAKE-BROCKMAN and BRANFOT recommended the operation with the *écraseur*, plain or heated, in preference to that performed.—Surgeon J. SMYTH mentioned a case in which some hæmorrhage had followed the use of the chain *écraseur*, and he had found difficulty in removing the whole of the growth with the instrument. He had assisted Surgeon Clarence Smith in the two operations reported, and had observed that there was very little hæmorrhage.—Surgeon CLARENCE SMITH, replying to an observation made by Mr. DRAKE-BROCKMAN as to the action of chunam used in chewing betel, said that that had occurred to him as a possible cause of malignant disease of the tongue, owing to the irritation which it produced. He defended his preference for Syme's operation, as modified by Jordan Lloyd, on the grounds that the *écraseur* did not do away with either primary or secondary hæmorrhage, and was apt to take away too much or too little; that the galvanic *écraseurs* always caused a slough, and that the *écraseur* could not do anything in the region of the tongue which could not be better done with the knife or scissors.

PATHOLOGICAL SOCIETY OF MANCHESTER.

WEDNESDAY, MAY 9TH, 1888.

A. W. STOCKS, M.R.C.S., President, in the Chair.

Meckel's Diverticulum.—Mr. G. GIBSON HAMILTON (Liverpool) described two cases of acute intestinal obstruction due to Meckel's diverticulum. Both had occurred in boys six years of age. One had been operated on eighteen hours after symptoms commenced the diverticulum being easily separated from its attachment to the mesentery. The patient made a good recovery. The second case had not been so acute, and was operated on at the end of a week, when the boy was almost moribund. The patient survived only a few hours. A specimen demonstrating how the obstruction had occurred was shown.

Malignant Tumour of Lung.—Dr. STEEL showed a large lympho-sarcoma of the upper part of the right lung, the centre of which had broken down, a cavity being formed. The patient aged 45, from whom the specimen was taken had suffered from hæmoptysis in May, 1887, and from that time his health had failed, although he had not suffered from cough and expectoration till winter. The physical signs, as well as the fetid sputa and the mode of their expectoration, had indicated the presence of a cavity during life. Centrifugal pressure symptoms had been well marked. The patient died on March 7th, 1888. No other tumours were found in any part of the body.

Liver in Phosphorus Poisoning.—Mr. JOSEPH COLLIER showed the liver from a case of acute phosphorus poisoning. The patient, a girl aged 20, died after two days' illness. The liver was large and fatty, not uniformly yellow, but mottled, with reddish patches, as in the slower cases of acute yellow atrophy. The lobules remained distinct. Sections under the microscope showed the hepatic cells to be in a state of fatty degeneration, many being distended by and converted into large fat-globules—a condition of things very different from the fine fatty granules found in acute yellow atrophy. There was no proliferation of biliary capillaries and infiltration of leucocytes, but the small bile-tubes were seen to be compressed by the enlarged lobules.

Tumour of Kidney.—Dr. HURTON showed a large tumour of the kidney from a girl aged 8. Microscopic preparations of the growth were also exhibited.

Epithelial Tumour of the Cornea.—Dr. A. EMRYS JONES and Dr. PETER YATES showed specimens and sections from a man, aged 57, first seen in January, 1885. Three years previously he had suffered from phlyctenular conjunctivitis in the right eye, and little vesicles were noticed on the edge of the cornea. When seen in 1885 there was a distinct lobulated growth covering nearly the whole of the cornea and the adjoining region of the conjunctiva. The eye was at once enucleated, and, after recovery,

May 19, 1888.]

he was not again seen. It was, however, reported that he died in January, 1886, from cancer in the neck. Microscopically, the tumour was found to be an example of tubular epithelioma, with cells arranged in tracts or cylinders. The stroma was composed of partially-formed fibrous tissue. At the surface there were a number of small cysts.

Sarcoma of Choroid.—Dr. A. EMRYS JONES and Dr. PETER YATES showed specimens and sections from a tumour of the eyeball taken from a woman aged 24. The eye had been dim for three months, but without pain. On ophthalmoscopic examination there was found on the inner side a large red growth pushing the retina in front. The translucency of the eyeball was tried according to Lange's method, but with negative results. There was a history of an aunt who had died from cancer of the breast. The growth occupied nearly one-third of the eyeball, and was of the spindle-celled variety of sarcoma. A few of the spindles were very large, and contained two nuclei, and some of the cells were forked and branched at one end.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, MAY 4TH, 1888.

E. ATKINSON, M.R.C.S., President, in the Chair.

Treatment of Uterine Myomata by Apostoli's Method.—Mr. MAYO ROBSON read a paper on his experience of the treatment of fibroid tumours of the uterus by electrolysis, and gave details of several cases. In one case a large tumour reaching to the ribs had been reduced to a simple pelvic enlargement in a little over two months, during which time a current varying from 150 to 270 milliampères had been applied twelve times. The menorrhagia, which on commencing the treatment required eighteen napkins a fortnight, was reduced to six napkins a month when the patient left. In another case, although the treatment had been just as efficiently tried—nineteen operations in three months, varying between 180 and 300 milliampères, for periods of ten minutes each application—the tumour had steadily increased. In several other cases improvement had been effected and hæmorrhage controlled. In no case had any inconvenience resulted from the operation. In all cases Dr. Apostoli's directions had been strictly carried out. Mr. Robson thought that in electrolysis we had a powerful means of treating with success some cases of fibroid tumours of the uterus, but that too much must not be expected, for in some cases it seemed to fail to give the slightest benefit. He thought that all cases in which the treatment had been tried ought to be reported in detail, so that the profession might be able to decide for itself on this important question, and so that an opinion might be formed as to what cases were likely to be benefited by it. His own experience led him to believe that benefit was most likely to ensue in cases accompanied by severe hæmorrhage. Mr. Robson had found benefit to accrue from the treatment of endometritis accompanied by menorrhagia, and related a case in illustration where the hæmorrhage at a menstrual period had been reduced from fifty napkins to fourteen. He used a battery of fifty 1-pint Leclanché cells, and employed a double collector, a rheostat, and a Gaiffe's galvanometer.—Dr. CAMERON pointed out that electric measurements were to a certain extent fallacious, as, according to the shape of the tumour, a definite current might act very differently, according as it was directed through a small portion or widely diffused.—Mr. LAW-FORD KNAGGS reviewed the published results of the operation. The great differences of opinion on the subject must be due to errors of diagnosis or inexperience in the methods of administration.

The Nature of Cancer.—Dr. BRAITHWAITE read a paper on this subject. He reviewed the various characteristics of the epithelium cell with regard to position, shape, size, and nutrition, and considered that the abnormal growth was due to the cell having pierced the basement membrane, and therefore being subject to conditions allowing of greater nutrition and consequent growth. Growths, while they remained encapsuled, were not malignant.—Mr. LITTLEWOOD thought the difficulties of the case had not been met by the paper. Encapsulation was no test of malignancy, as shown by the case of lymphosarcoma of the tonsil.—Dr. PURDY referred to Professor Hamilton's definition of cancer as an "in-growing wart."

Cases.—Dr. CHURTON showed two cases of Duchenne's Paralysis, members of the same family.

Pathological Specimens.—Mr. BENDELACK HEWETSON: A large

Rhinolith of 24 years' growth, removed by crushing; weight, 96 grains.—Mr. LAW-FORD KNAGGS: Ovaries, Fallopian Tubes, and Uterus at the close of menstruation.—Mr. TURNER: Microscopic Sections: 1, Duct Papilloma of Breast; 2, Intestinal polyp; 3, Alveolar Sarcoma of Chest Wall.

Antique Stethoscope.—The PRESIDENT showed a very early form of stethoscope, said to have been used by Mr. William Hey. He appealed to the members for gifts of obsolete and curious surgical instruments, as a collection was about to be formed of such objects in the museum of the Yorkshire College.

REVIEWS AND NOTICES.

MISCELLANEA MEDICO-CHIRURGICA. Second Part. Occasional Papers and Remarks by E. L. HUSSEY, F.R.C.S. Oxford Horace Hart.

WHETHER letters to local newspapers, reports of after-dinner speeches, discourses at town council meetings, and all those other ephemeral utterances of which a public man in a provincial town delivers himself during a long life, are worth collecting and publishing in a separate volume is scarcely an open question. But certainly if such a collection must be made, it is well to follow Mr. Hussey's example, and atone for slightness of material by the charming dress in which it is presented. Nothing could exceed the beauty of type and excellence of paper of this little book. It is in all respects worthy of the reputation of the Oxford press.

Mr. Hussey has not, we think, been careful of his posthumous fame in preserving and publishing certain of his opinions. What, for instance, could be more illiberal, and, indeed, unjust, than the following attribution of motives to the Fellows and Members of the Royal College of Surgeons in opposing their demand to be admitted to vote in the election of members of the Council of their own body? "The men who are calling for the power of voting are Fellows who are not likely to obtain seats in the Council by the vote of the existing Fellows and others who wish to get admission, as they now have into the Council of Education and Registration, that they may put down (as they think they will) unqualified or irregular practitioners, and make education so dear that a poor man will not be able to put a son into the profession. In short, they want 'protection,' which has been withdrawn from every other calling."

The dictum our author gives on the ventilation of hospital wards is scarcely up to the scientific level of the day—"I have not seen any arrangement for fresh air so good as that by doors, windows, and fireplaces"—while his proof of the excellence of the Oxford water supply falls very far indeed below it: "Without venturing to attach a definite meaning to the phrase ('the present defective sanitary conditions of the supply'), repeated over and over, in varying words, till people at a distance have come to believe in it, I cannot say that I have seen any proof offered that the health of people here suffers from drinking that water supplied by the city. For the last six or seven years I have not myself drunk (*sic*) any other water." Nor do we think that Mr. Hussey's qualified approval of the practice of admitting patients suffering from such fevers as scarlatina into general wards is capable of much defence.

It would be unfair, however, not to own that there are in this little work one or two notes worth recording. The following on medical knights, for instance, is interesting, and will, perhaps, be new to many of our readers. "During my attendance as a pupil at St. Bartholomew's Hospital, some five and forty years ago, I remember that I once asked an old practitioner some question about Sir James Earle and other gentlemen of title whose names had been known in connection with the hospital. He told me that it had been the custom to knight the senior surgeon of the hospitals in London; that when it came to Mr. Abernethy's turn to receive the honour he declined it. Mr. Vincent did the same, and the minister ceased to recommend the surgeons for the honour. The number of medical practitioners in possession of the honour has been declining for some years. Passing the baronets and the knights of the different orders, it appears from published lists of knights bachelors, to which I have the opportunity of referring, that there were thirty-three members of the medical profession among the number in 1849, and seventeen in 1871. At the present time there are ten, which is less than a tenth part of the number of lawyers now on the list." Mr. Hussey's ante-Jubilee prognostic

that a long string of provincial medical knights would not be made have, as our readers will recollect, proved absolutely correct. The "honour" of knighthood was offered to one or two of the leading members of our profession, who would have braced a peerage, but was otherwise reserved for local butchers, bakers, and quack benefactors, who were thought more worthy of the honour.

It is interesting to get a glimpse of a coroner's view of his office, and especially of its relation to the medical profession, but we can scarcely say that the glimpse is likely to delay the reform of this, with like survivals of feudal offices, which the advance of the age so imperatively demands. It is certainly the case that Mr. Hussey "magnifies his office," and one can scarcely prevent an amused recollection of "nothing like leather" crossing one's mind as one reads his recommendation that every death from small-pox should be referred to the coroner before the death is registered. The action of the Sheffield coroner in declining to view with his jury the body of a person who died from this disease scarcely seems to indicate that the coroners of the country would view such a duty with much pleasure.

The suggestion that the coroner should be able to summon a medical practitioner for his opinion or for information, to order him to make, if necessary, a *post-mortem* examination, and to take the evidence of the practitioner on oath before he decides on further action, is a good one if the medical practitioner be worthily remunerated. But Mr. Hussey's ideas on this point do not seem to be very generous. He says: "While it may be admitted that the fee is not large in return for a professional man's time, it should be borne in mind that it is nearly as much as the coroner gets for work which takes more of his time, and that a medical practitioner is the only professional person to whom a payment is made for the attendance before the coroner; also that it is not thought sound policy by those who are concerned in the administration of justice to remunerate too highly those who are required to give evidence in cases of public inquiry, especially when of a preliminary nature." The imputation apparently conveyed in the last clause of this sentence is, to our minds, a particularly odious one.

Some other suggestions made will not, we think, commend themselves to the admiration or acceptance of our readers. We certainly dissent from Mr. Hussey when he thinks "that it is open to question whether the house-surgeon, who is forbidden by the rules of his office from engaging in practice, comes within the definition of 'being at the time in actual practice.'" Nor do we believe that it is the duty of hospital officials in the case where a man has been readmitted with an old fracture of the spine treated in the hospital many months before, to send the coroner information of the patient's decease, or to do more than give a certificate to the registrar, stating clearly the cause of death. A protest should certainly be raised against the decision of coroners arrived at on a case of Mr. Hussey's, about which he asked their opinion. The patient died in the Radcliffe Infirmary in May, 1887 (we think it unfair to have given the exact month of the occurrence). She had been operated on without the consultation of all the surgeons to the Infirmary. She died, and the certificate gave "excision of uterine fibromata" as the cause of death. Mr. Hussey heard rumours of mistakes made by the surgeons in charge of the case, but came to the (in our opinion, proper) conclusion that erroneous treatment, even if proved, was not a reason for holding an inquest. His brother coroners when consulted, however, arrived at the decision, in which Mr. Hussey seems to have concurred, that the fact of giving a so-called false certificate of the cause of death was of itself a reason for holding an inquest, and that, if necessary, the body should be exhumed for the purpose.

The rest of the book consists of reports of speeches and letters concerning the management of the Radcliffe Infirmary, and the admission of fever patients gratuitously into its wards (a controversy in which Mr. Hussey seems to have had the best of the argument but the worst of the final decision), and miscellaneous letters on other subjects, in one of which he supplies a country clergyman with a list of drugs and directions for their administration, with the result that at the end of eight years the reverend gentleman stood high in the opinion of his parishioners as a (gratis) practitioner in medicine. Mr. Hussey does not inform us in what light his pupil was viewed by the more regular practitioners in the healing art.

REQUEST.—Mr. Baker, of Freemantle, Southampton, has bequeathed £5,000 to the Royal South Hants Infirmary.

NOTES ON BOOKS.

Shelley's Complete Press Directory for 1888. (Shelley and Co., 5, Leadenhall Street, London, E.C.)—In noticing the present year's edition of this work, there is little more to say than that it merits the good opinions we have already expressed of the earlier volumes, while it contains some additional features which cannot fail to add to its value. It is a well arranged portable volume, published in cloth at one shilling, giving with completeness the lists of the morning, evening, weekly, and other newspapers, with magazines and periodicals, to the number of 3,736, published in the United Kingdom.

Sell's Dictionary of the World's Press. (London: Sell's Advertising Offices, Fleet Street. 1888.)—This is a portly imperial octavo volume of over 1,300 pages, published for the low sum of two shillings, and must be regarded as an advertisement in itself. It differs from the ordinary press directories, inasmuch as in addition to the usual lists of newspapers, magazines, monthly, quarterly, and annual publications published in Great Britain, it gives an extensive and useful dictionary of the world's press. The chief publications throughout the four quarters of the globe are noted, with particulars of their circulation, together with some account of their character and politics. To the English press is given, in most cases, the advertising scale of charges. The value of the work is enhanced by a series of articles on matters cognate to journalism, such as "Practical Hints on the Law relating to Libels in Newspapers," by W. Blake Odgers, LL.D.; "The Rise of Provincial Journalism," by H. R. Fox Bourne; and others, giving a fair idea of the duties devolved upon the editor, the leader writer, the reporter, the interviewer, and the "special." The volume is illustrated by sixty-four portraits of leading editors—English, French, and American—having affixed, in many cases, a *facsimile* of their autograph.

1. *A Manual of the Operations of Surgery, for the Use of Senior Students, House Surgeons, and Junior Practitioners.* Illustrated. By JOSEPH BELL, M.D., F.R.C.S. Edin. Sixth edition. (Oliver and Boyd. 1888.)—2. *Operative Surgery on the Cadaver.* By J. J. GARMANY, A.M., M.D., F.R.C.S. (New York: Appleton and Co. 1887.)—Professor Bell's work, having reached its sixth edition, needs but little comment from us. On this occasion the author brings us up to the most modern processes and ideas. May we suggest, in a seventh edition, more woodcuts, and these, possibly, more worthy of the excellent letterpress? Dr. Garmany's work is good enough in its way, and we might have difficulty in finding fault with it, so far as its scope is concerned, and it is certainly a valuable and reliable textbook for the cadaver. What, however, it may be asked, is the advantage of so many books on operations on the "dead body?" We well remember an old and esteemed teacher, when we asked him to recommend us an Operative Surgery, saying: "Oh, take Fergusson or Liston into the dead-house, and make what you can of them." Old-fashioned, perhaps; but all modern Surgeries deal with the details of operation, and are equally available. The plethora of these works is simply astounding, and seems to form a sort of basis, and we trust it does, for many an aspirant to practice and fame. But is it not a little overdone? Many of our aspirants are clever enough at the desk. There is certainly room for an English work on the foreign lines, such as Farabœuf, Dubrueil, and Chauval. Why does not an "aspirant" do it?

A NURSING STRIKE AT SHEFFIELD.—At the annual meeting, held May 15th, of the Sheffield Nurses' Home, an institution for the provision of trained nurses, it appeared that owing to a dispute which had occurred between the committee and the lady superintendent, Miss Cowan, the latter had given three months' notice to resign her post, and the committee had since received a letter signed by thirty-one out of thirty-eight nurses connected with the home, stating that unless Miss Cowan was asked to remain, and does remain, they will each tender their notices to leave at the earliest possible period. A resolution was passed approving the action of the committee, and the Mayor, who presided, said there was no need to close the home because of the resignation of Miss Cowan or the nurses. They must consider Miss Cowan as dead when her notice expired, and act accordingly.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS, IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

SOLUBLE SACCHARINE.

MESSRS. BURROUGHS, WELLCOME, and Co., whose saccharine tabloids we have already noticed with approval, recognising the inconvenience likely to arise from the comparatively insoluble nature of ordinary saccharine, have sent us a sample of their soluble saccharine, which is free from the above objection. It consists of a fine granulated powder, and is put up in a very portable form in a bottle small enough to be carried in the vest pocket, and is conveniently accompanied by a small measure. It is supplied to the consumer at 2s. 6d. per bottle.

HYPODERMIC ANTISEPTIC INJECTOR.

WE have received from Dr. George Whyte, of Elgin, a hypodermic antiseptic injector, which he informs us was specially devised for use with hypodermic tabloids; but it answers equally well for ordinary hypodermic solutions. It differs from the common syringe in having an india-rubber pump in place of the usual piston—the pump having a guiding rod passing through its centre, to ensure its working evenly and smoothly. The following advantages are claimed for this instrument, which Dr. Whyte has patented:

"1. There being no piston to contaminate with the solutions, they never come in contact with the glass barrel. 2. It is worked entirely with one hand. 3. As the volume of fluid entering the injector exactly corresponds to the volume of air previously expelled, it is impossible that air can get into the tissues. 4. The injector may be safely trusted with nurses. 5. It never gets out of order."

The inventor says he has used one for over three years, and it has never once got out of order. The case containing the injector is also fitted with a small glass vessel and rod to make the solutions, and has space for four tabloid bottles. The glass barrels are conveniently tabulated for ten drops (sufficient for all practical purposes). The following directions are given for its use:

The instrument should be held between the first and second fingers, knuckles downwards, with the thumb on the pump. The pump is then compressed, and the point of the needle placed in the solution, and allowed slowly to fill the syringe. A fold of skin is then pinched up, and the needle rapidly inserted. The pump is again compressed, and the pressure kept up till the needle be withdrawn.

In using the tabloids, place one in the glass vessel; then fill the injector with water—warm preferred—and discharge it into the glass vessel, completing the solution by means of the glass rod. If warm water cannot be had, the application for a few moments of a lighted match quickly effects solution, but mostly all the tabloids are soluble in cold water. In recharging the injector, the glass vessel should be tilted slightly, and the eye of the needle turned downwards.

With solutions, the injector is first charged with water; then as many drops expelled as is intended to be used of the solution, and then allowed to re-fill slowly from the solution. Two or three trials will make this an easy proceeding.

The manufacturer is Mr. J. Gardner, 32, Forrest Road, Edinburgh.

NEW UTERINE DILATOR.

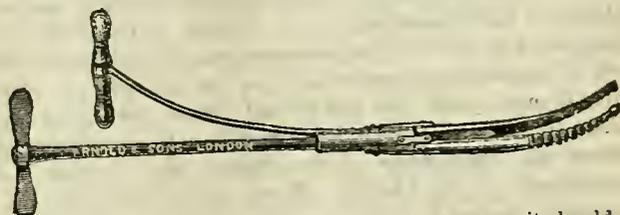

HAVING experienced the want of a rapid uterine dilator either for exploration of the cavity for diagnostic purposes, as in cases of hæmorrhage, etc., or to obtain more room for the application of curette or *écraseur* wire, I have been led to design an instrument for the purposes enumerated which will, I think, contrast favourably with those already in use.

Hegar's and Tait's instruments, though simple in design and

possessing the advantage of cleanliness, are very slow in action, and require the introduction of a considerable number before sufficient room is gained; and Tait's possesses another disadvantage—namely, that of slipping into the uterine cavity altogether when used in cases when the body of that organ exceeds the normal size.

The shape of my dilator being conical like Tait's, but curved (in which it differs from his) makes it, I find, easier of introduction by touch alone, and combines with this the additional advantage of divarication to the extent necessary to open the cervical canal sufficiently to admit the finger for exploration, one instrument thus doing the combined work of a number.

The cervix being steadied by either tenaculum hook or volsellum, five drops of a 5 per cent. solution of cocaine is injected into the tissue at either side of the os, the needle being made to penetrate for half an inch at least. When sufficient time has elapsed for the absorption of the cocaine, the point of the dilator, warmed and oiled, is then slowly introduced, either by touch alone (which I prefer) or by sight, the duckbill speculum affording a good view. The dilator being made to penetrate by boring action till past the inner os, the screw at the end of the instrument is slowly turned, as when using the *écraseur*, steadying the dilator by holding the cross-handle at the side, and judging of the amount of force necessary to be used by the resistance offered to the turning of the screw.

When the dilator is expanded to the required extent, it should be allowed to remain quietly for a minute or so, when the screw can be rotated in the opposite direction, when the blades will close by spring action, and, if preferred, they need not be allowed to close altogether before withdrawing the dilator from the cervix; thus the dilatation of the entire canal from within outwards can be secured.

Very slight bleeding, as a rule, follows the operation, and a camel hair pencil, charged with a saturated solution of alum in glycerine, I find the cleanest styptic. Turpentine can also be used with advantage, but I strongly object to iron, as it hides the source of bleeding, and by forming clots gives rise to subsequent trouble.

I can generally obtain the full amount of dilatation necessary for the introduction of the finger in from ten to fifteen minutes, and thus avoid the frequent introduction of a number of dilators. Should I wish to keep the cervical canal patulous, either for drainage or subsequent exploration on another occasion, I introduce one of my large-sized, spiral, wire stems, which I find so useful for preventing the contraction of the cervical canal after the operation of division of the os and cervix for stenosis.

The dilator can be easily cleaned by being whisked through hot water after use, or a brush applied while the blades are fully expanded.

The makers of both dilator and stems are Messrs. Arnold and Sons, whose name is a sufficient guarantee for good workmanship.

ALEXANDER DUKE, F.K.Q.C.P.I., etc.,
Ex-Assistant Master, Rotunda Hospital.

HEALTH COCOA.

MESSRS. H. THORNE AND Co., LEEDS.

THIS article represents pure cocoa of the best quality, deprived of part of the fat natural to cocoa beans, and prepared in the manner introduced by Dutch manufacturers. It leaves nothing to be desired as to so-called solubility—that is, it remains in complete suspension when prepared with boiling water or milk—purity, strength, and flavour.

AYR COUNTY HOSPITAL.—This hospital has benefited to the extent of £70 by the Ayr Charity Cup Football competitions. £90 was raised for the hospital by church collections on May 6th, Hospital Sunday in Ayr.

BRITISH MEDICAL ASSOCIATION.
SUBSCRIPTIONS FOR 1888.

SUBSCRIPTIONS to the Association for 1888 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the West Central District Office, High Holborn.

The British Medical Journal.

SATURDAY, MAY 19TH, 1888.

THE CHARTER OF THE COLLEGE OF
SURGEONS.

THE official announcement made by Sir W. Hart Dyke in the House of Commons, and the report which we publish in another column of the proceedings of the Council of the College of Surgeons, will afford to the profession what is probably to the bulk of our readers the sensation of a painful surprise. The Privy Council, under the well-devised official formula of declining to deal with contentious matter, have practically refused offhand the applications of the Fellows and Members for amendments of the Charter. There are probably few precedents for dealing in this summary way with a petition of so many thousands of the members of a College for the better recognition of their rights in their own corporation. The Privy Council, or rather the one or two distinguished gentlemen who act for it in these matters, received in this case a petition of almost unexampled numbers and weight from the educated members of a professional body, and a further formal request from a delegated deputation that if their claims were not admitted they might be heard by counsel in support of them. Nevertheless, it now appears that, without reply from the existing authorities of the College, and even without the usual courtesy of any further communication with the Association of Members, the advisers of the Queen have summarily snuffed out their claim. Such a course of action calls for immediate and energetic protest. The claims of the Members may be right or wrong, but no steps have been taken to convince them that they are unfounded either in policy, justice, or law. No answer of any sort has been vouchsafed to their arguments or their claims, although these were based, among other things, upon the strongest allegations as to the true constitution of the body whose charters were in question, and showed strong reasons for the belief that many matters in the existing organisation amounted practically to an abuse.

The Privy Council cannot have convinced itself either of the impolicy or of the want of legal basis for these contentions, since it neither received any answer in respect to them from the promoters of the charter nor afforded any opportunity for a judicial or quasi-judicial consideration of the issues involved. Trusting to the usual fairness and courtesy of great official bodies in such matters, no discussion has meantime been raised in Parliament, and at this period of the session it is difficult, if not impossible to secure the attention of Parli-

ment to the subject in any effective manner until next February. It is, perhaps, undesirable that the Members should be driven to enforce the rights they claim by any litigation with their own College, and especially so as these claims are much more largely based upon questions of public policy and general justice than of technical legal right, although the latter would appear not to be wanting.

Even yet, however, it is not too late for Her Majesty's advisers to reconsider their present attitude towards the question. It would appear to be still open to the Members to address an immediate petition to the Court praying that the matter of such petition and of the previous petition signed by 6,000 Members of the College already before the Privy Council, may be remitted to the Privy Council in its judicial capacity for further debate in order that they may advise the Crown with judicial responsibility, after hearing such evidence as the parties interested may desire to produce and the arguments of counsel thereon. We believe that there is nothing contrary to constitutional practice in such a course, although precedents of this precise character are, of course, rare, as are the circumstances which lead to it. It is highly unsatisfactory that so important a question should be burked by an official body, which practically sets aside a claim the equity of which it neither discusses nor decides. It must not be forgotten that even the limited supplemental charter which it is now proposed to grant will perpetuate and increase that autocratic form of administration against which the bulk of the Members have petitioned and protested, by empowering the existing authorities to hold and administer even a larger amount of corporate property than that which they already possess. The Members can hardly allow the matter to rest here, if they are well advised and properly led.

THERAPEUTIC STUDIES.

V.—THE CLIMATIC TREATMENT OF CONSUMPTION.

PHthisis has been regarded as the greatest scourge which afflicts mankind; for, although it does not inspire as much terror as a severe epidemic passing like a destroying angel through a country, yet it is always insidiously at work amongst us. Under the title, *The Experiences of a Poitrineire*, Dr. Friedmann, of Berka, has embodied observations on himself and others extending over seventeen years, in pamphlet form, as a reprint from the *Deutsche Med. Zeitung*, 1887. Dr. Friedmann very clearly lays down the principles upon which the best sanatoria are conducted.

We fight against phthisis in three modes, namely, by medicines, by dietetics—which include the patient's whole course of life—and by climatic influences. But the influence of drugs upon phthisis is practically nil. Neither benzoate of soda, quinine, kairin, the hypophosphites, nor any other drugs can be depended upon. Nor is the "prescription-writing physician" helped by the discovery of the tubercle bacillus; on the contrary, this discovery has proved rather an embarrassment than otherwise, for it has made the patient very nervous about infection by tuberculosis in crowded health-resorts, even when

May 19, 1888.]

phthisical himself. There remain as curative agents dietetics and climatic influences. The latter of these comprehends the former, for a radical change in the patient's mode of life is impracticable at his own home, and this radical change is, or should be, the keynote of the treatment; hence the extreme importance of a change of climate. But here, again, a wrong choice is disastrous; a winter is lost to no purpose, or, more probably, to the patient's deterioration.

Before deciding where the patient is to go, however, we must consider whether or not he ought to go, for it is not pretended that all should go away. The following three divisions comprise the group of those who should stay at home—namely, (1) young, uneducated people; (2) acute feverish cases; (3) patients who are so wedded to the routine of home life as to be unhappy anywhere away from home; and this class is a larger one than is commonly supposed. Of course, no one advises a removal in advanced cases. Where then are the suitable cases to go? The answer is, where they can breathe pure fresh air all day and all night. It is long since established that fresh air is the most powerful factor in the cure of phthisis. The deeply-rooted prejudices against the vivifying breezes, the unreasonable fondness for a hot-house temperature, and the prevalent fear of "taking a chill," must be discarded. The fear of "catching cold" is still too much a bugbear with both doctor and patient. The little vital capacity which the patient possesses should be increased by living as much as possible in the open air. It is the hardest task of the physician to combat this fear of the patients—namely, of taking a chill—a task which demands all his energies. The patient must be sent out of doors in all weathers, properly clothed, of course. If he perspires he must be dry rubbed, and must put on a change of clothing; if he is fatigued he must rest, but he must breathe fresh air. The bedroom window must be left slightly open too at night, a screen being used if the wind be at all strong. Those who are unable to walk about should use a well-cushioned and curtained long chair, as introduced by Detweiler, portable beds in fact. Dry frictions are extremely useful at intervals during the day. A certain gradation may be effected from dry rubbing to friction with a towel that has been wet with spirits of wine, and then partially dried; thence to the application of a wet sheet for a few minutes, succeeded by dry rubbing, and finally to the cold douche. The food must be abundant and varied in kind; there is no exclusive diet for consumptive patients. Plenty of wine (and even cognac) is recommended by Dr. Friedmann. If there is anorexia, which does not give way to a good bitter, such as condurango bark, with hydrochloric acid, recourse must be had to milk for a few days, with eggs and brandy if possible. In most of the hotels on the Riviera the dinner is taken at rather too late an hour for invalids; this is easily rectified by making the mid-day meal the chief meal of the day.

All this must be kept up after the patient has left the sanatorium, which is to be a school of living for the patient. Nothing new or unknown to the medical profession is used in the numerous sanatoria in the South of Europe; but the co-operation

of the minutest arrangements, a life strictly regulated in the smallest details, the "gross im kleinen"—the motto of Detweiler's classic *brochure*—are accompanied by their inevitable results for good.

The patient must be out of doors at an early hour, and so get an appetite for a good breakfast. On no account should the thermometer be used by the patient himself, for the attendant anxiety and depression if the reading is not exactly what it should be more than counterbalance any advantages. One thing more must be eschewed, and that is the reading of books on pulmonary disease, whether popular or strictly scientific. The glibness with which patients now talk about "infiltration," and "softenings," and "caverns"—terms which are connected with the strangest ideas in their minds—is to be deprecated, because such patients are apt to criticise the treatment at every stage. While on this point, it may be remarked that the first stage of phthisis, the most important for treatment, should not be made too light of to the patient. To call this stage, for example, "merely a slight catarrh of the apex of one lung," is to mislead the patient. On the contrary, he should be told of the danger he is in, so that he may make the necessary sacrifice and radically change his whole mode of life, with a full resolution to employ all his energies in his own cure.

Now as to the kind of air which the patient is to breathe. Dr. Friedmann is of opinion that the hygrometric condition of the air is of more importance than its density. As a rule, a fair proportion of moisture is beneficial, for though much moisture is somewhat depressing to the nervous system, it has a soothing effect upon the respiration. This question is usually made to turn upon that of the temperament, and most cases in the early stage of phthisis show the torpid "lymphatic" temperament, though this statement is contrary to the general opinion, Erythraism, however, is a characteristic of all advanced cases, and of acute early cases. But different places vary considerably as to moisture in different seasons, and on this and other grounds (temperature, etc.) a change is occasionally desirable, especially in early summer. High plains and mountains are suitable for all torpid and chronic cases. It is well known that feverish cases do not bear a residence at the seaside well. The tissue-changes being too much stimulated, temperature is a question of less importance, and patients can pass the winter in Europe very well, as the astonishing results at such sanatoria as Falkenstein and Göbersdorf teach us. The best place in Europe in winter for a consumptive patient is, owing to its exceptional situation, the Riviera. Italy itself, otherwise, from Pisa to Naples, is apt to be very cold in winter; but, south of Naples, all is warmth and sunshine again. The Alpine resorts claim attention in early summer.

The consumptive patient, then, is advised by Dr. Friedmann to winter in the Riviera; and, further, having gone to so much trouble and expense, not to economise in the wrong direction by dabbling in medicine chests, but to consult on arrival a local physician; a fellow-countryman for preference, to whom even the choice of the hotel should be left. By so doing he will be

saved the extremes of pessimism or optimism, according to his varying moods, and his life will be regulated for him to the best advantage on the principles above laid down.

TRANSPLANTATION OF NERVE FROM THE RABBIT TO MAN.

DR. GERSUNG, of Vienna, assistant to Professor Billroth, has recently performed a novel and interesting operation—the transplantation of nerve from the rabbit to man. The case has not hitherto been published in any medical journal, but owing to its general interest the bare fact had found its way into the lay newspapers. Our Vienna Correspondent has received from Dr. Gersung a verbal account of the salient points of this most remarkable operation, which has so far been conspicuously successful. The patient is Professor von Fleischl, the distinguished occupant of the chair of physiology in the University of Vienna; sixteen years ago he accidentally wounded himself while conducting a *post-mortem* examination, and severe inflammation of the whole right upper limb ensued. During the course of the disease the terminal phalanx of the thumb became gangrenous. The stump thus left was painful, and later on re-amputation was performed. This was followed by the formation of neuromata. For this condition the branches of the median nerve which supply the thumb were first resected, together with the terminal neuromata, and at a later period, when new neuromata began to develop, the central parts of the same nerves, together with the branches of the radial nerve which supply the thumb, were resected. Fresh neuromata now developed on the branches of the median nerve, which were treated, without any success whatever, by the injection of hyperosmic acid and electrolysis. Two years ago the neuromata were resected again, and the resection of the nerves was continued as far as the “ligamentum carpi volare;” on this occasion, the branches which supply the radial and the ulnar sides of the index, as well as the radial side of the middle finger, were resected to a great extent. The forefinger now became anæsthetic, except the dorsal aspect of its first phalanx, which, as is known, is supplied by the radial nerve; in the same way the whole radial side of the middle finger became anæsthetic. The pain, however, again recurred, as after the previous operations, and during the course of the second week after the last operation, the patient became aware that a fresh neuroma was developing. The suffering finally became so severe that the patient wished to undergo another operation, in order to procure, at least, temporary relief. Accordingly the following operation was performed: On March 4th the patient was put under the influence of chloroform, and the neuroma, which was situated behind the volar carpal ligament, was excised, the nerve being cut through behind the neuroma. The peripheral nerve stumps of the two digital branches above mentioned were then sought for. A rabbit was now killed, and as long as possible of the sciatic nerve of the animal, with the two branches into which it becomes divided, was dissected from it (the animal still presenting voluntary contractions). The sciatic nerve was afterwards inserted into the space between the central stump of the median nerve and its digital branches; the central end of the sciatic nerve was sutured to the connective tissue which

covered the median nerve, and the two branches were sutured to the digital branches of the median nerve; the portion of nerve, measuring about 6 centimètres, which was deficient was thus made up. After the operation severe pain persisted for some hours, but then entirely subsided. Healing took place by first intention. As two months have now elapsed since the date of operation and the pain has not returned, it may be hoped that the favourable result will become a permanent one. Sensibility, moreover, is becoming re-established in the part. Dr. Gersung has postponed the publication of the case, because he wished to observe whether complete sensibility would return; he hopes with confidence that this will be the case. The ultimate result will be awaited with great interest; for if it is as favourable as now appears probable Dr. Gersung's recommendation that the operation should be given an extended trial will doubtless be widely acted on.

SANITARY REGISTRATION OF LODGING HOUSES.

At a recent meeting of the Hastings Town Council, Mr. Councillor Bray moved a resolution of wide public interest, the purport of which was the proposal to establish a system of voluntary registration of houses by the Town Council after examination and report by the borough surveyor or nuisance inspector. The resolution also proposed to grant certificates to such houses as attained, in the opinion of the examining officer, a certain standard of sanitary excellence. After a lengthy discussion, Mr. Bray eventually agreed to withdraw his motion. Whilst acknowledging that Mr. Bray brought forward many cogent reasons for the introduction of such a system into Hastings, it must be allowed that considerable weight attaches to the dissentient views which were expressed at the meeting. In the first place there is nothing at the present time to prevent lodging-house keepers or house-owners from obtaining such certificates from competent persons, should they desire to do so; and no doubt they would do so, if the public were in the habit of demanding them. In the second place, it is very questionable if any public body like a Town Council would be justified in saddling itself with so onerous a responsibility to the public and to visitors as that for the sanitary condition of houses in the town, over which it would have but little real control, but for which it would be held liable should ill-health or disease ensue as the result of occupancy entered into on the strength of the assurance given as to good sanitary condition by the Town Council's certificate. Again, as the Mayor pointed out, if Mr. Bray's resolution were adopted, the Town Council might render themselves liable to house-owners for damages should certificates be withheld when applied for.

Although the system would be voluntary and would thereby avoid the chief defect which characterised the Sanitary Registration of Buildings Bill of last session, the discussion which that Bill gave rise to clearly showed that in the opinion of those best qualified to know, the sanitary officials of a public authority are not the people to be entrusted with the examination of houses and the granting of certificates; the possible abuses of such a system are too obvious. The signs are not wanting that at last the public is beginning to understand that lodgings at seaside and health resorts are often the least

May 19, 1888.]

desirable abodes for those who are in search of health. The only possible remedy for such a condition of things is so general an enlightenment as to sanitary matters, that the impending occupant of the "commodious apartments" at the seaside, will require to be satisfied as to the good condition of the drainage and water supply of the house before he trusts himself or his family inside its walls.

THE LAW AS TO WATER ANALYSIS.

By Section 21 of the Sale of Food and Drugs Act, 1875, at the hearing of the information against a person charged with an offence under the Act, "the production of the certificate of the analyst shall be sufficient evidence of the facts therein stated, unless the defendant shall require that the analyst shall be called as a witness." As a matter of practice we believe that it is rare for this requirement to be made, as the defendant is unwilling to increase costs against himself by insisting on the presence of the analyst. Certificates are no doubt generally correct, but the disclosures made in a case recently heard before the magistrates at Birmingham show that analyses are not always conducted so as to satisfy legal requirements. The summons was under Section 70 of the Public Health Act against the owner of a well, which was alleged to be so polluted as to be injurious to health. Under that Act there is no provision making the certificate of an analyst evidence, and the condition of the incriminated well had therefore to be proved, like any other material fact. Dr. Hill, the borough analyst of Birmingham, was called as a witness to prove the water to be polluted; and the result of the analysis made in his laboratory undoubtedly showed that there was a dangerous proportion of nitrates and nitrites in the water, and that the well was to some extent contaminated with urine. Dr. Hill, however, on cross-examination, admitted that he had not conducted the whole analysis himself, and could not say which part of the process he had personally conducted, though he said he took the responsibility of it. He also, in answer to the Bench, stated that he could not say the well was actually injurious to health, as there was no proof of any person having been injured; but it was certainly dangerous, and might be injurious at any moment. The Bench therefore dismissed the case, on the ground that the prosecution had failed to show the well to be so polluted as to be injurious to health.

The decision may be right as a matter of law, but the consequences may be serious. On this principle the Broad Street pump could not have been condemned till after it had spread death and devastation. If magistrates refuse to hold that a well which is contaminated by organic matter is dangerous until it has actually become specifically poisoned and has infected a neighbourhood, public health in such places stands on a rickety basis. There is, moreover, another moral to this case. The law, for obvious reasons, requires facts to be proved by persons who know them of their own knowledge, and have not derived them by hearsay from others. Dr. Hill stated that he had so many analyses to conduct that he could not afterwards say that he did any one part of any particular analysis. Probably, most analysts of any reputation have assistants in their laboratories, and get the greater part of the work of analysis done by them. In cases, however, where the

analyst is likely to have to give evidence in support of his analysis, he must take care to supervise and keep a record of the processes, so as to be able to prove the necessary facts from his own knowledge. The fee for an analysis, provided by Section 12 of the Sale of Food and Drugs Act (10s. 6d.) is certainly inadequate in cases where the analyst has to devote much personal care and trouble; but that is supposed to be in addition to the presumably satisfactory salary payable under Section 10. As a fact, many of the salaries paid by local authorities are miserably inadequate; but qualified men accept them. They do not devote their whole time to the performance of their duties as analysts, and are not expected to do so. Possibly, if they realise that the position of public analyst entails a greater amount of personal supervision and trouble than has hitherto been deemed necessary, and consequently leaves less time for other and more remunerative work, they may cease to be content with the salaries they have hitherto accepted. If so, the local authorities must pay more, or put up with the services of less competent men. An analyst, while he occupies the position, must discharge its duties properly himself. If he cannot do so, however skilful a chemist he may be, he is useless as an official employed to protect the public health.

MR. R. CLEMENT LUCAS, B.S., M.B., F.R.S., has been appointed Surgeon to Guy's Hospital in the place of Mr. Thomas Bryant, F.R.C.S., who has been appointed Consulting Surgeon. Mr. W. Arbuthnot Lane, M.S., F.R.C.S., has been appointed Assistant Surgeon.

By the resignation of Mr. Henry Smith a vacancy has occurred in the senior staff of King's College Hospital. Mr. William Rose has been elected full Surgeon to the hospital in charge of beds, and also Professor of Surgery in the College. Mr. Rose has long been known as an able surgeon and teacher, and there is no doubt that his accession to the staff will prove a source of strength to the hospital and school.

THE MARSHALL HALL PRIZE: THE ADDRESS.

It has already been announced that the Marshall Hall Prize of the Royal Medical and Chirurgical Society has been awarded to Dr. W. H. Gaskell, F.R.S., Lecturer in Advanced Physiology in the University of Cambridge. A special meeting of the Society will be held on Thursday next, May 24th, at 8.30 p.m., when Dr. Gaskell will give an address on "The Relations between the Function, Structure, Origin, and Distribution of the Nerve Fibres which compose the Spinal and Cranial Nerves."

A HOSPITAL POLL-TAX FOR ST. PETERSBURG.

It has been resolved by the *Duma* or municipal authority of St. Petersburg to impose a tax—that is, if the Czar will permit—on all the inhabitants over seventeen years of age, with certain exceptions, for the maintenance of the hospitals. The amount proposed is two roubles a head for men and a rouble and a half a head for women. (The value of the rouble is a little under two shillings.) All persons paying this tax will be entitled to free treatment in the hospitals they are thus to be compelled to support. There is a great outcry now that the hospitals are too full, and that numbers of deserving cases are refused admission. If almost every inhabitant is to be led to consider that he or she has an absolute right to admission, an immense increase in the accommodation at present available must be made, and the field open to private practitioners will certainly be greatly reduced. Many of these gentlemen have now a severe struggle for existence, and

such a wholesale attraction of the inhabitants to public institutions appears calculated to wipe the poor private practitioner almost out of existence.

LANOLIN IN CUTS AND BURNS.

A RECENT article in the *Pharmaceutische Rundschau* (No. 3, March, 1888) states that experience has shown that lanolin is an excellent dressing for cuts and burns. Professor B. Fränkel finds that it prevents the formation of scabs, and that burns under this treatment do not desquamate so much as under most others. In cases where it is desired to irrigate a wound, in order to reduce heat and irritation, lanolin may still be applied, as it is not readily washed away. If a small wound is immediately dressed with this ointment basis, hæmorrhage is stopped.

THE SUMMER LECTURES AT THE COLLEGE OF SURGEONS.

WE have already noticed that Mr. Bryant will lecture on Tension as met with in Surgical Practice, on June 11th and 13th; and on Surgical Interference in Cranial Injuries, on June 15th. Mr. A. E. Barker will deliver three lectures on the Operative Treatment of Tubercular Diseases in Joints, on Monday, Wednesday and Friday, June 4th, 6th, and 8th. Mr. R. Marcus Gunn will lecture on Light-Perceptive Organs, on Monday, Wednesday, and Friday, June 18th, 20th, and 22nd. It is important for all who wish to attend some of the above courses that they should bear in mind that each lecture will begin at 5 o'clock in the afternoon, and not at 4 o'clock, as before.

DONDERS MEMORIAL FUND.

THE ceremony at Utrecht on May 28th, to celebrate the seventieth birthday of Professor Donders and his consequent retirement from the professorship, will commence at 1.30 P.M. The sum collected, together with the roll of subscribers, will be formally presented. A public dinner will be held at half-past 5. After the ceremony of presentation, the Professor will name the scientific purpose to which he proposes that the fund shall be applied. The complete list of subscribers from this country is to be seen in our advertising columns on page 55, in the order in which they have been received. Any subscriber may verify the amount of his subscription by applying to Mr. Brailey, 11, Old Burlington Street, where the audited list may be seen. The total amount collected here is £290 11s. 10d. Professor Humphry, Dr. Hughlings Jackson, Mr. Hutchinson, and Mr. Brailey have been invited to attend as delegates to represent the subscribers, and it is hoped that many others also may be able to attend and by their presence do honour to Professor Donders.

MYXŒDEMA.

WE learn with satisfaction that the Committee appointed by the Clinical Society of London to study the nature of myxœdema has concluded its labours. The inquiry has been in progress for three or four years, and has proved a very laborious undertaking, as the Committee took a very serious view of its duties, and has worked earnestly to give a thorough answer to the question, "What is myxœdema?" A short summary of the report will be read by Dr. Ord at the meeting on May 25th, when there will doubtless be a full gathering of members, especially as it will be the last meeting of the session. The Clinical Society, by the preparation of this report and of similar reports on Charcot's joint-disease and on spina bifida, have established a good precedent; the study of such complicated clinical questions is an enterprise well within its province, though involving much labour, trouble, and some expense. To Dr. Ord, chairman of the Committee, and to Dr. Hadden, the honorary secretary, on whose shoulders a large share of the work has fallen, the warmest thanks are due. The

report will, we understand, be issued as a separate volume, and will be purchasable by persons who are not members of the Society.

SIR WILLIAM JENNER.

IN order to show the highest mark of the respect of the Fellow of the Royal College of Physicians, the chief officers of the College attended at Sir William Jenner's house on May 11th to present to him the resolution conveying the thanks of the College which was passed on April 26th. The President (Sir Andrew Clark), accompanied by the Senior Censor (Sir Alfred Garrod who had proposed the resolution in the Comitia, Dr. Quair the seconder of the resolution, and the Registrar (Sir Henry Pitman), constituted the deputation. Sir William Jenner was deeply gratified at their visit; and, in reply, stated, amongst other things, that it had always been his object never to endeavour to do more than one thing at the time; first, as an investigator secondly, as a teacher; thirdly, as a practitioner. Speaking of the College, he said that he hoped the time would never come when the Fellows would be chosen by examination alone, but that the character of the candidates for the Fellowship and their relations to the public and the profession, as well as the mere writing of scientific papers, should, in his opinion, form conditions for the Fellowship.

THE WORK-ROOMS AT THE COLLEGE OF SURGEONS.

AN advertisement inviting Fellows and Members of the College to apply for the privilege of making use of the work-rooms has recently been issued. The following "Conditions relating to the use by Fellows and Members of the New Work-Rooms at the College, have been drawn up, and are to be obtained on application to the Secretary, Mr. Trimmer. *Subjects of Research.*—Anatomy, Physiology, and Pathology, human and comparative, including Histology, Hygiene and Therapeutics in their relation to Surgery. *Conditions of Study in the Work-rooms.*—Appointments will be made by the Council for definite periods. When application is made for an appointment, a prospectus or description of the proposed investigation shall be sent in, with as complete a list as possible of the necessary instruments and apparatus. No new line of research, other than that originally approved by the Council, shall be undertaken without their previous sanction. Reports of progress shall be made to the Council at stated periods of investigation. The place and mode of publication of results of work shall be determined by the Council. If any assistance be required, the investigator may provide it, but the person or persons proposed must be approved by the Council. No fixed hours of attendance will be required, but a record must be kept of actual hours of daily work. The necessary instruments and materials will be provided and expenses of investigation will be defrayed by the College, but no purchase of any additional instruments or apparatus shall be made without the sanction of the Council.

ORPHANAGES AND CHARITY SCHOOLS.

MANY public orphanages have been founded by philanthropic people for the reception and training of children. Such institutions require careful management, and diligent attention to all matters of hygiene. The principles of ventilation, clothing, and dietary are well known to all who are acquainted with the principles of sanitary science. We desire to impress on all who are responsible for such institutions for children the great importance of discriminating among the children such as are in any way defective in development and constitution. Any large proportion of children defective in body or in brain power residing in a boarding-school is, in our opinion, a matter to be very carefully guarded against, as likely to lead to serious difficulty in discharging obvious

May 19, 1888.]

duties. Such children tend to lower moral and intellectual tone, and to promote bad habits among the other children. They are liable to suffer much from the effects of cold in the winter season, and in the school and the workshop they require different management from that provided for the stronger children. Any appreciable number of such cases—say 6 in a school of 200—will not only lower the results of good training, but also demand of the staff an amount of personal attention which cannot be bestowed with due regard to the requirements of the majority, thus leading to neglect, or to an increase in the strength of the staff. On the other hand, when an institution voluntarily receives and retains children of defective make, they must not be neglected, and a greatly increased responsibility is thereby thrown upon the management. A voluntary institution, to work economically and well, must follow one of two plans; either it must rigidly exclude children of defective constitution, or it must make due provision for them. In either case it is the duty of the management to see that such conditions in children be reported to them, either before admission, or soon after, and then to act or make such provision as they think best. In such matters skilled medical opinion is obviously necessary. In some schools for the blind this difficulty has long been felt. Blind children often have very awkward habits; defective action and constant automatic movements are common in such cases, giving many blind children the appearance of stupidity, though brain-power may not be permanently defective. In these schools the managers often require a probationary trial before they finally accept responsibility for the care and education of any child; much waste of teaching power is thus prevented. In the remarks here made only voluntary schools are referred to. The circumstances are, of course, quite different where admission is compulsory, as in establishments under the poor-law,

SWISS PERSECUTION OF ENGLISH DOCTORS.

UNLESS the Swiss Government can see its way to put an end to the war which is now being waged in the leading Swiss health resorts against the few English medical men who now reside there for the purpose of meeting the needs of English patients, there is likely to be a great decrease this winter in the number of English speaking patients who will resort there. Dr. Tucker Wise, at Maloja; Dr. Holland, at St. Moritz; and Dr. White, in the Canton Vaud, are among the limited number of resident English physicians to whom Switzerland is much indebted for aiding in the development of her winter health resorts. They are now being subjected to persistent persecution by the active enforcement of an old law, prohibiting the practice there of foreign physicians. Dr. Wise, to take a conspicuous example, has, it is well known, done much, to speak quite moderately, to develop the prosperity and resources of Maloja and St. Moritz and Wiesen. While these exertions were being made, and pending the afflux of patients, now attracted thither in no small measure by his writings and the confidence of his professional brethren in England, no objection was raised to his practising among his countrymen who came to reside there. Now, however, that the place has attained a reputation, and there is a considerable afflux of foreigners, of whom perhaps 95 per cent. are English-speaking, a war has been commenced against the medical benefactors of the place. Drs. Wise and Holland have been subjected to fines of £20 each for practising their profession, and threats of more severe measures have been held out. The short-sightedness and the injustice of the proceeding are sufficiently palpable. But such proceedings are likely to bring their own punishment; for it may be reasonably assumed that, deprived of the services of medical men of their own speech, and of whose school and methods of practice they have experience and confidence, English and American invalids will prefer to seek other places where such annoying restrictions are

not so vexatiously enforced. The future of health resorts lies very much in the hands of the medical profession, who, if they are deprived of the opportunity of placing their patients under the charge of men whom they know, and in whom they can confide from personal acquaintance, and who can carry on the English methods of treatment, will feel some hesitation in sending away their patients to distant and isolated places, such as Maloja, St. Moritz and other stations of the kind.

THE LIFE HISTORY OF FILARIA SANGUINIS HOMINIS.

It is interesting to note the long chain of inductive reasoning, combined with careful and laborious research, which has led to the unravelling of the complicated life history of the filaria sanguinis hominis. The discovery of bilharziac hæmaturia by Griesinger in Egypt, led Wucherer to search the urine of patients suffering from hæmaturia in Brazil, and it is just twenty years since he first saw the immature worm in the urine of these cases. Shortly afterwards the same parasite was independently discovered by the late Dr. T. R. Lewis in the blood of a patient in Calcutta, and to this acute observer is due the credit of establishing a connection between chyluria and the filaria. This observation led Dr. Manson to the surmise that the adult worm must establish itself in such cases in the larger lymphatic vessels, or even in the thoracic duct. Systematic search was consequently made; but it was not until 1876 that the adult was at length found by Dr. Bancroft, of Brisbane, who went a step further by suggesting that the mosquito was probably the intermediate host. This Dr. Manson proved to be correct by direct observation in 1877; the immature filaria is sucked up with the blood by the mosquito, which shortly resorts to water to deposit its eggs, and, having achieved this object of its existence, expires; not, however, before it has digested the greater number of the filariae. A few, however, escape, and are set free by the dissolution of the mosquito. It has been supposed that the filaria passes the next stage of its existence in the water as a free nematode, but can only attain full sexual development by entering the human body; it is believed to accomplish this by penetrating the skin of bathers, and to attain sexual maturity in a short time within the body, the conjunction of the sexes taking place in the lymphatics. Lewis once obtained a fragment of a male which was closely coiled around the female; but the specimen, described at page 1050 by Professor A. G. Bourne, of Madras, from a case of lymphoid scrotum, is the first found in a condition which permits the specific characters to be described. The chief point which now remains to be cleared up by observation is as to the manner in which the parasite enters the human body. Dr. Manson has proved himself on former occasions not only an able observer but an acute reasoner; still his theory mentioned above presents certain obvious difficulties.

EFFECTS OF EXPOSURE OF THE INTESTINES.

At the November meeting of the Berlin Obstetrical and Gynaecological Society, Professor Olshausen read a communication on a hitherto unrecognised cause of death after laparotomy where intestine has been allowed to lie outside the abdominal wall for a prolonged period. In this country, at least, surgeons are careful to prevent prolapse of the intestines. Coils which adhere to a tumour and cannot be at once separated are carefully covered with flat sponges, or with towels wrung out in hot water which often contains an antiseptic compound. As soon as the adherent coils are separated from the tumour, all bleeding points being secured, they are carefully replaced. As soon as the tumour is extracted through the abdominal wound, or indeed whilst it is slipping out of the incision, a broad flat sponge is slipped into the

peritoneal cavity to prevent any chance of prolapse, and to protect the gut from the suture-needles. The abdominal incision is, moreover, always made as short as possible, so as to avoid the sudden escape of coils of intestine. The Germans are less particular about eventration. Dr. Martin, in 1885, publicly recommended the dragging out of a large amount of intestine in cases where the tumour lay deep in the abdominal cavity, and declared that the greater part of the intestinal tract might be left hanging out of the abdomen during the whole operation, so that the surgeon might have plenty of room for manipulating the tumour. "This eventration," said Dr. Martin, "is quite free from danger; I have practised it in at least 90 per cent. of my cases without seeing any evil results." Professor Olshausen was more cautious, and directed attention to certain cases of collapse, often fatal, which followed cases of abdominal section and were not accompanied by symptoms of peritonitis. He concluded that prolonged exposure of the intestines in laparotomy might cause disturbance in the circulation in the walls of the gut, ending in venous stasis and serous infiltration, with ultimate formation of ecchymoses. At the same time the muscular coat is paralysed, often for several days; if the paralysis does not abate, symptoms of ileus set in. Fatal results of this kind are probably caused by the absorption of decomposing material in the intestinal canal.

FAIRS AND VENEREAL DISEASES IN RUSSIA.

DR. A. M. ZENKOFF, of Irbit, gives, in the *Shornik Permskako Zemstra*, December 27th, 1887, p. 421, some interesting particulars as to the manner in which syphilis is propagated by fairs in Russia. Irbit is a district town in the (East Russian) Perm Government, with a stationary population of 5,000, which is, however, periodically subject to very large increase during 2 or 2½ months, when the annual fair is held. This is officially open from February 1st to March 1st, and is a most important commercial meeting for wholesale transactions in tea, sugar, furs, wool, and leather; it is also one of the great centres of Russian prostitution. Dr. Zenkoff's report refers to 1884, but his description is equally applicable to subsequent, as well as to several preceding years. The information embodied in his paper was gathered by himself and Dr. N. V. Antonoff. The report deals only with the so-called "open" or "official" prostitution, and leaves out of consideration the unregistered or clandestine form which is practised to an enormous extent by numberless waitresses in beer shops, taverns, and inns, by attendants employed in public baths, by domestic servants, by hotel singers and harp players, by *kalatchnitsas* (female bakers of *kalatch*, a favourite national white or grey bread having the shape of a padlock), etc. The number of regular prostitutes in the town brothels was 20, all of whom were Russian single women, aged from 16 to 27, who had been "in practice" from 2 to 10 years; all but one were entirely illiterate; 13 had had syphilis. During the fair time (beginning in this case early in December) the "official" contingent rapidly rose to 292, scattered about in all sorts of extemporised brothels distinguished by the red lamp which is the recognised mark of such establishments all over Russia, just as a blue lantern is throughout China. The ages of 272 new comers varied, between 15 and 38, about 56.5 per cent. being between 20 and 25, 27.5 per cent. between 15 and 20, and 16.0 between 25 and 38. As to their nationality, 245 were Great Russian, 25 Tartar, 1 Little Russian, and 1 German. As regards their social position, 197 belonged to the peasantry, while the remainder were artisans, factory hands, etc.; there were also several daughters and wives of Crown officials, and one medical assistant's daughter. Only 12 could read and write, 14 others could only read, while the remaining 246 were utterly illiterate; 229 were single women, 34 married, and 9 widows. Only 84 (31 per cent.) of the new comers were professional prostitutes, while the remaining 69 per cent. practised prostitution only during the fair, subsequently

going back to their usual occupations. Out of fair time, 23 per cent. (of 272) earned their livelihood as cooks, chambermaids, and even nurses; 12 per cent. were professional needlewomen of various descriptions; others were usually employed as agricultural labourers, miners, laundresses, *kalatch* bakers, cigarette makers, etc. A special group of 32 women stated that their usual occupation was "household work," all of them living with their families. Many of this group confessed to the author that they had come to the fair with the full knowledge and permission of their relatives (husband or father, or both); in fact, they had come to earn something towards the support of their families. Everyone of the new comers (as well as of those belonging to the town) proved to be suffering more or less from chronic vaginitis. Three came with well-marked secondary syphilis, 3 with soft chancres, 1 with virulent vaginitis, 4 with marks of tertiary syphilis, and 48 with enlarged lymphatic glands following secondary attacks. The following figures referring to a period of five months (December, 1883, to April, 1884), and taken from the records of the small Irbit Zemskaja Infirmary give a faint idea of the pernicious influence of the fair on the health of the local population. There were treated as in-patients, during the period stated: *a*, for gonorrhœa, 19 women (including non-prostitutes), and 61 men; *b*, for soft chancres, 20 women and 14 men; and *c*, for syphilis (secondary), 17 women and 19 men; total, 150 patients (56 women and 94 men). A far larger number, however, came under the notice of the local medical men in their private practice during the same period. How many visitors to the fair carried infection back to their homes it is obviously impossible to say. It is a fact, however, that venereal disease is, in spite of registration and sanitary supervision of prostitutes, probably more rife in Russia than in any country the world, and there can be no doubt that this is largely due to local fairs of the kind here described.

VAN MILLINGEN'S OPERATION FOR ENTROPION.

THAT the treatment of entropion resulting from trachoma is not satisfactory may be inferred from the number of operations that have been invented for its cure. When the contraction of the conjunctival surface has entirely ceased, any of the best operations will succeed. Unfortunately, it is not always easy to say when this stage has been reached, and the condition is one that does not allow treatment to be postponed. The old operation of removing the margin of the lid has fallen into well merited disrepute, and excision of the hair follicles is only applicable to cases of partial entropion. The operations which have till now been most generally adopted in this country are Arlt's transplantation of the cilia-bearing margin, or some modification of this, or Bürow's operation, which consists in dividing the tarsus along its whole length into an upper and lower portion, accompanied or not by excision of a fold of skin. The latter operation is not infrequently followed by relapse, and in the former the lashes are very apt to be drawn down again by the cicatricial contraction of the raw surface left below them. The proceeding has consequently been modified by many operators, notably by Dianoux, who, instead of excising the fold of skin to make room for the ciliary flap, simply transposes the two flaps. The objection to this method is that a rather unsightly swelling is formed by the crossing of the flaps, and that the skin sometimes contains fine hairs which irritate the cornea. To obviate these drawbacks, Dr. Story, in 1885, substituted rabbit's conjunctiva, and, later, mucous membrane from the patient's lip, for the skin. Although Dr. Story appears to have suggested this operation, and practised it independently, it had already been extensively used by Van Millingen in Constantinople. The East offers so enormous a field for the observation of the results of trachoma, that Dr. Van Millingen is entitled to speak with authority on this subject, and

May 19, 1888.]

a paper by him in the November number of the *Ophthalmic Review* will probably lead to the universal adoption of his operation. It differs from nearly all other proceedings in that the extent of the conjunctival surface is increased, while no tissue is removed from the lid. The operation itself is exceedingly simple. The lid is split from end to end into an anterior and posterior layer, the division reaching to a height of 3 millimètres in the centre and less at the sides. This gap is opened widely, and is kept open by suturing the ciliary margin to the integument. A strip of conjunctiva is then dissected off the patient's under lip and laid in the gap, no sutures being used. On the second day the cutaneous sutures are removed. The only test of the value of an operation of this kind is the permanence of the results, and Dr. Van Millingen says that he has kept cases under observation for many years, without any relapse taking place.

ANTIPYRIN IN HÆMORRHAGE AND ULCERS OF THE LEG.

In view of the statements of Henocque and Huchard as to the hæmostatic properties of antipyrin, Dr. Alexöi G. Glinsky, of Kharkov, tried (*Transactions of the Kharkov Medical Society*, Part I, 1887, p. 23) the drug (in the shape of cotton-wool plugs soaked in a 5 or 10 per cent. solution, or powdered with the antipyrin) in a series of cases of bleeding, such as epistaxis, hæmorrhage from surgical or accidental wounds, etc. On the whole, his results were unsatisfactory. In some cases of lacerated wounds of the fingers (inflicted by a nail, etc.) hæmorrhage was arrested, but it was not certain that this effect was not rather due to pressure than to the antipyrin. Dr. Glinsky tried it on a wound on his own finger, but was obliged to have recourse to perchloride of iron. In three cases of severe epistaxis the bleeding came on again in five or ten minutes after withdrawing the antipyrin plugs, and ultimately could be stopped only by plugging the posterior nares. Antipyrin had no effect in checking hæmorrhage after excision of acute condylomata, labial papilloma, etc. On the other hand, Dr. Glinsky was much pleased with antipyrin as a dry dressing in indolent ulcers of the leg, fully confirming Dr. Bosse's observations (*Berliner Klin. Wochenschrift*, No. 33, 1886) on this point. The healing action of the drug in these cases is so rapid that he strongly recommends the use of antipyrin in powder when other means fail. He also obtained good results with antipyrin in acute articular rheumatism, in which it is said to act as effectively as salicylate of soda and more rapidly. It also proved useful in migraine and neuralgia of the fifth nerve. Unpleasant secondary effects (rash, sickness, collapse) occurred in his experience very rarely.

SCOTLAND.

SUICIDE BY SWALLOWING SULPHURIC ACID.

A FEW days ago a woman was brought into the Royal Infirmary, Glasgow, suffering from poisoning by sulphuric acid. She had been arrested by the police for creating a disturbance in the street, and had swallowed the poison shortly before her arrest. She was at once removed from the police-station, after examination by the surgeon, to the infirmary, but died soon after her admission.

DEATH OF DR. JOHN WILSON, GLASGOW.

It is with deep regret that we record the death of Dr. John Wilson, of Hillhead, Glasgow, on May 8th, at the age of 63. He had been in feeble health for some time past, but the end came suddenly, death being due to apoplexy. He was one of the most popular members of the profession in Glasgow, and his tall figure and genial, enthusiastic manner, will long be missed. Dr. Wilson was a man of scholarly habits and of considerable literary and

artistic power. He had very conspicuous ability in expressing his ideas both with pen and pencil. He frequently read papers before our various societies, and his last paper, read before the Medico-Chirurgical Society this session, on the Erect Attitude in Man will long be remembered for its sound anatomical knowledge, its wealth of illustration, and its felicity of expression.

LAKE DWELLING AT OBAN.

A DISCOVERY of more than ordinary interest to archaeologists has recently been made at Lochavullin, near Oban, of an ancient "crannog," or lake dwelling. It has been visited by Dr. Robert Munro, of Kilmarnock, author of *Ancient Scottish Lake Dwellings*, who has declared it to be a genuine "crannog," and the largest he has yet seen in Scotland. It measures about 85 feet by 60 feet. By digging in the mud three tiers of wooden piles were discovered, and more woodwork could be felt at a depth of 14 feet from the surface. Further excavations were, however, suspended till the water of the lake could be thoroughly drained off.

ACCIDENTS AT THE OPENING OF THE EXHIBITION.

CONSIDERING the enormous crowds which lined the streets of Glasgow and occupied every available elevation on the route of the procession on May 8th, it is fortunate there were so few accidents. The only cases reported are comparatively slight. A little girl, while climbing over a railing in the Park, got her leg broken. A crowd of people leaning against a railing caused it to give way and fall upon the people in the street below, of whom two, a man and a woman, had their legs broken. Late in the afternoon a man standing on the top of a tramcar overbalanced and fell to the ground on his head. All the injured were conveyed to hospital, and are now doing well.

PATHOLOGICAL AND CLINICAL SOCIETY, GLASGOW.

THE last meeting for the session was held on Monday, May 15th. Dr. Thomas Reid showed a case of fracture of the skull, with loss of sight of one eye, and hemiopia of the other. Dr. Newman showed two cases of complete laryngeal stenosis produced by wounds of the larynx in attempted suicide. Dr. H. C. Cameron showed a dermoid cyst of the ovary, with teeth and hairs growing on its outer wall, and a large Dupuytren's exostosis of the great toe. He also showed several large biliary calculi removed successfully by operation from the gall-bladder. Dr. Meighan showed an eyeball in which ossification of the choroid and lens had taken place. The following were the office-bearers elected for next year: *President*: Professor W. T. Gairdner. *Vice-President*: Dr. David Newman. *Secretaries*: Mr. Maylard and Dr. Lindsay Steven. *Treasurer*: Dr. J. B. Russell. *Council*: Drs. Middleton, Meighan, Finlayson, and Clarke. The recommendation of the Council that Dr. Joseph Coats be appointed representative of the Society at the Congress on Tuberculosis to be held in Paris in July next was unanimously adopted.

UNIVERSITY EXTENSION LECTURES.

ARRANGEMENTS have recently been made in Edinburgh for developing in the city itself the system of University extension lectures that has proved so satisfactory and successful in some of the surrounding districts. A course of twelve lectures on botany, by Mr. Patrick Geddes, has been initiated in connection with the Edinburgh Philosophical Institution; the hall of that institution being used as a lecture room. The first lecture was delivered last week, and there was such a crowded attendance as to necessitate the redelivery of the lecture subsequently to those who could not obtain admission on the first occasion. The course is, therefore, an assured success, and will probably lead to further developments in other branches of teaching in science, art, and literature.

ABERDEEN.

THE summer session of the University opened on April 23rd, and the various practical and systematic classes are now in full swing, bidding fair to maintain the character of the University as a working school. The entries, especially of freshmen, are larger than in any previous year, rendering evident the necessity for enlargement of some of the laboratories and classrooms. It is understood that this will be done in the course of the year by an extension of the buildings. Impatience is finding expression at the delay in getting on with the new Infirmary buildings. The money is subscribed, but, somehow, there is delay over the details of the plans which cannot be considered unavoidable. The parts to be first erected are the new surgical hospital and the detached pathological block. The inspectors of the Medical Council paid a visit to Aberdeen at the final examination last month.

THE UNIVERSITIES' (SCOTLAND) BILL.

A SPECIAL meeting of the Merchants' House at Glasgow was held on May 11th to consider this Bill. Dr. W. G. Blackie, who presided, explained that, since the Merchants' House had petitioned in favour of the Bill, very considerable opposition had been raised in the House of Lords to the clauses providing for university extension. These clauses, in the eyes of those who were in favour of university extension, were the cardinal clauses in the Bill, which, without them, would be of comparatively little value. The fear was that the opposition would cause these clauses to be dropped, and their present object was to impress upon Lord Salisbury the great importance of the affiliation clauses, so that they might be retained. The idea was that this would be best done by memorialising Lord Salisbury himself. It was stated that amendments had been prepared meeting the objections that had been raised to the affiliation clauses as they stood. Lord Rosebery had seen the amendments, had expressed his approval of them, and there were some hopes that he might take charge of them in the House of Lords. It was unanimously agreed to send a memorial expressing approval of the object of the Bill, especially the powers in the Bill for the extension of university teaching in Scotland, and those recognising extra-mural teaching under due regulations, and stating that the memorialists would deem it a grievous misfortune if these powers were in any form interfered with. The Education Board of University College, Dundee, have petitioned in favour of the Bill, expressing regret if any change is made endangering the proposals for extending the area of university education in Scotland, whether by the recognition of extra-mural teaching or by the affiliation or incorporation of other colleges, and expressing approval of the special clause relating to the Dundee College. The Glasgow Southern Medical Society, at a special meeting, held on May 11th, unanimously agreed to petition in favour of the Bill, the affiliation clauses being regarded as vital.

IRELAND.

NEW WATERWORKS FOR LIMERICK.

THE Board of Works have approved of the plans for the new waterworks for this town, and have sanctioned the immediate issue of the loan required for their construction.

ROYAL COLLEGE OF SURGEONS.

THE following gentlemen have been appointed examiners: J. D. Pratt, Preliminary Education; H. C. Tweedy, Public Health. Mr. Theodore Stock, Mr. Conolly Norman, and Mr. J. B. Story are candidates for the Council; the election takes place on the first Monday in June.

DEATH OF DR. BARRY DELANY.

THE death of Dr. Barry Delany, Superintendent of the Kilkenny District Asylum, is announced. The cause was angina pectoris. The appointment is worth £550 a year, with allowances. It is practically certain that Dr. Myles, the senior assistant at the Richmond Asylum, Dublin, will be promoted. The patronage is in the hands of the Lord Lieutenant.

MEDICAL SCHOLARSHIPS, ETC.

THE annual examinations for the Coulter and Malcolm exhibitions at the Royal Hospital, Belfast, have just been held, and the results declared. Mr. W. Quarry has obtained the former and Mr. James McConnell, B.A., the latter. Mr. R. W. Haslett, B.A., has been awarded the gold medal annually offered by the Belfast Hospital for Sick Children, at the close of the winter session, for proficiency in the medical and surgical diseases of children.

ELECTION OF CORONERS.

DR. McGRATH (Nationalist) has been returned for this office by a majority of 187 votes over his Unionist opponent, Dr. T. J. Browne. The contest seems to have been conducted purely on political grounds, as has unfortunately become the rule in such cases. It is difficult to see the connection between politics and a candidate's fitness to preside over the coroner's court. Dr. Alexander Heron, J.P., of Rathfriland, has been returned for the office of Coroner of the Southern Division of Co. Down. Dr. Martin, of Newry, and Dr. Smyth, of Banbridge, were at one time in the field, but retired upon the nomination day, leaving Dr. Heron in possession of the field.

HEALTH OF IRELAND: MARCH QUARTER.

THE death-rate was above the average for the March quarter, and was higher than the rate for any quarter since 1883. This result was due partly to the great prevalence of measles in many districts, and to the large mortality from diseases of the respiratory organs caused by the inclement weather which prevailed. The principal zymotic diseases caused 2,273 deaths, a number equal to a rate of 1.9 per 1,000, and showing an increase of .270 as compared with the number for the previous three months.

ENGLISH HOSPITALS AND IRISH SURGICAL QUALIFICATIONS.

THE Council of the College of Surgeons in Ireland has addressed the following letter to the Board of Trustees of the Bristol Royal Infirmary:—

Royal College of Surgeons in Ireland. May 9th, 1888. DEAR SIR,—The President and Council of the Royal College of Surgeons in Ireland, have had their attention called to the reported proceedings of the trustees of the Bristol Royal Infirmary, from which it appears that a motion has been made at their last meeting that a new rule shall be enacted, the effect of which will be to exclude from the medical staff of the Infirmary the Fellows of this College, in common with the graduates of most universities in England, and of all the colleges and universities in Scotland and Ireland. This College does not feel called upon to vindicate the status of its Fellows, except so far as it may be necessary to protect the interests of those who practise in England; but it has observed that the movers of the new rule in question have suggested that such regulation is advisable in order that the status of the medical officers of the Infirmary may be thereby raised, it being inferred that the Fellows of other Colleges, which are named, are of superior educational qualification. With the view of removing misapprehension on this point, I am directed to send, for the information of the Board (enclosed), copies of the Fellowship Regulations of the College, from which it will be observed that under no circumstances is any candidate admitted to that diploma except after several days' theoretical, practical, and operative examination, the scope of which is not in any respect inferior to that of any licensing body in the kingdom, and before and after the passing of these examinations strict guarantees are exacted from the candidate for the propriety of his professional

May 19, 1888.]

notice as a Fellow. Lest any doubt may exist as to the *bona fides* of these examinations, or as to their educational standard, the College has expressed to the General Medical Council its desire that these examinations should be submitted to any inspection which may seem necessary to remove any possible doubt on these points; and I am directed to say that if any question arises to the professional status of our Fellows, this College is ready to afford to your Board the most ample information to enable you to satisfy yourselves that there is no reasonable ground for such a motion as that which has been submitted to them, and the College invites them to make such inquiries as they may deem necessary.—I am, Sir, yours very faithfully, ARCHIBALD H. JACOB, R.C.S.I., Secretary to the Council.

PROPOSED SANITARIUM AT ROSTREVOR, CO. DOWN.

THE prospectus of a company recently formed for the foundation of a hydropathic establishment and sanitarium at Rostrevor, Co. Down, is just being issued. It is pointed out that a great need exists for an establishment of this kind in the North of Ireland, none at present existing in Ulster, in spite of the proved popularity of such institutions. The only thoroughly organised and efficient hydropathic establishment in Ireland is at Blarney, near Cork; and it is thus hoped that the proposed institution at Rostrevor might enjoy a virtual monopoly of patronage from the people of the North. The advantages of Rostrevor as a site are set forth in the prospectus with all the glowing language familiar in such documents. They are, however, sufficiently obvious and genuine to need no exaggeration. They consist mainly of two important features—shelter and natural beauty. The Mourne Mountains form an almost continuous rampart on the east and north, constituting Rostrevor one of the mildest of resorts, especially during the prevalence of east winds. The neighbourhood is also highly picturesque, and is easily accessible from all parts. Warrenpoint, the nearest railway terminus, is two miles and a half distant, and it is only seven miles thence to Greenore, which is five hours steaming from Holyhead. The site of the proposed sanitarium has a southerly aspect, and a frontage of 750 feet to Carlingford Lough. It is intended that the building to be erected shall have accommodation for fifty guests, and contain all the equipment of a complete hydropathic establishment. The capital of the company is to consist of £16,000, in 11,000 shares of £1 each, and £5,000 in 6 per cent. debentures. Mr. T. W. Russell, M.P., is one of the directors.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.—Mr. W. S. Savory, F.R.S., took the chair at the annual general meeting of this association. The following gentlemen were elected members: Wilson Coltart, L.R.C.P., M.R.C.S., medical officer to Epsom College; Peter W. Delamotte, M.R.C.P.E., M.R.C.S., medical officer to the West London Schools, Ashford; and Percival Kingsford, M.R.C.S., L.S.A., medical officer to the Welsh High School for Girls, and to the Feltham Reformatory. The audited accounts—showing a balance in hand of £39 2s. 11d.—were presented and passed. The officers for the ensuing year were then elected as follows:—*President:* W. S. Savory, Esq., F.R.S. *Vice-Presidents:* Sir Andrew Clark, Bart., Dr. Farquharson, M.P., Dr. Fuller, Dr. Brett, and H. Statham, Esq. *Treasurer:* Noble Smith, Esq. *Honorary Secretaries:* Dr. Alder Smith and Dr. Charles Shelly. In place of the four gentlemen retiring by rotation, the following were elected as new *Members of Council:* Dr. Abercrombie, Assistant Physician at the Children's Hospital, Great Ormond Street; Chune Fletcher, Esq., medical officer to the Merchant Taylors' School; William Holderness, Esq., medical attendant at Eton; and Surgeon-Major Lever, medical officer to the Military College, Oxford. *Auditors:* Messrs. Statham and Chune Fletcher were re-elected. The Honorary Secretaries then presented the Code on the Construction and Maintenance of School Infirmaries and Sanatoria, on the preparation of which the Council had been continuously engaged during the last eighteen months. This was considered and discussed by the meeting clause by clause. Certain modifications having been introduced into the text, it was then resolved that the Code should be printed and

published for the association, and that a copy should be sent to each member and to the head masters of the large schools. A vote of thanks to the Council, and a special vote of thanks to Dr. Shelly for his great help in wording and preparing the Code, were then passed unanimously. Several members and guests subsequently attended the annual dinner, at which the President presided.

PRESENTATIONS.—Mr. George Parsons Torney, B.A. Dublin, L.K.Q.C.P.I., who recently resigned the appointment of assistant medical officer in the Warwickshire County Asylum, Hatton, to accept the assistant medical officership at the Lincoln County Asylum, has been presented with an illuminated address, together with a handsome clock bearing a suitable inscription, a pair of valuable chimney-piece bronzes, and other objects of practical and artistic value from his brother officers, patients, and friends.—Dr. C. Knott, of Landport, has been presented by the members of Court Mechanics' Hope, No. 2,357 A.O.F., as a mark of their esteem, with a massive four-branch silver candelabrum, chased and ornamented, also a silver-plated fish slice and fork.

CLINICAL LECTURES ON CHILDREN'S DISEASES.—A course of clinical lectures and demonstrations commenced at the Hospital for Sick Children, Great Ormond Street, on Thursday, May 17th, at 3.30 P.M., when Dr. Cheadle lectured on Rheumatic Heart Disease in Children. On Saturday, May 19th, at 9.30 A.M., Mr. Howard Marsh will lecture on Abscess in Child—Diagnosis and Treatment. The lectures are practically free, though for attendance throughout a small fee is charged. A syllabus of the complete course can be obtained of the Secretary, Mr. Adrian Hope.

THE Glasgow Society for the Prevention of Cruelty to Children has during the past month dealt with cases involving the welfare of 118 children, some of a peculiarly distressing character. Of the children, 18 had been placed in industrial schools and training ships, and 43 had been placed under the supervision of the School Board. A fancy dress ball, held recently in aid of the society in St. Andrew's Hall, had realised £550 for the benefit of its funds.

LEGACY TO EDINBURGH ROYAL INFIRMARY.—Under the will of the late Mr. Henry Ritchie Cooper Wallace, of Busbie and Cloncaird, Ayrshire, a large residual sum, after paying other legacies, was left to the Royal Infirmary. The terms of the will were subject to a life rent, payable to the widow of the deceased gentleman, and were only to be implemented on her marriage or demise. The former alternative has been recently fulfilled, and the Royal Infirmary thus becomes the recipient of a handsome legacy, amounting to over £21,000.

A SCHOOL OF HOUSEKEEPING.—A school of housekeeping has been started in Brussels by the Countess of Flanders. Forty girls there receive a practical training in domestic economy, marketing, cooking, mending, and laundry. The pupils keep house-keeping books, and enter receipts and expenditure. Such an effort to improve practical knowledge deserves commendation and imitation.

THE Greenock Centre of the St. Andrews Ambulance Association held their second annual meeting on May 5th. The centre was reported to be in a prosperous condition, twenty-nine classes, comprising 1,000 persons, having been held in the two years of the existence of the branch. Of that number of persons nearly all had taken certificates, and forty-three had been awarded the Association's medallion.

LONDON SCHOOL OF MEDICINE FOR WOMEN.—The trustees of the Helen Prideaux Fund propose to make the first award of the Helen Prideaux Scholarship at the end of July, 1888. The amount of the scholarship will be £50. Particulars may be obtained on application to the Secretary, Miss Thorne, at the school, Handel Street, Brunswick Square.

METROPOLITAN CORONERS' DISTRICT.—The petitions in favour of dividing the Eastern District into two parts have been favourably considered by the Privy Council, and an Order in Council has been issued, directing that the district shall, for the purposes of the Coroners Act, be divided into two districts, to be called the North-Eastern District and the South-Eastern District.

DR. A. HUIJSMANN, of Utrecht, has recently had a patient with a tumour growing from the under surface of the epiglottis, about the size and shape of a large bean. It was removed under cocaine by the galvano-cautery, and proved to be a simple cyst, its contents being caseous and semi-fluid.

ROYAL COLLEGE OF PHYSICIANS.

At a meeting of the Royal College of Physicians, April 26th, 1888, on the motion of the Senior Censor, seconded by Dr. Quain, the following resolution was adopted unanimously:

"That the cordial thanks of the College are due, and are hereby offered, to Sir William Jenner, Bart., K.C.B., M.D., for the ability and judgment with which he conducted the business of the College during the seven consecutive years in which he filled the office of President, and also for the time he devoted to the duties of that office, and for his endeavours to advance, on all occasions, the interests of the profession."

On Friday, May 11th, a deputation consisting of the President, the mover and seconder of the resolution, and the Registrar, waited on Sir William Jenner, at 63, Brook Street, to present the resolution in the name of the College.

At the Comitia held on Monday, May 14th, Sir ANDREW CLARK, Bart., presiding, the newly-elected Fellows, whose names have already been published in the JOURNAL, were duly admitted.

A report was received from the Council, recommending the adoption of the following regulations for the Moxon Medal:

1. That the memorial consist of a gold medal, of the value of £30, to be awarded every third year to the person who shall be deemed to have especially distinguished himself by observation and research in clinical medicine.

2. That the award be not restricted to British subjects.

3. That the award be made on the recommendation of the President and Council (who may, if they see fit, call in the aid of assessors), subject to the approval of the College.

4. That in making the award the College should always have regard to discovery and originality in research rather than general personal reputation.

5. That the medal be presented immediately after the Harveian Oration by the President of the College; and that, in the absence of the medallist, the medal be given into the hands of the Registrar, who shall forward it to its destination.

6. That the medal shall present on the obverse the portrait of the late Dr. Moxon, with his name and the dates 1836-1886; and on the reverse the portico of the Royal College of Physicians, with the inscription "Ob artem medicam studiis et experimentis auctam," and, further, that the name of the medallist in his native language, with the date of the award, be engraved on the rim of the medal.

These regulations were unanimously adopted by the College.

A report was received from the committee appointed to consider the internal arrangements and requisite fittings of the rooms and theatre in the new building to be erected behind the Examination Hall, pointing out that it had been necessary to make a slight modification in the plans already sanctioned by the two Colleges, in order to allow more light to the houses in the rear. The committee also desired the sanction of the two Colleges to expend a sum not exceeding £50 in preliminary inquiries, both in England and abroad. Both these suggestions were unanimously adopted.

Sir HENRY PITMAN gave notice that at the next Comitia he would move the appointment of a committee of seven from this College, to form, with seven delegates from the College of Surgeons, a committee to superintend the work carried on in this building when constructed.

On the motion of Dr. THEODORE WILLIAMS, it was agreed to hold a *conversazione* in June, a committee for this purpose to be nominated by the President.

Dr. Herringham was appointed an Examiner in Anatomy.

ROYAL COLLEGE OF SURGEONS.

At the meeting of the Council of the College held on Thursday, May 10th, a letter, the contents of which, owing to a technical objection, we were unable to publish in the report of the proceedings of the Council in our last issue, was read from Mr. C. L. Peel, Clerk to the Privy Council, stating, by direction of the Lords of the Council, that their lordships are ready to consider favourably the grant to the College of some further powers to hold property, and for amending the existing charters in regard to points in which there is no controversy with the Fellows and Members of the College, omitting from the supplemental charter the controverted points, namely, those contained in Sections 2, 3, 4, and 5, and inquiring whether the College will be willing to accept the supplemental charter on this basis. It was resolved by the Council of the College to accept the supplemental charter on the basis

offered by the Lords of the Council. The net result of the application of the Council of the College to the Privy Council may be briefly summed up as follows:

The Privy Council is willing to grant additional powers to Council of the College to enable them (1) to hold more property than at present; (2) to enable Fellows to vote by voting paper at the annual meeting for the election of Fellows as members of Council, instead of having to record their votes in person hitherto.

The Privy Council refuses to insert in the supplemental charter the following controverted points contained in Sections 2, 3, and 5 of the Petition of the Council of the College:

1. That the regulations of admission to the Fellowship should be made otherwise than by law, as at present.

2. That the fee for the Fellowship should be determined by-law instead of by charter, as at present.

3. That the Council should have the power of electing ten instead of two members of the College of twenty years' standing each year.

4. That there should be two honorary Fellows elected each year.

THE COUNCIL OF THE COLLEGE OF SURGEONS.

In July, Mr. Cadge, Mr. Bryant, and Sir Joseph Lister retired by rotation, all three having been elected eight years ago, so that, excepting those members who have been re-elected after serving a full term, they stand at the head of the twenty-four members of the Council as it is now constituted. As it is highly advisable that the Fellows of the College should not lose time in considering how they may further their interests at the coming election, which will take place within two months, and as they may not have the history of the present Council at their fingers' ends, we supply the following statistics. The Council stands, at present, thus:

President: Mr. Savory (third year of office). *Vice-President:* Mr. Bryant and Mr. Thomas Smith. *Other Members:* Sir Jam. Paget, Sir T. Spencer Wells, and Mr. Marshall (all three former Presidents), and Mr. Lund, Mr. Henry Power, Mr. Hutehinson, Mr. Cadge, Sir J. Lister, Mr. Hulke, Mr. Christopher Heath, Mr. Croft, Mr. Sydney Jones, Sir W. Mac Cormac, Mr. Lawson, Mr. Berkeley Hill, Mr. Durham, Mr. Macnamara, Mr. Oliver Pemberton, Mr. Septimus Sibley, Mr. Reginald Harrison, and Mr. Willett. The elections have run as follows during the past eight years, a asterisk marking re-elected members. 1880.—Mr. Cadge, Mr. Bryant, Sir J. Lister, and Mr. T. Smith (substitute member 1881.—*Sir J. Paget, Mr. Hulke, and Mr. Heath. 1882.—*Mr. Marshall, *Mr. Power, and Mr. Croft. 1883.—*Mr. Cooper Forster (deceased), Mr. S. Jones, and Sir W. Mac Cormac. 1884.—Mr. Lawson, Mr. Durham, *Mr. T. Smith (see 1880), Mr. B. Hill (substitute member for Sir Erasmus Wilson), and Mr. Allingham (substitute member for Mr. Gay, and since retired). 1885.—*Mr. Savory, Mr. Pemberton, and Mr. Macnamara. 1886.—*Mr. Lund, *Mr. Hill (see 1884), Mr. Harrison, and Mr. Sibley (substitute member for Mr. Cooper Forster). 1887.—*Mr. Hutchinson, Mr. Willett, and *Sir Spencer Wells. The order under each of the above dates follows the number of votes which the candidates polled.

We may remind our readers of the signification of the term "substitute members." They are elected to fill up vacancies taking place among elective members of Council in any other way than by going out of office by rotation. Every person so elected holds office until the time when the person in whose room he shall have been chosen would have gone out of office. When that time has expired the substitute member must retire, but is eligible for re-election, and if re-elected becomes a member on his own account, so to speak, and may remain on the Council for the full term of eight years. There are but four provincial members at present on the Council—Mr. Lund, Mr. Cadge, Mr. Pemberton, and Mr. Harrison. Mr. Lund, re-elected in 1886, has the right of six more years on the Council; Mr. Pemberton, elected in 1885, may remain yet five years as an honoured and progressive provincial member, whilst Mr. Cadge, as we have already observed, will retire in July. The wishes of the Association will doubtless favour his return. There is but one representative of the general practitioners, Mr. Sibley, who has yet three more years before him as the substitute member for Mr. Cooper Forster, who was re-elected in 1883. Mr. Bryant and Sir Joseph Lister are so well-known to fame, and Mr. Cadge is so popular as a provincial member, that they will probably all be re-elected should they offer themselves

appears to be most probable according to trustworthy rumours. It is, should there be no further vacancy through retirement before the regulation period, the coming elections will not be of a very exciting character.

ST. MARY'S HOSPITAL.

The Festival Dinner in aid of the extension of St. Mary's Hospital held at the Hôtel Métropole on Saturday last, Lord RANDOLPH BURCHILL presided, and about 150 other gentlemen were present. The Chairman, in proposing the toast of the evening, spoke with admiration of the hospital system of London, voluntary, free, and independent, but costing about £650,000 a year, though enjoying an income of about £560,000 only, the deficiency being made up of legacies, which vary from £50,000 to £100,000 a year. The London hospitals assist annually about 1,300,000 people, but the chief of them are situated within a radius of about 1½ mile from Charing Cross; and, out of the 6,500 beds found in all these institutions, 4,500 are within that radius, whilst the population with which the hospitals have to deal covers an area extending 7 miles from Charing Cross, so that many people necessarily cannot obtain easy access to the hospitals, although the public-houses are always near their homes. Unfortunately, too, the income of 14 large hospitals derived from subscriptions has in 10 years increased only about £3,000 (from £32,000 to £35,000), whilst their expenditure at the same time has been augmented by nearly £50,000 (from £201,000 to £247,000). These figures warrant the opinion that there is a distinct falling off of the efforts of the rich in support of these great institutions. But the people themselves are making efforts to overcome these deficiencies, as evidenced by the increase in the Hospital Saturday Fund, the large amount (£5,000) collected in Islington for the Great Northern Central Hospital, the starting of hospitals in East and West Ham, whilst in the provinces, at Birmingham, Glasgow, Stoke, etc., the working classes contribute largely to the local hospitals. The hospitals, too, are the great schools at which doctors are taught and nurses trained; they, therefore, deserve far more support than they obtain. Turning next to St. Mary's Hospital, the Chairman showed how most of the faults of the London hospital system are intensified in the case of that institution, which has an inconvenient and inadequate site, is surrounded by an overwhelming daily growing population, for which it endeavours to provide medical relief always with a deficient income. A splendid opportunity had arisen for acquiring a piece of land in Praed Street, adjoining the hospital, which would give it a fine frontage in an important public thoroughfare, and this land must be acquired.

In the course of the evening Mr. RYAN, Secretary to the hospital, announced subscriptions amounting to £4,600 for the Enlargement Fund, which sum included 25 guineas from the Chairman, 50 guineas from Mr. John Aird, M.P., £400 from Mr. C. Vesey, and £286, collected in shillings, by Mrs. G. P. Field.

An excellent selection of vocal music, under the direction of Mr. Coates, assisted by Madame George and other artistes, was given; and the dinner committee, of which Mr. Malcolm Morris was chairman, and which comprised Mr. G. P. Field and other gentlemen, may be congratulated on the success that attended their efforts.

THE CORONERS BILL.

The Coroners Bill, as introduced by the Lord Chancellor, is one which the Parliamentary Bills Committee has already expressed its intention of opposing in its present form. This Bill practically proposes to hand over the appointment of coroners altogether to the Lord Chancellor. The Lord Chancellor already possesses an overwhelming mass of patronage far greater than he either can or does dispense to the public satisfaction, and nothing could be more unwise or unpopular than to hand over to this high functionary the appointment of the whole of the coroners of London. One inevitable result would be the appointment of lawyers to an office for which as a rule lawyers are very ill-fitted, and for which medical men are, on the whole, far better fitted. On the other hand, the election by freeholders undoubtedly gives rise to abuses, and is an inconvenient and costly method of appointing judicial officers. The creation of the new County Councils will afford a suitable body in whom the appointment should naturally be vested. An opinion has been expressed at the preliminary discussion of the Parliamentary Bills Committee in favour of vesting the future appointment of coroners in these new elective bodies,

and we are glad to see in the discussion in the House of Lords that Lord Herschell expressed an opinion in accordance with that of our Parliamentary Bills Committee, and intimated that he would move an amendment to that effect.

THE SANITARY CONDITION OF HAILEYBURY COLLEGE, HERTFORD.

In accordance with our promise, we publish Dr. Stevenson's last analysis and report on the quality of the water from the well at Haileybury College.

The samples were enclosed in glass-stoppered bottles, marked respectively, "Water direct from well at Haileybury College, April 18th, 1888," and "Water after Porter-Clark treatment, April 18th, 1888."

Both the samples were clear, colourless, and destitute of odour. The results below are in grains per gallon.

	Well.	After Treatment.
Total solid or saline matter	23.24	16.52
Loss on ignition	1.68	1.49
Combined chlorine	1.26	1.26
Equal to common salt	2.08	2.08
Nitrogen as nitrates	0.18	0.13
Nitrites	None	None
Ammonia	0.001	Trace
Albuminoid, or organic ammonia	0.0035	0.0050
Oxygen required to oxidise the organic matter	0.043	0.021
Hardness in degrees:—		
Temporary	13.6°	7.6°
Permanent	4.4°	4.0°
Total	18.0°	11.6°

The organic impurities found in the water lately, have entirely disappeared, and the results approximate to those met with when I made my analysis in October last. The waters are now both of the highest degree of purity, being almost destitute of organic matter.

It will be noted on comparing my present with previous analyses, that when the water from the well is organically pure, the proportion of saline matter is very sensibly greater than when the water is brown and organically impure.

(Signed) THOS. STEVENSON.

This analysis and the remarks speak for themselves as to the purity of the sample submitted to Dr. Stevenson upon April 18th, but we must remind Dr. Shelly, the medical officer of the college, who kindly forwarded us the copy for publication, that this sample was taken at a very favourable time during the holidays, when the boys and servants had been away from the College for a fortnight, and when there would necessarily be less putrescible matter on the surface to find its way vertically down the well to the water level beneath.

It would have been more applicable to the point at issue had he at the same time enclosed us a copy of Dr. Stevenson's previous analysis of and remarks upon the sample sent to him on or about Lady Day, which was in the possession of the school authorities at their council meeting on April 7th, soon after the school had broken up, and which, according to Dr. Shelly, was stated by Dr. Stevenson to have been "most discoloured," although qualified by his statement that "the organic matter present does not appear to be due to sewage."

We have no desire in any way to impugn the quality of the Haileybury water; all we wish to say is that so long as the well occupies its present position it is subject to suspicion, and that there are many authorities on the water question who will not readily believe that in the rainfall of March, which up to the date in question (March 23rd) amounted only to 1.65 inch in the neighbourhood of Hertford (and which was spread over twelve days), there was cause, atmospheric or otherwise, for the discoloration of the deep water in the chalk.

Lastly, we believe that most sanitarians will agree that, no matter what analyses taken at long intervals and at odd times may go to prove, the suspicion as to the quality of the water will not be removed as long as it is drawn from a well which is sunk directly under the building, and therefore invites insidious pollution.

MEDICAL MAGISTRATES.—Dr. Thomas Frederick Young and Dr. Thomas Munns Wills have been placed on the Commission of the Peace for the Borough of Bootle.

ASSOCIATION INTELLIGENCE.

NOTICE OF QUARTERLY MEETINGS FOR 1888.
ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Meetings of the Council will be held on July 18th, and October 17th, 1888. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before each meeting, namely, June 27th, September 26th, and December 28th, 1888.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No member can be elected by a Branch Council unless his name has been inserted in the circular summoning the meeting at which he seeks election.

FRANCIS FOWKE, *General Secretary.*

COLLECTIVE INVESTIGATION OF DISEASE.

THE Report upon the CONNECTION OF DISEASE WITH HABITS OF INTemperance, which was presented to the Section of Medicine in the Annual Meeting of 1887, will shortly be published in the JOURNAL.

Reports upon the two remaining inquiries, namely, that into DIPHTHERIA, and that into the GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES, are in preparation, and will be published as soon as ready.

The following inquiry only of the first series remains open, namely, that on the ETIOLOGY OF PHTHISIS.

A fresh inquiry into the ORIGIN AND MODE OF PROPAGATION OF EPIDEMICS OF DIPHTHERIA has been issued.

Memoranda upon these subjects, and forms for recording observations, may be had on application to the Secretary of the Collective Investigation Committee, 429, Strand, W.C.

BRANCH MEETINGS TO BE HELD.

STAFFORDSHIRE BRANCH.—The third general meeting of the present session will be held in the Bell Library and Medical Institute, Cleveland Road, Wolverhampton, on Thursday, May 31st. The chair will be taken by the President, Mr. W. D. Spanton, at 3 o'clock in the afternoon. The following papers will be read:—Dr. C. A. McMunn: Excretion of Reduction Products of Hematin in Disease. Dr. Alfred H. Carter: Practical Considerations on the Nature and Treatment of Chronic Cardiac Disease. Mr. E. Hurry Fenwick, London: The Electric Illumination of the Bladder and Urethra, and its Value in the Diagnosis and Treatment of Obscure Vesico-Urethral Diseases. Dr. McMunn will show a simple method of adapting a photographic camera to the microscope.—T. VINCENT JACKSON, Wolverhampton.

EAST YORK AND NORTH LINCOLN BRANCH.—The annual meeting will be held at the Infirmary, Hull, on Wednesday, May 30th, at 1.30 p.m. Gentlemen who intend to make any communication, or to propose any resolution, are requested to inform the Secretary not later than May 20th.—E. P. HARDET, Honorary Secretary, 80, Spring Bank, Hull.

MIDLAND BRANCH.—The annual meeting will be held at Nottingham on Thursday, June 14th, at 2 p.m. Members desirous of reading papers, exhibiting cases, etc., are requested to communicate with the Secretary before May 24th. Candidates for election by the Branch Council must send in their forms of application by the same date.—W. A. CARLINE, M.B., Honorary Secretary, Lincoln.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT.—The annual meeting of the above District will be held at the Kent and Canterbury Hospital on Thursday, May 24th, at 3 p.m., Dr. Parsons, of Dover, in the chair. The dinner will take place at 5 p.m. at the Royal Fountain Hotel. Agenda:—Usual business of annual meeting. Mr. Raven: Tendon Reactions in Health and Disease. Mr. Brian Rigden: Notes on a recent Epidemic of Measles. Anyone wishing to send papers, etc., should communicate at once with the Honorary Secretary, W. J. TYSON, 10, Langborne Gardens, Folkestone.

SOUTH-WESTERN BRANCH.—The annual meeting of this Branch will be held at the Devon and Exeter Hospital, Exeter, on Tuesday, June 28th, under the presidency of Dr. John Woodman, F.R.C.S. Notices of motion or communications to be intimated to the Honorary Secretary without delay, and it will facilitate arrangements if members will inform the Honorary Secretary as soon as possible if they hope to be present at the meeting. The following motion was passed at the Council Meeting on May 2nd:—"That inasmuch as the annual meeting assumes more or less the character of a day of recreation, and with a view of encouraging the district meetings, the business of the annual meeting shall be confined to the president's address, the business of the Branch, the exhibition of cases or of specimens with notes, and the annual dinner."—P. MAURAY DEAS, Wonford House, Exeter, Honorary Secretary.

NORTH OF ENGLAND BRANCH.—A meeting for the exhibition and discussion of microscopic specimens will be held on May 31st, at 3.30 p.m., in the dissecting-room of the College of Medicine, Newcastle-upon-Tyne. The Secretary will be glad to hear from any of the members who have interesting slides of any description. After the meeting there will be an informal dinner at 5 p.m., at the Douglas Hotel.—G. E. WILLIAMSON, 22, Eldon Square, Newcastle-upon-Tyne, Honorary Secretary.

LANCASHIRE AND CHESHIRE BRANCH.—The annual meeting will be held in Liverpool about the 13th of June. Gentlemen wishing to read papers or show cases are requested to communicate to CHAS. ED. GLASCOTT, M.D., 23, Saint John Street, Manchester, Honorary Secretary.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH.—The annual meeting of this Branch will be held in the Birmingham Medical Institute, on Wednesday, June 14th, at 3.30 p.m.

SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT.—A meeting of the above District will be held in the board-room of the new hospital, at Hastings, on Tuesday, June 12th. Dr. Bagshawe will preside. The Chairman, Mr. Tieburst, and Dr. Penhall, will contribute short papers on cases. Gentlemen interested in hospital construction will be at liberty to inspect the new building. Communications as to papers, etc., should be addressed to T. JENNER VERRALL, 97 Montpelier Road, Brighton, Honorary Secretary.

SOUTH INDIAN BRANCH.

THE annual meeting was held at the Central Museum, Madras, on January 13th, 1888, the PRESIDENT in the chair.

The minutes of the previous meeting were read and confirmed.

New Members.—The PRESIDENT announced that the following gentlemen had been elected by the Council since the last meeting of the Branch: Rev. H. S. Lunn, M.D.; C. A. Lafrenais, Esq., L.M.S.; Deputy Surgeon-General W. F. de Fabick, M.D.; Surgeon J. J. Routh, M.R.C.S.; Surgeon M. E. Reporter, L.R.C.P. and S. Edin.; Surgeon W. H. Karney, L.R.C.P. and S. Edin.

Financial Statement.—The HONORARY TREASURER then presented a statement of the accounts of the Branch for the past year, showing a balance of Rs. 521 6 8, also a Government pro. note for Rs. 1,000, to credit on December 31st. It was proposed by Surgeon-Major DRAKE-BROCKMAN, and seconded by Surgeon-Major ALLISON, that Brigade-Surgeon Fox and Surgeon C. M. Thompson be asked to audit the accounts for the past year. Carried unanimously.

Branch Subscription.—In accordance with Rule VI. it was proposed by Surgeon-Major E. F. DRAKE-BROCKMAN, and seconded by Surgeon-Major BRANFOOT, that the subscription for the year be fixed at Rs. 18 8. Carried unanimously.

Votes of Thanks.—A vote of thanks was then proposed and carried unanimously thanking the Honorary Treasurer for his exertions on behalf of the Branch during the year.—A vote of thanks was also proposed and carried unanimously thanking the Honorary Secretary for the manner in which he had discharged the duties of his office during the year.

Election of Officers.—The meeting then proceeded to the election of office-bearers for the year with the following results:—**President:** Surgeon-General G. Bidie, M.B., C.I.E. **Vice-President:** Deputy Surgeon-General S. B. Roe, M.B., C.B. **Committee:** Surgeon-Major E. F. Drake-Brockman, F.R.C.S.; Surgeon-Major H. W. A. Mackinnon, D.S.O.; Surgeon-Major A. M. Branfoot, M.B.; Surgeon D. F. Dymott, M.B.; Surgeon C. M. Thompson, M.B. **Provisional Members of Committee:** Surgeon-Major A. L. Hackett; Surgeon J. Smyth, M.D. **Honorary Treasurer:** Brigade-Surgeon C. Sibthorpe, F.R.C.P.I. **Honorary Secretary:** Surgeon-Major H. Allison, M.D. **Representative in Council:** Surgeon-General W. R. Cornish, C.I.E.

BORDER COUNTIES BRANCH.

THE Spring meeting was held at Cockermonth on May 4th; Dr. McLEOD, President, in the chair. Twenty members and one visitor were present.

Horse Tax.—The PRESIDENT having introduced the question of the taxing of doctors' horses as pleasure horses, it was moved by Dr. HAMILTON (Hawick) and seconded by Dr. ROBERTSON (Perth), that a letter should be sent to the Chancellor of the Exchequer protesting against the tax, and that a copy of the letter should be sent to the borough and county members in the District.

Fees to Witnesses.—In opening a discussion on the question of fees paid to medical witnesses at assizes and county sessions, Dr. HIGLET said that he had always wondered why the members of the profession had so quietly submitted to what in his opinion was short of a public scandal. Medical

men were themselves much to blame for this, and the public were inclined to estimate their services at what they cost, and not at what they were worth. He was, however, glad to see that the question was attracting the attention of the British Medical Association. In his mind there was no doubt what the answer should be. One guinea per day and two shillings a night for every night detained from home was a sum absurdly small, and when they considered the long distances many of them had to travel, and the detriment to their practice, in many instances left to take care of itself, it was no wonder that many of them fought shy of being called upon to give evidence. He begged to move the following memorial:

"The memorial of the Border Counties Branch of the British Medical Association sheweth: That your memorialists had, at their meeting held at Cockermonth May 4th, 1888, a representation made to them as to inadequate fees paid to medical witnesses in criminal cases at assizes and county sessions. That your memorialists regard the present rate of remuneration—one guinea per day—as altogether inadequate, considering the distance many of them have to travel, and the amount of time thereby taken up, and that this is a matter which requires serious attention at the hands of the President and Council of the Association, and a grievance which calls for an early remedy."

Recovery from long-standing Insanity.—Dr. CAMPBELL (of the Carlisle Asylum) read a paper "On Three Cases of Recovery after a Lengthened Duration of Insanity." He gave an analysis of five years' returns from the Carlisle and Edinburgh Asylums, and gave the percentages of recoveries in those institutions for that period, under one year, under two years, and above two years, showing that in the latter period at Carlisle the recoveries were 9.4 per cent., in the Edinburgh Asylum 5.3 per cent. He pointed out how advisable it was to take a hopeful view of cases, and to impress this on the staff of an asylum; and mentioned how beneficial it was for attendants always to have a certain proportion of curable cases in their wards. He advocated the change of ward, employment, attendants, and even of asylum in certain cases, with a view to recovery, and instanced the improvement he had seen both in groups of patients sent to him from other asylums and also in patients sent by him, owing to overcrowding in the Carlisle Asylum, to different other asylums in England. He gave a short account of (1) a female case of periodic mania, where complete recovery took place after a residence in the asylum of almost seventeen years; (2) a male case of delusional insanity, which recovered after a residence of almost nineteen years; (3) a female case of delusional insanity, which recovered after a residence of more than fourteen years. He concluded with remarks on the special features of the cases, calling attention to the following facts—namely, the rarity with which pathological lesions were found sufficient to account for delusions; the tendency, when delusions faded away, for the mental faculties to have become so weakened as to unfit the patient for active outside life; the rarity with which, on recovery, the patients were willing to discuss the delusions they formerly held.

Puerperal Eclampsia.—Dr. HIGHT (Workington) read notes of a case of puerperal eclampsia which had come under his care. The patient was a primipara, aged 18, unmarried, and the convulsions came on in the ninth month of pregnancy. The premonitory symptoms were headache, derangement of vision, and epigastric pain. The lower limbs were distinctly cedematous, face puffy, and urine highly albuminous. The convulsive seizures were most severe, and recurred with alarming rapidity. The treatment consisted in chloral enema, rupture of membranes, administration of chloroform, dilatation by Barnes's bags (os being soft and dilatable, head presenting, and pains commencing), and application of forceps. A living female child, of large size, was born, and the mother made a perfect recovery. He looked upon the result as a triumph to chloroform and the other anæsthetic agent, chloral, and he contrasted the line of treatment with that by bleeding.—In the discussion which followed, the PRESIDENT, Messrs. IRWIN and CRERAR, Drs. HAMILTON, SPEIRS, ROBERTSON, EATON, IMLACH, and ALTHAM took part.

Next Meeting.—The next meeting of the Branch is the annual, one and will probably be held at Penrith early in July.

SOUTHERN BRANCH: ISLE OF WIGHT DISTRICT.

The annual meeting was held at Yelf's Hotel, Ryde, on April 26th. The chair was taken by the President, Dr. WILLIAMSON.

New Member.—The minutes having been confirmed, Dr. Edward Fawcett was elected a member of the District.

Annual Report.—The PRESIDENT read a report of the proceedings for the past year, and suggested certain things which would help to make the meetings more useful. He then vacated the chair, which was taken by the incoming President, T. A. Buck, M.B., of Ryde.

Vote of Thanks to Outgoing President.—A vote of thanks to the outgoing President was carried unanimously.

President's Address.—Mr. BUCK gave an address on Therapeutics in Relation to Pathology, for which a vote of thanks was unanimously accorded.

Office-bearers.—The following officers were then elected; *Vice-President*, in place of Dr. Harvey, left the island: Surgeon-Major Grant. *President-elect*: Dr. Gibson, Cowes. *Vice-President-elect*: Dr. Wm. Hoffmeister, Cowes. *Honorary Secretary and Treasurer*: Mr. W. E. Green was re-elected.

Accounts.—The accounts, having been audited, were passed, and a subscription out of the surplus funds in aid of the Medical Benevolent College was given.

Next Meeting.—The selection of the next place of meeting was left to the Secretary.

Communications.—A Case of Presumed Cerebral Aneurysm was related by Mr. FRYER.—Mr. GREEN exhibited Pieces of Skull removed from a Patient who had made a determined attempt at suicide by means of a coal-hammer.

Dinner.—The members afterwards dined together.

BRITISH GUIANA BRANCH.

The quarterly meeting of this Branch was held at the Public Hospital, Georgetown, on April 6th. There were present, R. GRIEVE, M.D., the Surgeon-General, in the chair, Drs. Anderson, Pollard, Finlayson, Veendam, Castor, Wallbridge, Ferguson, Honiball, Ozzard, Delamere, Hill, Teixeira, Reid, Law, and the Secretary. Drs. Fallon and Pereira were there as visitors.

Miscellaneous Business.—The minutes of the last meeting were read and confirmed. Letters from Drs. Hillis and Massiah apologising for non-attendance, were received.—Dr. ANDERSON made a statement as to the report of the Committee appointed by the last meeting, to the effect that no report had been made on account of the non-attendance of so many of the members. A discussion followed, and, on the proposal of Dr. CASTOR, it was agreed that the Committee be discharged. This was then done.—Dr. DELAMERE gave notice that he would move at the next meeting for the appointment of another committee.—The printing of the transactions of the Branch was discussed on the motion of Dr. WALLBRIDGE, to increase the subscription for this purpose, but no decision was come to, it being deemed advisable to have the opinion of as many members as possible on the point.

Communications.—Dr. POLLARD read a paper on some cases of severe intestinal injuries, and on oleander as an agent for procuring abortion. This was followed by an animated discussion.—Dr. OZZARD read a paper on anchylostoma duodenale, and Dr. LAW reported and read notes of a case of this disease ending fatally. A number of members took part in the discussion which followed.—Dr. ANDERSON showed a specimen of abdominal aneurysm.

Next Meeting.—The PRESIDENT gave notice that the next meeting would be devoted to the discussion of yellow fever, and expressed a hope that all members would give the Branch the benefit of their knowledge and experience.

Votes of Thanks.—Votes of thanks were passed to the readers of the various papers, and the meeting closed.

BRITISH MEDICAL ASSOCIATION.

FIFTY-SIXTH ANNUAL MEETING.

The fifty-sixth Annual Meeting of the British Medical Association will be held at Glasgow, on Tuesday, Wednesday, Thursday, and Friday, August 7th, 8th, 9th, and 10th, 1888.

President: John T. Banks, M.D., D.Sc.(Hon.), F.K.Q.C.P.I., Regius Professor of Physic in the University of Dublin.

President-Elect: Professor W. T. Gairdner, M.D., LL.D., Professor of Medicine in the University of Glasgow.

President of the Council: Thomas Bridgwater, M.B., J.P., Harrow-on-the-Hill.

Treasurer: Constantine Holman, M.D., J.P., Reigate.

An Address in Medicine will be delivered by Thomas Clifford Allbutt, M.D., Consulting Physician, Leeds General Infirmary.

An Address in Surgery will be delivered by Sir George H. B. Macleod, M.D., Surgeon in Ordinary to Her Majesty in Scotland.

A Special Address on his "Recent Investigations in Surgery"

will be given by William Macewen, M.D., Lecturer on Clinical Surgery, Glasgow Royal Infirmary.

An Address in Physiology will be delivered by John Gray McKendrick, M.D., LL.D., F.R.S., Professor of Institutes of Medicine, University of Glasgow.

A. MEDICINE.—*President*, T. McCall Anderson, M.D. *Vice-Presidents*, W. L. Bowles, M.D.; George F. Duffey, M.D. *Honorary Secretaries*, J. McGregor Robertson, M.D., 400, Great Western Road, Glasgow; Robert M. Simon, M.D., 27, Newhall Street, Birmingham.

B. SURGERY.—*President*, George Buchanan, M.D. *Vice-Presidents*, James Dunlop, M.D.; Charles Robert Bell Keetley, F.R.C.S. *Honorary Secretaries*, David Neilson Knox, M.B., 8, India Street, Glasgow; Walter Pye, F.R.C.S., 4, Sackville Street, Piccadilly, London, W.

C. OBSTETRIC MEDICINE.—*President*, Thomas More Madden, M.D. *Vice-Presidents*, William Leishman, M.D.; J. Halliday Croom, M.D. *Honorary Secretaries*, William Walter, M.D., 20, St. John Street, Manchester; W. L. Reid, M.D., 7, Royal Crescent, Glasgow.

D. PUBLIC MEDICINE.—*President*, Henry Duncan Littlejohn, M.D. *Vice-Presidents*, James Christie, M.D.; D. Page, M.D. *Honorary Secretaries*, Ebenezer Duncan, M.D., 4, Royal Crescent, Crosshill, Glasgow; John C. McVail, M.D., Holmhead, Kilmarnock.

E. PSYCHOLOGY.—*President*, James C. Howden, M.D. *Vice-Presidents*, James Rutherford, M.D.; Julius Mickle, M.D. *Honorary Secretaries*, A. R. Urquhart, M.D., Murray House, Perth; Alex. Newington, M.D., Ticehurst, Sussex.

F. ANATOMY AND PHYSIOLOGY.—*President*, John Cleland, M.D., LL.D., F.R.S. *Vice-Presidents*, R. J. Anderson, M.D.; Henry Edward Clark, F.F.P.S.G. *Honorary Secretaries*, John Barlow, M.D., 27, Elmbank Crescent, Glasgow; Charles Barrett Lockwood, F.R.C.S., 19, Upper Berkeley Street, Portman Square, W.

G. PATHOLOGY.—*President*, Sir William Aitken, M.D., F.R.S. *Vice-Presidents*, Alexander Davidson, M.D.; Joseph Coats, M.D.; Charles Roy, M.D., F.R.S. *Honorary Secretaries*, G. Sims Woodhead, M.D., 6, Marchhall Crescent, Edinburgh; J. Lindsay Steven, M.D., 34, Berkeley Terrace, Glasgow.

H. OPHTHALMOLOGY.—*President*, Thomas Reid, M.D. *Vice-Presidents*, J. R. Wolfe, M.D.; C. E. Glascock, M.D. *Honorary Secretaries*, Henry Bendelack Hewetson, M.R.C.S., 11, Hanover Square, Leeds; A. Freeland Fergus, M.B., 41, Elmbank Street, Glasgow.

I. OTOLGY.—*President*, Thomas Barr, M.D. *Vice-Presidents*, John Astley Bloxam, F.R.C.S.; J. J. K. Duncanson, M.D. *Honorary Secretaries*, Johnstone Macfie, M.D., 23, Ashton Terrace, Glasgow; James Black, F.R.C.S., 16, Wimpole Street, London.

J. DISEASES OF CHILDREN.—*President*, Walter Butler Cheadle, M.D. *Vice-Presidents*, James Finlayson, M.D.; Henry Ashby, M.D. *Honorary Secretaries*, George S. Middleton, M.D., 23, Sandyford Place, Glasgow; W. Arbuthnot Lane, M.S., F.R.C.S., 14, St. Thomas's Street, S.E.

K. PHARMACOLOGY AND THERAPEUTICS.—*President*, James Morton, M.D. *Vice-Presidents*, John Dougall, M.D.; Theodore Cash, M.D., F.R.S. *Honorary Secretaries*, Alexander Napier, M.D., 3, Royal Terrace, Crosshill, Glasgow; Sidney Harris Cox Martin, M.D., 60, Gower Street, London, W.C.

L. LARYNGOLOGY AND RHINOLOGY.—*President*, Felix Semon, M.D. *Vice-Presidents*, George Hunter Mackenzie, M.D.; Peter McBride, M.D. *Honorary Secretaries*, D. Newman, M.D., 18, Woodside Place, Glasgow; A. E. Garrod, M.D., 9, Chandos Street, Cavendish Square.

Honorary Local Secretaries, John G. McKendrick, M.D., F.R.S., 45, Westbourne Gardens, Glasgow; James Christie, M.D., Hillhead, Glasgow; John Glaister, M.D., 4, Grafton Place, Glasgow.

PROGRAMME OF PROCEEDINGS.

TUESDAY, AUGUST 7TH, 1888.

- 9.30 A.M.—Meeting of 1887-1888 Council.
11.30 A.M.—First General Meeting. Report of Council. Reports of Committees. Service in the Cathedral.
8.30 P.M.—Adjourned General Meeting from 11.30 A.M. President's Address.

WEDNESDAY, AUGUST 8TH, 1888.

- 9.30 A.M.—Meeting of 1888-89 Council.
10.30 A.M. to 2 P.M.—Sectional Meetings.
3 P.M.—Second General Meeting. Address in Medicine by Thomas Clifford Allbutt, M.D., F.R.S.

THURSDAY, AUGUST 9TH, 1888.

- 9.30 A.M.—Address on his Recent Surgical Investigations by William Macewen, M.D.
11 A.M.—Meeting of Council.
10.30 A.M. to 2 P.M.—Sectional Meetings.
3 P.M.—Third General Meeting. Address in Surgery by Sir George H. B. Macleod, M.D.
7 P.M.—Public Dinner.
FRIDAY, AUGUST 10TH, 1888.
10.30 A.M. to 1.30 P.M.—Sectional Meetings.
3 P.M.—Concluding General Meeting. Address in Physiology by John G. McKendrick, M.D., F.R.S.
SATURDAY, AUGUST 11TH, 1888.
Excursions.

FRANCIS FOWKE, *General Secretary.*

SPECIAL CORRESPONDENCE.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

Disinfection of Tuberculous Sputa.—Transmission of Tuberculosis from the Human Subject to the Dog.—Experiments on Hereditary Alcoholism.—The Actual Caustery in the Treatment of Epilepsy.—Chloral in Diphtheria.

At the meeting of the Société de Médecine Publique et d'Hygiène Professionnelle, February 22nd, 1888, M. Grancher gave the results of researches made by himself and Dr. De Gennes, on the disinfection of tuberculous sputa. The air exhaled by tuberculous patients does not affect animals, therefore it does not contain bacilli. M. Grancher and Dr. De Gennes disinfected tuberculous sputa with carbolic acid at 5 per cent.; potassium, at 5 per cent.; sulphate of copper, at 5 per cent.; chloride of zinc, at 5 per cent.; corrosive sublimate, at 1 per cent. Guinea-pigs were submitted to injections of sputa thus disinfected. The results were not encouraging; the corrosive sublimate alone appeared to kill the tuberculous bacillus. It is difficult, however, and even dangerous, to use it at 1 per cent. Guinea-pigs were inoculated with sputa which had been mixed with hot water, and exposed to a temperature of 60°, 80°, and 100° C. It was discovered from these experiments that the bacilli resist water at 60°, are nearly always killed at 80°; and at 90° and 100° are always killed. M. Geneste and Herscher have constructed an apparatus to be placed near each hospital ward. M. Lailier asked if it would not be possible to have one apparatus only for each hospital, on account of the expense; and if the apparatus could not be heated by steam instead of gas. Dr. Ollivier remarked that M. Grancher's experiments proved the insufficiency of the ordinary means of disinfection, such as chloride of zinc. Meat should be always well cooked; and when prescribing it raw, the physician should ascertain that only non-tuberculous mutton was used. M. Grancher replied that raw meat was not dangerous. The experiments of M. Nocard prove that the bacillus of tuberculosis rarely exists in the flesh or juices of animals that die of this disease, unless there be tuberculous glands.

Dr. Bourgougnon publishes in the *Journal de Médecine*, March 18th, 1888, a case in which tuberculosis was transmitted from a human being to a dog. "The patient had suffered for some time from a slight, dry, exhausting cough, feverishness at night, and intermittent pains in the thorax. His father died of an affection of the heart, his mother of phthisis; two sisters died from tuberculosis, one at 19, the other at 27 years of age. The patient, when first examined, presented no symptoms of tuberculosis. After some months, however, cough and fever increased; the patient became breathless after going upstairs, lost flesh, and had nocturnal sweats. In the month of February, 1886, distinct crepitations and dulness were heard under the left clavicle. Finally, in October, 1886, he died with all the symptoms of pulmonary tuberculosis, the disease having lasted about fifteen months. On first visiting the patient I noticed a dog, whose extreme thinness attracted my attention. This dog barked at me whenever I entered the room, and I observed that after barking he was seized with a fit of coughing. The persistence of this symptom, together with the continual loss of flesh, awakened my curiosity and reminded me of the cases of contagion reported by Dr. Léon Petit. I advised the patient to have the dog sent to a veterinary surgeon. This was done, with the result that the animal was pronounced to be tuberculous. The dog became worse and worse, extremely thin, its hair rough, and as stiff as if it had been brushed backwards.

The owner would have had it killed, as its cough was distressing, the expectorations frequent, and the appetite quite lost, but I asked him to let the disease take its course, that the veterinary surgeon and I might make a *post-mortem* examination. Meanwhile I learned that the dog had been given to the patient's sister as a puppy, and during her illness had been literally brought up in her bed. After her death my patient had taken care of the dog, which had thus been brought up in contact with two tuberculous patients. The dog died in the last stage of phthisis in November, 1886. M. Plouchart, veterinary surgeon, of Tours, made the *post-mortem* examination in my presence. The lungs were riddled with tubercles; the left lung contained many patches of softening. The peritoneum was covered with miliary tubercles. The left kidney presented a great number of miliary tubercles; in the right we found four or five tuberculous nodules in process of softening. The stomach and intestines were healthy. It is evident that the disease was transmitted to the animal by my patient and his sister, tuberculosis being of very rare occurrence in dogs. The mode of transmission is not quite clear. The dog doubtless absorbed bacilli from swallowing the sputa or vomit of the patients, yet the healthy condition of the stomach and intestines would point to its having acquired the disease by the respiratory organs."

At the meeting of the Académie des Sciences on March 5th, MM. A. Mairet and Combemale related their observations on the degenerative hereditary influence of alcohol. Twelve puppies were born of a dog submitted to chronic intoxication with alcohol, and a young, healthy bitch with no defect. Two were stillborn, three died accidentally; the seven others succumbed to various diseases—epileptic attacks, verminous enteritis, pulmonary and peritoneal tuberculosis. At the necropsy lesions, evidently arising from alcoholic degeneration, were found: thickening of the bones of the skull, premature closing of fontanelles, adhesion of the dura mater to the cranial bones, difference in weight of the cerebral hemispheres, fatty degeneration of the liver. A strong, intelligent bitch, during the last three weeks of gestation, was intoxicated with absinthe, and gave birth to six puppies, of which three were stillborn; two were well developed physically, but were not at all intelligent; the third—a bitch X—grew slowly, presenting defective intelligence and a remarkable degree of anosmia. X, presenting symptoms of degeneration more especially of the nervous system, was coupled with a strong, intelligent dog. She gave birth to three puppies, one of which had flat foot, atrophy of several of the toes, wolf's mouth; a second died of marasmus; the third was attacked with atrophy of the hind legs. From the latter case it would appear that the degenerative influence of alcohol is greater in the second than in the first generation.

At the meeting of the Société Médicale des Hôpitaux, Msrch 23rd, 1888, M. Charles Féré called attention to an epileptic patient now under his care whom he had treated by applications of the actual cautery to the scalp. M. Féré has treated ten patients in his adult epileptic ward at Bicêtre. All the patients presented hemiplegia; some were affected with Jacksonian epilepsy, others with the common form. M. Féré applied the actual cautery every two or three days to the parts corresponding to the psychomotor zones of the brain, so as to prevent the possibility of suppuration. The attacks were remarkably diminished in frequency and violence in the cases thus treated.

Dr. Adolphe Mercier (of Besançon) has utilised the antiseptic properties of chloral in the treatment of diphtheria in children with excellent results. He proceeds in the following manner: when the tongue is thick, coated, and swollen, the child is given an emetic of ipecacuanha, without tartrate of antimony, which causes prostration. When vomiting has ceased, syrup of chloral, prepared according to the French codex (at 5 per cent.), is given every half-hour, in doses of two, three, or five grammes, according to the age of the patient. It is better to begin by giving the child rather large doses in order to keep him in a state of somnolence, as medicine is then more easily administered. The submaxillary and anterior regions of the neck are covered with a thick layer of belladonna ointment, and wrapped up in cotton-wool. In order to keep the throat impregnated, and prevent the chloral from causing pains in the stomach, the patient is given something to drink every time before, and not after, taking that remedy. As long as he continues taking chloral, to which M. Mercier regularly adds syrup of bark, the patient may eat and drink whatever he fancies—milk, wine, lemonade, or any solid food. This treatment must be rigorously carried out during forty-eight hours. No change ever takes place before twenty-four hours. In forty hours the false membranes begin to come away, and have com-

pletely disappeared by the forty-eighth hour. In the case of patients with fair hair and white skin, they may only come away on the third day. After the separation of the false membranes, the syrup of chloral causes smarting in the throat, and must then be stopped. In rare cases the loosening of the false membranes leaves the tonsils red or swollen. An astringent gargle will do away with any swelling of that kind. A thick coating of vaseline applied to the neck will get rid of any pustular eruption caused by the ointment. If during the illness any spasms or dyspnoea occur, the throat is painted with a 1 in 50 solution of hydrochlorate of cocaine. Prescribed in the last stages of the disease, when the voice is gone, and laryngeal diphtheria has set in, the chloral treatment would be rather injurious than otherwise.

VIENNA.

[FROM OUR OWN CORRESPONDENT.]

Complete Bilateral Symblepharon.—Excision of Indurated Tissue and Enlarged Glands in Syphilis.—Erythrophlein.

DOCTORS DR. S. CZERMAK brought before the Imperial Royal Society of Physicians a case of complete bilateral symblepharon in a young boy, who had had, two years before, an eruption of vesicles about the size of a bean, which, in part, contained a yellow and clear fluid, and, in part, a bloody liquid. The vesicles first appeared on the trunk, and later on also on the extremities; there were symptoms of fever at the same time, and the patient lost flesh considerably. After a year similar eruptions also came out on the face and eyelids. The latter were greatly swollen, and there was a purulent discharge. At present the eye-cleft was transformed into a shallow furrow, and no trace of the conjunctival sac was present; the upper eyelid was for the greatest part denuded of the eyelashes, and a longitudinal immovable tumour could be felt under it; the lower eyelid was normal in appearance. The mobility of the eyeball was much impaired owing to its adhesion to the conjunctiva. Similar conditions, though not so distinctly pronounced, were also present in the other eye. The perception of light was normal, but the projection uncertain. Numerous smooth and non-pigmented scars were, moreover, present on the face and the trunk. There was no doubt, Dr. Czermak remarked, that the symblepharon in this case was due to a "*syndesmitis degenerativa*" (Stellwag), or to an essential shrinking of the conjunctiva ("*essentielle Bindehautschrumpfung*"). According to recent observations, this affection was to be looked upon as a localisation of "*pemphigus vulgaris*" on the conjunctiva, which, in the opinion of Stephan, might also be seen here in an isolated condition. Taking into account the history of the patient, it was very probable that such causal relation was also present in the case under a consideration. No scars, indeed, were observed in pemphigus, which, so far, seemed to negative such a supposition; on the other hand, some vesicles had become covered with a croupous-diphtheritic layer. The occurrence of symblepharon was very rare, and only twenty-five cases of the kind had been recorded. The treatment was most unsatisfactory; attempts to induce shrinking of the conjunctiva by brushing it with nitrate of silver always failed; and the same was true of the instillation of olive oil into the eye.

Dr. Neumann showed a patient from whom he had a long time ago removed the primary hard sore, and the enlarged lymphatic glands, on the thirty-first day after syphilis had been contracted. A macular rash and desquamating papules nevertheless appeared over the lower part of the abdomen on the fifty-third day. The patient, who seemed to be quite cured after a long course of treatment, came again under the care of Professor Neumann, on April 16th of the present year, with the following syphilitic lesions; gummatous orchitis; syphilitic ulcers and gummata on the posterior wall of the pharynx and the soft palate, as well as periostitis of the tibia. This observation sufficiently proved in the opinion of the speaker, that extirpation of the primary indurated chancre and the lymphatic glands not only did not prevent the spread of the syphilitic affection, but that it did not even make the course of the disease milder.

Dr. Adolf Onodi gives, in the *Orvosi Hetilap*, a summary of his observations on twelve patients, and concludes that erythrophlein is undoubtedly a powerful anæsthetic, the effect of which comes on more slowly, but, on the other hand, lasts much longer, than that of the cocaine. Local anæsthesia persists for eight hours and even longer from the time of instillation. It has, nevertheless,

very disagreeable after-effects, such as headache, giddiness, sometimes even fainting fits; in particular it dims the cornea for several hours. When applied to the nose, the mouth, the soft palate, and the external orifice of the urethra, a 0.20 per cent. solution caused a slight sensation of burning. He did not venture to use stronger solutions.

BERLIN.

[FROM OUR OWN CORRESPONDENT.]

Dangers of Antiseptics.

At the last meeting of the Berliner Medicinische Gesellschaft, Dr. Emil Senger read a paper on the influence of antiseptic remedies on the organs of the body, with special reference to operations on the kidney. It is well known that after nephrectomy, or even nephrotomy, many patients die with symptoms of uræmia or anuria, even when it had been ascertained beforehand by careful examination that the other kidney was quite healthy and capable of secreting the necessary amount of urea. Dr. James Israël, chief surgeon of the Berlin Jewish Hospital, has propounded a very complicated theory as to certain nervous sympathies between the two kidneys, whereby an operation on one may give rise to degeneration of the other. Senger has now proved by experiments on rabbits and dogs that our antiseptic remedies are the cause of these complications. He injected into the animals, when in perfect health, one tenth or twelfth part of the quantity of corrosive sublimate, carbolic acid, etc., which is sufficient to kill them. He then extirpated one kidney, and examined it microscopically, with the result that in all cases he found glomerulo-nephritis. There was exudation between the glomerulus and the capsule, and the epithelium of the tubuli contorti was almost entirely destroyed. He found also fatty degeneration of the liver, the spleen, the heart-muscle, etc. The various antiseptic agents were found to be injurious in different degrees, corrosive sublimate being the most dangerous, then the others in the following order: iodoform, carbolic acid, salicylic acid, boric acid. Senger therefore recommends surgeons to avoid antiseptics in operations on the thorax and abdomen, and urges them either to employ sterilised water after the manner of your compatriot, Mr. Lawson Tait, or a solution of salt. By bacteriological and pathological researches he proved, first, that this kills the streptococcus pyogenes aureus in twenty-eight minutes, and that the effect is independent of the degree of concentration, for a 5 per cent. solution is just as effectual as a 20 per cent. Secondly, he claims to have shown that chlorate of sodium does not in any way injure the organs, and that no dose is strong enough to kill any animal.

SWITZERLAND.

[FROM OUR OWN CORRESPONDENT.]

Abdominal Massage in Habitual Constipation.

A VERY instructive lecture on the treatment of habitual constipation by abdominal massage was read at a meeting of the Medicinisch Pharmaceutischen Bezirksverein von Bern, by Dr. Bueler. The method (which, by the way, was employed in a rather primitive form by the celebrated Dr. Tissot, of Lausanne, in 1780) seems to find favour with the Bernese practitioners. Of 20 persons treated by Dr. Bueler after this plan, 18 were permanently cured; in one a relapse occurred in two months, and in another (a case of chronic gastro-intestinal catarrh, with dilatation of the stomach), the constipation still persists, though all digestive disturbances disappeared under the influence of a periodical evacuation of the stomach by means of manipulations in the epigastric region. Cure was effected in from four to six weeks, or after from twelve to twenty-five sittings (three sittings weekly). No unpleasant effects were ever observed, even when very energetic manipulations were performed on old people (of sixty-five, or thereabouts). Dr. Bueler lays stress on the fact that massage is not simply one therapeutic agent, but a combination of several factors powerful for good or evil, according to circumstances. The physiological effects of massage are said to be of the following four kinds: 1. The mechanical action, which is the most important of all, and which is not limited to the gastro-intestinal contents, but extends also to the large abdominal glands, removing obstruction of their ducts, etc. This has often been proved by the successful results of massage in cases of fecal accumulation, jaundice (depending on obstruction of the bile-duct), ileus, invagi-

nation, volvulus, etc. The most powerful mechanical effects are produced by kneading (*Kneten, pétrissage*), which loosens impacted fecal matters; and by stroking (*Streichung, effleurage*), which gives "a natural direction to the contents loosened" by the former manipulations. Sahli's massage by means of a cannon-ball (see JOURNAL, vol. i, 1887, p. 1171) is said to have only a mechanical effect. 2. The reflex effect of massage must be admitted, in view of the physiological fact that, on briefly touching the abdominal wall, a contraction of the intestinal muscular coat always follows. The effect is best produced by slapping (*Klatschung, tapotement*) with moderate force. Certain cases of habitual constipation can be cured solely by manipulations of this kind. This is well illustrated by Dr. Bueler's case of a student who had been suffering from constipation for five years, which resisted all treatment, and who was permanently cured after a course of eight weeks' duration, *tapotements* being repeated three times weekly. 3. The thermic action of massage is thought to be proved by Mosengeil's observations with Geissler's thermometer, the rise of the local temperature after a sitting varying from $\frac{1}{2}^{\circ}$ to 3° C., and lasting for three or four hours. To obtain the greatest thermic effect, "dry" manipulations (that is, without oiling the parts, or, still better, with a rubbing glove, or after covering the parts with a piece of flannel) are recommended. The therapeutic value of the thermic effects of massage is placed by the author side by side with that of the popular treatment of constipation by hot poultices, as well as with certain hydrotherapeutic methods. 4. The chemical action is more hypothetical. It is supposed that abdominal massage, while causing marked hyperæmia of the local integuments, *eo ipso* gives rise to an arterial anæmia, with venous hyperæmia of the peritoneum and relative accumulation of CO₂ in the intestinal circulation, leading to increased peristalsis. "The problem of the practitioner in every individual case of constipation before him," the author says, "is to find out which of the therapeutic elements of massage is most suitable and promising; whether the procedure must aim only at strengthening the tonicity of the abdominal muscles, or must act in a more mechanical way, or in a reflex or thermic manner." This question being settled, the procedure can be considerably simplified by omitting all unnecessary manipulations. The author condemns a routine practice of massage in all cases without discrimination, and insists on the strictest adaptation of the treatment to each particular case. Manipulations which lead to a rapid cure in one group of cases may be followed by injurious consequences in another. Thus, in cases of chronic constipation, caused mainly, if not solely, by extreme weakness and flabbiness of the abdominal walls (as in multiparæ, or in old men with pendulous bellies), such manipulations as forcible separation of the abdominal recti by inserting the tips of the thumbs and fingers deeply between the edges of these muscles along the linea alba are indicated. The muscles respond by sharp contractions, which are further intensified by strong transverse strokings in an outward direction from the middle line. At the same time the diaphragm should be strengthened by deep inspirations, etc. On the other hand, in cases of constipation depending upon atony of the intestine (as is often the case in persons of sedentary habits), Dr. Bueler begins the sitting with gentle, gradually intensified and deepened strokings, and finishes by moderately strong slappings. In cases of constipation caused by dyspepsia, and sometimes complicated with dilatation of the stomach, he limits his manipulations (strong strokings) to the gastric region. Two cases of the kind, which were treated in this way twice weekly, were permanently cured in four weeks. As some special experiments (by washing out the stomach, and the administration of salol combined with its subsequent detection in the patient's urine) have clearly proved, the epigastric rubbing empties the stomach under the manipulating hand. The author localises massage in a corresponding way also in cases of fecal accumulation in the cæcum and sigmoid flexure. In habitual constipation dependent on cerebral or spinal neurasthenia (in hypochondriacal or hysterical subjects), only such procedures as strong slappings with subsequent dry rubbings are indicated. In three of Dr. Bueler's patients hæmorrhoids (sometimes as big as half an egg) were present; in every case their size was greatly diminished after the very first sitting, the swelling disappearing completely and permanently in four weeks (earlier than the constipation). He adds: "I am so charmed with this observation that in future I will recommend to my hæmorrhoidal patients abdominal massage as the first thing to be tried."

May 19, 1888.]

The most disappointing results from the massage treatment seem to be obtained in cases of constipation depending upon adhesions left by previous attacks of general or local peritonitis. Dr. Bueler feels sure that "a large proportion of similar adhesions is due to the exaggerated fears of practitioners," who keep ice-bags on the belly or give opium too long. He thinks that it would be more rational to resort to a gentle *effleurage* as early as possible after the disappearance of acute symptoms in all cases of peritonitis. He adduces a case of acute perityphlitis in a lad aged 17, where from the thirteenth day of the disease (the ninth after defervescence) he daily made first gentle and then gradually intensified strokings in the ileo-cæcal region, and was highly gratified to see that the exudation, which was very considerable, melted away in about eight days, without leaving any trace.

MANCHESTER.

[FROM OUR OWN CORRESPONDENT.]

Owens College: Large Attendance of Students.—Chair of Surgery.

I STATED in my last letter that the attendance at the medical school of Owens College was likely to be large during the present summer. I understand that the attendance is very large—larger than in previous years. This is not to be wondered at, considering the fact that Owens College is in the centre of such an enormous population, and when it is known how thoroughly the laboratories of this school are equipped. It seems that the accommodation in the pathological and physiological laboratories is taxed to the uttermost, but the increased needs will speedily be met.

The Chair of Surgery is now declared vacant, and candidates are invited to apply for the office. It is said that there may possibly be some rearrangement of the duties of the professor, whereby the whole surgical department of the College shall in future be under the direction of the professor of surgery. We understand that Mr. Hardie, Mr. Jones, Mr. Southam, Mr. Collier, and perhaps other local surgeons, are likely to be candidates. As applications will be received until June 9th, it is possible that other candidates may be announced.

CORRESPONDENCE.

THE BIRTHPLACE OF CONSUMPTION.

SIR,—I always read your JOURNAL, and I get much good from the perusal. I was, however, surprised to see your editorial of February 25th, 1888, on the "Birthplace of Consumption." In that article you throw doubt on the validity of the law of soil moisture as one of the well-established laws of the disease, and that residence on a damp soil is one potent cause of it in England. You deem the researches made in two successive years by my friend Dr. Buchanan, and supported in the strongest manner by Mr. Simon, then medical officer of the Government, as of doubtful value as a proof of the existence of such a law. The statistics presented by these gentlemen, which I have always deemed most convincing, your editorial would throw aside as at least doubtful, if not worthless. In truth, in such a case, statistics, if not reliable, are worse than useless, because misleading. But, notwithstanding your commanding opinion, I do not give up my belief in the general accuracy of these English researches, because three years before they were announced I had found that in New England certainly the law holds good exactly as promulgated by Messrs. Simon and Buchanan. So assured have I been of its truth that I have acted upon it in my medical practice for the past quarter of a century. I always inquire about the residence of a patient as much as I do about the symptoms in every case. As a very important part of my treatment in a case of consumption I tell any patient who may be living on a damp soil or in a house having a damp cellar that removal from the house is absolutely necessary. I have found that removal from a damp valley to a dry hill within sight of the homestead has been of value as a remedial measure. Under these circumstances, you will, I think, admit that it is reasonable for me to doubt your conclusions, and that I should wish to lay before you for your candid opinion the facts I have gathered relating to the question.

I send by this mail an address delivered by me before the Massachusetts Medical Society at its annual meeting in 1862. In this

you will find data relative to the existence of this law in New England. The fact that here as a rule, as in the "Mother Country" (as we love to call "Old England"), residence on a damp soil is one cause of consumption, has made me desirous of persuading an International Congress to investigate the question in order to decide whether the law prevails generally over the globe. On three occasions I have tried to gain this by asking for a "World's Commission," consisting of one or more persons from every country represented in the Congress, whose duty it should be to get categorical answers if possible to the two following questions:

1. Is any part of your township (or any other definite division of the territory) more liable to have cases of consumption in it than are found in other parts of the same territory?

2. If so, what, if any, are the peculiarities of the spot, especially in regard to dampness of the soil, or its dryness?

Having been unable to be present at any of these International Congresses, the matter has not been mooted because the personal presence of the mover of such an investigation is required before the Congress will act.—I am, etc.,

Boston, U.S.A., April 24th.

HENRY J. BOWDITCH, M.D.

** Dr. Buchanan's conclusions in regard to the relation between soil moisture and phthisis were universally accepted until Dr. Kelly, the medical officer of health for East Sussex, proved them to be, in part at least, unreliable. Dr. Kelly found the order of precedence as to death-rate from phthisis of the districts examined by Dr. Buchanan during the period 1851-60 were materially altered when examined for the period 1861-70. He likewise points out that most of the impervious beds of subsoil are to the north of the South Downs, and that consumption seems most common in places which are bleak and exposed as well as damp. And in general he insists on the fact that in West Sussex (and, indeed, throughout England and Wales) there has been of late years a great decrease in the mortality from consumption. As there has been no change whatever in the drainage, this certainly throws a doubt on the validity of Dr. Buchanan's earlier inquiry as to the effects of sanitary improvements. Dr. Kelly is inclined to attribute it mainly to the progress which has taken place in the social state of the rural population (Fagge's *Medicine*, 1, 993).

THE ELECTRICAL TREATMENT OF DISEASES OF THE UTERUS.

SIR,—The discussion at the meeting of the Brighton and Sussex Medico-Chirurgical Society has not helped us much, for there is nothing new in the paper, and old stories are retold in the discussion. But in Dr. Steavenson's paper we have a complete corroboration of all that was known, and a pretty exact statement of what may be expected from this line of treatment.

I would like to repeat what I have already stated on this subject before: that it is only from an accomplished electrician like Dr. Steavenson that we are likely to get at the true facts of this most involved question. Dr. Playfair says that the "manipulation of the apparatus, so far as the electricity was concerned, offered no difficulty at all; any intelligent student could learn it in half an hour." And this kind of view, it seems to me, is the cause of the dreadful stories we hear about it. I have gone carefully into the question, and I am satisfied that only skilled electricians should attempt it. Further, let me say that Dr. Steavenson's results are stated from the openly displayed experience of a public institution, the work of a responsible officer carried out under the observation of skilled critics, and therefore to be regarded as having an importance altogether different from the utterances of anyone else who has yet spoken on the subject.

Concerning the discussion at Brighton, perhaps you will permit me briefly to allude to the strange remark by Dr. Aveling that "it was quite amusing to observe the flutter of excitement which the recent advancement of electrical treatment had caused among some distinguished abdominal sectionists. From their uncomely promising opposition and their abuse and ridicule, one was almost inclined to think these gentlemen feared their occupation was gone." I am not aware that any opposition, or abuse, or ridicule, has been directed towards the advancement of electrical treatment save in one direction, and that was Dr. Aveling's own proposal to apply it for the arrest of hemorrhage in cases of ruptured tubal pregnancy. I was guilty of saying that in such cases it would be of as much use as a pinch of snuff, and I am still of that opinion. On the other questions I am waiting for trustworthy evidence, like that of Dr. Steavenson.—I am, etc.,

LAWSON TAIT.

7, The Crescent, Birmingham, May 12th.

SIR.—I do not think it right that the case described as hydrosalpinx by Dr. Apostoli in the JOURNAL of May 12th should be received without criticism. At the same time I do not wish to be considered as an opponent of Dr. Apostoli, or of the line of treatment associated with his name.

It has occurred probably to most of your readers that the clinical course of events in this case would have been different under more favourable circumstances. Apart from an exact diagnosis, about which there are likely to be different opinions, the symptoms and physical signs point to an acute attack of inflammation in the neighbourhood of the uterus, and not only an acute attack, but to an attack accompanied by a large fluid effusion, for it may be taken for granted that the presence of evident fluctuation in a febrile inflammatory exudation is, if the bladder be empty, certain evidence of a large effusion either of serum or pus. It appears that the patient under these circumstances was not confined to bed, and was brought with difficulty to the clinic, and each time worse. What does the new method consist of? Practically nothing but a puncture into the walls of the sac by a fine needle, followed by the passage of a current of 100 to 150 milliamperes. Naturally this was at last followed by evacuation of the fluid. Many of us will probably feel that the simple treatment of absolute rest in bed and, if this was not alone sufficient, a direct puncture of the sac would have been at least equally efficacious.

We now turn to the diagnosis, and I would venture to say that whatever the condition of the tube may have been, the disease was retro-uterine perimetritis, with a large serous effusion. The clinical history and physical signs were almost typical, and without discussing them in detail, I may say without fear of contradiction that we have yet to learn that hydrosalpinx under any conditions ever gives rise to such symptoms and such physical signs. I will only mention the fixation of the uterus to the sacrum and the alteration of position of the punctures during convalescence as offering the strongest confirmation of the diagnosis of perimetritis.

Dr. Apostoli appears to have made his diagnosis on the character of the fluid evacuated only, having previously thought it a "peri-uterine phlegmon."

The gross pathological anatomy and clinical history of inflammation of the tubes and ovaries have yet to be studied and described, and until this is much further advanced than at present we must accept many statements about them with caution.—I am, etc.

WALTER S. A. GRIFFITH.

114, Harley Street, W.

THE ALLEGED SUBVENTIONS TO GERMAN NEWSPAPERS.

SIR,—I shall be much obliged by your allowing me to contradict a calumny directed against the *Cologne Gazette* by "An Occasional Correspondent" from Berlin in your last issue (No. 1428). After attempting to give an explanation of the so-called "Reptile Fund," he goes on to say that certain papers, which are commonly supposed to receive subventions (among them the *Kölnische Zeitung*) have come to be known among opposition journalists as the Reptilia.

Though all and each of these journals, as every German not blinded by partisanship well knows, are above the faintest suspicion of accepting bribes, I, as the editor of the *Cologne Gazette* (*Kölnische Zeitung*) may content myself with vindicating my own paper from such an imputation. It is quite as wrong and, I may add, quite as ridiculous to tax the *Cologne Gazette* with receiving a shadow of subvention from any quarter, or even to question its independence, as it would be to impugn the integrity of the *Times* or the *BRITISH MEDICAL JOURNAL*.—I am, etc.,

Cologne, May 15th.

DR. AUGUSTUS SCHMITS.

ANALYSIS IN AUSCULTATION.

SIR,—Under the above heading Dr. Mortimer Granville draws attention, in the JOURNAL of April 28th, p. 901, to the advantage of a cross-piece connecting the elastic tubes of the binaural stethoscope.

Two years ago I exhibited before the Clinical Society of London a stethoscope of the same pattern which had been constructed for me by Messrs. Matthews, and which I have had in daily use since. Inasmuch as this arrangement enables the auscultator to compare different parts of the chest in rapid succession with both ears by alternately closing one of the chest pieces, the term "comparing stethoscope" seems more appropriate than any other. I find, however, that my idea was forestalled in 1881 by Dr. Constantin Paul, who in the beginning of that year exhibited several

stethoscopes of various designs before the Académie de Médecine in Paris; and that Dr. Spencer's stethoscope, although constructed differently, fulfils the same purpose.—I am, etc.,

WILLIAM EWART.

33, Curzon Street, Mayfair, W., May 9th.

HAILEYBURY COLLEGE WELL.

SIR,—I wish to take the earliest opportunity of correcting a mis-statement made in my letter to you, published on May 5th. Some time previously I had asked a gentleman who has known the Haileybury well and its surroundings most intimately for the last thirty years to furnish me with particulars as to its relation to the River Lea and the Lea Valley. In the reply embodying his conclusions the words "above" and "below" were unfortunately (and unconsciously) transposed; and, in the haste necessary to ensure the early publication of my letter to you, I was unable to personally verify the statement in question. I would now, therefore, frankly retract my published statement on this point. The bottom of the College well is indeed some sixty feet below the Lea, as appears on the reduced sketch-plan enclosed herewith. It would probably be difficult absolutely to disprove "lateral percolation" from the river to the well; but it is significant that they are a mile and a half (in strict accuracy 1 mile 833 yards) apart.—I am, etc.,

CHARLES EDWARD SHELLY.

Hertford, May 14th.

THE TREATMENT OF PHTHISIS BY RESIDENCE AT HIGH ALTITUDES.

SIR.—In your account of the discussion of the paper on "The Results of the Treatment of Phtthisis by Residence at High Altitudes," read at the Royal Medical and Chirurgical Society on May 8th, I notice some errors which have inadvertently crept into the report of my reply, which I should like to correct.

In answer to Dr. Hermann Weber's allusion to Dr. Dettweiler's treatment, I mentioned "Falkenstein," not "Frankenstein," as the place where it is practised; and in defence of my theory of lung hypertrophy at high altitudes, due to rarefaction of the atmosphere, I cited the increase of "resonance," not "nausea," as reported—"the increase of chest capacity and of breathing power, as measured by the spirometer." Dr. Quain's remark as to the absence of mention of constitutional symptoms was made in error, as these were included under the heading of "history and nature of cases;" and I may add that the paper included some typical cases, which it would have taken too long to read at the meeting.

Dr. Quain and your leader both very rightly allude to the unfriendly and, I may add, ungrateful attitude of the Swiss authorities in refusing reciprocity to English practitioners, even when resident for many years in the country. The result will be that English physicians will not unnaturally hesitate to send patients where they are deprived of the services of their own countrymen, and will be induced to look to other high altitude stations, such as those of Colorado and New Mexico, which have been proved to be equally efficacious, where comfortable hotels abound, and where English medical men receive a warm welcome from our sensible and large-hearted transatlantic cousins.—I am, etc.,

Upper Brook Street, May 15th.

C. THEODORE WILLIAMS.

THE APOTHECARIES' HALL, AND THE TITLE OF ITS NEW LICENCE.

SIR,—The licence of the Apothecaries' Hall now being a full qualification, it is only reasonable to ask that we who hold its new licence should be entitled to some letters of distinction, whereby the public may know we are authorised to practise both medicine and surgery. Otherwise we shall always be at a very great disadvantage with practitioners who are granted separate medical and surgical diplomas issued by other conjoint examining bodies. The Hall licence is now granted under exactly the same rules and regulations as the diplomas and licences of other examining boards, therefore it would be a great injustice if we were not granted a fuller title, and I am sure our Medical Council never intended such an injustice to a large section of the profession. I hope the matter may be taken up at once, and the Medical Council induced to decide the question at their meeting next week. I would suggest the title (which not a few have already adopted), namely, L.M. and L.S.Lond., Licentiate of Medicine and Licentiate of Surgery, London. Remember the licence is no longer

May 19, 1888.]

licence of an apothecary simply, but a licence to practise medicine, surgery, and midwifery.—I am, etc.,
L.M. and L.S.Lond.

TEA AND TEETH.

SIR,—From your recent correspondence on this subject, it appears certain that tea has an injurious effect upon the teeth. It acts probably in more than one way. First, tea is undoubtedly the most potent cause of dyspepsia; and this, by increasing the acidity of the saliva, would tend to promote caries. Secondly, here is the ill effect of drinking a very hot liquid. And, thirdly, and I believe chiefly, there is the astringent effect of tannin upon the gums, lasting through their recession to exposure, and consequent decay of the fangs. It would be interesting to hear from Dr. Ffenning, who remarks that "the decay begins in or near the fangs," whether this is preceded by recession of the gums. Tea gives an almost neutral reaction to litmus, so that direct acidity cannot be laid to its charge.—I am, etc.,
RALPH W. LEFTWICH, M.D.
London, May 12th.

MR. GEORGE HASTINGS AND THE COMPULSORY NOTIFICATION OF INFECTIOUS DISEASE.

SIR,—At a meeting of the Greenock Medical Society held on May 9th, the following statement made by Mr. George Hastings, Chairman of the Select Committee of the House of Commons, as reported in the JOURNAL of May 5th, page 989, was considered:

"There is one great town in Great Britain which did adopt that very provision, which is the town of Greenock, where they imposed notification only on the householders, and I have the authority of the medical officer of health of that town for saying that the system of notifying by the householder proved a complete failure."

It was resolved that Mr. George Hastings be asked from what printed record he obtained such definite information, giving the date of such record; as the members present were led to believe on good authority that the medical officer of health now considered the compulsory notification being placed on the householders alone acted satisfactorily.—We are, etc.,

J. ROBERT BLACK, M.D., President.
JAMES PATON, M.D., Secretary.

Greenock.

NAVAL AND MILITARY MEDICAL SERVICES.

THE CHAIR OF HYGIENE AT NETLEY.

WE believe it is more than probable that Deputy Surgeon-General J. A. Marston, C.B., will take up the duties of the late Professor de Chaumont at Netley. He temporarily filled the chair during Dr. de Chaumont's illness last summer. It is said Dr. Marston will not retire, but will probably be seconded. It was a grievance of the late lamented Dr. de Chaumont's that retirement as Surgeon-Major was forced on him, to his detriment, when he became Professor.

THE NAVY ESTIMATES.

At the meeting of the Select Committee of the House of Commons appointed to consider the Navy Estimates, Mr. Campbell-Bannerman in the chair, Dr. Dick, Director-General of the Medical Department, gave evidence. He said he considered it would be desirable that naval medical officers on returning from abroad should have the opportunity of attending medical hospitals, to make themselves acquainted with the progress of science. He would recommend a system of one year's service at home. He thought an officer might remain at sea three years without opportunities of improving his knowledge. The number of sick daily in the navy averaged about 46 per 1,000. On board a man-of-war, such as the *Achilles*, with 700 men, the number of men sick daily would average about thirty-five, and there would be three medical officers. The removal of naval medical officers from Netley to Haslar was partly from economy and partly to prevent dissatisfaction among the officers. At Netley Hospital they became imbued with military ideas, which were not desirable. They had an excellent mess and were surrounded by military officers, and lived in an entirely different state of circumstances to naval officers. After being there six months they were drafted off, and then they found that the ideas they had formed at Netley were entirely delusive as regards the Naval Medical Service. They found they had

small cabin, and none of the military surroundings which they had at Netley, and he thought a good many surgeons left the service in consequence. They saved £2,500 a year, which was paid to probationers and professors at Netley. The proportion of cases in the hospitals at home suffering from certain diseases was about a third since the abolition of the Contagious Diseases Acts. Abroad the proportion was much smaller. A scheme for recruiting the Naval Medical Service on an emergency had been arranged and was ready to be put in force. They would be recruited from the civil profession. Efficient retired naval medical officers would be called upon to serve upon an emergency. They could be called out up to 55 years of age. At present the leave granted was fourteen days after a year on board. He should be glad to see the leave increased for all officers. Since the order of 1881 three staff-surgeons and six surgeons had retired voluntarily. Only three accepted the gratuity of £1,000 to which they were entitled in lieu of pension. Six inspector-generals, three deputy inspector-generals, and forty-three fleet-officers retired. The amount of the pensions depended on the length of service, and was from 6s. to 8s. a day. The Contagious Diseases Acts were suspended in 1883, and repealed in 1886. In 1870 the number of cases was 642; in 1871, 619; from 1872 to 1879 it varied from 738 to 887; in 1880 it was 994; in 1881, 1,124; in 1882, 1,169; in 1883, 1,943; in 1884, after the suspension of the Acts, 2,153; in 1885, 2,246; in 1886, 2,197; and in 1887 it had risen to 2,636. The cost of medical treatment for the men was about £5 11s. per head, and for feeding them it cost £18 9s. From that it would seem that medical treatment was as high as a third of their maintenance, but it included also provisions, stores, and other things. He agreed that about £3 per head was due to salaries, pensions, and allowances. They were allowed a staff of 416 medical men, and they had actually 397. The total cost of the medical service, including both effective and non-effective officers, was £209,093. Officers were entitled to retire after eight years' service. He thought that the fact of a door being open for retirement attracted men to the service, but when they got in they found themselves so comfortable that they did not wish to leave. Looking at the danger of accidents occurring in the dockyard, he did not see his way to trust to calling in civil practitioners there. They should not be left without medical assistance during the working hours. The general condition of the health of the navy was quite satisfactory, and in recent years had improved in a marked degree, apart from disease of a certain character.

VOLUNTEER MEDICAL STAFF CORPS.

THE distribution of prizes by the Duchess of Albany to the London Division of the Volunteer Medical Staff Corps took place at the Guildhall on May 12th, when the Lord Mayor, who presided, was accompanied by the Lady Mayoress and the Sheriffs of London and Middlesex. Among those present were Mr. E. Stanhope, M.P., Sir Guyer Hunter, M.P., Sir Thomas Crawford (Director-General), Sir Joseph Fayrer, etc. Surgeon-Commandant Norton having stated that what was commonly known as the Volunteer Ambulance Corps bore exactly the same relation to the volunteer force as the Medical Staff Corps bore to the regular army, spoke of the services which the corps had been enabled to render on public occasions. On Jubilee Day, for example, millions of persons were collected together, and no fewer than 500 cases were dealt with by the corps. The total strength of the corps was 403, with 371 efficient, earning a capitation grant of £763 10s. A new company was about to be formed, which would strengthen the corps by about 100 men. He hoped for the establishment of a great medical reserve, such as had recently been created in Germany, every member of which would be ready to do duty of any sort upon the arising of any national emergency.

THERE was a pleasant dinner at the Holborn Restaurant on Saturday, May 12th, of the officers of the Volunteer Medical Staff Corps. Surgeon-General Sir Guyer Hunter, M.P., Hon. Commandant, was in the chair. Among the guests were Mr. E. Stanhope, M.P., Secretary for War, who responded in an interesting speech to the toast of the "Army, Navy, and Reserve Forces;" Sir Andrew Clark, Bart., President of the Royal College of Physicians; Director-General Sir T. Crawford, and Director-General James Dick, R.N., Colonel Duncan, M.P., and many other distinguished members of the civil, military, and naval branches of the medical profession. The Volunteer Medical Staff Corps are to be con-

gratulated on the interest shown by those in authority in the excellent work they are doing.

CHANGES OF STATION.

The following changes of station among the officers of the Medical Staff of the Army have been officially notified as having taken place during the past month:—

	From	To
Deputy Surg.-Gen. G. M. Slaughter	Chatham	London.
" " T. Rudd, M.D.	Malta	Egypt.
Brigade-Surgeon J. J. Chappell, M.D.	Cork	Curragh.
Surgeon-Major A. Morphee	Bengal	Woolwich.
" " T. M. O'Brien	Devonport	Exeter.
" " J. Wilson	Bengal	Aldershot.
" " J. Fleming, M.D.	Hong Kong	Mauritius.
" " W. E. Riordan	Egypt	Sheerness.
" " J. Macartney, M.D.	Dublin	Curragh.
" " J. A. Campbell	Shorncliffe	Canterbury.
" " H. W. Joynt	Canterbury	Shorncliffe.
" " O. F. Molloy	Bengal	Aldershot.
" " P. A. Hayes	Portsmouth	Netley.
Surgeon J. G. MacNeece	Dublin	Belfast.
" " F. R. Barker, M.B.	Portsmouth	Weymouth.
" " J. G. S. Lewis	Dublin	Cork.
" " H. Martin, M.B.	Dover	Shorncliffe.
" " E. F. Smith	Dublin	Limerick.
" " W. D. A. Cowan	"	Belfast.
" " S. J. Flood	"	"
" " G. W. Robinson	"	Cork.
" " R. D. Donaldson, M.D.	Cork	Dublin.
" " G. T. Goggin	Bengal	Shoeburyness.
" " G. H. K. M.D. O'Callaghan	Devonport	Horfield.
" " J. G. W. Crofts	Lancaster	Fleetwood.
" " F. P. Nichols, M.B.	Bengal	York.
" " R. Fowler	"	Woolwich.
" " C. Birt	Bermuda	York.
" " H. L. G. Chevers	Aldershot	Dunbar.
" " H. M. Ramsay	Malta	Scots Guards.
" " W. N. Murphy, M.D.	Cork	Queenstown.
" " C. W. Keilly	York	Camraron.
" " H. S. Peeke	"	Hereford.
" " R. Crofts	Cape Coast Castle	Sierra Leone.

THE NAVY.

DEPUTY INSPECTOR-GENERAL D. M. SHAW, C.B., has been promoted to be Inspector-General. He entered the service as Surgeon, September 1st, 1854; became Staff-Surgeon, May 5th, 1862; Fleet-Surgeon, October 13th, 1876; and Deputy Inspector-General, February 16th, 1883. He served with the Naval Brigade at Eupatoria, in the Crimea, in the winter of 1854-55, and subsequently before Sebastopol in the *Spithead*, in which ship he was also present at the bombardment and capture of Kinburn (Crimean and Turkish medals, Sebastopol clasp); served with Royal Marines in China from 1857 to 1860; was present at the captures of Canton, Taku forts, and Pekin, also at "The Peiho Disaster," and actions of Sinho, Tongku, Chanchiawan, and Palikao (mentioned in despatches and specially promoted), medal with three clasps; was senior medical officer of the *Octavia*, flagship, during the Abyssinian war in 1868 (medal), and of the *Alexandra*, flagship, at the bombardment of the forts of Alexandria, 1882 (C.B., medal with clasp, and Khedive's Star).

Staff-Surgeon J. K. CONWAY, M.D., has been promoted to be Staff-Surgeon. His commission as Surgeon dates from March 7th, 1863, and as Fleet-Surgeon, December 25th, 1879.

The following appointments have been made at the Admiralty: JOHN FISHER, Inspector of Hospitals, to Plymouth Hospital; A. B. MESSER, M.D., Deputy-Inspector of Hospitals, to Malta Hospital; JOHN MACRIE, Staff-Surgeon, to the *Monarch*; G. D. TWIGG, Surgeon, to the *Impregnable*; E. A. SPILLER, M.D., Surgeon, to the *Triton*; H. F. NORRUBY, Deputy Inspector-General, to Plymouth Hospital; T. H. KNOTT, Fleet-Surgeon, and A. W. MAY, Surgeon, to the *Oriando*.

THE MEDICAL STAFF.

SURGEON-MAJOR A. B. R. MYERS, Scots Guards, is promoted to be Brigade-Surgeon, vice G. Perry, Coldstream Guards, who has been placed on retired pay. He entered the service as Assistant-Surgeon, September 26th, 1859; became Surgeon, March 1st, 1873; and Surgeon-Major, March 14th, 1883. He served in the campaign in the Soudan in 1885 with the 2nd Battalion of the Scots Guards, and received the medal with clasp and the Egyptian bronze star for the campaign.

Surgeon E. H. FENN, from the Grenadier Guards, is promoted to be Surgeon-Major Coldstream Guards, in succession to Brigade-Surgeon G. Perry. Surgeon-Major Fenn's commission as Surgeon dates from September 30th, 1875. He served in the Afghan war in 1879-80 in medical charge of a battery of Royal Artillery, and was present at the affair at Zaidabad; accompanied Sir Frederick Roberts in the march to Candahar, and was at the battle of Candahar (mentioned in despatches, medal with clasp, and bronze decoration). He was also engaged in the Soudan campaign in 1885 with the 3rd Battalion of the Grenadier Guards, and was present in the engagement at Hasheen and at the destruction of Tamai (medal with clasp and Khedive's star).

Surgeon-Major WILLIAM NASH, M.D., is promoted to be Brigade-Surgeon (ranking as Lieutenant-Colonel), vice W. J. Wilson, M.D., who has retired. His previous commissions are dated: Assistant-Surgeon, April 14th, 1863; Surgeon, March 1st, 1873; and Surgeon-Major, April 23th, 1876. He was in the Afghan war of 1878-80 (medal), and in the Egyptian war in 1882 (medal and Egyptian bronze star).

Surgeon-Major WILLIAM CREYK, M.B., is granted retired pay. His commissions bore date: Assistant-Surgeon, April 14th, 1863; Surgeon, March 1st, 1873; and Surgeon-Major, April 23th, 1876. He served in the war in Afghanistan in 1879-80, and received the medal for that campaign.

Surgeon JOHN MULRENNAN, M.D., who went on half-pay May 14th, 1885, is now granted retired pay.

Brigade-Surgeon J. DAVIS, who is serving in Bengal, is appointed to officiate on the administrative medical staff of the army, with the temporary rank of Deputy Surgeon-General, vice Deputy Surgeon-General E. H. Roberts, on sio leave.

Brigade-Surgeon T. H. WHITE, M.D., serving in Bengal, has leave of absence for six months on private affairs.

Surgeon J. FAYRE, M.B., serving in Bengal, is appointed to the civil medical charge of the Muttra district in addition to his military duties.

ARMY MEDICAL RESERVE.

SURGEON and Honorary Surgeon-Major H. W. KJALLMARK, Buckinghamshire (Royal Bucks) Yeomanry Cavalry, to be Surgeon-Major (ranking as Lieutenant Colonel).

The undermentioned officers to be Surgeons-Major (ranking as Majors) Surgeon and Honorary Surgeon-Major J. P. PURVIS, 2nd Volunteer Battalion the Queen's Own Royal West Kent Regiment (late the 3rd Kent); Honorary Surgeon-Major J. P. WADY, 3rd Battalion the Royal Irish Regiment (Wexford Militia); Surgeon T. M. DOLAN, M.D., F.R.C.S.E., 1st Volunteer Battalion the Duke of Wellington's West Riding Regiment (late the 4th West Riding); Surgeon H. F. HOLLAND, M.D., 3rd Volunteer Battalion the Bedfordshire Regiment (late the 1st Bedfordshire).

The undermentioned officers to be Surgeons (ranking as Captains): Surgeon F. F. MOORE, 3rd Volunteer Battalion the King's Liverpool Regiment (late the 13th Lancashire); Surgeon W. J. READY, 2nd Volunteer Battalion the South Wales Borderers (late the 1st Monmouth); Surgeon E. W. SYMES, M.D., 2nd West York (the Prince of Wales's Own) Yeomanry Cavalry; Acting Surgeon D. C. BLACK, M.D., 5th Volunteer Battalion the Highland Light Infantry (late the 10th Lanark); Acting Surgeon C. E. DOUGLAS, M.B., 6th Volunteer Battalion the Royal Highlanders (late the 1st Fife); Acting Surgeon G. W. MURPHY, M.B., 3rd Volunteer Battalion the Bedfordshire Regiment (late the 1st Bedfordshire).

THE INDIAN MEDICAL SERVICE.

The services* of the undermentioned officers of the Bengal Establishment, are temporarily placed at the disposal of the Government of the North-Western Provinces and Oudh:—Surgeon-Major G. GRIFFITH, Medical Officer 18th Bengal Lancers; Surgeon C. C. VAID, Medical Officer 11th Bengal Infantry; Surgeon-Major W. A. C. ROE, Civil Surgeon, Rawal Pindi, to officiate as sanitary commissioner of the Punjab during the absence, on furlough, of Surgeon-Major A. Stephen, M.B.

Brigade-Surgeon A. GARDEN, M.B., Bengal Establishment, has retired from the service, which he entered as Assistant-Surgeon, March 28th, 1855, attaining to the rank of Brigade-Surgeon on November 27th, 1879. He has no war record.

Surgeon-Major A. STEPHEN, M.B., Bengal Establishment, Sanitary Commissioner, Punjab, has leave of absence for one year on private affairs.

Surgeon H. HERBERT, Bombay Establishment, on general duty in the Mhow Division, is directed to officiate in medical charge of the 7th Native Infantry, during the absence of Surgeon H. P. Jervis.

It is reported from Poona, in the Bombay Presidency, that Surgeon-Major J. PRENDERGAST and a Lieutenant of Royal Artillery, were drowned there on April 20th, from the capsizing of their boat. Surgeon-Major Prendergast's commission as Surgeon was dated March 31st, 1874, and as Surgeon twelve years after. He was attached to the 2nd Battalion Royal Irish Fusiliers during the Egyptian war in 1882, and was present at the battle of Tel-el-Kebir (medal with clasp, and Egyptian bronze star). He was also with the expedition to the Soudan under Sir Gerald Graham in 1884, and was at the engagements of El Teb and Tamai, where he was severely wounded; he was mentioned in despatches, and received two clasps for this campaign.

Surgeon-Major ANDREW BARRY, M.D., Bombay Establishment, is promoted to be Brigade-Surgeon. He entered the service as Assistant-Surgeon, March 31st, 1865; was engaged in the war in Abyssinia in 1867-68 (medal), and in the Afghan war in 1880, when he took part in the march to the relief of Candahar with the force under Major-General Phayre (medal).

THE VOLUNTEERS.

ACTING-SURGEON G. BOLTON, 1st (late 5th) Durham Artillery, is promoted to be Surgeon.

Surgeon J. JOHNSTONE, 2nd Lancashire Artillery, is granted the honorary rank of Surgeon-Major.

Mr. F. D. S. M'MAHON is appointed Acting-Surgeon to the 2nd Volunteer Battalion Duke of Cornwall's Light Infantry (late the 2nd Cornwall).

Mr. W. J. PICKUP is appointed Acting-Surgeon to the 2nd Volunteer Battalion Royal Warwickshire Regiment (late the 2nd Warwickshire).

THE QUALIFICATIONS OF A VOLUNTEER MEDICAL OFFICER.

FRED. W. GIBSON, L.S.A.Lond., L.R.C.P. and S.Ed., Acting-Surgeon 1st Durham Volunteer Engineers, writes, in reply to "Medicus": I held the post of Acting-Surgeon to the 5th Volunteer Battalion, the Durham Light Infantry, on the L.S.A.Lond. I found no difficulty in obtaining the appointment, on after I was gazetted. In fact, at our northern reviews I always had a good post.

I cannot see any reason why an L.S.A.Lond. should not receive such an appointment, and I doubt whether any notice would be taken of any L.S.A. applying to-day, unless accompanied by a petition from some poor, jealous practitioner.

THE MEDICAL STAFF IN INDIA.

A "RETIRED MEDICAL OFFICER" sends us the following account of an inquiry which he made into medical politics during a recent visit to India.

1. A feeling of dissatisfaction and discontent pervades all ranks at the delay in definitely settling the question of the status of medical officers.
2. There is no little despondency over the threatened addition of a year to the tour of service.
3. The paucity in numbers of medical officers makes it very difficult to obtain leave of absence.
4. The youth and frequent changing of medical officers in charge of regiments is the subject of grave complaint by military officers at large. Out of a total of 200 officers of the Medical Staff in Bengal, there are only 55 senior officers; while of 140 surgeons, 100 draw the lowest rates of pay. The object in

May 19, 1888.]

employing this very large proportion of junior and less experienced officers is simply to save the Government money.

5. Medical officers cannot properly discharge their duties without horses, but they get no forage allowance.

6. Except at Rawul Pindi there are no medical messes, and as medical officers are nowadays very often not made honorary members of regimental messes, the mode of living by many is very unsatisfactory.

7. No charge pay is given to brigade-surgeons or others for greatly increased responsibilities and work in charge of large hospitals. This is a breach of faith, as it was one of the promises made when unification and station hospitals were introduced.

8. Medical officers are moved about often very unnecessarily, and at great expense to themselves.

9. Exchanges are not allowed after the reliefs are published in July until next trooping season, no matter how urgent may be the officer's private affairs at home.

10. It is very difficult for a junior surgeon to live on his pay; he receives 317 rupees a month, though ranking as captain, while veterinary surgeons receive 400 rupees, staff corps lieutenants in infantry 325, and cavalry 365 rupees per month respectively.

Our correspondent vouches for the above plain statement of facts.

MEDICO-LEGAL AND MEDICO-ETHICAL.

TOD-HEATLEY AND ELLIOTT AND FRY v. BENHAM.

THIS was an action brought by the owner in fee of No. 6, Gloucester Terrace, Old Brompton Road, now being used as the Queen's Jubilee Hospital, and the lessees and occupiers of Nos. 7 and 8, Gloucester Terrace, to restrain the defendant, Mr. R. Fitzroy Benham, M.R.C.S., the sub-lessee of the hospital premises, from using the place as a hospital for the treatment of certain diseases.

The case for the plaintiff was that the business of the hospital came within the scope of the prohibition in the lease, which forbade the carrying on of any noisome, obnoxious, or offensive trade; that persons suffering from unpleasant complaints visited the hospital; that in a high-class neighbourhood there was no need for such an institution; and that the poor who visited it came from a distance, as there were none in the neighbourhood.

Mr. Justice Kekewich delivered judgment in favour of the plaintiffs without calling on their counsel to reply. The question was one of the construction of the covenants in the lease. In *Bramwell v. Lacy*, the covenant was almost in the same language as in the present instance, and, in subject, was indistinguishable. The late Master of the Rolls in that case granted an injunction, one of the grounds for the decision being that the hospital was a business; and he went further, for he stated his own view in very plain terms when he said: "It is well known that there are some throat diseases which are contagious; and, moreover, it is very possible that a patient on his first visit to the hospital might be found to be suffering from some disease of an infectious or contagious nature, and not from an ordinary throat or chest disease;" and he accordingly held that, on the evidence it was conclusive that persons in the neighbourhood had suffered annoyance, and that the possible danger from infection was a matter of which they had a right to complain. The evidence on these heads was quite as strong in this case, which was a case on a very similar covenant, as the evidence in *Bramwell v. Lacy*. Following that case, therefore, his Lordship granted an injunction to restrain the defendant, his servants, agents, and workmen from using, or causing, or suffering No. 6, Gloucester Terrace, to be used as a hospital and surgical appliance department for the treatment of diseases of the throat, nose, and ear, skin, eye, fistula, and other diseases of the rectum, and various deformities of the human frame. The defendant must pay the costs of the action, but, under the circumstances, the injunction would not operate for six months.

ETIQUETTE OF SUBSTITUTES.

ETHICS asks for advice on the following two cases:—

1. I was suddenly called upon to attend Mrs. —, whose husband came to fetch me himself. The medical man originally engaged for the case was out, and had left no address behind where, in case of emergency, he might be found; neither had he left a list of his visits at his own or at his partner's residence. On arrival I found the case, which was a rather quick labour, completed by the nurse. However, I examined the patient, saw that everything was quite safe, and prescribed for the time being, leaving word with the nurse to inform Dr. — of my visit, etc., and telling the patient that her own doctor would undoubtedly call immediately after his return home, and attend her as agreed. The doctor has neither called upon nor written to me, nor has anything been mentioned by him about a fee or other matters to the husband. He simply attended, took his fee, and ignored me altogether. Can I demand the usual half fee from him, or can I claim any fee from the husband? Ought Dr. — to have called on or written to me in reference to the matter?

2. Mrs. — wished me to attend her in her approaching confinement. I had seen her husband first, and afterwards called upon her and made the

usual engagement. I now hear that she has engaged Dr. — since (partner to the doctor mentioned in 1). I was never given to understand that she wished to cancel the engagement, neither am I aware whether she had told her present doctor of her previous engagement with me. Can I claim my fee from her in the usual manner? I may add here that for reasons best known to herself she mentioned that I was not expected to make any intermediate calls since the date of our engagement. I thus waited until sent for.

. In such cases as 1, it is far better that the officiating practitioner should call upon, or by a courteous note apprise, the pre-engaged but absent accoucheur of his having attended the case, instead of entrusting a message to the nurse or other person, the delivery of which is not always to be depended on. Had the suggested course been adopted in the case in question, it would have entailed upon Dr. — an acknowledgment of such attendance, without affording any loophole of excuse on the plea of non-receipt of the message. Be that as it may, under the circumstances related by our correspondent he cannot, we think, justly claim from Dr. — the customary half-fee, but he is undoubtedly entitled to charge the husband for the visit and detention.

In reference to Case 2, there seems to have been a clear contract, and the fee should be claimed.

MEDICO-PARLIAMENTARY.

HOUSE OF LORDS.—Monday, May 14th.

Rabies in Dogs.—The Earl of CARNARVON inquired whether the Government proposed to introduce any Bill or issue any instructions for the more effectual suppression of rabies in dogs, in conformity with the recommendations of the Committee which reported last year.—Lord MOUNT TEMPLE said whatever legislation was passed ought to extend to the whole country.—Viscount CRANBROOK sympathised with the views expressed, but a great difference of opinion prevailed as to the best means of suppressing the disease. The Government had issued orders under the Contagious Diseases (Animals) Act, of which the authorities had largely availed themselves. If muzzling were carried out effectively it would, he thought, prove a complete remedy; but it would be almost impossible to enforce it. It was quite true that in certain countries the disease had been stamped out that way. While in Mauritius the disease prevailed, in Réunion it had been completely stamped out, and there had been no case for years past. In a large district in Prussia a similar policy had proved successful. The Government had given powers to deal with the danger to local authorities, and at Birkenhead and other parts of Cheshire those powers had been employed. By the Bill now under discussion in another place the new councils would have extensive powers in this respect. He did not, therefore, think it necessary to introduce a Bill. He had before him a long list of places which had issued orders under the general authority given by the Privy Council. The Government had procured the endorsement on dog licences of any symptoms of rabies which might have developed themselves in dogs so licensed, which he regarded as a valuable precaution.

Tuesday, May 15th.

The Coroners Bill.—The LORD CHANCELLOR moved the second reading of this Bill, and explained that the first part dealt with the powers of the coroner to hold certain inquests, and the second part with the mode of his election. The first section of the Bill, which gave the coroner power to hold inquests in respect of fires, seemed to be generally approved. Such inquests used to be held, but owing to a legal decision that had been given by the Courts, they had been discontinued. The present mode of election of the coroner was very generally condemned, but there was no such unanimity as to the system to be substituted for it. At present every freeholder in the district was entitled to vote. There was no register and great confusion, with consequent enormous expense, and many a candidate had been ruined by his success or failure. It had been suggested that the Parliamentary constituency should be substituted. There was a particular objection to that part of the Bill which vested the appointment of coroners in the Lord Chancellor, and he certainly should not jealously claim the patronage which the Bill gave him. It might be suggested that the new County Councils should have the power of appointing coroners; but the objection would at once arise that this could not be provided in the Bill, because no such bodies existed at the present time. Even if they did, it would require consideration whether the election of coroners by those who were themselves an elected body was altogether a desirable mode of meeting the difficulty. All he would say at present, therefore, was that the present system ought to be altered, and that when the Bill

reached Committee he should gladly welcome any suggestion which would get rid of the difficulty. He asked their lordships to read the Bill a second time.—Lord HERSHELL wished to express his strong objection to the first clause of the Bill with reference to the mode of appointing coroners. He entirely shared the view expressed by his noble and learned friend as to the extreme inexpediency of the present mode of appointment; and he looked upon the proposal to vest the patronage entirely in the Lord Chancellor as a very serious one. There could be no doubt that the abolition of the system by which the freeholders had a voice in the appointment of the coroner would be regarded by many with some jealousy. The mode of popular election was an unsatisfactory one, but there was a widespread feeling that the coroner ought to be regarded to some extent as a representative of the people, and should not be appointed by the Executive. The only step by which they would be able to accomplish what they had in view with general assent would be to vest the appointment in some elected body. Many of the municipalities had for years had the power of appointing coroners, and any proposal to take that power away from them would be regarded with the utmost jealousy and hostility. It seemed to him that the natural course would be to extend to the County Councils the power of appointing coroners. It was true that the County Councils were not yet brought into existence; but they had that night passed a Bill which was based upon the assumption that these Councils were going to exist. He would suggest, therefore, that the question of appointment should not be dealt with until they were able to deal with it in this way. He should feel it his duty to bring this question forward when the Bill reached the Committee stage.—The Bill was then read a second time.

HOUSE OF COMMONS.—Thursday, May 10th.

Naval Hospitals.—Dr. TANNER: I beg to ask the First Lord of the Admiralty, whether in all naval hospitals, since the abolition of Captain Superintendents, the power that they had of dealing with their men employed as nurses was relegated to the Inspectors-General of the said hospitals: and whether it is true that at the present time no medical officer ashore or afloat has the slightest power of dealing with the "Sick Berth Staff," and if so, can he state the reasons for which this change in the regulations of the Naval Medical Service has been made.—Lord GEORGE HAMILTON: On the abolition of appointment of Captain Superintendent of Naval Hospitals the administration and control of the establishment were placed in the hands of the Inspector-General, who now deals entirely with cases of neglect of duty or misconduct on the part of civilian nurses. The men of the Sick Berth Staff belong to the service afloat, and, being subject to the Naval Discipline Act, are dealt with by the Commanders-in-Chief at the ports on the representation of the principal medical officer. All medical officers, whether on shore or afloat, have full power over the Sick Berth Staff by means of reporting them to the commanding officer, and in this respect there has been no change.—Dr. TANNER inquired whether the same rule existed in regard to the Army Medical Service, or whether the Army Medical officers were unable to command the men belonging to the Medical Staff Corps.—Lord GEORGE HAMILTON could not answer the question.

Friday, May 11th.

Caffein.—The CHANCELLOR OF THE EXCHEQUER, in answer to Mr. BARTLEY, said the question of the admission free of duty of tea found to be unfit for human food, for the purpose of the production of caffein, subject to preliminary precautions to prevent the tea getting into consumption, was now under reference to the Board of Customs.

Prison Surgeons.—Dr. CLARK asked whether prison surgeons in Birmingham, Leeds, and Durham were appointed at a salary of £320 a year, while in the Scotch prisons of Perth, Glasgow, and Barlinnie they began at £200 a year, and what was the reason for the difference.—Mr. JACKSON, in reply, said that the surgeons at Glasgow and Perth received higher pay than they would in English prisons of corresponding population, while the surgeon at Barlinnie received less. The Scotch scales of salary were fixed by a Committee which had full knowledge of those adopted in England; but applications for increases had been received from the Scotch officers, and were under consideration.

Monday, May 14th.

Darenth Asylum.—Mr. RITCHIE, in reply to Mr. FRITH—who inquired as to the cost per head at Darenth Asylum being higher than that of any other asylum in England, and £10 per head

higher than Leavesden or Caterham—explained that in the case of the Metropolitan Asylums Board district asylums the cost include other items than those of maintenance (which was not the case with the county and borough asylums). The excess of cost at Darenth over that of Leavesden and Caterham was to some extent accounted for by the fact that Darenth had not had its full number of inmates. The cost of the food of the patients was practically the same in all three.

Contagious Diseases Act in India.—Sir J. GORST said, in reply to Mr. STANSFELD, that the administration of the Contagious Diseases Act in Bombay, Madras, and Bassein, the only places in which it was in force, had been suspended by the Government of India under a power contained in the Act. The Government of India was now engaged in a revision of the regulations made for preventing the spread of venereal disease in cantonments, under Section 27 of Act 111 of 1880; and a despatch was going out to India from the Secretary of State in Council, which would prohibit the compulsory examination of women, and the making of any regulations which could be justly construed into a legalisation of prostitution.

Tuesday, May 15th.

The Royal College of Surgeons.—Dr. FARQUHARSON asked the Vice-President of the Committee of Council on Education whether the petition of Members of the Royal College of Surgeons of England, for a modification of the charters of the College now under consideration by the Council, had received the favourable consideration of the Lord President, or whether it would be referred to the Royal Commission on University Education in London, recently appointed to consider, among other things, the means of facilitating University degrees for resident students in London; and whether the Royal College of Surgeons of England had yet presented to the Lord President any comments on, or reply to, the representations made on behalf of the Members of the College by the deputation which recently waited on him, or whether, in the absence of any such representation in support of the petition by 6,000 Members would be held to be conclusive.—Sir W. HART DYKE, in reply said the petition would not be referred to the Royal Commission. There had been a correspondence between the Council Office and the College on the subject of their petition for a supplementary charter, and the College had accepted a proposal from the Privy Council to omit from the supplementary charter points upon which there had been a controversy with the Fellows and the Members of the College.

Public Health Acts.—The Public Health Acts Amendment (Buildings and Streets) Bill was read a second time without discussion.

UNIVERSITY INTELLIGENCE.

CAMBRIDGE.

FRANK SMART STUDENTSHIP.—Percy Groom, B.A., late of Trinity College, has been elected to the Frank Smart Studentship in Botany, founded at Gonville and Caius College, by Francis Gray Smart, M.A., M.B.

LECTURESHIP IN GEOGRAPHY.—The new University Lectureship in Geography, the Cambridge electors to which are Dr. FERRERS, Dr. MACALISTER, Professor MICHAEL FOSTER, and Professor BROWNE, is announced to be vacant. The stipend is £200 a year. Candidates are to send their names, with brief statements of their qualifications and of the methods they would propose to adopt, to the Master of Gonville and Caius College, not later than Tuesday June 5th.

THE results of recent examinations for medical degrees are as follows:

Degree of M.C.

C. A. Morris, Caius.

Degree of B.C.

Beddoes, Pemb.; Whishaw, H. Cav.

Third examination for the degree of M.B. Part I.

Battersby, Trin.; Blaker, H. Cav.; Bowen, King's; Campbell, H. Cav.

Chaplin, Joh.; E. H. Colbeck, Caius; Courtney, Pemb.; Crisp, Caius

Eismore, Christ's; Foster, Trin.; Gervis, Trin.; Goddard, Caius; Gordon

Trin.; Hawkins, Caius; Hopkinson, Emman.; G. T. Lloyd, Joh.; Murray

Trin.; Musson, King's; Ogilvie, King's; R. J. Roberts; Rutherford

May 19, 1888.]

Sidney; G. R. Saunders, Cairns; Sortain, Caius; S. B. Syfret, Trin. H.;
Vaele, Christ's; Weber, Trin.; G. H. Wickham, Caius.

Part II.

Barber, Cath.; Copeland, King's; Harris, Christ's; Hicks, H. Cav.; King,
H. Cav.; Little, Down; Percival, Trin.; Pollock, Trin.; Prowse, Noun-
coll.; Smithson, Christ's; Watts, Corpus.

ROYAL UNIVERSITY OF IRELAND.

EXAMINATION RESULTS.—At the recent medical examinations following were the results. Primary: (M.B. qualifying examination) 31 examined, 15 rejected. Second medical: 72 candidates, 39 rejected. Third medical: 134 examined, 67 rejected. M.Ch., 21 examined, 5 rejected; M.A.O., 11 examined, 5 rejected.

The following are the candidates recommended by the examiners as having passed the undermentioned Examinations:

Second Examination in Medicine.

Upper Pass Division.—J. Ambrose, Queen's College, Cork; J. M. C. Brown, Queen's College, Belfast; J. E. W. Cruise, Catholic University School of Medicine; P. H. Keary, Carmichael School of Medicine; J. K. O'Connor, Queen's Colleges, Belfast and Cork; H. Stranaghan, Queen's College, Belfast.

All the above Candidates will be admitted to the Further Examination for honours:

Passed.—J. Alexander, School of Physic, Trinity College; J. H. Anderson, Queen's College, Belfast; R. Boyd, Queen's College, Belfast; P. Brannan, Catholic University School of Medicine; J. A. Browne, B.A., Queen's College, Belfast; W. Cluff, Queen's College, Belfast; F. A. Craig, Queen's College, Belfast; R. Creighton, Royal College of Surgeons and Royal College of Science; J. Dodd, Queen's College, Cork and Catholic University School of Medicine; T. S. Downer, Queen's College, Belfast; J. Gahan, Queen's College, Galway; J. D. Graham, Queen's College, Belfast; W. J. Gregory, Queen's College, Galway; D. Jamison, Queen's College, Belfast; J. H. Jones, Ledwith and Catholic University School of Medicine; R. J. Keane, Queen's College, Cork; J. Lane, Queen's College, Cork; R. McCarthy, Catholic University School of Medicine; N. O. McCormell, Queen's College, Belfast; J. R. McLaren, M.A., Queen's College, Belfast; J. Mills, School of Physic, T. C. D.; W. Moody, Queen's College, Galway and Belfast; J. Priestley, B.A., Queen's College, Belfast; Hester D. Russell, London School of Medicine for Women; M. C. Staunton, Carmichael College and Catholic University School of Medicine; J. T. Wallace, B.A., School of Physic, T. C. D.; L. Wheeler, Queen's College, Belfast.

Third Examination in Medicine.

Upper Pass Division.—Eleonora L. Flenny, London School of Medicine for Women; J. M. Hall, Queen's College, Belfast; R. W. Haslett, Queen's College, Belfast; J. Jackson, Queen's College, Cork; G. W. Jenney, Queen's College, Cork; J. W. C. Macpherson, Queen's College, Cork; G. J. Pierce, Queen's College, Galway; C. Porter, Queen's College, Belfast; J. Smyth, Queen's College, Cork; R. Wilson, Queen's College, Belfast; J. W. Wolfe, Queen's College, Cork.

Passed.—J. Adrain, Queen's College, Belfast; C. J. Beattie, Queen's College, Galway; W. T. Brand, Queen's College, Belfast; J. Buchanan, Queen's College, Belfast; A. Burgess, B.A., Queen's College, Belfast; J. Caldwell, Queen's College, Belfast; H. R. Corbett, Queen's College, Cork; P. H. Donovan, School of Physic, T. C. D.; R. Forsyth, Queen's College, Belfast; J. Fulton, Queen's College, Belfast; H. T. Gill, Queen's College, Belfast; D. H. Hamilton, Queen's College, Belfast; S. Irwin, Queen's College, Belfast; P. Jennings, Queen's College, Cork; J. A. Kelly, Queen's College, Belfast; J. Kenny, M.S., Queen's College, Belfast, and Catholic University School of Medicine; J. McConnell, Queen's College, Belfast; W. P. McRidoney, Queen's College, Belfast; F. McKee, Queen's College, Belfast; J. McKnight, Queen's College, Belfast; H. T. N. Merrick, School of Physic, Trinity College; A. T. Morrison, Queen's College, Belfast; N. of Physic, Trinity College; C. V. H. Nesbitt, Queen's College, Belfast; Morton, Queen's College, Belfast; C. V. H. Nesbitt, Queen's College, Belfast; M. J. O'Hegan, Queen's College, Cork; J. V. Ryan, Queen's College, Belfast; M. J. O'Hegan, Queen's College, Belfast; J. B. Smith, B.A., Queen's College, Cork; D. C. Smiley, Queen's College, Belfast; W. J. Taylor, Queen's College, Cork; C. A. Stone, Queen's College, Cork; W. J. Taylor, Queen's College, Cork; R. Thomson, Queen's College, Belfast; J. T. Walker, Queen's College, Belfast; W. Weatherup, Queen's College, Belfast; W. A. Wheeler, Queen's College, Belfast; S. H. Withers, Queen's College, Belfast; C. R. Zimmer, Carmichael College and School of Physic, Trinity College.

The following candidates will be permitted to present themselves at the Further Examination for Honours:

Eleonora L. Flenny, London School of Medicine for Women; J. M. Hall, Queen's College, Belfast; R. W. Haslett, Queen's College, Belfast; J. Jackson, Queen's College, Cork; G. J. Pierce, Queen's College, Galway; R. Wilson, Queen's College, Belfast; J. W. Wolfe, Queen's College, Cork.

M.B. Examination.

Upper Pass Division.—T. E. Dunne, Carmichael College; A. E. Mahood, School of Physic, T. C. D.; M. Molony, Queen's College, Cork; P. J. O'Brien, Queen's College, Cork.

Passed.—J. H. Corcoran, Queen's College, Cork; D. Crowley, Queen's College, Cork; W. R. Gore, Royal College of Surgeons, Ireland; J. Griffin, Queen's College, Cork; J. Hunter, Queen's College, Belfast; W. Kelleher, Queen's College, Cork; G. Love, Queen's College, Belfast; D. McKee, Queen's College, Belfast; L. O'Clery, Queen's College, Cork; M. Semple, Queen's College, Galway; H. Smith, B.A., Queen's College, Galway; J. W. Wilson, Queen's College, Belfast.

Spring Examinations, 1888. The Examiners have recommended that the following candidates should be adjudged to have passed the undermentioned Examinations:

M.Ch. Degree Examination.—J. F. St. J. Annesley, Queen's College, Bel-

fast; J. Clifford, Carmichael College, Dublin; J. H. Corcoran, Queen's College, Cork; D. Crowley, Queen's College, Cork; R. B. Gorsuch, M.D., Queen's College, Cork; J. Hunter, Queen's College, Belfast; J. J. Lynch, Catholic University School of Medicine; D. McKee, Queen's College, Belfast; P. McKenna, Catholic University School of Medicine; A. E. Mahood, School of Physic, Trinity College, Dublin; C. W. Morgan, M.B., Queen's College, Belfast; J. J. O'Brien, M.D., Queen's College, Cork; P. J. O'Brien, Queen's College, Cork; L. O'Clery, Queen's College, Belfast; M. Semple, Queen's College, Galway; H. Smith, B.A., Queen's College, Belfast.

M.A.O. Degree Examination.—J. H. Corcoran, Queen's College, Cork; D. Crowley, Queen's College, Cork; J. R. Davison, M.D., Queen's College, Belfast; A. E. Mahood, School of Physic, T. C. D.; H. Smith, B.A., Queen's College, Galway; J. Tomb, M.D., Queen's College, Belfast.

INDIA AND THE COLONIES.

INDIA.

INDIAN UNIVERSITIES AND THE GENERAL MEDICAL COUNCIL.

L. M. S. (Bombay) writes: You will be doing a great favour to the hundreds of unrepresented, fully qualified men of India, by inserting this.

The Medical Act of 1886 provides for the due recognition of Indian and Colonial medical degrees by the General Medical Council, but as yet nothing has been done because they are in no way represented, and they have none to speak for them; I therefore desire to draw the attention of the Council, through your columns, to this matter. It is high time that they should consider and decide this question. I need not go into the merits of the question, for I am sure the Council must have all the requisite information; suffice it to say that the degrees or licence are granted in India at the three Universities, after a course of medical training extending over full five years, and the teachers and professors are experienced men from Her Majesty's Army and Indian Medical Service, and the training is in no way inferior to that of the teaching bodies in Great Britain and Ireland, and the tests are equally good, if not more severe than at some of the British licensing bodies. In connection with this I should particularly like to draw attention to one well known fact. I know of several men (and I am prepared to give names and full particulars, if I am called upon) who, having been rejected in the examinations in medicine and surgery of the Bombay University on more occasions than one, have come up to Great Britain and Ireland, and got through the examinations of some of the licensing bodies here, and obtained the licence very easily. I have cited this fact only to show that the tests of the Indian Universities and particularly of Bombay are as good, and in some cases, I make bold to say, more searching than those of the British licensing bodies, the Royal College of Surgeons of England excepted. Thus, then, if a candidate is rejected in Bombay he comes over here, goes to one of the licensing bodies of Glasgow, Edinburgh, or Ireland, and invariably succeeds in obtaining the licence to practise, and can therefore put his name on the British Register, and enjoys all the rights of a qualified man. While if another happens to be more successful, and after a severe test gets the diploma of the Bombay or other Indian University which the former has failed to obtain, and comes over here to prosecute his studies further as a qualified man, why he is not recognised, and labours under a greater disadvantage than the other. This absurd anomaly ought to be done away with, and the sooner the better. We only ask for justice. It is high time that the General Medical Council should consider this question. We men from India are British subjects, we are educated by the British, for which we are ever thankful, and we are, after a proper test, declared by your own men to be fully qualified; and we are even employed by the Government as assistant-surgeons, in charge of dispensaries, and even some hospitals, gaols, &c.

I ask then why should we be ignored in this country? When your own men admit us into this noble profession, why should we not be recognised here? I think it is a great injustice and real grievance, and ought to be soon remedied. The General Medical Council meet this month, and I hope they will take up this question.

OBITUARY.

ARTHUR CRESWELL RICH, M.B.LOND., M.R.C.S.ENG.

THE medical profession in Liverpool learnt with deep regret of the demise, after a few days' illness, of Dr. Arthur Creswell Rich, on May 15th from an attack of purpura hæmorrhagica, at the early age of 31. Dr. Rich was the eldest son of Mr. J. D. Rich, the popular postmaster of Liverpool. He was educated at the Liverpool School of Medicine (now the Medical Faculty of University College, Liverpool), and also at St. Thomas's Hospital. He obtained the degree of M.B. from the London University with first-class honours, and was also a Member of the Royal College of class honours, and was also a Member of the Royal College of Surgeons. He was soon after appointed to a house-surgeoncy at the Liverpool Royal Infirmary, and subsequently filled the important post of pathologist to that institution. He was also a Fellow of the Obstetrical Society, a member of the British Medical Association, and a valued special correspondent for this JOURNAL. During the visit of the Association to Liverpool in 1883, Dr. Rich was the courteous secretary to the Reception Committee, the arrangements of which he carried out in a most successful manner.

Dr. Rich was very zealous as an ambulance lecturer, and the Liverpool police will especially regret his loss. At the time of his

death he was senior medical officer to the Liverpool Post Office, and surgeon to the Liverpool Rifle Brigade of Volunteers. His death brings with it a widespread feeling of regret that such a promising career has been so suddenly cut short. He leaves a young widow to mourn his loss.

Dr. William Carter, who had known Dr. Rich from boyhood, and who attended him in his last illness, has sent us the following tribute to his memory:

"Dr. Rich's multitudinous labours soon told on a health previously injured by malaria, yet it was with great difficulty, and only after more than one serious attack of blood-poisoning, that he could be persuaded by Dr. Carter, whom he consulted, to abandon his pathological work. His reports as pathologist, many of which have been read with admiration by the writer of this sketch, were models of fulness and accuracy, but were only drawn up by the sacrifice of much needed repose. He never failed to respond to a call; and when it is mentioned that within ten days of his death he insisted on visiting, at ten o'clock at night, a member of the post-office, and that he was in so prostrate a condition that it was only by the aid of a kindly administered stimulant that he could be got home without fainting, it will be seen how far his resolute will and heroic devotion to duty carried him. His noble self-forgetfulness probably precipitated the end. His young wife had recently undergone a severe illness, to convalesce from which it was necessary that she should be sent to the south; and although he himself became utterly prostrated in health during her absence, as the above related incident shows, yet he continued to write to her cheerfully daily, and absolutely refused to have any intimation sent to her that would curtail her sojourn by a single day. He was equally determined in resisting entreaties made to him again and again to rest from his work, and to avail himself of medical aid. On his wife's return, however, which was just eight days before his death, she was so shocked by his altered appearance, that she insisted on instantly requesting the attendance of Dr. Carter, who found him in such a condition of prostration as scarcely to afford hope of rallying. The lower extremities were very oedematous, and stained by large subcutaneous hæmorrhages; he was profoundly anæmic, had a high temperature, and a very quick and weak pulse. His friend, Dr. Charles Macalister, at once relieved him of all official duties, and devoted himself night and day to watching over him, ably assisting Dr. Carter by carrying out every detail of treatment. Delirium set in, and Dr. Rich sank exactly eight days after having given up his work. Throughout his short but busy life he was ever anxious to help in any good work. A man of quiet and unostentatious piety, he gave his services freely to many charitable societies, such as the Shoeblocks' Home, the Aged Women's Home, etc. In addition to all his other duties, he undertook and performed those of local secretary to the Collective Investigation of Disease Committee. So much work condensed into so short a life is very rarely seen."

HENRY C. MACEWEN, B.Sc., M.B., C.M., of Glasgow.

THE death from diphtheria of this young and promising member of the profession, at the Belvidere Fever Hospital, of which he was an assistant physician, after an illness of little more than five days' duration, came as a shock to his numerous friends, by whom a feeling of regret will be felt akin to that which was felt on the death of Dr. David Foulis, seven years ago, from the same cause. Born at Glasgow in 1861, the youngest son of Mr. William Macewen, formerly Dean of Guild, many years Chairman of the Royal Infirmary, and a prominent and highly respected citizen, Dr. Macewen had reached the age of twenty-seven years. After a liberal education in the Glasgow Academy and at Merchiston, he decided to enter the medical profession, and began his studies in the University of his native town, where he took his degree of B.Sc. in 1881. He then removed to Edinburgh University, where he completed his curriculum, and graduated M.B., C.M., in the year 1885. As he suffered a good deal at this time from tenderness of the eyes, he took a voyage to New Zealand, acting as surgeon of the ship in which he went out, and returned perfectly cured. Desiring to study some special subjects, he went to Vienna in the autumn of 1886, and whilst there he devoted his time chiefly to the study of skin diseases, and to laryngology. Whilst on the Continent, he visited some of the other German medical schools; and, on his return to Glasgow, he entered on his duties as one of the Resident Assistant Physicians in the Royal Infirmary, in which he continued eleven months, having been reappointed for a second period of six months.

Anxious to acquire a knowledge of fevers and their treatment,

he applied for and obtained an appointment in Belvidere, which he entered on two days after leaving the Royal Infirmary, the interval having been spent as a holiday. He was very happy in his new sphere, and apparently in the best of health and spirit. On Saturday, April 28th, he left the hospital early and went to Arran to join some friends with whom he made an annual excursion to that favourite island. In the evening, after having climbed some of the hills, exposed to a biting east wind, he complained of headache and sore throat, and, this continuing next day, he remained in his lodgings, expecting to see the rash of scarlet fever develop on him; but, as it did not appear, he left by the early steamer next morning, and returned to Belvidere. On seeing him Dr. Allan, the kindly and experienced Physician-Superintendent at once attended to him; but as symptoms of diphtheria developed themselves, and were becoming serious, he called in the aid of Dr. Robertson, the family physician, but without avail, as death took place early next morning. It was a shock and surprise to all who knew him, and to many more who only knew of him through his family connections; and by all it was felt as if a personal loss had been sustained. Dr. Macewen was an assiduous student, of a cheerful nature, and unassuming in character. His Vanduyck-like face will long be remembered and his loss mourned by his old fellow assistants in the Royal Infirmary. Widespread sympathy is felt for his family in their bereavement. The funeral took place on May 7th, and residents and nurses in both hospitals in which he had served sent their floral tributes to the tomb of the deceased in token of their remembrance of him.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

THE REGISTRAR-GENERAL'S QUARTERLY RETURN.

THE Registrar-General has just issued his quarterly return relating to the births and deaths registered in England and Wales during the first or winter quarter of this year, and to the marriages in the three months ending December last. The marriage-rate, although slightly above the exceptionally low rates that prevailed in the fourth quarter of the two preceding years, was considerably below the mean rate in the corresponding period of the ten years 1877-86. The mean temperature of the air at the Royal Observatory, Greenwich, was considerably below the average, but the weather was, on the whole, favourable to the public health.

The births registered in England and Wales during the three months ending March last were 223,838, equal to an annual rate of 31.4 per 1,000 of the population, estimated by the Registrar-General to be more than twenty-eight and a half millions of persons. This birth-rate showed a further slight decline from the rates recorded in the corresponding quarters of recent years, and was as much as 3.0 per 1,000 below the mean rate in the first quarters of the ten years 1878-87; it was indeed lower than that recorded in the first quarter of any year since 1833, when registration was undoubtedly defective. The birth-rate in the quarter under notice in the several counties ranged from 24.5 in North Wales, 25.2 in Rutlandshire, and 25.6 in Sussex to 34.3 in the extra-metropolitan portion of Middlesex, 34.6 in South Wales, and 36.7 in Essex and in Monmouthshire. In the twenty-eight large towns for which the Registrar-General publishes weekly returns the birth-rate last quarter averaged 32.5 per 1,000, ranging from 22.7 in Brighton, 26.5 in Huddersfield, and 28.3 in Bradford to 37.7 in Newcastle-upon-Tyne, 39.5 in Preston, and 43.9 in Cardiff. The births registered in England and Wales during the quarter under notice exceeded the deaths by 73,824; this represents the natural increase of the population during that period. From the Board of Trade returns it appears that 59,288 emigrants sailed from the various ports of the United Kingdom at which emigration officers are stationed; of these, 28,935 were English, 6,238 Scotch, and 7,113 Irish. The proportion of British emigrants to a million of the respective populations of the three divisions of the United Kingdom were 1,013 from England, 1,546 from Scotland, and 1,485 from Ireland.

During the first quarter of this year the deaths of 150,014 persons were registered in England and Wales, equal to an annual rate of 21.0 per 1,000 of the estimated population. This death-rate, although showing a slight increase upon the exceptionally low rate in the corresponding period of 1887, was 1.0 below the

May 19, 1888.]

ean rate in the first quarters of the ten years 1878-87. Among the urban population of the country, estimated at upwards of fifteen and a quarter millions of persons, the rate of mortality during the quarter under notice was equal to 21.3 per 1,000; in the remaining and chiefly rural population of about ten and a quarter millions, the rate was 20.6 per 1,000. The urban rate was 9 per 1,000 below, while the rural rate was 0.4 above, the mean rate in the first quarters of the seven years 1881-87. The rate of mortality among infants under one year of age, and among persons aged upwards of sixty years, exceeded the average; while the death-rate of persons aged between one and sixty years was below the average of the ten preceding corresponding quarters.

The 150,014 deaths registered in England and Wales during the three months ending March last included 4,428 which were referred to whooping-cough, 2,129 to measles, 1,868 to scarlet fever, 447 to diphtheria, 1,362 to "fever" (including typhus, typhoid, and simple fever), 1,295 to diarrhoea, and 533 to small-pox; in all, 3,112 deaths resulted from these principal zymotic diseases, equal to an annual rate of 1.84 per 1,000, the average annual rate in the ten preceding corresponding quarters having been 2.20 per 1,000. The mortality from measles, scarlet fever, "fever," and diarrhoea, was considerably below the average for the corresponding quarters in the ten preceding years; while the mortality of whooping-cough, small-pox, and diphtheria exceeded the average. The deaths referred to small-pox, which had been 30, 47, 70, and 358 in the four quarters of 1887, further rose to 533 during the first three months of this year, of which 318 occurred in Sheffield, 15 in Bristol, 13 in Manchester, 13 in Leeds, 11 in Ashton-under-Lyne, and 10 in Rotherham. In London only 4 fatal cases of small-pox were recorded during the quarter.

The rate of infant mortality, or the proportion of deaths under one year of age to registered births, was last quarter equal to 146 per 1,000, and slightly exceeded the average proportion in the ten preceding corresponding quarters. While the rate of infant mortality in London during the first three months of this year was 43 per 1,000, it averaged 150 in the twenty-seven provincial towns, among which it ranged from 114 in Sunderland and 119 in Huddersfield to 178 in Preston, 199 in Plymouth, and 203 in Blackburn.

HEALTH OF ENGLISH TOWNS.—During the week ending Saturday, May 12th, 5,696 births and 3,174 deaths were registered in the twenty-eight large English towns, including London, which have an estimated population of 9,398,273 persons. The annual rate of mortality per 1,000 persons living in these towns, which had been 18.9 and 18.7 in the two preceding weeks, further declined to 17.6 during the week under notice. The rates in the several towns ranged from 12.5 in Cardiff, 14.1 in Derby, and 14.3 in Brighton to 23.6 in Wolverhampton, 24.7 in Halifax, and 26.7 in Bolton. The mean death-rate in the twenty-seven provincial towns was 18.5 per 1,000, and exceeded by 1.9 the rate recorded in London, which was only 16.6 per 1,000. The 3,174 deaths registered during the week under notice in the twenty-eight towns included 287 which were referred to the principal zymotic diseases, against 328 and 329 in the two preceding weeks; of these, 109 resulted from whooping-cough, 43 from scarlet fever, 40 from measles, 32 from diarrhoea, 29 from "fever" (principally enteric), 26 from diphtheria, and 6 from small-pox. These 387 deaths were equal to an annual rate of 1.6 per 1,000; in London the zymotic death-rate was 1.6, and corresponded with the mean rate in the twenty-seven provincial towns, among which the zymotic rates ranged from 0.4 in Portsmouth and in Sunderland and 0.7 in Bristol to 2.7 in Plymouth, 3.1 in Blackburn, and 3.9 in Salford. Measles caused the highest proportional fatality in Nottingham and Bradford; scarlet fever in Huddersfield and Blackburn; whooping-cough in Derby, Manchester, and Salford; and "fever" in Leicester and Nottingham. The 26 deaths from diphtheria in the twenty-eight towns included 15 in London, 2 in Liverpool, and 2 in Norwich. Of the 6 fatal cases of small-pox recorded during the week under notice, 3 occurred in Sheffield, 1 in Manchester, 1 in Preston, and 1 in Leeds. The Metropolitan Asylums Hospitals contained 11 small-pox patients on Saturday, May 12th, and no new cases were admitted during the week. These hospitals also contained 904 scarlet fever patients on the same date, against 967 and 921 at the end of the two preceding weeks; there were 91 admissions during the week. The death-rate from diseases of the respiratory organs in London was equal to 3.2 per 1,000, and was considerably below the average.

HEALTH OF SCOTCH TOWNS.—In the eight principal Scotch towns, 839 births and 534 deaths were registered during the week ending Saturday, May 12th. The annual rate of mortality, which had been 21.0 and 19.5 per 1,000 in the two preceding weeks, rose again to 21.1 during the week under notice, and exceeded by 3.5 per 1,000 the mean rate during the same period in the twenty-eight large English towns. Among these Scotch towns the lowest rates were recorded in Leith and Dundee, and the highest in Edinburgh and Glasgow. The 534 deaths in these towns during the week under notice included 40 which were referred to the principal zymotic diseases, equal to an annual rate of 1.6 per 1,000, which corresponded with the mean zymotic death-rate during the same period in the large English towns. The highest zymotic rates were recorded in Perth, Paisley, and Glasgow. Fifteen fatal cases of whooping-cough, and 10 of measles were recorded in Glasgow. The mortality from diseases of the respiratory organs in these towns was equal to 4.4 per 1,000, against 3.2 in London.

HEALTH OF IRISH TOWNS.—During the week ending Saturday, May 12th, the deaths registered in the sixteen principal town-districts of Ireland were equal to an annual rate of 22.9 per 1,000. The lowest rates were recorded in Dundalk and Lurgan, and the highest in Wexford and Lisburn. The death-rate from the principal zymotic diseases in these towns averaged 2.4 per 1,000, and was highest in Armagh and Galway. The 156 deaths registered in Dublin during the week under notice were equal to an annual rate of 23.1 per 1,000, against 31.5 and 21.7 in the two preceding weeks. The 156 deaths included 17 from the principal zymotic diseases (equal to an annual rate of 2.5 per 1,000), of which 9 were referred to whooping-cough, 4 to scarlet fever, 2 to "fever," 1 to measles, and 1 to diarrhoea.

EDINBURGH HEALTH SOCIETY.

The Edinburgh Health Society has published its annual handbook, the eighth of the series since the foundation of the Society. It contains the lectures delivered to non-professional audiences under the auspices of the Society during the winter months. The present issue contains lectures by Dr. T. S. Clouston, on How Pleasant Surroundings and Conditions affect the Health and Happiness; by Dr. W. Russell, on Indigestion, its Causes and its Consequences; by Dr. Kerr, on Healthy Clothing; by Dr. R. W. Felkin, on Heredity, its Influence on Man in Health and Disease; and by Mr. A. W. Hare, on The Channels of Infection. The lectures are all written in a simple, clear, and popular style, and are calculated to do good to the class for whom they are specially intended.

INFECTIOUS DISEASES AND THE SALE OF MILK.

A DAIRY-KEEPER at Paisley has been fined £1, with £1 7s. 6d. expenses, and with the alternative of seven days in prison, for allowing a girl to milk cows or handle vessels used for the milk whilst she was coming in contact with a girl, a daughter of the dairy-keeper, suffering from measles. The dairy-keeper explained that as soon as she knew what was wrong with her daughter no one who attended her was allowed to do anything in the dairy. A similar case from another parish was similarly dealt with.

BURIAL REFORM.

THE tenth annual meeting of the Burial Reform Association was held on Monday last at Grosvenor House under the presidency of the Duke of Westminster, when the following resolution, proposed by Mr. F. Seymour Haden, F.S.A., was carried:

"That the present mode of interment in brick vaults and crowded graves should be discontinued as dangerous to the health of the living, and that 'earth-to-earth' burial should be encouraged with the use of readily-perishable coffins, and that the Home Secretary be memorialised to institute an inquiry into the condition of cemeteries."

The speaker opposed cremation.

Mr. WOLLASTON PYM said that fifty years ago Brompton Cemetery was condemned by the sanitary authorities, yet 5,000 bodies were still interred there every year.

IS A SMITHY A NUISANCE?

A MEMBER asks whether we think a smithy, consisting of a forge and horse-shed, and situated about ten yards from the village school, could be condemned as a nuisance injurious to the health of boys in that school? This smithy is at present in course of erection, and the question of a nuisance in time to come has arisen.

. The case stated does not, in our opinion, come in any way under the

Public Health Acts. There is no absolute necessity that a forge, etc., should be a nuisance and injurious to health; and the erection of such a building could not be prevented. Should it become a nuisance on account of carelessness, etc., the occupier could be proceeded against.

MEDICAL NEWS.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH, AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The quarterly examinations in Edinburgh for the Triple Qualification took place in April and May with the following results.

First Examination.—Of 62 candidates, the following 32 passed: A. M. Gray, Isle of Man; W. L. Lemon, Co. Armagh; Miss Louisa Rosa Cooke, Yorkshire; Miss Edith Mary Brown, Whitehaven; S. Wood, Rochdale; D. K. Muir, West Hartlepool; C. Pearce, Chilli; H. Whalley, Bradford; F. Hall, Lancashire; E. F. Jamison, Co. Down; D. Doherty, Co. Donegal; P. D. Minchin, Kilkenny; R. W. Clayton, Wrexham; J. B. Wilson, Co. Cork; E. G. MacSweeney, Macroom; A. Hestage, Chester; P. J. Munn, Kirkcudbrightshire; T. Marshall, South Shields; L. G. Fink, Calcutta; J. A. Fink, Calcutta; L. F. Bucknell, Sydney; J. Orr, Co. Antrim; G. Macdonald, Kirkintilloch; J. E. H. Gentil, Mauritius; R. Holmes, Westmeath; T. White, Antrim; J. C. Edwards, Llanrhaidr; A. T. Brown, Dunfermline; R. Scott, Kinross-shire; D. V. Ryan, Co. Cork; C. E. Ross, Skye; and A. Mackellar, Glasgow.

Second Examination.—Of 83 candidates, the following 32 passed: G. S. Pope, Madras; J. G. McCandlish, Leeds; H. R. Preece, Cheltenham; D. Mark, Belfast; C. Pearce, Chilli; S. Wilson, Hanley; W. J. Leitch, Tyrone; D. M. B. Myers, Cloumel; G. Mason, Birmingham; H. H. H. Addenbrooke, Smethwick; F. H. Amner, Kew; T. S. Allan, Glasgow; W. Pirie, Arbroath; G. M. Grieve, Dundee; R. F. Granger, Whitby; F. M. Graham, Monmouth; W. Rae, Glasgow; P. McElligott, Kerry; J. M. Rohan, Mauritius; W. R. Lemon, Co. Armagh; W. J. H. Cumming, Kent; E. A. C. Hindmarsh, Calcutta; J. Nesbitt, Co. Derry; T. C. Patterson, Co. Donegal; T. E. Jones, South Wales; O. W. Morgan, Ceylon; J. S. Boyd, Renfrewshire; A. R. Douglas, Newcastle; T. Young, Kilwinning; P. F. Godfrey, Tipperary; W. D. Sweeny, Co. Mayo; and R. Maclean, Ross-shire.

Final Examination.—Of 70 candidates, the following 44 passed, and were admitted L.R.C.P. Ed., L.R.C.S. Ed., and L.F.P. and S. Glasg. G. A. Bannatyne, Rutherglen; E. A. Simeon, Delhi; A. E. Vaughan, Crewe; W. A. Frizell, Liverpool; J. B. Meredith, Queen's Co.; S. Mellor, Huddersfield; R. Aldous, Norfolk; H. Buxton, Lancashire; F. W. Browning, Monmouthshire; A. B. Watson, Norfolk; F. J. Pacey, Melbourne; W. Yorke, Glasgow; C. R. Pigg, Newcastle-on-Tyne; J. K. Coutts, Aberdeen; K. B. Narayan, Kuch Behar; A. Siddon, Bangalore; Miss Jessie Crossfield, Liverpool; W. Grey, Northumberland; S. J. Dunlop, Co. Antrim; A. Mill, Co. Antrim; H. Chadwick, Burnley; A. Bradshaw, Sierra Leone; H. Osborne, Notts.; P. J. Mehta, India; B. E. Jones, Crewe; J. H. Pestell, Australia; R. P. Shaw, Hereford; C. H. Sharpe, Norwich; C. F. Lovibond, Bridgewater; W. Bell, Enniskillen; A. Macdonald, Edinburgh; D. Barry, Co. Cork; W. W. Williamson, Scarborough; E. E. Craster, Middlebrough; A. G. Laidler, Stockton-on-Tees; H. F. Lawrence, Tasmania; A. H. Goodwyn, Devonshire; G. O. Moorhead, India; H. G. Mackie, Canada; C. Smyth, Limerick; H. C. C. McNell, Folkestone; G. H. Douthwaite, Warrminster; I. Crawford, Omagh; and W. B. Marston, jun., London.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—During the April sittings of the Examiners, the following candidates passed the Final Examination, and were admitted L.R.C.S.E.:

Miss Jane Elizabeth Waterston, Inverness; D. M. Greig, Dundee; and G. Abbott, Titchmarsh.

The following candidates passed the First Professional Examination for the Licence in Dental Surgery:

A. E. Donagan, Cambridge; E. J. M. Hodgkinson, London; T. Gregory, Edinburgh; J. S. Walker, York; R. K. Common, Edinburgh; K. E. O'Duffy, Dublin; and T. C. McKenzie, Edinburgh.

The following candidates passed the Final Examination, and were admitted L.D.S. Edin.:

G. W. Welham, London; H. B. Ezard, Bath; J. S. Walker, York; and K. E. O'Duffy, Dublin.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—At the usual Monthly Examination Meeting of the College, held on Friday, May 11th, the following Registered Medical Practitioners were admitted as Licentiates of the College:

The Licences to Practise Medicine and Midwifery.—D. M. Lindsay, L.R.C.S.I., Kilkree, Co. Down; J. A. St. George Whitty, L.R.C.S.I., Drogheda.

The Licence to Practise Medicine only.—J. A. Coen, L.R.C.S.I., Castlereagh, Co. Roscommon; J. M. Tidmarsh, L.R.C.S.I., Limerick.

The Licence to Practise Midwifery only.—J. P. Hubbard, M.R.C.S. Eng., Bloxwich, Walsall, Staffordshire; G. F. Hugill, L.R.C.P. Lond., Chislehurst, Kent.

At the same meeting of the College, the Licences to practise Medicine and Midwifery were conferred upon the following candidates who had passed the Fourth, or Final Professional, Examination under the Conjoint Scheme with the Royal College of Surgeons in Ireland, at the April Examinations, namely:

C. J. Hughes, Willowdale, Glenageary, Co. Dublin; P. G. Lee, Sydenham Terrace, Monkstown, Co. Cork; R. MacDougall, Drumleck, Hewth; H.

D. Mason, Yorrley, near Birmingham; W. F. Rowantree, Forthill House, Sligo; J. Seanson, 1, Chalgrove Terrace, South Circular Road, Dublin; V. P. Shiel, Mullingar; J. H. Swan, Diamond, Monaghan; Florence Nightingale, Tonus, Chard, Somerset.

MEDICAL VACANCIES.

The following Vacancies are announced:

- BALTINGLASS UNION.**—Medical Officer, Dunlavin Dispensary. Salary, £12 per annum, and fees. Applications to Captain Heighton, J.P., Honorary Secretary, Donard House. Election on June 13th.
- BIRMINGHAM AND MIDLAND SKIN AND LOCK HOSPITAL.**—Acting Surgeon. Applications by May 26th to J. E. Hartley, Esq., 13, St. Paul Square, Birmingham.
- BRIDGNORTH AND SOUTH SHROPSHIRE INFIRMARY, Bridgnorth.**—House-Surgeon. Salary, £120, with rooms, coal, gas, and attendance. Applications by May 23rd to the Honorary Secretary.
- BRIGHTON, HOVE, AND PRESTON DISPENSARY.**—House-Surgeon. Salary, £140, with apartments, etc. Applications by June 2nd to the Assistant Secretary.
- BRISTOL ROYAL INFIRMARY.**—House-Physician. Salary, £100 a year, with board, washing, and apartments. Applications by May 19th to the Secretary.
- CHELSEA HOSPITAL FOR WOMEN.**—Clinical Assistants. Applications by May 19th to the Acting Secretary.
- CHELSEA HOSPITAL FOR WOMEN.**—Resident Medical Officer. Salary, £80, with board and residence. Applications by May 31st to the Secretary.
- CHILDREN'S HOSPITAL, Birmingham.**—Assistant Resident Medical Officer. Salary, £40, with board and lodging. Applications by June 6th to the Secretary.
- CHILDREN'S HOSPITAL, Birmingham.**—Resident Medical Officer. Salary, £80, with board and lodging. Applications by June 6th to the Secretary.
- CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victor Park, E.**—Assistant Physician. Applications by June 7th to the Secretary.
- COUNTIES ASYLUM, Carlisle.**—Assistant Medical Superintendent. Salary, £120, with board. Applications by May 29th to Dr. Campbell, Garland Carlisle.
- EAST LONDON HOSPITAL FOR CHILDREN, Shadwell, E.**—Assistant Surgeon. Applications by May 23rd to the Secretary.
- EAST LONDON HOSPITAL FOR CHILDREN, Shadwell, E.**—Surgeon. Applications by May 23rd to the Secretary.
- FULHAM UNION.**—Resident Medical Superintendent of Infirmary, and Medical Officer of the Union Workhouse. Salary, £350, with residence, etc. Applications by June 5th to the Clerk to the Guardians.
- GORDON HOSPITAL FOR FISTULA, etc., Vauxhall Bridge Road.**—Assistant Surgeon. Applications by May 26th to the Secretary.
- HALIFAX INFIRMARY AND DISPENSARY.**—Senior House-Surgeon. Salary, £80 per annum, with board and residence. Applications by May 22nd to Dr. E. West Symes, Hope Hall, Halifax.
- HOSPITAL FOR DISEASES OF THE THROAT, Golden Square.**—Resident Medical Officer. Salary, £50 per annum, with board and lodging. Applications by May 26th to the Honorary Secretary.
- KING'S COLLEGE HOSPITAL.**—Assistant-Surgeon. Applications to the Secretary.
- LONDON TEMPERANCE HOSPITAL, Hampstead Road.**—Surgeon. Applications by June 16th to the Secretary.
- LOWESTOFT FRIENDLY SOCIETIES MEDICAL INSTITUTION.**—Surgeon. Salary, £160 per annum, with extra fees. Applications by May 21st to Mr. J. Hammond, 4, Raglan Street, Lowestoft.
- METROPOLITAN ASYLUMS BOARD: SMALL-POX HOSPITAL SHIP'S Long Reach.**—Assistant Medical Officer (Clinical Assistant). Board, furnished apartments, and washing. Applications by May 25th to the Clerk to the Metropolitan Asylums Board, Norfolk House, Norfolk Street, Strand, W.C.
- METROPOLITAN HOSPITAL, Kingsland Road.**—Assistant House-Surgeon. Salary, £40 per annum, with board and residence. Applications by May 21st to the Secretary.
- NORTH LONDON CONSUMPTION HOSPITAL, Hampstead and London.**—Resident Medical Officer. Salary, £50 per annum, with board and lodging. Applications by June 2nd to the Secretary.
- NORTH STAFFORDSHIRE INFIRMARY.**—House-Physician. Salary, £100, with board, washing, and apartments. Applications by May 23rd to the Secretary.
- OWENS COLLEGE, Manchester.**—Professor of Surgery. Applications by June 9th to the Registrar.
- ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road.**—Junior House-Physician. Salary, £50 per annum, with board and lodging. Applications by May 19th to the Secretary.
- ST. PETER'S HOSPITAL FOR STONE, etc., Henrietta Street, Covent Garden.**—House-Surgeon. Honorarium, 25 guineas, with board, lodging, etc. Applications by May 24th to the Secretary.
- SMALL-POX HOSPITAL, Birmingham.**—Resident Medical Superintendent. Salary, £150 per annum, with board, etc. Applications by May 25th to the Chairman, Health Committee, Council House, Birmingham.
- UNIVERSITY COLLEGE, LONDON.**—Professor of Botany. Applications by May 30th to the Secretary.
- VICTORIA HOSPITAL FOR CHILDREN, Chelsea.**—House-Physician. Honorarium of £50, with board and lodging. Applications by June 2nd to the Secretary.
- VICTORIA HOSPITAL FOR CHILDREN, Chelsea.**—House-Surgeon. Honorarium of £50, with board and lodging. Applications by June 2nd to the Secretary.

May 19, 1888.]

WELLINGBOROUGH AND DISTRICT MEDICAL INSTITUTE.—Medical Officer. Salary, £230, and fees, with dwelling-house, etc. Applications to G. Bayes, Esq., Jackson's Lane, Wellingborough.

VEST LONDON HOSPITAL, Hammersmith Road, W.—Assistant Surgeon.—Applications by May 24th to the Secretary.

WESTPORT UNION.—Medical Officer, Westport No. 2 and Louisburgh No. 2 Districts. Salary, £39 per annum, and fees. Election on June 24th.

MEDICAL APPOINTMENTS.

ANDERSON, John, M.D., C.I.E., appointed Visiting Physician to the Seaman's Hospital Society, Greenwich, vice H. T. Griffiths, M.D., resigned.

BOOTH, A. E., M.B. Edin., appointed Assistant House Surgeon to the Liverpool Infirmary for Children, vice H. E. Jones, M.B., resigned.

BEDIN, H. A., M.B., M.R.C.S., appointed Surgeon to the No. 1 Section of the Manchester Ship Canal.

BREWIS, A. S., M.B., M.R.C.S., appointed House-Surgeon to the Monkwearmouth Dispensary, vice H. Sheldermine, M.B., resigned.

RYDEN, F. W. A., L.S.A., appointed Assistant House-Surgeon to the Rotherham Hospital.

LARKE, W. F., M.R.C.S. Eng., M.B. Lond., appointed House-Surgeon to the Newport and County Infirmary, vice W. Basset, M.R.C.S., L.R.C.P., resigned.

LENDINEN, J. George, reappointed Medical Officer of Health to the Coseley Urban Sanitary Authority.

OLMAN, W. S., M.B. Lond., M.R.C.S., appointed House-Physician to the Hospital for the Paralysed and Epileptic, vice R. T. Williamson, M.B., M.R.C.S., resigned.

LAWSON, W. E., appointed Physician to the "Churchill Home" for Women, Cliswell Street, Finsbury Square, E.C.

HACKETT, C. Alex., M.R.C.S., L.R.C.P. Lond., L.S.A., appointed Junior House-Surgeon to the Ancoats Hospital, Manchester.

MUTT, W. K., M.R.C.S. Eng., L.S.A. Lond., appointed Junior House-Surgeon to the Bury Dispensary Hospital, vice L. Hickey, M.B. Durh., M.R.C.S., resigned.

ISAAC, G. Washington, M.B. Edin., appointed Honorary Medical Officer to the St. Pancras Female Charity School and Orphanage, vice A. W. Cadman, M.R.C.S., etc., resigned.

ONES, John Thomas, L.R.C.P., L.R.C.S. Edin., appointed Medical Officer and Public Vaccinator to the Whitford District of Holywell Union, vice H. L. Davies, M.B., resigned.

LANE, W. Arbuthnot, F.R.C.S., appointed Assistant-Surgeon to Guy's Hospital.

EACH, J. Comyns, M.D. Durh., reappointed Medical Officer to the Rural Sanitary District of Sturminster.

UCAS, R. Clement, M.B., F.R.C.S., appointed Surgeon to Guy's Hospital, vice Thomas Bryant, F.R.C.S., resigned.

MCQUITTY, W. B., M.D., M.Ch., M.A.O., appointed House-Surgeon to the Royal Hospital, Belfast, vice S. A. Powell, M.B., M.Ch., M.A.O., resigned.

HARRY, John William, L.R.C.P., L.R.C.S. Edin., appointed Medical Officer to the Workhouse, Holywell Union, vice H. L. Davies, M.B., resigned.

HENDALL, Percy, M.D., M.R.C.S. Eng., appointed Assistant Colonial Surgeon at the Gambia.

PENCER, Walter, L.R.C.P., L.R.C.S. Edin., appointed Deputy-Coroner for the Bedford District of the County of Nottingham.

PENCER, W. H., M.A., M.D. Cantab., appointed Consulting Physician to the Bristol Royal Infirmary.

Dr. GRANT BEY, of Cairo, has been elected an honorary member of the New York State Medical Society.

THE LATE DR. WILLIAM E. BUCK.—A chapel has been erected at the Leicester Infirmary in memory of William Elgar Buck, M.A., M.D., formerly honorary physician to the infirmary.

THE POPE has been graciously pleased to confer upon Dr. L. Kenny, M.B., Ch.B. Melb., the title and dignity of Chevalier of the Order of Gregory the Great. Dr. Kenny is a member of the British Medical Association.

Dr. MACPHAIL, who has acted as Assistant Medical Superintendent of the Cumberland and Westmoreland Asylum at Carlisle or the last six years, has been appointed Medical Superintendent of the Derby Borough Asylum. Dr. Macphail is a graduate of the Edinburgh University, and was awarded the medal of the Medicopsychological Association in the year 1884, for his researches on the blood of the insane.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—The following officers have been elected for 1888-9. *President*: Dr. J. W. Martin; *Vice-President*: Dr. de Bartolomé; *Treasurer*: Mr. G. S. Taylor; *Secretary*: Mr. Simeon Snell; *Other Members of the Committee*: Mr. Garrard, Mr. W. F. Favell, Mr. A. Jackson, Mr. Pye-Smith, Dr. Wynne, Mr. Browning, Mr. E. Skinner, and Dr. Hargreaves. *Pathological Committee*: Mr. C. Atkin, Mr. Frank Harrison, Dr. Locking, and Dr. Burgess.

THE MEDICAL COLLEGES AND SCHOOLS. SCHOLARSHIPS AND PRIZES, WINTER SESSION, 1887-88.—LONDON HOSPITAL COLLEGE.—Clinical medicine: scholarship, Mr. H. E. Skyrme; hon. certificates, Mr. W. S. Fenwick, and Mr. Beckett (equal). Clinical

surgery: scholarship, Mr. W. S. Fenwick; hon. certificates, Mr. H. E. Skyrme, Mr. M. A. Rudd.—ST MARY'S HOSPITAL SCHOOL.—The first-year prize of £3 3s. in anatomy and histology, Mr. Evans, and that of £3 3s. in chemistry, Mr. Mander Smythe. The second-year prize of £3 3s. in anatomy, Mr. L. Rogers, and that of £3 3s. in general physiology, Mr. Winter. The third-year prizes of £3 3s. in medicine, £3 3s. in surgery, £3 3s. in pathology, and £3 3s. in operative surgery, Mr. R. H. Cole.—KING'S COLLEGE.—The Warneford scholarship of £25 per annum for two years, Mr. Harry Lambert Lack; the surgical clinical prizes of £3 each, Mr. Harry Lambert Lack and Mr. Arthur Henry Cheadle.—UNIVERSITY COLLEGE.—The Fellowes gold clinical medal, Mr. G. R. Murray; the Fellowes silver clinical medals, Messrs. W. B. Ransom, B. M. H. Rogers, and W. J. Broadhurst; the Liston gold medal, Mr. W. E. Ransom.

DIARY FOR NEXT WEEK.

TUESDAY.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8.30 P.M.—The following papers will be read. Dr. P. Kidd and Mr. H. H. Taylor: On the Value of the Tubercle Bacillus in Clinical Diagnosis. Sir William B. Dalby: The Removal of Bony Growths from the External Auditory Canal. Drs. Alfred Sangster and Frederick W. Mott: Pemphigoid Eruption with Changes in Peripheral Nerves.

WEDNESDAY.

BRITISH GYNECOLOGICAL SOCIETY, 8.30 P.M.—The following papers will be read. Dr. Fancourt Barnes: Complete Chronic Inversion of the Uterus. Mr. Lawson Tait: The Influence of Removal of the Uterus and its Appendages on the Sexual Appetite. Dr. Henry T. Rutherford: Treatment of Uterine Fibroids by Hydrastis Canadensis. Specimens will be exhibited. Council, 8 P.M.

THURSDAY.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8.30 P.M.—Special Meeting.—Marshall Hall Prize, 1888.—Dr. Walter Holbrook Gaskell, F.R.S.: The Relations between the Function, Structure, Origin, and Distribution of the Nerve-Fibres which compose the Spinal and Cranial Nerves.

FRIDAY.

QUEKETT MICROSCOPICAL CLUB (University College, Gower Street), 8 P.M. Papers by Messrs. Buffham, Smith, and Priest.

CLINICAL SOCIETY OF LONDON, 8.30 P.M.—Dr. Ord will read a summary of the conclusions arrived at by the Committee on Myxœdema. Mr. A. E. Barker: A case of Intussusception of the Cecum, Ascending and Transverse Colon treated by Abdominal Section. Mr. R. W. Parker: Two cases of Intussusception, with special regard to Symptoms and Treatment. Mr. Page: Two cases of Rupture of Intestine without External Wound. Dr. Ward Cousins: Case of Stone, in which Lithotomy was performed twice within two months. Living Specimens:—Dr. White and Mr. Henry Baker: Two cases of Unusual Congenital Deformity.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 5s. 6d., which should be forwarded in stamps with the announcement.

MARRIAGES.

WRIGHT—KENT.—On May 9th, at St. Mary's, Kippington, Sevenoaks, by the Rev. Prebendary Tate, vicar, and the Rev. C. E. J. Carter, of St. Giles, Cripplegate, Bernard D. Zorapore Wright, M.R.C.S., and L.R.C.P., second son of J. W. Zorapore Wright, of Barton Fields, Canterbury, to Alice, third daughter of the late William Kent, of Jondaryan, Darling Downs, Queensland.

SNELL—GOLDNEY.—On the 14th April, at All Saints' Church, Berbice, British Guiana, by the Ven. Archdeacon Farrar, B.D., assisted by the Rev. Canon Butt, B.A., and the Rev. Francis Welch, George Snell, M.R.C.S. Eng., Medical Superintendent Public Lunatic Asylum, to Louisa Augusta, youngest daughter of G. J. Goldney, Manager, Colonial Bank, Berbice.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS respecting editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

In order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the office of the JOURNAL, and not to his private house.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate beforehand with the Manager, 429, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication. CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

CLINICAL LECTURE

ON
HÆMATURIA.*Delivered at University College Hospital.*By BERKELEY HILL, F.R.C.S.ENG., M.B.LOND.,
Professor of Clinical Surgery in University College, London.

HÆMATURIA, or bloody urine, is only a symptom; but one which varies much in importance. It may signify a trivial injury or a dangerous and rapidly fatal condition. Therefore an analysis of the characters that hæmaturia may assume is worth our attention this afternoon.

Blood may escape into the urine at any part of the urinary tract. Hence, for convenience, I shall arrange the various forms according to their locality, namely, from the kidney, including the pelvis and ureter; from the bladder; from the prostate; and from the urethra. The multitude of the causes of hæmaturia compels me to dwell in my remarks only on those varieties which concern the surgeon. Nevertheless, he should know all the causes that he may distinguish those needing surgical treatment.

General Causes.—Old age brings to some men enlargement of the prostate, and the enlarged organ, if congested, is more liable to bleed than when in its unenlarged condition. In women, at the menopause, or even before that crisis is reached, blood is sometimes voided from the kidney vicariously for the menstrual flow. Also, in women, mixing of the menstrual discharge with the urine after it has left the urethra must not be forgotten. In children, malignant tumours of the kidney are more common than in adults, and they often bleed copiously. In certain countries parasitic diseases prevail which have hæmaturia for a leading symptom. In Egypt and South Eastern Africa, the bilharzia hæmatobia is the common parasite which produces the hæmaturia. In China, bloody urine is caused by the filaria sanguinis hominis. Some general diseases which modify the blood, such as purpura, scarlet fever, measles, or typhoid, and in warm climates, malarious affections, may cause hæmaturia. Certain drugs, for example, lead, mercury, arsenic, cantharides, turpentine, or copaiba, and, it is said, asparagus, will provoke bleeding from the kidney. Exposure to cold and damp, heart-disease, or gonorrhœa, by causing congestion of the kidney, will produce bloody urine. Likewise, sudden suppression of a customary discharge, such as epistaxis or hæmorrhoidal flux, may be replaced by hæmaturia. Violent exertion of any kind will determine congestion of the kidney in some persons. Even shaking in a rough carriage, hunting, long marches, carrying heavy weights, wrestling, the vomiting that sometimes occurs during the throes of parturition, and excessive copulation produce hæmaturia. It must be admitted that chronic renal disease is often present when bleeding follows the exciting causes I have mentioned.

The characters of bloody urine vary much. Sometimes the effusion of blood is sudden and unexpected; sometimes there are premonitory signs. The quantity and appearance of the blood also differ much. The urine, often clear and limpid, is rosy or crimson when it has been evacuated immediately after extravasation; but if the blood has remained some time in the bladder, the urine acquires a dirty brown hue, porter-like if copious, smoky when scanty. This change is due to the hæmaglobin being changed to methæmaglobin by the action of the acid in the urine.

Again, clots like black 'currant jelly, or narrow worm-like coagula, may come away. The latter are casts of the urethra, or, in rare cases, of the ureter. Under the microscope minute clots of thread-like form may sometimes be detected; these are casts of the kidney tubules.

The corpuscles undergo changes. By soaking in urine they swell up, become vacuolated, and grow colourless. They may then be confounded with discoid oxalates or torulæ; both these objects are smaller than blood cells, and the torulæ are generally oval, and have a bright nucleus. Besides, the ocular test, which suffices to distinguish most cases of blood in the urine, and are the only ones by which the condition known as hæmaglobinuria can be diagnosed from bloody urine there are the tests with guaiacum and with the spectroscope. For the guaiacum test, shake a

few drops of fresh tincture of guaiacum in a drachm of urine. Then, if some ozonic ether be added, a blue colour comes to the mixture. Two sources of fallacy exist. The urine does not always give the blue tint, and if iodide of potassium be present, a blue reaction will occur, even if no blood be present.

The spectroscope: this somewhat complicated process of medical physics and chemistry is too intricate to explain in a few words, but we have some specimens prepared for us by Mr. Barton, Dr. Ringer's house-physician, who will presently demonstrate them to you. For a detailed description of the processes to be employed you may also refer to Dr. McClun's work, *The Spectroscope in Medicine*, 1884.

It is often possible to ascertain at which part of the urinary tract the blood escapes into the urine by draining the urine from the bladder as soon as it oozes through the meatus of the ureters, by placing a catheter in the empty bladder after that organ has been carefully washed, and leading the secretion at once from the body. Indeed, attempts have been made to collect the urine from one ureter only by means of a catheter with a short beak and a long eye. The catheter is so laid in the bladder that its long eye shall lie closely against the outlet of one ureter, and drain away the urine dripping from that ureter to the exclusion of the urine arriving by the other ureter into the bladder. When there is blood in the urine, the act of micturition is often more frequent than at other times, partly because the effusion of blood excites the bladder to contract, partly because cystitis is a common accompaniment of hæmaturia, and probably in some cases by irritation sympathetic with renal disease. The quantity of blood lost varies much. The bleeding may be constant, that is, the urine may be always tinged with blood, or the urine may be at times perfectly free of blood. The duration of the attack also varies much; usually, when intermittent, the length of the attack is short, and the intervals extend over weeks or months, or even years.

Local Causes.—With respect to the kidney, blows on the loin wounding the kidney or the ureter, and operations on the kidney produce hæmaturia. The condition called "movable kidney" is also frequently characterised by hæmaturia. Common causes are nephritis or pyelo-nephritis set up by calculi, tubercle, cancer, or villous tumour in the kidney or ureter. The irritation of stronguli or other entozoa in the pelvis may be the exciting causes of hæmaturia. Either with or without these accidental provocatives, blood is lost from the kidney in various inflammatory affections, as in acute suppurative nephritis, in acute congestion without suppuration, or in advanced stages of Bright's disease.

The kidney is probably the most frequent source of bloody urine; but the signs of renal hæmorrhage are often negative, and the diagnosis is reached in many cases only by exclusion. Indicative of renal bleeding are the following: pain or sense of weight in the loins, with tenderness on pressure. In the sediment of the urine casts of the kidney tubules, with minute calculi or uric acid crystals attached to the casts, are often found. When the bleeding is due to some general condition, or is a sequela of acute disease, the diagnosis of the renal source of the blood is helped by the history of the illness, by signs of cardiac disease, by the presence of anasarca, and, as renal bleeding is often scanty, by the dark, smoky aspect of the urine. "Smokiness" is produced when the quantity of blood is small and evenly diffused through the urine, but it is not necessarily only set free from the kidney. There will be in other cases the signs special to the affection of the kidney that causes the hæmorrhage. There would be also no indication of disease in the bladder, prostate, or urethra. If there have been injury, exposure to cold, or excessive exercise, the bleeding will be free though short-lived. When renal calculus is the cause of the bleeding, the blood is rarely copious. The urine is acid, and has a plentiful deposit of mucopus, with perhaps tubule casts. There is often a history of long-lasting pain in the loins, shooting along the course of the ureter, exciting in some cases slight pain at the neck of the bladder, and increased frequency of micturition. Added to these signs may be an enlarged kidney, easily felt by reason of its dilated pelvis, which may even fluctuate on palpation through distension with urine and pus, when the ureter has contracted after ulceration.

Tubercular disease would have similar symptoms, but small calculi or uric acid crystals would be absent from the urinary deposit. There would be pus in the urine long before the advent of blood. Tubercular disease may attack the ureter, and so allow blood to mingle with the urine. This complication would be in-

dictated by tenderness on pressure along the course of the ureter, with pain in the loin and groin. Tubercle of the ureter is probably never seen unless the kidney or bladder is affected also.

In cancer of the kidney, in addition to lumbar pain, frequent and painful micturition, there is sometimes enlarged kidney, or a tumour in the loin is palpable. Bleeding is a constant symptom, sometimes copious and intermittent, more often scanty and continuous, though varying in amount from mere smokiness of the urine to a dark porter-like fluid with coagula. With such uncertain signs it would not be possible to diagnose cancer from calculus, tubercle, or other renal affection. In time the growth will sprout into one of the calyces, and fragments of it may be found in the deposit of the urine. Gradually, the increasing severity of the symptoms and the wasting of the patient confirm the malignant nature of his disease.

Syphilis is occasionally the cause of renal bleeding. In a patient under my care, who had tertiary disease of the pharynx, there was for some weeks persistent albuminuria; to this was added a sudden attack of hæmaturia, with dull pain in the right loin. The urine was dark like coffee for four days; after that it became light brown, then smoky, and gradually regained its natural colour; ultimately no more than traces of albumen remained. Dr. Sandby (*JOURNAL*, December 17th, 1887) relates a somewhat similar case, but in his case some hyaline casts were also detected in the urine, and the infection was inherited.

In the bladder blood may escape into the urine through rupture of that viscus by blows on the hypogastrium, by laceration in crushed pelvis, or by too rough handling of the lithotrite or sound. Even too rapid evacuation of the bladder after over-distention may produce it in patients whose veins are varicose beneath the mucous membrane about the neck of the bladder. Cystitis from any cause, and the ulceration produced by stone, tubercle, or cancer, often bring on bloody urine. The fibrous, the sarcomatous, and the villous tumour, each in their degree, though the villous more than any other, have bleeding as an important symptom. Lastly, the bilharzia hæmatobia has its most frequent seat in the walls of the bladder.

When bleeding is caused by stone in the bladder, the loss of blood is commonly slight, intermittent, and mainly at the end of micturition, when the chafed part of the bladder against which the stone lies is compressed. Then a few drops of blood are expelled from its surface. Where ulceration is extensive, or where the mucous membrane is inflamed, the urine is often discoloured by blood which has exuded between the acts of micturition. The quantity of the blood is usually increased by rough exercise. In addition, there would be painful micturition, alteration of the stream, and other signs of stone to be obtained by sounding.

Tubercular disease, though extending into middle life, mainly affects youths and young adults. Here bleeding is a very minor symptom. It shows itself in the shape of clot in the purulent deposit, or clots are washed out with the first flow of urine, or a little bright blood comes away at the end of the stream. The signs of tubercle closely resemble those of stone: the distinctions being the escape of clots before the flow, and the early appearance of severe pain during and after the flow of urine. Sounding the bladder is also much more painful to the patient when tubercle is present, owing to the customary seat of tubercle being at the neck of the bladder, and the sound strikes the ulcerated surface.

When a tumour growing in the bladder is the source of the hæmaturia, the form the bleeding takes varies somewhat with the structure of the tumour, though this variation does not always take place. One reason why all the different growths may have free bleeding for an early symptom is the fact that the several tumours may have a papilloma as a part of their structure, while the base is fibrous, sarcomatous, or even epitheliomatous. Roughly speaking, the papillomata bleed abundantly at intervals, without causing much pain or inconvenience. The fibromata and sarcomata also bleed obstinately, and at short intervals. The epitheliomata usually cause much pain and irritation before the bleeding becomes important.

Bearing in mind the exceptions to this general habit, it may be inferred that the tumour has a dendritic or villous form if the blood is voided copiously at first, appearing without pain or increased frequency of micturition, and giving the patient no physical distress. The loss of blood continues for an indefinite time, from three or more days to a week or more, and then stops as suddenly as it began. While going on it seems not to be affected either by rough exercise or by rest. The amount of blood present

in the urine varies much. Most commonly it is copious and florid, sometimes dark crimson; when the loss of blood is very slight the urine may be merely smoky. A great characteristic when the bleeding is scanty is the flow at first of clear urine, but as the bladder empties, the stream becomes mainly bright blood. In such cases the patient may feel a little smarting as the contraction of the bladder squeezes blood from the growth. Characteristic also of bleeding from papilloma is the kind of deposit which settles in the urine. It consists of a loose reddish-brown sediment made up of brown coagula and whitish flocculent masses of discoloured fibrine. Not infrequently the deposit contains fragments of the tumour, which can be recognised, and the diagnosis thereby made certain. By sounding the bladder, in many cases the sound can be so directed as to catch against or to slip over the growth, and thus mark its position in the bladder.

The hæmorrhage having ceased, the urine becomes clear, and may remain so for months. More commonly, a little blood is lost at the end of micturition on most days, but it may disappear utterly for years. Sooner or later, nevertheless, perhaps in the same painless way as before, the bleeding reappears, and after the second or third recurrence, increased frequency of micturition and dull, aching pain at the end of the flow become constant phenomena. When clots like black jelly are washed along the urethra, they cause pain if they are large. This intermittent hæmaturia may recur for years without affecting the patient's health or apparently shortening his life. There are specimens of bladders with such tumours in the museums, taken from persons who lived to be 80 years of age, and died from causes unconnected with the bladder. Further, cases are recorded where the whole tumour was extruded, and the patient recovered completely. Such a happy ending must not be looked for; in nearly all cases, if untreated, the papilloma sets up cystitis, or causes obstruction of the outlet of an ureter, and so dilatation of the pelvis, with destruction of the gland, and ultimately death by great suffering.

The following case of simple papilloma was treated by me in this hospital in 1885. A temperate man of 55 first noticed loss of blood from the bladder in the summer of 1879. At that time, during micturition, the urine came away at first quite clear; then a sense of more to come was felt, and a few drops of pure blood would be ejected. Micturition was not increased in frequency, nor was there any pain. The escape of blood, until the spring of 1880, was only occasional and never large. In March, 1880, the urine for two days was charged with blood, and bright crimson in colour. The bleeding then stopped altogether till the beginning of January, 1881; then one copious loss of blood took place. On January 22nd there was a repetition of bleeding at every voidance of urine; great clots came away, and a little scalding was felt for a few minutes after the flow had ceased; thenceforward no discomfort was felt till the next discharge of urine. There was no increased frequency; the urine was retained all night. There was no spasm nor violent effort to drive out the clots; but there was pain if the clots were large enough to fill the urethra. This attack of hæmaturia continued for nine days, and then suddenly stopped. After thirteen days the blood reappeared, and the urine was more or less charged with it for six weeks, and then bleeding again entirely ceased for a month. The blood came again copiously and again ceased; but thenceforth the urine usually contained a copper-coloured sediment, and at the end of micturition a few drops of blood escaped, with a twinge of pain. Three and a half years after the first bleeding cystitis began, and the patient's suffering gradually became severe. Fifteen months later, the patient, being exhausted by cystitis, allowed me to operate on him. This was done on May 5th, 1885. A perineal exploring incision was made, and a suprapubic one into the bladder. Through the upper incision a long frimbriated growth could be seen attached to a short stump, near the opening of the left ureter. This was noosed by an *écraseur* passed through the perineal incision. The patient's exhausted state made the recovery slow and tedious. In January, 1886, he again came under my care, and I crushed a small calculus. Since that operation the patient has enjoyed good health, and there has been no return of vesical disorder.

When the tumour is sarcomatous or epithelial, and no part of it is papillomatous, blood does not escape, as a rule, in the copious manner that attends papilloma. The progress of the disease is more rapid, and there is usually pain in the hypogastrium or perineum before bleeding commences; though cases are recorded where eight or ten years elapsed in which intermittent hæmaturia

was the leading symptom before the condition of the patient became urgent. Usually ulceration begins in a year or less; then voidance of clot is a daily occurrence, and the urine is purulent from cystitis. With epithelioma the patient is nearly always approaching old age; but sarcoma and papilloma, though affections of late middle life, are occasionally met with in young adults.

The following case is a good example of epithelioma of the bladder. I saw with Mr. Marrant Baker, in October, 1885, a gentleman, aged 61. The first attack of bleeding had occurred one year before and, stopping for a fortnight, had recurred, to again subside, leaving only a dull pain after micturition, which act took place about every three hours by day and night. When I saw him the bleeding had set in again, and was accompanied by great spasm and almost constant calls to make water. For a few days his suffering was constant. The urine was dark crimson, mixed with clots that could be got rid of only with great difficulty. This attack lasted about a fortnight and then subsided, to return two weeks later in greater severity. The tumour, which is now before you, I removed through the perineum; Mr. Baker and Mr. Pollard being good enough to help me. Its structure is partly papilliform, but mainly epithelial. The fragments of tumour, as you see, fill a six-ounce bottle. The patient was thoroughly relieved of his sufferings by the operation, and for a time did well; but six weeks later, the tumour began to grow again, and the patient sank under an attack of peritonitis of four days' duration.

Last summer we had in our wards a case of intermittent hæmaturia from bilharzia in a woman who had lived her whole life in England, and therefore her history is of much interest to us. The bilharzia hæmatobia was discovered by Bilharz in 1851 in Cairo when, in conjunction with Griesinger, he was investigating the diseases of the Egyptians. It is an elongated bisexual entozoon. In its perfect phase, it inhabits the veins of the portal system, the hæmorrhoidal veins, and the veins of the bladder, ureter, and pelvis of the kidney. From these proper habitats, it may invade others. Griesinger found egg shells in the blood of the left ventricle, and Kartalis found the ova in the vena cava inferior, and Mackie in the lungs and liver. The entozoon most probably enters the human body in drinking water, for it is very prevalent in Egypt among the fellahen who drink the Nile water unfiltered, and among the native population of South Africa, while Europeans who are careful of the purity of their drinking water escape the disease. Dr. John Harley, who proved the Egyptian disease to be endemic in South Africa, suggested that the animal may enter by penetrating the skin as well as by the stomach to reach the uropoietic system.

The male has a flattened body, about half an inch long; he is thicker and shorter than the female, which he receives for purposes of copulation into a groove, or gynæcophoric canal, and thus has a somewhat cylindrical appearance. The female is cylindrical and filiform, about three-quarters of an inch long. The mature entozoa, after impregnation, lie in the submucous tissue of the kidney, or other part to which they migrate, the bladder, transverse colon, descending colon, or rectum, in smooth-walled spaces formed from dilated blood-vessels. There the female lays the eggs, which gradually work their way to the mucous surface. The ova are about 1-170th of an inch long, almost oval, having an outer shell of hard material; the contents are granular. A spike is attached to the smaller end of the cell of those which escape in the urine; but the spike is at the larger end of those which come from the intestine. The granular contents of the unripened egg become, when mature, a definite cell within the outer case, and, according to Sir William Roberts, exhibit at that stage slowly expanding and oscillating movements. The eggs do not apparently hatch in the urine until that fluid is diluted with plain water; at least, that was so in our patient. In water the hatching is rapid, and the embryo, more elongated than the ovum, ("flask-shaped," Sir W. Roberts), splits his shell and emerges covered with cilia. The cilia give him independent motion, so that he may be seen rolling on his long axis across the field of the microscope. What further development the embryo undergoes before he is ready to enter the human body to perfect his form is unknown. Probably he utilises some water mollusc as his second host, and then, escaping as a cercaria, is swallowed by man in drinking. It is supposed that the spinee assist the ova in boring their way to the surface of the mucous membrane, under which they collect in numbers and cause inflammatory swelling; so that the surface is marked by irregular projections of nodular or polyphoid form. Some of the raised patches are injected and

echymotic, others yellowish or covered with tough mucus or bloody exudation which contains masses of ova. From time to time these masses soften, ulcerate, and blood escapes in quantity with the cells so set free. In some cases the excrescences become so polypoid that they form real tumours, as may be seen at the College of Surgeons. Such projections have been removed by Dr. Mackie, of Alexandria, with the *éraseur* from the wall of the rectum to the great relief of the patient. When the eggs mass together in the ureter, that duct is narrowed; urine may collect in the pelvis of the kidney, and thus hydronephrosis is produced. The congeries matted together by mucus often form the nuclei of stones in the bladder. In the intestine, dysentery with ulceration is produced. When an indefinite time has elapsed, the parasite dies and many patients recover after years of more or less constant suffering. In a considerable number nevertheless death follows by exhaustion through cystitis and perineal abscess with fistulæ or even rupture of the bladder. In the tracts of these fistulæ Mackie found the ova in great quantity. To these sequelæ must be added the effects of septic disease and of great loss of blood. Similarly, fatal disease of the intestine or pelvic organs may follow the proliferation of the parasite in the portal or hæmorrhoidal systems.

The symptoms are essentially chronic and vary according to the locality infested by the parasite. Respecting the length of time necessary for the maturation of the worm after its inception into the body, Sir W. Roberts noted that bloody urine appeared about four months after the patient had drunk the water of the Nile in Egypt. The common symptoms are occasional attacks of lassitude, pains in the back or limbs or perineum, with intermittent hæmaturia and pain at the end of micturition. Between the attacks the patient feels well and the urine may be free of sediment, though the cells still pass in the urine. In time there comes generally cystitis, and the urine is turbid during the intervals of hæmorrhage, and micturition is frequent. In severe or fatal cases the course depends on the particular complication which sets in. The case which I am about to relate to you afforded us an opportunity of witnessing many of the symptoms described by those who have watched the disease in Egypt and elsewhere. The lassitude, the dull pain, the intermittent hæmorrhage, and perhaps the enlarged kidney, were characteristic; while the presence of ova in the urine was pathognomonic of bilharzia.

The following case of bilharzia hæmatobia is, I believe, the second observation which has been recorded as occurring in a person living wholly in this country. The other case is mentioned by Mr. Reginald Harrison. That case was, at the time Mr. Harrison wrote, under the care of Dr. Davidson in the Liverpool Royal Infirmary. No details are given by Mr. Harrison. These are the notes of the case which occurred in this hospital.

Mary Ann A., aged 40, was admitted under the care of Dr. Graily Hewitt on February 18th, 1887. Her general history was good. She was born in Kent, and had lived all her life at Erith or Gravesend. Her parents, brothers, sisters, and children were all healthy. She had seven children and one miscarriage. The last child was born in June, 1885. The catamenia appeared at 16, and remained regular till the present illness, which began in October, 1886. At that time the catamenia were delayed for fourteen days. A free hæmorrhage then took place *viâ* the urethra, during micturition, in which the patient estimated that three pints of blood were lost in twelve hours. During her stay in hospital the catamenia resumed their accustomed regularity. This slight disturbance of the menses was the only premonitory symptom of sufficient gravity to attract the patient's attention before the bleeding began. Until January there was no copious bleeding, but small clots were frequently passed in the urine. The bleedings were preceded by chilliness and coldness of the extremities. In December there was low fever, which lasted several weeks. On January 7th there was again bleeding to half a pint, and on the 8th a smaller quantity was lost. After that date small clots were passed till the 27th, when over two pints of clotted blood came away. On February 11th bleeding began again, to be repeated on three subsequent occasions to a small amount. Before the hæmorrhages the urine was very scanty and high-coloured, but quite clear, and micturition was painful towards the end of the act, not afterwards. Each time that the bleeding ceased the urine was abundant and pale, and the act of passing it was no longer painful. When the blood was ejected in large quantity it settled at the bottom of the chamber-pot, leaving the supernatant urine clear and of the ordinary yellow colour. Micturition took place usually every two hours by day and twice by night. When the patient

was admitted the right kidney could be felt, but was not obviously enlarged. It was not tender. The character of the blood was as already described. The quantity varied between 25 ounces and 72 ounces in the way already mentioned. On the subsidence of the hæmorrhage the quantity increased rapidly. The urine was always turbid, usually acid, sometimes neutral or alkaline. Albumen was always present, never less than one-twentieth part. The specific gravity varied greatly with the quantity. The deposit, during the first five weeks of the patient's stay in hospital, consisted of blood clot, blood discs, pus, and mucus. The peculiar cells of the ova of bilharzia were not discovered till later. After the patient's admission the bleeding was copious on February 24th and from March 11th to 15th, but the latter in part followed a dilatation and digital exploration of the urethra, which I performed at the request of Dr. Graily Hewitt on March 14th. At the time of the examination the right kidney was much enlarged, very movable, and indistinctly lobulated. Its anterior border reached to a point midway between the umbilicus and the iliac crest. It was also painful when handled. In the bladder nothing was felt beyond a slight unevenness of the wall near the fundus on the right side. The urethra was healthy. The womb was slightly retroverted.

On March 25th, the patient was transferred to my ward. During the following week the urine was carefully examined by Mr. J. Pearson, the dresser, being drawn from the bladder by catheter for this purpose. That gentleman detected in the deposit on March 31st, besides blood discs, pus, and epithelium cells, a few oval cells of peculiar form to be presently described. On April 4th, the chilliness premonitory of free hæmorrhage appeared, but on this occasion the amount of blood lost was much less than had previously escaped. The cells were abundant. They were oval, about 1-170th of an inch long, distinctly encapsuled, more pointed at one end than at the other, and from the sharper end a conical process or spike projected. The cells were afterwards allowed to filter into plain water under the microscope, when the hatching of the embryo was witnessed on several occasions by Mr. Pearson and by Mr. Blake, the house-surgeon, and by others at different times. Mr. Victor Horsley, to whom the cells were shown in the first instance, at once pronounced them to be the ova of bilharzia. The ova were afterwards seen several times by me, but I was not so fortunate as to observe the exit of the embryo. They were precisely the same as the eggs preserved in undoubted specimens of this disease. The cells were tested in various ways. None were preserved, as all the media which were tried destroyed the capsule of the ovum, and the cells did not stain with colouring matters. Before specimens could be put up permanently the discharge of blood and ova ceased. On April 30th the patient had lost all pain, and the kidney did not alter perceptibly. She remained thus till June 14th, when her general condition being tolerably good, she left for home at Erith, and was lost sight of. In October her husband informed me that the woman had died in August after an illness of three days' duration, accompanied by violent pain in the belly.

Considering the great interest which attaches to the case, it is most unlucky that we have no *post-mortem* record, nor a permanent specimen of the ova to show. That this is so is not the fault of Mr. Blake or of Mr. Pearson, who spared no pains to secure good examples of the ova.

These cells and embryos agreed in all respects with the descriptions given by those who have observed the parasite in Egypt. Especially interesting was it to observe the ova, which could retain their vitality for an indefinite time in the urine without undergoing further change, pass through the hatching process in a few seconds when transferred to pure water. The moment the embryo escaped from the shell it wriggled its way to any solid matter in its neighbourhood, and there remained quiet unless some current floated it off again. So far as our observations enabled us to follow them, the embryos remained ciliated, bilmy, elongated cells with somewhat granular contents.

Of bleeding from the prostate perhaps the most common form occurs in old age, where the organ is large and the veins dilated. Under the strain of sudden engorgement the prostate swells, the circulation through the veins is obstructed, one or more burst, and the bladder quickly fills with blood. In these cases the bleeding is very abundant, so that for a time the contents of the bladder are much more blood than urine. If the bladder be kept at rest by free drainage, the congestion subsides and the bleeding stops, otherwise the irritation of the bladder and the constant calls to pass water which cannot be gratified not seldom bring a fatal

termination to the case. If the bleeding stops, the urine becomes brown from disintegration of the clot, and the bladder is gradually cleared of blood. Sometimes the hæmorrhage is the result of injury to the prestate by attempts to pass instruments to relieve retention, in which case the condition of the patient is aggravated. Corroborative of the prostatic origin of the hæmorrhage would be the enlarged and tender state of the organ felt *per rectum*, and probably a history of long-standing impediment to micturition or attacks of retention.

Tubercular ulceration of the prostate is a cause of bleeding in young men. It shows itself in the form of clots washed out in the first part of the stream. In such cases there is cystitis, and the prostate is often irregular, hard, and tender to the touch. In other particulars the affection is not distinguishable from tubercle of the bladder, with which indeed it is usually associated.

Masturbation in youths causes prostatic hæmaturia. The urine is voided at short intervals, is coffee-coloured or even dark brown for some days, and there is aching in the perineum, with some lassitude. The presence of blood and a slight increase in the amount of mucus form the only changes of the urine from the healthy standard. The attack passes off in a few days, and the patient is well till a repetition of the unnatural practice brings a return of the hæmorrhage.

The prostate may be implicated with malignant growths extending from the rectum, and their presence may give rise to moderate hæmaturia.

Gonorrhœa also causes prostatitis, in which slight bleeding is common.

Malarial poison as a cause of prostate bleeding came under my notice lately. As you know, it frequently happens that any operation or shock will rekindle the activity of malarial poison in persons who have been attacked by it. This patient had had stricture for more than twenty years; and fourteen years before he consulted me he had suffered from a bad attack of tropical fever, which was followed by bloody urine. Again, six years afterwards, another attack of fever was attended by hæmaturia. The stricture was placed at two inches from the meatus; that is, of course, in the penile portion of the urethra. But there was no contraction, except muscular spasm, elsewhere. The stricture proved rebellious to simple dilatation, and it was cut internally. The first micturition passed off well; but twenty-three hours after the operation, sense of weight came in the rectum, followed by much spasm and difficulty in passing urine. There was also a slight chilliness, and the temperature rose to 99.8° F. Soon afterwards, as the patient himself expected, from experience of former attacks, he voided dark, reddish-brown urine with black clots. In forty-eight hours the bleeding ceased, and the temperature fell to 98°. Two days passed without bleeding. Then, at the same hour as before, a similar series of sensations were experienced at the neck of the bladder, and the urine again became charged with dark blood and clot. Quinine was then taken freely; the bleeding stopped, and did not return. During the second attack, the temperature ranged between 97° and 99° for four days; after that it remained steadily at 98°. That the blood came from the prostate was shown by the fact that there was no blood oozing from the urethra in the intervals of micturition. The dark brown and black colour of the urine, with black clot expelled at the end of the flow, indicated that the blood had escaped into the bladder before it was voided from the body. It must be recollected, also, that the incision was made several inches away from the prostate.

When the urethra is the locality of the bleeding, the blood is often moulded into long worm-like clots which float in the chamber-pot. Besides the form of the clot, the appearance of blood between the acts of micturition and also with the first drops of urine is characteristic of bleeding from the urethra.

Laceration of the urethra by the passage of a sound may cause very dangerous hæmorrhage. Some years ago I had under my care in this hospital a man who was in the habit of treating his stricture with his wife's knitting needles, which he himself bent to a suitable curve. His ingenuity cost him dear. On one occasion, when using a fine needle, he pushed it through the wall of the urethra and wounded the erectile tissue behind the stricture. This led to free hæmorrhage; and the blood, being penned back by the stricture, passed into the bladder, which it distended till that viscus reached to the umbilicus, and, for hardness, resembled the gravid uterus. The patient's sufferings were extreme; but, by dividing the stricture through the perineum, the coagula were quickly washed from the bladder and the patient recovered.

Rupture of the erectile tissue can in another way let loose dangerous bleeding. Some years ago there was a case in this hospital of a boy aged 19, a weakly lad, who had during excessive copulation ruptured some of the vessels of the erectile tissue about the bulb, from which blood flowed so freely that the patient became blanched before the hæmorrhage was arrested. Such cases of copious hæmorrhage are rare, but small bleedings are not infrequent from this cause.

Injuries of very slight amount may set up small bleedings; for example, the passage of a calculus, or of a sound even when very lightly handled. Also rupture of the urethra by a fall on the perineum is often denoted by a few drops of blood oozing from the urethra before the act of micturition is attempted. To make the diagnosis precise, reference would be taken to the history, to the painful bruising and swelling of the perineum, to the sudden pain when attempt is made to pass urine, followed by retention, and succeeding to this failure would be the signs of extravasation. Finally, it would often be impossible to pass a catheter to the bladder.

Sloughing sores or the rupture of the erectile structure during chordee produce hæmorrhage from the urethra, though the hæmorrhage does not take the form of bloody urine.

In females the small vascular aruncles of the urethra may bleed freely if torn by the stream of urine as it escapes from the meatus urinarius.

The following list of writings has served to supply the very brief account of bilharzia given above: Bilharz, *Zeitschrift für Wissenschaftl. Zool.*, 1851; Griesenger, *Archiv der Heilkunde*, 1854; *Dictionnaire de Méd. et de Chirurg. prat.*, par Jaccoud, 1870, art. Distoma; Sossino, *Archives Gén. de Méd.*, Juin, 1876, p. 650; Cobbold, *Parasites of Man and Animals*, 1879; also Quain's *Dictionary of Medicine*, 1882, p. 107; Mackie, *BRIT. MED. JOURN.*, Oct. 7th, 1882; J. Harley, *Med.-Chir. Trans.*, vols. xlvii, lii, liv; Zancanol, *Path. Trans.*, xxxiii, Jan. 3rd, 1882; Wortabet, *Edin. Med. Journ.*, 1879-1880; Sir W. Roberts, *Urinary Dis.*, 4th edit., 1885, p. 648; Reginald Harrison, *Surg.-Dis. of the Urin. Organs*, 1887, p. 249. This author gives an excellent summary of the writings of others, and also adds new matter gathered from communications and specimens sent to him by Dr. Mackie for exhibition. One specimen, shown to the Pathological Society in 1886 (*Path. Trans.*, 1887), is now in the Museum of St. Bartholomew's Hospital. Another, shown to the same Society in 1888 by Mr. Eve, is in the Museum of the Royal College of Surgeons.

ABSTRACT OF
CLINICAL LECTURES

CARCINOMAS OF THE BREAST WHICH
REQUIRE AN OPERATION.

By N. C. MACNAMARA, F.R.C.S.,
Surgeon to the Westminster Hospital.

LECTURE II.

In my last lecture I endeavoured to define the class of patients suffering from carcinoma who were unlikely to benefit by an operation for excision of the breast. Excluding cases of rapidly growing cancers, and those tumours which develop late in life and grow very slowly, as also patients otherwise unfit to undergo an operation, we have left by far the majority of instances of carcinoma of the mammae. Of this majority it may be said, if the affected gland were excised in the early stages of the disease that one-fourth of the patients so treated would remain free of cancer for the rest of their lives, and the other three-fourths would be saved from much suffering, and in not a few instances, life would be considerably prolonged by means of the operation. If this be true, evidently it is important to recognise cancer of the breast in its early stages; and although there are no definite symptoms which indicate the commencement of the disease, we can form a sufficiently accurate opinion as to its nature to enable us to follow without hesitation the correct line of treatment. We know little about the etiology of cancer, but it arises, in persons predisposed to the disease, in continued, or in repeated, irritation of glandular epithelium. It is often difficult, in specimens under the microscope, to say where simple chronic irritation ends and car-

cinoma begins; clinically, the difficulty of distinguishing between the two conditions in the early stages of cancer is still greater; but in the mammae the products of irritation, unless they suppurate, usually pass away in the course of a few months, whereas carcinoma may be said never to disappear. If, therefore, a patient, of from 30 to 50 years of age, consults us on account of an extremely hard almost painless nodule in one of her breasts, which may be about the size of a walnut, which has been noticed for six months or upwards, the growth having a roundish form, and being inseparably connected with the gland, it is probable we have to deal with a carcinoma. In such a case no time should be lost in making an exploratory incision into the tumour, and if it offers a resistance like that of an unripe pear when it is cut into, and has no defined outline separating it from the surrounding tissues, the entire gland should at once be excised; I would urge you to study what Sir B. Brodie has to say on this subject in the lecture to which I have so often referred. As an instance in point, I have made the following abstract from the notes of a case reported for me by my dresser, Mr. Shipley Part.

E. McC., aged 35, was admitted into hospital on September 26th, 1886. She is the mother of five children; her family history and general health have been good. Some four months before coming into hospital she had a considerable amount of pain in the left breast, and subsequently she noticed a lump towards the outer part of the gland; this nodule is now about the size of a walnut and of stony hardness; it is imbedded in the gland, and causes her but little pain unless it is roughly handled. The skin and axillary glands are unaffected; the nipple is retracted. On September 30th an exploratory incision having been made into the growth it was found necessary to excise the gland. On the following day the dressings were changed, and again on November 3rd and November 7th; the wound having then healed the patient left the hospital, and has since remained in perfect health.

Upon microscopic examination the growth was found, in places, to consist of enlarged tubes and acini crowded with cells, and in the surrounding connective tissue alveolar groups of epithelial cells were abundant. In other sections the tumour showed evidence of induration.

I think there can be little doubt that this growth had originated in lobular inflammation, and that carcinomatous changes had commenced in the weakened tissue, which, if left to itself, would have spread to surrounding structures and killed the patient probably within three years. It is equally certain, supposing this nodule to have been cancer, that the only way of averting untold suffering to the patient, and a fatal termination of the disease, was to have excised the tumour together with the gland in which it had grown before the surrounding tissues were infected. E. McC. doubtless progressed favourably after the operation; the wound healed in ten days, and the dressings only required changing on three occasions, but in eight out of ten such cases similar results may be secured by means of dry dressings and free drainage.

But if carcinomata of the breast can be excised with so little risk to life and so little pain in their early stages, how is it we meet with so many cancers in their pronounced form? It seems to me Sir Charles Bell, in the passage quoted in my last lecture, has answered this question. He states it is because excision of the breast affected with carcinoma is not resorted to sufficiently early in the progress of the disease that we meet with so many incurable cases. Sir Charles further observes that most patients suffering from cancer of the breast apply to their medical attendants in the first instance; these gentlemen are consequently largely responsible for the want of efficient treatment when alone there is a hope of eradicating the disease. Some practitioners do not believe that cancer is curable in any of its stages; I am convinced this is a mistake. Others, if consulted by a patient with a suspicious nodule in the breast, hope for the best, but cannot bring themselves up to the point of performing their obvious duty, and so months slip away, and the chance of doing any permanent good is gone. I can safely say I have not as yet met with an instance in my own practice, nor have I heard of a surgeon having to regret making an exploratory incision into a suspicious tumour of the breast, but I have repeatedly seen patients and practitioners who have had good reason to feel sorrow for not having resorted to this practice. No doubt it would be satisfactory if the symptoms presented by persons suffering from carcinoma enabled us clearly to determine the nature of the tumour from its commencement, without incising the growth, but in not a few doubtful cases

this is the only way to arrive at an accurate opinion on the subject.

It may be a nodule in the breast is caused by sarcoma; if so, the sooner it is removed the better; it may be cystic, but tumours of this description are seldom met with unless in conjunction with sarcomas or in carcinomas. Should the nodule have formed before the patient had reached her thirtieth year of age, it is not likely to be cancer, more probably it is an adeno-fibroma. These tumours are usually single, peripheral, and more mobile in the gland than carcinomas; but if in doubt we must make an incision into the growth. Should nothing more be necessary the wound may be closed, it will heal in the course of a week or ten days; on the other hand, if we wait and watch the suspected tumour until it is so far developed as to render the diagnosis certain, supposing it to be cancer, we shall have waited too long, the time will have passed when we might possibly have saved the patient from one of the most terrible deaths to which a human being can be subjected. It is well to bear in mind the fact, that cancer occurring in patients from 30 to 50 years of age, form by far the greater number of tumours of the breast we meet with in practice, and that every one of them has had a beginning.

In conclusion, we can safely answer the question referred to at the commencement of my last lecture in the affirmative; modern improvements in surgery enable us to modify the rules laid down fifty years ago as to the desirability of excising carcinomata of the breast, because the risk to life from such an operation has been lessened, and, further, the system of dressing wounds has much diminished the pain of the after-treatment. But what I wish particularly to impress on those of you who intend to follow general practice, is not to procrastinate or shirk your responsibility when consulted by a patient suffering from a persistent hard nodule in the breast. It may be, and indeed is, often necessary to clear up any uncertainty that exists in your minds as to the nature of the growth by means of the knife; should the nodule then seem to be a carcinoma excise the entire gland. You may thus save some of your patients from the further development of the disease, and you will certainly lessen their sufferings and prolong life.

ON BONE-SETTING.¹

By W. J. PENNY, F.R.C.S.,

Assistant-Surgeon to the Bristol General Hospital; Demonstrator of Anatomy to the Bristol Medical School.

MR. PRESIDENT AND GENTLEMEN,—I am obliged to you for the compliment you have paid me, in asking me to open the discussion this evening. The subject selected is more complicated than appears at first sight. The time at our disposal will not allow me to enter into it as fully as I should wish, but I will endeavour to bring its principal features before you as clearly and briefly as possible.

Bone-setting commonly so-called, means not a setting of fractured bones, but the term has arisen from the erroneous view imparted by quacks to the general public, that in many cases of distorted and useless joints a bone is out and requires setting in place again. This setting consists of some forcible movement, during which a crack is usually elicited. This crack is supposed to be caused by the bone slipping back into its place. Among affections successfully treated in this way are cases of fibrous adhesions within and around the joint ligaments and synovial membranes; cases of true complete dislocation; cases of partial dislocation or subluxation; cases of adhesion of tendons to each other, or to ligaments or other structures; disarrangement of ligaments; displacement of tendons; hysterical affections; cases of muscular spasm; ganglia which have been ruptured.

In some cases, bodies foreign to the part, such as new growths, detached pieces of cartilage, displaced cartilages, thickened synovial fringes, organised blood-clot, and numerous others, have become nipped between the bones forming a joint, and have thus interfered with its functions.

Not infrequently inflamed or strumous joints, or even malignant enlargements, have been treated in the same manner; I need hardly tell you with what results. I have seen three cases of amputation from improper use of these forcible movements.

Bone-setting has been little studied by the legitimate members

of our profession, and as cases amenable to treatment are common, quacks and charlatans have had an extensive field for their operations. Many of these quacks, especially one lately deceased, have acquired considerable skill in the treatment of these cases, and no small reputation from the good results they have obtained. The majority, however, have little knowledge of the subject, and consequently have numerous failures as well as successes. The public do not fail to laud the cures obtained by these men, or women, especially when properly qualified surgeons have previously failed to cure the complaint; and they seem rather pleased to have the chance of "having a slap" at their regular attendant. On the other hand, if a bad result ensues, they are ashamed to confess their lack of faith in their own surgeon, and dislike having the laugh turned against themselves; consequently we hear little of the bad results. Many of these quacks do not even know the anatomy of the parts affected, let alone the pathology; their knowledge as a rule amounts to this—"Here is a stiff joint, it must be worked." They know that the majority of cases are improved, a small proportion are made worse. If a bad result ensues, they frequently lay the blame on the previous attendant, by saying to the patient—"You should have consulted me before, and you would not have come to this." The more brazen their assertions, the more easily are they swallowed by the majority of the British public, who apparently like to be gulled.

Now, gentlemen, I hold it is our duty to beat these quacks on their own ground. The public are perfectly within their right to get cured wherever they can. They do not care, and why should they, whether the cure is wrought by a Member of the College of Surgeons, or by the village blacksmith, with a strong arm and a taste for backing his muscular powers against the stiffness of the patient's joint. They want relief from their ailments, and do not consider they have any special call to maintain Members of the College of Surgeons, if they cannot cure them. It is, however, our duty to expose these ignorant pretenders on all occasions; they do not spare our reputations, we need not consider theirs. It does not do simply to abuse them as impostors; patients, not unnaturally, judge by results; we must recognise the fact that they often cure cases in which we have failed. It appears to me that very often we treat the cases just long enough to make them fit for the bone-setter, and then, sometimes from lack of patience on the part of the sufferer, sometimes from lack of enterprise on the part of the surgeon, they drift into the hands of these quacks and get cured. The only way in which we can hope to compete successfully with these men is by a careful study of the anatomical, clinical, and pathological conditions associated with these affections. Having thus gained a sounder knowledge than they, and not fearing to act on it, our successes will prove to our patients that properly qualified scientific men are the more trustworthy, more likely to effect a cure and less likely to aggravate the complaint. I will take as my text the following anecdote.

My father, many years ago, had a valuable horse, which fell and cut one knee badly. The joint was opened. For many weeks it was under the care of a veterinary surgeon with a good reputation. After a time the joint, which had been enormously swollen and discharged pus freely, subsided, and the wound healed. The horse had a stiff knee. "Turn it out to grass for three months," said the vet.; this was done. At the end of that time there was only a slight blemish on the knee, it was the same size as the other, but the horse was perfectly useless for driving, as the knee was still stiff and the horse extremely lame. The vet. then gave up the case in despair, and my father, in disgust, sold the animal for a very small sum. Lo and behold within a day or two the new owner getting impatient at the horse's slow progress, gave it a smart cut with a whip; the animal, a well-bred spirited beast, plunged forward, and from that minute lost its lameness, and went as well as ever. I have seen it many times since, and it has never been lame. A great many lessons can be learnt from that case. A few fibrinous adhesions must have existed, probably within the joint. The pain caused by them prevented the horse, though spirited, from bending the knee; the sudden plunge caused by the whip ruptured them, and the horse was cured. They may have been no larger than threads of cotton. The structures round and in the joint were free from inflammation, and the constitution was sound; a typical example of the cases suitable for bone-setting. My father, a man of common sense, naturally wished to know why the veterinary could not have foreseen this; he now has less faith in him than formerly, and I almost fancy that, in spite of the empirical treatment of the other man, he would prefer his opinion in a similar case, and the result justifies this.

¹ Read before the West Somerset Branch of the British Medical Association.

If this horse had been a man, it is not at all unlikely he would have been treated in a similar fashion. The surgeon in attendance, recognising the danger of exciting inflammatory mischief in the joint, might not have cared to adopt such energetic treatment. The patient might then have drifted into the hands of a bone-setter, entirely ignorant of pathology, who would have told him "the bone was out," given the joint a wrench, ruptured the adhesions, and the case would have been cured. The original attendant, who had brought the case safely through the dangers of a wound of a large joint, would not only have lost all credit for that, but would have been considered less competent than the quack; I do not think we can say quite without reason.

A very short time ago I broke down, almost with a couple of fingers, some adhesions in the shoulder-joint of a man who had been unable to use his arm properly for ten years. Before the operation, if the scapula were fixed, the arm could only be moved one inch away from the side. The patient had been in the habit of pressing his elbow firmly against his side, by this manoeuvre saving the strain on the shoulder-adhesions when he worked the hand. The day after the manipulation he could easily move the arm six inches from the side, and he is now progressing satisfactorily towards recovery. The adhesions were very slight, and no perceptible inflammatory mischief was excited by the operation. He had consulted several surgeons, all of whom had failed to treat the case sufficiently freely. There was marked muscular spasm, which made the ankylosis more apparent; this, of course, disappeared under chloroform, and rendered the rupture of the adhesions a very simple matter. I hope to publish this case later on.

that the capsule either folds itself in various directions like a purse, according to the movements of the joint, or it is drawn out of the way by the muscles inserted around the articulation. Let me refer to the shoulder-joint. The capsular ligament is attached round the margin of the glenoid cavity, and to the anatomical neck of the humerus. It is very lax, so much so, that when all the muscles are removed, the head of the humerus can be drawn about an inch away from the scapula, without laceration of the capsule. All the muscles inserted into the tuberosities send a few fibres into the capsule; when either of these muscles act, the capsular membrane, instead of folding anyhow, is drawn out of the way before the bone (Fig. 1). If it folded anyhow, it might possibly get nipped between the bones, or it might get creased the wrong way, and so impair movement. This nipping is especially likely to happen at the back of the elbow, between the olecranon process and its fossa. The same rule holds good, I believe, in all the joints of the body (Fig. 2). I have examined most of them, and find it to be so. The importance of the fact is this. If the joint be moved in certain directions by its muscles, the capsule is drawn out of the way, or folds in such a manner that the movements are not interfered with. If it is moved passively, or by violence, the capsule is not drawn out of the way, and does not necessarily fold
